the part played by the insane in ancient religions. In the light of such a possibility and in the hope of hastening the approach of the millenium, it would seem pertinent to suggest that John Alexander Dowie should at an early day be made minister to the Congo Free State. The resultant blessings would be somewhat evenly distributed between "Darkest Africa" and Zion City, Illinois.

TESTIMONY IN RAPE CASES.

In our medicolegal items this week there is quoted some new legislation in Virginia regarding testimonies in cases of rape, that seem meritorious. There is no doubt that the public examination in court of the victim in such cases is often an outrage on decency, and may inflict an injury that can never be atoned for, perhaps blighting a whole life and adding infinitely to the hardship already undergone. Under the new Virginia law this evil is largely, if not entirely, removed. There is another and a more medical aspect of the case that is worth noting; the possibility of hysterical accusations is well recognized, and the prospect of a public examination and public sympathy in such is liable to only aggravate the hysterical tendency, at least in many cases. It seems to us that the private examination, properly conducted, is far more likely to determine the actual mental state and reliability of the witness. It is within the power of the judge to have competent expert assistants in taking this testimony, and the presence and counsel of a skilled physician in such cases might be of the utmost value and would be very naturally suggested by the defense. Perhaps a specific provision for such aid might be an advantageous addition to the law.

ENDOCARDITIS AS A COMPLICATION OF MUMPS.

The belief may still prevail in some quarters that all children must at one time or another pass through the exanthematous diseases, and it may still be the practice in some families to expose all of the children to the risk of infection when any one suffers from one of those diseases, but it has been so frequently and so conclusively demonstrated that any infectious disease, no matter how apparently mild, may be attended with serious if not disastrous consequences that no intelligent physician will sustain such belief or sanction such practice. Of the exanthemata, as of other infectious diseases, it has been shown that endocarditis is by no means a rare complication. Among these, mumps or epidemic parotitis is considered so insignificant a disorder that often a physician is not called in attendance, and, as a matter of fact, the disease usually pursues its course without more serious complication than suppuration of the parotid gland. At times, however, orchitis or ovaritis or mastitis occurs in the course of the disease. Less commonly metastasis apparently takes place to other structures, such as the nervous system, the organs of special sense, the mucous membranes, the serous membranes. Endocarditis has been recorded as a rare complication, the number of cases reported being small and the references in current literature and text-books to

this association being few. On this account the recital by Rudolf Taschner¹ of four cases in one family must be considered as extraordinary. The children were 11, 9, 7 and 5 years old, respectively, and each had an attack of mumps at a time when the disease was epidemic in the community. In all there developed symptoms of endocarditis, which it seemed reasonable to attribute to the attack of mumps, inasmuch as, among other things, the presence of any other infectious disease appeared to be excluded. This observation suggests that endocarditis may be a more frequent complication of mumps than has heretofore been suspected, and it should likewise carry with it the admonition that an attack of mumps ought not to be neglected, but, on the contrary, the possibility of the occurrence of endocarditis as a complication should not be ignored, and precautions be taken to lessen the likelihood of its development.

LOW RATES FOR THE PORTLAND SESSION.

We are glad to announce that very low rates have already been agreed on by the western railroads for the Portland session. The round trip rate will be \$45 from all Missouri River points. The passenger associations that have thus far acted have agreed on a half rate from their eastern territory to Missouri River points. This will make the rate from Chicago, for instance, \$56.50. From present indications, half rates will be given from all points South and East, with the possible exception of the New England Passenger Association territory. The time will be practically unlimited, terminating late in the fall. Thus those who desire can make the trip to Portland their summer vacation. Arrangements are being considered whereby a special train or trains will run a week before the session by way of Yellowstone Park, giving a chance to spend a week there on the way West. Similar arrangements can be made by individuals or parties for the return trip. Members will be able to go by one route and return by another. In future issues of THE JOURNAL we hope to be able to give a description of the various routes and their attractions.

FAMILIAL TABES DORSALIS.

There will probably be no dissent from the view that syphilis, if not the sole cause, is at least the most important etiologic factor in the development of tabes dorsalis. Further, while the definitive demonstration is as yet wanting, there is no reasonable doubt that syphilis is an infectious disease. Strictly speaking, syphilis can not be considered an hereditary disease, the transmission to the fetus in the uterus taking place, as a rule, by way of the maternal blood through the placenta. We have, under such circumstances, to deal rather with a difference in the medium than in the mode of transmission, and the acquisition of the disease on the part of the fetus is entirely comparable with that which takes place in postnatal existence. A number of diseases are known to exhibit at times a familiar distribution, and it is to be inferred that this fact is dependent on some inherent vice of development or is indi-

1. Wiener med. Woch., No. 31, 1904, p. 1453.

cative of a susceptibility to the specific exciting causes of the respective disorders in question. Cases are on record in which several members of the same family, although exposed to different conditions, have presented symptoms of tabes dorsalis. Dr. M. Nonne¹ has only recently reported the occurrence of tabes in a mother and two daughters, the latter on close scrutiny being found to exhibit stigmata of congenital syphilis. The cases, apart from occurring in women, were interesting further, because of the presence of optic atrophy, in conjunction with a slight degree of ataxia. A healthy child was born between two infected children. Nonne refers also to other cases in his experience illustrating a familial distribution, due possibly under varying circumstances to different causes. Thus a child, its mother and its father all developed tabes in the sequence of extragenital infection with syphilis. In another instance, a syphilitic husband, his wife and a child born five years after the infection of the father all became tabetic. It seems probable that in the cases cited and in others of similar character different factors may be operative in different cases. In some there may be a familial predisposition or susceptibility. In others, perhaps the syphilitic virus may have a specific activity with reference to the nervous system, especially the posterior roots and columns; while in still other cases other influences may be at play. Altogether the subject is one deserving of further investigation.

Medical News.

CONNECTICUT.

Thousands to City Hospital.—Miss Mary Terry, who died in Venice a month ago, left \$300,000 to the City Hospital of Hartford, Conn.

Infectious Diseases.—The State Board of Health received reports during September of 2 cases of smallpox, 4 of measles, 44 of scarlet fever, 1 of cerebrospinal fever, 115 of diphtheria, 3 of whooping cough, 138 of typhoid fever and 16 of consumption.

School Inspection at Waterbury.—The Waterbury Board of Health has decided to appoint two medical inspectors, who shall inspect all schools in the city once every two weeks. Drs. Charles A. Monagan and William A. Goodrich have been appointed the medical inspectors.

September Deaths.—During September 1,167 deaths were reported, equivalent to an annual death rate of 14.3 per 1,000. Of these 158 were due to diarrhea in children under 5, 134 to diseases of the nervous system, 111 to heart diseases, 103 to consumption, 68 to violence and 31 to pneumonia.

ILLINOIS.

Recovering.—Dr. Ira Brown, Milford, who was seriously injured by falling from a bicycle, is making a satisfactory recovery.

Smallpox.—The inspector of the State Board of Health reports that he has found 7 cases of smallpox in a mining camp near O'Fallon.

Bequests to Peoria Hospitals.—By the will of the late Henry Schwabacher, Peoria, bequests of \$200 each are made to the Cottage and St. Francis hospitals.

Diphtheria Epidemic.—It is reported that diphtheria is raging in Deerfield, that three deaths have occurred, and that the village school has been closed.—The disease has spread from East Peoria to Wesley City where six families are under rigid quarantine.

Chicago.

Praises Interne System.—At the annual banquet of the Cook County Hospital Alumni Association Dr. William E. Quine was toastmaster, and Dr. Frank Billings declared the interne system at the hospital to be the best in the world.

A Healthy Year Thus Far.—The Health Department Bulletin states that at the close of October there had been 22,058 deaths from all causes since the first of the year. This total is 1,817 fewer than for the corresponding period of 1903. The rate for 1904 may be even lower than that of the year 1901, which now holds the record with a rate of 13.88 per 1,000 of population.

Charities.—The Schwabenverein at its annual meeting donated \$150 each to the German Hospital, Alexian Brothers' Hospital, St. Elizabeth's Hospital, Michael Reese Hospital, South Chicago Hospital, St. Joseph's Hospital and St. Anne's Consumption Hospital, and \$50 to St. Francis' Hospital, Park Ridge.—The will of Moses Bensinger devises \$1,000 to Michael Reese Hospital and \$500 to Alexian Brothers' Hospital.

A Low Death Rate.—The average annual October death rate from 1893 to 1903 was 14.24, the lowest 11.98 in 1898, and the highest 17.89 in 1893. For October, 1904, the rate was 11.58—3.3 per cent. lower than the record lowest, 18.6 per cent. less than the average for thirteen years, and more than 35 per cent. lower than the highest of that period. Diphtheria deaths were 38 less (exactly one-half), heart disease 20 less, nervous diseases 29 less, pneumonia 47 less, scarlet fever 8 less, suicide 11 less, and typhoid fever 12 less than in October, 1903.

Unripe Vaccine.—On account of the extraordinary demand for vaccine virus, which has caused some producers to place "unripe" lymph on the market, the health commissioner has tendered to all producers of vaccine the services and facilities of the laboratory of the Health Department, and of its expert clinicians, in the bacterial and clinical examinations of their vaccine products offered for sale and use in Chicago. All vaccine submitted for such examinations, and found to be pure—that is, free from disease-producing organisms, and potent—that is, producing not less than 90 per cent. of successful primary vaccinations—will be so certified by the department. Defects in either respect will be duly notified.

MARYLAND.

Granted New Trial.—Dr. Joseph Ohlendorf, adjudged guilty a few days ago at Upper Marlboro of manslaughter in committing criminal abortion, has been granted a new trial and released on bail for \$7,000.

Personal.—Dr. B. Curtis Miller, surgeon in charge of the Western Maryland Hospital, Cumberland, has resigned and has been succeeded by Dr. Clinton Brotemarkle, formerly of Lonacoring.—Dr. William J. G. Whiteford of Baltimore County is on a visit to St. Louis.

Seeks Restraining Order.—Dr. Basil B. Crawford of Montgomery County has filed a bill asking that a Mr. Dorsey be restrained from suing him for damages. A temporary injunction was granted. In November, 1903, Dorsey brought suit against Dr. Crawford, alleging malpractice in the treatment of a fracture of the leg, and last March the case was nolle prossed.

A Maryland Abortionist Gets No Pardon.—Mention has been made of a petition to the governor for the pardon of Dr. George C. Worthington, a convicted abortionist now serving a ten years' sentence in the Maryland penitentiary for manslaughter by criminal malpractice. On this petition were the names of state senators and representatives, a member or two of Congress, lawyers, merchants, clergymen, women and doctors. November 2, backing this appeal, a large delegation appeared before the governor at Annapolis. The spokesman, an ex-state senator, appeared in behalf of "the citizens of Baltimore and the state of Maryland." The object of the appeal, he said, had become a physical wreck since his incarceration; his financial condition was also a wreck; his wife and daughter were without means of support; a mother in her eighty-ninth year awaited him; the majesty of the law had been vindicated, and transgressors taught that they would be punished for their offenses; a multitude of people desired the pardon; the jury had unanimously signed a petition for his release; he would henceforth live beyond the confines of the state; while he may have done wrong, who shall cast the first stone? If the operation had been successful and shame had been saved the woman's family, nothing would have been said, etc. A state senator said that at least one-half of the members of the house of delegates and a majority of the members of the senate had signed the

1. Berliner klin. Wochenschrift, Aug. 8, 1904, p. 845.

petition. A physician is reported to have stated to the governor "that he had practiced medicine eighteen years and could readily understand how Dr. Worthington had fallen into an indiscretion, and while the law had been violated, it would be well to remember that by his acts he had saved many a young woman from going forth marked with disgrace and shame." Silence ensued, broken only by a sob from near the door. This evidence of grief was supposed to come from some of Dr. Worthington's friends. "Is there anything further to be said?" asked the governor. There was silence for a few seconds when, in a half-hesitating way, the slight figure of a woman approached the governor, who turned and looked inquiringly. A convulsion of grief shook her from head to foot. It was but for an instant. Then, throwing her head erect, with both hands outstretched, she cried: "I am the mother of the dead girl!" A storm of pent-up grief burst forth while the members of the delegation stood aghast. Controlling herself as best she could, the woman continued: "I object to this pardon. I am a Christian woman. I have lived eighteen years in my neighborhood and you may ask any of my neighbors concerning my respectability. I am not responsible for the death of my poor girl. I tried to rear her properly. She told me on her dying bed that Algive was responsible for her condition and that Dr. George C. Worthington had performed the operation which later caused her death. I could tell you more that she said, but on account of this frightful crime I have keenly felt the disgrace which it has brought to me and my family, and on these grounds, lone mother that I am, I come here to protest in my humble way against granting a pardon to this man and to ask that he shall serve out his full time and receive full punishment for the crime he has committed." This unexpected appeal fell like a bolt out of the clear sky. Several minutes elapsed before the members of the delegation could collect themselves, and the governor showed plainly the effects of the incident. The governor was the first to speak, saying that the opinion was almost universal that the punishment meted out to the prisoner was not commensurate with the grave crime committed by him. He, therefore, declined to extend executive clemency. The members of the delegation then fled out in silence, while the woman took the governor's hand, exclaiming: "God bless you!"

Baltimore.

Hemmeter Given Desk.—At the close of his lecture on physiology at the University of Maryland, October 31, Prof. John C. Hemmeter was presented by the class of 1906 with a handsome polished oak lecture desk of massive design.

Adjunct Faculty Society.—The Adjunct Faculty of the University of Maryland School of Medicine has formed a society, whose purpose is to co-operate with the faculty in improving the service in the University hospital, in extending its advantages to visiting alumni and in creating a healthy esprit-de-corps among the members of the staff and those connected in one way or another with the institution.

Personal.—Dr. I. Mori of Japan is visiting Baltimore.—Dr. G. H. Foster, United States Marine-Hospital Service, hitherto attached to the immigration bureau here, has been ordered to Naples, Italy, to inspect emigrants from that port. His place will be filled by Dr. P. Clark, Philadelphia.—Dr. John C. Scofield was painfully injured by being thrown from his buggy, October 22.—Dr. Ella X. Quinn will spend the winter in Florida.

Favors Isolation Hospital.—Mayor Timanns has declared himself in favor of an infectious diseases hospital and so has the Board of Public Safety. Several years ago a site for one was purchased in the suburbs, but residents objected and the legislature was induced to prevent the scheme. The city declined then to take the site and a suit is now pending in consequence. An appropriation is available and it is believed that the matter will soon be taken up.

The Osler Memorial.—Although it is stated that the committee has not arrived at a definite decision, the Osler memorial building is being generally discussed by the profession here and the idea meets with universal approval. It has been suggested to purchase Dr. Osler's residence, No. 1 Franklin Street, West, and adapt it to the purpose. Dr. Osler's deep interest in and services to the medical library render it appropriate as the instrument for commemorating his life and work here. The matter has been taken up by the newspapers of Baltimore since its first mention in THE JOURNAL of October 29. Dr. Osler's many friends throughout this country and Canada will doubtless be most happy to contribute to making this project a success.

The Locke Bicentennial.—The two hundredth anniversary of the death of Dr. John Locke, the philosopher, was celebrated in McCoy Hall, Johns Hopkins University, November 1. The idea originated with Dr. Osler, who spoke of Locke as student of medicine, practitioner and medical philosopher. As a friend of Sydenham, he exerted an important influence on modern medical thought. His views were strongly modern. He was the first to treat echinococcus of the liver instrumentally, which he did by means of a silver drainage tube on his patron. Conway Lloyd Morgan, principal of University College, Bristol, Eng., spoke of Locke's philosophy and psychology, as did also Prof. F. J. E. Woodbridge of Columbia University. Prof. J. McBride Stretter of George Washington University spoke on Locke's toleration.

MICHIGAN.

Personal.—Dr. DeWitt C. Wade, Holly, is very ill in a hospital at Flint, and only slight hopes for his recovery are entertained.

Comparative Mortality.—For October, 1904, compared with the average for October in the ten years, 1894-1903, smallpox, measles and puerperal fever were more than usually prevalent; and dysentery, intermittent fever, cholera morbus, cholera infantum, remittent fever, erysipelas, pneumonia, diphtheria and whooping cough were less than usually prevalent.

The Most Dangerous Communicable Diseases.—Meningitis was reported present during October at 5 places, whooping cough at 12 places, measles at 19 places, pneumonia at 29 places, diphtheria at 63 places, smallpox at 79 places, scarlet fever at 82 places, typhoid fever at 182 places and consumption at 303 places. Meningitis was reported present at 3 places less, whooping cough at 5 places less, measles at 9 places less, pneumonia at 4 places less, diphtheria at 5 places less, smallpox at 10 places more, scarlet fever at 9 places more, typhoid fever at 14 places less, and consumption at 1 place less, in October, 1904, than in the preceding month.

Opposes Indiscriminate Gratuitous Hospital Treatment.—The following resolutions were unanimously adopted at the meeting of the Wayne County Medical Society, October 31, and a committee of ten was appointed to confer with the Board of Regents, regarding the action therein referred to:

WHEREAS, The members of the medical profession, as citizens, are entitled to the same privileges which are enjoyed by other citizens; and

WHEREAS, The board of regents of the University of Michigan have ruled (*Michigan Alumnus*, October, 1904, pp. 2 and 3) that the medical faculty of the University of Michigan must grant gratuitous medical and surgical treatment to everybody applying therefor, whether rich or poor; and

WHEREAS, Such a condition is contrary to all customs and rules governing the relation of one citizen to another; and

WHEREAS, Such a ruling deprives the medical citizen within the radius of the influence of the University of Michigan of part of their rights in an unwarranted manner, and is harmful to the state as well as to the medical profession; therefore, be it

Resolved, By the Wayne County Medical Society, Michigan, that the board of regents of the University of Michigan be asked to rescind its ruling concerning the indiscriminate free medical and surgical treatment of those who apply for treatment at the University clinics, and

Resolved, That the board of regents of the University of Michigan be asked to give a hearing to representatives of the Wayne County Medical Society.

MINNESOTA.

Senior Student Dies.—C. B. Morey, Winona, a senior student of the medical department of the University of Minnesota, who went to New Orleans last month, intending to complete his course at Tulane University, and for the benefit of his health, was found dead in his bed, October 11, from nephritis and asthma, aged 24.

Old Physician Honored.—Dr. Edward J. Davis, Mankato, president of the Blue Earth County Medical Society, was tendered a banquet by his medical and lay friends, October 24, on the eve of his departure for a new field of labor at the Soldiers' Home. On behalf of his friends, Dr. John W. Andrews presented Dr. Davis with a silver loving-cup.

Large Damages Awarded.—In the case of Miss Anne Mohr, who charged that Dr. Cornelius Williams, St. Paul, operated on the wrong ear without her consent, and claimed that she was damaged to the extent of \$20,000 by reason of the defendant's malpractice and negligence, the jury found the defendant guilty of technical assault, and assessed the damages at \$14,322.50.

One Building Instead of Cottages.—The cottage plan proposed for the construction of the sanatorium for consumptives, to be erected on the site recently selected by the commission of physicians appointed by the governor, has been abandoned

as too expensive, and one large building will be erected instead. As originally proposed, the institution would have consisted of half a dozen cottages, located on a wooded site of 700 acres, recently purchased on the banks of Leech lake, near Walker. The present plans call for a building, three or four stories high, accommodating between 200 and 300 patients.

Personal.—Dr. Emil S. Geist, St. Paul, has returned after a stay of three years in Europe.—Dr. Edward A. Meyerding has been appointed first assistant city physician of St. Paul, vice Dr. Paul B. Cook, term expired, and Dr. Frank J. Savage has been made second assistant physician.—Dr. C. L. Francis, Mapleton, after half a century of practice, has retired, at the age of 83.—Dr. Donald A. Nicholson, physician at the St. Peter State Hospital for the Insane, has resigned and will locate in Spokane, Wash.—Dr. Lewis B. Wilson has resigned from the faculty of the University of Minnesota; Dr. Jacob E. Shadle, St. Paul, has been appointed professor of diseases of the nose and throat, vice Dr. Winfield S. Laton, Minneapolis, and Dr. James E. Moore has been made professor of surgery, succeeding the late Dr. James Henry Dunn.

MISSOURI.

Acquitted of Murder.—Dr. Warren Smith, Sikeston, accused of the murder of Harry Miller of Sikeston, was found not guilty, October 22.

Quiet for Patients.—The ordinance designed to repress hucksters while in the vicinity of hospitals and public schools was passed by both houses of the Kansas City Council, October 9. Hucksters are prohibited from shouting their wares within a block of these institutions.

Physicians to Have Rigat of Way.—The Kansas City Board of Health, on October 24, adopted the badge of the Red Cross to be worn by physicians and ambulance drivers as a passport entitling them to drive through funeral processions while using the thoroughfares in answer to calls for their services.

Pasteurizing Laboratory Closed.—The distribution of pasteurized milk by the Pure Milk Commission of St. Louis was discontinued November 1, because of a lack of financial support, and the pasteurizing laboratory closed. Since July 1 \$4,000, which had been subscribed for the maintenance of the work, has been expended.

Declared Insane.—Dr. Norman Brokaw, St. Joseph, was adjudged insane and committed to State Hospital for the Insane No. 2, October 18.—Dr. Moritz F. Weyman, after scattering \$2,000 in gold and silver in a wild ride through the streets of St. Joseph, was arrested, found insane and committed to the State Hospital for the Insane, October 24.

A novel combination of clinical demonstration and laboratory diagnosis occurred at the Kansas City Medical College, October 1, when Dr. Frank J. Hall, professor of pathology and laboratory diagnosis, presented a malarial patient, in the characteristic "chill", to the senior class during its regular laboratory period. He provided each of the 30 members of the class with a fresh blood smear and the *Plasmodium malarie* was demonstrated by each member.

NEBRASKA.

Disease Closes School.—Bloomer school, Omaha, was ordered closed for a week, on October 23, on account of the prevalence of diphtheria.

Creighton Wins Prize.—The authorities of Creighton Medical College, Omaha, have been notified that a gold medal has been awarded the pathologic and histologic exhibit of the college at the Louisiana Purchase Exposition.

Smallpox at Monterey.—Monterey township is having an epidemic of smallpox. The health department physicians discovered 12 cases, mostly in an advanced stage. A farm hand from the southern part of the state is believed to have been the conveyor of infection.

NEW YORK.

Personal.—Dr. Henry E. Allison, medical superintendent of Mattewan State Hospital, is seriously ill and his recovery is despair of.

Fined for Failure to Register.—Dr. Franklin Stuart Temple, Buffalo, formerly associated with "Antonius" the "healer," was fined \$100 and costs in Buffalo, for violating the ordinance requiring physicians to register with the department of health.

Must Be Vaccinated.—Commissioner Lewis of the state health department has informed the village boards of health

that the law imperatively requires all school children to be vaccinated before they can be permitted to attend the public schools and that there is "no quarantine" to be lifted in that regard.

Two Have Golden Jubilee.—The meeting of the Ontario County Medical Society at Catandaigna, October 11, was made a jubilee meeting at which was celebrated the fiftieth anniversary of membership of Drs. John Richmond Pratt, Manchester and W. Scott Hicks, Bristol. Dr. William W. Keen, Philadelphia, made a reminiscent address, Dr. Roswell Park, Buffalo, spoke, and presentations were made to the two venerable guests of honor.

The Lunacy Commission's Work.—The chief objects of progress accomplished by the lunacy commission in the last three years are as follows:

1. The reorganization of the Pathological Institute.
2. Provisions for the addition of 5,147 beds to the capacity of the present hospitals.
3. The segregation of the tuberculous insane, at first in solariums and tents at the various hospitals, and later by the construction of three tuberculosis hospitals for 100 each.
4. The securing of an appropriation for the construction of 10 isolation pavilions for infectious diseases.
5. The passage of a law providing for emergency commitment of serious cases of insanity.
6. Large additions to the means of treatment in asylums in the way of surgical operating rooms, hydrotherapeutic apparatus and numerous electrical medical and surgical appliances.
7. The introduction of a system of careful registration of each patient restrained or isolated, which has resulted in a large diminution in restraint of patients by mechanical means, etc., and in the reduction of the number kept in solitary seclusion.
8. Throwing open the 14 state hospitals to 30 clinical assistants, who have the same opportunities for study, and for giving the same benefits to these institutions, as the similar arrangement for medical internes in the general hospitals.
9. A marked increase in the number of alien insane deported and improving facilities for discovering and deporting them.
10. The adoption of a more satisfactory dietary and larger rations than that allowed under the Atwater system.
11. The appointment of a medical inspector for the more continuous supervision of the 33 private asylums of the state in which about 1,000 patients are cared for.
12. Numerous systematic improvements demanded in such private retreats as did not approach the standard of care set by a general letter sent out by the commission to the private asylums in January, 1902.
13. The development of a definite policy in the matter of provision of care of the insane by the state, which should be applicable, not only now, but for future years.
14. The appointment of boards of consulting specialists at a number of state hospitals located sufficiently near to cities resulting to grant benefits to the institutions concerned.
15. The establishment of a summer colony at the lake shore for convalescent and curable patients in connection with the Rochester State Hospital.

Buffalo.

Personal.—Dr. Emil S. Tobie has returned from Europe.

Sewage Threatens Health.—The sewage from a territory having a population of 40,000 now drains into the Ohio basin, which has a very restricted outlet. This results in stagnant sewage, which is a menace to health. At present there are many cases of typhoid fever in the wards of the city adjoining this basin, and the health commissioner believes the discharge of the sewage into this basin should be stopped.

Mercy Hospital's Attending Staff.—The board of managers of the new Mercy Hospital has appointed the following physicians as the attending staff: Medical Department—Drs. James W. Nash, James E. Culbert and A. L. Benedict; alternates, Drs. Ira F. Trevett, James J. Brown and Robert E. De Ceu. Surgical Department—Drs. Edward M. Dooley, Verner Kershner and William J. O'Donnell; alternates, Drs. Frederick M. Boyle, Bernard H. Brady and Daniel Murphy. Department of Gynecology—Dr. Stephen G. Howell; alternates, Drs. Cornelius J. Carr and Michael A. Sullivan. Department of Electrotherapeutics—Drs. John H. Daniels and P. H. Honrigan. Special Diagnosis—Dr. Thomas B. Carpenter. Laryngologist—Dr. W. Scott Renner. Department of Ophthalmology—Dr. Robert K. Grove. Genitourinary surgeon—Dr. J. Henry Dowd. Department of Neurology—Dr. William C. Krauss. Department of Dermatology—Dr. Alfred E. Diehl.

New York City.

Diphtheria at the Navy Yard.—Diphtheria has broken out in the marine barracks at the Brooklyn Navy Yard. The cases are mostly mild in form.

Semon in New York.—Sir Felix Semon was the guest of the section on laryngology and rhinology at the Academy of Medicine on November 2, where he read a paper. A dinner was afterward tendered him.

Hospital Room at Brooklyn Bridge.—Commissioner McAdoo has ordered a hospital room erected on the platform of the Brooklyn bridge so that immediate care may be given in case of accident. A trained nurse will be constantly in attendance.

To Aid Doctors' Widows and Orphans.—The New York Society for the Relief of Widows and Orphans of Medical Men has just issued its sixty-third annual statement, which shows the total assets to be \$265,376 and the amount disbursed during the past year, \$22,495. The members now number 133, of whom 110 are life and 23 annual members.

Contagious Diseases. There were reported to the sanitary bureau for the week ending October 29, 299 cases of diphtheria, with 17 deaths; 358 cases of tuberculosis, with 133 deaths; 165 cases of scarlet fever, with 8 deaths; 114 cases of typhoid fever, with 16 deaths; 55 cases of measles, with 7 deaths; 77 cases of chicken-pox, and 10 deaths from cerebrospinal meningitis.

Columbia Anniversary.—Columbia University's celebration of its one hundred and fiftieth anniversary, October 31, was marked by the conferring of the following degrees to those well known in medical work: The degree of Doctor of Laws was conferred on Prof. Edward Gamaliel Janeway, Prof. Francis Delafield, Dean William Meeklenburg Polk, Prof. John Green Curtis, Prof. William Henry Welsh, Dr. Andrew James McOsh and Prof. Walter Belnap James. The degree of Doctor of Science was conferred on Prof. William Stewart Halsted, Prof. Moses Allen Starr, Prof. Luther Emmett Holt, Prof. George Sumner Huntington, and Dr. Ernest Joseph Lederle.

Sprinkling versus Flushing.—The merchants' association recently made a formal protest to Commissioner Woodbury, complaining that as the pavements instead of being washed were covered with thin mud with consequent danger to persons and horses, the method of cleansing the streets should be changed. Commissioner Woodbury in his response said that such conditions were due to sprinkling by private corporations and not to flushing as performed by the street cleaning department. The method used by the department was that of delivering at an angle of 48 degrees with the muzzle velocity of 40 pounds' pressure to the square inch, a volume of water from hoses which thoroughly cleansed the pavements and did not make it slippery. Commissioner Woodbury called attention to the low death rate in the properly washed and cleansed districts as compared with other localities. He said that agar plates exposed after sprinkling and after flushing showed 460 colonies to the former with only 10 colonies to the latter. He thought all efforts should be directed to securing the passage of a bill which would make it impossible for a private corporation to get a contract for street sprinkling next spring. All street cleaning should be entirely in the hands of the department and the work would then be performed in a more satisfactory manner than was now possible.

OHIO.

New Hospital Appointments.—Drs. Derrick T. Vail and Louis Stricker have been appointed ophthalmologists to Presbyterian Hospital, Cincinnati, vice Dr. Christian R. Holmes, resigned.

Hospital Cornerstone Laid.—The cornerstone of the hospital at the Masonic Home, Springfield, was laid with impressive ceremonies, October 26. The hospital will be ready to receive patients in June.

Illegal Practitioner Fined.—C. J. Stevenson, an electrical and magnetic "healer" of Lisbon, was found guilty of violating the statutes governing the practice of medicine in Ohio, was fined \$25 and promised to practice no more in the state.

Convalescent Hospital Burned.—Rainbow Cottage, the convalescent hospital for children at South Endlid, was destroyed by fire, October 31, fortunately without loss of life. The loss is \$30,000, partially covered by an insurance of \$16,000.

Mercy Hospital Dedicated.—On October 19, Mercy Hospital, Hamilton, was formally opened with impressive ceremonies. The principal address was given by Dr. E. Gustav Zinke, Cincinnati. At the banquet which followed Dr. Frank M. Barden, Hamilton, officiated as toastmaster.

Internes Leave Hospital.—The four internes who have completed their terms of service at the Cincinnati City Hospital, will assume practice as follows: Dr. Meile Fleener will open an office in Hamilton; Dr. F. W. Krueger, in Richmond, Ind.; Dr. H. E. Schilling at Troy, and Dr. Earl H. Bruns, having passed the examination for the Army Medical Department, will enter the Army and Navy Medical School, Washington.

PENNSYLVANIA.

An Award for Science.—By virtue of an agreement made before her death, the heart of Mrs. Mary O'Neill was awarded to Dr. Henry Martin Hall, Pittsburg, by a coroner's jury, October 8.

Free Antitoxin in Hazleton. The Board of Health of Hazleton at its last meeting decided to furnish antitoxin free to families in the city too poor to pay for this agent.

Smallpox in Pottstown.—Smallpox continues unchecked in Pottstown and wholesale vaccination has been inaugurated. Dr. Elmer Porter, chief Burgess, visited the infected portion of the town and, with his assistants, vaccinated over 200 in the community.

To Aid Pittsburg Consumptives.—Pittsburg will probably have a hospital for the treatment of its consumptives. William McConway has offered a desirable building for the establishment of a hospital of this character. The physicians of the city will use every endeavor to see the project succeed, as there is no such institution in that part of the state.

Injured and Ill.—Dr. Charles O. Johnston, Claysburg, while on a hunting trip lost his right hand at the wrist by an accidental discharge of his shotgun.—Dr. James A. C. Clarkson, Lewisstown, while attempting to board a train at Petersburg, was thrown over the subway rail to the road, twenty feet below, alighting on his back and suffering a severe concussion of the spine.—Dr. Will L. Shindel, Sunbury, is reported to be dangerously ill in a hospital in Philadelphia.

Philadelphia.

Abortition Convicted.—Mrs. Elizabeth Ashmead, Philadelphia, October 31, was found guilty of causing the death of Mary B. Sloan by a criminal operation.

Cancer Hospital Instituted. On October 31 application was made to Court No. 1 for a charter for the American Oncologic Hospital "for the study and treatment of cancerous growths and other tumors."

Emigrants Barred by Trachoma.—Two hundred emigrants booked for this port from Liverpool were debarred from passage by the existence of trachoma. The disease was detected by the vigilance of the ship's surgeon, as the great majority had been passed by the doctor at Liverpool.

Residents Object to Hospital.—The private hospital for the treatment of consumptives, Gowen Avenue and Sprague Street, Germantown, has proven objectionable to the residents of that section of the city, and an effort is being made by them to have the institution removed, as they claim it is a menace to the community. They have entered an injunction branding it an institution of nuisance.

Health Report.—The total number of deaths for the week was only 386, a decrease of 21 from those of last week, and a decrease of 34 over the corresponding week of last year. Two hundred and seventeen cases of contagious disease, with 13 deaths, were reported, as compared with 244 cases and 28 deaths over the preceding seven days. The cases of contagious disease reported are as follows: Diphtheria, 89; scarlet fever, 73; typhoid fever, 53; smallpox, 2. Two schools were closed during the week from the existence of smallpox in the homes of attending pupils.

New Building for College of Physicians.—At the last meeting of the College of Physicians plans were submitted for a new building, to cost \$240,000. The building will provide shelves for 30,000 volumes, a floor for museum exhibits, a large lecture and assembly room, with other rooms and modern conveniences. The college has at its disposal, including cash and real estate, about \$570,000. The site for the new college purchased at Twenty-second and Ludlow streets for \$80,000 has been condemned. A committee, therefore, has been selected to report on new sites at the next meeting. It is probable that the new building will be erected on the present site of the college at Thirteenth and Locust streets.

Work of Hospitals.—The Presbyterian Hospital admitted 207 patients in October and discharged 239; 2,204 patients were treated in the dispensaries.—The Methodist Hospital admitted 90 patients and administered 2,590 treatments in the dispensary.—The Woman's Hospital admitted 95 patients to the wards, and treated 1,462 in the different dispensaries.—Germantown Hospital admitted 97 patients, and 1,345 were treated in the various dispensaries.—Six thousand and ninety patients were treated in the Medio-Chirurgical Hospital.—The Prisoners' Hospital admitted 218 patients, and 6,321 were treated in the different dispensaries.—St. Joseph's Hospital admitted 223 patients, and 2,114 visits were made

to the out-patient department.—St. Agnes' Hospital admitted 111 patients to the wards, and treated 3,428 in the dispensaries, making a total of 33,661 patients treated in the different hospitals reported in the month.—During the past year the Kensington Hospital has cared for 1,015 patients at a cost of \$23,325.15. There were 641 operations performed.

GENERAL.

Manila Overcrowded with Physicians.—A physician who recently returned to this country from the Philippines says that there is little opportunity for successful practice in Manila, as the city is suffering from a superabundance of medical men.

Consumptives Barred from Government Positions.—The Civil Service Commission has decided that hereafter persons suffering from consumption will not be employed in the postoffice, or in any other government position from which they are likely to spread the disease. In future all applicants must submit to a physical examination, according to an order recently sent out.

Swindled by Forged Check.—A young man, aged about 28 years, blonde, 5 feet 6 inches in height, weighing about 135 pounds, of genteel dress and manner, representing himself to be a graduate of Starling Medical College, applied for admission in one of the medical schools in Washington, D. C., and presented a check supposedly issued by Dr. Starling Loving, on the Commercial National Bank, Columbus, Ohio, in favor of Dr. J. H. Loving, and requested that \$60 of the proceeds of the check be applied to the tuition fee and \$40 be handed him in cash. The dean of the school, being personally acquainted with Dr. Starling Loving and being of an unsuspecting mind, promptly complied with the request, with the subsequent result that the check was pronounced a forgery.

National First-Aid Society.—At a meeting of the Chicago First-Aid Society, held November 5, it was unanimously agreed that the foundation of a national first-aid society on the lines of the St. John's Ambulance Association of England and the Samantha Society of Germany was desirable, and it was resolved to incorporate an association to be called the American White Cross First-Aid Society, with the following objects: To educate the public in the principles and methods of first-aid emergency treatment of those injured by accident or suddenly stricken by illness; to install ambulances, stretchers and first-aid material at places which may be considered necessary; to organize volunteer ambulance brigades for service in peace and in war, and to contribute personal and material aid for the mitigation of national disasters. A committee was appointed, consisting of Drs. Nicholas Senn, Charles Adams and S. C. Stanton, and Messrs. E. Howe and Lewis A. Stebbins, to take immediate steps to arrange for the incorporation of the society and to nominate the administrative committee.

CANADA.

Registration of Births in Montreal.—Every physician is now compelled to register the births occurring in his practice within forty days. Of the 500 births registered in one month and a half, 435 were reported by physicians.

Toronto Senate Elections.—The following members of the medical faculty were elected to represent the graduates in medicine on the senate of the University of Toronto: Professors George A. Bingham, I. H. Cameron, Adam H. Wright and J. Algerton Temple.

Nova Scotia Society.—The annual meeting of the Nova Scotia Branch of the British Medical Association was held in Halifax, October 5. The election of officers resulted as follows: President, Dr. C. D. Murray; vice-president, Dr. W. H. Hattie; treasurer, Dr. G. M. Campbell; secretary, Dr. E. D. Farrell; council, Drs. Goodwin, Hattie, Hare, Mader, G. M. Campbell, Mathers and Ross.

Drug Inspector Wanted.—The College of Physicians and Surgeons of Quebec adopted a resolution calling attention to the abuses, the serious accidents and numerous losses of life resulting from the actual sale of prepared and patent medicines, and requesting the government for legislation to control their sale. The organization declares that the sale of any such preparations should not be tolerated unless each package or bottle bears the name of the preparation, the quantity of each dose, the maker's name, that of the seller, and the price.

Consumption of Spirits in Canada.—The consumption of spirits in Canada during the last fiscal year amounted to 5-343,954 gallons, or .958 gallons for each person of the total population. This is the largest consumption since 1885, when it reached 1,126 gallons a head. Last year the consumption

of beer was 27,608,518 gallons, an average of 4.918 gallons a head. The use of beer has been steadily on the increase since 1869. The consumption of last year was the largest on record except for the year 1902, when it reached 5,102 gallons a head. The average since 1869 was 3,182 gallons. The consumption of wines remains about the same, .96 gallons a head. The average quantity of tobacco used a head per annum has been 2,178 pounds for thirty-five years. Last year it reached 2,765, the largest on record.

Montreal Marriage and Birth Rates.—According to the recent annual report of the medical health officer of Montreal, the mean birth rate for the past sixteen years in that city, without distinction as to nationality, was 39.10 per 1,000 of the population. The French-Canadian birth rate was 49.95 per 1,000; that of other Catholics, 25.95, and of Protestants, 24.96 per 1,000. For 1903 the total birth rate was 36.98 per 1,000; for French-Canadians, 43.64; other Catholics, 30.69, and Protestants, 20.52. The birth rate is the highest since 1896. The marriage rate for 1903 was 10.16 per 1,000, giving an increase of 1.18 over the mean rate for the last sixteen years, or an increase of .94 per 1,000 of the population over the rate for 1902, and 2.01 over that of 1901. The marriage rate among the French-Canadians was 10.75 per 1,000; other Catholics, 7.35; Protestants, 10.36 per 1,000.

A New General Hospital for Toronto.—The government of Ontario has proposed to make a grant of \$100,000 to the Toronto General Hospital, at the solicitation of the University of Toronto, which institution desires to provide abundantly for the needs of its medical faculty. The estimated cost of the new hospital is about \$750,000 and it is likely that the city of Toronto will contribute another \$100,000, making four gifts of \$100,000, real or proposed. Over 600 medical students attend Toronto University, and there is great lack of facilities for clinical instruction. Toronto now contributes to its hospitals on the per diem basis, paying out last year \$55,066. This amount was distributed among the hospitals as follows: General, \$11,723; St. Michael's, \$10,316; Grace, \$3,046; Western, \$3,357; St. John's, \$132; Convalescent Home, \$611; Consumption Sanitarium, \$2,476.

FOREIGN.

Wine Adulterer Fined.—A wine manufacturer of Carcassone, France, has been fined \$19,500 for adulterating wines with an admixture of ingredients dangerous to health.

Prize Offered by Life Insurance Examiners.—The International Association of Medical Examiners has appropriated \$150 to be awarded for the best work on the subject of albuminuria in candidates for life insurance and means for distinguishing between physiologic and pathologic albuminuria. Competing works may be in English, German, French or Dutch, and must be received at the office of the association in Brussels before May 1, 1906.

Verdict Against a General Practitioner.—A parturient succumbed to hemorrhage the morning after forceps delivery and the obstetrician's lack of skill was alleged to have been the cause of death. The obstetrician in question is a prominent general practitioner in a German city. Medical experts differed as to whether the postmortem findings implicated him or not. The physician was fined \$125, with the alternative of 50 days' imprisonment, the verdict assuming manslaughter having been abandoned.

The Nobel Prizes.—Dr. Koch of Berlin is talked of for the Nobel prize in medical sciences this year. Dr. Koch's retirement from his Berlin position at the head of one of the great bacteriologic institutions is thought by some European editors to furnish the proper occasion for the recognition of his great services to science, as was mentioned in detail on page 823. The exact amount distributed in the Nobel prizes is the income from the total endowment, now representing a value of \$8,400,000. The income is divided into five prizes after deducting expenses of administration.

Attempt to Poison a Town's Water Supply.—In order to test the engines and pumping plant of the new water-works at Kingsbridge, Devonshire, England, it was decided to fill one of the two large storage tanks, which have a capacity of 40,000 gallons each. Before filling the tank, however, the survivor entered it to ascertain whether all was in order. He discovered the odor of carbolic acid, and found the floor of the tank covered with a sticky substance. Samples of the substance were sent to a public analyst and his report stated that the substance was the residuum of soluble carbolic acid.

Italian Medical Congresses.—Italy has been holding the national congresses for internal medicine, for surgery and pediatrics during the last month. The subjects discussed at the former were, "Fever of Unknown Cause," "Physico-Chemistry in Connection with Diagnosis and Therapeutics," and "The Centers for the Pupil Reflexes." Rissio and Cipollina related further favorable experiences with their serum for treatment of syphilides. Their record now is 12 cases, all cured, and a case of tertiary lesion on the nose, but they are waiting for more extensive experience before officially publishing their methods and results.

Salkowski's Sixtieth Birthday.—Prof. E. Salkowski's name is closely connected with the development of modern physiological chemistry. Especially in regard to digestive and kidney affections and anomalies in metabolism, his researches and those of his pupils in the modest quarters allotted for his laboratory, have rendered incalculable services to medicine, and spread his fame far and wide. His sixtieth birthday was celebrated October 11, and some of our German exchanges issue special numbers in his honor, among them the *Berliner Klinische Wochenschrift*. He is director of the chemical department of the Pathologic Institute, connected with the Charité Hospital at Berlin, associated with Virchow's name.

Judicial Verdict on Sanozin.—The remedy for consumption prepared and sold by Professor Sommerfeld of Berlin under the name of sanozin has been described in these columns. Dr. Sommerfeld declared that his experiences with the mixture have been very favorable. A Frankfurt daily warned its readers against the remedy, declaring that it was liable to injure sound lungs and to augment the process in affected lungs, while it was sold at a price altogether out of proportion to the cost of production. Sommerfeld instituted a suit for libel. Four medical experts testified that the remedy induced temporary improvement, like many other less expensive medicines, but that it was unable to cure diseases of the lungs. The defendant was acquitted, as no libelous intent was established.

Schweninger's Victory.—Bismarck's medical attendant was an irregular practitioner, Schweninger by name, and Bismarck's influence not only secured him an official chair in the Berlin medical faculty, but enables him to this day to have every wish gratified. He was appointed a few years ago to the directorship of a large and important hospital, but this institution was omitted from the list of those where the medical graduates were to receive their final, practical training as "praktikanten." Schweninger protested against this slight, and the authorities have now added his hospital to the list. Our German exchanges regard this Schweninger matter as a national disgrace. At the recent International Congress of Dermatology a formal protest was made against his teaching that mercury is useless and harmful in syphilis. He treats that disease with hydrotherapy alone.

Health Exhibition in Bombay.—In connection with the industrial and agricultural exhibition of the Twentieth Indian National Congress, to be held in December, it has been resolved to have a health exhibition, under the auspices of the Bombay Sanitary Association. The section on hygiene will include the following: 1, water supplies and filtration; 2, drainage and the modern systems of sewage disposal; 3, infectious diseases and their prevention and disinfection; 4, ventilation of buildings and factories; 5, modern sanitary appliances; 6, food and milk, their values and preservation; 7, conservancy and refuse disposal; 8, model dwellings; 9, literature relating to sanitation. This should be an interesting exhibition and help forward sanitation throughout the Indian Empire. It is also proposed to have lectures on subjects pertaining to tropical hygiene and sanitation, the lectures to be illustrated by microscopic and stereopticon demonstrations.

The Persian Imperial Sanitary Board.—By order of the shah, a sanitary board of the Persian Empire was formed, under date of August, 1904, with the view of carrying out the measures prescribed by the sanitary conference of Paris (1903). The board is composed of the minister of police; representatives of the foreign, home, customs, postal and public instruction offices; of the chief of the municipality of Teheran; of the European physicians of the imperial court; of the medical attachés of the Russian, British, French and German legations and the Turkish embassy (there are no medical attachés to the United States, Italian, Austrian, Belgian and Dutch legations); and of such Persian physicians as the board may see fit to nominate. The presidency has been trusted to Dr. Schneider, surgeon colonel of the French army and particular physician to the shah. The council is to hold ordinary meet-

ings once a month and special meetings whenever necessary. The first meeting has already been held, and a committee on hygiene has been appointed with the duty of inspecting and reporting on the cemeteries and slaughter houses of Teheran.

Indian Sanitary Commission.—The offices of sanitary commissioner of the government of India and director-general of the Indian medical service have been separated, as was the case prior to 1880. Major Leslie, I.M.S., has been appointed sanitary commissioner. He will organize and direct research throughout India, which will steadily increase with the progress of the scheme already sanctioned for the establishment of fully-equipped institutes for the study of health problems in India, including a central laboratory devoted mainly to general original research and the making of antivenene and curative serums. In each of the larger provinces there will also be local laboratories for bacteriologic diagnosis and research. The new officer will control all these investigations and decide what work shall be done and by whom it shall be undertaken. The salary of the new appointment will be from \$640 to \$800 a month. The office will usually be held by an officer of the Indian Medical Service specially selected without reference to strict seniority, and the appointment will be for five years, which may be extended, and he will be independent of the director-general. Other officers for this department will be appointed from the Indian Medical Service.

DUBLIN LETTER.

Diarrhea in Children.

In the last monthly report of Sir Charles Cameron, the medical officer of health for Dublin, there is collected a quantity of valuable information on the occurrence of infantile diarrhea in this city. Although in comparison with other cities, both in England and America, the infant mortality of Dublin is very low, yet the subject is, in every center of population, one of primary importance. In East Ham, an eastern suburb of London, the rate of mortality from diarrhea reached this summer the astonishing figure of 16.5 per 1,000 living persons; in Hull it was 14.8; in Salford (which forms one city with Manchester), 12.3, while in Dublin the highest point reached was 5.5. Sir Charles Cameron discusses the subject entirely from the practical point of view without raising any question of the causative organism at work, and he fairly enough blames dirty and improper food as the main cause of the disease. He was able to obtain particulars as to the feeding of a number of those who died during the month of August, and, as might be expected, the disease was specially incident in the bottle-fed. In Dublin nursing at the breast is almost universal, but nevertheless, of 74 infants under one year of age who died of diarrhea, only 11 were breast-fed. Of those who suffered in their second year nearly all were affected within a very short time of the substitution of artificial for natural feeding. Though in most cases the milk used for children's food was not in itself of bad quality, yet it was often kept over night in insanitary surroundings before use, and the feeding bottle was never properly cleansed. Sir Charles Cameron notes among the "extras" supplied to young infants as food such various items of diet as cabbage, cake, potatoes, sweets, rusks and bread and butter, while he finds that it is not unusual to administer porter as a sedative to a fretful child. As in most cases this improper feeding is the result rather of ignorance than of blameworthy carelessness, he thinks that much good can be done in the way of prevention by tactful teaching of the poor. It is proposed to send female instructors round the poor quarters to offer simple advice to the wives of workmen on the feeding of infants. More useful, probably, though with not so rapid a result, would be the instruction of the girls in the national schools in the elements of hygiene and the care of children.

Insanity in Ireland.

The publication recently of the Annual Report of the Inspectors of Lunacy, although nearly two years late, has attracted more attention than is usually devoted to an official document. Although insanity in Ireland is increasing at an extremely rapid rate and is sufficient to cause grave anxiety, yet the situation can not be said to be new, nor does the present report differ in any marked feature from its predecessors. The inspectors year after year show the greatest anxiety to maintain the belief that the increase in lunacy is only apparent, and that the increase of admissions to the asylums only represents an insane population which formerly remained outside asylum walls. Fifty years ago there was calculated to be one insane person in every 600 of the Irish population, whereas to-day there is one in every 170. This change is far too great

to be explained by any doctrine of a large but hypothetical uncertified insane population. It is to be noted, too, that the number of admissions to asylums increases year by year even within the past five or ten years, during which time there can have been but little change in the feelings of the people toward asylum treatment. It is curious that the rate of insanity is much lower in England (1 in 288) than in this country, since most of the causes which are commonly assigned are more active there than here. Syphilis, common in a town community, such as the English population mostly is, is practically unknown outside two or three cities in Ireland. Sexual excess is equally rare in the rural population from which the lunatics mostly spring, and, indeed, one popular writer incurred great odium some months ago by assigning sexual repression as the principal cause of disease of the mind in the rural parts of the country. Alcoholic habits, which are often supposed to be very marked in Ireland, are in reality much less than in England, if one may judge by the annual drink bill of the country. Roughly speaking, an inhabitant of Great Britain consumes the same quantity of spirits, twice the quantity of beer, and as much and a half wine, as the inhabitant of Ireland, yet lunacy does not increase in England at nearly so great a rate as in Ireland. Of the other causes assigned for insanity it is needless to speak. Tea drinking, which looms large in the minds of many, is not so much practiced in Ireland as in England, and the toxic qualities of tea have never been proven. Heredity explains nothing, merely putting the difficulty a generation back. With more reason one may blame emigration, since the continual stream of the young and hardy from our shores tends to leave behind a weak and decadent population. When one turns from the general question of insanity in Ireland to the administration of the present system of asylums, one is astonished at the variety that is disclosed as regards cost of maintenance. Curiously enough, the cost a head is highest in the largest asylum in the country, the Richmond asylum, where it reaches \$210 a year, while it is lowest in the small asylum at Castlebar—\$115. This is all the more remarkable as in the Richmond asylum it has been found possible to employ over 80 per cent. of the patients in industrial occupations.

Correspondence.

Pan-American Medical Congress.

CHICAGO, Nov. 7, 1904.

To the Editor:—I should like to supplement your official announcement of last week concerning the Pan-American Medical Congress by some information which will be of value more especially to men throughout the middle west. Unfortunately, the time is too short to permit of much preliminary preparation, either scientific or social, but for any one of the profession wishing to take advantage of the opportunity for a winter's outing nothing more favorable could be offered.

Assuming Chicago to be the starting point, one can reach New Orleans in a day's journey. There has recently been put into operation a line of freight and passenger steamers of first-class character, from New Orleans direct to Colon, taking about five days, sailing every Friday at 10 a. m. Allowing one week from Chicago to Colon, one week on the isthmus and one week for the return journey, the trip may be made a short one at an expense easily within \$200. There is no doubt that the government of Panama with its appropriation of \$25,000 will do very much to make the congress one of entertainment as well as of scientific interest, and the program as outlined (see last week's JOURNAL), shows how instructive will be the week spent there. If one wishes to spend a fourth week on the trip, the stay on the isthmus may be prolonged, or the return may be made via either Havana or Vera Cruz. Up to the present no active effort has been made to organize an excursion, but I feel sure that if such members as expect to go from New Orleans would work together, the railway and steamer companies would gladly offer inducements in the line of lower rates; but this is a matter demanding prompt attention.

Considering the inter-American character of the congress, the interest hitherto shown by our government in promoting

it, the ambition of the Republic of Panama in becoming the host, and the real importance of showing the most cordial desire to participate in such a gathering, we of the profession in the United States should make a decided effort to send a delegation commensurate with our size and scientific reputation.

I have been asked to help in stimulating a general interest in this matter. To any who desire any further information I will send what I can from time to time, and if those who seriously wish to attend the congress will communicate with me I will do my best to arrange routes and rates so that all may go together. The last steamer available will leave New Orleans December 23.

ALBERT B. HALE.

103 State Street.

A Preliminary Fifth Year in the Medical Curriculum.

NEW YORK CITY, Oct. 28, 1904.

To the Editor:—There has of late been much agitation about the deficiencies in medical education and at the same time about the desirability of terminating the course at a comparatively early age. As some recently published statistics show that there is no material difference in the schedules of 43 of our presumably best schools I ask permission, for purposes of giving details exactly, to cite without naming the institution, the difficulties and the possible solutions, which are before one of these colleges. The facts are applicable to all and should be of general interest.

In a course of four years, each of about 30 actual working weeks, containing six days with an outside limit of eight hours available for teaching there are 5,700 hours which can be devoted to lectures, clinics, laboratory exercises, recitation and small clinic classes for bedside and other practical work. The school used for illustration requires 4,145 hours, or about five and three-quarter hours a day, of attendance on exercises, each of at least one hour duration. The study or preparation required of the student is not considered in this. Five and three-quarter hours (in many schools, if their statistics are to be believed, it is much more) may not seem excessive to the uninitiated, but with all the study hours which they involve experience has shown that every year a certain number of men, especially in the advanced classes, break down physically and have to leave college before the spring examinations; in other words, it is certain that the limit of student endurance has been reached, if it already has not been much exceeded; and yet complaints are constantly appearing in the journals that this or that subject is entirely neglected; that, for example, no adequate attention is given to psychiatry or to the duties of life insurance examiners, or to those of public health officers. There is much justice in all this, but where does the poor student come in? In New York, and probably in every large center, all the "best" undergraduates very properly regard the medical course itself as a preliminary to the more thorough training for the needs of their professional career obtainable as interne in the service of a hospital. Such positions are granted here only on the results of a most severe competitive examination, both theoretical and practical. For each place there are always from 10 to 20 or even 30 candidates, and no better means could be devised for keeping up the standard of medical education. The object of every school should be to produce competent practitioners, and the hospitals want only the best of these. All the student's energies are directed toward success in these rather than in his college examinations. Probably none of the schools gives its students any option in lessening the required college work to provide more time for study for these competitions; the tendency is rather the other way, as the rivalry between the faculties causes a close watch to be kept on the results and more instruction is added wherever weak points are discovered.

Putting in a few more weeks each year would seem the cheapest way of providing more time, but practically it does not. The course lasts now from the last week in September until the second week in June, or nominally 38 weeks. Taking

out the time for holidays in this period (the longest of which, by the way, are this year just 10 days at Christmas), and that devoted to examinations, the actual working weeks approach closely to 30. Hence, as this seemed short, the faculty offered, about two years ago, supplementary work for the remaining whole or part of the summer. But even when this opportunity was made practically free, none availed themselves of it, and the faculty feel that anything like the "quarterly" system by which the college may be kept in active operation throughout the year, is impossible, at least in New York. The general educational habits, if not the summer climate, prevent it.

But the necessity of providing more time for both pupil and teacher is becoming more apparent, and the problem narrows itself down to demanding better preparation for medical work, higher entrance requirements in other words, or another year for the medical curriculum. In the broadest sense the expense and time elements in these two propositions are practically the same for the student; as he must know more of everything, especially of natural science, he must take more time for it and pay for it. A year more than the average high school requirement is sufficient to acquire all the non-technical subjects in the medical curriculum and the others grouped under the heading of biology, which are urgently needed. The most economical method of attaining this will be pointed out.

The requirement of the A. B. degree preparatory to the medical course can be dismissed as unjust and impracticable if only because it is very costly. Those who are fortunate enough to obtain so good an education prove its worth by almost invariably surpassing all others in the hospital competitions. In addition to maturity, they possess as much social as intellectual and hereditary advantages, but they represent only 8 per cent. of all the medical students of the country. Even if this number showed any prospect of increasing, the addition of another institution open only to such men would be a very expensive experiment and one of doubtful utility to the community. A great advance can, however, be made by dropping from the curriculum inorganic chemistry and physics. In the entering class in the college used for illustration last year, about 70 per cent. showed that more or less knowledge of these subjects had been obtained in preliminary education; this year the number rose to 80 per cent., but an examination equivalent to that held at the end of the first medical year, proved that only about 2 per cent. knew enough to be advanced to organic or physiologic chemistry. The primary schools are evidently not sufficiently equipped or advanced as yet to thrust even this work back on them, and with the growing importance of chemistry to medicine it is doubtful if they ever will be. In the statistics above referred to, this subject occupies an average of 375 hours, and general medicine only 544 hours. The manifest disproportion can only be remedied, not by abbreviating chemistry, but by transferring the inorganic part with physics in a preliminary fifth year. They can thus obtain adequate treatment, for, in spite of the suspicion with which they are regarded by the older practitioners, these subjects are those on which the whole future of medicine depends. With them should be grouped thorough courses in general biology, including zoology, embryology, bacteriology and comparative anatomy and physiology. There is enough matter to fill the year to overflowing, but not enough students. The expense to all concerned would be at present only less than that leading to the combined A. B. and M. D. degrees, or seven years' course, nevertheless there are all the indications that it soon must come, and it is time the way were being prepared.

The loss of students, which would inevitably result to the school inaugurating a compulsory five-year course in competition with the numerous excellent schools offering courses of four years, alone prevents the advance. The necessary instruction is really a minor item in the account, as the subjects of a fifth preliminary year (inorganic chemistry and physics, general biology, with zoology, bacteriology, embryology, comparative anatomy, both gross and histologic, and physiology)

are to a greater or less extent taught at present, and a little elaboration and a few more hours for the teaching staff will suffice. The difficulty lies in forcing the students to expend the time and money.

With the certainty that inorganic chemistry and physics are occupying hours which should be filled by purely technical matter, it is legitimate to so arrange the curriculum that only the ablest and best prepared men can avoid dividing their first year into two. For all of these subjects, together with organic and physiologic chemistry, usually given in the second year, can, by proper arrangement, be placed in the first year, the first half of which can be given over to the primary work, and the second half to the more advanced division of the subject, and at the same time by grouping the other subjects into periods, the entire present field can be covered.

In the school used for illustration, there are a total of 954 hours of required work in the first year, and 1,164 in the second. The combination suggested would make only 1,158 hours in the first year, and is not excessive. Furthermore, the applicant for admission can be allowed to prolong the first year into two, and if he does, to have a wide choice of courses in other natural sciences. The relief to the present advanced years would be considerable in the consequent displacement backward to an earlier period of a fundamental subject like pathology, and at the same time better preparation would mean better appreciation.

With rigid examinations at the middle of the first year and failure to "pass" successfully its inorganic chemistry and physics meaning refusal to admit to organic and physiologic chemistry in the second half of the year, only the brightest men could escape a compulsory two years, which now is one. In the second half of the first year they would have to repeat the work they had failed to accomplish and to this could be added the biologic studies, which are so desirable. They could not begin organic and physiologic chemistry until the following year which, by a little adjustment, could be readily filled to overflowing with primary medical studies. They could not enter another school in the middle of the first year, and would realize their deficiencies and take the desired five years to complete their course. A payment of \$25 for each subject about covers the cost of material, and would foster a preliminary training in at least chemistry and physics. A high school student could then continue his regular studies and take these subjects at the same time in the medical college. Or the usual yearly tuition, payable in a lump sum in advance, could be made to cover as many of the other natural sciences as the candidate, unsuccessful in the first half of the year, could take in the second half. As it is now in the school mentioned, between 30 per cent. and 35 per cent. of the first-year class are "dropped" each spring, and the arrangement proposed is more equitable to them than the present. It provides for every kind of preliminary education, for as a rule the state laws permit part of it to be made up during the first medical year, and college competition, in spite of protests to the contrary, countenances very generally the admission of such badly handicapped individuals. As the practice is bound to persist the five year course mitigates the evil as much as possible, and one or two natural science subjects are legitimate offerings as part of the premedical studies. Those who are capable of crowding all of their physics and chemistry into the present first medical year have the opportunity to do so and graduate in four years, with far more time for digesting the advanced part of the present curriculum than now. They could not have the advantage of the biologic subjects, but would obtain more of the technical work. The best fitted students, the 8 per cent. who have had academic college training with natural science accessories, can, with proper arrangement of the schedule, enter the present second year, and as by law they are so permitted in this state, obtain their A. B. and M. D. degrees at the end of seven years. This condensation of all subjects not strictly medical, into the first of the four years is difficult but feasible, and by virtually forcing a five-year course on all but the brightest and best prepared men, is the only economical way of an ad-

vancement which is becoming compulsory in all schools by the natural progress of events. The natural sciences, particularly inorganic chemistry and physics, are essentials in every good general education, and the threat of a five-year technical course would be a powerful factor in placing these troublesome subjects where they belong, namely, in the preparatory curriculum.

JOHN ROGERS,
Secretary of the Faculty of the Cornell University
Medical College.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PROCEEDINGS OF CONGRESS OF ARTS AND SCIENCE.

NEENAH, WIS., Oct. 9, 1904.

To the Editor:—How and where can I obtain a copy of the addresses delivered at the recent International Congress of Arts and Science at St. Louis? I noticed by your recent editorial that they were being printed, and the information asked would be very much appreciated. F. E. M.

ANSWER.—The proceedings of the Congress of Arts and Science will be edited and published under the auspices of the Exposition Company. It is expected that the matter will occupy at least twenty volumes. We are informed that these will be divided so as to include departments, so that one may purchase copies covering the branches in which he may be interested. We are unable to secure any further details at present.

Marriages.

HARRY E. HUNT, M.D., to Miss Irma Mary Fischbein, both of St. Paul, Minn., October 25.

SUMNER A. FURNISS, M.D., Indianapolis, to Miss Lillian Morris of Louisville, October 26.

HENRY E. FARREL, M.D., St. Louis, to Miss Louise Sarrrett of Cambridge, Mass., November 1.

WALTER S. HANLEY, M.D., to Miss Caroline E. Moorehead, both of Philadelphia, October 25.

JACOB FRANKLIN MEYERS, M.D., to Miss Mabel Edna Gauby, both of Lisbon, Iowa, October 26.

FRANCIS E. LAFORCE, M.D., Burlington, Iowa, to Miss Edith Ferguson of Chicago, November 1.

WILTON A. DAY, M.D., Deer Park, Wis., to Miss Cora L. Roberts of Eveleth, Minn., October 27.

JOHN G. SOUTH, M.D., Frankfort, Ky., to Miss Christine Bradley, at Louisville, November 2.

WILLIAM H. KNOTT, M.D., Hume, Mo., to Miss Katherine Rollins of Keokuk, Iowa, October 26.

ANDREW CALLAHAN, M.D., Philadelphia, Pa., to Miss Elizabeth Gibson of Wilkesbarre, Pa., October 5.

GEORGE TROTTER TYLER, M.D., Owensboro, Ky., to Miss Theresa Bullitt Coles of Philadelphia, October 27.

Deaths.

Alfred S. Wolff, M.D. Academy of Medicine, Paris, France, 1841, a member of the American Medical Association and for twenty-five years the efficient inspector and quarantine officer of the Texas State Health Department at Brownsville, died at his home, October 30, aged 88. He was born at Lyons, France, the son of Dr. Simeon Wolff, a noted physician of Paris. After graduating in medicine he entered the French army as surgeon and served throughout the Algerian campaign of 1846, and for two years thereafter, receiving the Cross of the Legion of Honor for gallantry. He then went to Holland and took his second degree in medicine from the University of Leyden, thence going to London, where he qualified and engaged in private practice. In 1859 Dr. Wolff came to America and settled in New York state. At the outbreak of the Civil War he entered the United States volunteer service as surgeon of the Fifty-fifth New York Infantry, but on account of his experience and ability in hospital work, was transferred and assigned to duty

first in Lincoln Hospital, Washington, and then at the Carver Hospital. At the close of the war he was appointed physician to Clinton Prison, New York, and remained there four years. In 1875 he removed to Texas and located in Brownsville. Two years later he was appointed state quarantine officer at that place, and held the position continuously until the time of his death. His service was especially efficient at the time of the yellow fever epidemic in 1882. Dr. Wolff was at one time president of the Northern New York Medical Association, was a member of the New York State Medical Society, the Vermont State Medical Association, the American Public Health Association, Medicolegal Society of New York, and Texas State Medical Association. In token of respect to the memory of its deceased officer, the State Health Department was ordered closed on October 31 until 2 p. m.

James Dritt Reilly, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1859, of Washington, D. C., surgeon of the One Hundred Twenty-seventh and One Hundred Seventy-ninth Pennsylvania Volunteer Infantry in the Civil War, died at the home of his son in College Park, Md., October 12, from paralysis, after an illness of one year.

Benjamin Franklin Hart, M.D. Ohio Medical College, Cincinnati, 1844; Bellevue Hospital Medical College, 1864, a former member of the American Medical Association, member of the Ohio State Medical Society and the Washington County Medical Society, died at his home in Marietta, Ohio, November 5, after an illness of two weeks from paralysis, aged 82.

Alfred H. Powell, M.D. Jefferson Medical College, Philadelphia, 1853, surgeon in the Confederate service during the Civil War; sometime professor of surgery in Washington University of Baltimore, and for many years resident physician of Capen Springs, died at his home in Baltimore, November 4, from heart disease, aged 73.

Walter Walton White, M.D. University of Maryland, Baltimore, 1870, physician to the jail and penitentiary; assistant surgeon to the Presbyterian Eye, Ear, Nose and Throat Hospital, etc., died at his home in Baltimore, November 2, from the effects of influenza, aged 61.

Andrew J. Dean, M.D. University of California Medical Department, San Francisco, 1881, a member of the Medical Society of the State of California, died at his home in Haywards, Cal., October 26, from rheumatism of the heart, after a short illness, aged 46.

Walter S. Carr, M.D. University of Vermont Medical Department, Burlington, 1884, member of the Massachusetts Medical Society and the North Berkshire Medical Association, died at his home in North Adams, Mass., from tuberculosis after a long illness, aged 43.

David G. Hetzell, M.D. Jefferson Medical College, Philadelphia, 1861, surgeon of the Thirty-fourth and Twenty-third New Jersey Volunteer Infantry throughout the Civil War, died from apoplexy at his home in West Philadelphia, October 25, aged 68.

William H. Philpot, M.D. Atlanta (Ga.) Medical College, 1856, of Talbotton, Ga., division surgeon in the Army of Northern Virginia during the Civil War, died at the home of his son in Columbia, S. C., October 22, after a protracted illness, aged 76.

O. S. Belden, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, Pa., 1853, surgeon of the Fifty New Jersey Volunteer Infantry in the Civil War, died at his home in Camden, N. J., October 26, aged 75.

John E. Jones, M.D. Medical College of Ohio, Cincinnati, 1853, surgeon of the Seventy-ninth Ohio Volunteer Infantry in the Civil War, died at his home in Cincinnati, October 31, after a long illness, from heart disease, aged 71.

Edwin E. Webster, M.D. St. Louis Medical College, 1856, honorary member of the state and local medical societies, one of the oldest practitioners of St. Louis, died at his home in that city, October 26, aged 82.

Howard Grant Baird, M.D. Jefferson Medical College, Philadelphia, 1893, a member of the Saline County (Kan.) Medical Society, died at his home in Falun, Kan., from Bright's disease, October 27, aged 38.

Frederick D. Cnrphey, M.D. College of Physicians and Surgeons of Kansas City, Kan., 1902, mayor of Thomas, O. T., died at his home in that city, October 28, after an illness of one week.

Ralph Bridge Linn, M.D. Medical-Chirurgical College of Philadelphia, 1899, formerly of Wilcox, Ariz., died recently at his home in Los Angeles, Cal., and was buried October 20, aged 27.

Alexander J. Smith, M.D. the College of Physicians and Surgeons, Baltimore, 1885, died suddenly from valvular heart disease at his hospital in Clarkston, Wash., October 24, aged 50.

Benjamin F. West, M.D. Rush Medical College, Chicago, 1881, formerly of Tecumseh, Neb., died at Lincoln, October 24, from paresis, after an illness of three years, aged 47.

J. Henri Kessler, M.D. Missouri, 1878, of Portland, Ore., died at St. Vincent's Hospital in that city, October 13, from prostatitis, after an illness of three weeks, aged 54.

George B. Ellis, M.D. Vanderbilt University Medical Department, Nashville, Tenn., 1883, died at his home in Ellis Mills, Tenn., October 29, from cancer of the liver.

Samuel Huston Lynde, M.D. University of Buffalo Medical Department, 1889, died at his home in Buffalo, October 25, from pneumonia, after a short illness, aged 35.

Florence A. Solomon-Pressler, M.D. College of Physicians and Surgeons, Boston, 1896, of Attleboro, Mass., died in Boston, October 27, after an illness of four years.

Charles H. Thomas, M.D. Bellevue Hospital Medical College, New York City, 1875, of New Orleans, died at Johns Hopkins Hospital, Baltimore, October 29, aged 55.

J. S. Jones, M.D., of New Martinsburg, Ohio, died suddenly at the home of his daughter in Washington Court House, Ohio, October 20, from heart disease, aged 77.

Joseph Butler Draper, M.D. Harvard University Medical School, Boston, 1888, died at his home in Westford, Mass., October 30, from typhoid fever, aged 42.

Truman E. Parkman, M.D. Albany (N. Y.) Medical College, 1886, died at his home in Rock City Falls, N. Y., after an illness of a year, October 24, aged 82.

Mary Frances Green, M.D. Ohio, 1871, died at her home in Fort Wayne, Ind., October 27, after an illness of fourteen weeks, aged 68.

Mordecai A. Posey, M.D. Jefferson Medical College, Philadelphia, 1882, died at his home in Chanceford, Pa., October 28, aged 58.

Franklin Brooks, M.D. Illinois, 1853, was suffocated by an escape of illuminating gas at his home in Chicago, November 2, aged 80.

Joseph Rich, M.D. Geneva, Switzerland, 1835, died at his home in Saginaw, Mich., October 23, from bronchitis, aged 100.

John D. Kergan, M.D. Royal College Surgeons, Dublin, Ireland, 1860, of Detroit, Mich., died in San Francisco, October 18.

Pleasant Fair Chapman, M.D. Arkansas, 1854, died at his home in Porterville, Cal., October 10, aged 73.

Helen Leeker Lynch, M.D. Illinois, 1890, died at her home in Highland Park, Ill., October 22.

Richard Alexander Smith, M.D., died at his home in Raleigh, N. C., October 12, aged 75.

J. M. Lester, M.D. Kentucky, 1893, died at his home in Otter Bend, Ky., October 14.

Book Notices.

THE EXAMINATION OF WATERS AND WATER SUPPLIES. By John C. Thresh, D.Sc. (Lond.), M.D. (Vic.), D.P.H. (Camb.), Honorary Diplomat in Public Health, Royal College of Physicians and Surgeons, Ireland. Cloth. Pp. 460. Price, \$4.00. Philadelphia: P. Blakiston's Son & Co. 1904.

His long experience as health official has brought the author of this work into direct contact with many of the practical problems that depend for their solution on technical data. The present book is divided into three parts, dealing with: 1, The examination of the sources from which water is derived; 2, various methods of examining water and the interpretation of the results; 3, analytical processes and methods of examination. The book as a whole appears to reflect faithfully the present state of opinion in Great Britain on the subjects treated. The illustrations drawn from the writer's experience are often especially illuminating. It is perhaps unfortunate that, as regards both method and interpretation, so much divergence should exist between workers in this country and in Great Britain as is revealed in the treatise before us. Such statements as the following (p. 79) serve to show how wide the divergence really is: "The amount of nitrite in water is very rarely determined, as such a determination serves no use-

ful purpose." On p. 137, in comparing the standards of "bacteriologic purity" proposed by Miquel and Macé, Dr. Thresh is evidently attacking a man of straw, for he fails to note the fact that the peculiarly long period of plate incubation adopted by Miquel is entirely different from that of practically every other investigator and forbids the use of his tables in such a comparison as here instituted. The somewhat faltering attitude shown in general by the author in dealing with bacteriologic questions is exemplified in the following extract: "My impression decidedly is that in water recently polluted by sewage, the *B. enteritidis sporogenes* and the *B. coli communis*, can always be detected in reasonable amounts of the water if the degree of pollution is so great as to be dangerous" (p. 165). The use of the expression "reasonable amounts" is not adapted to allay inquiry. We anticipate that most American workers who have to do with the bacteriology of water will be induced by the appearance of Dr. Thresh's book to express more openly the surprise they have long felt at the singular failure shown by their fellow-workers abroad to differentiate more thoroughly the various groups of gas-forming bacilli. Much of the perplexity and confusion displayed by Dr. Thresh in discussing the validity and nature of the "coli test" is due to this point.

THE PRINCIPLES OF HYGIENE. A Practical Manual for Students, Physicians and Health Officers. By D. H. Bergey, A.M., M.D., Assistant Professor of Bacteriology. Illustrated. Second Edition, Thoroughly Revised and Enlarged. Cloth. Pp. 536. Price, \$3.00 net. Philadelphia, New York and London: W. B. Saunders & Co. 1904.

This second edition contains many important revisions and additions, showing the advances which have been made in the field of preventive medicine in the short space of four years. The most important changes are found in the chapter on "Immunity and Susceptibility." Ehrlich's theory is given in a much clearer and simpler form than in the first edition; the subject of precipitins and their relation to legal medicine is taken up; the latest work in the preparation of bactericidal sera, done by Marmorek, Morer, Aronson, etc., is given full consideration, and also the experiments of Wechsberg and of Besredka on immunization. There is a new section on the "Relation of Insects to the Spread of Disease," with methods for the extermination of insects, anti-mosquito campaigns, etc.; new sections on "Trypanosomiasis," "Ucinariasis," "Spotted Fever" and "Helminthiasis." Additions to the chapter on vaccination appear in the form of a much needed paragraph on the precautions to be used in its administration. The author's attitude toward the danger of tetanus infection through vaccination appears over-optimistic in view of MacFarland's researches. It is better to face facts courageously than to cover them up through fear of unduly alarming the public. A chapter which one would gladly see enlarged and amplified is the one on the important subject of the housing of the poor. So much valuable investigation of tenement life in large cities has been done in our own country, in New York, Boston and Chicago especially, that it seems a pity to draw only on the material furnished by foreign statistics.

THE NERVOUS AFFECTIONS OF THE HEART, Being the Morison Lectures Delivered Before the Royal College of Physicians of Edinburgh in 1902 and 1903. By George Alexander Gibson, M.D., D.Sc., F.R.C.P. Ed., F.R.S.E., Honorary Member of the Medico-Chirurgical Society of Norwich. Cloth. Pp. 99. Edinburgh and London: Young & Pentland, 1904.

Again medical literature is enriched by a contribution from the pen of the distinguished Gibson, who has succeeded to the reputation of his late famous teacher and predecessor, George Balfour. As stated on the title page, this book of 99 pages is a reproduction, with a few verbal alterations, of certain lectures which were originally published in the *Edinburgh Medical Journal*. They consist of six lectures, divided into two sections, the first three dealing with the clinical, pathologic and therapeutic aspects of the sensory disturbances, and the three comprising the second section being devoted to the rate, rhythm and force of the heart as displayed in its motor disturbances. The book is well worth the perusal of every practitioner of medicine and in particular such physicians as are interested in life insurance examinations. The physiology of the innervation of the heart and of its motor mechanism is

entered into clearly and with sufficient detail, yet without tediousness. Practical observations and conclusions are given and there are many valuable therapeutic suggestions. Of particular interest and value are the lectures dealing with the disorders in rate and rhythm. A knowledge of the facts contained in this book will be of material aid in the understanding of many cases of disordered cardiac function that would otherwise fail to be understood or corrected.

TEXT-BOOK OF NERVOUS DISEASES AND PSYCHIATRY, For the Use of Students and Practitioners of Medicine. By Charles L. Dana, A.M., M.D., Professor of Nervous Diseases and (ad interim) of Mental Diseases in Cornell University Medical College. Sixth Revised and Enlarged Edition. Illustrated by 244 Engravings and 3 Plates in Black and Colors. Cloth. Pp. 690. Price, \$4.00. New York: Wm. Wood & Co., 1904.

In the sixth edition of Dana's work some of the remarks on therapeutics have been omitted and a description of mental disorders added. Cytodiagnosis is touched on as an important addition to neuralgic medicine since the last edition appeared, and a few new cuts have been added. In the section on mental diseases the author follows largely the modern ideas, especially those of Kraepelin, which at present dominate American psychiatry. In a new chapter on general psychology the elementary facts and definitions are briefly but clearly given. In treating of the special forms of mental disorders the author's statements are based largely on personal experience and this portion affords the advantages of a neurologist's point of view of mental diseases. There is necessarily brevity, but the treatment of the subject is as adequate as could be expected within the compass allowed. The relations between nervous and mental diseases are close and this section of the work forms a valuable supplement to the more strictly neurologic portion of the text. It will undoubtedly add to the well-deserved popularity of the work.

CLINICAL LECTURES ON MENTAL DISEASES. By T. S. Clouston, M.D., Edin., F.R.C.P.E., President of the Royal College of Physicians of Edinburgh. Sixth Edition. Cloth. Pp. 758. Price, \$4.25. Philadelphia and New York: Lea Brothers & Co., 1904.

Notwithstanding its somewhat peculiar arrangement this treatise has deservedly taken high rank among works on mental disorders. This edition is considerably altered from the former ones, and the alteration is an improvement. Dr. Clouston is one of the best clinical observers among modern alienists and what he writes is always worthy of attention. He has added to this work notice of the more recent advances and while he does not follow the lines at present most generally popular in this country, his work will be found a valuable one to consult on diagnosis and treatment. If we were to offer a criticism it would be that the author does not lay sufficient stress on the matter of intoxication from the digestive tract as a factor in the causation and continuance of certain mental disorders. The therapeutic bearings of this subject are such that it can hardly be ignored. We do not say that Dr. Clouston ignores it, but he does not attribute to it apparently all the importance it deserves and this is perhaps more notable since certain other Scotch alienists have even included paresis as a result of intestinal auto-intoxication. The present edition is enlarged to some extent by the addition of pathologic descriptions and plates illustrating the more recent work in this line especially by British workers.

EPITOME OF NERVOUS AND MENTAL DISEASES. A Manual for Students and Physicians. By Joseph Darwin Nagel, M.D., Consulting Physician to the French Hospital, New York. With 46 Illustrations. Cloth. Pp. 276. Price, \$1.00 net. Philadelphia and New York: Lea Brothers & Co., 1904.

This little work belongs to a class of books which are sometimes condemned as being too brief and superficial to be of real value. Although they have their limited use, the chief objection to them is that the use is not sufficiently limited. The present instance is perhaps as good as the average, but it ought not to be depended on as a sole guide—even for examinations—as we fear it will be by some.

VETERINARY STUDIES for Agricultural Students. By Dr. M. H. Reynolds, B.S.A., D.V., M.D., professor of Veterinary Medicine, University of Minnesota. Cloth. Pp. 246. Price, \$2.00 net. St. Paul: Published by the Author, St. Anthony Park, Minn., 1903.

This book is intended chiefly as a text-book in agricultural colleges. The anatomy and physiology of the common domes-

tic animals is described sufficiently as a foundation for the comprehension of disease. The various disorders and diseases are presented in a clear and concise manner.

BEAUTY THROUGH HYGIENE. Common Sense Ways to Health for Girls. By Emma E. Walker, M.D., Member of the New York Academy of Medicine. Illustrated. Cloth. Pp. 306. Price, \$1.00 net. New York: A. S. Barnes & Co., 1904.

This is another book whose circulation will make for health. It is a guide for young women on every part of life and habits that has ought to do with health and beauty. We have read a good deal of it and find no advice that is not sound and to be commended.

Miscellany.

The Physician's Wife.—A French medical journal—the *Journal des Practiciens*—is gravely discussing the sort of wife a physician should marry, and another, the *Revue Médical*, has been conducting a symposium on the question, whether a physician should marry at all. Bandouin, in his *Gazette Méd. de Paris*, comments that work in the medical profession is one thing and marriage is another, and they have nothing to do with each other. He adds, however, that he is awaiting with interest the article, yet to be written, on the husband of the medical woman.

Notes of a German School Inspector.—The newly founded monthly magazine for social medicine, *Monatsschrift für soziale Medizin*, contains in No. 4 an article from M. Cohn, giving the results of four years' experience as school inspector at Charlottenburg. Two schools with about nine hundred children each were in his care. He found curvature of the spine in 40 per cent. of the children in the upper grades, while it was noted in only 4 per cent. of those first entering school. He advocates closing a schoolroom at once when an epidemic of infectious disease is first noted. After the length of time required for the incubation of the disease and the disinfection of the room, it may be reopened. He urges more instruction in hygiene by the teacher in the lower grades and by a physician in the upper ones. Instruction should be given in cleaning, in bathing, in gymnastics and in skating. The attention of the children may be won by giving them objects to handle connected with the subjects. He recommends school sanatoria for the larger communities.

Medicine and the Literary Career.—Under this heading the *Semaine Médicale* for October 5 describes the career of one of the greatest and most popular of modern Russian novelists, A. P. Tchekhov, who recently succumbed to tuberculosis at the age of 44. He was a duly registered physician and during the epidemic of cholera in 1892 he left his literary work to help combat the disease. The editorial compares him to Rabelais, Schiller and our own Holmes, and comments on the aid that a medical training is able to give to a professional literary man. It teaches him to observe, to be able to grasp the salient points of an event and to comprehend the psychology of the individual, for the physician has to study the soul and the mind of the patient before him as well as his lungs and his heart. He must be a psychologist as well as a scientist, and Tchekhov himself attributed great importance to his medical studies as the foundation for his literary work. The writer of the editorial is apparently not acquainted with Weir Mitchell's brilliant works, and he has yet to make the acquaintance of Conan Doyle's Sherlock Holmes, but they are only additional proof of the truth of his contention that a medical training is a remarkable aid to a novelist. In a recent address Conan Doyle remarked that he believed the time would come when young men who were going to do anything in the world would be passed through medicine as they used to be passed mechanically through the bar. He knew of no other means by which a young man could get to the fundamental and absolute facts of life. The editorial referred to above concluded with the old saying: "Medicine leads to anything on condition that it is abandoned," but comments that this condition is by no means indispensable nowadays.

Notes on American Hospitals.—Campbell Douglas, L.R.C.P. Ed., writing in the *Glasgow Medical Journal*, says: "The spectator at an operation in an American hospital is struck by the attention to detail, or apparent attention, observed by the various actors in the drama, and by the general tendency toward an aseptic régime, which is the aim of most of the surgical institutions. Yet every now and again one sees things which make him wonder whether after all they are not missing the greater in too careful attention to the lesser things which make toward idealism. Thus patients in the Johns Hopkins Hospital, undergoing operation for hernia and appendicitis, and not urgent cases, were placed on the table without any preparation of the patient's skin beforehand. The shaving and scrubbing up of the abdomen and genitalia were then carried out in a few minutes by the theater porter, whose duties are to clean up the place and make himself generally useful. In one big New York hospital, with a more than local reputation for being up to date, I watched a surgeon don sterilized gloves without having sterilized his hands, transfer his eyeglasses from his vest pocket to his nose, and proceed to open a cerebellar abscess through the mastoid process, in a patient whose head had not been shaved, and whose hair had not been clipped. Later on, I asked the house surgeon if that was one of their best surgeons, and he assured me that he was—one of their finest. Frequently, after an abdominal section, the house surgeon was left to close the abdomen and apply the dressing. Surely, if the operation were worth beginning, it was worth finishing by the surgeon."

The Model Maternity at St. Petersburg.—A letter in the *Münch. med. Wochenschrift* for June 21, describes the new home of the unique clinical gynecologic-obstetric institute at St. Petersburg, formally inaugurated last February. The building and equipment have cost nearly two millions, and there are accommodations for 170, or at need for 200 patients. Prof. D. von Ott was the moving spirit, and has introduced many innovations. There is a constant supply of sterilized water and of physiologic salt solution, and hundreds of spray apparatus keep the air constantly moist. Ice is made artificially from sterilized water, and each bed is supplied with a telephone and is connected with a fine organ, installed at an expense of about \$15,000, for research on the influence of the musical vibrations on the sick and well. Lavish use is made of electricity for heating, lighting, etc. A double sewerage system enables the sewage to be sterilized before it leaves the building. The left wing is for the maternity patients, the right for the gynecologic, the halls, etc., in the center. The beds can be wheeled into a sun parlor with southern exposure. Prof. von Ott is accoucheur to the royal family, director of the Woman's Medical Institute and Midwives' Institute, besides his work in the Maternity above described. He will complete next December the twenty-fifth year of his professional career, and his friends and pupils are getting up a *Festschrift* to present to him on this occasion. Prof. W. Stroganow of St. Petersburg has the matter in charge. Ott's method of ventrosopy was described in *THE JOURNAL*, 1902, xxxix, p. 454.

Immunization Against Anthrax.—According to the *British Medical Journal*, Mr. J. A. Gilruth, M.R.C.V.S., veterinary surgeon and bacteriologist to the New Zealand Department of Agriculture, has met with some success in immunizing animals against anthrax by adopting the method of mixed infection. He finds that guinea-pigs, rabbits, and sheep can completely resist the inoculation of large doses of virulent anthrax bacilli, provided that these organisms are mixed with a larger dose of certain other organisms which are non-pathogenic to the animals in question. In order to secure this result it is necessary that the anthrax bacilli should be actually mixed with the other organism used; for if the dose of each organism be injected separately, under different parts of the skin, no resistance is obtained. It is not claimed that a single inoculation establishes immunity, and it is conceded that an animal which has suffered with impunity the injection of a large dose of anthrax bacilli, when mixed with a foreign organism, may

succumb later to a much smaller dose of pure anthrax culture. If, however, the doses of mixed cultures be repeated in increasing quantities, Mr. Gilruth finds that, in the case of rabbits and sheep, immunity to large doses of pure anthrax bacilli can be conferred. For the purpose of admixture with his anthrax cultures, he has found the bacillus of Gaertner a convenient organism to use. The following results of Mr. Gilruth's investigations are worth quoting: He has succeeded in producing in a rabbit an immunity to 4 c.cm. of pure virulent anthrax culture, and in another rabbit an immunity to 3 c.cm.; moreover, two sheep and a pig have each offered a successful resistance to 5 c.cm. of a similar culture. The antagonism of other organisms to anthrax has long been known, but the value of mixed inoculation as a practical preventive measure is not yet clear.

State Boards of Registration.

COMING EXAMINATIONS.

- Maine Board of Registration of Medicine, November 15, Augusta. Secretary, A. K. P. Meserve, M.D., Portland.
- New Mexico Board of Health, Santa Fe, December 5. Secretary, B. D. Black, M.D., Las Vegas.
- Ohio State Board of Medical Registration and Examination, Columbus, December 13-15. Secretary, Frank Winders, M.D., Columbus.
- State Medical Examining Boards of Delaware, Wilmington and Dover, December 13-15. Secretary, P. W. Tomlinson, M.D., Wilmington.
- The Medical Examining Board of Virginia, Richmond, December 13-16. Secretary, R. S. Martin, M.D., Stuart.
- Board of Medical Examiners of Maryland, Baltimore, December 14-17. Secretary, J. McP. Scott, M.D., Hagerstown.
- Missouri State Board of Health, St. Louis University, St. Louis, December 19-21. Secretary, W. T. Morrow, M.D., Kansas City.
- Iowa State Board of Medical Examiners, Capitol Building, Des Moines, December 21-22. Secretary, J. F. Kennedy, M.D., Des Moines.
- Oklahoma Medical Examining Board, Guthrie, December 28. Secretary E. E. Cowdrick, M.D., Enid.

Minnesota October Report.—Dr. C. J. Ringnell, secretary of the Minnesota State Board of Medical Examiners, reports the written examination held at St. Paul, Oct. 4-6, 1904. The number of subjects examined in was 12; total number of questions asked, 95; percentage required to pass, 75. The total number examined was 34, of whom 24 passed and 10 failed. The following colleges were represented:

College	PASSED.	Year Grad.	Per Cent.
Homeo. Dept., Univ. of Minnesota	(1904)	70.2
Coll. of Med. and Surg., Univ. of Minn.	(1904) 80.35, 82.2,		83.8, 83.6.
Hamline University, (1904)	86.85, 75.15, 83.3;	(1903)	75
Homeo. Dept., Boston Univ.	(1904)	81.1
Johns Hopkins	(1904)	78.2
Hahnemann Med. Coll., Chicago	(1904)	84.6
Coll. of Med. and Surg., Chicago	(1904)	77.9
Kooken Med. Coll.	(1900)	76.3 (1904)
Jefferson Med. Coll.	(1904)	83
Laval Univ., Montreal	(1903)	83.7
Coll. of P. and S., Chicago	(1904)	82.85
Univ. of Pennsylvania	(1907)	86.4
N. W. Univ., Chicago	(1904) 80.45, 82.2,	(1902)	83.75
Rush Med. Coll.	(1901) 87.45, (1904)		86.75
FAILED.			
Hamline Univ.	(1904)	58.5, 74.4, 66.7
Univ. of Lausanne, Switzerland	(1903)	50.9
Univ. of Michigan	(1901)	68.9
Washington Univ., St. Louis	(1902)	72.5
Hahnemann Med. Coll., Pa.	(1897)	61.7
Coll. of P. and S., Chicago	(1904)	71.3, 71.4
Women's Med. Coll., Chicago	(1890)	65

The board has notified all medical colleges in the United States that graduates of medical colleges granting advanced standing for work done at other than medical colleges shall not be eligible to the examinations given by that board. By non-medical institutions the board refers to colleges of literature, arts, science, pharmacy, dentistry, veterinary surgery, etc. This, however, does not apply to students who were granted advanced standing prior to September, 1901.

The following questions were asked:

CHEMISTRY, URINALYSIS AND TOXICOLOGY.

1. Define atomic weight, valence and alkaloid.
2. Give symptoms and treatment of poisoning by prussic acid.
3. Give a quantitative

and a qualitative test for angar in the urine. 4. What diseases may cause a sediment in urine? 5. Give a test for uric acid in the urine.

EYE AND EAR.

1. Name main points to be considered in an examination of the eye. 2. Corneal ulcer, etiology, symptomatology, treatment. 3. What is proper treatment for (a) abscess of external meatus; (b) discharging ear chronic. Discuss a case. (c) Cure of eyes of newborn. (d) Care of eyes of school children. 5. What eye and ear complications are liable to follow, (a) measles; (b) diphtheria; (c) scarlet fever?

MATERIA MEDICA AND THERAPEUTICS.

1. Name the principal mineral acids given internally in medicine and the dose of each. 2. Prescribe mercury internally for a adult with the beginning secondary symptoms of syphilis. 3. How would you treat constipation in a breast-fed infant of six months? 4. Give directions for the diet and hygiene of a patient with chronic interstitial nephritis. 5. What is wrong with this prescription: R. Argenti nitrate gr. jss. Hydragryi chloridum gr. j. Aque destillata oz. vj.

Misce et solve. Sig.: For urethral injection. 6. Give a safe and efficient dose for an adult of cocaine hydrochlorate; resin of podophyllum; tincture of digitalis; sulphate of strychnia; tincture of opium. 7. Prescribe a lotion containing carbolic acid for a case of papular eczema. 8. Name the two best diuretics and the dose of each. 9. What is an emulsion? Name an efficient emulsifying agent for oils. 10. What is the official title of Epsom salts, of Dover's powder, of Fowler's solution, of tartar emetic, of blue pill?

PATHOLOGY AND HISTOLOGY.

1. Give the pathologic differences between lobar or croupous pneumonia, and lobular or bronchopneumonia. 2. Give pathology of cirrhosis of the liver. 3. What is the condition of the heart muscle after a long and severe attack of typhoid fever? 4. Describe the specific lesions of the intestines in typhoid fever. 5. Give characteristic differences between follicular tonsillitis and diphtheria, pathologically considered. 6. What is found in the urine of an advanced case of Bright's disease, chemically and microscopically considered? 7. Differentiate the pathological between round ulcer and cancer of the stomach. 8. Differentiate between heart muscle and ordinary striated muscle. 9. Describe the red blood corpuscle; the white blood corpuscle. Give the function of each. 10. Describe briefly squamous and ciliated epithelium. Give some of the locations in which each is found.

MEDICAL JURISPRUDENCE.

In these questions the examiner aims to cover general principles only. The modifications of the common law in matters pertaining to medical jurisprudence are so many and so various in the different states and jurisdictions that the student is not assumed to be familiar with them all. 1. Give a good medical definition of insanity. 2. In a body partially decayed, what would guide you in your efforts to identify the sex, the outward and obvious signs being obliterated by decomposition. 3. Tell how strychnia causes death, and give postmortem appearances. 4. Give the respects in which arsenic and strychnia differ. 5. Give the medical jurisprudence; give synonyms, and state in what particulars, if any, it differs from state medicine. 5. What would you consider a lethal dose to an adult person of each of the following: carbolic acid, chloral hydrate, hydrocyanic acid, morphia sulph., assuming that habit has not established a tolerance?

SURGERY.

1. Give classification of wounds. 2. Etiology and treatment of acute osteomyelitis. 3. Describe tenotomy; myotomy. 4. Symptoms and treatment of empyema of the chest. 5. Give etiology and clinical history of spondylitis. 6. Name the varieties of dislocation of the hip, and give the approximate percentage of each. 7. Diagnose and treat a case of talipes equinovarus. 8. Describe and treat a ganglion. 10. Give usual strength in which the following antiseptics are employed in surgery: 1. Corrosive sublimate; 2, permanganate of potash; 3, lysol; 4, kreolin; formalin.

PHYSIOLOGY.

1. What are the more important physiologic uses of bile? 2. Give the more advanced views of the normal formation of liver-glycogen and its more important uses physiologically. 3. Give mechanism and physics of eye accommodation. 4. Differentiate complemental, residual, stationary and supplemental air as applied to respiration. 5. What is the effect of urea in promoting pancreatic secretions? 6. Give functions and physical characteristics of red blood corpuscles. 7. The same of white blood corpuscles. 8. How (if at all) is urea derived from ammonium carbonate? 9. What effects would follow removal of the suprarenal capsules? 10. Name and locate some of the centers in the cerebral cortex.

DISEASES OF WOMEN.

1. The broad ligament (a) describe briefly; (b) infection of, give causes, diagnosis and treatment. 2. Tuberculous peritonitis, etiology, symptomatology, prognosis and treatment. 3. Pueritis vulvae: etiology, symptomatology and treatment. 4. Uterine polypus: Etiology, varieties, symptomatology, diagnosis and treatment. 5. Congenital stenotomy, sometimes called dyspareunia: treat a case of talipes varus. 9. Describe and treat a ganglion. 10. Give usual strength in which the following antiseptics are employed in surgery: 1. Corrosive sublimate; 2, permanganate of potash; 3, lysol; 4, kreolin; formalin.

DISEASES OF CHILDREN.

1. Chlorosis: Etiology, symptomatology, diagnosis and treatment. 2. Lobar pneumonia: Etiology, symptomatology, diagnosis, prognosis and treatment. 3. Acute endocarditis: Etiology, lesions, symptomatology and treatment. 4. Chronic lobarcolitis: Etiology, symptomatology and treatment. 5. Acute rheumatism: Etiology, symptomatology and treatment.

THEORY AND PRACTICE.

1. Give a complete diagnosis of psoriasis. 2. Give full symptomatology of paretic dementia. 3. Give causes and diagnosis of myxedema. 4. Give causes and treatment of gastric dilatation. 5. Give causes and prognosis of cystitis, and differential diagnosis between it and gonorrhoea. 6. Describe anemia. When would you employ iron and when arsenic in its treatment? 7. Give causes of pulmonary congestion and pulmonary edema with differential diag-

nosis. 8. Describe the pathologic changes of the heart resulting from insufficiency of the mitral valves. 9. How would you tell an anemic murmur from another functional murmur or organic murmur at the apex? 10. How does the normal respiratory sound under the left clavicle differ from that under the right?

ANATOMY.

1. Describe the pulmonary artery and give its origin. 2. Give origin and insertion of the biceps flexor cubiti, gastrocnemius, and sartorius muscles. 3. Name the branches of the abdominal aorta. 4. Describe the sphenoid bone and give its articulations. 5. Give the gross anatomy of the kidney. 6. Name the cranial nerves. 7. How many ligaments enter into the formation of the knee joint? Name them. 8. Describe Scarpia's triangle. 9. Describe the internal abdominal ring. 10. What arteries supply the uterus; give their origin?

OBSTETRICS.

1. Give differential diagnosis between pregnancy and (a) ovarian cyst, (b) subperitoneal myomata, (c) dropsy. 2. Give treatment for vomiting of pregnancy. 3. Describe the normal mechanism of labor in vertex presentation. 4. What other presentations of the head are there beside that of the vertex? 5. What is placenta previa? Treatment. 6. How do you distinguish a breech from a face presentation? What are the dangers of a breech presentation? 7. How do you guard against rupture of the perineum? How do you correct it, if it occurs? 8. What are the dangers of labor in twin pregnancies? 9. What is puerperal septicaemia? Give prophylaxis. 10. How do you prevent ophthalmia neonatorum?

HOMEOPATHIC MATERIA MEDICA.

1. Describe the skin affection to which rhus tox. is homeopathic. 2. Distinguish ipecac and antimony tart. in bronchopneumonia. Mention three remedies analogous in such conditions. 3. What are the most characteristic stomach and bowel symptoms of veratrum alb. 4. Distinguish acon., arsen., bell., bry. in feverish states. 5. Give characteristic symptoms of lachesis, lycopodium, podophyllum, china, pulsatilla.

ELECTRIC MATERIA MEDICA.

1. Give the use of ecbinacea, calcium sulphid and the dose of each. 2. Give the uses of ichtbyol; hamamelis. 3. What are the indications for the use of potassium iodid, tuja, corydalis. 4. Name four diuretics and give dose of each. 5. Give specific indications for sodium salicylate, eupatorium, potassium chlorate. 6. Name three sedatives and give specific indications for each. 7. Give specific indications for cactus grand., atrophanthus, digitalis. 8. What is the physiologic action of laborand., elaterium, hyoscyamus? 9. Give physiologic action of ergot, strychn., potassium bromid. What is the dose of each? 10. Name three reliable hypnotics and give indications and dose of each.

Rhode Island October Report.—Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, Oct. 6-7, 1904. The number of subjects examined in was 7; total questions asked, 70; percentage required to pass, 75. The total number examined was 11, of whom 9 passed and 2 failed. The following colleges were represented:

Table with 5 columns: College, PASSED, Year Grad., Per Cent. Lists Boston University, College of P. and S., New York, Harvard University, Kentucky School of Medicine, Maryland College, Syracuse University, College of P. and S., Baltimore, University of Vermont.

WYOMING.

Johnson, S. W., Cambria.
Murray, E. S., Rock Springs.

Sutton, R. L., asst.-surgeon, detached from the Naval Hospital, New York, and ordered to the *Wassachusetts*, November 25.

Winn, C. K., and de Vallin, Hugh, appointed A. A. surgeons from October 28.

Geiger, A. J., asst.-surgeon, detached from the Naval Hospital, Yokohama, Japan, and ordered home.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Nov. 2, 1904:

Peckham, C. T., surgeon, granted extension of leave of absence for ten days from November 8.

Smith, A. C., P. A. surgeon, to proceed to New York and report to chairman of board of examiners for examination to determine his fitness for promotion to the grade of surgeon.

Cumming, H. S., P. A. surgeon, relieved from duty as member of board of examination of Asst.-Surgeon J. W. Amesse, to determine his fitness for promotion to the grade of P. A. surgeon.

Clark, Talafierro, P. A. surgeon, to proceed to Baltimore, Md., for temporary duty in connection with inspection of aliens, relieving Asst.-Surgeon A. D. Foster.

Lumsden, L. L., A. surgeon, relieved from duty at Vera Cruz, Mexico, and directed to proceed to the Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty.

Richardson, T. F., P. A. surgeon, relieved from duty at Laredo, Texas, and directed to proceed to Savannah, Ga., and assume command of the service, relieving Surgeon S. D. Brooks.

Richardson, T. F., P. A. surgeon, granted leave of absence for fifteen days.

McClintic, T. B., P. A. surgeon, to report to director, Hygienic Laboratory, for duty. Granted leave of absence for seven days from Oct. 31, 1904, under Paragraph 191 of the Regulations.

Goldberger, Jos. P., A. surgeon, relieved from duty at Tampico, Mexico, and directed to proceed to Washington, D. C., and report at bureau preliminary to assignment to duty in the Hygienic Laboratory for course of instructions.

Trotter, F. E., P. A. surgeon, detailed as member of board for examination of Asst.-Surgeon J. W. Amesse, to determine his fitness for promotion to the grade of P. A. surgeon.

Gwyn, M. K., asst.-surgeon, relieved from duty at Jolo, P. I., and directed to proceed to the United States and report arrival at San Francisco.

Foster, A. D., relieved from duty at Baltimore, Md., and directed to proceed to Naples, Italy, and report to P. A. Surgeon J. M. Easer for duty in the office of the United States Consul.

Robertson, H. McG., asst.-surgeon, to proceed to Baltimore, Md., and assume temporary charge of service during absence of Asst.-Surgeon C. W. Wille.

Woods, C. H., pharmacist, granted leave of absence for fifteen days from October 27.

BOARD CONVENED.

Board convened to meet at the Marine Hospital, Chelsea, Mass., Nov. 2, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Surgeon R. M. Woodward, chairman; Asst.-Surgeon W. C. Rucker, recorder.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from Oct. 29, to Nov. 4, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, Oct. 15-22, 1 case.
Illinois: Chicago, Oct. 22-29, 14 cases.
Michigan: At 59 places, Oct. 15-22, present; Grand Rapids, Oct. 22-29, 1 case.
Minnesota: Oct. 17-24, Hennepin Co., 11 cases; Ramsey Co., 5 cases; Stearns Co., 17 cases.
Missouri: St. Louis, Oct. 22-29, 8 cases, 2 deaths.
Pennsylvania: Philadelphia, Oct. 22-29, 1 case.
Tennessee: Memphis, Oct. 22-29, 1 case.
Wisconsin: Milwaukee, Oct. 22-29, 9 cases.

SMALLPOX—FOREIGN.

Africa: Cape Town, Sept. 17-24, 4 cases.
Austria-Hungary: Prague, Oct. 8-15, 7 cases.
Belgium: Brussels, Oct. 8-15, 1 death.
Brazil: Bahia, Oct. 1-8, 2 deaths.
China: Hongkong, Sept. 10-17, 1 case.
France: Paris, Oct. 8-15, 10 cases.
Great Britain: Glasgow, Oct. 14-21, 1 case; Leeds, Oct. 8-22, 4 cases; Oct. 8-15, Manchester, 1 case; Newcastle-on-Tyne, 5 cases; Nottingham, 1 case.
India: Bombay, Sept. 28-Oct. 4, 4 cases.
Italy: Palermo, Oct. 8-15, 11 cases, 2 deaths.
Russia: Moscow, Oct. 1-8, 3 cases, 2 deaths; Odessa, Oct. 8-15, 1 case; St. Petersburg, Sept. 25-Oct. 8, 11 cases, 1 death.
Spain: Barcelona, Oct. 10-20, 2 deaths.
Turkey: Alexandria, Oct. 10, epidemic; Beirut, Oct. 8-15, present; Constantinople, Oct. 2-17, 39 deaths.

YELLOW FEVER.

Cuba: Punta de Sal, Santiago, Oct. 24, 1 case.
Cuba: Havana, Sept. 30-Oct. 5, 1 death.
Mexico: Coahuacalcos, Oct. 15-22, 2 cases, 2 deaths; Oct. 16-22, Merida, 1 case; Tehuantepec, 1 case; Tuxtlapec, 53 cases, 5 deaths.

CHOLERA.

India: Bombay, Sept. 27-Oct. 4, 7 deaths; Madras, Sept. 24-30, 1 death.
Persia: Oct. 17, Enseli, epidemic; Resht, 120 to 140 deaths daily; Senenditah, epidemic.
Russia: Transcaucasian District, Sept. 17-29, 44 cases, 23 deaths.
Turkey: Bagdad and vicinity, Sept. 12-20, 1,513 cases, 1,017 deaths.

PLAGUE.

Brazil: Bahia, Oct. 18, 1 death.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Nov. 5, 1904:

Geer, C. C., asst.-surgeon, returned from sick leave of absence to sick in General Hospital, Washington Barracks, D. C.
Ford, J. H., asst.-surgeon, granted two months' leave of absence, to take effect about Nov. 15, 1904.

Robbins, C. P., asst.-surgeon, relieved from duty at Fort Terry, N. Y., and ordered to Fort Ethan Allen, Vt., for duty.

Polhemus, A. S., surgeon, ordered before Army retiring board at Fort Leavenworth, Kan., for examination.

Stiles, H. R., asst.-surgeon, ordered to report to commanding officer at Washington Barracks, D. C., for duty as surgeon.

Birmingham, H. P., surgeon, relieved from duty at Washington Barracks and ordered to report to the commanding general, Department of Texas, for duty as chief surgeon of that department.

Jones, P. L., asst.-surgeon, ordered to proceed from Fort Monroe, Va., to New York City for duty as transport surgeon, transport steamer.

Owen, Wm. O., surgeon, granted thirty days' leave of absence.
Purville, Wm. E., surgeon, Pipes, Henry F., and Bingham, E. G., asst.-surgeons, left San Francisco on the *Sherman* en route to Manila, P. I.

Dunn, D. F., asst.-surgeon, leave of absence extended fifteen days.
Volven, F. Homer, contract dental surgeon, arrived at San Francisco, October 17; ordered to Fort Adams, R. I., for duty.

Whinnery, Jean C., contract dental surgeon, arrived at San Francisco October 17; granted leave of absence for two months and at expiration to report at Vancouver Barracks, Wash., for duty.

McMillan, Clemens W., contract surgeon, relieved from further duty at Fort Myer, Va., and directed to proceed at the expiration of his present leave of absence to Fort Terry, N. Y., for duty.

Halwood, James B., contract surgeon, left Fort Leavenworth, Kan., October 27 on leave of absence.

Mason, George L., contract dental surgeon, granted leave of absence for one month.

Wing, Franklin F., contract dental surgeon, ordered from Fort Riley, Kan., to Fort Des Moines, Iowa, for temporary duty.

Adair, George F., contract surgeon, relieved from temporary duty at Fort Du Point, Del., and ordered to return to his proper station, Fort Wadsworth, N. Y.

Sievers, Robert E., contract surgeon, arrived at Fort Harrison, Mont., October 25, from temporary duty at Fort Assiniboine, Mont.

Dade, Waller H., contract surgeon, relieved from further duty in the Philippine Division and directed to proceed at the expiration of his present leave of absence from Henderson, Ky., to Fort D. A. Russell, Wyo., for duty.

Hull, Alva R., contract surgeon, on relief from duty at Fort D. A. Russell, Wyo., ordered to San Francisco for transportation to the Philippine Division.

Boak, S. Davis, contract dental surgeon, left Fort Slocum, N. Y., November 4 on leave of absence for one month.

Jenkins, Frederic E., contract surgeon, left Fort Barrancas, Fla., November 2 on two months' leave of absence.

Pinkston, Omar W., contract surgeon, granted leave of absence for two months.

Navy Changes.

Changes in the medical corps of the Navy, week ending Nov. 5, 1904:

Lando, M. E., appointed asst.-surgeon from October 26.

Hart, G. G., A. A. surgeon, ordered to Marine Barracks, Dry Tortugas, Fla.,

China: Hongkong, Sept. 10-17, 4 cases, 4 deaths.
 Egypt: Alexandria, Sept. 10-30, 12 cases, 8 deaths; Port Said, Sept. 17-23, 1 case.
 Great Britain: South Shields, Sept. 19, 1 case on S. S. *Bishops-ate* from Rosario, via Hamburg.
 India: Bombay, Sept. 27-Oct. 4, 50 deaths; Karachi, Sept. 25-Oct. 2, 14 cases, 8 deaths.
 Mauritius: July 8-Aug. 4, 8 cases, 6 deaths.
 Peru: Eren, Oct. 8, present; Lima, Sept. 1-Oct., 13 cases; Tacusmayo, Oct. 8, present.

Society Proceedings.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirtieth Annual Meeting, held in Cincinnati, Oct. 11-13, 1904.

(Concluded from page 1409.)

The Prevention of Appendicitis.

DR. WILLIAM M. HARSHA, Chicago, stated that from available figures it would seem that this disease is more frequent in America than elsewhere. This is on the assumption that the mortality rate is much the same in England, Germany and France, where modern methods of medical and surgical treatment are practiced, and where statistics are or should be reliable. In England and Wales, with a population of about 33,000,000, there were 1,244 deaths from appendicitis and ptyphlitis in 1901, or 38 per million. In 1902 there were 1,485 deaths, or 45 per million. In Illinois, with a population of about 5,000,000, there were in 1903, 471 deaths from appendicitis, or 94 per million. In Chicago alone, which represents nearly two-fifths of the population of the entire state, there were 249 deaths in 1902 and 260 in 1903, being at the rate of 140 per million. The same high death rate was approximated in other cities of the United States, especially in similar latitudes. New York City had, in 1903, 439 deaths, or 123 per million. Statistics of deaths from this disease in various cities both at home and abroad were given. Dr. Harsha believes that errors of diet are the most frequent cause. The disease occurs most frequently at the age and in the sex in whom faulty habits of eating and errors of diet are most common. It is common to see attacks follow an immoderate meal, or the ingestion of indigestible articles of food. Cholera morbus ushers in many cases of appendicitis, which are regarded as the primary trouble. The individual case must be considered and treated by itself. Proper hygienic conditions should be secured to keep the vital resistance up to the highest point. During the past six or seven years he has advised these measures as preventive after one attack in which there had been no operation, and so far as can be known, he believes recurrence has not occurred in over 20 per cent. Most of these were in young people, partly because of the greater frequency in the young, and in part because of lack of the patient's intelligent co-operation. The consensus of opinion is that more than 50 per cent. of the cases not operated on recur.

The Etiology of Fissure in Ano.

DR. J. RAWSON PENNINGTON, Chicago, expressed the opinion that the theories usually accepted as the cause are erroneous and that a more comprehensive etiology is needed. He regards the location of the ulcer as anatomic, and as depending principally on the support given to the tissues of the anal canal by the sphincters and levator ani muscles. When the canal is over-distended the dorsal surface receives the least support from these muscles, the anterior the next, while the sides receive the greatest. At the terminal portion this relative support is due to the difference in the distance between the posterior commissure and the tip of the coccyx, the origin of the external sphincter, and the tendinous center of the perineum, its insertion and the anterior commissure. The posterior fibers of the muscle are more deployed than those of the anterior, hence, when pressure is made from within outward it is obvious that the weakest point in this muscle is at or near the posterior commissure; the next weakest point, at or near the anterior commissure. Therefore, when this canal is placed under sufficient stress to rupture its tissues, the tear, all things being equal, should occur first on the dorsal surface, as

it receives the least muscular support; second, on the anterior surface, as it is the next weakest point, and lastly, on the sides.

Hereditary Predisposition in Tuberculosis.

DR. CHARLES L. MIX, Chicago, said that hereditary predisposition was usually defined as a specific predisposition toward tuberculosis, the nature of which is purely speculative, and it exists to-day because of the difficulty of demonstrating actual infection. The argument in favor of hereditary predisposition is as follows: Tubercle bacilli are ubiquitous; everyone is constantly breathing them in. Half the people become tuberculous; half escape. Half are, therefore, predisposed, and half are immune. The major premise is false, as was shown by a table illustrating the number of individuals to each consumptive, and explaining the maximum incidence of tuberculosis at the ages of from 20 to 35 years. Dr. Mix said that there are many fallacies in the usual statistics tending to support the theory of hereditary predisposition. Hereditary predisposition implies hereditary immunity, but the latter apparently has no existence.

DISCUSSION.

DR. G. W. McCASKEY said that the important thing to remember is that tuberculosis is always an infection. There is little doubt that everyone living in a civilized community inhales tubercle bacilli at one time or another, the inoculations proving effective or otherwise, according to the local and constitutional states of the individual.

DR. A. P. BUCHMAN, Fort Wayne, said that one does not invariably become tuberculous on exposure to the tubercle bacillus; otherwise everyone would be tuberculous. Often tubercle bacilli may be found in the absence of manifest tubercular infection.

DR. C. L. MIX said that acquired predisposition exists, and the individual may also inherit a predisposition, not only to tuberculosis, but to any of the infections.

Treatment of Tubercular Pleuritis.

DR. JAMES A. BURROUGHS, Asheville, N. C., reported cases in which he had injected salt solution into the pleural cavity for pulmonary hemorrhage in tuberculosis.

DISCUSSION.

DR. X. MCKITTERICK, Burlington, Iowa, said that such injections in the presence of diseased lungs and pleura, to compress the lung, are dangerous and that the method does not merit much consideration in the statistics given by Dr. Burroughs.

DR. CARL VON RUCK, Asheville, agreed as to the danger and said that in tuberculosis of the lungs, the cavities tend to work toward the pleural surface of the lung. To prevent rupture Nature causes a thickening of the pleural surface of the lung at that point. The injection of air or fluid into the pleural cavity to bring about the control of pulmonary hemorrhage through pressure requires the breaking up of the adhesions which Nature has formed, in order to accomplish compression of the lung.

DR. J. A. BURROUGHS considered the matter still in an experimental stage.

The Obstetric Significance of the Transverse Diameter of the Pelvis.

DR. JOSEPH B. DE LEE, Chicago, reviewed the facts that there is a diminished transverse diameter in funnel-shaped, assimilation, masculine, and infantile pelvis. Dr. De Lee believes that in such cases there is frequently difficulty in delivery, especially in the passage of the shoulders and the extraction of the aftercoming head. He also said that the expectant method should not be tried too long, as frequently the forceps suffice for delivery. Not infrequently symphyiotomy may be indicated. In breech cases delivery may often be facilitated by the application of forceps to the aftercoming head.

DISCUSSION.

DR. HENRY F. LEWIS, Chicago, said that the contraction of the transverse diameter of the pelvic outlet is probably more frequent than is generally supposed. In these cases the tor-

ceps should be applied early. In cases of infection in the male type of pelvis, when the head is well advanced, if the forceps fail, symphysiotomy is often an ideal operation.

DR. DE LEE stated that in a breech case we were formerly instructed to put the forceps in our pocket. In such cases we should now put the forceps on to boil. As a matter of fact, the forceps fit the aftercoming head better than when the head presents. The exaggerated lithotomy position is sometimes of value. He reported a case in which an assistant performed tracheotomy on the child in a breech case. The child lived.

Hydrotherapy in Nervous Diseases.

DR. CHARLES W. HITCHCOCK, Detroit, described the effects of hyriatic applications, and showed that water may be made a promotor of elimination and a stimulant to all the vegetative processes. Properly applied, it is a powerful tonic and may be an excitant, but it is also the finest sedative at our command.

The Treatment of the Morphin Habit.

DR. CURRAN POPE, Louisville, Ky., pointed out the necessity of appreciating the peculiar state of mind of these patients. Too much importance can not be attached to the condition of the excretory organs. There should be complete elimination before commencing the reduction of the drug, after which reduction may be painlessly carried to a certain point, and all shock avoided. Help should be given, not as a substitute, but in the shape of a neuro-cardio-vascular support. When the drug is entirely removed a substitute should be used, not hyoscine. The value of non-medical treatment, such as massage, vibration, electricity, hydrotherapy, isolation and moral control, can not be overestimated in these cases. The value of aftertreatment and the need of keeping in touch with the patient is a part of the system.

DISCUSSION.

DR. FRANK P. NORBURY, Jacksonville, Ill., said that his experience has not always been ideal. Recovery is not always smooth, and relapses are frequent. It is advisable to place these patients at rest in bed at once, and after perhaps two weeks the drug may be withdrawn. Often sodium bromid is useful as a substitute for morphin, and cannabis indica is frequently of value as a stimulant. Relapse is especially frequent in neurasthenic women. He reported a case in which the patient used heroin instead of morphin.

DR. JOHN PUNTON said that the patient must be made to understand at the start that he must co-operate with the physician. The idiosyncrasies of patients to the drug differ. Hyoscine is a most valuable drug when properly used, but is very dangerous when used promiscuously. The majority of physicians who come for treatment claim they can not spend the time necessary to effect a cure.

DR. ALBERT E. STERNE, Indianapolis, did not think that Dr. Pope laid sufficient stress on the reduction of the basis on which the drug habit rested. One must take into account the fundamental nerve weakness which even the physically strong may present. Habituation is not purely functional; there is a structural change in the nervous system, which supplies the physical basis for the condition. The use of drugs is to be deprecated. Many of the so-called abstinent symptoms are really not such. Hyperacidity often requires treatment.

DR. T. B. GREENLEY, Meadow Lawn, Ky., said that many morphin habitués are able to work and earn sufficient to pay for the drug consumed, but make barely a living, and can not afford to take proper treatment.

DR. GEORGE P. SPRAGUE, Lexington, Ky., said that the drug should be discontinued immediately. It may be withdrawn in from five to ten days except in perhaps one case in twenty. Often the patient is sustained by a minute quantity of morphin. Some claim that one-eighth of a grain is satisfactory, and the reduction to that point is not objected to by them. It is better not to stop the drug altogether until a decreased dosage of one-twentieth of a grain or less has been reached, or until twenty-four hours can be passed without the drug without unpleasant symptoms.

DR. R. E. HAUGHTON, Richmond, Ind., regarded this condition as a practical toxemia affecting the cellular elements of the brain. Absolute control of the patient is necessary for success. We must sustain the individual and at the same time secure elimination.

DR. T. D. CROTHERS said that psychotherapeutics and hydrotherapeutics are useful. Nerve rest is important and drugs should be avoided.

DR. FALK said that in prison practice he withdraws the drug at once. The use of ergot, and the administration of elixir of chloral and bromid at night prevents any unpleasant results. None of the cases had been cured permanently.

DR. B. F. BEEBE, Cincinnati, said that a week or ten days is too short a time for the removal of the drug. Elimination should be as rapid as possible, and the patient should be built up as the drug is withdrawn.

DR. POPE insisted on from four to six weeks for the aftertreatment, because nutrition must be improved.

Effect of Direct and Indirect Violence on the Skull and Brain.

DR. ALBERT E. STERNE, Indianapolis, said: "Injuries of impact, however extensive, offer a better immediate and remote prognosis than those of momentum, but must be treated with as little delay as possible, and almost always surgically. In injuries of momentum lesions through *contre-coup* are more apt to occur. After trauma to the skull and brain, the immediate necessity is free drainage and avoidance of intracranial pressure. The possibility of fracture should be kept in view after injuries to the head, and scalp wounds should, if necessary, be freely enlarged to determine the wisdom of further operative interference. Progressive coma, after momentum injuries, is a strict indication for operation."

The Mental Disorders of Adolescence.

DR. FRANK P. NORBURY, Jacksonville, Ill., discussed dementia precox, katatonia, hebephrenia, hysterical excitement, etc., and said that the family physician must recognize early these important mental disorders and co-operate with the alienist in treatment. Prompt and energetic treatment is imperative.

Insanity in Relation to Obstetrics and Gynecology.

DR. HENRY F. LEWIS, Chicago, stated that there is no true puerperal insanity. Normal pregnancy and even normal menstruation are not devoid of certain eccentricities of temper, tastes, appetites, or even morals. Some degree of mental instability must pre-exist if the eccentricities are to be exaggerated into insanity. One can only grant to child-bearing an exciting causal relation. The predisposing instability of mind, often largely hereditary (traceable in three-fourths of the cases) await some awakening impulse in an acute physical or psychic disturbance, which may be furnished by disorders of the genital organs in the performance of their normal functions. Evidence from autopsies and gynecologic examinations of insane women by a large number of authorities show the presence of noticeable pelvic disease in about 25 per cent. A considerable number of gynecologists have operated on insane women at asylums for their genital lesions and have secured a gratifying percentage of cures and instances of improvement. Ovarian lesions seem to influence the mental state the most, uterine next, and vaginal the least. Neoplasms are the least prone of all the pathologic conditions to cause mental disorder.

Newer Conceptions of the Management of Bright's Disease.

DR. ALFRED C. CROFTAN, Chicago, considers Bright's disease as a cardio-vascular disorder of manifold origin, involving primarily the heart and arteries, secondarily those organs chiefly supplied by end arteries, namely, the brain, the retina, and the kidneys. The degeneration of the kidneys therefore, is a very common and important, but not a determining, feature of the disease. Bright's disease in early stages not infrequently occurs without renal involvement. Primary nephritis with the retention of excrementitious bodies may occasionally be a cause of the cardio-vascular changes. This sequence of events,

however, is relatively rare. The management of Bright's disease should be directed toward the prevention or removal of factors operative to affect the heart and arteries. The treatment of the nephritis is incidental, but important. He discussed the rest cure of the kidneys, diet (dangers of exclusive milk feeding) and hygiene and medicinal treatment on the basis of the above conceptions.

DR. CHANNING W. BARRETT'S paper, "The Mortality of Appendicitis," and Dr. G. W. McCaskey's paper, "Infections of Intestinal Origin," will be published in full in THE JOURNAL.

The following papers were likewise read and discussed:

"Plastic Surgery of the Urethra," by Dr. G. Frank Lydston, Chicago; "Causation and Radical Cure of Gynsly," by Dr. John F. Barnhill, Indianapolis; "Cranial Injuries," by Dr. Shelby C. Carson, Greensboro, Ala.; "Internal Hemorrhoids and Their Treatment," by Dr. Wells Teachnor, Columbus, Ohio; "A Case of Bilateral Tic Douloureux Treated by Removal of the Right Gasserian Ganglion and the Left Inferior Dental Nerve," by Dr. W. O. Bullock, Lexington, Ky.; "Hernia of the Tube," by Dr. Frank T. Andrews, Chicago; "Pseudo-Membranous Croup," by Dr. R. E. Carlton, Latonia, Ky.; "Bacteriology and Immunity—What It Is; What It Teaches; What It Does Not Teach," by Dr. R. E. Haughton, Richmond, Ind.; "Two Etiologic Factors in Pelvic Diseases in Women, Their Prevalence and Prevention," by Dr. J. H. Firestone, Freeport, Ill.; "Prognosis," by Dr. John M. Batten, Downingtown, Pa.; "Foreign Bodies in the Esophagus," by Dr. Carl E. Black, Jacksonville, Ill.; "Operative Work in the Ureter," by Dr. Bransford Lewis, St. Louis; "Foreign Bodies in the Cornea," by Dr. Dudley S. Reynolds, Louisville, Ky.; "Etiology of Ectopic Gestation," by Dr. H. B. R. McCall, Kansas City, Mo.; "Brain Abscess of Otitic Origin," by Dr. George F. Kelper, Lafayette, Ind.

BUFFALO ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 4, 1904.

The President, Dr. Arthur W. Hurd, in the Chair.

Gallstones.

DR. JOHN PARMENTER spoke of conditions which simulate gallstones. He referred to the similarity of gall bladder and the appendix in the symptoms disease of either gives and the similarity in treatment of these affections. Gallstones may often be detected by holding the phonendoscope over the gall bladder and hearing crepitation. They may also be suspected if when holding the fingers under the ninth costal cartilage and then having the patient take a deep breath there is much tenderness and rigidity. Again, the gallstone may be found in the stool.

Dr. Parmenter said that there are three cardinal symptoms: 1, pain; 2, nausea and vomiting; 3, tenderness. Superadded to these there may be: 4, jaundice; 5, temperature; 6, tumor.

The pain is due either to distension from accumulated bile behind the stone lodged in the duct or in the gall bladder, or to an inflamed area. It varies according to the virulence of the attack, position of the stone, and the temperament of the person attacked. Its character is colicky; it is intermittent, but, unlike other pains in this locality, does not cease entirely. There is a spasm of the overlying muscles and parts which is visible to the eye and can be felt accompanying the pain. The position of the pain is the ninth costal cartilage and often also beneath the angle of the right scapula. Rarely, according to Murphy, may its seat also be on the left side (one case in ten). Pain is not necessarily present in chronic obstruction in the ducts. It may last from a few minutes to a few days. Nausea and vomiting, which arise reflexly, are important signs if present with other symptoms, but of themselves may, of course, arise from many other conditions. Dr. Parmenter believes that tumors do not occur nearly so often as is claimed. He has frequently found that such an apparent tumor of the gall bladder disappears under anesthesia (phantom tumor). This is due to a relaxation of the parts, and sometimes the stone may be passed following anesthesia. The tenderness varies according to the individual character of the disease and method of examination. The parts should be palpated carefully. Jaundice is a very inconstant symptom. It is the exception rather than the rule, especially if the stone is in the gall bladder or cystic duct, and when present it is intermittent, whereas the jaundice of chronic obstruction (cancer, stricture of duct, etc.), is constant, and where it persists it points to obstruction in the common or hepatic ducts. Jaundice due to gallstone is preceded by other symptoms of

that condition and there are no changes in general health accompanying it, such as the great loss of appetite and cachexia noted in malignancy.

There may or may not be any temperature. It is not marked unless the infection is in the common duct. If the temperature is not above 101 degrees it points to the location of the stone in the cystic duct or gall bladder. The tumor varies also as to the infection and at times the bulk of the tumor is due to muscular spasm, not to an enlarged gall bladder. With gallstones the gall bladder is not so much enlarged; a dilated gall bladder argues for obstruction in the biliary passages from causes other than stone, such as malignant growth or stricture. The tumor, if present, moves with respiration.

The conditions which may simulate gallstone disease are: 1. Acute cholecystitis where no stone is present. 2. Renal calculus, in which the pain is lower, referred to testicles, and blood is often passed in the urine. 3. Plain colic from gas in the hepatic flexure of the colon; this pain is remittent. 4. Appendicitis: Because of pain in this region a child was operated on for appendicitis. The appendix was found normal, but the pain was due to a diaphragmatic pleurisy. 5. Acute intestinal obstruction. 6. Simple indigestion: This condition is, however, relieved by vomiting; more often gallstone colic is wrongly called a gastric indigestion. 7. Movable kidney, when torsion of the pedicle is present; in this condition the kidney can be replaced. Liver symptoms are lacking; urinary symptoms are present (frequent micturition, etc.). 8. Carcinoma: This may be preceded by gallstones; in this condition cachexia is present and there are signs of diffuse carcinomatosis. 9. Acute pancreatitis and cancer at the head of the pancreas. 10. There is a nervous hepatic colic described which is hysterical and strongly resembles gallstone colic; with this there is neither fever nor stones.

Biliary Drainage in Operative Work on the Gall Bladder.

DR. EUGENE A. SMITH said that, judging by his experience of 31 operative cases, biliary drainage in operations on the gall bladder and biliary tract is necessary in 90 per cent. of such operations. Gallstones were formerly considered the cause of chronic disease of the gall bladder and biliary ducts, as fecal concretions and other foreign bodies were supposed to cause appendicitis. Such diseases are due to infection and its continuation with exacerbations and periods of quiescence, and gallstones in the implanted gall bladder are an accompanying feature and a result of the infection. Acute pyogenic infections demand drainage to prevent suppurative cholangitis and hepatic abscess before gallstones can form. Typhoid and colon bacillary infection infrequently demand early operation, but later may require operation because of exacerbation or secondary infections with gallstones, which meanwhile have formed as a predisposing cause. Early operation for cholecystitis is urged to prevent alteration of structure and dangerous complications due to local peritonitis and adhesions beside disturbances of nearby viscera of associated digestive function—especially the pancreas. This view emphasizes the need of biliary drainage to dispose of the infectious bile and infecting agent in the tissues of the gall bladder and biliary ducts. Deaver's argument to prove that chronic biliary tract infection leads to biliary cirrhosis is good and biliary drainage is demanded for its relief. Of the operative methods to drain the biliary tract cholecystostomy is advocated, because it is safer and easier. Permanent biliary fistule reformation of calculi and later malignant degeneration of the gall bladder are possible, but too infrequent to affect the advantage of this operation over cholecystectomy. In cholecystectomy overlooked gallstones may cause trouble. Cholecystectomy with drainage of the cystic or common duct is indicated for cases of stricture of the cystic duct, distorted thickened gall bladder and malignancy of the gall bladder. Mayo's stripping of the mucosa is indicated for gangrenous exfoliation of the mucosa and empyema of the gall bladder. Cholecystectomy without drainage is indicated for gallstone colic when the history shows painful attacks without sepsis and when operation shows little or no infection of the biliary tract and when obstructive jaundice is absent. The

removal of gallstones with closure of the gall bladder and no drainage is ideal, but not practical and not satisfactory. Cholecystenterostomy or drainage into the intestine is performed for hopeless stricture or malignant growth obstruction in the common duct. Calomel unloads a torpid liver by the bowel. The knife is the calomel of the infected biliary tract and biliary drainage is the avenue of cure.

DISCUSSION.

DR. MARCEL HARTWIG emphasized the importance of very careful palpation in examining for tumors in the region of the gall bladder. He stated that he now has a case where the woman had lost weight, was jaundiced and had clay-colored stools. He performed a cholecystostomy, removing many stones, and could feel that there also existed a stricture of the common duct. The case still drains through the incised wound, but the patient feels much better. A secondary cholecystenterostomy will probably be made later. He also related a case with symptoms of hepatic abscess in which he made an exploratory puncture negatively a number of times, and postmortem the liver was found studded with miliary abscesses.

DR. HERMAN HAYD said that in many cases drainage is required because it is the only rational method to get rid of the trouble in the hepatic radicles and the cholangitis and congested liver with its tendency to cirrhosis as demonstrated by Deaver. In some cases such as a shriveled and distorted or acute gangrenous gall bladder, it should be removed. The method of drainage as described by Dr. Smith is simple, easily performed and to him has proven satisfactory. Concerning what Dr. Parmenter had said about the importance of pain and its character in biliary colic, one would believe that this would be all that was necessary to make a diagnosis, but many of these gallstone cases are extremely difficult to diagnose and those conditions which in his experience were most easily confounded with this condition are a tender floating kidney fixed forward, a cancer of the pyloric orifice of the stomach, duodenal ulcer and hysterical pains described by Charcot, which are associated with hysterical painful ovaries. This pain is felt in the epigastric region and a little to the right and is reflex or neurotic.

DR. CHARLES E. CONGDON uses the oblique incision for the operation, as he can get at the bladder or duct more readily and for drainage uses a smaller incision, closing the original incision and so overcoming a tendency to hernia. Through this smaller incision the tube is drawn and drainage takes place perfectly. If there is infection from the discharge it is more localized as when the drainage takes place through the larger opening.

SEVENTEENTH FRENCH CONGRESS OF SURGERY.

Held at Paris, Oct. 17-22, 1904.

Professor S. Pozzi in the Chair.

In his opening address Pozzi expatiated on the great responsibility of the surgeon aside from his operating. The surgeon summoned to operate for appendicitis should be able to correct the diagnosis at need and point out a mistakenly diagnosed liver or kidney colic, just as the physician should be able to detect, for instance, a hidden osteomyelitis, a typhoid of the limbs simulating true typhoid fever. He illustrated his idea by quoting the saying, "A cask full to the brim of nuts can yet hold several measures of oil." He referred to his recent trip to this country and his scientific pilgrimage to the private hospital of the Mayo brothers.

A number of foreign surgeons had been invited to speak, among them von Bergmann and Sonnenburg of Berlin, Ceccherelli of Parma, Fargas of Barcelona, Kocher of Berne, Mikulicz of Breslau, and Czerny of Heidelberg. An exhibition of surgical instruments and appliances was for the first time one of the features of the congress.

Decapsulation of the Kidney.

Ceccherelli related experimental and clinical experiences which demonstrate that decapsulation of the kidney is not at all a serious operation. The capsule is regenerated by the end

of a month and adhesions form, numerous and strong. For this reason he supplements every nephrorrhaphy now with decapsulation, the adhesions insuring firm fixation. The vascular adhesions are liable to have a favorable effect in modifying certain pathologic conditions in the kidney.

Omentopexy.

Monprofit delivered the address on surgical treatment of liver cirrhosis. He has collected statistics of 224 operations, with 129 operative cures. Recurrence was noted in 25, and 26 patients were only materially improved, but 70 were completely cured; 8 have been lost sight of. The operative mortality was 37 per cent. A complete cure was obtained in about a third of all the cases. The statistics in future will be more encouraging, as intervention will not be limited to such desperate cases as in the past. Other members of the congress related their personal experiences, over 50 operations of the kind being thus marshaled, with satisfactory results in about half the number. Vidal reported that omentopexy has a very favorable action on hematemesis by reducing the portal hypertension. His experience has been so encouraging in this line that he regards severe hematemesis as the essential indication for the intervention. The ascites may recur, but the hemorrhages are arrested.

Means of Avoiding Dangers of Chloroform.

Thiery of Paris expressed surprise that more extensive use is not made of tracheotomy followed by insullation in cases of threatened chloroform death. In 23 cases the subjects were resuscitated and the 3 failures were due to defective technic.

Castration in Treatment of Inoperable Mammary Cancer.

Reynés of Marseilles was able to realize the apparent complete cure by utero-ovarian castration of a young nullipara with inoperable cancer of both breasts, menstruating normally. The neoplasms have entirely retrogressed, all but one small nodule in the place of the former extensive ulcerations. Eighteen months have passed since. In another case the castration proved useless. This patient was a iv-para, 39 years old, who had nursed her children for more than a year each. The cancer was a malignant process in a milk-producing breast; the patient had not menstruated for nearly two years. Thiery also reported the complete retrogression of inoperable recurring double mammary cancer in a woman at present in good health a year after the operation.

Cancer and Its Treatment.

One session was devoted to this question, Tuffier urging that a distinction should be made between cancers of the skin, those of the mucosæ and deep-lying cancers. Those of the skin seem to be the only ones amenable to radiotherapy, and not all of these. Czerny stated that radium possesses the property of decomposing lecithin in the tissues. As cancer tissue is particularly rich in lecithin, this may be the clue to its mode of action. Doyen reported that he had treated 242 cases of cancer with his fluid derived from cultures of the micrococcus neoformans which he had isolated from cancers. Of the total 242 cases 42 have been permanently cured, 46 are under treatment but promise a cure. In 128 cases no result was apparent, either because treatment was commenced too late or had been interrupted. Six patients have died from accidental causes after recovery. He asserts that this micrococcus is able to create any variety of neoplasm according to the nature of the tissue primarily infected. Poirier commented on Doyen's statements, remarking that no one but Doyen has been able to discover this micrococcus, and Folet suggested the nomination of a commission to pass final judgment on the Doyen method of treatment of cancer. This session was rather sensational on account of the Doyen-Crocker controversy, mentioned on page 1320. The *Gazette Médicale Belge* comments on the affair that "if Mr. Crocker had consulted his family physician he would have been told that Doyen is a genius as a surgeon, but he is also a shrewd business man and an actor, always hatching out some audacious project. Mr. Crocker would have been advised to demand to see the cured patients." Our latest Paris exchanges contain full reports of the congress, and the English also devote some space to the Doyen cancer serum.

Travel Notes.

XVI.

CEYLON.

FROM AUSTRALIA TO CEYLON—ISLAND OF CEYLON, ITS CLIMATE, PEOPLE, DISEASES—COLOMBO GENERAL CIVIL HOSPITAL—CEYLON MEDICAL COLLEGE—CEYLON LEPER COLONY—LEPER BUDDHIST CELEBRATION—KANDY GENERAL CIVIC HOSPITAL.

NICHOLAS SENN, M.D.
CHICAGO.

MADRAS, INDIA, Aug. 30, 1904.

The voyage from Adelaide to Colombo takes fourteen days. I left Adelaide August 11 and arrived at Colombo on the 24th, a little ahead of the stipulated time. The only rough weather we encountered was for four days in crossing the great Australian Bight, a part of the ocean that has an unenviable reputation with people who are subject to seasickness. Our good, staunch, storm-tried ship, the *China*, played with the foam-crested waves by a graceful combination of rolling and pitching which, unavoidable and well intended, brought about the usual result—reversion of the peristaltic action of the stomach—in a fair percentage of cases among the small number of passengers. It seemed to me, however, that the Australian and English people are, on the whole, less susceptible to seasickness than the more nervous Americans, and a number of the lady passengers alone occupied their places at the table during meal-time. A few hours' stop was made at Fremantle, which gave me an opportunity to see this important western port of Australia and from there make an excursion by rail to Perth, 12 miles distant. Perth is a new and modern city with 25,000 inhabitants. The activity in the principal streets reminds one very much, at least on a small scale, of State Street in Chicago. The business importance of both of these western Australian cities depends largely on the rich gold mines in that section of the country. Fremantle has a public hospital with accommodations for 40 patients; the hospital at Perth is a new and modern building with a capacity for 200 patients. As we left the harbor of Fremantle we were followed by our faithful escort of albatrosses, which had never deserted us in the open ocean since we left the New Zealand coast, but on this occasion these magnificent living kites of the air left us at dusk the first day out, never to return. With the exception of occasional schools of flying fish, water and air were sterile from coast to coast. Cool weather continued for two days after leaving Fremantle, when the winds gradually subsided, the sun displayed his tropical properties and the drizzling rains saturated the atmosphere with moisture, all of which made the heat very oppressive. Blankets and heavy clothing were laid aside and the officers set the example for the wearing of clothes appropriate for the tropics. The low palm-fringed coast of Ceylon, lightly veiled in a rising fog, came in sight Wednesday morning and during the forenoon we were comfortably quartered at the Grand Oriental Hotel, Colombo.

CEYLON.

The island of Ceylon, called Singhal by the natives, is about 55 miles from the southern extremity of Hindustan, from which it is separated by Palk Strait. It lies between 5° and 9° N. latitude, hence in the very midst of the tropics. The interior is mountainous, the highest peaks being Pedral Allagalla and Adams' Peak; the former rises to an altitude of 8,200 feet, the latter 7,420 feet. The island is noted for its tropical forests, impenetrable jungles and luxuriant vegetation. This island has had an eventful political history. It was taken possession of by the Portuguese in the seventeenth century, passed later into the hands of the Dutch by conquest, and was finally annexed to the British crown in 1795. The two first nations never conquered the entire island, and the British forces underwent many hardships and met with fierce opposition in the interior of the island before the last rebellion was suppressed in 1817. Since that time the peace of the island has never been disturbed and it has become, under a wise, conservative government, the wealthiest and most prosperous colony of the British empire. The principal articles of export are

tea, coffee, cinnamon, cacao and cinchona bark. The cocoanut palm, which is found here in all its productiveness along the seashore, in the lowlands, valleys and high up on the hillsides, not only furnishes the natives with a considerable part of their sustenance, but is an important source of revenue. The annual value of the produce of this tree alone amounts to \$10,000,000. In looking at the palm forests of Ceylon no one could forget what this tree does for the untutored natives, as

"It is meat, drink and clothes to us."—Rabelais.

And who would not think almost instinctively of the beautiful words of the psalmist:

"The righteous shall flourish like the palm tree; he shall grow like a cedar in Lebanon."—Psalms xcii.:12.

Ceylon supplies the markets of the world with cinchona bark, amounting to about a million of pounds a year. The cinnamon tree is indigenous and reaches a height of from 40 to 60 feet and a circumference of from 3 to 6 feet. The cinnamon bark, however, is not obtained from the old trees, but from annual shoots from a very short stump, which is pruned and sprouts from year to year. Another important source of revenue are the more than 4,000 gem quarries. Ceylon has now more than 1,500 miles of railway, over 2,000 schools, 36 newspapers and upward of 100 hospitals and dispensaries. The Ceylon tea is the best in the world, and since it has been found that the hardy shrub which grows this commodity will thrive best at an altitude of 7,000 feet, the forests are rapidly making way for the tea industry up to an altitude of 6,000 feet. As an important protection against deforestation from this and the timber industry the government has very wisely stopped the sale of timber land above an altitude of more than 6,000 feet. Ceylon is the paradise for the hunter, as large herds of elephants still inhabit the jungles at a safe distance from human habitations and buffalo, elk, deer, bear and wild boar, as well as a great variety of birds, are quite plentiful and furnish the best opportunities for most interesting sport. The scientist finds here an endless field for study and investigation. The great fertility of the soil, the copious rains and the variations in the climatic conditions on different parts of the island have created a vegetation noted for its luxuriance and endless variety. The forest trees alone are a great attraction. We find here the satin, sandal and ebony trees, from which the most valuable timber is obtained. It may not be generally known that less than one-third of the wood of the ebony tree (*Diospyros ebenum*), is black, and this is found in the center of the stem; the outer two-thirds of the wood is white and without value. In the botanical garden at Kandy I saw an Indian rubber tree (*Ficus elastica*), planted by the Dutch in 1833, which has reached a height of 130 feet, and the multiple stems and their colossal branches cover a circular area where several hundred people could find protection against rain and sunshine at the same time and be much less crowded than in the streets of Kandy at a Buddhist celebration. In the same place I saw a nux vomica tree more than 50 feet high with a graceful crown of small elongated deep green leaves in a state of budding for the next year's crop of disc-like nuts so familiar to the physician as the source of strychnin. The botree (*Ficus religiosa*) is one of the giants of the forests. Its broad acuminate leaves tremble in the breeze like the leaves of our aspen. The trunk is very short and from the top the treelike branches form a wide-spreading crown. This tree is worshipped and is held in great veneration by the Buddhists. A very strange tree is what is known as the jack tree, a large tree which bears the largest edible fruit known. The fruit is suspended from the trunk and the larger branches by a short stalk. The edible part of the fruit is a yellow pulpy viscid mass. The smell and taste of the fruit when ripe are strong, and to the European unpleasant, but the flavor is akin to that of our may apple and quite agreeable, at least it proved so to me. The elephant is very fond of the leaves of this tree. The Area palm, a very slender tree, grows a nut which bears in its structure a close resemblance to the nutmeg. This nut, scraped and mixed with a white paste made of slacked lime, served on a green leaf, is the betel so much in use by the natives as a chewing material. This practice is no worse from a hygienic

and esthetic standpoint than the chewing of gum and tobacco by Americans, but the betel contains a red coloring material and its habits do not improve their looks by the red lips, tongue and teeth, which looks to the uninitiated very much as though the chewers, instead of enjoying the pastime, might be the subjects of purpura hemorrhagica, or had just escaped from the chair of an aggressive dentist. How helpless the practitioner of medicine would be if Ceylon did not supply him with cinchona and nux vomica, to say nothing of cloves, cinnamon, cajeput, pepper, nutmeg and other aromatics and carminatives with which we are in the habit of disguising the taste and smell of more powerful drugs and which often prove so efficacious in the treatment of slight gastrointestinal derangements. But there are still more remarkable trees in Ceylon, which prove the perfect foresight of the Creator in meeting urgent wants of man and beast. Wherever there are cocoa palms man's immediate wants are met, as it supplies him with drink and meat; the milk of the unripe fruit will quench his thirst and the meat of the ripe nut supplies him with food. The rain tree (*Inga sausa*) is a large tree with thick, short stems and widely-spreading branches. Around the lake of Kandy these trees are of enormous size. It has a pinnatifid leaf like the acacia. In the evening these leaflets fold themselves into a small cup, in which the falling dew is collected and retained until sunrise, when it unfolds, and in doing so the thousands of drops of water give rise to a shower on a small scale, hence the name "rain tree."

Ceylon is the home of a great variety of palms. Of these the talipot palm is one of the most remarkable. For the first ten years it grows only from scaped leaves. Next the stem grows as straight as a mast to a height of 100 feet. Each annual growth is indicated by a ring. The fan-shaped leaves are of enormous size, sometimes 15 feet in radius. They are so large that three leaves make an ample and waterproof tent. The leaf, cut into pieces of convenient size, has been used for centuries as a substitute for writing paper.

In the octagonal tower of the Temple of the Tooth at Kandy thousands of manuscript volumes record the early history of India on strips of the leaves of this palm. When the tree reaches maturity it develops a gigantic bud at the end of a pole-like prolongation projecting 10 to 15 feet above the crown of fronds. This bud in due time bursts with a report and a lovely white blossom unfolds itself and spreads with a pyramid of cream-colored flowers. After this final act of propagating its species the tree soon sickens and dies. It was my fortune to see one of these trees a very short time after bursting of its pod and expansion of the liberated flowers. The undergrowth in forest and jungle is represented by a variety of shrubs, the principal one being the *nutu*.

The density of the forest is increased by twining plants, many of which, especially the *Thunbergia*, with its beautiful pale blue flowers, reach to the very tops of the highest trees. Orchids, pitcher plants, the gorgeous passion flower and several species of rhododendrons are worthy representatives of the rich flora of the island.

CLIMATE.

When Nature goes to work to create a botanic garden she must necessarily have at her disposal a fertile soil and a hot, moist climate, a climate congenial to luxurious vegetation but hostile to man. Such is the climate of Ceylon. The intensity of the heat is made almost intolerable during the rainy season, from February to July, by the saturation of the air with moisture. When I arrived at Colombo the rainy season was practically over and yet the atmosphere was so surcharged with moisture that in the absence of a breeze, natural or artificially produced by fan or pankah, breathing was a difficulty and the sense of heat distressing, although the thermometer in the shade only showed a temperature of 92 degrees F. The coolest months are October, November, December and January, and the hottest correspond with our spring months. In Colombo it is always hot and the use of blankets is almost unknown. The continuous heat from one end of the year to the other is depressing and Europeans find it necessary to seek a cooler climate every three or four years to recuperate, and have to ab-

stain from hard work, mental and physical, as much as possible during their entire residence. In the mountains at an elevation of 2,000 and more feet the nights are cool, and even at Kandy, 1,600 feet above the level of the sea, the nights are often chilly. The chains of mountains traversing the island have a marked influence on the rainfall and temperature of the high latitudes. It is often the case that on one side of the range it is sultry and fogs and rain prevail, while on the opposite side the atmosphere is dry and cool and a bright sunshine adds to the cheerfulness of the bracing mountain climate, with a reversal of climatic conditions occurring with a change of the prevailing winds. It is well known that a prolonged residence in Ceylon shortens the lives of the Europeans, and consequently those who are obliged to live there find themselves under the necessity of leaving the island every few years for several months in order to rid themselves of that lassitude and depression incident to a prolonged residence in the tropics and to regain their recuperative power that is so essential in resisting the insidious influences of tropical and other diseases.

THE PEOPLE.

The population in 1891 was 3,008,466. The natives are increasing very rapidly, as the estimated population of the island on Dec. 31, 1902, was 3,685,267. This is confirmed by the birth and death rate for the same year; 141,893 births were registered and 99,680 deaths. The birth rate was 39.0, against 37.5, and the death rate of 27.4 against 27.6 per mille in the previous year on the estimated population in the middle of the year (Medical Report of Dr. Allan Perry, principal civil medical officer and inspector general of hospitals, 1902). This record is not in accord with the fate of our Indians and the Polynesians of the islands of the Pacific, whose rapid decimation and eventual extermination followed so promptly the footsteps of civilization. Three explanations deserve consideration in accounting for this difference. The Ceylonese have for centuries been in touch with the outside world by much frequented waterways and they have, perhaps more than any other primitive race, retained more persistently their original habits, and as most of them are Buddhists they have escaped the fearful consequences of alcoholism so common among other savage races as soon as the white man satisfies their morbid desire for liquor. The Singhalese and Tamil do not encumber themselves with European clothes; the comboy (loin cloth) is the only article of dress which he makes use of, and which continues to satisfy all his needs as far as appearance and protection are concerned. The diet, habits and manner of living remain the same. The population of Ceylon is a very mixed one, consisting of Singhalese, Tamil, Portuguese, Dutch, Malays, Parsees, Turks, Afghans and half-castes of all shades of color between almost pure white and jet black. The Singhalese and Tamils, however, form the bulk of the population. The Europeans are in a very small minority. The Tamils are the Indian coolies who immigrated from the southwestern part of India and became the laborers of the planters in the interior uplands of the island. The Singhalese are averse to hard labor and have always shown a preference for the plains and valleys. The Tamils are a low race, far beneath the Singhalese in intelligence. The Singhalese is proud of his race. Half-castes bear the humiliation brought on them by the admixture of European blood with a becoming patience and fortitude, but they regard the accident of their birth rather as a disadvantage than otherwise in their social position and best possibilities in life. The question of caste, even in Ceylon, plays quite an important rôle, consequently the Singhalese and Tamil seldom intermarry. The former is a gentleman by birth, and as such is averse to menial work, for which, if he can afford it, he hires the man of burden, the lowly-born Indian coolie, who in most respects resembles the low-caste Chinese and Japanese. The Singhalese is a very fine specimen of manhood, tall, slender, with long, very thin legs, face clean cut with regular outlines, well shaped nose, high forehead, black eyes, bushy eyebrows of the same color, delicate hands, and in complexion varies from a sienna to almost as black as the negro. The hair is long and straight or wavy and is worn by combing it back or parting it in the middle, tied behind into a knot, which

is surmounted by a semicircular comb of tortoise shell. The manner of wearing the hair and the delicate face in the young men with scanty beard and similarity in dress makes it often very difficult to distinguish between the two sexes before advancing age draws more distinct facial lines. The young men appear very effeminate, more so than in any other race that I have ever seen. Tailors and shoemakers do very little business in Ceylon. With a few yards of cloth men and women drape themselves very gracefully, leaving at least one-half of the body uncovered. The combos differ only in length from a narrow strip of cloth to a petticoat reaching below the knees, worn by some men and all the women. Another two or three yards thrown over the left shoulder covers at least a part of the chest and leaves the right arm unencumbered. Hair and skin are kept saturated with palm oil, a very important hygienic measure, as it preserves the hair and protects the skin against the burning rays of the sun, rain and insects. The Singhalese are almost free from baldness, as they do not injure the nutrition of the hair follicles by the use of harmful head-dress and make free use of palm oil, which is undoubtedly an important nutrient to the hair and the hair follicles. The women are much smaller than the men and can make no pretensions to beauty. The flush of youth begins to decline before they are 30 years old, and then they are inclined to obesity. They are fond of jewelry. Many of them cling to nose and ear rings, toe rings, wristlets, anklets and arm bands of silver. The Singhalese has many excellent qualities; he is cheerful, content, honest and peaceable. Theft and robbery are almost unknown. Willful premeditated murder is very rare. During the year 1903 36 men were sentenced to death for murder and of these 22 were hanged; in the other cases the sentence of death was commuted to long terms of imprisonment. Major de Wilton, inspector of police (Prison Report, 1903), makes the following comments on the crime of murder: "It is very difficult to make any conjecture as to the cause of the prevalence of the crime of murder. The offenders do not, as has been repeatedly pointed out, belong to the criminal class. They are, as a rule, men without previous convictions, who up to the time of the crime have led a comparatively blameless life. The offense is not generally committed with the deliberation of the hardened criminal, but in the fiery heat of passion or under the influence of liquor, and it is a matter of regret that even the death penalty brings with it no direct effect."

The knife is the implement most frequently used when violence is resorted to. The number of persons committed to prison for all kinds of offenses during the year 1903 was 2,396, a figure which shows well for the morale of the island. Of 2,508 convictions during the year 1903 49 were Protestants, 361 Roman Catholics, 1,509 Buddhists, 314 Hindoos, 260 Mohammedans; other religions, 15. Notwithstanding the heroic labors of missionaries of different denominations for the last two centuries and the expenditure of millions in efforts to convert the natives, the results have been very unsatisfactory. The mass of the people cling to their Buddhist faith with great tenacity. The bareheaded, barefoot yellow-robed priests remain in power and attend to the spiritual needs of the people. The Roman Catholic church has accomplished more than any other denomination. Those who have abandoned Buddhism and have joined a church do not always live in accordance with the teachings of the new religion and continue many of their former customs and practices, which perhaps unconsciously cling to them from force of habit. For instance, Christianity has made very little impression on the morality of the people. The natives are a temperate people, as the teachings of Buddha prohibit the use of alcohol in any form, and with few exceptions, indeed, the Buddhists are total abstainers. The Singhalese have taken kindly to the professions. The most prominent and successful physicians and lawyers in Ceylon are natives or half-castes.

PREVAILING DISEASES.

The bubonic plague has never had a foothold in Ceylon. This is the more remarkable, as its harbors are visited daily

by ships from all Oriental ports and the exemption from this scourge must be due to the extraordinary care exercised by the department of health. Accurate information regarding the present prevailing diseases can be gleaned from the Annual Report of Dr. Allan Perry, principal medical officer of the island.

Malaria.—In the western, central and north central provinces malarial fevers were very slight. The disease is most prevalent in the northwestern and eastern provinces. The disease is quite prevalent in Colombo and observations are now being made to determine the places where infection takes place.

Cholera.—During the year 1902, according to this report, there were 179 cases of cholera, with 116 deaths. The largest number of cases occurred in Colombo and vicinity.

Smallpox.—There were 146 cases of this disease, with 25 deaths, in the north of the island, and 118 cases were admitted to the Infectious Diseases Hospital, Kanatta, which, with two from another province, made 120, with 32 deaths.

Dysentery.—This disease is equally distributed throughout the island. It was most prevalent in the central and western provinces. The largest number treated in any one institution was at the General Hospital, Colombo, where 488 cases were admitted, of whom 89 died.

Enteric Fever.—The number of cases treated in the various hospitals throughout the island was 242, with 63 deaths. Pollution of water and milk are the commonest causes of this disease. The cesspit system, which exists in some of the large towns, notably Colombo, Kandy and Galle, has much influence in increasing the number of cases.

Leprosy.—The total number of cases reported during the year 1902 was 560, against 590 in the previous year, being a decrease of 30 cases; 382 cases were treated in the leper asylum, Ilendala, and 30 in the Kalmunai wards. The leper ordinance came into operation at the beginning of the year, and 113 cases have been reported.

Ankylostomiasis.—It seems that this disease, which is so very prevalent, is constantly being introduced from India by Malabar coolies. The disease is increasing. There were 1,609 admissions in all hospitals, with 257 deaths. The danger of the disease to life is in the profound anemia, which so lowers the vitality that the victim is carried off by any insignificant intercurrent affection.

Plague.—The Plague Committee is a standing committee, including besides the principal civil medical officer, the collector of customs of the ports, the government agent and the mayor of Colombo. Regular meetings are held and precautions instituted to combat an outbreak of the disease. All returns of plague from infected ports are received by the committee; telegraphic accounts of plague occurring in places adjacent to Ceylon are received regularly. It is to the eternal watchfulness of this committee and the prompt action of the staff of port surgeons that is due the freedom of the island from this Asiatic disease. Galle continues to be the plague port; only one case of this disease was reported from the harbor of Colombo during the year. The patient contracted the disease at Hongkong and was landed and isolated at Galle, and the contacts for this port were placed in quarantine. The patient recovered. Rat destruction was carried out at the customs premises and by the municipalities of Colombo and Galle.

Syphilis.—Colombo, Kandy and Galle are provided with a special hospital for the treatment of women suffering from venereal diseases. The total number of new cases admitted was 351 which, with 20 remaining from the previous year, makes a total of 371. Of the 371 women treated in these hospitals 27 were affected with primary syphilis, 68 secondary, 62 tertiary, 4 hereditary, 156 gonorrhoea and 54 unclassified syphilitic lesions.

Parangi.—The hospital records show that this disease has steadily increased during the last five years. The death rate is remarkably small; out of 3,434 admissions for this disease during the year there were only 10 deaths.

Vaccination.—Vaccination is carried out vigorously in the

island, as is shown by the Report on Sanitation. During the year 149,901 subjects were vaccinated; of this number 7,760 were revaccinations.

Lack of Sewerage.—In Colombo, Kandy and Galle the fecal matter is removed at night and buried. In Colombo the experiment was made of using the contents of the cesspits as a fertilizer, but it proved undesirable and was abandoned as a failure. What these cities need is a system of sewerage, as they all have an excellent location to carry out such a plan with success.

(To be continued.)

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Chlorosis.

The *Medical Times* suggests the following treatment for this condition: Iron is recommended as being the chief drug indicated. It should be begun within a few days after the diagnosis is made. It may be necessary at first to correct digestive disturbances. Iron sometimes can not be taken by the stomach, and in these cases the ammonium citrate may be given hypodermically in one-grain doses dissolved in ten minims of distilled water. Inject it very slowly and deeply into the back, where the pain from the injection will be comparatively slight. Of the other forms of iron many are recommended. If an organic preparation is given and it does not help the patient it is well to change and give an inorganic one, e. g., iron filing or iron reduced by hydrogen or saccharated carbonate or sulphate; one of the best is the protochlorid, which is a French preparation. On the theory that every preparation of iron is changed to the protochlorid this preparation would seem to be especially valuable.

Clark, believing that the disease is due to constipation, gave as a laxative:

R. Ferri sulphatis.....gr. iv-v	25-0.30
Magnesi sulphatis.....ʒi	4
Acidi sulphurici, dil.....m. x	65

With a little tincture of ginger or infusion of quassia. Or he gave sulphate of iron, bicarbonate of soda and sulphate of soda, the vehicle being chloroform water. Clark had these two prescriptions; he had his acid mixture and his alkaline mixture, and apparently he could not know, until he tried, which one of them would agree. So he tried one, and if it failed, tried the other, and if neither agreed with the patient he came back to Blaud's pill, which is the best thing after all.

Hemorrhage from Hemorrhoids.

The *Journal des Praticiens* states that the simplest remedy for such hemorrhage is an enema of very hot or very cold water, to which has been added 5 per cent. of alum. The following prescription may also be added:

R. Benzoin.....gr. xv	1
Aluminis.....gr. xxx	2
Aquæ Pagliarij.....ʒv	20

M. Sig.: Tablespoonful to a pint of hot or cold water as an enema.

The styptic liquid of Pagliari is made by boiling for six hours, 8 ounces of tincture of benzoin (containing about 2 ounces of the balsam), 1 pound of alum and 10 pounds of water, in a glazed earthen vessel, stirring constantly and adding hot water from time to time to supply the loss by evaporation. The liquid is then strained and kept in well-stoppered bottles. Cracked ice in a bag of goldbeaters' skin may be introduced into the anus. A valuable hot injection is:

R. Acidi carbolicis.....gr. iʒss	30
Glycerini.....ʒss	25
Aquæ bullientis.....ʒviiss	225

M. For an enema.

The following prescription has also been used:

R. Ext. suprarenalis (1-1,000).....m. l	3
Aquæ dest.....ʒss	15

M. Sig.: Saturate a cotton tampon with this solution and place in the rectum for ten minutes. It should then be replaced by a tampon powdered with antipyrin or iodoform.

R. Cocainæ hydrochloratis.....gr. 9/20	03
Ext. suprarenalis (1-1,000).....m. xxx	2
Petrolati.....ʒss	16

M. Sig.: Use a small quantity by rectum.

A suppository that has proved serviceable is:

R. Cocainæ hydrochloratis.....gr. 3/20	01
Ext. suprarenalis (1-1,000).....m. v	30
Olei theobromatis et cææ, q. s. ad.	

M. For one suppository.

A more elaborate formula is:

R. Ext. suprarenalis (1-1,000).....m. v	30
Antipyrin	
Salol, aa.....gr. iii ¾	25
Ext. belladonnæ.....gr. 3/20	01
Olei theobromatis et cææ, q. s. ad.	

M. For one suppository.

Suppositories, however, may bring on defecation and subsequent hemorrhages. Gelatin must be carefully sterilized before using, in 5 to 10 per cent. solutions in water. Hypodermic injections may be used of a combination of gelatin, 25 to 1,000 of water, and sodium chlorid, 7 to 1,000. Calcium chlorid may be given internally:

R. Calci chloridj.....ʒi	4
Inf. citri acidæ florum.....ʒiv	120
Syrupi.....ʒi	30

M. Tablespoonful every hour.

As an enema calcium chlorid may be administered once or twice daily in the proportion of 60 grains to one quart of water. The pressure should be mild.

Sycosis.

Hall, in the *Clinical Journal*, discusses this condition and gives the following treatment, which he states has been most successful in his hands. All authorities are agreed that sycosis is difficult to treat and requires a long time to entirely disappear.

SHAVING.

Authorities likewise disagree in respect to close shaving of the face. Some favor the removal of infected hairs by epilation and keeping the beard cropped with scissors. The author agrees with others who favor close shaving. He says: "For my part I am convinced that proper treatment consists primarily in constant close shaving. On the regularity with which this is done each day will largely depend the success of the treatment. On this point I have no hesitation in speaking strongly, and since adopting this method of treatment some years ago I have not seen a single case in which improvement has not quickly taken place." The close shaving will have to be kept up regularly for months, and it is best to advise the patient to do his own shaving. Barbers, as a rule, will only shave under protest a patient suffering from this disease. Sharp razors are essential. Two at least must be available. Very hot water, prolonged lathering and previous oiling of the face help to soften the beard.

LOCAL APPLICATIONS.

A boracic acid lint fomentation is applied over the whole chin and cheeks, covered with gutta percha tissue, and kept on by means of a handkerchief carried round and tied to the top of the head. This is worn every night for many weeks. In the daytime the ordinary compound calamin lotion:

R. Calaminæ	
Zinci oxididj, aa.....ʒi	30
Glycerini.....ʒiii	8
Lotio plumbi et opii.....ʒss	15
Aq. rosæ, q. s. ad.....ʒiv	120

Later, when the greater part of the inflammation has subsided, it will be found that pustules keep arising here and there, and the patient should be advised to pull out the hair with a pair of fine tweezers before shaving in the morning and to apply a little white precipitate ointment or biniodid of mercury in spirits on a pointed match stick in the follicle. Some patients may find the calamin paste too drying for the skin, in which case some simple ointment may be applied after shaving, such as Ung. glycerini plumbi subacetatis or a dusting powder of zinc oxid and starch, preceded by an ordinary bay rum spirit lotion. This method of treating must be varied according to the individual needs. Great stress is laid by the author on the persistence in shaving.

The following are also recommended for sycoosis: After the crusts have been softened with oil and removed, the hair should be closely cut and epilation of loosened hairs practiced daily.

R.	Resorcinum	ʒi	4
	Glycerini	ʒii	8
	Ung. aque rose, q. s. ad.....	ʒii	60
M. Sig.:	Apply several times a day.		
Also:			
R.	Acidi salicylicij	ʒi	4
	Ung. picis liquidæ.....	ʒi	4
	Petrolati mollis, q. s. ad.....	ʒi	30
M. Sig.:	Apply several times a day.		

Medicolegal.

SOME LEGISLATION OF THE YEAR 1904.

Massachusetts.

Gives Hospital Ambulances Right of Way.—Chapter 161 of the Acts of Massachusetts of 1904 provides that hospital ambulances shall have the same right of way which fire engines or police patrol wagons now have in the streets of all cities and towns.

Care of Infected Poor.—Chapter 395 of the Acts of Massachusetts of 1904 provides that the State Board of Charity may, if found expedient, remove any person who is infected with a disease dangerous to the public health and who is maintained or liable to be maintained by the commonwealth, to any hospital provided for state paupers, or may provide such place of reception for such person as is judged best for his accommodation and the safety of the public, which place shall be subject to the regulations of the board, and may remove such person thereto. Any expense incurred may be paid from the annual appropriation for expenses in connection with smallpox and other diseases dangerous to the public health.

New Jersey.

Free Diphtheria Antitoxin.—Chapter 232 of the Laws of New Jersey of 1904 provides that, whereas, diphtheria antitoxin has become of vital importance in the treatment and prevention of diphtheria; but, whereas, by reason of its cost, it is impracticable to use it to any great extent; therefore, the State Board of Health shall contract with some responsible manufacturer to supply free of charge, on the certificate of the attending physician, to such indigent patients as shall require it, such antitoxin as may be necessary for their proper relief, at a cost not exceeding \$4,000 per annum.

Prohibits Selling or Prescribing Cocain.—Chapter 76 of the Laws of New Jersey of 1904 provides that no person shall knowingly sell, furnish or give away any cocain, or any patent or proprietary remedy containing cocain, except on the prescription of a registered practicing physician, dentist or veterinarian in his own practice; nor shall any such prescription be refilled; nor shall any physician or dentist prescribe cocain, or any patent or proprietary remedy containing cocain, for any person known to be a habitual user of cocain; provided that the provisions of this act shall not apply to persons engaged in the wholesale drug trade, regularly selling cocain to persons engaged in the retail drug trade.

Forbids Marriage of Epileptics, Etc.—Chapter 137 of the Laws of New Jersey of 1904 provides that it shall be unlawful hereafter for any person who has been confined in any public asylum or institution as an epileptic or insane or feeble-minded patient, to marry in New Jersey, without a certificate from two regularly licensed physicians of the state that such person has been completely cured of such insanity, epilepsy or feeble mind, and that there is no probability that such person will transmit any of such defects or disabilities to the issue of such marriage; any person of sound mind who shall marry with any such epileptic, insane or feeble-minded person, with knowledge of his or her disability, or who shall advise, aid or assist in procuring any marriage contrary to the provisions of this act, shall be guilty of a misdemeanor.

As to Distributing Medicine and Circulars.—Chapter 88 of the Laws of New Jersey of 1904 provides that it shall be lawful for the common council or other governing body of any city, town, township, borough, etc., by ordinance, to regulate and prohibit the distribution or leaving on the public streets, highways, public places, or on private property, or in any private place within any such municipality, any medicine, medicinal preparation or preparation represented to cure ailments or diseases of the body or mind, or any samples thereof, or any advertisements or circulars relating thereto; provided, however, that such municipality shall not be authorized to prohibit a delivery of any such article by handing the same to any person above 12 years of age willing to receive the same. Any such municipality may provide for a penalty of \$50 for any violation.

New York.

Appropriation for Antitoxins and Investigations.—Chapter 728 of the Laws of New York of 1904 making appropriations for the support of the state government appropriates for necessary expenditures for the manufacture and standardization of tetanus, streptococcus and diphtheria antitoxin, and for further investigations of serum therapy in tuberculosis, typhoid fever and kindred diseases, \$14,000, or so much thereof as may be necessary.

Virginia.

Restricts Location of Pest Houses.—Chapter 179 of the Acts of Assembly of Virginia of 1904 provides that it shall be unlawful for the council or board of health of any city or town, or the board of supervisors or the board of health of any county, to establish, locate or maintain any hospital or pest house for patients suffering from smallpox, yellow fever or cholera within fifty yards of any street, public road, public park, or public cemetery, in any city, town or county, nor shall any such pest house be hereafter established within 150 yards of any public road, etc.

Provision for Inspection of Laborers.—Chapter 186 of the Acts of Assembly of Virginia of 1904 provides: Whereas, There are prevalent throughout many sections of the state smallpox and other contagious diseases, by reasons of collecting large bodies of laborers without proper medical inspection or attention thereto, Be it enacted that any person, firm, or corporation employing large bodies of laborers in Virginia constructing works of public improvement, shall, unless said firm, etc., has its own physician for that purpose, be required to have a regular inspection by the board of health of the counties in which the laborers are employed at such times as the board of health may determine. And the said firm, etc., shall pay to the physician designated to make such inspection by the board of health of said county \$10 for such inspection; in the discretion of the examining officer the laborers shall be vaccinated at the expense of said firm, etc., the said obligation of \$10 and cost of vaccination to have the force and effect of a fee bill of an officer and be collected by the sheriff as any such fee bills may be collected.

Authorizes New Procedure in Rape Cases.—Chapter 18 of the Acts of Assembly of Virginia of 1904 provides that before or during the trial of an indictment for rape, or attempted rape, in which the female who is alleged to have been assaulted is a witness, the judge of the court in which the same is tried may, in his discretion, direct that the deposition of such witness be

taken at a time and place designated in said order. Such deposition shall be taken by said judge, by the clerk, or by any officer authorized to take depositions in the presence of said judge, who shall rule on all questions of evidence, and otherwise control the taking of the same as though it were being taken in open court; and there shall be present also the attorney for the commonwealth, as well as the accused and his attorneys, who shall have the same rights in regard to the examinations of such witness as if she were testifying in open court; and no other person shall be present unless expressly permitted by the judge. Such deposition shall be read to the jury at the time such witness might have testified if such deposition had not been taken, and shall be considered by them, and shall have the same force and effect as though such testimony had been given orally in court. But the clerk of the court, in case no appeal is taken, shall, after the time for granting a writ of error has elapsed, withdraw the deposition from the record of the case and destroy the same.

- 1 The Domain of Physiology and its Relations to Medicine. S. J. Meltzer.
- 2 *Observations on Latent and Masked Malarial Infections with an Analysis of 365 Cases. C. P. Craig.
- 3 *Is Not the Treatment of Congenital Clubfoot Begun Too Early? A Plea for Infantile Hygiene and Feeding. V. P. Gibney.
- 4 *Angina Pectoris. John Knott.
- 5 Modern Medicine. Wm. E. Ulrich.

2. **Masked Malarial Infections.**—Craig emphasizes the importance of a blood examination as a routine measure in every case of disease, because in that way only is it possible to discover these cases of malaria that closely simulate other conditions.

3. **Treatment of Congenital Club Foot.**—Gibney cites a number of cases that were treated while the patient was still of a tender age and which show that the results obtained were far from being perfect. The long course of treatment to which nearly all cases of congenital club foot must be subjected leads him to question the propriety of beginning treatment before the child is ready to walk. He advises that the treatment be deferred until after such time when the problems of infant feeding and hygiene have been solved. He feels that excoriations, the strained tendons and ligaments, must surely inhibit digestion, and if digestion is inhibited nutrition can not proceed to our satisfaction. During the first 18 months of life, Gibney says his contention has been along the lines of mitigating the severe forms of treatment. It is known to all orthopedic surgeons, as well as to many general practitioners, that a certain number of cases of club foot of moderately high degree are corrected, fully 80 per cent. or 90 per cent., by the mother's hand alone. In such cases physicians are called in to supplement this good work by simpler forms of apparatus. The mother can be taught to apply a side splint with a soft roller bandage reinforced by a strip of rubber adhesive plaster, and this can be removed as often as she has time for manipulation and stretching and unrolling. The medical man in attendance can give her the necessary instructions, and it is safe to say that the "worrying of the child" will not be carried to the extent of inhibiting digestion and, as a corollary, nutrition. Gibney regards the feeding and the hygiene as supreme, and that a congenital club foot, to be cured, must be treated by mechanical as well as operative means immediately after birth. He also emphasizes that the weight-bearing function is a very important factor in the treatment of the deformity.

4. **Angina Pectoris.**—Knott's paper is a very extensive review of this subject, historical and clinical, containing a great number of citations from several prominent writers, especially with reference to its etiology and pathogenesis. Nothing new is presented.

Medical Record, New York.

- 6 *Surgical Reflections on the Diagnosis of Cancer of the Stomach. A. G. Gerster.
- 7 *Conditions Simulating and Mistaken for Acute Appendicitis. H. Roth.
- 8 Some Random Considerations on Tuberculosis. A. A. Eshner.
- 9 *Sterile Water Anesthesia in the Operative Treatment of Anorectal Disease. S. G. Gant.
- 10 *The Role of the Prostate in Affections of the Urinary Tract. A. L. Wolbarst.
- 11 *Music as a Therapeutic Agent. F. S. Kennedy.

6. **Diagnosis of Cancer of the Stomach.**—Gerster argues that what the practitioner needs is a recognition and sound interpretation of the symptoms to be observed during the initial stages of the disorder, by the aid of which the surgeons may be enabled to take the active measures at a time when the inherent conditions are still, and in an overwhelmingly hopeful manner, favoring curative success. We are confronted, however, by the dilemma that if we wait until the diagnosis is reasonably certain, especially if we delay until a palpable tumor exists, it is too late to expect cure from operation. A reliable diagnosis of cancer of the stomach in the incipient stage, in which it is susceptible of successful operative treatment, is with our present knowledge a sheer impossibility, and therefore we must make up our minds to submit the patient to the risk of an operation before the diagnosis is firmly established. The author concludes that when in a clearly progressive case of an intractable disorder of the stomach the local and general symptoms, conscientiously collected and weighed, strongly justify the suspicion of cancer, diagnostic laparotomy should be considered not only admissible, but obligatory.

7. **Conditions Simulating Acute Appendicitis.**—H. Roth gives in detail the histories of nine cases in which inflammation of the appendicular region was simulated by various other conditions, such as cholecystitis, intermittent hydronephrosis, intussusception, two cases of inflammatory disease of the uterine adnexa, ovarian cyst with twisted pedicle causing general peritonitis, a prevesical and a preperitoneal abscess, and pneumonia.

9. **Sterile Water Anesthesia in Rectal Operations.**—Gant describes the excellent results he has had in substituting plain sterile water for cocaine and other solutions that are in vogue for the production of local anesthesia. The method has been found of such value that the author has been able by its means to operate on most rectal cases without a general anesthetic or sending them to a hospital, circumstances much appreciated, especially by the better class of patients. Anesthesia apparently is produced merely by the pressure of the fluid on the nerve terminals in the tissues, and sufficient water should be introduced thoroughly to distend the tissues, causing them to become anemic and assume a glassy, whitish appearance, when anesthesia immediately follows. This distension does not require a large amount of water, from 10 minims to half a dram only being necessary for small hemorrhoidal tumors, and from one-half to four drams in more extensive operations. In introducing the water it is not necessary to use more force than is usually employed in making the ordinary hypodermic injection. In conclusion, he states that, while anesthesia by the injection of sterile water is not effective and can not be applied in all major operations, he has employed it, to the exclusion of general and local medicinal anesthetics, in nearly all of his operations on the rectum (for hemorrhoids, fistula, fissures, etc.), and with such gratifying results that he would heartily recommend its thorough trial by other surgeons for operations in the anorectal and other regions of the body.

10. **Prostate in Affections of the Urinary Tract.**—Wolbarst discusses the anatomic and functional peculiarities of the prostate, which give it a double rôle, for, although a sexual organ in health, in disease it is essentially a urinary organ. The author's conclusions are summed up as follows: Urinary symptoms are most often directly due to prostatic disease. Any pathologic lesion of the prostate which increases its size favors interference with the urinary stream to a greater or lesser degree. Inflammation of the prostate is always accompanied by urinary symptoms. The genital symptoms are least marked. In reference to gonorrhœa, the prostatic urethra is the most important portion of the urinary tract: it is the favorite seat of

chronic urethritis; it is the way by which the inflammation travels from the urinary to the genital tract. The prostate is solely responsible for the important urinary conditions which result as a consequence of its senile hypertrophy. Prostatic concretions may lodge in the bladder and act as the nucleus of larger vesical calculi. Chronic contracture of the bladder neck, neuralgia of the prostatic urethra, prostatic tuberculosis, malignant prostatic disease, prostatic cysts and trauma of the organ, are all made evident by their effect on the urinary function. Lastly, the numerous urinary effections justify the consideration of the prostate as a urinary organ, second only to the kidneys in importance.

11. Music as a Therapeutic Agent.—Kennedy says that much assistance is in many instances to be derived from the intelligent use of music, either vocal or instrumental, as a therapeutic adjunct. Melancholia, insomnia, hysteria, family affliction, business reverses, delirium, pain, fatigue, mental or physical, will all be helped by the beneficial influence of music, rightly used. As a postoperative measure it would have an undoubted influence for good in taking the patient's mind from his bodily distress. So also could "painless" dentistry be relieved of some of its pain and distress by the quieting influence of music, which would, as has been amply demonstrated, produce a pleasant mental influence during the administration of nitrous oxid or other anesthetic. A German writer recently stated that in a number of test cases in which music was provided during the administration of the anesthetic, there was an absence of distress and resistance on the part of the patient; also an absence or reduction of the postoperative nausea under the same circumstances. To be advantageous the nature of the composition must be carefully selected with a view to the needs of the individual case, and the execution must be as nearly faultless as possible.

12. Moser Antistreptococcus Serum in Scarlet Fever.—The method of preparation and the use of Moser's serum are described by Shaw. Up to the present time Moser has isolated nearly thirty different types of streptococci, bouillon cultures of which, taken directly from the patient, are injected into horses, so that the serum is a true polyvalent one. The subcutaneous injections are given for over a week in gradually increasing doses. It takes from seven to nine months to produce a suitable serum. When sufficiently cogent, the serum, in a dilution of 1 to 250,000, should agglutinate these streptococci. The serum is generally employed in only the very severe cases, those having symptoms of general intoxication, and in the lethal cases. It is injected, in doses of 200 c.c., subcutaneously in the abdomen. Results are noticed within a few hours. There is a marked improvement in the general condition of the child, all the symptoms of toxemia rapidly disappearing. Sequelae and complications are less frequent, and when they do occur they are less severe. No fatal case of nephritis has occurred in any of the injected cases. During a period of three and one-half years 1,069 cases of scarlet fever were admitted to the Anna Children's Hospital of Vienna, 228 of which received the serum. The mortality for four years before the serum treatment averaged 14.5 per cent., and for the four years since its employment the mortality averaged 8 per cent. For the same period, in other hospitals in Vienna, where the serum was not used, the mortality averaged 13.1 per cent. The only unpleasant result following the use of this serum is the serum exanthem. This is accompanied by fever, and while it is not dangerous, it makes the children very uncomfortable. The younger the child the more pronounced are the symptoms, and

the smaller the quantity of serum injected the less apt is the exanthem to follow. Serum sickness followed the injection in 73 per cent. of the cases. Moser injected 10 c.c. of the serum as a prophylactic measure in 14 children, and of these four came down with the disease. The attacks in all these cases were lighter than the ones to which they were exposed. Twenty-five children, who were exposed in a hospital ward, received a prophylactic dose and not one contracted the disease. The fact that the serum is prepared only at the Vienna Serum Institute, and is not on the market, has necessarily limited its use.

13. Osteoplastic Gastrostomy for Stricture of the Esophagus.—Meyer reports the case of a boy, aged 14, who swallowed a large quantity of caustic lye by mistake. One month later a gastrostomy and division of the stricture by Abbe's string method was done. The patient remained in the hospital about a year, a bougie being introduced every few days and left in the esophagus for from 24 to 48 hours. But in spite of all that was done the stricture re-formed at the end of the year and a gastric fistula, according to Witzel's method, had to be established. The boy was fed through the fistula for seven years. The stricture was then absolutely impermeable. The electric cystoscope, introduced through the gastric fistula, failed to reveal the cardia. Examination with the Rochester cystoscope and with a long urethroendoscope likewise proved futile. All efforts at passing the stricture failing, Meyer resolved to raise the left border of the ribs by means of an osteoplastic operation, as recently described by Marwedel. He did not, however, succeed in re-establishing the patency of the esophagus and the osteoplastic flap was fitted back in its former place and sutured. Feeding through the gastric fistula was resumed, the patient improving steadily in general health. Meyer expects to repeat his efforts at some later time.

- 18 "Some Observations of the Occurrence of Broadbent's Sign." A. W. Tallant.
- 19 "The Mamma, Its Physiologic Purposes." T. H. Manley.

18. Broadbent's Sign.—According to Tallant, retractions in the left back are much more common than is generally supposed, although it is probable that they would be noted more frequently if always looked for during the routine physical examination. Systolic retraction of a marked degree, similar to and often identical with that described by Broadbent, is found in many cases of cardiac hypertrophy in which there is no other reason to suspect pericardial adhesions. Systolic retraction, more often involving the interspaces only, may be seen in the left back in thin individuals, especially if there is marked emaciation. The reason for many of these retractions would seem to be as follows: Since the pericardium is even under normal conditions adherent to the central tendon of the diaphragm, it is conceivable that with each systole there is a slight pull on the diaphragm. Under ordinary circumstances this is not marked enough to be transmitted to the points of attachment of the diaphragm to the chest wall, but if the heart is hypertrophied or is acting very vigorously, the pull may be sufficient to be visible externally, while in a thin individual even a slight movement would be more easily perceived.

29. **Haab's Giant Magnet.**—The ease with which the Haab magnet attracts from the vitreous, without injury to the crystalline lens, splinters of iron or steel, into the anterior chamber, from which location they are easily removed, prompts Weill to cite a few examples. He says that there is no danger of the magnet attracting too forcibly, since the strength of the magnet can be regulated with a rheostatic arrangement. In all cases it is well to administer the mydriatic frequently during the two hours preceding the operation, so as to dilate the pupil to its maximum in order that the iris shall not interfere with the passage of the splinter into or from the anterior chamber. When the steel in the eye is anterior to the vitreous, the corneal route is the natural one for its extraction and, if possible, this should be accomplished without the entry of any portion of the instrument into the anterior chamber. Those cases where the splinter enters the vitreous via the sclera, in which there is promise of some vision, should invariably be extracted with the giant magnet around the lens and through the cornea. In the first case cited, a small pyramidal splinter pierced the cornea and iris without injury to the lens and lodged in the vitreous. Five days after the receipt of the injury the splinter was extracted. The giant magnet guided it forward around the lens, where it caught in the pupillary portion of the iris, although the pupil was dilated ad maximum. An iridectomy was done and the splinter extracted. In the second case an exceedingly small splinter, which had penetrated the crystalline lens and had lodged in the vitreous, was extracted two days after the receipt of the injury. The vision in both cases is improving.

38. **Ozena and Pulmonary Tuberculosis.**—Theisen considers the etiology and diagnosis of ozena and also the relation of this disease to the etiology of pulmonary tuberculosis. Forty cases of ozena are recorded, 14 of which had pulmonary tuberculosis, 2 of them being also complicated by a laryngeal tuberculosis. Tubercle bacilli were found in the sputum of 9 cases, and physical signs were present in all the cases, so positively in the remaining 5 that a sputum examination was deemed unnecessary. Five of the 14 patients died while under Theisen's observation. He believes that this is more than a coincidence; in fact, points to an etiologic relationship. When it is considered that in ozena the normal functions of the nose are interfered with, it can readily be understood how a tendency to tuberculosis may be established. Normal nasal mucus has bactericidal properties. In ozena there is no normal nasal mucus. All inspired substances cling to the thick tenacious crusts, which are so characteristic of ozena and which in many cases consist of nothing more than dried pus from the accessory sinuses in which bacilli find a perfect culture medium and may later be carried to the throat and lungs.

41. **Prognosis of Laryngeal Tuberculosis.**—Levy maintains that all cases of laryngeal tuberculosis are not hopeless, but that early recognition of a primary lesion or secondary complication is essential to a favorable termination. The patient's environment, his ability to rest his voice, suitable hygienic and climatic conditions also are necessary to a favorable outcome. On the other hand, Levy cautions that one cure should not cause too much optimism. The prognosis of laryngeal tuberculosis depends very largely on an understanding of its nature, its varieties and its stages. Disturbances of phonation are due to infiltration, to ulceration, or both combined. In many cases the voice may be much improved. In extreme infiltration, where improvement may not be obtained, the process does not necessarily go on to ulceration or cause general decline. Intra-laryngeal lesions improve more rapidly than those situated on the epiglottis or ary-epiglottic folds. Disturbances of deglutition may be due to swelling without pain, or to pain, namely, dysphagia or odynophagia, and here the character of the lesion influences the prognosis. Laryngeal tuberculosis materially influences pulmonary and general symptoms, although in some cases, it may possess no bearing on the general course of the disease. The course of pulmonary invasion always markedly affects the laryngeal complication.

 49 *The Rachitic Hand. Henry Koplik.

45. **Influence of Laboratory Feeding on Infants.**—Ladd studied the influence of laboratory feeding on 216 infants with diseases of the gastroenteric tract, the great majority of which were cases of fermental diarrhea and ileocolitis. The acute cases were ill on the average, 17 days, and the chronic cases 3.2 months before they were brought to the clinic for treatment. They were kept on the laboratory milk for periods varying from one to 31 weeks. As an aid in comparing the influence of the feeding on infants at different ages and stages of development, the nutrition of each infant at the beginning and at the end of treatment was judged by the estimation of its weight development. This was calculated from the weight index, which is simply the ratio of the weight of a given infant to the weight of the average normal infant of the same age. Judged by this standard, over 50 per cent. of the cases had a weight development of only from 40 to 70 per cent. when first seen. As a result of the treatment the series is divided into four groups: Group 1.—Cases which maintained or increased their weight index while on laboratory milk and entirely recovered from the acute gastric and intestinal symptoms for which they were brought to the clinic. This group comprised 109 cases or 50.4 per cent. The group, as a whole, gained 8 per cent. in weight index or a maximum average gain per week of 156 grams from the lowest weight reached during treatment. Group 2.—Cases which showed a loss in the weight indices and yet recovered from their acute gastric and intestinal symptoms and showed material gains in weight. This group includes 58 cases, or 26.8 per cent. The maximum average gain per week from the lowest weight reached was 94 grams. This group received treatment on the average for only 5.9 weeks, as compared with 8.5 weeks in Group 1. Group 3.—Cases which for the most part recovered from the acute gastric and intestinal symptoms while under treatment, but whose weight was not materially increased. This group includes 37 cases, or 17.2 per cent. The average length of treatment was 3.7 weeks; the loss in weight index 7.2 per cent., and the average loss in weight from the lowest point reached was 6.5 grams per week. Eleven cases in this group were "not improved" while under treatment. Of these 8 could not be traced, and some of them have died. Group 4.—The fatal cases. They were 12 in number, making a mortality of 5.6 per cent. in the series of 216 cases, the results of which were known the time treatment was stopped. All the

cases in the series were sick infants, and the results are not to be compared, says Ludd, with those obtained in the feeding of average healthy infants. The infants were fed on appropriate modifications of laboratory milk, usually beginning with very weak whey-cream mixtures. This milk was administered within twelve to eighteen hours after the first visit, and was gradually increased in strength. In half of the cases there was no initial loss in weight following this method; in 87 per cent. of the cases the initial loss was less than one-half pound (248 grams).

49. **The Rachitic Hand.**—Attention is called by Koplik to a peculiar manifestation of rachitis observed by him, one which might easily be mistaken for syphilitic disease of the bones, to which he has given the name of the "rachitic" hand. Most of the infants and children in whom he succeeded in demonstrating the rachitic hand suffered from marked rachitis accompanied by pain in the bones, to such an extent that one would be apt to think of syphilis. The phalanges of the fingers are thickened and bowed, at first glance giving one the impression that the hand was very fat. The fingers of the rachitic hand are longer and more tapering than is usual and this is probably due to a laxity of ligamentous structures of the joints or the phalanges. The distance between the extremities of the phalanges which make up the joints is greater in the rachitic than in the normal hand.

- 50 *Pancreatic Inflammations in Their Relationship to Cholelithiasis and Their Treatment. A. W. Mayo Robson.
51 Some Cases Illustrating Difficulties in the Diagnosis and Treatment of Tumors. (To be continued.) Wm. Oldright.
52 *Tubercular Peritonitis. C. H. Mayo.
50. **Pancreatic Inflammations.**—Mayo Robson shows that recent clinical observations and operative experience prove that inflammatory affections of the pancreas or its ducts are very much more common than is generally supposed. In showing the frequency of pancreatitis, and the very serious nature of the acute, subacute and chronic varieties of the disease, Robson demonstrates that very much can be done for these patients by timely surgical intervention. Cases of pancreatitis due to gallstones may be prevented by timely interference, and that with barely 1 per cent. of risk. Gallstones may exist in the gall bladder without causing trouble, and without giving notice of their presence, but, as is well known, as soon as they pass into the cystic duct, or as soon as they begin to produce catarrh, they give evidence of their presence. If the concretions are removed in that stage there should be no mortality and, Robson continues, the operative treatment of cholelithiasis, undertaken before the onset of deep jaundice and infection of the bile and pancreatic ducts, with due care and in skillful hands, is almost devoid of danger. Furthermore, the early surgical treatment of gallstones will prevent the occurrence of many serious cases of pancreatitis that cause danger to life. This paper is an excellent résumé of modern knowledge of the subject of pancreatitis, but is so lengthy that we must refer our readers to the article itself, contenting ourselves with the few excerpts given above.

52. **Tubercular Peritonitis.**—After a brief review of the subject in general, Mayo discusses the treatment. He has practiced many of the methods in vogue at the particular time the operations were made, but as some cases required two or three operations and a few relapsed after apparent cure, and others were not cured at all, he was gradually led to search for the original lesion and remove it, leaving the peritoneal condition to cure itself, and closing the abdomen without drainage. The abdominal conditions always point to the source of disease by the congestion, increased matting of the miliary deposit, or increase of general adhesions. Of course, says Mayo, some cases must be refused operation, as their general condition is such as to render an operation extremely hazardous as well as futile. In males the incision is made over the appendical region, while in women it is so arranged as to explore the pelvis. A tubercular appendix at an early stage, before miliary deposits appear, may at times be diagnosed at operation by the large size of the glands of the mesenterium. The utmost care must be em-

ployed not to open the bowel in separating plastic adhesions of the intestine, as they are the most difficult fistula to close, and usually gradually exhaust the patient. As a rule, it is best to keep close to the parietal or pelvic peritoneum, separating as few adhesions as possible in exposing the region affected. In some cases of tubal infection the mass can be pierced and its entire contents of caseating debris removed, leaving the outer fibers and peritoneal layer in situ, then applying iodine or iodiform emulsion in glycerin to the diseased area and closing the abdomen without drainage. Of 59 operations for tubercular peritonitis by the older methods 42 were cured, 15 improved and 2 died. There were 58 operations for the removal of tubercular tubes, with 56 recoveries and 2 deaths, and 27 cases of tubercular appendicitis without a death.

55. **Pneumococcus Endocarditis.**—Preble's paper can be summarized as follows: Endocarditis complicates pneumonia in about 1 per cent. of all cases, and in 5 per cent. of the fatal cases. The pneumococcus may cause endocarditis of any degree of intensity, but in over three-fourths of the cases it is of the severe or so-called malignant type. The exudate is usually massive, but there is less disposition to ulceration and perforation of the valves than in endocarditis due to the streptococci and staphylococci. Endocarditis due to the pneumococcus comprised about 25 per cent. of all cases of bacterial endocarditis. The affection is much more often left than right-sided, but involvement of the tricuspid and pulmonary valves occurs about four times as often as it does with endocarditis in general. Aortic valves are attacked more often than the mitral. Infarcts occur in about one-half of the cases. Meningitis complicates the pneumococcus endocarditis in about 60 per cent. of the cases. The clinical picture of pneumococcus endocarditis does not differ from that due to any acute endocarditis. The complication may develop before, during or after the pulmonary involvement. A considerable number of cases show a period of normal temperature, usually three to four days and rarely longer than a week between the fever due to the pneumonia and that due to endocarditis. The pulse is usually rapid and irritable, but bradycardia is more frequent than in other forms of acute endocarditis. Subjective symptoms referable to the heart are usually absent, except in cases where there is an old heart lesion, when they are due to the old, rather than the recent endocarditis. Physical signs may be absent. Leucocytosis is frequently absent. Blood culture will usually show the pneumococci. The diagnosis is difficult, impossible, in fact, when the affection develops during the course of the pneumonia, but endocarditis should always be suspected in a case of pneumonia which is followed by an irregular temperature not sufficiently accounted for by some other complication, such as empyema. The prognosis is extremely grave, for 60 per cent. of the cases have a complicating meningitis, but it is probable that the percentage of recovery is higher than the reports so far published would lead one to infer. The

treatment consists merely in rest, absolute rest, with good, supporting food and stimulation, as required.

56. **Ulcerative Endocarditis.**—Sicard gives a short résumé of the history of ulcerative endocarditis, the pathologic anatomy of the disease and the etiologic factors, together with a short synopsis of 32 cases. Eight occurred coincidentally with rheumatism, one apparently with a strain of the back accompanied by hematuria; 7 gave a history of old rheumatic attacks; 3 of having had scarlet fever or diphtheria; 2 of palpitation and dyspnea; 7 of typhoid fever, influenza or malaria; the remainder having apparently always been well. The disease is rare among young children. No cases have occurred in the children in the Presbyterian Hospital of New York during the last ten years. In the 32 cases reported, staphylococci were found in 4, micrococcus lanceolatus in 3, staphylococci and pneumococcus together in 1, and streptococcus in 2 cases. In 22 cases the blood cultures failed to give results and the diagnosis rested on pathologic findings or clinical signs. From an observation of these cases Sicard concludes that malignant endocarditis is a disease of bacterial origin; that it differs from simple acute endocarditis in the extent of endocardial inflammation and tissue necrosis; in the fact that the right heart is more often attacked; in the more frequent embolic processes which are septic in character. Micro-organisms are found in the blood during life, in the emboli and on the heart valves after death. There is nothing in the clinical appearance distinctive of any particular variety of germ causing them. Primary cases are rare, though they do exist. More cases accompany rheumatism, septicæmia, the acute infectious diseases, or are engrafted on an old endocarditis. Almost all cases are fatal; those due to severe infection in a few days; the septic ones in a few weeks. The first variety have a leucocytosis of 15,000 or over, the latter usually below that number, some being very slight. Emboli and hemorrhages are of frequent occurrence, and may be fatal in their results. The urine usually shows evidence of nephritis; it may contain blood and pus from hemorrhage or infarct. Treatment is usually unavailing, excepting the serum therapy, which is of uncertain value.

59. **Pseudoleukemia Gastrointestinalis.**—Wells and Maver report a case of pseudoleukemia which supports the conception that the infective agent, if such there be, might have entered by way of the tonsils, infected the cervical glands, and later became generalized throughout the body. In this instance, however, by far the most advanced manifestation of the disease was in the stomach, and next to the stomach the glands that receive its drainage. Although all the lymph glands were more or less enlarged, none compare with those about the stomach in size. Another peculiarity noted by the authors in reviewing over 200 autopsies in pseudoleukemia as reported in the literature, was that whereas in the universal enlargement of lymphatic tissue that of the alimentary canal usually participated little or not at all, yet when it does become involved to any extent, it is likely to happen that it is then involved much more in proportion than any of the other lymphatic tissue. These cases do not differ either clinically or etiologically from the ordinary cases, and anatomically the difference lies solely in the distribution of the lesions. Such cases stand particularly near the lymphosarcoma and the confusion in nomenclature of pseudoleukemia has added to the difficulty of distinction in many of the reported cases. Tuberculosis as a cause of Hodgkin's disease was negative in this case, inasmuch as animal inoculation as well as microscopic examination failed to demonstrate the presence of tubercle bacilli.

60. **Croup Due to Staphylococcus.**—Anzinger's cases were cases of preliminary sore throats in children, followed by severe obstructive symptoms in the larynx and requiring tracheotomy. In none of the cases was there evidence of a pseudo-membrane. The clinical symptoms pointed to a local infectious process with the elaboration of toxins. In two of the cases the diagnosis of diphtheria was entertained, and antitoxin was given, but with negative result. Bacteriologic examination revealed the presence of practically pure cultures of staphylococci in the trachea and larynx. The organism in recent

artificial cultures proved to be unusually pathogenic to white mice. Pathogenesis was displayed only by direct inoculation into the lymph or blood circulation. From an analysis of his investigations, Anzinger draws the following conclusions: 1. The winter epidemics of tonsillitis and sore throat in children at times give rise to laryngeal complications. 2. This condition is always serious owing to the ease with which the juvenile throat may be obstructed. 3. Individual predisposition to laryngeal complication is quite probable. 4. Staphylococcus, a common denizen of the throat, may, under favorable conditions, give rise to grave symptoms, as exemplified in the cases reported. 5. The rapidity of onset and severity of symptoms may at times suggest diphtheria. 6. A reliable bacteriologic examination of the throat is a prerequisite. 7. Antitoxin, although to be used in doubtful cases, will be of no service in cases in which the Klebs-Loeffler organism is not the causative factor. The failures of antitoxin are often credited to such cases. 9. A careful analysis should be made of each case, basing the diagnosis on both clinical and bacteriologic evidence.

67. **Case Simulating Abscess of the Liver.**—Beebe reports a case in which a collection of pus in the pleura immediately over the diaphragm burrowed through the latter into the liver, producing symptoms resembling those of abscess of the liver.

68. **Simple Method of Gastroenterostomy.**—Hepperlen makes use of a mechanical device, consisting of gelatin molded in size and form to meet the requirements for the different operations in which it may be used. It is made aseptic and of proper thickness and hardness to retain its shape 15 to 30 minutes, after which it is absorbed. When the gelatin support is placed in position, he inserts a few interrupted sutures through all the coats of the bowel to hold the parts in coaptation. He then completes the work by using a suture which is original with him. He uses a fine intestinal silk 24 inches long, double, with a needle on each end, having the knot where the silk is tied in the center. He starts his first suture under the mesentery attachment, inserting a needle with each hand, at the same time, through the two outside coats of the bowel, an eighth of an inch from the cut margins, picks up a loop about one-twelfth of an inch in length, draws the parts together and ties them at each stitch, continuing thus until he has completely encircled the bowel. The opening in the mesentery is closed with the same suture, care being taken to pass the needles under the small vessels in the peritoneal coat so as not to constrict the blood supply more than necessary. The gelatin device used for gastroenterostomies has a small flange molded on one end of the gelatin cylinder to hold it securely in the bowel where opened. This secures practically the same result obtained by the Murphy button, is as rapid, and is a much safer operation because there is no danger of retention of the device. For ureteral work he uses a small cylinder with an opening through the center, oval at each end. The technic of the operation is the same as described above.

1. Treatment of Accidental Hemorrhage.—Macan summarizes his paper as follows: In the absence of disease, all accidental hemorrhage has a natural tendency to stop. It commences as an internal hemorrhage, and many times ceases spontaneously without having been diagnosed, or, if so, only by finding old

clots on the surface of the placenta postpartum. A large proportion of cases of so-called accidental hemorrhage is due to low insertion of the placenta. The diagnosis of this condition is difficult, and can not always be made with the finger. Hemorrhage from low insertion of the placenta is not likely to cause either internal or combined hemorrhage. Rupture of the circular sinus of the placenta gives symptoms that are very similar to those of internal or even combined hemorrhage. There are other factors besides want of tone in the uterine walls that tend to cause the hemorrhage to remain internal—for example, lessening of the first *vis a tergo*; the position of the first hemorrhage; its amount, and the firm adhesions around it. In the worst cases, where the cervix is long and the os rigid, it is (probably ?) necessary to deliver the woman immediately. Cesarean section, either vaginal or abdominal, is a better way of doing this than accouchement forcé. Less severe cases, when the cervix is long and the os rigid, should be treated by a properly applied vaginal tampon.

Uterine contraction may cause the hemorrhage to cease during the contraction, but not during the intervals, except indirectly as favoring thrombosis. Accidental hemorrhage is often due to uterine contractions—for example, after the sudden escape of excessive liquor amnii and after the birth of the first of twins. When the hemorrhage escapes from under the placenta, the tendency to further separation of the placenta is lessened, because the membranes (unless morbidly adherent) are more easily separated than the placenta. Rupturing the membranes must always cause a diminution in the intrauterine tension, and makes it more difficult to increase this tension by tamponing the vagina. Therefore, rupture of the membranes is not good treatment for ordinary cases of accidental hemorrhages, unless it causes rapid expulsion of the child. It is, however, a most efficient way of stopping accidental hemorrhage which is caused by a persistence of the bag of waters far into the second stage or by a low insertion of the placenta. The great danger in affecting delivery of the child *per vias naturales*, when the cervix is only partially dilated, is due to the difficulty there is in judging how much time is at our disposal to affect the dilatation. In tamponing the vagina and in the application of a tight binder and a firm perineal bandage we have a most efficient method of treating all but the worst cases of accidental hemorrhage, perhaps even these. Adhesions may stop internal accidental hemorrhage by causing localized increase of tension, but their presence can not be determined. If the original seat of the hemorrhage is at the very center of the placenta, the whole of the placenta will become detached; and if the placenta is situated exactly at the fundus, the membranes also will be all separated before the hemorrhage becomes external. Prolapse of the placenta depends on both these conditions being present. All cases of accidental hemorrhage should be reported, not the severe cases only, and the position of the rupture in the membranes carefully noted.

2. "Ovarian" Pain.—Herman states that he knows of no morbid change in a freely movable ovary that causes chronic pain. The so-called "chronic ovarian pain" is either a reflected pain due to some cause other than the ovary, or is due to neurasthenia, or is a manifestation of hysteria. It is not curable either by surgical treatment of the ovaries or by their removal. The only exception to this is the reflected pain of dysmenorrhea, which is cured when menstruation is stopped.

6. Hysterectomy.—In the course of a discussion on the indications for this operation, Bland-Sutton says that in suitable, carefully selected cases of cancer of the cervix uteri, the uterus is best removed by the vaginal route, as it enables the surgeon to excise the tissues about the cervix widely and to avoid the bladder, the ureters and the rectum. Out of 100 consecutive patients with cancer of the neck of the uterus, about 5 per cent. are favorable subjects for operation. The disease should be limited to the cervical tissues, and the broad ligaments should be free from any suspicion of infiltration. This must be determined with the patient fully anesthetized. The remote results of hysterectomy for cancer of the body of the uterus are very good when performed before the disease has perforated the uterine wall.

The best results are met with in the rarer instances in which the disease arises in a senile uterus. When it is absolutely necessary to remove the uterus for fibroids complicating pregnancy, it is usually to the patient's advantage to perform supravaginal hysterectomy. Under certain conditions, however, myomectomy, abdominal enucleation and hysterectomy are very useful measures. Panhysterectomy is as safe an operation as supravaginal hysterectomy; it is desirable in many cases to remove the lower cervix, but it is not necessary. says Bland-Sutton, to do this as a routine procedure. The reasons for these opinions are discussed by the author at great length.

8. **Lupus Vulgaris.**—Morris gives a brief record of his experience of a quarter of a century in dealing with lupus vulgaris. In choosing a method of treating this affection, he says a number of things have to be taken into account. First, the seat of the disease; second, the extent; third, the type of the lesion and the stage of its evolution; fourth, the health of the patient. He has treated more than one thousand cases by various methods. In the large majority of the cases the treatment was so mixed that it is impossible to say how much of the result was due to one and how much to another agent. His experience, like that of every other dermatologist, has been that while small superficial patches are curable by almost any of the recognized methods, when the disease is at all extensive it often resists all kinds of treatment. As a rule, he uses chemical caustics only after the application of the light rays or cautery. In cases in which these agents are inapplicable, he employs salicylic or pyrogallic acid, or both together. Minute nodules may be bored with a solid stick of nitrate of silver. Acid nitrate of mercury is very effective, but if used freely produces an unnecessary amount of scarring and pain. Lactic acid he has found useful, at times, as an application to ulcerated surfaces. He believes that the galvanocautery is still the best method in cases in which the Finsen light or the x -rays can not be applied, especially when the areas to be treated are small. The cautery should be used at white heat, and care should be taken not to do much at one sitting, so as to avoid severe reaction. The scarification method he has practically abandoned. Volkmann's method of scraping has yielded excellent results in his hands. In some cases a single operation has effected a permanent cure. Of course, the method has its disadvantages. Excision is applicable when the patient has no time nor money to spare for the use of less vigorous but more tedious procedures. He has used the Finsen light method for four years and a half and arrives at the conclusion that phototherapy, while no more infallible than any other method, gives on the whole more satisfactory results. The x -rays are most useful in supplementing phototherapy. When the disease is extensive, the ground may be prepared with advantage for the light by the preliminary use of the x -rays. When mucous membranes are the seat of disease, the x -rays are more effectual than light. They are also of value as a palliative treatment. It must, however, be admitted, says Morris, that although the x -rays rapidly dry up discharge, heal ulceration, and disperse edema, they are of less use in eradicating the disease than is Finsen's method. Morris concludes his paper as follows: 1. It must be confessed that after every kind of treatment, whether used alone or in combination with others, recurrence is still very common. 2. As a general statement it may be laid down that small superficial quiescent

patches are curable. 3. When the disease is of moderate extent and situated on the face, Finsen's method, either alone or combined with the application of the x -rays and supplemented by the use of caustics, is the most efficient method in regard to cosmetic effect and probably also in regard to permanency of result. The treatment, however, requires so much time that it is practically incompatible with the pursuit of any avocation needing close personal attention, and directly or indirectly entails considerable expense. 4. If a rapid effect is desired, reliance must still be placed on gentle cautery, if the disease is on the face, and excision if it is on the limbs or the trunk, supplemented in the former case by salicylic acid, nitrate of silver, or other caustics. 5. Very extensive and severe cases in which the health is affected must be dealt with by the general methods used at the present day in the treatment of pulmonary tuberculosis.

9. **Alcohol as a Food.**—Goddard concludes that in small doses only, alcohol is most undoubtedly a food, but when large doses are taken about 50 per cent. of it is excreted from the system and it cannot, then, be considered a food in the proper sense of that term; and if still larger quantities be taken, it is more than probable that this contention would apply with even greater force.

10. **Hætol in Tuberculosis.**—Heggs cites seven cases in which hætol was administered intravenously. The technic and method employed were as follows: Thorough disinfection of the skin and sterilization of all instruments. Any sufficiently large veins of the arms were used. The method of graduated increase of dose on alternate days, as advised by Landerer, was followed. The maximum dose varied from 20 to 50 milligrammes, never getting any ill effects. In all the cases a definite leucocytosis was produced by each injection. As the result of his experiences, Heggs concludes that hætol, though not a specific, is a useful adjunct to any other treatment of tuberculosis.

12. **Treatment of Pyopneumothorax.**—The following general rules are laid down by West: 1. In the early stage when suffocation threatens, the air should be removed and the pressure relieved by paracentesis, repeated if necessary; if this is not sufficient, it is justifiable even to leave the side fully open rather than to lose the patient. 2. In the later stage, when effusion forms, its nature should be at once ascertained. 3. If the effusion is serous, the case should be treated on the general lines of serous effusion. 4. If it is purulent, immediate evacuation by free incision should be carried out. A piece of rib should not be excised, for it is rarely necessary. If it is necessary, no more should be removed than is required to get free drainage. 5. An aspirator should never be used in pneumothorax under any condition; it is unnecessary and dangerous.

20. Treatment of Fecal Fistula Consecutive to Femoral Hernia.—Delbet explains that the reason why these fistulas persist so long is that the inner, adherent walls of the two loops forming the hernia are not sloughed off like the rest, but remain, forming a barrier to the passage of fecal matters from one loop into the other. As soon as permeability of the gut is re-established by removal of this obstructing wall the feces pass on through the natural passages and the fistula heals. Le Dentu uses to resect this barrier Dupuytren's enterotome, and calls the little operation "kentrotomy." In the 15 cases on record conditions were restored practically to normal by this kentrotomy in a few instances, but in 9 it proved to be impossible of application for anatomic reasons. Laparotomy was necessary and a vertical incision along the outer margin of the rectus proved to be best suited for the purpose. The incision terminated below, 2 cm. from the previously tamponed fistula. By thus operating at a distance from the fistula the surgeon works in sound tissue and the exclusion of the fistula insures its rapid healing. Kentrotomy and direct suture are applicable only for the simplest cases.

21. The Organic Phosphoric Principle in Grains.—On page 1013 the previous announcements of Gilbert on this subject were summarized. He here gives his clinical experience with the organic phosphorus derived from the cereals applied to the treatment of pathologic conditions due to defective assimilation or excessive elimination of phosphorus. Out of 200 patients thus treated he has followed 75 for a sufficiently long period to fully establish the direct nutritive and dynamic properties, the latter manifested in the stimulation of the general nutrition of the tissues and cells. In convalescence from severe illness, in anemia and chlorosis, in pulmonary tuberculosis and in neurasthenia, rapid improvement in the general health was almost constant. The most striking effect is the increased appetite apparent from the first. In the 18 cases of neurasthenia this improvement in the appetite impressed the subjects themselves, and was soon followed by the subsidence of the other troubles and morbid tendencies disappeared. In short, he concludes, the new phosphoric principle isolated by Posternak from the grains of chlorophyll plants must be ranked as one of the most powerful stimulants of nutrition yet known.

22. The Nascent State.—Tommasi ascribes the peculiar energy of drugs in the nascent state to the heat generated by their liberation. With peroxid of hydrogen as much as 21.6 cal. is generated as the oxygen is liberated. This heat favors its entering into other combinations and explains its greater activity in the nascent state.

26. Phosphoric Acid in Therapeutics.—Cautru affirms that anhydrous phosphoric acid has no toxic action. Guinea-pigs killed after having ingested what would be equivalent to doses of 200 gm. a day for a man, showed no evidences of fatty degeneration of the kidneys or liver. The microscope findings were those of normal organs, as also in dogs. Some of his patients have been taking from 2 to 4 gm. for more than five years, without showing evidences of intolerance. The morbid

conditions in which it is most beneficial are those in which there is demineralization of the organism with hyp acidity of the urine. It is especially effectual when the nervous system seems to have partially lost its resisting power. True neurasthenia, for instance, is accompanied by considerable elimination of the alkaline phosphates in the urine, the logical consequence of the exaggerated consumption of phosphoric acid occasioned by the overexertion of the brain. The nervous balance can not be restored until the lost phosphorus has been replaced. In neurasthenics in whom the nerve cells are secondarily affected from some digestive or other trouble, the urine will be found hypoaacid with phosphaturia or "hypophosphatia" and the phosphoric acid may be required for years. In arthritis, rheumatism, tuberculosis, malaria, dyspepsia, etc., during the phases accompanied by demineralization of the organism, phosphoric acid will be found surprisingly effective, as also in the nervous troubles of pregnancy and overrapid growth. Years of experience have only rendered him more emphatic in the recommendation of phosphoric acid in therapeutics.

30. Adiposis Dolorosa.—In the case described a tumor had developed in the orbit during youth. It grew to considerable size, but seemed to become arrested about the twenty-fifth year. During the thirtieth year symptoms of Dercum's disease began to develop, and at 60 the patient presented a typical case of adiposis dolorosa. Thyroid and other treatment had no effect, and Delbecq is now trying an extract of the pituitary body, thinking that possibly pressure on this organ from the tumor in the orbit may have been the cause of the affection.

31. Dysenteric Anasarca.—Remlinger writes from Constantinople to call attention to the anasarca observed during and after dysentery in certain subjects free from heart or kidney trouble. By exclusion he arrives at the assumption that the sodium sulphate given copiously during the dysentery may possibly have induced retention of chlorids and this in turn have induced the anasarca. Sodium sulphate is the classic remedy for diarrhea in certain localities, but these experiences show possibly the need for caution in its use.

36. Fat in the Stools.—Gaultier points out that it is not the quantity of fat eliminated, but its condition, that is important from a diagnostic point of view. When normally digestible fat is found untransformed in the feces, some affection in the biliary apparatus or the pancreas may be assumed, or both together. The entire lack of any change in the fat ingested speaks for the last two conditions. When fat is found in the feces transformed into an easily assimilated form, but yet not utilized, the trouble must be some functional disturbance in the small intestine. The proportion of fat utilized averages 95 per cent. in normal conditions. In case of obstruction to the flow of bile the proportion of unutilized fat rises to 49 per cent. on a milk diet, but about a third of the fats are found transformed into a readily assimilable form (Müller). In case of obstruction to the flow of pancreatic juice, the proportion of unutilized fats is from 52 to 83 per cent. (Deutscher), and in intestinal catarrh and other affections the proportion ranges from 18 to 40 per cent. or more, but in these latter cases more than three-quarters of the total amount is transformed into an assimilable form. Gaultier urges that the general physician should pay more attention to these findings, perhaps not wasting time on the search himself, but consulting some working laboratory where such research can be done at trifling expense.

37. Kephir in Therapeutics.—Hayem regards kephir as both a food and a medicine. As a food it is milk already undergoing digestion and thus rendered much more easily assimilated, while the large proportion of carbonic and lactic acid and traces of alcohol, confer on it the properties of a medicine. Kephir is almost the only food which nourishes while allowing the stomach almost absolute rest. It has also some antiseptic and sedative action. Hayem reviews its various indications, which can be deduced from the above. It is contraindicated in case of pyloric obstruction or stagnation in the stomach from any cause.

41. Epidural Injections in Treatment of Urinary Incontinence.—Cantas reports 15 cases in which the incontinence

dated from two to eight years, all completely cured by Cathelin's epidural injections with 2 exceptions, and in the latter the improvement nearly amounts to a cure. The simplicity, entire harmlessness and efficacy of this method commend it, he thinks, above all others for the treatment of incontinence. He found the dose of 10 c.c. more effectual than a smaller one, and cocaine better than mere salt solution. The interval between injections should be long enough to prevent habituation.

60. Puncture of Membranes in Artificial Delivery.—Eighty-two per cent. are still living of the children artificially delivered on account of contracted pelvis in 54 cases at von Herff's clinic. When delivery is not urgent, and the diameter of the pelvis ranges from 7.25 to 9.5 cm., early puncture of the membranes has established its usefulness, according to de Reynier, as affording the best prognosis for mother and child.

61. Results of Artificial Delivery in Contracted Pelvis.—It has been the experience at Basle that fully 20 per cent. more children are born alive when delivery is induced prematurely than when Nature is left to deliver the child spontaneously in cases of contracted pelvis. Twice as many children are alive by the tenth day among the artificially delivered as among the spontaneously born infants. The number of women with pelvis from 6.9 to 8 cm. in diameter was 498. Out of the 2,080 deliveries, 774 were artificially induced, and 188 of the children were born spontaneously. Only 29 per cent. of the latter were alive the tenth day, while 59.1 per cent. of the artificially delivered children were then alive, and 53.6 per cent. are still living. Only a small percentage of the children naturally delivered have survived to date.

63. Extraction of Beans, Etc., from Air Passages.—Nehr-korn has had occasion to treat 3 children who had drawn beans into their air passages. After the first symptoms of suffocation had subsided as the bean settled down in some nook, a period of calm followed, which lasted for twelve to twenty-four hours, or until the bean began to swell. As it swelled it caused increasing suffocation. In one case the extraction of the bean by upper bronchoscopy took three hours, and tracheotomy was necessary the next day on account of inflammatory swelling of the glottis, evidently the result of compression by the bronchoscope. For this and other reasons he advocates immediate tracheotomy for low bronchoscopy, without wasting time on upper bronchoscopy, in case of aspiration of a foreign body by young children. He indorses von Eickens' warning that bronchoscopy should be done whenever there is even the slightest suspicion of aspiration of a foreign body into the bronchial system, and with the greater urgency if it is one liable to swell.

64. Antibodies of Streptococcus Serum.—The results published from the research described indicate that there is a third kind of specific action by the specific serums, which is different both from the antitoxic and the bactericidal action. This third action resembles the bactericidal, but it requires direct co-operation on the part of the cells. Phagocytosis is induced, but not until the bacteria have been acted on in some specific manner.

65. Technic of Tests for Cutaneous Sensibility.—Strümpel's extensive experience has demonstrated that the sensation of pressure may be missing while the most delicate sense of contact persists intact. He thinks the sense of pressure is transmitted by the soft parts below, and suggests the following schedule for diagnostic determination of the sensibility: A. Sensibility of skin, 1, for simple differences in tension. Contact sensitiveness. Sensibility of the hairs; 2, for injurious painful stimuli (pricks). Pain sensation; 3, for heat stimuli. Heat sensation; 4, for cold stimuli. Cold sensation. B. Sensibility of the deeper parts, 1, sense of difference in tension in the fascia, muscle and periosteum. Pressure sensation. Pressure sense; 2, sensation for differences in tension in the tendons, muscles, ligaments and joint surfaces. Movement sensation. Muscle sense. Tests for the above with a brush, needle, hot and cold water and the hands, answer all practical purposes.

66. Suture Material.—Mikulicz has been using for seven years the Hofmeister formalin catgut, and has had no cause for changing. He does not venture to use silk for buried sutures, except in surely aseptic wounds. In his private clinic he always operates in thread gloves, and his assistants wear the same, frequently changed, but in the less favorable conditions of the polyclinic they all wear rubber gloves. In order to delay absorption of catgut, he has it prepared in a special fashion by a kind of tanning process devised by Miyake. The catgut is stretched tight over a sheet of glass and tanned for twenty-four hours in a 5 per cent. aqueous solution of quebracho, after which it is prepared for use by the Hofmeister formalin technic. Quebracho extract is derived from a kind of oak that grows in Argentina, peculiarly rich in tannic acid. It is being used more and more in the tanneries instead of native trees. Catgut thus prepared is stronger than the untanned, and persists for four weeks and more with scarcely any indications of swelling. After this it gradually yields and is absorbed, but it still held to the sixty-fifth day in the tests and was not finally absorbed until the eighty-third to the ninety-ninth day. He remarks that the reputation of a surgeon sometimes depends on the manner in which the skin is sutured, and he always insists on his pupils paying special attention to this suture. He uses alternately fine silver wire and catgut, where the aspect of the scar is important. Halsted's percutaneous silver wire suture ensures ideal scars. Another means to avoid stitch-hole suppurations is to remove the threads promptly, and incise parallel to the folds of the skin, as, for instance, circular in operating on the neck. An incision made on this principle gapes so little that the stitches can safely be removed as early as the second day. Another advantage is that the scar remains linear and tends to shrink instead of broadening.

70. **Softening and Rupture of Esophagus.**—Beneke comments on the 25 observations of rupture of the esophagus on record. The subjects were usually drinking men, and the rupture occurred during convulsive vomiting. In 11 cases of softening of the esophagus which he has discovered at necropsies, the microscopic findings indicated that the process was intravital. He suggests as a possible explanation that the gastric juice may become corrosive under the influence of some severe disease, such as tuberculous meningitis, peritonitis or cancer. If the cardia should relax the gastric juice might find its way into the lower part of the esophagus and, stagnating there, injure the walls and entail their softening with consecutive rupture. If a pleural effusion should be noted it would presumptively confirm the existence of such a rupture, and aspiration would show either a simple effusion or stomach content. To decide the question the necropsy should be done early, and the body should be laid in the ventral decubitus in order to prevent postmortal softening at other points.

72. **Operative Treatment of Cicatricial Lockjaw.**—Manasse illustrates several ways of treating cicatricial lockjaw. He followed Israel's technic, slightly modified, in the case described, taking a flap from the neck to cover the gap left by resection of the corner of the mouth on each side.

73. **Therapeutic Application of Permanent Pressure.**—Heermann has been using for several years a mode of local treatment by permanent pressure. He illustrates the various devices which have proven their usefulness in his experience, an elastic wet sponge, a rubber bag or cushion, placed on the part, with a folded compress opposite, the whole strapped tight by a broad strap wound once or twice around the region and buckled. The most effectual is the rubber cushion, inflated after it has been strapped to the part. The aim is to apply compression only at one or two points, not circular. He uses permanent compression to reduce swellings, to maintain what has been accomplished in treating stiff joints and cicatricial contractions, especially after burns and after injuries liable to cause stiffness. Superheated air can be applied with the part thus dressed.

83. **Infectiousness of Gumma.**—Delbanc reports a case and reviews 4 similar ones previously published by others, in which an ulcerative tardy syphilitic on the genitals transmitted syphilis to the wife. He is inclined to think that the rarity of such occurrences is due to the fact that gummatous growths are usually located at points where direct transmission is scarcely possible, for instance, on the periosteum. As the gumma can transmit infection, it follows that it must necessarily still harbor the syphilitic virus. The gumma indicates the presence of living virus. The manifestations in

the late stage of syphilis are, therefore, not essentially different in regard to their etiology from the products of the secondary stage. The danger of direct or hereditary transmission of the infection during the gummatous stage is very remote, but, at the same time, a positive prognosis against such infection is impossible. In conclusion he reviews recent communications on the subject, citing von Zeissl, whose views agree with his own.

91. **Multiple Cutaneous Gangrene.**—Latte has had occasion to observe 3 typical cases of multiple gangrene of the skin, and from his experience and that of others he is inclined to regard them as self-inflicted injuries. The subjects were all women and all exhibited signs of hysteria. Another point was that the left side was the one affected, where the subjects could easily reach the parts with the right hand. He thinks that a number of cases recorded as tropho-neurotic processes belong in this category, although he does not deny the existence of the latter, and presents a few examples from the literature.

92. **Operating Pen.**—Dreyer has found very useful a small scoop the shape and size of an ordinary steel pen. It is fastened in an ordinary penholder, and persons who shrink from any operation requiring a knife never make the slightest objection to the use of this operating pen. A fold is taken up in the skin and after it is frozen under ethyl chlorid, the pen is passed flat through the fold, as deep as may be necessary. It is thus possible to remove warts, nevi, molluscum contagiosum, incipient cancriods, etc., with the minimum of annoyance to the patient. Scraps can also be obtained for histologic examination without objection on the part of the subject. Dreyer gives an illustration of his pen, but refrains from saying anything in this connection about the pen being mightier than the sword.

94. **Multiple Neurotic Gangrene of the Skin.**—Brandweiner's case was that of a neuro-psychopathic individual presenting multiple gangrene at points on the legs and later on the trunk. The affection had lasted about four years, finally involving the arms and face. The lesions at first resembled herpes zoster, but each terminated in actual superficial gangrene of the skin. The patient submitted to a number of tests with chemicals, but none induced a reaction differing in any respect from those observed in normal subjects. The remarkable phenomenon was noted, however, that serum from the blisters, injected at other points, caused other blisters and final gangrene, while the same serum, injected into other subjects, induced nothing of the kind. Blood serum from the patient behaved the same, but with a weaker action. He suggests that the neurotic influence caused the production of some chemical agent (toxin), which caused the efflorescence and final gangrene on a predisposed soil. Not the slightest effect on the lesions was obtained with any therapeutic measure. The lesions were treated locally, with antiseptics, but even cauterizing with carbolic acid was unable to prevent the development of the gangrene. He reviews other articles on the subject of true spontaneous gangrene. Singer has pointed out that the absence of any peripheral redness as an indication of inflammatory reaction, speaks against a self-inflicted injury.

95. **Pseudo-Parasitic Cell-Inclusions in Cancer.**—Unna describes certain phases of degeneration of the cells when invaded by cancer, especially the degeneration of the nuclei. Fragments of the nuclei break off and their aspect, as he describes in detail, is remarkably like that of Plimmer's corpuscles.

96. **Treatment of Epithelioma.**—Mibelli does not hesitate to proclaim that it is possible to cure epithelioma completely and permanently with local application of arsenious acid. He has been using it since 1897, and 15 out of 20 patients thus treated have been permanently cured. He describes his experimental and clinical research to determine the mechanism of its action, and relates his conclusions in regard to the indications for this treatment. Even in the cases in which it offers little prospect of a cure, it may be found an excellent palliative. It does not interfere with the application of other

measures later. He uses a stronger concentration than Truncheon, generally 1 per cent., occasionally .5 per cent., and sometimes 2.5 per cent. He has further combined it with ether, in the proportion of 1 part arsenious acid, 20 parts ether and 30 parts alcohol. A peculiarly convenient form of applying it to the face is in a gelatin, containing 1, 2 or 3 per cent. arsenious acid. Recent research has shown that the drug is "ionized" through the gelatin just as effectually as in an aqueous solution. A cotton wad is impregnated with the fluid and is pressed firmly on the surface of the epithelioma after the latter has been cleaned and freshened. A permanent bandage is then applied above, the dressing renewed every day for four or five days. The epithelioma heals in a month or so, leaving a smooth, small, scarcely apparent scar, unless it is peculiarly malignant, but even in this event more or less permanent improvement is realized. If recurrences develop later, further application of the arsenious acid will cure them permanently. In his experience the alcohol-ether mixture proved most effectual applied under a tight dressing. This communication was one of the addresses at the recent international congress of dermatology, and gives the particulars of each case treated.

97. **Neurology and Orthopedics.**—Vulpius is anxious to draw the attention of neurologists and physicians in general to the borderland between neurology and orthopedics. The borderland affections are the most interesting and the most promising of all that come to the orthopedist. The results of tenotomy are really surprising in many instances. The prospects are better the more circumscribed the paralysis and the greater the functional capacity of the muscles supplying the power, but success is obtained even when an antagonist muscle is utilized. He believes that the antagonist muscle always acts during a co-ordinated muscular movement, and that when it is transplanted it assumes the rôle of the muscle it substitutes, although after-exercises are necessary to accomplish the desired result. He describes what he calls tenodesis, midway between tenotomy and arthrodesis, which cures a flail joint by shortening all the tendons surrounding it. The transplantation method of treating the results of injuries and affections of the nerves, with resulting dystrophy, is a particularly promising field. He never delays a moment to recommend it in presence of an irreparable, isolated radial paralysis, etc., as also for obstetric plexus paralysis. Intercostal neuralgia accompanying scoliosis is frequently due to compression of the nerves, and can be relieved by orthopedic treatment of the spine, with resection of the compressing rib in extreme cases. He adds that the Sauerbruch air chamber may possibly prove an aid in this line. He devotes much space to the orthopedic treatment of poliomyelitis and its consequences, asserting that there are very few cases in which it is not possible to essentially improve or cure the patient by carefully individualized orthopedic treatment. Orthopedic appliances or orthopedic surgery can also afford valuable results in transverse myelitis, and the former will be found useful in tabes, not only for the spine, but for the knee and ankle. Splints check the use of the limb somewhat, and relieve the weight while counteracting the destructive process in the cartilages of the joint. An actual curative action can be

ascribed to them in tabes and syringomyelia unattainable by any other means. In case of spondylitis, gradual forcible correction of the hump may prevent development of paralysis or cure it. If this fails or is not applicable, laminectomy should be considered. The prognosis is most favorable when the spondylitis is already healed and the compression of the spinal cord is due merely to a fragment of bone or thickened tissue. He has been very successful with tenotomy in a number of cases of paralysis subsequent to apoplexy.

98. **Gallstone Affections.**—Decker remarks that he has found gallstones in 10.6 per cent. of all his necropsies during the last two years. Riedel estimates that there are two million suffering from gallstones throughout the German empire, but the local frequency varies, the highest percentage to date having been found at Strasburg, where 25.2 per cent. of all the cadavers over 60 years old present gallstones. Decker emphasizes the importance of examination of the liver region in every person suffering from a stomach affection. The latter is frequently merely the first symptom of gallstones. Icterus is absent in fully half the cases of the latter. Carcinoma of the gall bladder developed on a basis of cholelithiasis in 14 per cent. of his cases. He goes over the various points for the diagnosis and states that acute, mild cholecystitis, the attacks which terminate with expulsion of stones, and acute occlusion of the bile duct, all these require internal treatment alone. Operation is frequently but not absolutely indicated in processes in the biliary passages threatening perforation, in hydrops of the gall bladder and in severe acute cholecystitis. He warns that the disposition to gallstone affections is frequently acquired during school life, but can be avoided by sports and hygiene. In treatment he advises six to eight glasses of Carlsbad water at the natural temperature (that of the Sprudel is nearly 160 F.), which can be taken at home, supplemented by application of heat to the abdomen or liver region in bed for two or three hours, followed by a hot bath and renewed heat to the liver region for an hour. This treatment is repeated morning and afternoon, with deep breathing exercises. If the subjects go a year without trouble he advises a repetition of the course for three or four weeks. When physicians learn to diagnose gallstone affections earlier, when they systematically examine the liver region in every case of stomach trouble, and when they treat the gallstone affection so soon as diagnosed on the energetic lines here suggested, the internists will win back a large part of the domain which has passed into the hands of the surgeons solely from the neglect of diagnosis and treatment by the internists.

102. **Metal Filling for Carotid Canal.**—The gasserian ganglion was resected in the case of the douloureux and psychosis described. The operation was accompanied by severe hemorrhage from the sinus cavernosus, which persisted only temporarily controlled by tamponing. As a last resource the services of a dentist were secured, and the gap in the temporal bone over the carotid canal was plugged with an amalgam filling, like a cavity in a tooth. The operative results were so satisfactory that they should encourage further trials of this application of dentists' fillings in general surgery. In conclusion, a mode of access to the gasserian ganglion is proposed which allows much ampler oversight than other technics, but has not yet been tried on man.

112. Uses of Condiments with Food.—Liebreich presents scientific data to show that condiments are by no means mere luxuries, but are stimulants to the appetite or serve some other physiologic purpose. Mustard, for instance, aids the chemistry of digestion by destroying the putrefaction bacteria, and also by stimulating the gastric secretions, like wine or brandy. As with the latter, too large amounts induce injurious hypersecretion or habituation. It is possible that the active principle of the mustard, absorbed into the blood, may display disinfecting powers. His experimental research unmistakably demonstrated that an internal disinfection had been realized after administration of non-fatal doses. It has been found that prisoners remain in better health and appetite when condiments are allowed, than without. Baer states that stomach troubles have been much less frequent in the prisons since this has been recognized. The psychic factors which enter into appetite and digestion, and which are lacking in prisons, are partly substituted by the use of condiments.

114. Epidural Injections.—Strauss is an ardent advocate of Cathelin's method of epidural injections. He here relates his successful application of them in 7 cases of enuresis, 5 of pollutions, 2 of spermatorrhea, 1 of prostaticorrhea, 2 of impotence, 1 of sexual neurasthenia and 1 of pruritus pudendi. They frequently prove successful after failure of all other measures. They generally induce marked improvement, and frequently a complete cure, although relapses may follow. They will be found especially useful in enuresis infantilis, incontinence without mechanical cause, pollutiones nimie, impotence, spermatorrhea and neuropathic polyuria.

120. Significance of Fever in Childbirth.—The simpler, the more rapid, and the more natural the delivery, in case that fever is observed, the greater the chances that the puerperium will progress favorably and that the temperature will approximate normal. The height of the fever and chills intrapartum are no criterion of the seriousness of the case. The behavior of the pulse is the main point for prognosis. When the pulse rate is high the prognosis is less favorable, even although the temperature may decline. Fever with the bag of waters intact seems to have a more favorable prognosis. These conclusions were deduced by Ihm from study of 200 cases of fever intrapartum. The most important factor in its etiology is the premature or early rupture of the membranes. Long protracted delivery after the rupture does not seem to affect the prognosis unless it lasts more than three days, and the fever sets in soon after the membranes rupture. The prognosis for primiparæ is only a trifle less favorable than for multiparæ and the latter are much more liable to have a febrile puerperium than the former when the birth has proceeded normally.

127. Histologic Indications of Benign Chorioepithelioma.—Velts remarks that about 200 cases of chorioepitheliomas are on record, and the opinion seems to be gaining ground that the possibilities of a permanent cure are even better than in case of sarcoma or carcinoma. On the other hand, some cases seem to be even more rapidly fatal. The microscopic findings in the cases that proved to be benign, invariably indicated a diminished vitality of the Langhans cells, evidenced by the scanty or lacking mitosis. This absence of mitosis was ac-

companied by the appearance of migrating cells, which indicate the dissolution of the syncytium. These cells are the products of the degeneration of a chorio-epithelioma, as well as of a hydatidiform mole undergoing destruction.

A SERIES OF MISTAKEN GYNECOLOGIC DIAGNOSES.*

THOMAS S. CULLEN, M.B.
BALTIMORE.

While it is advisable to chronicle our successes in diagnosis and treatment, I think it is equally necessary for us occasionally to look back and see where we have failed to make an accurate diagnosis before operation, or to critically review our judgment in a given case to ascertain if, in a subsequent and similar case, we could not do better.

From a perusal of the literature one is often led to believe that the exact nature of abdominal tumors is easily determined before operation. While this is undoubtedly true in the greater number of cases, yet it is well to remember that in a goodly number of instances, before operation, it is only possible to determine that the operation is necessary, the exact nature of the malady only being ascertainable when the abdomen is opened. From the accompanying group of cases, which I report in detail, the surgeon who does not always make a positive diagnosis before operation, or the one who may perchance render an erroneous opinion, will possibly derive a certain amount of comfort.

CASE 1.—**Diagnosis:** Very large ovarian cyst. **Actual condition:** A partially parasitic uterine myoma, associated with 51 liters of ascitic fluid. (Fig. 1.) **Recovery.**

Patient.—Woman, aged 54, unmarried, was admitted to the Church Home, Oct. 29, 1902, complaining of marked abdominal enlargement.

Examination.—Her face presented a drawn, pinched appearance, and she was very thin. The abdomen was tremendously and uniformly distended. From the pubes to the sternum in the mid line there was dullness, in both flanks tympany, and on percussion a very distinct wave of fluctuation was easily detected. A diagnosis of ovarian cyst was made, and after a delay of a few days, on account of a slight bronchitis, the abdomen was opened.

Operation.—We found the peritoneum much thickened. The great distension was due to ascitic fluid. Attached to the fundus by a very small pedicle was a myomatous nodule 16 cm. long (Fig. 1). Plunging into the upper or free surface of this nodule were a large number of blood vessels, each about 3 or 4 mm. in diameter, tortuous and closely resembling angle worms. On tracing them upward they proved to be the enlarged omental vessels. The omentum as such was recognized as a fringe not more than 5 mm. long, projecting from the lower edge of the transverse colon. The altered omental vessels were exceedingly friable and ruptured on the slightest manipulation. The parasitic myoma derived part of its blood

supply from the bladder, to which it had become intimately attached. After tying off the blood supply of the myoma, this growth was removed and the patient made a rapid recovery.

In this case I had to rely entirely on the physical signs, as the patient was of unsound mind, and up to the day of operation no history could be obtained. The facial expression and the abdominal signs tallied in every particular with those referable to an ovarian cyst, and without the clinical history a correct diagnosis was impossible. The tympany in the flanks is, on first thought, difficult of explanation, but when we remember that this myoma with the omental vessels attached stretched almost the entire length of the abdomen, it is readily seen that the small intestines were held back and at the same time forced out laterally. Under any circumstance there would have been dullness over the entire anterior abdomen, as the intestines, even if not held back by the tumor and omental vessels, could not have reached the surface, their mesentery not being long enough. I know of no instance in the literature where such a large quantity of ascitic fluid was associated with a myoma. The condition in this case was analogous to that found where a fibroma of the ovary exists. In the latter we have a solid tumor so moving that there is often partial torsion of the vessels bringing about the outflow of ascitic fluid. In our case the myoma rolled around so much that the omental vessels were partially twisted. This was undoubtedly the case, as is shown by the fact that there has been no further appearance of the ascitic fluid since removal of the myoma. Had this patient been in the possession of her mental faculties the diagnosis would have been fairly certain, as the family physician told me at the time of operation that he had first noticed a hard abdominal tumor attached to the uterus and that the ascites had developed subsequently.

Schwarzenbach¹ reports a most interesting case. The patient was 30 years old and the mother of six children. In 1896 she had a pelvic hemocele, with pronounced symptoms of internal hemorrhage. In 1897 a subperitoneal myoma the size of a child's head was detected. In 1899 she gave birth to a child, and in 1901 an exploratory abdominal section was made. Numerous arteries and veins springing in the vicinity of the stomach lay perfectly free in the abdomen, and passing downward spread out on the surface of the subperitoneal uterine tumor. Considerable ascitic fluid was present in the abdomen. The abdomen was closed, as the growth was thought to be malignant. The patient improved, and in 1902 the abdomen was again opened. The omentum, which at the first operation showed marked atrophy, had now entirely disappeared. The patient was two months

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

1. E. Schwarzenbach: *Eigenhämliche Entartung des an einem Uterusmyom adhärenten Netzes, Beiträge zur Geburtskunde und Gyn. Rudolf Chrobak. Aus Anlass seines sechzigsten Geburtstages. Gewidmet von seinen Schülern und Freunden, vol. 1, p. 220.*

FIG. 1.—A PARTIALLY PARASITIC UTERINE MYOMA ASSOCIATED WITH 51 LITERS OF ASCITIC FLUID.

Attached to the fundus by a narrow pedicle is a subperitoneal myoma. Plunging into the top of the myoma are the omental vessels. The omental fat has almost entirely disappeared. The myoma is intimately blended with the posterior surface of the bladder. The abdomen is markedly distended with ascitic fluid. The small intestines were effectually held back by the tumor and omental vessels.

pregnant. The large vessels were tied and the myoma was removed. The pregnancy was in no way disturbed. All trace of the pelvic hemocele had disappeared except for the presence of some pelvic adhesions.

It seems quite probable that the hemocele in this case was due to rupture of one of the omental vessels instead of to the rupture of a tubal pregnancy. This case has many points in common with ours.

CASE 2.—Diagnosis: Myomatous uterus. Actual condition: Adenocarcinoma of the body of the uterus, with secondary subperitoneal nodules. (Fig. 2.)

Patient.—Mrs. C., aged 59, was admitted to the Johns Hopkins Hospital, April 22, 1903. She had had three children. Menses stopped at 49. Four years ago uterine hemorrhages commenced and lasted several months. Since then they have been irregular. There is a continual leucorrhœal discharge with some odor.

Examination and Diagnosis.—On vaginal examination we found the uterus about twice the natural size. It was quite nodular. As the patient was in good condition and had a nodular uterus which in general contour corresponded closely with a myomatous uterus (Fig. 2), we made a diagnosis of myoma, especially as the hemorrhages could readily be accounted for by the presence of myomata and since the vaginal discharge was but slightly offensive.

FIG. 2.—ADENOCARCINOMA OF THE BODY OF THE UTERUS WITH SUBPERITONEAL NODULES.

The specimen is viewed from the front. The right round ligament is drawn upward by a cancerous nodule situated at its junction with the uterus. Scattered over the surface of the uterus are cancerous nodules varying from a pea to a marble in size. The insertion of the left round ligament is at a much lower level than is that of the right round ligament. The general contour of the enlarged and nodular uterus closely resembles that of a myomatous organ.

Operation.—At operation we found the uterus as I have described, but the nodules that were supposedly myomata were at points at which the cancer of the body of the uterus had extended to the surface. Here they formed raised nodules beneath the surface and at several places had become attached to the intestines. Complete hysterectomy was performed. The patient made a temporary recovery, but it is doubtful if the entire growth was removed.

In this case mere curettage, even without a microscopic examination, would have been sufficient to establish the diagnosis. But in cases where myoma is diagnosed and hysterectomy advised, we hardly deem it necessary or wise to curette.

CASE 3.—*Diagnosis:* Subperitoneal and intraligamentary myomata. *Actual condition:* Hydrosalpinx, adenocarcinoma

of the right side, and very prominent, was what appeared to be a subperitoneal myoma about 5 cm. in diameter. The right side of the pelvis was filled by a growth which apparently sprang from the uterus and filled the broad ligament. This growth in contour and consistence resembled a myoma.

Operation.—On opening the abdomen (February 2) I found the uterus moderately enlarged. The supposed subperitoneal myoma proved to be a very tense hydrosalpinx which was kinked forward, thus accounting for its prominence. The growth on the right side was a carcinoma of the ovary. It filled the broad ligament and had infiltrated the bladder wall. Attached to the cancerous mass was the omentum and a loop of small gut. As the gut at this point was markedly constricted, I attempted by gentle dissection to release it, but the bowel was so infiltrated by cancer that it commenced to tear and resection of a portion was imperative. It was decided that

FIG. 3.—TUMOR OF THE SIGMOID FLEXURE DUE TO RUPTURE OF DIVERTICULA INTO THE SURROUNDING ADIPOSE TISSUE. SMALL PELVIC ABSCESS.

The lumen of the bowel below the promontory of the sacrum is considerably narrowed. At this point is a definite tumor made up of adipose tissue. Projecting into it are two diverticula, one seen in longitudinal, the other in cross section. At the point indicated by the three arrows the diverticulum has given way and its contents have percolated through fat. This fat on histological examination showed evidence of acute and chronic inflammation, thus accounting for the denseness of the tumor. Between the tumor and the pelvic floor is a small abscess.

of the right ovary, involvement of the small bowel and marked extension to the bladder.

Hysterectomy, partial removal of the cancerous growth, resection of a portion of the small bowel; temporary recovery.

History.—On Jan. 25, 1904, I saw the patient, who was 48 years of age. Her menstrual periods continued regularly until she was 44. Since then the flow has appeared every three or four months, and there has been a slight vaginal discharge. Two years ago she passed a calculus, apparently from the left kidney.

Examination.—On vaginal examination I found the uterus half as large again as normal. Projecting from the fundus on

the only hope of even temporary relief would be hysterectomy with as thorough removal of the growth as possible. This was done, but a raw, green, offensive, cancerous area, fully 6 cm. in diameter, remained attached to the surface of the bladder. Three inches of the bowel were then resected and the ends united by means of the Connell suture, supplemented by the Lembert suture. The anastomosed bowel was then placed among healthy loops of gut as far removed from the necrotic area as feasible. The pelvis was drained through the vagina and abdomen. The patient recovered promptly, but naturally still has a small abdominal sinus. We have employed a retention catheter continuously, as even its temporary removal was

promptly followed by the signs of ascending renal infection. The patient is now in fairly good condition and has been entirely relieved of abdominal distension and cramps, to which she was subjected for some time prior to the operation.

In this case the clearly outlined subperitoneal nodule associated with the growth on the right side gave us a clinical picture very characteristic of multiple myoma, and this diagnosis was further strengthened by the healthy appearance of the patient. Some may doubt the wisdom of attempting any operative procedure in these cases, but in the liberation of the constricted and friable intestinal loop the bowel was opened, and then the more radical procedure seemed to offer the best chance of temporarily relieving the patient. In this case an absolute diagnosis would have been impossible without opening the abdomen.

CASE 4.—Diagnosis: Pelvic abscess, with retroverted myomatous uterus. Actual condition: Rectal diverticula, with rupture into the surrounding rectal fat, producing a definite tumor. Small abscess between the tumor and the pelvic floor. (Fig. 3.)

History.—This patient was seen early in February, 1904. She was 60 years of age. For some time she had experienced slight difficulty in defecation, and for a few days had been running a temperature varying from 100 to 103° F.

Examination.—On vaginal examination, I found the uterus somewhat enlarged. Posterior to it, and apparently continuous with it, was a globular mass. This was very hard and resembled a myoma in contour. There was, however, a hard ridge over its lower portion, as is so often noted where pelvic abscess exists.

Operation.—On February 13 I made a small incision in the vaginal vault just posterior to the cervix, and after peeling back the mucosa entered Douglas' pouch with a pair of blunt artery forceps. A very small amount of pus and a few flakes of fibrin escaped, but the mass was in no way diminished in size. Realizing the presence of an unusual condition, I packed the opening in the vault and immediately entered the abdomen from above. Filling Douglas' sac almost completely was a tumor mass evidently springing from the sigmoid flexure, which had rotated 90° and had become firmly embedded in the pelvis. It closely resembled a rectal cancer. On careful manipulation it was brought out of the pelvis, and on inspection no lymph glands were demonstrable. The diseased segment of gut was removed and an end-to-end anastomosis done with Connell and Lembert sutures, the former being employed at the mesenteric junction and for about two-thirds the circumference of the gut. A portion of the descending colon was brought up into a small incision in the left inguinal region and made fast, so that if occasion demanded it could be opened with a thermocautery at a moment's notice. Drains were then introduced into the vagina and also through the lower angle of the abdominal incision. At the end of the fourth day there was considerable abdominal distension and the patient was very weak. We accordingly opened the descending colon at its point of attachment to the abdominal wall and at the same time forced the patient's nourishment. She promptly recovered. The small fistulous opening was a few weeks later readily closed under local anesthesia, and the patient is now perfectly well.

Examination of Tumor.—On laying the tumor open we found that there were two rectal diverticula passing out into the adipose tissues, and communicating with the lumen of the gut by openings not more than 1 mm. in diameter (Fig. 3). The larger diverticulum was 1 cm. in diameter and filled with a fecal mass. The floor of this diverticulum had given way, and the surrounding fat was everywhere infiltrated by inflammatory products. The excessive hardness of the tumor was due to the fat being in many places replaced by recent connective tissue. The small abscess between the tumor and the pelvic floor was due to the extension of the inflammatory process to the peritoneum of Douglas' pouch. The diverticula were lined by

atrophic mucosa. A rectal examination of this case would have yielded little beyond some narrowing of the lumen of the bowel, which is often present in cases of pelvic abscess. In this case cancer of the bowel might very readily have been diagnosed and a colostomy made.

It will be readily admitted that the preceding cases are unusual ones, and that a positive diagnosis before operation would have been extremely difficult. The possibility of such conditions should always be borne in mind when we are dealing with cases that at first sight seem so easy of diagnosis. While it is always very gratifying to be able to make an absolute diagnosis, yet in many cases it is only possible for us to give a tentative opinion before operation. In this group of cases, notwithstanding our inability to solve the riddle prior to operation, the outcome was as satisfactory as we could have anticipated under the existing circumstances.

ESOPHAGOSCOPY AND BRONCHOSCOPY.

E. FLETCHER INGALS, M.D.
CHICAGO.

Esophagoscopy has been practiced so long and is so familiar to some general surgeons as well as to laryngologists, that its history would not be of great interest. However, its great value in some cases calls for at least a word, and I wish to present the history of one very interesting case in which it enabled me to make a successful operation where other methods failed.

Bronchoscopy is of more recent origin and must become of great interest to laryngologists because of the aid that it affords in removing foreign bodies from the air passages, especially in cases that can not be relieved by tracheotomy alone, and also in many other cases where the resulting scar and the dangers of pneumonia render the latter operation objectionable.

The ease with which foreign bodies can usually be removed from the trachea and often from a main bronchus after tracheotomy, makes this latter operation preferable in most cases, but when the diagnosis is in doubt or when the foreign body has passed into one of the divisions of a bronchus, bronchoscopy affords a means not only of diagnosis, but of successful operation, infinitely superior to transthoracic bronchotomy.

We are greatly indebted to Prof. Gustav Killian of Freiburg, Germany, who first demonstrated the practicability of bronchoscopy, and whose paper, read to the British Medical Association August, 1902,¹ first brought us to a realization of the capabilities of esophagoscopy and bronchoscopy.

Bougies may pass foreign bodies in the esophagus without touching them, and sometimes the radiograph will not show objects because of their character or because they are hidden by the shadow of the vertebrae. On this account Killian says "direct esophagoscopy is the only absolutely reliable method."

In a recent article,² Eicken states that Desormeaux first perfected the principle in the urethroscopie, 1853. Killian states in his article that Kussmaul attempted esophagoscopy in 1868, but that the operation has been developed and perfected by von Mikulicz, von Hacker, Rosenheim and others, and that many foreign bodies have been removed by this method. However, "if the foreign body is large, has sharp edges, points or hooks, as, for instance, dental plates, all attempts at extraction

1. Journal of Laryngology, Rhinology and Otolaryngology, Sept., 1902.
2. Archives of Laryngology and Rhinology.

are dangerous; these may lead to fatal injuries of the gullet. In such cases esophagotomy is indicated. If the foreign body is situated no deeper than from 24 to 26 centimeters from the upper incisors (von Hacker); if deeper, gastrotomy or posterior mediastinotomy (Enderlin) is called for. An exception may be made in the case of vulcanite plates without large metallic parts." Killian also specially recommends direct laryngoscopy through a straight tube for detecting and removing foreign bodies from the larynx in children. He says: "In children insurmountable difficulties often arise (to ordinary laryngoscopy). In these cases direct laryngoscopy (Kirstein's autoscopia) can always be successfully employed, especially after administration of an anesthetic, the patient's head being in a dependent position. Of course, if there is much dyspnea a preliminary tracheotomy must be performed." He says that a similar procedure is even more valuable for foreign bodies in the trachea.

Fig. 1.—Case 1. Radiograph of fleur-de-lis chatelaine pin in esophagus, just above the level of the interclavicular notch. The pin has been outlined in black for the sake of clearness.

When foreign bodies have passed deeply beyond the main bronchi, bronchoscopy renders the greatest possible service, for the reason that we may thus locate and accurately grasp substances heretofore beyond our reach. Killian says: "We may, without fear, press the bronchi, which are highly elastic tubes embedded in soft tissue, into the median line, and bring trachea, larger bronchus and branch into one straight line."

I procured a set of Killian's instruments soon after reading his article, and have attempted their use for diagnosis in two esophageal cases for removal of foreign bodies in the esophagus in two cases, for removal of foreign bodies from the air passages in two cases. In the cases for diagnosis the first was satisfactory, but in the next, where a pin had been swallowed and had apparently passed into the stomach, the profuse secretions prevented a satisfactory examination. Of the next two cases, in one I made three or four efforts to introduce the esophagoscope, but had to quickly abandon it be-

cause the child could not tolerate chloroform; the other was successful, and in one of the last two I did not use the instrument at all because the electric light failed before the operation was begun, and I then removed the foreign body by tracheotomy; but in two most difficult cases, one of esophagoscopy and one of bronchoscopy, the operation proved entirely successful, where the ordinary surgical procedures completely failed. In the esophagoscopy I used Kirstein's lamp as a means of illumination as recommended by Killian, but in the bronchoscopy, although I tried this lamp, I obtained much more satisfactory illumination with a lamp placed on a longer carrier which I had made for the purpose.

In the article published by Killian, September, 1902, he states that bronchoscopy had up to that time been attempted in 20 cases, in 5 of which it proved a failure. Eleven of these cases were his own. He refers also to cases by Coolidge of Boston, von Schroetter, Wild of Zurich, J. A. Killian of Worms, Hajek, Eicken of Bruns, Neuneyer, Spiers, Thost and Spiess. Since the publication of Killian's article other cases have been reported, and the article just published by Eicken³ brings the record down to the present time with the

Fig. 2.—Kirstein's lamp.

exception of two cases of lower bronchoscopy, one by A. Schwyzer of St. Paul, and one by Bodmer, and my own case of upper bronchoscopy, a preliminary report of which was recently published.⁴ Eicken mentions the names of several others who have used bronchoscopy for diagnosis or more or less successful operations. Some of the cases were not published. In this list I find the names of Pienazek, Heryng, Schech, Schmidt of Odessa, Gust and Brunner, making all told 34 cases, of which 19 resulted in successful removal of the foreign body, 10 by upper and 9 by lower bronchoscopy. Eicken's article is very complete, and should be read by every one interested in the subject. In my search it is possible that some cases have been considered twice, but there appears all told to have been up to May of this year 14 successful cases of removal by lower bronchoscopy and 11 cases by upper bronchoscopy. Of the lower bronchoscopy, G. Killian has done 3, Coolidge 2 and Eicken, Neuneyer, Hajek, Spiess, Harrington, Wild and Lermoyez-Guisez. Bod-

mer and Schwyzer each one. Of the upper bronchoscopy Killian has done 5, H. von Schroetter 2, J. A. Killian 2, and Eicken and myself each one.

Killian and most of the other operators use the Kirstein lamp as the source of illumination. In my operation I had the Kirstein lamp; indeed, used it for a few minutes at the beginning of the operation, but in

Fig. 3.—Handle for Killian's tube forceps.

this particular case I obtained better results with the small lamp (Fig. 7) introduced to near the distal end of the bronchoscope. This was not at all in the way in searching for the foreign body, and it gave me no inconvenience in swabbing out the secretions, for an assistant removed it instantly and reintroduced it when-

Fig. 3, continued—Killian's tube forceps. a. Sharp tooth, natural size. b. Stem 45 cm. in length. c. Safe forceps, natural size.

ever I wished. One great advantage of this source of illumination is that the operation can be done in a light room, whereas with the Kirstein lamp it must be in a darkened room.

It is a great advantage to the anesthetist to have the room light in order to watch the patient, and it is much more convenient for the operator in handling his various instruments. The small light in the bronchoscope enables the operator to move his head at will without interfering with the illumination, and it enabled me to show the branches of the bronchi and the pin in position to all the physicians in the room. I did not find the lamp carrier any obstruction to the introduction of instruments, for although it took a little room, this interference was more than compensated for by the better illumination. In examining branches of the bronchi too small for passage of the bronchoscope, one of these tiny lamps on a longer carrier might be passed directly into the bronchus. From my limited experience and from numerous experiments I have made with the bronchoscope, it appears to me that even with the Kirstein lamp which leaves the whole lumen of the bronchoscope available for instrumentation, it will rarely be possible to grasp the object while actually under inspection, for the head must be moved to allow introduction of instruments and the instruments themselves cut off a large part of the illuminating rays. These, I think, generally compel the operator to locate

the object, and then introduce his forceps in the right position and to the proper depth and close them in the dark. Fortunately, this can be done with almost as much accuracy as under actual inspection. In removing the fleur-de-lis chatelaine pin from the esophagus, I tried for a long time to catch it under direct inspection, but the necessity of moving my head to introduce the forceps and the cutting off of the rays of light by the forceps themselves, appeared to make this impossible, so that I at length removed the esophagoscope and attempted to reach the foreign body with various esophageal forceps, but owing to the edema of the esophagus its wall appeared to fold over the foreign body, and I could not even feel it with an instrument. I then reintroduced the esophagoscope, and having accurately located the body at the end of the tube passed in the forceps to the right depth with the blades in the proper position and without seeing the body at the time, caught it easily. In removing the pin from the bronchus with the small lamp down within a centimeter of the end of the bronchoscope, I was at once able to see the pin at the instant I caught it; but this certainly can not be necessary in most cases if the operator is thoroughly familiar with the location of the body and the relations of the forceps. In the case of esophagoscopy in which the secretions were so profuse, I used a local anesthetic only. I obtained a good view of the upper part of the esophagus, but not of the lower. I then resorted to a horse-hair extraction, which seemed to demonstrate that the pin was not in the esophagus.

In the bronchoscopy the parts were also anesthetized by cocaine, and bleeding and probably secretion were somewhat checked by suprarenalin. In the bronchoscopy

Fig. 4.—Case 2. Radiograph of pin in right bronchus with the head directed downward and outward. The pin has been outlined in black for the sake of clearness.

the operation was much facilitated by the vise-like grip with which Dr. Corwin held the patient's head in any position I desired; and I think also by the sixth of

a grain of atropin which I had given hypodermically before the anesthetic was begun for the purpose of checking secretion. In the latter operation the patient did not breathe well for a time, but after the bronchoscope had passed into the bronchus there was no difficulty, although two or three times she appeared not to be breathing at all when really she was respiring easily. At these times the advantage of a lighted room were great, for otherwise the operation would have been suspended. The employment of a chloroform inhaler that permitted us to introduce the vapor through a small tube was also a great convenience.

each 2x4 mm., made in my bronchoscope from 5 to 10 cm. above its distal end. I can see no objection to these, and I find that they overcome the difficulty fully without in any way interfering with the use of the instrument.

ESOPHAGOSCOPY.

CASE I.—April 11, 1903, I received notice from the Presbyterian Hospital that a child, H. C., had come in who had a foreign body in the esophagus.

History.—I had the child brought to my office and then I learned from the mother that a radiograph had been taken at the hospital which showed the foreign body located at the

Fig. 5.—Killian's bronchoscope and handle.

During the search for the pin, although I had on glasses, I was much annoyed by the vapor of chloroform being blown into my eye and causing much smarting. This I have since avoided by having an assistant hold a pane of glass between the eye and the end of the bronchoscope; this has also been very serviceable in preventing the patient from coughing into the operator's eye. In both of these operations it was impossible to extract the foreign body through the tube, therefore,

narrow part of the esophagus just above the level of the inter-lavicular notch, but she did not have the picture. The little girl was 2½ years of age. Six days previously she had swallowed a fleur-de-lis chatelaine pin and had suffered severe nausea for several hours, and since that time had been unable to swallow solid foods.

Examination.—I found her pale and weak, but fairly well nourished. With the fluoroscope I searched some time before I could see the shadow of the foreign body, and but for the positive statement that the radiogram showed it I should have believed there was nothing there, but finally I made out the very faint but distinct outlines, as shown in the radiograph. (Fig. 1.)

Operation.—I gave the patient chloroform and then, darkening the room, introduced Killian's esophagoscope, illuminated by Kirstein's lamp. (Fig. 2.) The secretions in the esophagus were quite abundant, but I swabbed them out with absorbent cotton on Killian's cotton carriers and soon discovered a small part of the pin in the folds of the collapsed esophagus at the end of the tube. I made many efforts to seize it with Killian's tube forceps (Fig 3) under direct inspection, but this proved to be impossible, as I could not introduce the forceps without moving my head, and when they were in, on account of their length, I could not get my head near enough to the esophagoscope to throw in sufficient light to enable me to see the object. I tried to overcome this difficulty by springing the forceps, and finally by bending them, but did not succeed. After about half an hour spent in these futile efforts, I removed the esophagoscope and tried to catch the foreign body with the ordinary long bent, and also tube forceps, but I could not even feel it with either of these. I then re-introduced the esophagoscope, and, having exposed a part of the pin, introduced the forceps with the blades in the right position to grasp it. I pushed them down gently about a centimeter below the end of the tube, and on closing them found that I had the pin firmly in my grasp. It was much too large to be extracted through the tube, so I drew them both out together.

Result.—Whatever injury may have resulted to the esophagus from this procedure was speedily recovered from, and the patient was discharged cured in 4 or 5 days.

BRONCHOSCOPY—REMOVAL OF PIN FROM LUNG.

CASE 2.—Miss B. E., aged 17, came under my care March 23, 1904.

History.—She had drawn a large glass-headed pin into the air passages eleven months previously. She had attacks of cough for 3 days after the accident, but for the following month

Fig. 6.—Eropby inhaler.

after it had been seized and drawn firmly against the end of the instrument, it was held there and both were removed together. In both of these cases the radiograph was of signal service in furnishing information as to the location and position of the foreign body. In view of the interference in respiration by the unaffected lung, when the bronchoscope is passed into one of the main bronchi, Killian had a large oval opening made in some of his bronchoscopes some distance above the end. To meet this indication I have had a number of holes,

the symptoms were so slight that her friends could not believe that she had inhaled the pin. Afterward the cough gradually grew worse, so that in six months she had to leave school and finally became so bad that, as she said, she was like a person in the "last stages of consumption." At times she could feel the pin move about in the air passages, and one time it was coughed up to the larynx and caused a spasm that nearly proved fatal. Her sensations had always been referred to the right side or to the center of the sternum. She was short of breath, particularly when lying down at night. She at times expectorated a great deal for 4 to 5 hours at a time, and frequently the sputum contained some blood. The x-ray was used three times, but nothing could be discovered. In the latter part of January she had been sick in bed with considerable fever and after about two weeks (February 6) Dr. Allison of her home town had opened the tra-hea and sought for the pin, but, being unable to find it, had closed the wound, which healed promptly. The patient stated that an abscess had been

vapor was administered through the bronchoscope. The patient was drawn up so that her head hung over the end of the table, where it was held by Dr. Corwin. I was seated directly back of her head. With a modified Kirstein spatula the tongue was pressed forward and the bronchoscope introduced; but first I got it into the esophagus. After passing the narrow portion of the esophagus where the wall of the gullet folds down closely over the end of the bronchoscope, the esophagus was more or less open, showing an open tube for several centimeters below the end of the instrument. This was at first confusing. The walls of the esophagus under these conditions expand and contract with respiration, but they do not entirely close. I withdrew the bronchoscope and with my finger directed it into the larynx as I would an intubation tube, a plan that is easier for me than under inspection. When the patient was nearly under the chloroform, I sprayed into the larynx a moderate quantity of the following solution, which was also used later several times to anesthetize the bronchi and

Fig. 7.—The lamp on the long carrier.

found at the time of the operation and that there was considerable expectoration of pus. Subsequently she had very little cough until she took a cold about two weeks later.

Examination.—At the time I first saw the patient the scar from the tracheotomy caused a raised welt which was very sensitive to the touch and she was having more or less pain, severe on coughing, the principal seat of which was beneath the third right costal cartilage; the pain extended from the second to the fourth ribs and from the middle of the sternum about 9 cm. to the right. The patient was large and tall for her age. I found her fairly well nourished. She usually weighed 120 pounds, although she had lost considerable flesh; the pulse was 90, temperature normal and appetite and digestion good. She was coughing a good deal and expectorating from three to six ounces of muco-pus daily. The nares and throat were negative, but at the site of the tracheotomy there was a granulation tumor in the trachea about 7 mm. in diameter.

thus permit of a smaller amount of chloroform. Three or four times during the operation the patient breathed poorly.

Turning the patient's head to the left I readily passed the bronchoscope into the right main bronchus and examined its various branches, removing the secretions from time to time with a pledget of cotton carried in by a long cotton carrier. At the beginning of the operation I used a Kirstein lamp, but later substituted the small lamp of which I have already spoken. (Fig. 7.) The light from the latter at first caused confusing reflections because of its brightness and I could not regulate it

Fig. 8.—Hooklets. a. For removal of foreign bodies, but not coming caught in some lateral branch. b. For searching safely in but the stems are 45 cm. in length. c. Removable handle, half

 size.

I could not see the lower half of the trachea. There were a few feeble rales and slight feebleness of the respiratory murmur at the inner part of the lower lobe of the right lung. Otherwise physical signs were normal. A radiograph taken at the hospital showed the pin (Fig. 4) located on a line between the second and third ribs in front and the fifth and sixth interspace behind and from 3 to 4.5 cm. to the right of the median line, with the head directed downward and outward.

Operation.—At 5:30 p. m., March 24, assisted by Dr. George H. Kennett, who gave the chloroform, and by Drs. A. M. Corwin, O. T. Froer, X. P. Colwell and F. L. Kenyon, I operated with Killian's bronchoscope 35 cm. in length and 9 mm. in diameter. (Fig. 5.) I first gave the patient gr. 1-60 of atropin hypodermically to check secretion, then administered chloroform through a Beproy inhaler (Fig. 6) by which the vapor is blown through a small tube. During the operation the

accurately by the battery, as could have been done by a rheostat, but the lamp at length became partly dimmed by a thin coating of blood, which was a material benefit. Although I could easily see all the main bronchus and its branches running downward and outward I could not find the pin, though I searched for it a long time. At length I took a blunt hooklet furnished with the set (Fig. 8-a) and after sweeping it about the various bronchi for several minutes finally brought a part of the pin across the end of the instrument. I was unable to see either the head or the point of the pin, and I concluded that the head must have passed backward into a bronchus, the opening of which was not visible. Feeling confident that I would not lose the pin, I demonstrated it to Professor Senn and various other physicians who were present, and then seized it with Killian's tube forceps (Fig. 5) and by manipulating the forceps and bronchoscope tried to bring the

point of the pin into the tube. I let go of the pin and seized it again several times in this effort, but found it impossible; at length, concluding that the point was sticking into the wall of the bronchus, I finally determined that it would be better to scratch the air tubes all the way up than to take farther risks of losing the pin again, therefore I seized it firmly and drew the pin and bronchoscope out together. I found that the pin had been grasped near the head and it came out bent. In grasping the pin I did not actually see the blades close on it only once, for the forceps when opened shut off the field of vision. By measuring off the length of the bronchoscope on the forceps and marking this with a rubber strap about the forceps I could readily tell how far to introduce them before closing the blades and by a knowledge of the position of the pin the blades could be turned in the proper direction. The operation took, all told, an hour and a half.

Result.—At 9 p. m. the pulse was 90, at 3 next morning 78, and at 8 a. m. the pulse, temperature and respiration were normal. There was no temperature afterward. The tongue where it had been hurt by the tongue forceps, was sore and the bronchi were sore, but this had all disappeared in a couple of days. Four days after the operation the patient went home feeling well, excepting a little cough, which soon disappeared. I examined the trachea just before she went home and found that the granuloma had been rubbed off during the operation. On May 12 she wrote me that she was perfectly well, had gained several pounds, weighed 122 pounds and was in better health than before the accident.

A NEW MATERIAL FOR SUTURES AND LIGATURES.

TENDONS FROM THE LEG OF THE CRANE.

CHARLES F. KIEFFER, M.D.

Major Surgeon United States Army.

FORT D. A. RUSSELL, WYO.

There is still room in the armamentarium of the surgeon for a reliable, slowly absorbable suture and ligature material. I have been recently investigating a material from a very curious source which I believe to be entirely new. Dr. George P. Johnson of Cheyenne called my attention to the long and strong tendons in the legs of the bird commonly known throughout the United States as the blue crane (Fig. 1). He had used this material with excellent results as a suture for the aponeurosis in a case of hernia, the suture giving no trouble and apparently being absorbed in time. I obtained from him a number of these tendons and immediately began a series of experiments to test their value as sutures and ligatures. These experiments comprised tests of the breaking strain of the tendons wet and dry, of the possibility of rendering them aseptic, of the effect of sterilizing processes and finally, tests to determine, if possible, the rate of their absorption in the body. As a result of these studies I have come to the conclusion that we have here not only a valuable suture and ligature material, but one easily obtained in all parts of the world and easily prepared for use. It is not only sufficiently strong for all practical purposes, but is absorbed very slowly indeed in the tissues and therefore seems peculiarly adapted for the cases in which a reliable and slowly absorbed suture is required. It certainly answers all of the requirements for which kangaroo tendon has hitherto been used and, in many ways, is superior to it.

As favorable results were obtained, these studies were not limited to the blue crane, but included two others, the sand hill crane and a rather more rare and larger species known as the whooping crane, one specimen of which I was fortunate enough to secure. The

tendons used are the extensor and flexor tendons which run from the thighs down to the toes. Usually from 6 to 8 useful tendons can be obtained from each leg or from 12 to 16 from each bird. It seems likely that the tendons from all of the larger grallatorial birds will be found equally useful. This would mean a wide source of supply, since these birds are distributed all over the world in two large families, the *Ardeidae* and the *Gruidae*, the herons and the cranes.

Probably the commonest bird of this type and the one most generally distributed in the United States is the blue crane, though improperly, known as the blue heron. As a matter of fact it is not a crane at all but a heron, and therefore should be called the blue heron (*Ardea herodias*). It attains an average height of 3 1-3 to 4 feet, with a spread of wing of about 6 feet. Nearly half of its height is in the slender legs. Like all the rest of the family it is aquatic in its habits, feeds on fish and builds its nest in trees near swamps and streams. The leg tendons from this bird

Fig. 1.—Blue Heron (*Ardea herodias*).

will average 11 inches in length and, in large specimens, there may be quite 14 inches of tendon up to the tendinous expansions in the muscles of the thigh. When dry they are flat, glistening bands resembling rough silk worm gut and are about 1-16 to 1/8 of an inch wide. There is a still larger species of this family of birds found in the southeastern United States and popularly known as the great white heron of Florida, *Ardea occidentalis* (Fig. 2). I have not been able to obtain a specimen of this bird but its leg tendons should be considerably longer than those of *Ardea herodias*. The family *Ardeidae* is abundantly represented in Europe, Asia and in Africa, in which continent the largest known species is found, *Ardea goliath*.

The chief representatives of the second group, the *Gruidae*, in the United States are the common crane generally known as the sand hill crane, *Grus canadensis*, and the stately whooping crane, *Grus americana*. The sand hill crane is fairly common, the whooping crane, more rare. There are about 17 species of this

family distributed over all the great zoo-geographical regions excepting, perhaps, the neo-tropical, in which they are not abundant. The common species of these two families are so well known in this country that a more extended description is unnecessary. The leg tendons of the sand hill crane will average 14 inches in length. The tendons from the one specimen of the whooping crane which I had varied from 14 to 16 inches in length.

A large number of the leg tendons were tested for their tensile strength in the following manner. The tendons selected first for trial were leg tendons of the blue heron, *Ardea herodias*, that had been roughly dried without any attempt at preservation—in other words, the tendons were used just as they came out of the legs of the birds after being dried in the sun (Fig. 3). A number were made pliable by immersion in water for a few minutes. The average breaking strain was found to be 25 pounds. Then the wet tendons were tied in hard knots; the breaking strain at the knot was found to vary from 24 to 27¹/₂ pounds.

Fig. 2.—Great White Heron of Florida (*Ardea occidentalis*).

Perfectly dry tendons without preservation or preparation of any kind were then tested. A hard square knot tied in the continuity of the material broke at 24 pounds. Another knot under the same conditions sustained a weight of 30 pounds without breaking. Tendons immersed in the iodine solution for the sterilization of cat-gut according to the Claudius method, were then tried. After being immersed in this solution for 21 days the breaking strain of a number of tendons averaged 29 pounds. It may be that these were peculiarly strong tendons, but they seemed to be of the same size and stoutness as the others employed and while it may not be true that the tendons are actually stronger after being immersed in the iodine solution, it seems certain at least, that this process of sterilization does not weaken them. These results with the tendons of *Ardea herodias* are shown graphically in the appended illustration (Fig. 4).

The tendons of the sand hill crane, *Grus canadensis* (Fig. 5), tested in the same manner, proved to be, on an average, ten pounds stronger than the tendons of the

blue heron. Separate tendons of this variety sustained a pull of 35 pounds without breaking when wet; with an average tensile strength of 33 pounds in ten specimens. The average strength of the unprepared and unprepared dry tendons was 31 pounds. When tied in square knots either wet or dry these tendons behaved as the others; that is to say, even a hard dry knot showed no appreciable weakness from cracking or splitting of the fibers and sustained a pull as strong as the untied tendon.

Fig. 3. Tendons of *Ardea herodias*, sun dried.

Immersion in iodine solution showed the same results as with the tendons of the heron, an average increase of strength of 21¹/₂ pounds. One knotted piece sustained a weight of 37 pounds without breaking. From the specimen of the whooping crane (*Grus americana*), I obtained a number of tendons quite 15 inches in length, of extraordinary strength. Much stronger than the tendons of the sand hill crane and as strong as the heaviest kangaroo tendon. One of these tendons sustained a weight of 50 pounds without breaking.

Fig. 4 Showing tensile strength of tendons of *Ardea herodias*.

Only one process of sterilization was tried; the Claudius method for sterilizing cat-gut. Heron and crane tendons immersed in this solution take a deep mahogany or blackish-brown color. The solution seemed to have no deleterious effect whatever. They were smooth, if anything more pliable than in the fresh state and in appearance very much resembled ordinary heavy cat-gut or kangaroo tendon submitted to the same process. As has already been shown the tests applied to determine the strength of the iodized tendons

showed not only no diminution but an apparent increase of strength. Inoculations were made from the tendons treated in this manner and it was found that the tubes remained sterile when the tendons had been in the solution three days or longer. The method of making the inoculations was to take a tendon, cut it into small bits with sterile scissors and wash it thoroughly in absolute alcohol in order to remove as much as possible of the free iodine remaining in the tissue. The free iodine being an excellent antiseptic might hold a growth in check, although active germs might be present in the mass. To ensure the removal of the iodine, the tendons were well teased apart during the alcohol washing. Following this they were thoroughly rinsed in a large quantity of sterile water and directly planted on gelatin, agar and broth tubes and scattered free on the top and bedded in the substance of agar plates. All the tubes and plates, whether at the room temperature or incubated in the thermostat, remained sterile.

The tendons can not be sterilized by heat, as the temperature of boiling water destroys them in a very few

Fig. 5.—Whooping Crane (*Grus americana*).

minutes, converting them into a jelly-like mass. Boiling in alcohol was not tried.

After assuring myself of the reliability of the sterilization I employed the tendons in a number of cases. I tied the brachial artery with a moderately large tendon in an amputation near the shoulder for a railroad crush of the left arm. The tissues were widely devitalized by the injury beyond the level of apparent gross destruction. As a result there was some amount of breaking down of the skin flaps. One deep suture of cat-gut became infected and was discharged. The heron tendon gave no trouble and was not heard from. In a second case, I used a heavy tendon in suturing the aponeurosis of the external oblique in a modified Halsted operation for hernia. Four weeks after the operation the suture could still be indistinctly felt through a rather thin abdominal wall. Two weeks later it could no longer be felt. In a third case, with old enlarged glands in the left groin, probably of venereal origin, a clean dissection of the groin was made and all the enlarged glands were removed. A heavy heron tendon was used in the deep layer of the

wound and a light one was used as a subcuticular stitch for the skin surface. The wound healed *per primam*. The subcuticular stitch was removed on the seventh day. It showed little if any alteration. The latest case in which I used this material was a cystic ovary with a heavy broad pedicle. After crushing the pedicle with an angiotribe, a heavy crane tendon was used to tie it off in the groove made by the instrument. Prompt healing was obtained and the ligature has not been heard from.

An effort was made to determine just how long these tendons would last in the tissues. Tendons of *Ardea herodias* were buried in incisions in the erector spinæ mass of two dogs at intervals of a week. At the end of six weeks when the dogs were killed, each dog had a series of six tendons, the oldest of which had been in

Fig. 6.—Showing diagonal course of fibers in kangaroo tendon. (a) Longitudinal course of fibers in Heron tendon (b).

the tissues six weeks and the most recent one week. The one-week tendons were practically unchanged. The two week tendons showed a slight decrease in size, which was progressive in the remaining ones. Of the six week tendons, two had almost entirely disappeared; these were thinner than the other two. The remains of the two heavier six week tendons showed a breaking strain of 4 and 5 pounds respectively.

It is apparent to me that we have here a valuable suture and ligature material; particularly where it is desirable to have a material slowly absorbable, as in operations for hernia and for ligations of large vessels and pedicles. The heavier tendons of the grallatorial birds answer these requirements admirably. The lighter

tendons make excellent superficial sutures. I do not know what effect chromization would have on them, but I do not believe that it is necessary or desirable. One of the chief disadvantages of chromicized cat-gut and kangaroo tendon is the uncertainty and unevenness of the results of the process. Kangaroo tendon is very hard to sterilize on account of its structure, cat-gut on account of its source. In this material all gross original contamination may be avoided. Indeed, I believe that with care, tendons practically sterile could be obtained in the first place. In any event they can be readily sterilized by the Claudius process. Kangaroo tendon is very irregular and difficult to handle. As purchased in the markets it is very uneven. Some of it is exceedingly good; others almost worthless. When kangaroo tendon is closely examined it is seen to be made up fibers, many of which run diagonally to the length of the tendon (Fig. 6a). In handling, these fibers split off, leaving a ligature which tapers from a stout cord to a filament. In the bird tendons the fibers are longitudinal (Fig. 6b). Kangaroo tendons are cylindrical while the bird tendons are flat, ribband like and therefore easier to tie.

CONCLUSIONS.

The following conclusions seem warranted: The leg tendons of the large grallatorial birds make an excellent suture material; strong enough for all practical purposes, readily made aseptic, slowly absorbable and easily prepared. The source of supply is practically world wide. I believe this new material warrants further investigation. Think of the comfort to the civil or military surgeon in isolated places of knowing that he can have a reliable suture material at the end of his shotgun.

RETARDED ERUPTION OF THE TEETH; THEIR LIBERATION OR EXTRACTION.*

M. H. CRYER, M.D., D.D.S.

PHILADELPHIA.

In order to fully understand this subject one should first be thoroughly familiar with the typical positions of the teeth when entirely erupted and in normal occlusion with those of the opposing jaw. It is also necessary to have a complete knowledge of the internal anatomy of the alveolar process. Therefore, a few illustrations showing the typically erupted teeth, with their occlusion, and the internal anatomy of the alveolar processes will be shown.

Figure 1 is a side view made from an almost perfect skull of a white woman. The teeth are fully erupted and are almost typical in their position and occlusion. It is evident there has been but little interference with the nutrition of either the jaws or the teeth of this subject. It will be noticed that the mental foramen is on a line drawn vertically downward from between the premolar teeth. This is quite typical and will be again referred to.

The mental foramen is located in the true non-movable cortical bone of the jaw on a line drawn vertically downward between the premolars. It is the external opening of a small tube communicating with the inferior dental canal. For this small tube, which I have described in previous papers, the name "mental tube" is suggested. Its internal opening into the inferior den-

tal canal is situated in the movable cancellated tissue near the apex of the root of the canine. If the skull of an infant be examined at birth it will be found that the mental tube, or short canal, passes directly outward nearly opposite the lower portion of the germ of the canine tooth. Then, again, if the skulls of children of various ages, up to adult life, be examined, it will be found that the inlet of this mental tube has been carried forward along with the cancellated tissue of the teeth, while the outlet has, apparently, moved backward, the distance varying according to the age of the child until adult life is reached.

Fig. 1.—Side view of a typical skull with typical occlusion of the teeth.

Fig. 2.—Under view of two skulls. A. From a subject about 20 years old. B. From one well advanced in years.

The position of the first molar during its early development was immediately below the upper or inner angle of the jaw. As it increases in size and the other molars are developed, the entire mass of cancellated tissue containing the teeth moved forward, the upper portion a little farther than the lower, as is indicated by the curvature of the trabecular and small cribriform tubes passing from the main tube or canal to the roots of the various teeth. To accommodate this growth the mandible proper—the cortical portion—enlarges interstitially as this process is carried on. Interference with

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

this forward movement of the teeth in the cancellated tissue would have a tendency to arrest the enlargement of the jaw, no matter whether the interference be caused by artificial means or by pathologic conditions.

The development of the alveolar process of the upper jaw is somewhat different. While the teeth are developing and erupting the process extends outward and forward without the extension of the maxillæ which is observed in the mandible. When the teeth are finally

Fig. 2.—Side view of the two skulls shown in Figure 1.

lost in extreme old age and the alveolar process of both jaws is resorbed, the extended rim of the mandible remains, while the upper jaw recedes until the roof of the mouth becomes very small, as is well illustrated in Figures 2 and 3.

Figure 4 is made from the skull of a child about six years old. The external plates of the alveolar process of the upper and lower jaws have been removed exposing the roots of the deciduous teeth and the crowns of the developing permanent

Fig. 4.—Skull of a child about 6 years of age, showing all the deciduous teeth with their roots and crowns of nearly all the permanent teeth.

teeth, except those of the lower third molar and the upper first, second and third molars.

In the majority of children's mouths, at about the age of 6, barring accident or decay, the upper and lower teeth (deciduous) are typical in their arrangement in the alveolar process; they are also typical in their occlusion. While pathologic and other disturbances seem to interfere but little in the arrangement of the deciduous

teeth, they greatly influence the placing of the permanent teeth.

The positions of the non-erupted teeth shown in Figure 4 vary in regard to their depth in the bone. Some are deeply set, for example, in this instance the upper canine, while others are quite superficially placed, as illustrated by the lower canine. Others still are found located between the roots of the deciduous teeth, as the crowns of the premolars in the figure. If we take the positions of the developing permanent teeth into consideration, it is comparatively easy to understand why they should often be retarded in their eruption or deflected out of their typical course. If the deciduous teeth are interfered with in such a manner that their physiologic functions are impaired, they, in turn, will interfere with the physiologic functions of the tissue surrounding the permanent teeth.

Local or general pathologic conditions often cause the alveolar arch to become narrowed or shortened, which, in turn, will have more or less influence on the eruption of the permanent teeth. Malocclusion of the teeth is often accompanied by impaction, as will be shown in some of the illustrations. Occasionally supernumerary teeth, odontoma or odontoceles may cause impaction of the teeth.

Fig. 5.—An inverted impacted lower third molar.

ORDER OF IMPACTION.

My experience has been that the frequency of impacted teeth is as follows: First, the lower third molar; second, the upper canine; third, the upper third molar; fourth, the upper central incisor; fifth, the lower second premolar; sixth, the upper second premolar; seventh, the lower canine. The first and second groups of this classification will, without doubt, be accepted by all familiar with the subject under discussion. In the museum of the dental department of the University of Pennsylvania the following specimens will be found: Twelve impacted lower third molars, nine impacted upper canines, two of which are in one jaw; two impacted upper third molars, both in the same jaw; two impacted lower second premolars.

Examination of Figure 4 makes apparent reasons for this order of impaction. It will be seen that the germ of the lower second molar is well back and partly within the ramus of the jaw. The germ of the lower third molar is still further upward and backward. As these

teeth are developed and the jaw grows, the teeth and the cancellated tissue pass forward between the U-shaped cortical bone. If this sliding forward and down-

Fig. 6.—An impacted canine tooth.

ward of the tooth be interfered with by reason of inflammatory phenomena within the substance of the jaw, causing the cancellated and cortical portions to become adherent, the already erupted teeth will be prevented from yielding slightly to the eruptive force of the moving molar, and there will be no room for this tooth to slide into its proper position. The lower portion of the capsule is more liable to become retarded or fixed than the upper; consequently, in such a case the upper portion or crown of the tooth is carried forward and downward, causing it in many cases to take a horizontal position. In some instances it is turned directly upside down (see Fig. 5).

If the position of the germ of the upper canine be examined, it will be found on a higher level and deeper in the bone than the other teeth. The first premolar is erupted about three years before the canine and often closes in toward the lateral.

Fig. 7.—Two impacted canine teeth.

erupted five years previously, especially if the deciduous canine has been lost early. Under ordinary circumstances the canine will be forced into a fairly typical position, but if any inflammatory condition of the jaw has been manifested the bone may become firm and the

canine more or less impacted. Similar conditions can be predicated of nearly all impacted teeth.

Impacted permanent teeth should, as a rule, be either liberated or extracted. When the impacted tooth can be brought into a useful position through extraction of supernumerary teeth, or by the removal of other causes impeding its eruption, the necessary steps for its liberation should be taken. If left in their impacted state these teeth are liable to prevent the proper nourishment of other teeth and also to interfere with the healthy nutrition of the surrounding tissue. They may press on the branches of the trifacial nerve producing neuralgia, not only locally, but in remote parts, and through reflex action they may cause various disturbances in and about the head and face. They are liable to bring about inflammatory conditions of this region, produce cellulitis in the tissues of the mouth, neck, throat and temporomandibular articulation, interfere with deglutition, etc. They may cause other teeth to become impacted, or even cause malocclusion of other teeth. Then, again, parts of the roots may penetrate into the maxil-

Fig. 8.—A common form of impacted lower third molar.

lary sinus or the nasal chambers, under which conditions, if they become devitalized, they are liable to cause the infection of these cavities.

These four illustrations (Figs. 5, 6, 7, 8) are made from dried specimens. They will give some idea of the most common form of impacted upper canines and lower third molars.

Figure 5 is from a dried specimen belonging to Dr. T. M. Whitney of Honolulu. It shows an inverted impacted lower third molar, the crown of which is partly erupted in the submaxillary fossa. This tooth would be rather difficult to extract in the living subject. From the appearance of the illustration I would judge that it would have to be extracted through the submaxillary triangle.

Figure 6 shows the anterior surface of an impacted canine tooth resting near the anterior surface of the bone. This tooth could have been diagnosed by the use of an excavator, as the crown was quite superficially covered.

Whenever canine teeth are missing from the arch there is good ground to suspect that they are impacted somewhere within the jaw, unless there is satisfactory

evidence that they have been extracted. This is not to be assumed in the case of a missing upper lateral incisor or third molar of either jaw, and occasionally the premolars, all or any of which are often missing through non-development. As an example, I recall the case of a patient about 35 years of age, from whose arch the two upper second premolars are missing, and who claims that they have not been extracted. As he suffered from neuralgia in the anterior portion of the maxilla, I thought that these teeth might be impacted somewhere within the jaw, but a careful exploration with instruments and radiographs taken at different angles and by several experts, failed to show any evidence of the missing teeth. The failure of these methods of exploration leads me to believe that the teeth in question have never developed.

The extraction of a tooth, such as Figure 6, would not be difficult. A longitudinal incision could be made over the crown of the tooth, and then by passing a very small spiral osteotome around the crown one would be enabled to pass a universal elevator between tooth and bone. The tooth could then be forced outward: if room

Figure 9 is made from a plaster cast taken from the mouth of a young woman about 25 years old in the practice of Dr. S. Merrill Weeks of Philadelphia, showing an impacted lower third molar.

could be made so that a small pair of forceps could be used it might be better to use them instead of the elevator.

Occasionally I have found that the bone surrounding such teeth has become very dense and closely adherent to the tooth. Under these conditions the tooth is liable to break, if great care is not exercised, and sometimes it is necessary to use a small spiral osteotome to remove the surrounding bone nearly to the apex of the tooth before it can be extracted.

Figure 7 shows two impacted canines in the roof of the mouth. They were covered principally by bone which extended down nearly to the point of the crown. These teeth had caused the devitalization of the left first and second premolars and the right first premolar, also of the lateral incisor of the left side. The apex of one of the teeth penetrated the maxillary sinus.

It is more difficult to extract canine teeth when in this position than when situated as shown in Figure 6, as the danger of causing an opening between the mouth and nose, or mouth and antrum, is greater. It is a good plan to remove the bone from the lingual surface of the tooth, so the tooth can be carried slightly downward and inward without danger of fracture. Usually there is

not room to extract it in the line of its axis before it strikes the other teeth or alveolar process.

Figure 8 shows a common form of impacted lower third molar.

The anterior cusps of the tooth are often interlocked against the concave distal portion of the second molar. In order to extract such teeth it is often necessary to cut these cusps away with either a carborundum disc or an osteotome. When this has been done the instrument

Fig. 10.—An impacted second premolar and a third left molar.

can be passed under the tooth, between it and the bone, or both, until the elevator can be passed into the opening. By this means the tooth can usually be removed in a comparatively short time.

The following are from practical cases:

CASE 1.—A patient was suffering from neuralgia on the right side of the face. The molar teeth apparently had been extracted from that side of the mandible, but on a closer examination a slight elevation was found about in the position

Fig. 11.

of the right second molar, and by passing an excavator into the enlargement a tooth could be felt. An x-ray picture confirmed this diagnosis. The tooth was removed and the neuralgia ceased. In the x-ray picture the condyloid process is seen plainly resting against the under surface of the eminentia articularis.

In all the radiographs I have seen of this region, when the mouth was wide open, the condyloid process

has been found in this position, indicating that the external pterygoid muscles acting together when the angle is comparatively fixed by other muscles, among which are the masseter and internal pterygoid, serve to assist in separating the jaws, by drawing the upper part of the ramus forward, which compels the anterior portion of the mandible to drop, opening the mouth.

CASE 2.—Is a patient of Dr. Dray's of Philadelphia. This patient was suffering from neuralgia of the right side of the face. An x-ray picture showed an impacted third molar with the crown resting well forward against the distal root of the second molar. In such cases the resorption of this root often takes place, producing neuralgia and devitalization of

Fig. 12.

the tooth. There was a great probability that the second molar was diseased and causing the neuralgia. It was, therefore, thought advisable to extract it, which proved the diagnosis to be correct.

CASE 3.—Figure 9 is made from a plaster cast taken from the mouth of a young woman about 25 years old in the practice of Dr. S. Merrill Weeks of Philadelphia. The central incisors are erupted with their cutting edges pointing slightly inward instead of outward, probably due to some pathologic condition of the deciduous incisors. The alveolar process around the incisors is harder than normal, which condition prevented these teeth from being carried outward during the eruption of the others. They were thus locked against the incisors of the lower jaw, causing these and other lower

Fig. 13.

teeth to be held back to a greater or lesser degree, which in turn would cause the impaction of the lower third molars. The right central is directed more inward than the left and in proportion the right lower third molar was more deeply impacted than the left lower third molar. The left impacted tooth was extracted about a year before the casts were made. The right one was interlocked against the second molar. The occluding surface of this tooth was cut away by the use of a carbide disc, which allowed the crown to rise slightly, as is shown in the illustration, thus making the tooth more prominent and easier to extract.

Figure 10 is a radiograph taken from a cleaned specimen of the right side of the lower jaw, showing the teeth in position

in the cancellated tissue. One might well imagine that a modern orthodontist had moved the first molar "half its width backward" or held it in such a manner that it could not advance. Whether done by mechanical appliance or by pathologic changes, the tooth was held and impaction resulted. If the cancellated tissue be examined, as seen in the x-ray picture, it will be noticed that it is more dense around the first and second molars than anteriorly to these teeth. As the result of an inflammatory condition the cancellated tissue has become united with the cortical bone, thus making another factor in preventing its sliding forward. It will be noticed that the roots of the lower teeth are also thickened by the overaction of the cementoblasts caused by this inflammatory condition.

The inferior dental canal or cribriform tube is slightly deflected from its true course below the roots of the impacted third molar, and is also slightly deflected downward below the roots of the second molar.

It will be noticed that the second premolar stands below the occluding line of the other teeth. It has evidently been retarded in its eruption, perhaps through premature loss or de-

Fig. 14.—The second deciduous premolar is not in position.

vitalization of the second deciduous premolar. In such cases these roots are resorbed very slowly and often cause inflammatory conditions. It is possible that this was one of the primary causes of the non-eruption of the third molar.

CASE 4.—Figure 11 is from a photograph of a plaster cast of the jaw of a young man about 22 years old. Two impacted upper third molars were diagnosed by the use of an excavator. The teeth were afterwards extracted by first removing the overlying tissue and then using small forceps.

Figure 12 is from a photograph taken of the same cast (Fig. 11), with the extracted impacted teeth placed near the tuberosity of the jaw.

CASE 5.—A patient had some neuralgic trouble within the

Fig. 15.

ear, and after having excluded several possible causes, the teeth were suspected, as the upper first and second molars appeared to be sensitive, and a radiograph was taken which indicated an impacted upper left third molar. At this time the patient was referred to me by Dr. George Darby. When one becomes accustomed to examining x-ray pictures it is not difficult to detect a shadow of the crown of a tooth in the region where the upper third molar might be impacted, but this picture gave but a slight indication as to the depth of its occluding surface. No idea was possible as to whether it was near the buccal surface of the alveolar ridge or on the lingual surface. The roots of the tooth, their number, shape and position were not shown in the radiograph. All of this practical surgical

diagnosis had to be learned by other means. In this case a careful exploration was made with an excavator, and the position of the crown of the tooth was practically located. After the tissue covering the crown of the tooth had been cut away the tooth was grasped with small forceps. The firmness of the tooth indicated that the roots were crooked and held by bone harder than normal. By carrying the handle of the forceps in the line of least resistance, which was outward, backward and upward, the roots were unlocked from under the over-calcified bone.

Figure 13 is made from four photographs of the tooth after extraction. *A* shows the occluding or grinding surface with the points of the roots extending outward. *B* shows the upper surface, or the root end, with the four roots spread outward, approaching a horizontal line. *C* shows the distal surface, with the hook-like form of the buccal roots, and *D* shows the anterior surface. It may be interesting to know that the ear has improved since the extraction, and that the other molars appear to have lost their sensitiveness, indicating that the tooth was interfering with the nerve supplying these teeth and through reflex action with the ear.

Figure 14 was made from a plaster cast of a patient of Dr. G. Marshall Smith of Baltimore, who has kindly permitted me to use it in this paper. The patient is a girl 13 years old. Figure 14 is a side view of a plaster cast of the teeth and alveolar processes. The teeth are undersized, the incisors and canines are too nearly vertical or do not flare enough, especially in the lower jaw. The upper teeth are all erupted, for this age, except the second molars, which are ready to erupt. In the lower jaw they are all through except the second premolar, which is impacted. The space for this tooth is very narrow, in fact, not sufficient to allow it to take its proper place in the jaw. The description of the teeth on one side of the jaw may also be applied to those of the other side.

If the cancelled tissue in the region of the premolar has become solidified and attached to the cortical bone, this impacted premolar will, to a certain extent, prevent the first and second molars from advancing; these in turn will have a strong tendency to cause the impaction and malocclusion of the third molar.

The primary cause of this pathologic condition of the lower jaw is that the upper anterior teeth have not moved forward in the usual manner, as they bite over the lower anterior teeth, consequently the teeth and alveolar process of the lower jaw are held back, as shown in the illustration, and in order to liberate the second premolar and prevent the third molar from becoming impacted, the upper anterior teeth should be forced forward, which will allow correction to be made in the lower jaw.

CASE 7.—A young man about 21 years old, who has suffered from neuralgia of the left side of the mandible. On examination with an excavator, impacted lower right and left third molars were diagnosed, the left one being somewhat broken. The history of the case is that part of the crown of the left third molar has been broken away in an endeavor to extract the tooth, leaving the pulp exposed. A radiograph showed that the crown was deformed, also that the anterior buccal cusp was apparently interlocked under the second molar. By careful examination with an excavator it was found that both of the anterior cusps were so far down in the tissue that a disc could not be used to remove them. The patient being etherized, a mouth-gag was placed in position and a portion of the soft tissue was removed with a small knife. The revolving spiral osteotome was placed within the broken crown, or into the pulp chamber, cutting almost through the remainder of the crown, and between it and the bone a space was made, partially in the bone, which allowed the point of a universal elevator to pass between the tooth and the jaw.

I seldom use the forceps to remove a tooth after loosening it with the elevator. In using the elevator on

the left side, as in this case, it is operated with the right hand, the surgeon standing on the left side of the patient. The left forefinger is placed in the mouth by the lingual side of the tooth, and the thumb is placed on the buccal side of the second molar. This gives steadiness to the jaw and reduces the risk of slipping. As the tooth is raised from its socket the forefinger is placed so as to bring the tooth out of the mouth. If the tooth to be removed is on the right side, the elevator should be used with the left hand, if possible (the surgeon standing on the right side). If the operator must use the elevator with his right hand, he should, however, manage to guard and steady the parts with his left hand.

Figure 15 is made from three photographs of the tooth after extraction. *A* shows the outer or buccal side of its roots, in about the same position as when in the jaw. The distal cusps were broken away in a former endeavor to extract it. The greater portion of the crown was cut away with the surgical engine. On the side of the tooth there is a groove extending backward, downward and inward, cut by the osteotome. It was along this groove that the elevator was forced under the tooth, causing the slight portion of the crown that remained to fracture. In *B* the tooth is turned slightly outward, in order to show three roots and the line of fracture which liberated the tooth. In *C* the tooth is turned on its buccal surface, showing the two anterior cusps which were locked under the distal surface of the second molar.

DISCUSSION.

DR. EDWARD A. BOGUE, New York City—What does Dr. Cryer mean by "pre-molar"?

DR. CRYER—A tooth that is in front of the molar tooth.

DR. BOGUE—Dr. Cryer, in his paper used the term "pre-molar" for a deciduous tooth. I am sorry to hear such misuse of terms. He also stated that Dr. Angle says that if the sixth year molars are correct in their occlusion all the rest will be right. If he will make further reference to Angle's book he will find that he states that the largest part of irregularities are to be found when the principal molar is in correct, or nearly correct occlusion. I want to acknowledge my indebtedness to Dr. Cryer; I never hear him without benefit; at the same time, if any defect in his teaching occurs I want to call attention to it, that it may be corrected. As I understand his remarks in regard to impacted third molars he favors extraction. I have a case on hand now in which by tying a small grass line between the impacted third molar and the second molar below I am bringing that third molar to a proper occlusion. I have done this a number of times.

DR. CRYER—I said "liberated or extracted."

DR. BOGUE—I am glad to see that Dr. Cryer's remarks tend in two directions. He advocated the forward development of both jaws. I agree with Dr. Cryer, whose experience is so much greater than mine, that one should be wary of the pressure backward.

DR. M. L. RHEIN, New York City—Dr. Cryer's idea about the correction of the irregularity early in life and the sacrifice of the third molar later in life is one with which I thoroughly agree. It is expected in these cases of degeneration which cause a lack of space in the mandible itself that there will not be sufficient room for the 16 teeth to come properly into position. His conclusions, so far as they can be put into practice, I think are the proper ones; that under these circumstances it will most likely be necessary to sacrifice this third molar, and it is the one that can best be sacrificed. I sympathize with all the work that has been done for the preservation of thirty-two teeth in the arch, and especially against the loss of any of the teeth forward of the third molar. There is such a thing as going to extremes on both sides of this question, and if there are any four of these thirty-two teeth to be lost the ones that can be spared with least detriment to the patient are the third molars without the occlusion suffering. In the case of the young Baltimore girl, there seemed to

be little question as to what to do. It comes in the category named of gaining sufficient space between the first molar and the first bicuspids. If separation is made there Nature will cause that bicuspids to erupt without any difficulty. The undue prominence of the chin and the lack of bone development above it shows to me that it will not make the chin any more prominent. There is plenty of room above the chin for the osseous development, if this forward movement is brought about. I have had a number of cases in which after space was provided Nature brought the teeth into position.

DR. MDIRAN K. KASSABIAN, Philadelphia—The dental and medical professions have derived equal benefits from the introduction and application of the x-rays. The diagnostic value of the rays in cases of unerupted teeth is shown by Dr. Cryer's cases. The ordinary methods of probing with an explorer did not locate the absent teeth, which in some cases were bicuspids and third molars. These had insinuated themselves deeply between other teeth and the alveolar process was so dense that nothing but the x-ray could locate them. I employ two methods for skiagraphing dental conditions, the intraoral method and the extraoral or buccal method. In the intraoral method a small piece of film (which is light and moisture proof) is placed over the gum tissue at a point where trouble is suspected, placing the tube in such a position that perpendicular rays will be cast on the teeth and film. This method covers a smaller area but produces a picture with very sharp details, and is especially recommended for anterior teeth. The extraoral or buccal method requires that a plate 5x7 be brought in contact with the jaw at the region of the suspected trouble. The patient inclines the neck and head to an angle of about 45 degrees. The tube is placed over the shoulder to the opposite side at a distance of 20 inches from the face to avoid superimposition of the jaws. This process produces a picture of greater area and is intended for bicuspids and molars. Two skiagraphs are taken from two angles or directions to determine whether we have a buccal, lingual, distal or mesial presentation, and I might mention here that Dr. Cryer suggested that I make stereoscopic skiagraphs which permit viewing by a reflecting stereoscope, and as a result instead of observing flat pictures, we obtain a relief or stereoscopic perspective effect, which shows the exact position of the teeth. I have received very good results with my stereoscopic skiagraphs at the Philadelphia Hospital, where I used a special table which I had built for the purpose. There is no danger of x-ray burns in skiagraphing these conditions; the time of exposure is short, being from one second to two minutes.

DR. T. C. STELLWAGEN, Philadelphia—The important illustrations made by Dr. Cryer explain how great damage has been done by meddlesome dentists. "Orthodontia" is an incorrect term, the correct one would be "taxodontia." By attempts to correct dental irregularities without a proper knowledge of the development of the jaws an amount of mischief has been done which the profession does not take into account. Early in my practice there occurred a number of instances of patients saying that they had had irregularities corrected, and that since then they had suffered more or less pain and soreness about the teeth; conditions resembling those following fracture or sprain when the weather seems to bring about a neuralgic state. Very often the violence used for such correction has been sufficient to cause permanent inconvenience. Many of the cases, credited to the efficiency of the appliances used, would have been better if left to Nature. Dr. Cryer shows us that the development and growth of the jaws are not confined to any particular locality, but are general throughout, and that under peculiar circumstances we find certain centers of growth arrested, just as we see in hip-joint disease, and then permanent deformity results. The interesting question in connection with the case of the Baltimore child is, can we awaken that trophic influence? Some years ago the permanent cuspid teeth of a patient had failed to erupt, still the deciduous cuspid teeth were *in situ* to work on. Irritation of the teeth until they evinced considerable pain and soreness failed. Ligatures tied around them, hoping thereby to revive or reawaken this

trophic force, failed. Extraction of one deciduous canine failed. So far there is but little, if any, hope of ever stimulating these trophic centers. The case mentioned is of interest, as the lad had spasms, caused seemingly by the canine pressure on filaments of nerve in the jaw. The spasms came only occasionally, it is true, but so growth has remissions of energy. I believed that we could do nothing better than to look forward to the time when the growth and alterations of the permanent canine teeth would cease, somewhere about his twelfth year. For about forty years, although still living, the patient has been free from spasms. That the reawakening of the trophic force could have been brought about in his case I very much doubt.

DR. BOGUE—In a case of a child 12 years of age, in whom the left central incisor had not developed, instead of tapping on that bicuspids tooth, as did Dr. Stellwagen, I put in wedges and spread the right central and left lateral widely apart, and inserted a large central on a rubber plate. The left central came down, even at that age, into correct position. I have done the same thing in the last six months. In other words, I got the room which Dr. Cryer has been telling us we ought to get. The plaster cast of impaction shown us by Dr. Cryer shows also a retracted condition of the incisors, and I think he is mistaken as to the cause. It seems presumptuous for me to question Dr. Cryer, but he must not draw conclusions from the facts he presents to us, unless he expects to be criticised. The irregularities of the incisors in that case seem to me to have nothing to do with the other irregularities which he showed us.

DR. STELLWAGEN—There was abundant room for the cuspid to come down, the teeth were separated and had enough space.

DR. EUGENE S. TALBOT, Chicago—Dr. Cryer's specimens are fine and show many pathologic conditions. The explanation of an individual case does not, however, give accurate information as to the etiology. To understand the etiology, the evolution of man, including heredity and neurasthenia in the parent as well as in the child, must be considered to show the production of these conditions. If there were time, I should like to go over these slides and from these basic principles show how these deformities are produced. Starting with the evolution of man, the face and jaws, like the vermiform appendix, small rib, little toe and other structures of the body are degenerating under the law of economy of growth for the benefit of the organism as a whole. At about four and one-half months of fetal life, the first period of stress occurs. At this period owing to the neurasthenia of the parents and improper nourishment, arrests take place. Owing to the transitory nature of the face and jaws, they are more easily affected than permanent structures of the body. Arrests of development of some parts and excess of development of others (due to an unstable nervous system) account for all malformations. The point brought out by Dr. Stellwagen in regard to pain in the alveolar process is not uncommon. It occurs after teeth have been regulated and the question naturally arises when and how far we are warranted in the correction of irregularities, owing to the interstitial gingivitis produced. This pain occurs in ordinary forms of interstitial gingivitis, as well as in interstitial gingivitis due to injury. This disease is associated with the alveolar process throughout life. Pain may be experienced at any period. The cribbing of the horse when returned to the stall after a summer's outing and disuse of the anterior teeth is a marked illustration of this pain. The eruption of the cuspid tooth seems to be a providential process by which the anterior and posterior teeth are, in a measure, moved forward or backward for the purpose of enlarging the dental arch.

DR. CRYER—In regard to the use of the term "pre-molar," I perhaps should not use this word before a dental society, as I believe they have arbitrarily adopted another term, which, however, I can not accept in my writing. A pre-molar is a tooth anterior—in time or position—to a molar tooth. Dr. Bogue says we have not a deciduous pre-molar. In one sense, all the deciduous teeth are premolars, but the term is more especially and more properly applied to what are commonly called, by the dental profession, the deciduous molars. If I understand the meaning of deciduous, it means not lasting but destined to be lost or shed in time. The deciduous (pre-molars) molars are shed and

their places taken by the permanent premolars, or as they are known in accepted dental nomenclature, the bicuspid. The lower jaw certainly grows forward. The upper jaw I claim does not grow forward, but its alveolar process does. It extends forward, and its base is the upper jaw. The upper jaw is one thing; the alveolar process and its teeth are distinctly another. When teeth are lost, and the alveolar processes are resorbed, the rim of the lower jaw, which has gone forward, remains there, while the upper jaw, not having gone forward, is found to be almost the same as in early life. I want to put it on record that four years ago the city authorities of the Philadelphia Hospital recognized the dental profession by adding four doctors of dental surgery to the medical staff of that great hospital, giving them the same standing as the medical men. Last year, at the suggestion of the dental staff, an extensive apparatus for *x*-ray work was added to the already well-supplied hospital, and the dental department was put in the highest possible condition for usefulness. Dr. Kassabian has spared neither time nor energy in working up the use of the *x*-ray for the benefit of the dental students who have attended the dental clinics given at the hospital.

MULTIPLE ABSCESES OF THE OMENTUM.

REPORT OF TWO CASES.*

HUGO O. PANTZER, M.D.

INDIANAPOLIS.

Under the title of "Das Netz als Schutzorgan," E. de Renzi and G. Boeri¹ of the first medical clinic of the University of Naples, publish the results of experimental researches. Like von Recklinghausen, Bizzozzero and others, they have demonstrated a striking similarity in contrasting the function of the omentum with the lymph system, in its activity in the absorption of substances from the peritoneal cavity.

The attraction of the omentum to the site of injury, foreign body or inflammation, in its endeavor to protect the abdominal cavity, is well known. Experimentally, by these men, it is shown that in young animals, after the removal of the omentum, there is retardation in general development, and in adults their susceptibility to abdominal infection is markedly increased after the removal of the omentum. After the circulation in certain viscera, notably the spleen, has been impaired by the ligation of the afferent or efferent vessels, the omentum is shown to envelope, partially at least, that organ, and by anastomosis of vessels, to successfully aid the circulation through the impaired viscus. Its tendency to form collateral circulation with the viscus or parietes to which it so attaches itself, has led surgeons to utilize this function for the establishing of compensatory circulation, as in the operation for the relief of cirrhosis of the liver.

These experiments have further shown that if both afferent and efferent vessels of the spleen be ligated, that organ becomes necrotic; but soon the omentum forms a dense network over it, a veritable capsule, and in time the splenic substance undergoes a complete absorption. Nor does the animal suffer from its lack of spleen, but enjoys its usual health, thus showing a substitutional function in lieu of the lost spleen in its hemolytic capacity.

If, however, the omentum is removed and the afferent and efferent vessels are ligated, the animal soon dies, the death being due to rapid autodigestion or fermentative

changes in the splenic tissues and the absorption of the same. The protective action on the part of the omentum, however, walls off promptly the spleen, and, supplying it with a circulation, prevents autodigestion; while affording a dense capsule, allows of such slow absorption that the body is able to form autolytic or zymostatic substances whereby to protect itself. A similar function of the omentum was observed when the vessels of one kidney were ligated; this was followed by absorption of the kidney by the omentum, which had formed a dense capsule about it.

Foreign bodies introduced into the peritoneal cavity were promptly walled off by the omentum. Clinically, this plastic power of the omentum is shown when that organ is applied to the resected surface of the liver, against a wound of the pancreas, or against any intra-abdominal injured surface.

The sparsity of literature of the omentum is remarkable, and on this account the above abstract is supplied here. The following cases are reported as showing a pathologic condition of the omentum nowhere encountered in literature. The cases, to me, seem to indicate a protective power of the omentum exceeding its ordinary well-established function. Commonly, septic matters and bacteria, brought in contact with the omentum, undergo their hemolytic destruction within the omentum without leaving any anatomic trace of their visitation on the tissues of the omentum. In the cases about to be reported this function is varied from. The *materia morbi* had passed the prohibitory portals of the omentum and had become implanted in the omentum at various points, and were there held in more or less inoffensive isolation or incarceration for a long period of time. Occasionally, incident probably to physical strain or debility, or the disturbance of an altered menstruation, the poisonous elements contained within these foci were liberated, and symptoms of grave systemic sepsis prevailed for the time.

Both cases occurred in individuals who had been celiotomized for simple, non-inflammatory conditions, and in each instance a general peritonitis had immediately followed the operation. Years had passed after this occurrence before the cases came to me. Meanwhile the patients had suffered more or less invalidism from abdominal tenderness and pain, and occasional outbreaks of constitutional sepsis, indicating gravity by the attendant fever and extreme systemic depression. Each individual, during the intermission between attacks, showed outwardly little or no evidence of disease.

The physical examination in neither instance had given characteristic evidence of unusual pathologic conditions before the operation. Characteristic of the condition found, were multiple abscesses strewn through the omentum. The abscesses were small, surrounded by a tissue which macroscopically resembled granulomatous or sarcomatous tissue. Around this there was the thickening of the part of the omentum in which the abscess was situated.

The great number of these abscesses in the first case precluded the removal of all of them. Portions of the greater omentum removed then, and others taken at the postmortem, two days later, were subjected to bacteriologic and microscopic examination. The former revealed the presence of streptococci in pure culture, and the tissue was granulomatous, such as would result from chronic irritation.

The second case was complicated with gallstones, and only these were removed at the operation. The appearance of the omental tumefactions, indicating numerous

1. Berliner klin. Wochn., No. 34, 1903.

suppurative foci, surrounded with granulomatous tissue and increased thickness of the fat immediately adjacent, reminded me too vividly of the gravity of the affection in the former case to encourage further efforts at this time, owing to the enfeebled condition of the patient. After satisfying myself that it really had these characteristics, whereby but least handling possible of the tissues was incurred, I decided not to attempt any more at this sitting. This patient, like the former, died within less than three days from grave sepsis. In neither case was there evidence of infection about the wound nor general peritonitis.

The first of these cases I operated on at my sanitarium in April, 1897; the last at the Deaconess' Hospital in March, 1903. These cases stand out in my experience without further parallel.

CASE 1.—Miss P., nurse, aged 33, presented herself first in February, 1897. She was operated on two years previously at Chicago by a noted abdominal surgeon for retroflexion of uterus, the uterus being ventrofixed. The operation was followed by general peritonitis. The fixation sutures were removed on the second day. Patient recovered slowly, but never fully regained her general health. The menstrual period was afterward attended with more or less chilling, pain and fever. Between periods, notably after physical exertion, there was more or less abdominal pain and tenderness. Patient attempted light nursing, but every now and then, on account of her physical suffering and weakness, was incapacitated. An operation was undertaken one year later for her relief by another surgeon. The patient related that this was witnessed by her sister. This effort was abandoned, even before the incision had reached the abdominal cavity. Why this was abandoned, she never heard, but thought it pertained to difficulty in the narcosis.

Examination.—Patient was a well-formed, muscular individual of excellent constitution, naturally healthful and cheerful. It seemed difficult, seeing her, to believe that she was really suffering seriously. She complained of much abdominal pain, weakness and lack of endurance. I found indefinite tumefaction in various parts of the abdomen. These were difficult of examination on account of rigidity of the abdominal wall. Vaginal and rectal touch revealed uterus in retroflexion, prolapsed and enlarged ovaries, tissues massed together by adhesions.

Diagnosis.—Chronic peritonitis, with suppurating foci.

During a few weeks of local and general tonic treatment, the patient gained a little in strength, and pelvic swelling became smaller and less tender. The next menstrual period, however, was accompanied with chill and fever, yellow skin, depression and great weakness. This condition indicated to me that my treatment was little more than temporizing, and that more radical measures must be looked to for relief.

The patient, a very intelligent woman, expressed her conviction that she was gravely ill and must have something done, lest she die.

Operation.—The operation revealed the condition of the omentum already described, that part nearest the pelvis being most heavily involved with these suppurating foci. This part was removed. The uterus and ovaries were released from their adhesions, the latter removed and the uterus fixed by ventral suspension. These organs seemed not involved in the suppurative disease.

The patient early developed sepsis as before, but of a graver type. The temperature ran up to 103 and 104; the pulse was rapid and weak from the beginning, and grumous vomiting preceded death, which occurred after a little less than three days. The tissues were subjected to microscopic and bacteriological examination, with the results as stated.

CASE 2.—Referred by Dr. Crose. Mrs. M., aged 37.

History.—Was operated on for an ovarian cystoma by a local surgeon about eight years previously. Both ovaries were removed on this occasion. There had been no inflammatory dis-

ease of the pelvis before, but the operation was followed by general peritonitis, which very nearly took the patient's life. The recovery lasted three months, and ever afterward she suffered much abdominal pain and distension and inability to endure strain. Strain was followed with fever and great general debility. Gradually, however, she gained, and for a time promised full recovery. About four years ago she began to suffer attacks of acute pain, referred to the stomach. They were associated with indigestion, and, in turn, she had consulted numerous physicians and been treated for months at a time at various renowned sanatoria. She had obtained little and only temporary relief, if any, at these places. Latterly the attacks recurred at shorter intervals, were more severe and lasting, and were very weakening. Dr. Crose saw her a week before I was called, when he prescribed to relieve her pain, but made no thorough examination. He was recalled the day before he called me to see the case with him. This time he found the patient jaundiced, vomiting; the liver enlarged and very painful; a tumefaction in the right hypochondriac region. The stools were various, bilious and acholic. Temperature, 100 to 103.5; pulse, 120 to 140.

Examination.—I found a woman of fair nutrition, rather septic in appearance, yellowish skin, vomiting mucus or mucobiliary matter; of heavy mind; limbs drawn up; abdomen very tense, especially over right half; liver dullness increased upward and downward, and continuous down from it to very near Poupart's ligament, a heavy, doughy swelling completely filling that side of the abdomen in an anteroposterior direction, and of a hand's width or more.

Diagnosis.—A diagnosis of gallstones with cholelymphangitis was made. The swelling in the right side below was not determined, but it seemed to stand associated with the same process. An unusual location and degree of distension of the gall bladder was considered.

Treatment.—Ice bag over the liver, sodium salicylate and salt solution by rectum and other rectal feeding were resorted to for a few days, with some symptomatic relief, before operating. As in the other case, the patient herself was impressed by the serious nature of her disease, and anxiously desired relief.

Operation.—The operation revealed the swelling below to be composed of almost the entire omentum. This was drawn to the right and lay there rolled on itself, thickened greatly, adherent to the ascending colon and small intestines. At many points it was studded with suppurative foci, so much resembling those seen in the former case as to suggest the same condition. The gall bladder was found considerably distended with fluid and gallstones. From the history of the case it seemed probable that the patient's recent suffering was caused more directly by gallstones. I therefore decided to attempt no more at this time than to remove the gallstones and establish a bilinary fistula. Upward of 400 stones were removed from the gall bladder and common duct, the stones varying from the size of a millet seed to that of a filbert, there being only a few large stones in the lot. This was accomplished without opening the common duct, stripping it being found efficacious. The cholecytic contents were nonpurulent, the walls not more than hypertrophied and congested. No bile was spilt into the abdominal cavity. The omental tumefaction, beyond a slight effort to disentangle it, and to satisfactorily examine into the nature of the nodular swellings found through its substance, was not dealt with. The patient rallied from the narcosis and operation without shock. There was good drainage from the fistula, and there was bilinary discharge through the bowel within 24 hours. There was no abdominal distension and little vomiting, and the patient declared herself much relieved and was very hopeful. After the first 24 hours there developed evidence of a grave sepsis, involving temperature, rapid heart's action and breathing. Local conditions appeared entirely negative. The wound remained throughout without swelling or tenderness, the abdomen without distension, or even pain, excepting tenderness over the tumefaction in the lower right side. There was little vomiting until the last, death ending the scene about the third day.

Autopsy was not permitted.

From my consideration of the first case, I think that I can exclude sarcoma. The presence of pus in each nodule, the long existence of the disease without metastases, the recurrent attacks of septicemia, and the beginning with a febrile peritonitis, all speak for an inflammatory infection. Then there was the finding of streptococci in pure culture.

The second case was complicated with gallstones, and this may be assumed to cloud its diagnostic reading. Besides, none of the nodules were subjected to a bacteriologic or microscopic examination. The history and the gross appearance were strikingly similar to those of the first case. I think I may exclude an accidental infection at the time of the second operation to account for the fatal septicemia.

I have never seen the omentum display a similar appearance in cases where grave sepsis prevailed. In my experience, abscess of the omentum is confined to these cases. The morbus materie taken up by the lymph channels of the omentum are generally destroyed and disappear without evidence of implantation within its tissue. Thus, a part of omentum lying contiguous to an infected region will become adherent to it, but if stripped off will show no gross evidence of inflammatory activity within itself. The dissemination of purulent foci, as in the cases mentioned, surrounded by the products of inflammatory reaction, and persisting, as in these cases, for years. I have been unable to find reported anywhere.

THE PROPRIETY, INDICATIONS AND METHODS FOR THE TERMINATION OF PREGNANCY.*

FRANK A. HIGGINS, M.D.
BOSTON.

It is apparent that there is a strong tendency generally in the medical profession toward a broadening of the indications for the termination of pregnancy. It seems that the wisdom of this can scarcely be questioned. While it may be said that this may open the way for the not overconscientious physician, by distortion of the symptoms and indications, to perform abortion in many unnecessary cases, it is believed that this will not be true to any large extent, as the great majority of physicians are undoubtedly honest in this respect as in other things, and are no more likely to go astray than formerly. Temptation and opportunity are always present for those who may wish to take advantage of it. That errors of judgment or of unintentional misunderstanding may occasionally arise there is no doubt.

I believe I am right in stating that it has always formerly been considered that the termination of pregnancy was indicated only in the presence of some acute condition which immediately and seriously threatened the life of the mother, such as pernicious vomiting, hemorrhage, convulsions or the toxemia of pregnancy. On the other hand, in diseases not of an immediately threatening nature, but which usually become dangerous at or near the end of pregnancy, such as certain forms of heart disease, chronic nephritis, diabetes and phthisis, abortion was not to be thought of as a prophylactic measure early in pregnancy, as a preventive to the progress of the diseased condition. But, if late in pregnancy the disease

should come to threaten the mother's life, then induction of labor was entirely justified. That is, if the woman became pregnant, she was held in a way to be directly responsible for that pregnancy, and nothing could be done immediately to prevent a probable dangerous condition in the future, or to stay the advance of a serious disease which pregnancy was almost sure to aggravate.

That there is a change in belief and also in practice is seen by consulting the older and the newer text-books on obstetrics. The former, as a rule, hold that induction of abortion is justifiable only when the patient is suffering from such grave disease that her life is in imminent peril, while the more recent works grant that the termination of pregnancy is entirely justified to prevent the advance of what might later prove to be a fatal disease.

Accordingly, then, we have under these somewhat changed conditions what may be known as the medical indications for abortion in early pregnancy. These are seen chiefly in the presence of a certain few chronic diseases which usually become seriously aggravated by the occurrence of pregnancy.

TUBERCULOSIS.

Tuberculosis is, perhaps, the most common of these conditions. I believe it was formerly held that tuberculosis was kept in a quiescent state during pregnancy, or even that pregnancy exerted a favorable influence on tuberculosis. Contrary to this former belief we now know that pregnancy has a most unfavorable influence on the course of tuberculosis. In many patients even with incipient phthisis, the disease makes such rapid progress that by the end of pregnancy the patient is hopelessly overcome by it, and often scarcely able to outlast the labor. It is conceded that cases of early tuberculosis in which under proper surroundings and medical care a cure might easily be effected, when subjected to the extra strain of pregnancy, rapidly become in a condition beyond the reach of medical skill. If, in such a patient, the pregnancy is terminated early, the prognosis for complete recovery under suitable treatment is often good, and the patient may live to bear healthy children in later years. Otherwise the mother's life is kept in grave danger for the sake of the child, whose chances are not too favorable when born under these circumstances.

A case of this nature was seen by me in consultation recently. The patient was a young woman, married one year, apparently perfectly healthy at marriage. No trouble was noticed till about the time she became pregnant, when she was found to have early tuberculosis of the lungs. As pregnancy advanced, she ran down very fast. In the later weeks of pregnancy it was largely a question whether or not she would live till labor began. Her labor was easy, but after a short first stage she was delivered by forceps under light anesthesia. She survived the labor only about a week. Under an early induced abortion and suitable treatment, it seems that she might have recovered and lived to bear and nourish other children.

On the other hand, there is much less danger from pregnancy to the mother in the more chronic forms of tuberculosis. Many of these women bear several children before apparently any serious burden is added to their condition. A patient whom I have had under observation through four pregnancies is a notable example of this condition. Nine years ago she had an operation for tubercular empyema. She made a fair recovery, but has had a cough and expectation since. In this time she has had four children, the last after in-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

duced labor for serious symptoms at the seventh month. Her condition from year to year has not changed much until recently, as the first three pregnancies were endured without disturbance. There is little doubt that if she had not been subjected to the strain of these repeated pregnancies she would to-day be a comparatively well woman. She has repeatedly been advised not to become pregnant, but it is a case in which one would not feel justified in performing abortion to relieve her of the pregnancy because of absence of acute symptoms, and because the disease did not appear to be making notable progress. In fact, no serious symptoms were shown at any time until near the end of the last pregnancy, and labor was then promptly induced.

It has been considered that unless abortion was performed early in pregnancy in tuberculous subjects, that it was unwise to interfere, and often in the latter part of pregnancy it has seemed as if nothing were to be gained by the induction of premature labor. Yet in experimental work in pregnant animals inoculated with tuberculosis, when early abortion occurred, the mothers survived longer than when the pregnancy was advanced or went to full term.¹ Moreover, my experience with the patient mentioned above would seem to controvert the idea that in such a case nothing is to be gained by inducing premature labor, because of the feeling that the mother's condition anyway is hopeless. This premature infant, now nine months old, is in good condition, and the mother, who has gone from the city to live in Sharon, is gaining fast, and bids fair to obtain a new lease of life. At the seventh month, when labor was induced, it seemed that she would not survive till full term if pregnancy were allowed to continue.

Pregnancy in certain women with a bad family history may almost be regarded as a predisposing cause of tuberculosis, and some statistics seem to show that a number of cases of tuberculosis develop largely as a result of pregnancy. While we might consider it impossible to terminate pregnancy in a person with merely a marked predisposition to tuberculosis, yet undoubtedly it would be perfectly proper in such a case to strongly advise such a woman not to subject herself to the risks of pregnancy.

HEART DISEASE.

Heart disease is a condition which often may not require the interruption of pregnancy, although in its presence the patient should always have the most careful oversight. Many women with heart disease go through pregnancy without any discomfort whatsoever. The appearance of any signs of cardiac disturbance early in pregnancy, I believe, is an indication for early interference with the pregnancy, because with the increased size of the uterus there is certain to be increase of the cardiac disturbance, and the mistake of waiting too long is easily made. Because under rest in bed and tonics, the patient for a while seems to be doing well and gaining, it is no indication that she will be able to continue through the pregnancy, since rapid changes may occur later, and then interference is likely to end in the death of the patient.

NEPHRITIS.

Chronic nephritis is usually an indication for the early interruption of pregnancy; not that a consider-

able number of cases would not survive the pregnancy, as the danger of the onset of eclampsia is small, but the kidneys are left in a very bad state after delivery. It has been shown that about 33 per cent. of women with chronic nephritis who go through pregnancy and who survive labor die not long after, while the fetal mortality in patients delivered at term is high, and has been estimated to be about 60 per cent.²

Bové has recently called attention to the fact that pregnancy is dangerous to women after removal of one kidney, and even although the remaining kidney is sound, he advises prevention of conception, or, in case conception occurs, the induction of abortion.

In the acute nephritis of pregnancy, or in the so-called toxemia of pregnancy, emptying the uterus may not always be the first indication, even in the presence of convulsions. If, under thorough treatment, the symptoms do not relax, but the condition grows progressively worse, then there is usually no question as to the treatment. A discussion of this, however, would bring up the treatment of eclampsia, which I do not wish to do now.

OTHER CONDITIONS.

There are a number of other chronic maternal diseases, such as grave anemia, diabetes, chorea, etc., none of which are very common in connection with pregnancy, but all of which may become serious, and in the presence of the severer forms of which termination of pregnancy is usually indicated.

Another maternal condition which, although not recognized as a separate disease itself, presents all the difficulties in treatment of serious disease, is the pernicious vomiting of pregnancy. There is little new that can be said in regard to its cause or treatment, although I believe it should be classed among the toxemias of pregnancy. Many cases yield only when the uterus is emptied. When the vomiting is continuous, regardless of the ingestion of food or liquid, and when absolutely at rest in bed, the patient rapidly becomes weak and exhausted, rectal feeding suffices for only a short time, and the indications for terminating the pregnancy rapidly become prominent. All writers insist that the operation must not be postponed too long, and I would simply repeat the same. While most cases do well and recover quickly after delivery, yet not all do, and I have recently seen two fatal cases. The first was undoubtedly fatal from the start, as she was in very poor condition. She was under the care of a most careful practitioner, and the operation was quickly done under very light anesthesia. The second case proved fatal because of delay owing largely to the religious question.

Acute diseases arising early in pregnancy are not usually an indication for emptying the uterus, but in the presence of most of the acute infectious diseases when severe and accompanied by high temperature, fetal death and abortion are apt to occur. Late in pregnancy, it is usually conceded better not to bring on labor, especially by rapid dilatation and delivery, as labor often tends to aggravate the symptoms. If labor intervenes, however, it is usually well to hasten its termination in a moderate way.

In acute conditions when there is threatening the loss of any of the special senses, such as the eyesight in Bright's disease, or the mind in melancholia or other nervous affections, there should be no question of the propriety of terminating the pregnancy.

The foregoing comprise the chief medical conditions

1. British Med. Journal, Dec. 12, 1903, *epit.*, p. 92; Borsl, 11 *Collectn.*, Oct., p. 303.

2. Hofmeister: Monats. für Geburts- und Gynäkol., Oct., 1902.

for which the induction of abortion is apt to be indicated. In addition there are certain surgical conditions which it is only necessary to mention in this connection. Pregnancy with tumors in the pelvis, cicatrices and tumors in the vagina, and incarceration of the retroverted pregnant uterus, are now better treated by other methods than by the induction of abortion. Early pregnancy with cancer of the cervix is probably best treated by a prompt operation for removal of the whole uterus.

The method of procedure in pregnancy, complicated by contracted or deformed pelvis, is not nearly so difficult a problem as formerly. It would be an extremely rare instance in which one would now be justified in emptying the uterus early in pregnancy because of any degree of shortening of the pelvic diameters, and then only in the presence of some positive contraindication to the cesarean operation at term.

On the other hand, I believe that the mother does have a right to say for herself whether she prefers to have cesarean section performed at term, or to have labor induced at the seventh or eighth month, although we know that the mortality of the premature fetus, even at the thirty-sixth week, and when surrounded by the most favorable conditions, has been very high, probably in the vicinity of 50 per cent.

Induction of labor is usually indicated in placenta previa as soon as the diagnosis is made, although in a favorable case one may be justified in waiting for a short time, when the fetus is approaching the viable period, and the patient can be carefully watched and kept at rest.

I am aware that occasionally in connection with this subject the religious question seriously confronts the physician, and he must always be careful to respect the belief of the patient and her family. The physician, however, can not let this influence him in considering his patient's condition. If the termination of the pregnancy is, in his opinion, necessary, then it becomes his duty to advise it. When the circumstances are such that the spiritual adviser forbids an operation, it is sometimes very difficult for the patient and her husband to decide the question, but in the presence of the severer forms of disease, the condition of the patient is so distressing that they rarely hesitate long.

The position of the Roman Catholic Church in this matter I regard as perfectly just and logical. We could scarcely expect a religious body which stands for morality to do any other thing than to forbid the taking of life, even when intrauterine and before the viable period. I believe that the strenuous position of the church in this matter, in many instances, may prevent the operation for criminal abortion, and in the long run I imagine it may preserve many more lives than are sacrificed to religious scruples. I also believe that the penalties are not too severe, when abortion is done for serious conditions, by a physician and against the advice of the clergy.

METHOD OF OPERATION.

The operation of emptying the uterus in the early months of pregnancy is not usually a difficult one nor severe for the patient, under proper conditions. It can be done quickly with the curette and under very light anesthesia, so that except in extreme cases there need be very little anxiety for the patient as a result of the operation. In the later months, induction of abortion or premature labor, if performed under proper aseptic precautions, is of itself practically without mortality to

the mother, and is not difficult of performance in most cases.

The most common method in use for the induction of premature labor is to insert a bougie into the uterus and keep it in place by vaginal packing. Its chief objections are that it is frequently slow in action, and also it is said to be not always certain. I have adopted this method in a considerable number of cases in which there was no reason for haste, and the result has always been accomplished. The longest time before labor started after introduction of the bougie has been four days. It is good practice at the end of twenty-four hours, if nothing has been accomplished, to withdraw the vaginal packing, carefully clean the vagina and insert a second bougie, and to repeat this again on each succeeding day till labor pains begin. The bougies should not be removed after the pains begin till labor is well under way, otherwise the pains may quiet down. The first bougie may be difficult to insert and may require a little ether to dilate the cervix and to separate the membranes which may be attached just about the internal os, but after these membranes are separated a little from below, I have never found any difficulty in inserting the bougie. Lately two bougies have been inserted at the start, and I believe that the two have proved more efficient in stimulating pains than one. I have never ruptured the membranes to induce labor, as I believe their preservation may be of importance.

The employment of the colpeurynter or of Voorhees' inelastic bag as a means of inducing labor is highly recommended, especially where the membranes are ruptured or where time is not important. The cone shape of the bag causes it to act as a cervical dilator much like the unruptured amniotic membranes. The chief objections to its use are that it is often difficult to properly insert, and there is danger of displacement of the presenting part resulting in prolapse of the cord. The cone-shaped inelastic bag is undoubtedly the best substitute for nature in suitable cases and it almost always acts as an efficient stimulator of pains.

The injection of fluids into the uterus as a means of inducing labor is not to be recommended as serious results have ensued even from the introduction of sterile water.

Other forms of induction of labor worthy of serious consideration are those by which the results are accomplished by forcible dilatation of the cervix either by the hand or by instruments. Deep cervical incisions after the method of Dührssen of Berlin find only a few advocates, and most conservative men hesitate to adopt the practice because of its very obvious dangers.

There are commonly three methods of manual dilatation of the cervix: First, when one hand is approximately brought into the shape of a cone and pushed as a wedge into the cervical canal. Second, by which one hand is used and one finger after another gradually introduced into the cervix, and separated. Third, the bimanual method, by which two fingers of each hand are introduced and then separated. In manual dilatation of the rigid os, the greatest difficulty is often encountered in forcing the cervix open, and only after repeated attempts by first one hand and then the other, and by all the known methods is one successful in accomplishing dilatation. But even after the closed fist can be inserted and pulled out through the os there is often great difficulty in the delivery. Manual dilatation in many cases can not be considered at all satisfactory, but until recently it has been the only possible thing in most cases in *accouchement forcé*.

Complete instrumental dilatation of the cervix for rapid delivery is rather a new proceeding, and is still *sub judice*, owing to the fact that there has never been until recently any instrument devised which could efficiently and thoroughly dilate the cervix up to the full dilatation.

Many men object to instrumental dilatation as a dangerous procedure because of the danger of deep cervical lacerations, but in many cases it is impossible to dilate the cervix by hand and not cause tears. Williams, who is not in favor of the instrumental dilatation, although he speaks guardedly, in a recent article reports two fatal cases of rupture of the uterus after manual dilatation in *accouchement forcé*,³ also seven other cases in which deep tears of the cervix required immediate operation for control of the hemorrhage. I am myself cognizant of several cases of rupture of the uterus which have occurred after manual dilatation.

Any contention over the use of methods or of instruments can be settled, I believe, in only one way, and that is by the results of the individual operator. If one finds that by adopting certain methods he obtains better results than by others, then that method is by all means the one for him to pursue. Other observers may get different results and naturally make their deductions accordingly. To the average man the operation which accomplishes the result in the easiest manner and with the least damage is the most satisfactory, and that operation, whether it be by hand or by instrument, is the one for him to adopt.

That there is a certain legitimate demand for a mechanical dilator of the cervix in pregnancy and in labor is, I believe, plainly evident. This demand is attested by the various instruments which have already been devised for this purpose, although no one of these, except the recent one of Bossi, has ever met with much approval outside of the hands of its inventor. The danger of tearing the tissues is, I believe, in many cases not as great with the metal dilators, if they are used properly and carefully, as it is with the hand attempting to force itself into the closed cervix.

I have found that the use of the instrument gives one the greatest feeling of security because of the comparative ease with which the work is accomplished directly under the eye of the operator, where the speed may be increased or diminished according to the readiness with which the cervix stretches. The unopened os can be fully dilated from twenty to thirty minutes, but with the instrument it is not so much a question of how fast the os may be dilated, but, on the contrary, it is altogether a question of how fast the cervix will admit of being stretched, and only so fast should the dilating arms be expanded.

DISCUSSION.

DR. C. LESTER HALL, Kansas City, Mo., said that the objection to the induction of premature labor is held not only by the Roman Catholic church but by us all. It is dangerous to discuss this question before the general profession, and it is particularly dangerous for the public to have the impression that labor can be induced prematurely without danger. As operators, we know it can be done, and we are prepared to do it in certain cases, but those who deal with women and their weak husbands know that there is a constant outcry, even among good people, for the bringing about of this very thing. Speaking from a moral standpoint, when a woman, because of a contracted pelvis, heart disease, or some other condition that may jeopardize her life, can not bear children, we should suggest methods for preventing impregnation rather

than to suggest remedies for getting rid of the fetus. That, too, is a moral question that confronts us and each must decide for himself. There is a feeling of sympathy on the part of the husband, and a great regard for his own comfort, that makes him agree to the induction of labor when his wife begins to vomit and suffer otherwise. Vomiting of pregnancy, while it is one of the most distressing things in the world, can be endured the longest. The correction of a displacement, the treatment of an erosion of the cervix, not carried to the extent of producing an abortion, but simply local applications, with rest and moral suasion, often will correct the trouble. The induction of labor should be a last resort. Dr. Hall said that if he were compelled to produce an abortion he would use Dr. Higgins' instrument in preference to the finger. We can never have our hands clean, and if there is any time when they should be clean, it is in an operation of this kind. Any method of producing dilatation quickly would be preferable to the finger, sound or bougie. We are glad to have an instrument of this kind at our command, but Dr. Hall is fearful of the ultimate results of this paper.

DR. C. S. BACON, Chicago, said that in considering the induction of labor in cases of chronic heart disease, nephritis and tuberculosis, we must consider not only the disease, but also the social condition of the patient. The patient may be in a condition that makes it impossible for her, under ordinary conditions, to carry the pregnancy to term without a spontaneous abortion, or without suffering seriously in health. If the woman can have the very best care, and can remain in bed during the latter part of her pregnancy, have a good nurse, etc., she may go through her pregnancy very well. Hence the circumstances of the patient is a point we must take into consideration. Vomiting of pregnancy is an indication for the induction of labor that must be handled with great care. The proper treatment of this condition is not understood nor generally followed. It is customary to neglect the first symptoms, or to make light of them. The patient is allowed to be around until she is in a very serious condition. Put her to bed, starve her for a time, eliminate in every possible way and usually she will get along very well. There can be no doubt that a clean obstetric operation is the proper method. Rupture of the membranes is indicated in one or two conditions, in hydramnion, or when there is much distension of the abdomen. The combined use of the bougie and bag is of value; the bougie first for a few hours to soften the cervix, and then the bag; and this should always be placed inside of the egg sac. Dr. Bacon has never been convinced that five or six or eight blades are better than four; he is not sure that four are better than two. It is a complicated mechanical problem which is still an open question. The efficiency of the Bossi dilator is still unsettled. The results so far have been bad. There are so many serious results and tears following the use of this instrument and its modifications, that it is extremely doubtful whether it ever can gain a place as a means of inducing labor or hurrying the termination of labor. One thing is true, the rapid induction of labor is accomplished better by a vaginal cesarean section than by means of any such instrument.

DR. R. W. HOLMES, Chicago, said that the induction of abortion is largely an ethical and religious one, while the induction of premature labor is purely a matter to be decided on its scientific merits. The former is absolutely prohibited in the Catholic church, while the latter is permitted, as it is not done with the intention of directly injuring the child. Abortions are sometimes necessary for the preservation of maternal life; the conscientious physician must inform the family of the stand of their church, must inform them of the necessity of the procedure, must inform them of the true conditions and the serious consequences if the pregnancy should continue and let them decide the course to be pursued. If the decision is contrary to his opinion he may easily and gracefully retire in favor of another practitioner. Dr. Holmes said that the surgical treatment is, in general, the best; dilate the os with Hegar's or Goodell's instruments, clean out the uterine contents with the finger or possibly a dull curette;

the final act of the procedure must be a re-examination of the uterus so that we may be sure the uterus is thoroughly emptied. Do not curette and then stop. A friend of his had an abortion; the fetus was expelled, he curetted, packed the uterus, and the next day removed the tampon. A few hours thereafter something was expelled which proved to be a fetus—she had twins. This error never would have happened if he had re-examined the uterus. Such incompleteness in cleaning out an abortion is of frequent occurrence where re-examination is not made. One surgeon curetted many uteri previous to doing hysterectomies to ascertain how effectively it was possible to remove the endometrium. On opening the uteri he found that islands of varying size of uterine mucous membrane had been left, illustrating that the uterine lining can not be completely removed with the curette; in fact, if the uterus is scraped as we are instructed to do by books we never would have an endometrium again—these islands represent Thiersch grafts of endometrium. The Higgins dilator is more simple than the Bossi, but is equally as dangerous. The tips are too sharp, so that there is danger of injuring the uterus. The tips should be blunt, or better, have rubber tubing slipped over them. It does not make any difference whether labors are spontaneous or accelerated by the various methods of dilatation, there will invariably be cervical tears—the more rapidly dilatation is accomplished, the more certainly are these tears going to be serious.

Dr. F. A. HIGGINS said that he endeavored not to advocate any radical measures, but the subject has gradually been developing, and although no paper, so far as he is aware, has been written covering the whole subject, some of the more recent books have taken it up to a certain extent. The suggestion that it is better to instruct patients how to prevent conception, than to end a pregnancy, might be true in certain cases, but it would not always be possible to do this. Moreover, he feels that this would not be as safe a proceeding in the long run, and he knows of no way to absolutely prevent conception, except by operative measures, which we are rarely justified in resorting to. If the instrument is used with ordinary care bad results will be less frequent than with forced manual dilatation. Great damage is not infrequently done by so familiar an instrument as the obstetric forceps in unskillful or rough hands, but we can not discard the instrument itself. He said that the question is still *sub judice* but he believes that instrumental dilatation properly done under careful observation, is safer with a rigid primiparous cervix than is manual dilatation or incision. He advised against instrumental dilatation in placenta previa, because the cervix is usually too soft and friable and also because of the opportunity for free hemorrhage, which may be largely controlled by the hand in the vagina.

HYPNOTIC REMEDIES IN MENTAL DISEASE. THE INDICATIONS THEREFOR AND THE USE THEREOF.*

A. R. DIEFENDORF.

Lecturer on Psychiatry, Yale University Medical School.
MIDDLETOWN, CONN.

The paramount importance of insomnia as a symptom of mental disease always places the discussion of the indications for and the use of hypnotic remedies foremost in the therapeutics of psychiatry.

In discussing the subject I shall consider two phases of insomnia: 1, The insomnia characteristic of the early stages of mental disturbances, and, 2, the insomnia encountered after the psychosis has become well established. The two differ from each other and demand radically different methods of treatment.

The insomnia of the prodromal period is an almost

invariable symptom, varying in intensity from the simple mild form of sleeplessness to the most aggravating and intractable, demanding drastic procedure. It may exist for many months before the outbreak of the more acute symptoms. It has no marked distinguishing features, but is usually accompanied by some more or less definite head symptoms which tend to reveal its true character. The great importance of the early recognition of this insomnia, with its underlying diseased condition, offers an excuse for presenting the accompanying somatic and psychic symptoms somewhat in detail.

These symptoms may exist in the form of peculiar sensations or feelings in the head, such as are so common in neurasthenia, a feeling of weight at the occiput or over the vertex, or a feeling of constriction; or it may be a vague and indefinite "deep in" feeling, involving the whole head. Some complain of a feeling of numbness, others of fullness. Not infrequently these various sensations give rise to the idea that they are becoming insane. During this prodromal period one encounters not only the malaise that naturally succeeds disturbed sleep, but also a tendency to present a certain reserve, and solitariness, but more especially an irritable mood. The patients appear as if worried. Indeed, close questioning often discloses the fact that they are brooding over what they fear to be impending "loss of mind," whence originate suicidal thoughts and attempts in one whom you may believe to be suffering only from a simple insomnia.

This period of insomnia is very often aggravated by dreams of the most distressing character, the memory of which remains and haunts the patient for many days.

Other symptoms of considerable importance accompanying this insomnia are a gradually progressive loss of weight, and anorexia. Furthermore, inquiry into the sexual life often reveals definite disturbances in this field that can not be disregarded—such as reduced sexual excitability, giving rise to fear of impending impotency, or, on the other hand, greatly increased sexual desire.

The presence of some of these various symptoms facilitates the recognition of the real character of the insomnia, and indicates the great necessity of at once establishing suitable treatment. Undoubtedly many cases of mental disease could be permanently arrested by appropriate treatment at this time.

In discussing the treatment, one must admit at the outset that there is no specific remedy. The first indication is to remove exciting causes, whether they be somatic or psychical in character. This matter assumes greater importance in this type of insomnia, because of the presence of a defective constitutional basis in the majority of these cases which strongly predisposes to an easily disturbed mental equilibrium. For this reason I may, perhaps, be pardoned for offering such common suggestions as that gastric and cardiac disturbances, nasal or pharyngeal irritation, etc., should be corrected, and that altered constitutional states, such as lithemia, gout, anemia, habitual constipation and genito-urinary disorders should be given careful attention. Again, the altered mental and physical state of the individual peculiar to the critical periods of life, namely, pubescence and involution, should be carefully considered. Although they present less definite indications for treatment, yet it is often possible to alleviate some of the physical symptoms, and particularly in the youth, to establish a more healthy mental attitude and dispel foolish apprehensions by giving some sound advice.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Solis-Cohen and O. T. Osborne.

A very important matter is the removal of irritating and exciting factors in the environment and daily life of the individual. These may exist in fatiguing employment, a noisy neighborhood, needless worry over business, anxiety about illness and many other conditions that may accompany the vicissitudes of life. The irritating influence of such conditions is undoubtedly magnified by increased susceptibility on the part of the patient, also the outcome of the disease, yet it is possible to materially ameliorate the conditions by careful attention to the environment, and inability to improve these conditions may make it necessary to remove the patient to different and more restful surroundings.

It is a trite saying that in attempting to control insomnia, hypnotic drugs should be the last resort, after having exhausted all accessory remedial agencies. This maxim is a particularly valuable guide in treating the insomnia of insanity because of its chronic character and the necessity of prolonged administration of the hypnotic drug. The accessory remedial agencies referred to are probably well known to most of you, and include the warm bath, the wet sheet, massage, hot liquid nourishment, suitable exercise, etc. In employing any of the more gentle agencies, it should be borne in mind that to be most effective they must be applied at a time when the organism is tending toward sleep. So, one finds in patients who awake after a couple of hours' sleep to lie restless the remainder of the night, that the hot liquid nourishment is best not given until the patient awakes.

A simple measure of considerable importance, especially in asthenic individuals, is the maintenance of the body temperature by the minimum of heat production. This demands consideration of the room temperature and the external application of heat.

The ideal hypnotic drug, such as will promptly induce quiet, natural sleep, the extended use of which does not require increasing dosage or lead to an accumulative effect, and which is agreeable to taste and easily administered, is as yet undiscovered. It is not the fault of the manufacturing chemists who vie with each other in attempting to supply this demand. Most of these products, however, after an extended trial, fail to maintain a place among the valuable hypnotics.

The hypnotic best adapted to the insomnia of the prodromal period is one of the bromid salts, preferably potassium bromid, given alone or in combination with the sodium and ammonium salts. Their sedative effect on the sensory portions of the nerves of the cord and cerebral cortex and in relieving this so-called "pent up" or "tense feeling" renders them peculiarly valuable in this period of the disease, where there is increased irritability and nervous sleeplessness.

A combination of the bromids, especially the potassium and sodium bromid, 3 1/3 grs. each with 3 1/3 grs. chloral at a dose in the syrup of the bitter orange peel, is usually efficacious where the bromids alone fail.

Bromopin, the organic compound, which usually does not give rise to cutaneous eruption or gastric disturbance, is an excellent substitute for the bromids, given in doses of from 4 to 8 teaspoonfuls.

Trional is also valuable in this type of insomnia, always being preferable to sulfonal because its action and elimination is more rapid, and it is generally without cumulative effect. Its action on the mind fulfills the demands of the best hypnotics, producing difficulty of comprehension and reducing the impulses for movement. It is administered in hot solution (milk or

broth), dosage 10 to 25 grains on alternate nights and continuously for not more than two weeks. It should be observed that large doses, to which one so often resorts, sometimes are followed by gastric and intestinal disturbances, ataxia, tremor, depression, irritability and hemolysis.

Veronal and somnos, two new proprietary drugs, are useful in controlling this insomnia. Fuller mention of them is made later.

The insomnia of a well-established mental disease is usually less urgent in its demands for treatment. It is not so universally present as in the early stage, sometimes being absent altogether and again appearing only during exacerbations.

Nevertheless, next to the conditions of nutrition and excretion, it is the most important indication for treatment. The insomnia encountered here differs in the various psychoses because of its intimate association with and dependence on other fundamental symptoms of the psychosis; particularly pressure of activity, the presence of disturbing hallucinations and delusions and abnormal emotional states, especially fear. It seems best, therefore, to take up in order the more important psychoses and discuss the various hypnotic remedies adapted to each.

In delirium tremens, and to a less degree in alcoholic delusional insanity, forms of mental disease frequently encountered by general practitioners, the employment of hypnotic measures is very essential to successful treatment. The procurement of sleep is equally important to the maintenance of nutrition and the establishment of free excretion. The second is readily accomplished, as the patient usually takes nourishment greedily. The other two indications are best met by the use of the warm wet pack, 95 degrees lasting one hour, which produces a profound diaphoresis followed by quiet and sleep.

The patients sometimes submit to the prolonged warm bath (95 degrees to 98 degrees several hours in duration) where this measure fails.

If one must resort to the use of hypnotic drugs, chloral in combination with potassium and sodium bromid 3 1/3 grains each at a dose, repeated until sleep is secured, is by far the best, unless contraindicated by cardiac complications. The dose should not be repeated oftener than every hour up to 60 grains of chloral, and then not repeated for several hours. Where such complications as fatty heart, valvular insufficiency, athroma or myocarditis exist, paraldehyd, though less efficient than chloral, is the best substitute. The first dose should not be higher than 45 minims. It may be increased to 2 drams, and is given in ice water or whisky.

Next in efficiency to paraldehyd is chloralamid, which can be given with safety where cardiac and vascular symptoms exist. Its pleasant taste and prompt action with freedom from depression of cardiac and respiratory centers make it a valuable substitute for the two preceding drugs. It is best given in from 30 to 35 grain doses in a weak alcoholic solution. It must not be administered in alkalin or hot media. If all of these hypnotics fail one will usually succeed with a combination of a large dose of ammonium bromid with a moderate dose each of chloral and morphia. Prolonged deep sleep is not to be sought for, as this comes only with the general improvement.

There are several forms of insanity in which the insomnia is accompanied by and in great part due to a

great pressure of activity. This sort of psychomotor activity and its attendant insomnia is especially characteristic of manic-depressive insanity, but also occurs in dementia precox, particularly the catatonic form, and sometimes in dementia paralytica.

The hypnotic chosen here must subserve the function of a psychomotor sedative as well.

The only satisfactory remedy suitable for prolonged application is the prolonged warm bath—95 to 98 F. The patient remains in this for several hours until the desired effect is obtained, when he is returned to bed. The patient regularly alternates from the bed into the bath as needed, and can remain continuously in the bath without deleterious effects for many days.

Considerable difficulty may arise in keeping the patient in his first bath, and for this purpose a preliminary dose of hyoscin hydrobromate may be administered. But the patient once accustomed to the bath usually likes it.

Where the bath is inaccessible or for any reason inadvisable, and a hypnotic drug must be employed, the best is hyoscin hydrobromate. The chronic character of these psychoses makes it necessary that drugs be employed only to control insomnia and the pressure of activity at the height of the psychosis or when most needed during exacerbations. Idiosyncrasies for hyoscin are by no means infrequent, so that the first dose should be 1/250 to 1/200 of a grain, and it should be employed only with care in asthenic cases and where there is circulatory disturbance. The dose may be cautiously increased to 1/50 grain.

Scopolamin stands next to hyoscin hydrobromate, and by some is even believed to be more satisfactory, especially the product manufactured by Merck, which appears to be more uniform in its action and to give equally good results in somewhat smaller dosage, and, furthermore, is never followed by depressing effects. It is given in similar dosage as hyoscin. Where it seems necessary to repeat the dose of hyoscin or scopolamin more than twice daily, it is well to combine it with paraldehyd, which always gives very prompt and satisfactory results.

Cannabis indica is an old and standard remedy for this type of insomnia, but less reliable than hyoscin and scopolamin. It may be administered either alone 1/3 grain of the extract or in combination with the potassium bromid, 30 grains of the latter to 5 c.c. of the tincture. The lack of uniformity in the preparations of this drug is a distinct drawback to its use.

Trional and veronal are two drugs that are often employed, but the results are not satisfactory and their influence tends to wear off. Yet trional combined with paraldehyd sometimes promptly brings sleep and quiet where other drugs fail.

The type of insomnia which is accompanied by and in part due to distressing hallucinations and delusions is encountered most often in melancholia, in some cases of dementia precox, and occasionally in dementia paralytica.

The picture of profound despondency, attended by great mental anguish, lamentation and agitated restlessness with marked insomnia is well known and demands alleviation. The best therapeutic agent at our disposal for this purpose is the deodorized tincture of opium given in the smallest dose that will produce the desired effect, and it may be increased to from 20 to 25 minims two and three times daily. Morphin in doses of 1/32 grain repeated five times daily is highly recommended

by some and gives better results than when given in 1/16 grain doses three times daily. If good results, it appears within two weeks, otherwise the drug must be gradually withdrawn. It is contraindicated where an asthenic condition of the patient exists and where there is gastric disturbance or albuminuria.

It can be asserted without reservation that opium or its derivatives are not indicated in any other form of insanity unless the condition is aggravated by pain; and in melancholia, unless it does good, it is distinctly harmful.

The rest treatment should be insisted on in all cases of melancholia, and with its application a moderate degree of insomnia existing independently of prolonged agitation and mental suffering does not demand energetic treatment.

Should the insomnia become troublesome, then the simple hypnotic measures ought to be first employed, as hot liquid nourishment or warm sponge bath at the hour of retiring. If hypnotic drugs seem necessary, either trional, paraldehyd, chloralamid or veronal usually suffice.

The insomnia of the depressive phases of dementia precox and of manic-depressive insanity are best ameliorated by the use of the cold or warm pack. Where there is no success by these means, one may employ the combinations of chloral 3 1/3 grains with potassium and sodium bromid 3 1/3 grains each; paraldehyd alone, trional, veronal or somnos. The insomnia of the depressive phase of dementia paralytica is most difficult to control, and often does not yield to any remedy. Chloral with the bromids given in larger doses, paraldehyd alone and in combination with trional and veronal alone should be tried.

For the extreme insomnia of the exhaustion and infection psychoses, where there is great clouding of consciousness, delirious excitement and a tendency to an asthenic physical condition, alcohol is most valuable, given in large doses in the form of whisky and brandy. It is readily added to the liquid nourishment, as forced feeding by nasal or stomach tube is usually necessary in these cases. In employing alcohol in these psychoses, special attention must be paid to the tongue, skin, pulse and respiration; if the skin and tongue become moist and the pulse and respiration slower, while the delirium subsides, one is justified in continuing the treatment, but absence of improvement demands its immediate cessation. The chief indication here is not to control the insomnia, but to fortify nutrition, guard the heart and prevent self-injury. This observation may seem unnecessary to many, but the irrational abuse of sedative and hypnotic drugs in these acute psychoses is so often encountered, and occasionally leading to fatal results, that too much stress can not be laid on it.

Prolonged warm baths are usually successful in controlling the insomnia. In conjunction with them hyoscin or scopolamin in doses of from 1/200 to 1/150 grain can be used with good results. Trional, combined with paraldehyd, is adapted to these cases, but no hypnotic drug should be long continued.

In all of these conditions the insomnia tends to persist a long time, consequently it is impracticable to attempt to do more than reduce the degree of insomnia at the height of the psychosis and at the periods of exacerbation.

One of the most obstinate forms of insomnia with which the psychiatrist has to contend is that occurring in senile dementia. The sleeplessness is accompanied by more or less intense motor restlessness, which reaches its height at night.

The occasional success accomplished by employing the more simple hypnotic measures before resorting to drugs justifies one in giving them a trial. Of the hypnotic drugs paraldehyd and chloralamid are most efficient and best adapted to these cases, because they do not interfere with cardiac function and are not contraindicated by vascular and cardiac disease.

In the limited time allotted to this paper, it has been possible to cover only the common forms of mental disease in which insomnia is a prominent symptom. Before closing, something should be said of the new hypnotics which have been so widely advertised. During the past decade many new hypnotic drugs have been discovered and placed on the market, but most have failed to prove themselves of much value in controlling the insomnia of mental diseases. These are urethran, hedonal, hypnon, ural, tetronal, somnal, isopral, chloralose.

Two recent hypnotics, still unproved, however, merit some consideration, namely, somnos and veronal.

Somnos, a definite synthetic chemical known as chloroethanal alcoholate, it is claimed, is a reliable and uniformly active drug, given in doses of one-half to one ounce, producing a quiet, restful and natural sleep, without depressive effect on the heart, circulation or respiration, and unaccompanied by unpleasant after-effects. The few reports which, unfortunately, are mostly generalized, thus far published tend to confirm the many experiments of Dr. Colin Steward, at the University of Pennsylvania, on animals, and to establish the drug as a valuable hypnotic, but more extended experience is needed before its relative position among hypnotics can be fixed.

Veronal, which was discovered by Fischer and Mering in 1903, has rapidly acquired many clients among the best neurologists and psychiatrists in Europe, including Mendel, Kron, Wiener, Berent, Poly, Jolly, Lillienfeld and Oppenheimer. The claims are that it is relatively harmless and within a wide range in dosage is free from disturbing after-effects, is prompt in action (one-half to one hour), producing a quiet, dreamless sleep several hours in duration. It is given in small doses, 3 to 15 grains, and can be employed in chronic nephritis, suburemic conditions and uncompensated heart trouble. After a trial extending over one year (Van Heusen), it appears to show a slight advantage over trional. Like trional it sometimes tends to show a cumulative effect, and so should be alternated with other hypnotics.

DISCUSSION.

DR. CLEMENT B. LOW, Philadelphia—An old minister, an inmate of a home for supernannated ministers, complained of persistent insomnia, and talked and thought about it all the time. I asked him what remedy he found most effectual. He replied: "I keep a little sulphonal by the side of my bed, and when I can't sleep I wet one of my fingers and take up a little sulphonal and put it in my mouth and I go right to sleep." I mention this case because I think it one of auto-hypnotism, for I know that sulphonal is so insoluble in the gastric juice that it would take several hours before it could dissolve and produce its effect. Even then the quantity he took was too small to have any effect. His going to sleep after taking it was simply the effect on his mind. Knowing of its insolubility, I think it strange that so many physicians prescribe sulphonal in dry form, when they should have it dissolved in hot water. Patients wonder why they do not sleep at night after taking sulphonal powders, and why they are sleepy all the next day.

DR. WILLIAM J. ROBINSON, New York City—With regard to hypnotics in general, in my opinion there is no such thing, and

probably never will be such a thing, as an absolutely safe hypnotic. There can not be in the nature of things; sleep is too complicated a process. It is improbable that any one will ever discover a hypnotic agent that will be entirely free from deleterious effects. Has Dr. Diefendorf had any experience with apomorphin in alcoholism and delirium tremens and other convulsive diseases? Has he given any trial to strontium bromid, which seems to be more acceptable than some of the other bromids? He mentioned several proprietary remedies. Does he think that there are any remedies in the Pharmacopoeia which will take the place of those which he used?

DR. J. W. FOSS, Phoenix, Ariz.—I wish to emphasize the harmfulness which may result from the use of hypnotics. When a distinguished alienist, such as Dr. Edward Cowles of Waverly, Mass., says that one of the great causes of insanity is the abuse of hypnotics, it should be a warning to every physician, and it has been a warning to me when prescribing various hypnotics. It has led me to be very careful in prescribing this class of drugs, for fear of establishing a habit.

DR. W. A. WESTCOTT, Atlantic City—In connection with the preceding speaker's remark, I wish to say that the copying of the prescription on the box is largely responsible for the habit of self-medication. Unless the patient is in the hands of a trained nurse he will take the box and have it refilled whenever he wishes to, and thus learns the name of the drug that he is taking.

DR. W. F. WAUGH, Chicago—The condition of sleep is so dependent on the cerebral circulation that the use of agents which modify vascular pressure will bring on the condition of sleep. Much better than the use of hypnotics, which simply smother the consciousness in producing their effect, is the use of digitalin, or aconitin, according to the state of the blood tension; and these, when properly used, will bring on sleep in a way that will simply surprise those who have not yet availed themselves of these drugs in their practice for the purpose indicated.

DR. HEINRICH STERN, New York City—I wish to add a few words concerning the eventual deleterious effect of sulphonal, trional and tetronal on the organism. Hematoporphyria following the administration of sulphonal has been noticed in more than one hundred specified instances. As a matter of fact, there are only very few instances of hematoporphyria on record which had not been the result of medicaments belonging to the sulphonal group. The hematoporphyrin is very likely due to the anomalous and excessive disintegration of the hemoglobin which is brought about by the hypnotics of the sulphonal group.

DR. WILLIAM W. TOMPKINS, Charleston, W. Va.—Is it not a fact that in most of these cases we let the patients make their diagnoses for themselves? They come to us with their minds made up as to what is the matter with them, and often they also try to dictate the treatment. We begin usually with the bromids and similar remedies, but usually end up with morphia or the synthetics mentioned by Dr. Diefendorf. I was struck by the smallness of the doses he mentioned, the 1/32 of a grain of morphia and 3/2 grains of the bromids. In my own experience patients have taken these in much larger doses before coming to the physician. And in the treatment we have as much to do with breaking up the habit of taking drugs as we have with the treatment of insomnia. What is Dr. Diefendorf's experience in the use of digitalis and other coal-tar preparations than those he has mentioned?

DR. JOSEPH CLEMENTS, Nutley, N. J.—These are abnormal cases to begin with, and in the use of drugs we add their abnormal effects to those which we already have. Dr. Diefendorf called attention to the various means and methods of putting the patient in a normal condition before resorting to the use of drugs. In this way we obtain by simple methods the desired effect, and with the least amount of medication. For instance, if we can largely accomplish the purpose with the aid of a hot bath, only a small amount of any drug may be needed to continue the effect.

DR. O. T. OSBORNE, New Haven, Conn.—Very often in these troublesome insomnias, the tension of the blood vessels has a

great deal to do with it. Digitalis will relieve it if too low, and, if too high, as in arteriosclerosis, anything that will dilate the blood vessels will relieve it. That is the reason why a little alcohol is sometimes so efficient in old people in overcoming insomnia. Nitroglycerin in small doses will often do as well.

Dr. A. R. DIEFENDORF—The trend of the discussion indicates that insomnia is being regarded in a more rational and serious light. It really is a diseased condition which demands as careful study as any obscure nervous disorder. The unquestionable value of hygienic measures is attested by the fact that in some large insane hospitals not a single dose of any hypnotic drug has been given for many months. Relative to the small doses of bromids, I intended to convey the impression that they are efficacious only in connection with small doses of chloral, and as regards small doses of morphin, this drug is better given in dosage of 1/32 gr. five times daily than 1/16 gr. three times daily. What has been said by Dr. Osborne about the value of nitroglycerin in selected senile cases is borne out by my experience.

SOME ASPECTS OF THE NEWER PHYSIOLOGY OF THE GASTROINTESTINAL CANAL.*

LAFAYETTE B. MENDEL.

Professor of Physiological Chemistry in the Sheffield Scientific School of Yale University.

NEW HAVEN, CONN.

The relationship which exists between the functions of the digestive tract and that ensemble of biologic processes termed nutrition is both manifold and far-reaching. It may perhaps be regarded as one of the shortcomings of the strictly "cellular" physiology of the century just closed that it failed to point out the conditions of interdependence and co-operation noticeable between different physiologic tissues. The modern organo-physiology is again beginning to emphasize a large number of such connections which have too frequently been overlooked, especially in a practical way. The physician should recognize in the study of alimentation something more than the mere consideration of the solvent action which the digestive secretions can exert. Thus Bidder and Schmidt wrote over fifty years ago in their classic work, *Die Verdauungssäfte und der Stoffwechsel*: "Wir finden einen zweiten und wesentlichen Theil der Bedeutung der Verdauungssäfte darin, dass sie Träger und Vermittler des innerhalb der Grenzen des Organismus, und in gewissem Sinne unabhängig von neuer Zufuhr und dem entsprechender Ausgabe, stattfindenden Umsatzes der lebenden Materie des intermediären Stoffwechsels sind, und koennen nicht umhin, auf dieses Verhältniss ein um so groeßeres Gewicht zu legen, als wir durch dasselbe in den Stand gesetzt werden, nicht auf die Abschätzung des äusseren Umfanges jenes wichtigen Lebensvorganges uns zu beschränken, sondern zugleich, wenigstens theilweise, die einzelnen Glieder jenes Totaleffectes kennen zu lernen." It is eminently fitting, therefore, that the discussion of the perversions of metabolism should include some consideration of the recent contributions to our knowledge of the physiology of the gastrointestinal canal. My purpose is to present a number of the more important advances which the past few years have witnessed, and to point out, if possible, the lines of progress which they inaugurate.

INNERVATION AND MOVEMENTS OF THE ALIMENTARY CANAL.

We may properly begin this review with a consideration of the innervation and movements of the alimentary canal, to the explanation of which valuable experimental data have lately been contributed. In the case of the stomach movements it has been customary almost to the present time to look on the classic experiments made by Dr. Beaumont on Alexis St. Martin as generally applicable. You will recall that these involved the observation of the movements of a thermometer, the end of which was inserted through a gastric fistula. It appeared as if the contractions of the stomach wall tend to produce a movement of the gastric contents from the cardia along the greater curvature to the pylorus, and then back again along the lesser curvature. In this way a thorough mixing of the food with the gastric secretion was assumed to occur. Such a view of the mechanical changes taking place in the stomach has, however, been radically changed by recent observations, notably those made by Cannon on living animals by means of the fluoroscope and x-rays. It now appears probable that there is a marked difference between the effects of the mechanical activities of the pyloric and the cardiac portions of the stomach. In the latter there is no marked peristalsis, and the food, held in the tonic grasp of the gastric musculature, shows no sign of movement; on the other hand, in the pyloric portion a vigorous peristalsis assures a thorough mixing of the food and secretion. At intervals the sphincter of the pylorus relaxes and allows the semi-fluid contents to escape. According to the newer data, then, the motor functions of the stomach are almost entirely confined to the pyloric area, the fundus acting as reservoir and only gradually impelling its contents onward.

Several features of practical importance arise from the facts just presented. In the first place, the acid reaction of the gastric contents develops only slowly in the fundus reservoir in the absence of marked triturating movements. The progress of gastric digestion may thus be delayed; but at the same time the continuance of salivary digestion in the stomach is provided for. It is well known that acids markedly inhibit the amolytic action of saliva, the effective enzyme being promptly destroyed by a mere trace of free hydrochloric acid. Likewise the interval intervening before a reaction for free hydrochloric acid can be obtained in the stomach contents is known to be not inconsiderable, in some cases as much as three-quarters of an hour elapsing. Trials made by Cannon and Day on cats and dogs from one to one and a half hours after feeding showed that "the contents of the pyloric end were invariably strongly acid, but the internal mass in the cardiac end remained unchanged in its reaction. Inasmuch as salivary digestion may continue so long as free acid is absent, the conclusion was drawn that salivary digestion might proceed in the fundus for an hour and a half or longer without interference by the acid gastric juice." These observations have been confirmed in various ways. Later, when the contents of the fundus become more thoroughly mixed, proteolysis begins more vigorously.

The movements of the intestine have likewise formed a recent subject for discussion to which Bayliss and Starling and Cannon have contributed much. In place of the older notion of a progressive peristaltic wave by which the intestinal contents are forced along the tube we may substitute a somewhat different picture. True peristaltic waves pushing along the whole mass un-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Solls-Cohen and O. T. Osborne.

doubtedly occur. But these are usually combined, according to Cannon, with segmentation; that is, as the food is advancing constrictions separate it into portions which may subsequently unite or join with other fragments. The orderly progression of the bolus at any point is attended by an augmentation of contraction above and an inhibition of contraction below it. Bayliss and Starling find this two-fold response to be the characteristic response of the gut to local stimulation; indeed, such a "contrary" or "reciprocal" response is apparently involved in every motor function.

Physiologists have been slow to appreciate the importance of inhibition in biologic phenomena; the illustration which progressive movement in the intestine affords of this principle is sufficiently striking to deserve particular emphasis. Thus of two adjoining parts of the gut the lower is relaxed while the upper one contracts. Meltzer has taken occasion to point out some pathologic consequences of the failure of this co-ordinated functional arrangement. If, for example, vigorous peristalsis forces onward the alimentary contents while strong contractions at the lower portion of the canal prevent their progress, the phenomena designated as colic may arise. When similar pathologic disturbances arise in the stomach, namely, when the pyloric sphincter and the sphincter antrum pylori or antrum contract simultaneously, we have a type of gastric colic. Such effects may be induced by abnormal stimuli and heightened irritability of the stomach or nervous system. The inhibition factor is wanting in these cases, whereas it is over-emphasized when signs of emotion, such as fear, distress or rage, are accompanied by a total cessation of the movements of the alimentary canal.

With reference to the lower part of the gut Cannon has found that the usual movement of the transverse and ascending colon and cecum is an antiperistaltic. This, as he says, "gives new significance to the ileocecal valve: for the food, now in a closed sac, is thoroughly churned and mixed by the constrictions running toward the cecum, and again exposed to absorbing walls without any interference with the processes in the small intestine." As the material accumulates it is then carried forward by peristalsis. The ileocecal valve is thoroughly competent for food entering the colon from the ileum.

It remains for the future to afford a synthetic conception of the entire sequence of movements which propel the intestinal contents along their path. The epoch making researches of Pawlow have made a beginning in this direction in indicating that the reaction of the food masses is the determining stimulus for the reflexes which contract or inhibit the pyloric sphincter. The novelty in this view consists in the substitution of chemical for purely mechanical factors as the effective agents in these reflexes. Free acid in the stomach induces an opening of the pylorus. The contact of the acid contents with the duodenal surfaces in turn provokes a reflex by which the sphincter pylori is closed. Simultaneously a flow of bile and pancreatic juice gradually neutralizes the acid, and a fresh outflow of gastric contents is in turn allowed. The physiologic advantage in this complicated chemical reflex is manifest. The intestine is protected from an excess of food at any time, the intestinal ferments are allowed to continue their functions, and by means of this regulatory action the acid gastric digestion gradually gives way to the more alkaline intestinal processes. Cannon has lately shown that a remarkable difference exists between carbohydrate and proteid foods in the readiness with which their ingestion is followed by a passage of contents out of the

stomach. Both classes of food-stuffs provoke abundant secretion; with carbohydrates free acid develops immediately, hence the pylorus relaxes; the discharge of proteids is delayed so long as they combine with the acid and no free acid is present. Gastric proteolysis is thus facilitated by this automatic arrangement.

SECRETORY FUNCTIONS OF THE GLANDS.

Far greater progress than that already mentioned has attended the study of the secretory functions of the glands discharging into the alimentary canal. The results already gained have largely been due to the influence of the work of the St. Petersburg school and the new experimental methods introduced by Pawlow. They have pointed out with striking effect the complicated nature of the reflexes which call forth secretion. Purely mechanical or thermal stimuli can no longer be regarded as sufficient to provoke the flow of saliva or of gastric juice which attends the ingestion of food. It has been the merit of the newer physiology to emphasize the interaction of chemical and psychical factors to a degree never before appreciated. The trend of these studies is doubtless already familiar to most of you; less well known is the functional adaptation which has been found to exist between the character of the food and the resultant secretory product. A few examples will suffice to illustrate this. The flow of saliva or of gastric juice which follows the introduction of an insoluble substance like sand into the mouth or stomach of an animal is minimal and insignificant in comparison with the "psychical" secretion provoked by thought or sight or smell of food. Even more effective is the actual ingestion of true foodstuffs, and here in turn the quality of the secretion varies markedly with the composition of the food. Thus the activity of the enzymes of the pancreatic juice seems to be correlated in a marvelous way with the corresponding elements of the diet. A régime rich in fat calls forth a secretion containing a relative abundance of lipolytic (fat-splitting) enzyme; with a meat diet the proteolytic enzyme preponderates, and so forth. Furthermore, this regulative action can apparently be modified by the conditions of the diet. One is almost inclined to speak of a physiologic education of the digestive glands, and to conceive of them as being trained for fat, or proteid, or carbohydrate digestion powers by the presence of the corresponding compounds in the alimentary canal. Indeed, this conception has already been raised above the realm of mere fancy. I have repeatedly found the intestinal secretion of adult dogs free from lactase—the enzyme which splits up milk-sugar—whereas, it is uniformly present in the suckling puppy. Weinland has succeeded in inducing the formation of lactase in the pancreas of rabbits by feeding them on milk; and the very recent experiments of Bainbridge in Professor Starling's laboratory indicate, so far as they go, that extracts of the intestinal mucous membrane of milk-fed animals, injected into dogs not fed on milk, cause the pancreas to secrete lactase. We are only beginning to understand the rôle of such functional adaptations in the work of the digestive apparatus; but even now it is possible to foresee that research in this domain will yield a treasure of observations directly applicable to pathology and therapeutics as well as to physiology.

The effects of the disuse or misuse of a gland may become as clearly defined as are the analogous consequences in a muscle; the errors of one-sided diet, the possibility of the gradual functional development of digestive organs by appropriate dietetic measures, the importance of the psychologic element with its attending inhibitions

or stimulations—such are the problems which the modern experimental science hopes soon to present in a rational light. This occasion will not permit any detailed review of the facts already gained. One or two of the recent acquisitions deserve notice, however. The flow of gastric juice such as occurs in the so-called “psychical” secretion, independently of the contact of food with the stomach, has repeatedly been demonstrated; and it has likewise been shown in our laboratory that stimulation of the gastric glands may take place without any direct gastric irritation in consequence of the influence of alcohol absorbed from the intestine. These observations have been extended by Wallace and Jackson to indicate that the reaction in the latter case is a purely reflex one, and that it is not limited to alcohol, but is possessed by other irritant substances, such as oil of peppermint.

Starling has indicated the existence of a remarkable mechanism for the control of pancreatic secretion in vertebrates. It has long been known that the introduction of acids into the duodenum will provoke a flow of pancreatic juice, even after the exclusion of nervous impulses from without these organs and after inhibition of all local nervous elements (by atropin). According to Bayliss and Starling the chemical stimulation of the gland cells is due to the production (by the action of the acid) of a specific substance, secretin, from some precursor, prosecretin; the secretin enters the circulation and incites the gland to increased activity. That the active agent is not the hydrochloric acid itself is sufficiently shown by the fact that this alone does not provoke secretion when introduced directly into the blood current.

The pancreatic juice collected directly from a fistula in man or animals is practically without action on proteids. It has long been known that the proteolytic enzyme is stored up in the gland cells in the form of an inactive zymogen, trypsinogen, and is apparently secreted as such. To Schepowalnikow, a pupil of Pawlow, is due the distinction of having discovered a remarkable property of the intestinal juice in “activating” trypsinogen, i. e., converting into trypsin the zymogen of the pancreatic juice. This action is due to a peculiar enzyme, enterokinase; and the discovery of this “ferment of ferments” has led to the observation of the wide occurrence of enzymes capable of activating zymogens. Following the suggestion of Delezenne and others we may call them kinases. The presence of enterokinase in the intestinal juice of man has been demonstrated by Hamburger and Hekma, and this secretion is thereby given an importance which it has not heretofore been assumed to possess. To this may be added Cohnheim’s finding of erepsin, a peculiar proteolytic enzyme which splits the primary products of digestion (proteoses and peptones) into simpler nitrogenous compounds, although it fails to act directly on most of the proteids. If the activity of the sugar-splitting enzymes (sucrase, maltase, lactase) of the succus entericus is likewise considered, we need no longer continue to say that “in the work of digestion it plays at most a very subordinate part.”¹

We may appropriately pause for a moment to picture to ourselves a small part of the alimentary changes in the upper part of the canal in the light of the newer facts. The tightly closed pyloric valve retains the gastric contents until digestion in the stomach is well under

way, whereon the acid reaction developed is a sufficient stimulus to cause a reflex inhibition of the sphincter. Immediately on the discharge of the acid chyme into the upper duodenum a contrary closing reflex is inaugurated. Simultaneously the acid contents of the gut reacting on the mucous walls develop a chemical product, a secretory stimulant, secretin, which is absorbed into the blood and being carried to the gland is sufficient to incite the pancreatic flow. The resulting alkaline fluid in turn gradually neutralizes the intestinal contents; with the removal of the acid the secretory excitant is no longer produced, the flow subsides and the original conditions allowing a fresh portion of chyme to enter the duodenum again prevail. The acid chyme also exerts an influence on other glands involved in digestion. The flow of bile is increased and, according to Delezenne, the secretion of intestinal juice with its contained enterokinase is likewise facilitated by acid in the duodenum. Thus the proteolytically inert pancreatic juice is activated by the kinase so that it acts more energetically on the proteids of the food, apparently undergoing self-destruction at the same time, so that by the time the lower end of the gut is reached the intestinal contents contain very little trypsin.

Starling has suggested that “the excoriation and irritation of the lower part of the bowel and anus, which may occur in cases of diarrhea, may owe their production to the hurrying on of the active juice from the higher portions of the small intestine.” Incidentally the beneficial effects following the widely practiced administration of hydrochloric acid in a variety of digestive disturbances appear in a new light; and Enriques has already been encouraged to employ this simple therapeutic agent in diverse forms of intestinal dyspepsia in the belief that the contact of the acid with the duodenal cells is a potent stimulus for increased secretory activity. The pathologic erosions which have been observed in animals after inducing a flow of pancreatic juice into the empty gut by means of intravenous injections of secretin warn against any hasty therapeutic use of this substance, for it is possible that erosions produced by a reflux of the juice may lead to the production of gastric ulcer.

The secretory processes which accompany digestion are thus being analyzed into a series of nervous and chemical factors, many of them unique in physiology, interdependent, manifold, variable and correlated. The most important practical bearing of this recent work seems to me to lie in the appreciation of the co-operative working of many functions—in the conception of digestion as “an ordered march of events.” The mechanical theories of a few years ago have been replaced by a chemico-physiologic explanation of the secretory functions; and in dealing with a given pathologic condition in any part of the alimentary apparatus we must, as Starling has said, “not direct our attention to this part alone, but attempt to trace back the processes and to discover at what stage of the process, and how far back, the disturbing factor has entered.”

CHEMICAL PROCESSES IN THE ALIMENTARY CANAL.

We may now turn our attention to the more purely chemical processes which characterize the digestive changes within the alimentary canal. Cohnheim has recently remarked that the importance of the small intestine in digestion is at length receiving that recognition which its central and conspicuous anatomic position demands. From this it must not be inferred, however, that the chemical transformations occurring in the stomach are of minor significance; the newer contribu-

1. Attention may here be directed to the recent announcement by Kossel and Dakin of the occurrence in the intestine of an enzyme which they term arginase, and which has the remarkable property of converting arginin, a product of tryptic digestion, into urea and other simple compounds. (*Zeit. f. physiol. Chem.*, vol. xli, p. 321, 1904.)

tions have merely served to expand our knowledge of intestinal changes never before appreciated.

The possibility of a continuance of salivary digestion for some time in the less motile portions of the stomach—a feature pointed out by Cannon and Day—has already been referred to. It has long been claimed that a cleavage of fats with liberation of fatty acids may take place in the stomach. That this is the case has been made more likely by the observations of Volhard on the production of a lipolytic enzyme within that organ; the activity of the lipase seems to be inhibited readily by hydrochloric acid and pepsin. The problem of fat digestion and absorption has been the subject of no small literature, much of which is controversial in character. It seems safe to conclude from the data now available that the fats are in large part saponified in the intestine and that the resulting fatty acids are absorbed either as soaps or in solution in the bile which forms an excellent solvent for them at body temperature. The regeneration of these products into neutral fat before they enter the general circulation is equally certain. Fleig has very lately shown that soluble soaps in contact with the intestinal mucosa produce a compound, sapokrinin, which will excite secretory processes in the pancreas in much the same way as does secretin, thus giving one more illustration of the intimate connection between the digestion products and the act of secretion.

With reference to the important subject of proteolysis the possibility of a far more complete cleavage of the proteids than was formerly regarded as possible within the alimentary tract has been demonstrated. A number of simple nitrogenous compounds hitherto undiscovered in this connection have been isolated from the products of prolonged tryptic and peptic digestion in the laboratory. Trypsin and erepsin have been found to occasion a vigorous proteolysis under favorable conditions; and no little attention has been devoted to the action of the various autolytic tissue enzymes. But that such profound changes are actually taking place in the intestine during life is by no means certain. In other words, the experimental evidence at present available fails to convince one that the proteids of the food are as completely disintegrated before absorption as the beaker studies in the laboratory might indicate.

The researches of Zunz and of Reach on dogs have shown that proteoses arise in predominating quantities in the stomach and intestines after a meal rich in proteid. Peptones are found in the intestinal contents, if at all; and, like the simpler crystalline end-products, they are doubtless speedily removed by absorption as soon as formed. Unpublished experiments which Dr. Rockwood has carried out with me have made clear a marked difference in the readiness with which proteoses and peptones, in contrast with the proteid from which they arise, disappear from a thoroughly washed and ligated loop of small intestine in the living animal. The soluble "native" proteids are apparently by no means so speedily absorbed in the absence of suitable digestive enzymes as has been assumed by many clinicians in considering the utilization of nutrient enemata.

Despite these facts we have as yet no adequate conception of the actual process of proteid absorption from the alimentary tract. It has long been taught that the proteoses and peptones formed in digestion are regenerated to coagulable proteids during their passage through the intestinal wall. Glaessner has attempted to demonstrate such a possibility in the case of the stomach. His experiments are by no means convincing. Embden and Knoop have been unable to find any

actual synthesis of proteid in the intestinal mucosa, while Cohnheim, Kutscher and Seemann, and Loewi assume a complete cleavage of proteid substances within the intestines into non-proteid fragments. It remains, however, for the future to demonstrate the actual immediate fate of the digestion products, whether they leave the gut in the form of the relatively complex proteoses or simple compounds like leucin, tyrosin, etc. None of these proteid derivatives are normally and constantly found in the blood; and for the present we must necessarily continue to ascribe to the intestinal wall that prominent function in the assimilation of digested proteid which has so long been attributed to it. The mechanism involved still remains obscure. There is something attractive in the theory which assumes a complete breakdown of the food stuffs prior to their anabolism into living tissue or circulating blood constituents. It is not difficult to conceive how the organism can construct from these fragments the tissues peculiar to itself and accordingly maintain its chemical integrity although the ingesta may vary widely in composition—in other words, how foreign flesh and cereal and milk-proteids may all give rise to the same serum albumin or muscle globulin. To-day our actual knowledge of such changes has scarcely passed the limits of conjecture.

The question, "Why does not the stomach digest itself?" has long formed a theme for academic discussion. We are familiar with various answers, none of which is entirely satisfactory. A similar question arises with reference to the intestine and we are still face to face with an unsolved problem. For the pancreas the answer is perhaps to be found in the absence of any active trypsin in this organ, zymogen alone being assumed to be present. In the other cases it has been customary to cover our ignorance by attributing to the living cells, in distinction from dead protoplasm, an inexplicable power to resist digestion. We know that living intestinal parasites may remain intact and thrive in the alimentary canal of their host under conditions in which dead tissues of similar composition are speedily dissolved. Weinland has noted that the extracts of such parasites have the power of retarding peptic and tryptic digestions *in vitro* and has demonstrated the existence of antienzymes—antipepsin and antitrypsin—in them. Similar enzymes can be isolated from the gastric and intestinal mucosa. They are looked on as a product of the life of the mucosa cells and as the cause of the resistance of the alimentary tract to self digestion. The blood-serum likewise has a pronounced antitryptic power, and specific antienzymes are being claimed in rapid succession for numerous organs. The significance of such discoveries, as yet largely unverified and influenced by analogous phenomena in the study of immunity, remains to be seen. It may be that the antienzymes (or the lack of them) play an important rôle in such pathologic processes as the formation of gastric ulcer, etc.

There is a further peculiar and highly significant function of the gastric and intestinal mucosa which is little understood or recognized in any practical way. I refer to the property of eliminating substances from the circulation, i. e., of acting as a true excretory organ. Isolated observations on this function are widely scattered in the literature of physiology and medicine. Thus various organic poisons, including morphin and snake venoms, have long been known to be secreted into the stomach and other parts of the alimentary canal when they are introduced subcutaneously into the body; and the therapeutic possibilities involved in gastric lavage are already being applied with beneficial effects in such

cases as acute morphin intoxication. For the most part, however, we still adhere to the long-established custom of regarding the kidney as the only organ of importance involved in the elimination of either foreign or naturally occurring inorganic compounds from the body. In a paper recently published with Mr. Thacher I have tried to point out some of the errors into which this attitude has repeatedly led physiologists and have cited various older theories of the absorption of iron derivatives as a conspicuous illustration. The failure to recognize the intestinal epithelium as a factor concerned in the removal of iron from the system naturally allowed a false interpretation to be placed on the occurrence of this element in the feces. To the earlier observers, iron in the stools was a direct indication of lack of iron-absorption, particularly in view of the extremely scanty elimination of ferric salts usually noted in the urine during the same period. But the establishment of the fact that the gut may be directly concerned in the excretion as well as in the absorption of the iron compounds made possible a new interpretation of the earlier observations. Iron might now be present in the contents of the alimentary canal, either owing to the failure to be absorbed, or equally well because it had been discharged into this channel, through the epithelial walls. It became necessary to follow the paths of elimination when the introduction of this element directly into the alimentary canal was avoided. Since it has been found that iron may be introduced either subcutaneously or even directly into the blood-current, without producing any marked increase in the output in the urine, while the feces may contain noticeable quantities of it, the significance of the intestine with reference to the elimination of this element becomes apparent.

Observations like those reported from Professor Cushny's laboratory by Good, in which lithium was found to be excreted into the stomach and intestine in larger quantity than through the kidneys, indicate the desirability of more extensive investigation carried out with this point in mind. A long list of inorganic compounds which enter the intestine in noticeable quantity when they are introduced into the body in other ways than per os might be enumerated. Calcium and phosphorus compounds are conspicuous examples. For the most part we are uninstructed regarding the relative participation of the gut as an excretory organ under conditions like those which pertain in renal insufficiency; and the significance of such an excretory function in the local reactions and responses throughout the intestine is scarcely known. The production of serious gastroenteritis owing to the local excretion of substances is unquestioned; and this may be a potent factor in the action of toxins which produce intestinal symptoms.

Some interesting phenomena bearing on this topic have been described by J. B. MacCallum in the case of the saline purgatives. Investigations carried out in our laboratory along these lines have contributed to emphasize the importance of the gastrointestinal canal as a path of excretion for the salts of cesium and strontium—two elements selected for study mainly because they are foreign to the body and can readily be detected. Strontium salts, for example, were found to be eliminated to a relatively small extent only by the kidneys, even after direct introduction into the circulation. The excretion in the urine begins soon, and ceases usually within twenty-four hours. The larger portion of the strontium eliminated is found in the feces, whether the introduction of the element be per os, subcutaneously, intravenously or intraperitoneally. The place of excre-

tion is apparently restricted to the region of the alimentary tract beyond the stomach.

One further recent change of view deserves mention before concluding this résumé. It has been customary to regard the feces as composed primarily of indigestible and undigested food-residues. But increasing evidence is pointing to the fact that this is frequently, if not commonly, correct to a small extent only. It is true that coarser foods and substances rich in cellulose pass through the alimentary canal in considerable proportion without utilization. On an ordinary mixed diet, however, the foodstuffs are absorbed remarkably well, and the feces owe their origin in large measure to the waste and secretions of the alimentary tract itself. A diet may thus be feces-forming in proportion to the digestive work which it entails, as well because of its chemical and physical character; and feces thus resulting must be considered as real metabolic products in distinction from the food residues.

EDITOR'S NOTE: The paper of Dr. Mendel is one of a symposium, in which Drs. Sollmann, Futeher and Hutchinson also participated. Their papers and the discussion will follow later.

THE NEW OPHTHALMOLOGY AND ITS RELATION TO GENERAL MEDICINE, BIOLOGY AND SOCIOLOGY.*

GEORGE M. GOULD, M.D.
PHILADELPHIA.

The distinction between what may be called the old ophthalmology and the new is one of almost unique clearness, as compared with other departments of medicine or science. Especially in medical practice the modern status has usually grown out of the older and oldest by infinitesimal increments and gradual modifications. In ophthalmology it is not so, and this fact explains why there are such profound differences of opinion as regards the claims of the new. Although both are usually practiced by the same men, they may be, and often are, as distinct in origin, theory and practice as, e. g., are otology and ophthalmology.

The "old ophthalmology" was, and is, concerned with inflammatory and surgical diseases alone, remaining ignorant of and indifferent to such relations as might exist between the eye and the general system, except as regards those minor and few diseases which arise in the body and then affect the eye. Ocular inflammations, ocular operations, and the ocular results of systemic disease—these were the limits of its interests. Even in recent text-books on medical ophthalmology, there is no thought of any other relations of general medicine and ophthalmology than those morbid ocular ones originating outside. That the eye is the starting point of systemic disease was unsuspected. In the latest, greatest, best and most official text-book on medical practice, that of Allbutt, there is not a word from the first page to the last which hints at the ocular origin of any systemic disease, not even of headache. In the text-books of general medicine by continental authors, there is the same official ignoring of the claims of the new ophthalmology. In America also most of the text-books either ignore entirely, or, what is worse, list the remote causes of one or two systemic symptoms as possibly due to the eye, but so mechanically and inattentively as to turn the student aside

* Read before the Section on Ophthalmology, International Congress of Arts and Science, Universal Exposition, St. Louis, Sept. 24, 1904.

more effectively than the silence of the utter ignorers. The "praise" is very "faint," indeed, with which they condemn.

The new ophthalmology finds its objects of study and interest precisely in those systemic results of ocular conditions. I do not mean in such ways as the circulatory or metastatic transfer of inflammatory or infectious diseases from the eye to other organs, nor to the extension of localized inflammations to adjacent or even distant ones. That is another matter, and of it the old ophthalmology took sufficient cognizance. The field of study of the new ophthalmology is topographically well defined, its title clear, its methods, instruments of culture, the seed, and the crop itself, distinct, both genetically and evolutionally.

The abnormal conditions of the eye which set up morbid systemic results may, in strictness, scarcely be called abnormal, except by a strain put on the word. At least they are *per se* not morbid. They might better be called physiologically aberrant or variant. They do not originate in inflammatory or pathologic conditions, but simply in optical ones. But for us all physical optics leads to physiologic optics; primarily and fundamentally it pertains to the eye as an optical instrument, but as a living one, a physiologic camera obscura. If the photographer's camera had an elastic lens instead of a rigid one, and if its refractive power were spontaneously governed by the desire of the camera for an accurate focus of the picture, the analogy would be almost perfect. But the photographer's camera can neither direct itself nor renew its own sensitive plate, so that in spontaneous choice of scene, change of focus, and renewal of sensitive plate, the living camera is superior to the dead one. The natural difficulties of the choice of scene and of the resensitization of the plate have been beautifully overcome in the eye by the God of evolution, but other obstacles have not been overcome. The ocular camera, for instance, is double and stereoscopic, and accurately to superpose the images of both cameras is frequently impossible even after ages of workmanship. As all physiology leads to pathology, so, for physicians, all physiologic optics ends in pathologic optics. The twelve ocular muscles have a highly complex and skilled task; hence heterophoria and strabismus. Moreover, the spontaneously elastic lens grows inelastic in forty-five years, and presbyopia, at least before the days of spectacles, was a frightful tragedy. Lastly, the transparent lens could not, formerly, retain its transparency in old age, and the blindness from cataract at the end of life has not yet been entirely prevented.

The chief difficulties of the mechanic of the living camera were to secure to 1,500,000,000 human beings and to their successors in each generation, eyeballs which did not vary more than about 1/300 of an inch from a given diameter, and to make all corneas of the same radii of curvature in all meridians. These difficulties have been so great that there has probably never been such a mathematically perfect and optically exact pair of eyes in the world. Those chosen by natural selection, the elimination of the unfit and the mystery of heredity, to survive and to repeople the earth have been such as were not so widely variant as to disqualify their possessors for work and service; and the majority of their children, those now living in the world, have eyes so near accuracy in optical dimensions as to render their owners at least partly functional in the process of evolution.

This almost infinitesimal variant of 1/300 of an inch, the thickness of a sheet of paper, in eyeball measurements, may throw the unfortunate possessor out of the struggle for existence, so far as perpetuation of the race goes, at least in civilized life, and for some occupations, or it may render him a most pathetic sufferer. I say it may do so, not that it does do this invariably or generally. The simple law is that the greater the anisotropia the greater the certainty that it will do so, and the more limited the range and choice of occupations. The lower, not the positively lowest, errors of refraction, however, in civilization are they which in moral persons cause the greatest personal pain and suffering. The high errors brutalize, immorelize and exclude the owner from most occupations, the lower cause pain and illness.

Eyestrain is the unfortunate and inexpressive term that has come into use for the results that follow the attempt of the eyes, brain and correlated organs, to neutralize the defective function of the optically imperfect eyeballs and mechanisms. The optical defect is not morbid and has no relation to morbidity. It is at best pathogenic, secondarily or indirectly, not primarily. Its secondary effect—the straining of physiologic muscles and nerve centers—is not in itself pathologic, but it illustrates, and best illustrates, the great truth which text-books, teachers and medical science itself are sadly prone to forget, that abnormal physiology is the origin of most pathology. Unnatural action and overaction start the morbid function which finally leads the physiologic on the postmortem table. To ignore this truth is itself pathologic pathology; to scorn it is to add unscientific sin to the symptom-complex of the scientist's disease.

It should be noted that as eyestrain is itself simply functional, not organic, so its results are at least primarily the same. Headache, the paroxysmal neuroses, many nervous and psychic disorders, epilepsy, chorea, migraine, sickheadache, gastric, digestive, and pelvic disorders, influenza, anemia, denutrition, etc., when due to eyestrain, are at first and essentially purely functional. Even those more severe diseases, such as spinal curvature, appendicitis and pulmonary and renal diseases, which are sometimes directly and indirectly the results of eyestrain, are at first characterized by a peculiar stage of functional and remediable disorder, preceding the organic, inflammatory, and incurable one.

There are valuable lessons to be gleaned from the fact of the origin of eyestrain in optics, at once historic, physical and physiologic. There is the observation that medical science and pathology did not discover it. The science of physiologic and pathologic optics came to medicine almost entirely from without. It is the gift of students of physics. Even when physicians busied themselves with it they did so purely from their interest in vision and clear-seeing, not from that of pathology. Astronomers, physicists and opticians presented their gift to medicine. Even Donders had little or no thought of the extension of the practical science made by the practical American ophthalmologist. The earliest refractionist—we must use the word—more or less accidentally and incidentally discovered the facts of the relief of systemic diseases by their spectacles. The patients made the discovery that their headaches and nervous symptoms disappeared when they wore astigmatic lenses, and they came back and told the astonished and delighted oculist about it. Mitchell, not an

oculist, heard the story from Thomson, and he told the profession about a little of it. The profession would not listen and utterly ignored it. For several hundred years the official profession would not even have anything to do with the spectacles which the non-professional invented. It allowed Franklin to invent the bifocal lens, and failed to adopt it for a hundred years. There are to-day neurologists, diagnosticians and physicians of international renown who wholly deny that eyestrain causes reflex diseases of any kind. A special meeting of the New York Academy of Medicine was recently held in which great neurologists and ophthalmologists vied with each other in ridiculing the absurdity. It is no wonder, therefore, if the stone which the medical builders refused should become the cornerstone of the temple of the opticians. These gentlemen naturally think they have a right to practice the art and science of refraction. Those who scorn the new ophthalmology would, in fact, reduce the refractionist to an optician. It is a costly blunder which the profession will resent and must unlearn, because refraction is a medical art and science in the strictest sense of the term, one requiring the highest intellectual qualities. Hence their claim can never be allowed, and the profession must, therefore, now wage a hundred-year war, which it might have prevented, against an enemy which it might have made a friend and ally.

What are the relations of the new and the old ophthalmology? They are most intimate, sociologically and clinically. In a word, the scientific correction of ametropia prevents almost all inflammatory and surgical diseases of the eyes—I should say about nine-tenths of them. It will not, of course, prevent the few ocular results of systemic disease, such as albuminuric and diabetic retinitis, optic neuritis, toxic amblyopias, etc., but such things are uncommon, and not seldom the systemic trouble had its individual grounding in morbid ocular function. The far greater proportion of all ocular diseases are those of the extrinsic muscles; inflammations of the conjunctiva, cornea, and iris; glaucoma; high and increasing myopia, and cataract.

As to the external muscles, there is now an almost unanimous agreement that heterophoria is due to uncorrected or miscorrected refraction anomalies, and that the plunge made into tenotomies, graduate, undergraduate, or postgraduate, was into a blind alley of error and waste which has done irreparable harm to true ophthalmology by making the professional and lay world suspicious and even contemptuous. The heterophoric trouble is innervational in nature and refractive in origin.

As to strabismus, the same truth is at last becoming manifest and admitted. A recent English book, Browne and Stevenson, on the "Squint of Children," is a striking proof. Get glasses on the child early enough and there will be no squint. Even when the fatal delay has been negligently permitted, the operation does not do away with the necessity for the spectacles, and there are some of us "extremists" who contend that the operation is of little or no good even at the late date.

With the exception of relatively few cases, due to trauma, infections, malnutrition, etc., conjunctivitis and keratitis are of eyestrain origin. When one sees a few thousand cases of spontaneous recovery after the patients get proper glasses the truth needs no further mention.

As to iritis and glaucoma, did any skilled refractionist ever see the disease appear in eyes which for years

previously had been fitted with right correcting lenses? It may be that such cases occur, but observation shows that the eye which is morbidized by eyestrain has such low resisting power that only a slight inciting cause is needed to develop the otherwise powerless hint.

Concerning retinal and choroidal diseases, it is also a truism that they are usually caused by the ciliary strain of uncorrected ametropia. The "woolly," hyperemic and suffering retinas, the "pepper-and-salt," unhealthy macules, the abnormal pigmentations, noted ophthalmoscopically as the result of long-continued eyestrain, are suggestive and characteristic.

There is one refraction-anomaly, high or malignant myopia, which is the direct consequence of disease of the eyeball. Does anyone now doubt that this, the stretching or stretched eyeball, is the result of ametropia? If so, he should go to Germany to live. And why does the lens so often grow opaque in the old? Why, it would be better asked, does it grow opaque toward the end of presbyopic failure? The suggestion comes that it is at least partly because of the denutritive conditions set up by the severe strain of presbyopia added to that of pre-existing ametropia. This theory derives clinical support from the fact that cataract does not arise when the eye has been kept in an optically correct, healthy and physiologic condition for twenty years before the cataract-age.

And thus the good American motto, *e pluribus unum*, applies to ophthalmology as well as to statesmanship. In the many diseases of the eye, there is at last but one disease. There was plainly an overhasty recourse to surgery when the surgical disease could have been prevented. As has been well said, an ancient hunger for the miraculous has come down to our times and to our medical science, and operation is the modern medical miracle.

At last we have begun to see that prevention is better than cure, and the ophthalmic surgeon is becoming the refractionist. In the same way the ophthalmic therapist is disappearing to return immediately as the preventor of disease, the keeper of good eyes good. Therapeutics is fast merging itself into prophylaxis, and the practitioner of medicine is becoming the hygienist. It is a sort of benevolent suicide of the old ophthalmologist for the benefit of his heir, the well-insured new young man. It is fortunate that the new and the old science are in reality carried on in America by the same practitioners so that no rivalry nor ill will can take place. For a time, to be sure, the dual ophthalmologist may privately discuss with his conscience the question as to whether he will undertake to prevent the strabismus of the little one, and the cataract of the presbyope, or operate later, etc., but in this and many other similar instances I do not contend that the old ophthalmologist is Mr. Hyde, although I am sure that the new one is Dr. Jekyll.

The unity of the organism and the interdependence of all functions is the dominating and moulding truth of medicine, the monism of physiology, the evolution principle of medical science and practice. No organ lives to itself alone; there is no function that does not influence every other. This is the truth which disallows a narrow specialism, prevents the exaggerator from becoming an extremist, and forbids the extremist from becoming a hobby-rider. In obedience to it the specialist must always be on the sharp lookout for all the lines of cause and effect which may subtly run back and forth, either way, between the diseases of his chosen

field of study, and that of all the other specialists. We are, in truth, all of us, specialists nowadays, the general physician fully as much so as any other. While knowing profoundly one specialty, as willy-nilly we now must do, it is our common duty to maintain a keen outlook over the work of others and preserve a large sanity of mind, and a genuine sympathy of feeling with our collaborators in all other fields. The direction to speakers at this meeting is to choose out and emphasize the relations running between their specialties and those of others, between one science and the other sciences. We are to bind into unity, or preferably discover the number and nature of the existing bonds, which make the organism one and its parts interdependent, and which resolve all organisms into a universe.

The relations which exist between refraction anomalies and general medicine are almost solely of one kind—those, namely, in which the ocular condition is causal. There are few bodily conditions or diseases that influence the ametropia.¹ Large changes in general body weight, I have demonstrated, do so, a decided increase of fat tending to lessen the anteroposterior diameter of the globes; an extensive decrease of fat, conversely, lengthening the eyeballs. I have also noticed that after a severe illness refraction changes will probably be found. Other illustrations may be omitted.

When one turns to observe the number of organs and ways in which eyestrain results in extraocular disease, there is at once, of course, a recognition that, compared with direct ocular reflexes, they are few. The eye and ear have extremely few, if any, interdependencies, and they are relatively unimportant. And yet an expert might write an interesting monograph on the subject. One would say that the dentist and oculist had little in common, and yet I have had more than one patient who had violent toothache in sound teeth whenever he read or wrote five minutes.

The specialist in diseases of the upper air passages must never forget the oculist. It is a significant fact that eyestrain patients locate their headaches directly in or behind the frontal sinuses. We list them as frontal, but understand thereby that the forehead is the location of the pain. For many years I had noticed that there was a suspicious relation between eyestrain and frontal-sinus disease, and in several patients I had definitely traced it. Dr. Phillips of Buffalo has made a close study of ten such cases in which the sinus disease was clearly due to eyestrain.² Reflex congestion of the upper air passages, pharyngitis, laryngitis, aphonia, common colds and influenza, may be due, and more frequently than is supposed, to eyestrain.

In general surgery nothing, a short time ago, would have seemed more absurd than to say that eyestrain could at least prevent appendicitis, surgical diseases and operations. Yet Dr. Robert T. Morris of New York,³ whose character and professional standing need no setting forth, writes as follows:

A very large group of cases of intestinal fermentation is dependent on eyestrain. These cases are perhaps quite as often overlooked as any others, but as soon as we have all become familiar with the external signs of eyestrain fewer cases will get to the surgeon with the diagnosis of abdominal disorder. Those that I see are sent to the office most often with the request to have the appendix examined, because the

distension of the cecum is apt to cause more pain than distension of other parts of the bowel and attention is attracted to this region. If there are external evidences of eyestrain these cases are referred to the ophthalmologist, along with my cases of "nervous dyspepsia" and "gastric neuralgia," and some of the most brilliant results that I have observed in any kind of medical practice have come out of the treatment that was instituted.

If an oculist had first made such a statement the grin of derision would have extended across the face of the continent. Because the general surgeon thus annually turns away from his office thousands of dollars' worth of operations, it derives at least the merit of unselfishness.

There is no truth in medicine more certain and demonstrable, although the gastrologist has not heard of it, than that eyestrain produces anorexia, denutrition, intestinal fermentation, constipation, and many disorders of the digestive organs, including, especially, the liver. If so, it is, of course, admitted that the surgical diseases secondary to such disorders may be ocular in remote origin, and the warning may not in future be safely unobserved by the appendicitis specialist, the gastrologist, the gynecologist, etc. Within a year a famous medical journal has editorially stated that all obscure gastric symptoms demand the excision of the gastric ulcer. That is, surely, surgery gone mad.

In orthopedic surgery a new causal relation has most recently been discovered between eyestrain and spinal curvature. Scoliosis begins in childhood and adolescence as spinal curvature, and in thousands of patients the spinal disease is unsuspected by child, parent, and doctor. Within a few months I have discovered 30 or 40 cases of tilted heads, most of which caused or might cause secondary or compensatory scoliosis, and all due to an axis of astigmatism (about 15 degrees unsymmetrical, and to one side of 90 degrees or 180 degrees in the dominant, that is, the dextral eye in the dextromanual), which compelled a habitual lateral inclination of the head in order to see plainly. And the compensatory curvature of the spine induces a score of other systemic diseases. We formerly allowed our patients to tilt the head while making refraction tests, and so missed locating the astigmatic axis correctly.⁴ By keeping the head vertical during the testing we now apply glasses that keep it straight afterward, and when the spinal curve is still functional we likewise straighten it by glasses alone.

No pediatricist henceforth may forget the eyes in all of his patients over 18 months old. The chances are high that, without other definite and easily ascertained cause exists, eye-train is the source of the mischief in the child which suffers from night-terrors, breakfast anorexia, tics, chorea, nervousness, disorders of digestion and nutrition, irritability, headaches, etc. I have cured nocturnal enuresis in children by spectacles alone. Alert-minded pedagogists are fast becoming aware of the tremendous rôle of eyestrain in the health and success of their pupils. As every year of school life passes the proportion of diseased pupils increases, until in the upper grades it may rise to 60 per cent.; it is 40 per cent. on the average in Columbus, Ohio. The diseases are precisely those which every capable oculist knows are often due to eyestrain. The rule is so certain that discerning teachers know that

1. Although one well-known neurologist and one orthopedist have said that the eyestrain is a result of the systemic disease, rather than the reverse—an amusing betrayal of a lack of knowledge of what ametropia is!

2. American Medicine, 1904.

3. Medical Record, Dec. 26, 1903.

4. An excellent rule of ophthalmic office practice is that when we fail to cure eyestrain results by our glasses, it is perhaps because we have allowed the head tilters to hold their heads as they pleased during the tests.

those pupils who are one, two, or three years behind their classes, have severe eyestrain, and without further inquiry they are sent to the oculist. There is hardly a page of that magnificent book on "Adolescence," by Dr. G. Stanley Hall, that does not need rewriting with this new knowledge—unfortunately and strangely ignored—in the mind of the writer. Its splendid power and truthfulness could have been doubled had its gifted author looked into the vast existing literature, written by capable and scientific minds, confirmatory of the rôle of eyestrain in school life.

In neurology there is almost no limit to what the refractionist may justly claim. And posterity will allow it, although the neurologist of to-day is unconscious and contemptuous of the truth. Neurasthenia and hysteria he claims as his exclusive possession.

Private sanitariums or rest-cure establishments may be of limited and infrequent service for chronic patients whose vitality and resisting powers have been worn to a thread by a half-life of torture for which no therapeutics availed. But even the ordered rest-cure could often be avoided by correction of eyestrain, and in perhaps 75 per cent. of cases the neurasthenic breakdowns and chronic hysterias could have been prevented by attention to the matter in adolescence. Not infrequently it is plain that the resting is curative because the eyes are rested. With reading and writing interdicted there are often astonishing cures; with resumption of reading and writing, relapses and returns to the sanitarium are required.

Every sensation and its every correlated motion is an example of reflex action, and yet there are those who airily scoff at the very possibility of reflex neuroses, and other diseases due to reflex action. There are those who speak scornfully of mysticism and mystery in medicine, while satisfied with a practice which reduces itself to diagnosis and naming unknown mysteries as migraine, neurasthenia, hysteria, psychosis, etc.

Psychiatry seems to have reached the goal of its ambition. Diagnosing and naming a morbid mental condition as "a katatonic state," "major psychosis," "melancholia of involution," "psychical tonus or contracture," "dementia precox," "*forme fruste*," "manic depressive insanity," "confusional psychosis," "pseudoneurasthenia," "mysophobia," "topoalgia," "neurasthenical syndrome," etc., all of which terms are culled from one short article, seems to end in the air so far as bettering conditions. Logomachy does not help. Who has examined the refraction of the insane? What patient with extreme eyestrain or migraine has not feared insanity? The sanest of men, Parkman, was pronounced insane, and so was Wagner and others, by great authorities, at the climax of their sufferings. Was not Nietzsche's "atypical paralysis" intimately connected with his most evident eyestrain? A competent oculist finds the majority of the young criminals of the Elmira Reformatory afflicted with so high a degree of ametropia as to make study, reading and writing and ordinary handicrafts impossible. What else could many of the poor boys do but play truant and steal? The statistics showing the relation of crime to truancy indicate that some of both may be due to bad eyes.

In 252 cases of suicide, 187 were due to ill health. About 50 per cent. of chronic epileptics have unsymmetrical astigmatism and anisometropia—a surprising ratio of a defect especially prone to upset the cerebral health and balance. The peculiarity of the diseases of eyestrain is their tendency to produce psychic and emotional disorder, despair, melancholy, etc.

There is scarcely any disease which the general physician or internist is called on to treat that may not be and that frequently is not due to or influenced by eyestrain. The commonest is designated by that silly and meaningless word, migraine. The term has little or no significance nowadays. It is, in fact, the vulgarization of a misnaming and meaningless designation of a mal-observed and trivial symptom, which in the majority of cases is not present, of a widely prevalent and ingravescent disease, with indescribable symptoms, which may, in extreme cases, wreck life and morbidize the mind, the etiology and pathology of which are unknown, the location or organs affected being also unknown, and of which no treatment avails. It is made to cover the conditions indiscriminately called scotoma scintillans, headache, sickheadache, gastric and intestinal disorders, insomnia, melancholy, etc.; in a few severe cases such patients have all of the symptoms. It is almost always due to eyestrain, and, except in the rarest worn-out chronic cases, it is almost immediately curable by relieving the eyestrain. It is the commonest of all affections, the great manure of the ground for other and terminal diseases, the supporter of quacks and patent-medicine syndicates. From 10 to 20 per cent. of Americans suffer from it, under one alias or another, recognized or unrecognized. The larger number of these, taught by sad experience, have given up the hope of cure, and they are neighbors of the person who says migraine has no relation to eyestrain, and who does not know that thousands are now being cured by two little pieces of glass. Eyestrain effects have a peculiar tendency to periodicities and waves of better or worse. The nervous centers can endure for a time the burdens and irritations laid on them, but at last give away. This is so of mental states and diseases, and the eye as psychologists know is the chief creator of intellect. Hence those diseases or symptoms when not dependent on organic disease, like headache, sickheadache, fickle appetite, the paroxysmal neuroses, cardiac palpitation or irregularity, chorea, epilepsy, neuralgias, insomnias, and colds, which exhibit such waves of exacerbations and depression, may be due to ocular irritation.

A key to many mysteries of disease might be found in a careful classification of such as have increased with civilization as compared with those conditions outside which have been changed during the progress of civilization. Among these changed conditions none can be more noteworthy than the new kind of labor, and the tremendous addition of the amount of it thrown on the eye by the printing press, schools, sewing, clerical, and urban life. No other organ has been subjected to such a change of work and stimulus, and in all other functions the same kind of work is now demanded as before. The eye, however, was brought into function to use in distant vision, and if for near, for but an instant. Osler says that dyspepsia is the besetting malady of this country, due to improper diet, etc., although modern food is many times more certain in amount and good in quality than ever before. It is certain that stomachic and nutritional diseases seem to have increased inordinately. What is the cause of this contradiction? One, surely, is eyestrain, which is extremely prone to upset the digestive function. See several thousand cases of nausea, "dyspepsia," loss of appetite, constipation, etc., relieved at once by glasses, see the disease return at once when the glasses are broken, a lens reversed in a frame, or when the refraction changes, and one recognizes the fact of the

interrelation. Allied to this class of cases are those in which the keen ophthalmologist detects more than hints that renal affections, hepatic ones surely, including gall-bladder diseases, may possibly be set up or aggravated by severe reflexes from the eyes to the secretory and eliminative organs. Some day it will be established that eyestrain is a large factor in the production of diseases of the kidney.

One of the more subtle but still easily recognizable methods in which eyestrain works perniciously is by a slow and general denutrition and reduction of mental and physical vitality whereby the resisting powers of the system are reduced to such a degree that it becomes the easy prey of infections, and of general and terminal diseases. This makes eyestrain a factor in the tuberculosis and pneumonia crusade. The life study of patients and their diseases—the biographic clinic—will make such a connection more often manifest. The sad story of the life of John Addington Symonds is in this way suggestive.

The age-long superstition whereby almost all the diseases of women were traced to the sexual organs and functions,⁵ is fast giving way to a new view more in correspondence with facts. That puberty and menstruation should inaugurate a host of terrible evils, and the menopause another legion, is at the least contradictory. The proper name for the cause of many supposed disorders of menophania and puberty is study with astigmatic eyes; that for supposed menopausal woes is presbyopia. In a large number of instances *δφθαλμός* may replace *ὄστρα* as the organ primarily at fault. The oculist and gynecologist should be good friends. The connection between the eye and sexualism is known of old, and is a deep and profound one. Love of any and all kinds dilates the pupil, the designation of the grand sympathetic system itself arising from the fact. A certain profound relation of vision and sexualism will sometime be established which as yet is unsuspected.

Justly motived, therefore, is the question: Why has this great truth been so long ignored, and why now do so many reject it? Some of the answers are these:

1. The progress of science has not yet reached the stage that will enable certain minds to see its truth.

2. The conditions of life and professional evolution have made surgery of supreme importance.

3. Organic diseases had first to be studied.

4. The laws and status of infectious diseases had first to be made definite.

5. A mere habit of neglecting the eye and its all-important function and diseases has with some grown into a blind dogmatism.

6. The theory of optics, and the elaboration of mathematical formulas, satisfied too many minds, and there was no proceeding to the practical application in clinical work.

7. Specialists in medicine, other than ophthalmologists, have overstated the effects of the diseases of special organs.

8. The ophthalmic tenotomist has made unwarranted claims and so made the profession blind and deaf to the warranted claims of the refractionist.

9. The commercial medical journal plays to the galleries, and flatters the prejudices of its readers.

10. Patent medicine venders, drug-sellers, and quackery within the profession carry on the irrational tendency.

5. A sad error that much mars the large sanity and lessens the benefits of Dr. G. Stanley Hall's great book.

11. Suffering and pain are positive, relief and cure negative. The patient, therefore, is prone to forget the primary misery, nor does the physician recognize the cause of the cure by glasses, which is ascribed to fate, *gale répercutée*, the doctor and his drugs, etc.

12. The method of eliciting symptoms and of clinical note-taking is so faulty that the very existence of the chief symptoms of eyestrain is not recognized. The patient thinks the vomiting, abdominal symptoms, migraine, headache, dyspepsia, insomnia, loss of energy, etc., have no possible connection with the eyes, does not allude to them, and they are thus wholly ignored. Thousands of such have been cured by glasses, and the fact unsuspected by either physician or patient. In another, less large, number of cures the method of cure is known or suspected by the oculist, who is silent concerning it because of the desire to "stand well with the profession," or to secure reference cases from those physicians and neurologists who disbelieve in the "extremist" and all his work.

13. The desire for consultation practice, referred cases, professorships, hospital positions, and "success" make the cunning silent or conservative. "Faddism" and "hobby-riding" charged to a budding reputation are ruinous.

14. Poor refraction work on the part of oculists is the greatest cause of scepticism. Those who do accurate refraction know perfectly well that, broadly speaking, the ophthalmologists of the world have done their refraction work badly. The logical and pathologic conclusions of the labors of Donders, Helmholtz and others have been practically made only by some American, and one or two European, refractionists. "I sent my patient to the oculist and glasses had no effect on the disease," means utterly nothing. "Is not my oculist a man of the highest renown and ability?"—may mean as little. Does this man of renown and ability teach, and in the persons of his patients demonstrate that so-called "migraine," headache, sick-headache, dyspepsia, spinal curvature, insomnia, neurasthenia, anemia, the blues, and the rest of the list, are often, very often, due to eyestrain? Belief in the truth is a prerequisite of ability to cure; and is absolutely essential to a rigid attention to at least "78 reasons why glasses failed to give relief." From 50 to 75 per cent. of glasses prescribed in the world are inaccurate and can not relieve eyestrain. Then it is also true that fully 90 per cent. of the adjusting of opticians is so bad that any possible therapeutic result is not obtained.

To be entirely frank one should add an argument which is, indeed, a two-edged sword, but which needs occasional use to keep it from rusting. It is this: Those who deny that migraine and the many other diseases mentioned may be due to eyestrain have not of course cured such patients in their own private practice. That is a self-judgment which is most severe. Those on the other hand who claim that such diseases are curable by ametropic correction, unless utterly unprofessional, must have cured such patients. If they do not cure they would surely be soon found out and their reputations and practices ruined. They seem to prosper! I heard one astute oculist say that if this absurd skepticism continued a few years longer his fortune would be made. He is very "successful" and is conducting his work in an honorable manner. The enthusiasm and gratitude of a patient permanently relieved of the tragedy of "migraine" or "neurasthenia" is irrepressible.

A corollary is that refraction is not taught, there is not a single adequate and thorough-going school wherein it may be taught, or wherein there is any outfitting, or attempt to teach, this most skilled, most infinitely subtle and difficult art and science. Two years at least of study, daily, exclusive study and practice, after the general course in medicine, under expert teachers, and on the part of the best type of student minds, is a too short period to introduce a man to the work, and to legally justify him in entering on such specialist practice. An endower and maker of such a school would do the world a greater service than either Carnegie or Rockefeller have so far dreamed of doing.

(To be continued.)

DIFFERENTIAL DIAGNOSIS BETWEEN PSEUDOMEMBRANOUS ANGINA OF SYPHILIS AND DIPHThERIC ANGINA.

R. R. CAMPBELL, M.D.

Professor of Skin and Venereal Diseases, Chicago Polyclinic; Associate Dermatologist, Staff of Cook County Hospital; Attending Dermatologist, Passavant Memorial Hospital.
CHICAGO.

A positive or correct diagnosis of these two conditions should be made at the earliest possible moment, lest a serious, not to say a fatal, mistake be made, and every means to surmount the difficulties which lie in our way should be conscientiously employed and thoroughly exhausted. That the clinical picture may lead us to error is sufficiently proven when we see such authorities as the elder Fournier, the world's most prominent syphilographer, an acknowledged authority of pre-eminence, err in his diagnosis by relying too implicitly on, as he supposed, a well-established clinical picture.

Bacteriology has made possible the study and classification of the pseudomembranous angina; has demonstrated their different varieties, and placed at our command an almost, if not quite, certain means of establishing a diagnosis. The physician meets with many conditions which present an almost identical picture, both macroscopically and microscopically, but which are due to vastly different causes. Most of the infectious diseases of the buccopharyngeal cavity may manifest themselves by pseudomembranes. Buccopharyngeal syphilis and diphtheria, particularly, may cause the formation of false membranes, the appearance of which are identical. The lack of knowledge on this point, and the failure to consider the same, is responsible for the errors of diagnosis recorded in our medical literature. In our textbooks very little stress is laid on the importance of a correct differential diagnosis between these two conditions, and on what may be the result of our error in not exhausting every possible means to clarify our diagnosis. On the one hand, we may expose many to the known contagion of diphtheria, and, on the other, we lay the attendants and perhaps other patients open to the possible infection of syphilis.

Due perhaps to secondary infection, the syphilitic localization on the buccopharyngeal cavity is not always abrupt. A change of the tonsil may assume a pseudomembranous appearance and be accompanied by well-pronounced general phenomena. In some cases its onset is presumably sudden, but, as a rule, it is slow in making its presence felt. It is frequently accompanied, however, by a rise of temperature to 100 F. or 102 F.; rapid pulse, anorexia, dysphagia, foul breath, anemia and marked depression or fatigue. And just here it might

be well to remark that too much importance must not be placed on unilaterality (or the lesion involving but one side), for the reason that in the secondary period or stage of syphilis, when pseudomembranes form, they often involve or cover both tonsils, the pharynx and uvula. When such a pseudomembrane is removed, a bleeding and ulcerating mucosa is disclosed. In these cases we always have glandular enlargement present.

Our diagnosis should always be based on the results obtained from culture tests, and some little consideration be accorded the personal history, as we do have cases in which we have both the diphtheritic and syphilitic infection manifest at the same time in one individual. When this double infection does occur, our first duty is to destroy the Loeffler bacillus infection, and subsequently direct our attention to the syphilitic. A third element which may enter into the differential diagnosis is the angina produced by Vincent's fusiform bacillus, which also at the beginning presents symptoms similar to those of diphtheria.

This infection, however, can be readily recognized by the aid of the microscope. Just here, before citing some cases in point, allow me to insist on the use of the microscope, and the necessity of making cultures in all cases of pseudomembranous affections of the mouth and throat.

Fournier's case—that of diphtheria mistaken for syphilis:

CASE 1.—Child (whose father was known to be syphilitic), was admitted to the Hospital Saint Louis, suffering with a membranous affection of the throat, and presenting an undoubted syphilitic eruption on the body. The patient grew rapidly worse, and twenty-four hours after the diagnosis of syphilis had been made diphtheria was suspected and positively diagnosed. The patient died promptly of diphtheria. This, however, was before the introduction of antitoxin, the use of which, had it been known, might possibly have brought about a different termination.

Petges¹ reports the following cases:

CASE 2.—Diphtheria mistaken for syphilis.

History.—Male patient, a hussar in the Tenth Regiment, Bordeaux, presented himself for medical examination. An indurated chancre which had been present between two and three weeks was found in the balanopreputial folds. This appeared sixteen days after an intercourse.

Examination.—Secondary manifestations promptly appeared, and on Jan. 6, 1901, mucous patches appeared on the tonsils. Notwithstanding energetic anti-syphilitic treatment the patient became anemic and rapidly emaciated, the pharyngeal lesions increased and membranes formed. Diphtheria having appeared in a few members of the regiment, the possibility of this being a case was considered. January 16 dysphagia was noted to have increased, and the temperature had gone up to 100.5 degrees F. January 18 the patient's general condition had grown more alarming, and on January 19 he was placed in the diphtheria ward and a culture made, which showed a pure growth of the Loeffler bacillus.

Treatment.—Injections of antitoxin, 30 c.c. in all, resulted in the patient's recovery, after which anti-syphilitic treatment was energetically employed, with gratifying results.

In this case, as you will note, we have the two conditions or infections existing at one and the same time.

Rouflay² reports another case of diphtheria likewise mistaken for syphilis:

CASE 3.—Patient, male, artilleryman, aged 22 years. March 4, 1896, was admitted to the Hospital Fontainebleau.

Examination.—Examination revealed a marked secondary syphilitic eruption, with pseudomembranous patches on the

1. Arch. de Med. et Pharmacie, 1902, vol. xxxix, p. 313.
2. Arch. de Med. et Pharmacie, 1896, p. 175.

fauces and pharynx, which also involved the larynx, producing difficulty of breathing. Roullay suspected and suggested diphtheria as the probable diagnosis, but was overruled by consultants, and no culture was made.

Treatment and Results.—On the day following, however, the patient's condition became alarming and tracheotomy had to be performed.

The patient promptly died, and on postmortem examination the false membrane was found to have extended down into the bronchi, and cultures made from the larynx demonstrated the pure Loeffler bacillus.

Petges³ reports the following case, in which a chancre of the tonsil, with syphilitic angina, was mistaken for diphtheria:

CASE 4.—Patient, male, was admitted to the Hospital St. Nicholas July 17, 1900. Denied all history of syphilis.

Examination.—Culture made the following day was negative in results as to Loeffler's bacillus, but showed abundant streptococci and staphylococci. The tonsils, uvula and the pillars of the fauces were covered with false membranes.

Treatment.—The treatment, consisting of antiseptic gargles, had no effect on the condition. July 30 marked atypical adenopathy was noted at the angle of the jaw on the left side. On account of the size of the ulceration, the atypical adenopathy, and the general condition of the patient, the physician was thrown off his guard as to syphilis, and thought the case one of tuberculosis of the tonsil. A general tonic course of treatment was instituted, and followed for about six weeks, without appreciable results. Finally, when the secondary eruption appeared, the correct diagnosis was made, and anti-syphilitic treatment was instituted, with gratifying results.

In December, 1903, I saw, in consultation with the family physician, a patient whom I had under treatment for syphilis.

CASE 5.—Male, 27 years of age; bookkeeper by occupation.

Examination.—When seen by me in December, 1903, he presented a pseudomembranous affection involving both tonsils, the pillars of the fauces and the uvula. Temperature, 101 degrees F.; rapid pulse and marked mental depression.

Treatment and Result.—The family physician diagnosed diphtheria, without making a culture, and injected antitoxin. No improvement having followed after ten days had elapsed, I was asked to see the patient, and made a diagnosis of syphilis, which the negative results of a culture made at this time and the results obtained from anti-syphilitic treatment proved to be correct. (Syphilis, four months.)

Guillemands⁴ reports the following interesting case:

CASE 6.—Female patient was treated with anti-streptococcal serum for what had been diagnosed as chronic tonsillitis. After five or six weeks she was admitted to the hospital.

Examination.—Examination showed yellowish membranous patches on both tonsils, with well marked adenopathy.

Treatment.—Diphtheria was at once suspected and an injection of antitoxin given. A culture taken at this time revealed streptococci and staphylococci. No improvement followed the injection after a week's time and a second culture was made, and this time Loeffler's bacillus was found.

During this time the patient gave birth to a child, with unmistakable signs of congenital syphilis. The child lived but a few hours. The mother then acknowledged having had syphilis, and under anti-syphilitic treatment the membranes promptly disappeared and her recovery was rapid.

Numerous other cases in point might be cited, but my object in presenting this paper was not to enter into a résumé of the literature, or to advance any new theories, but simply to direct attention to the difficulties of differentiating these conditions, and the serious consequences which may follow as a result of an error in diagnosis.

CONCLUSIONS.

In conclusion, I wish to emphasize the following points:

1. Pseudomembranous syphilitic anginae are not rare.
2. The differential diagnosis of pseudomembranous syphilitic anginae and diphtheria can not always be made from the clinical picture.

3. Culture tests and the microscope should be employed in all suspected cases.

4. In all cases in which we are highly suspicious of diphtheria, antitoxin should be used promptly while awaiting the maturity of our culture tests.

Clinical Reports.

COMPLETE INVERSION OF THE UTERUS WITH SUBSEQUENT REDUCTION AND RECOVERY.

J. M. M'COMAS, M.D.

Consulting Surgeon to the Southwestern Hospital.

ELK CITY, OKLA.

Patient.—Mrs. W. F. M., age 29 years, a farmer's wife, who had been delivered of a female child Feb. 10, 1902, was admitted to the Southwestern Hospital, Elk City, Okla., March 12, 1902.

History.—Patient's own statement: "I have always been stout and well, have given birth to three children, one aged 4, one aged two years, and the one just recently born. When my labor came on I sent for a midwife, Mrs. Hughes, my neighbor who lives near by, and when my child was born I was so nearly dead we sent for a physician, who came and said I had a large tumor, gave me some medicine and left the house."

The social and family history of this patient gives no information other than that she was without constitutional taint and had always followed a plain and simple mode of living.

Examination.—An examination, made at the hospital by Dr. T. E. Standifer and myself, March 12, 1902, thirty days after confinement, revealed a completely inverted uterus, filling up the vagina, from which exuded a bloody discharge of offensive odor. Patient complained of throbbing pains and there were marked distention and tenderness over the lower half of the abdomen with characteristic facies. Edema of the lower limbs; lymphadenitis, with inability to void the urine, accentuated the serious character of the illness. Temperature on date of admission 103, pulse 130, respirations 30.

Treatment.—From date of admission until discharged the treatment consisted mainly of supporting measures, such as highly nutritious food, baths and douches of hot creolin solution in the vagina. No attempt was made to reduce the temperature.

March 15, three days after entering the hospital, the gravity of the patient's condition, coupled with the unusual character of her illness, prompted Dr. Standifer to invite a number of his colleagues to examine the patient and to decide, if possible, the best course of treatment to pursue. Included in this number was Dr. J. C. Baker, Port, Okla., who saw the patient at her home February 12, two days after confinement, and who, recognizing her true condition, administered an anesthetic and attempted reduction of the inverted uterus, after Emmett's method, without success. At this consultation it was decided that, when the patient's condition would permit, another attempt to replace the inverted uterus should be made, and failing to effect a reduction, a vaginal hysterectomy should be proceeded with at once, while the patient was still anesthetized.

During the intervening period, from March 15 to March 25, when reduction was effected, the patient's condition remained practically the same, except as to the improved character of the vaginal discharges and the physical evidences of improve-

3. Arch. de Med. et Pharmacie, 1902, vol. xxxix, p. 313.

4. Theses, Paris, 1897, No. 257.

ment due to the more acceptable regimen supplied at the hospital.

Operation.—March 25, forty-three days after confinement, having decided we could not gain more by waiting, and the patient having already been prepared by baths and douches for as nearly an aseptic operation as possible, Dr. T. E. Standifer, with his unaided hands, one molded into a cone shape, the other pressing the cervix through the abdominal wall, succeeded, after an exhausting effort of fifty minutes, in reducing and replacing the inverted organ.

After-treatment and Result.—The patient recovered fairly from the anesthetic, but suffered from severe shock and complained of cutting pains in the lower abdomen. Both pain and shock were believed to have resulted from the breaking of possible adhesions between the peritoneal surfaces. As some degree of infection would seem almost inevitable, we were not surprised, a few hours later, to find the patient with an accelerated pulse, 140, and a temperature of 105.6. This high temperature remained nearly stationary for twenty-one days, during which time the most constant and careful attention was required to sustain the patient.

Practically the same treatment was followed after replacement as before, with the addition of intrauterine irrigations of a 2 per cent. creolin solution for a few days only.

After passing the long period of high temperature, iron was cautiously administered for the toxemia without noticeable good effect.

A slow and not very satisfactory convalescence of some weeks found the patient without funds, but, as she thought, sufficiently improved to leave the hospital, which she did May 10, 1902.

Nov. 5, 1903, eighteen months after leaving the hospital, I visited the patient at her home, found her physical health good and ascertained that her pelvic organs were performing their perfect functions.

COLD-AIR TREATMENT IN TETANUS.

W. J. MCCRANN, M.D.

SOUTH OMAHA,

AND

CHAS. C. ALLISON, M.D.,

Professor of Surgery, Creighton Medical College.

OMAHA.

Patient.—F. McK., aged 10, was first seen Sept. 5, 1904.

Examination.—His symptoms were those of tetanus and on examination we found a splinter in the bottom of the left foot. The history was that the splinter had been in the foot eight days. This was removed and tincture of iodine applied to the wound, which was suppurating slightly.

Course of the Disease.—At this time and during the two following days the muscles of the neck, back and abdomen were rigid, respiration was difficult, moderate opisthotonos was present and he complained of pain in the head and stomach; convulsive movements appeared when he made an effort to move or talk. Two doses of anti-tetanic serum were given hypodermically and he was placed on full doses of chloral and bromids. The symptoms grew progressively worse during the first three days of our observation, when it was decided to employ the cold-air treatment, which had been suggested by Dr. McCrann, whereon he was taken to the cold-storage room of a local brewery, his symptoms being so severe as to make the outlook most discouraging.

Cold-air Treatment.—He went into the cold-air room at about 8 o'clock p. m.; within two hours the symptoms had improved in a marked degree and he rested well until about 2 o'clock in the morning, when he awoke, and on account of his being frightened at the unusual surroundings his parents took him home. During the following day, when at home his symptoms grew much worse, opisthotonos was very pronounced, respiration difficult, convulsions more frequent, during which his tongue was severely bitten. He was unable to take any nourishment and his temperature reached 103 degrees. The

prospects seemed altogether bad, and it was doubtful in our minds whether he would again be able to reach the brewery, which was twenty blocks away.

Results.—On readmission the symptoms again improved, and his complete recovery was uninterrupted. He remained in the cold-storage room for seven days, and in an adjacent building for the remainder of a week, after which he went home.

Remarks.—While in the cold-storage room his body was at all times well protected with blankets and rubber cover. The most noteworthy features of the case, in our judgment, are the following: This was an undoubted case of tetanus of severe type, which seemed not to respond to the usual treatment, but which showed good improvement after a few hours of inspiring cold air, with a recurrence of all the bad symptoms when he returned home. The symptoms became alarming during the fifteen hours he remained at home, and prompt progressive improvement followed readmission to the cold air. So pronounced was the change that it would seem altogether reasonable to look on this plan of the application of cold as very useful, and we would advise its further trial.

New Instrument.

A NEW NEEDLE FOR USE WITH THE MCGRAW ELASTIC LIGATURE.

S. EDWARD SANDERSON, M.D.

DETROIT, MICH.

This needle has the following advantages: It is simple in construction, being all in one piece (Fig. 1); the diameter is small, the size, 3 mm., will hold a ligature of 5 mm. diameter;

Fig. 1.—Three-quarter size.

it is of convenient length, $4\frac{1}{2}$ inches; as it is to be threaded by the operator or his assistant, it can be used any number of times; although the needle is designed in different sizes for different sized ligatures, yet, by tapering and trimming the ligature and then threading single or double, one sized needle may answer for all sizes of ligature.

Fig. 2.—Sectional view, three-quarter size.

The end of a large ligature can be tapered so as to pass far enough through to be grasped and then drawn through beyond the tapering point, which is cut off. The compressed end is held by the grasp of the needle (Fig. 2). A smaller ligature can be threaded by the use of a loop of braided silk or other strong cord, pulling the ligature through double. The loop of

Fig. 3.

silk should be passed in through the hole on the side, made to emerge far enough to loop the ligature through it, when sufficient traction is made to lessen the diameter of the ligature and draw it into the end of the needle far enough to hold when the thread should be cut off (Fig. 3). See illustrations.

315 Stevens Bldg.

Morphin in Shock.—*The International Journal of Surgery* states that morphin should never be administered to a patient who is unconscious or in whom pain is abolished through shock, as it will deepen these conditions and will distinctly increase the danger.

SATURDAY, NOVEMBER 19, 1904.

THE ABUSE OF CLIMATIC TREATMENT OF TUBERCULOSIS.

We are gradually abandoning the idea that the care of tuberculosis is dependent on certain climatic conditions. Experience is proving that abundant food, fresh air and rest are the essentials of such a cure, and that they can be applied in practically all climates. Yet in the minds of many, both medical men and laymen, the idea still survives that certain places have an almost magic effect on this disease, and that if the tuberculous patient can only reach one of the famous resorts of the West and Southwest, he will get well without anything else being needed. It is certainly true that a sojourn in a dry, fairly equable, sunny climate, in the open air, with abundance of food and freedom from mental worry or hard work, constitutes the ideal treatment for a consumptive, but if all the other elements are left out and the climate alone remains, the chances are enormously against any benefit being derived from a sojourn in any health resort, while the same amount of money expended in home treatment might result in cure.

The Carolinas, California, Colorado, Arizona and New Mexico, as any physician in these states will testify, are filled with pitiful wrecks of humanity, who should never have been allowed, much less encouraged, by their physicians to leave home in the late stages of tuberculosis, with no prospect of being able to obtain proper treatment after their arrival at their destination. Too often their slender resources are exhausted by the long and expensive journey, and they are forced to look for some light work to support themselves. But for every opening of that sort there are numerous applicants, the wages paid are low, as is always the case under such circumstances, and the patients, beside, are often in a condition when work of any sort is contraindicated. Unable to pay much for their living expenses, they take rooms in cheap lodging-houses, where precautions against infection are not enforced, and get their meals in cheap bakeries and restaurants. Add to this, homesickness, forlorn surroundings, loneliness, worry over money matters, lack of proper medical care, and no one will claim that the climate, admirable as it is, can do much for them. These cases literally through the health resorts throughout the West. Tent life and sanitarium life are expensive, all the necessities of life are high, and the person of moderate means, even if he is assured of a steady income, will be obliged

to makeshift to reduce his expenses, and often will be obliged to manage without the comforts he is accustomed to at home, and with an amount of "roughing it" which, to many people, is absolute misery. Nor is the loneliness of the life a negligible factor. A patient who can go accompanied by his friends is fortunate, but a woman who has had to leave a family of small children behind her will pine in spite of all treatment. The lack of home restraint and of healthful amusements works the ruin of many a young consumptive sent out alone to the far West and finding his only acquaintances and amusements in saloons.

This horde of hopeless cases, dumped on those of our states which have become famed as health resorts, constitutes the greatest problem with which the philanthropic associations in those states have to deal. Mr. Frank D. Witherbee,¹ who has had experience as a charity worker in Philadelphia and New York, has recently investigated conditions in Phoenix, Arizona, a typical health-seeker's town, and as a result, calls on the medical profession throughout the country to do all it can to prevent the "inexcusable stupidity which sends these people hither to die friendless and alone." Phoenix has a population of 15,000 to 16,000, almost one-fifth of whom are health seekers, and of these, 3,000 or 4,000, fully two-thirds, if not four-fifths, should never have been allowed to leave home, according to the opinion of the physicians in Phoenix interviewed by Mr. Witherbee. The hospitals, sanatoria, and almshouse are filled with indigent, dying consumptives. Public and private charity is taxed to the uttermost, but the demand is so much greater than the supply that many a wretched patient dies alone and unattended in a lodging-house. The supervisors of the poor say that three-fourths of the money expended on the inmates of the almshouse goes to alien consumptives.

Our knowledge of the proper treatment of tuberculosis has increased so enormously of late years that there is no longer any excuse for this blind, indiscriminating method of shipping out West consumptives of all classes in all stages of the disease. Rather let us reserve that treatment for the favored few who have ample means, and for the others let us direct our energies, in the first place, to the providing of sanatoria in our own states; sanatoria for those of small means and for those of no means at all. In the second place, and this is even more important, let us endeavor to devise methods of home treatment for tuberculosis, for this is the only way in which the modern treatment for that disease can ever be applied to the great majority of its victims.

THE CHEMICAL THEORY OF CERTAIN INFECTIOUS DISEASES.

We are so thoroughly imbued with the idea that all infectious diseases are caused and carried on by living germs that we are hardly in a fit mood to receive kindly

¹ *Charities*, Nov. 6, 1904.

and weigh carefully any other theory of infection. In view, however, of the fact that modern microbiologic methods have not yet unraveled the etiologic problems of many easily communicable and highly infectious diseases, such as the acute eruptive fevers, syphilis, typhus fever, yellow fever, rabies and foot-and-mouth disease, we may do well to seriously consider the question whether a too strict adherence to the microbial theory of infectious diseases is closing our eyes to other methods of research. Have we really the right to irrevocably conclude that living, multiplying microbes are absolutely essential for the development and spread of diseases like those just mentioned?

Benjamin Moore, professor of biochemistry in the University of Liverpool, points out in a suggestive paper¹ that there is no proof in the observed facts regarding infection "that the infective agent is necessarily a living cell." He argues in favor of the alternative view that infection may be carried also by non-living chemical substances, such as enzymes. But how can enzymes fulfill requirements in this relation that we heretofore have believed could be fulfilled only by living things? We believe to-day that the unknown "virus" of yellow fever is living because it reproduces itself in so evident a manner. Moore acknowledges that we have no evidence of the reproduction of enzymes, so far as their fate may be studied in the test-tube, but are we, on this account, permitted to conclude that in the living cell, with its varied chemical processes, there may not be energy enough to lead to a regeneration of an infecting enzyme or chemical substance? Hardly. Moore turns to the phenomena of autocatalysis for analogy. In autocatalysis action proceeds very slowly until the products of the reaction accumulate and give the reaction increasing speed, so that, in some cases, it may finish with explosive vehemence. When copper or mercury are placed in contact with pure nitric acid, there is at first no action; but as nitrous acid develops it acts as a catalyzer, increasing the velocity of reaction and its own production at the same time. If nitrous acid is added in the early stages, the action is at once hastened. Similar autocatalytic reactions lead to the explosion of gun-cotton; and so there may be abnormal cellular reactions, autocatalytic in character, producing bodies identical with those that start the reaction. In this way, hypothetical chemical "virus" may increase in amount and spread not only throughout the body first "infected," producing in this passage the clinical picture of the disease, but pass also to other individuals in whom the process would repeat itself.

It may be pointed out that many chemical substances, especially enzymes, are radically changed by treatment with the heat, and the disinfectant agents employed to destroy "virus" of various kinds, so that we are not able by these means to distinguish between living and non-

living substances. Moore, on the other hand, urges the great resistance of vaccine virus to various disinfecting agents—glycerin, sodium bichlorate, boracic acid, carbolic acid, chloroform—as evidence of the chemical nature of this particular virus, because it remains potent after exposures of weeks and months to these agents in such proportions that they kill all germs demonstrable by present methods within a few days. Finally, he also points to the fact that among the diseases of unknown etiology here considered are the most highly infectious diseases known, and he suggests that this great infectivity may be dependent on the minute subdivision and the stability of the infecting material if of chemical nature.

Professor Moore's chemical theory of certain infectious diseases contains much that is plausible. Particularly interesting is the use he makes in its elaboration of autocatalysis, which may be regarded as its cornerstone. As yet the theory is without experimental proof. The fact that vaccine virus remains potent after long treatment with disinfectants does not positively exclude its being living material, because we know that bacterial spores, for instance, have a powerful vitality. And microbiologists if pressed would not be slow to point out that Professor Moore has not brought forward any new facts that do not harmonize with the microbial theories of infectious diseases. Fortunately, there are in this class of diseases those that affect animals and with which it is possible to make experiments freely, and it may be hoped that the chemical theory, as advanced, will lead to experimental studies from the chemical point of view. In this way the theory may prove itself of great service.

THE TRAINING OF THE SURGEON.

The occasional medical address is apt to be rather perfunctorily prepared and delivered, but the speaker who made the annual oration in medicine at Yale University last June, dealt with topics of unusual interest, and gave expression to thoughts and ideas which are worthy of attention in a circle larger than that of his immediate audience.

The title of the address, which was recently published,¹ is scarcely commensurate with the matters debated, for not only was the training of surgeons discussed, but, in addition, the gradual rise of surgery was depicted, the condition of surgery in Germany was contrasted with that in America, the organization of an ideal surgical clinic was described, and the relations of hospital workers and surgical practitioners to university teaching and research were examined.

The speaker, drawing on the history of surgery, warned his hearers against satisfaction with present achievement and blindness to the possibilities of future development. Boyer, over a hundred years ago, declared that surgery had then reached almost, if not

1. The Journal of State Medicine, April, 1904.

1. Halsted, W. S.: The Training of the Surgeon. Bull. Johns Hopkins Hospital, Baltimore, vol. xv, 1904, pp. 267-275.

actually, the highest degree of perfection of which it was capable, and yet, only fifty years later, a quarter of a century was to begin in which pain, hemorrhage and infection, the three great evils which had always embittered the practice of surgery and checked its progress were to be, almost in a moment, robbed of their terrors.

The intimate interdependence of physiology, pathology and surgery was strongly emphasized. It was shown that without progress in physiology and pathology, surgery could advance but little, though surgery pays the debt by contributing much to the knowledge of the pathologist and physiologist. The studies of a Harvey, a John Hunter, a Pasteur or a Lister revolutionize the work of the surgeon. In Germany, a professor of pathologic anatomy was, in 1865, at the instigation of Helmholtz, called to the chair of surgery in Heidelberg, and the choice, though a surprise to many, proved to be most happy. Dr. Halsted believes that the stress formerly laid on postgraduate anatomy as a preparation for surgery would be disproportionate to-day; the necessary anatomy, now that knowledge of that subject is so definite, may be easily and quickly acquired, so that time will be available for very thorough training in pathology and physiology.

The fact that Germany was the first country to adopt antiseptic surgery, and that almost all surgeons in the German universities eagerly embraced Lister's system practically simultaneously was used by the lecturer as a text on which to make some comments regarding German surgery and German surgeons. Professor Halsted is evidently a great admirer of the scientific and practical training of surgeons in Germany. The ideal facilities for the learning of surgery and for prosecuting researches offered by great university clinics in Germany, the great amount of clinical material, the opportunities for operative work, the special surgical laboratories for working up pathologic material derived from operations or autopsies, the encouragement of research and the possibilities of finally becoming invited to fill a professorial chair, a position of such prestige there that we in the United States who have not lived abroad can not truly comprehend it—these, Halsted says, are among the inducements which make young men in Germany willing to devote eight or twelve years of hospital service as an assistant in some large university clinic as preparation for the practice of surgery.

Contrasted with the German conditions, the defects in the existing methods of medical education in America, and especially in the opportunities for the advanced training of surgeons, Dr. Halsted thinks, are obvious. The period of hospital internship is too short. The hospital interne suffers from inexperience, but also from overexperience. He is given responsibilities which are too great for him; he acquires a confidence in himself and a self-complacency, useful, perhaps, in emergencies, but tending to blind him in his inadequacy and

to warp his career. Hospitals and surgical departments directly under the control of the university professor and his staff are rare. Staff organization is imperfect; the establishment of close and mutually stimulating relations between chief and assistants is difficult. Professorial chairs in some of the principal medical schools actually go begging of men who would adorn the positions.

With regard to the relation of university professors of surgery to private practice, the speaker seems to hold views regarding restriction which are in sympathy with those which have been expressed by Welch, by Keen and by Barker. He urges, however, and many will think with propriety, that there are forcible objections to prohibiting the acceptance of fees by professors of surgery in universities. He favors a compromise between the extremes of prohibition on the one hand and of a large private practice on the other. He would let the surgeon accept fees from certain patients in the university hospital; he would restrict him to consultations and operations at the hospital; possibly in very exceptional cases he would permit him to visit a patient in his town or state or in another state if it were impossible for the patient to come to him. Private patients in a hospital need consume little or no more of the chief surgeon's time than the patients in the public wards.

Though critical of the defects in American conditions, Professor Halsted closed his address with a strong eulogy of American surgery. Courage, ingenuity, dexterity, resourcefulness—prominent characteristics of our countrymen—have led to surgical contributions which have carried the fame of American surgery throughout the civilized world. He believes that there are "few operations in surgery which can not be performed as well in this country as anywhere in the world, and not a few operations are best performed by the surgeons of America."

CIRCULATORY CONDITIONS DURING PREGNANCY AND THE PUERPERIUM.

The statement has been made that the heart undergoes hypertrophy during pregnancy, and this result has been attributed, among other things, to increase in the number and size of the vascular channels, in the quantity of blood, and in the intra-abdominal pressure, with insufficient expansion of the chest and compression of the lungs. The evidence to date on these points, as determined both by postmortem and by clinical observation, is, however, not conclusive. Also a systolic murmur or souffle has been referred to by numerous writers, and the pulse rate has been found diminished. With the view of forming an independent judgment in the matter, Drs. Alfred Stengel and W. B. Stanton¹ undertook a clinical study of the heart and circulation in seventy pregnant women, including physical examina-

1. Univ. of Penn. Med. Bull., September, 1904, p. 202.

tion before and after parturition, together with determinations of the blood pressure and sphygmographic tracings.

Thirty-nine of the patients were primiparæ and twenty-one multiparæ, while in ten cardiac or renal disease antedated the pregnancy. As a result of these observations, the conclusion was reached that pregnancy is not attended with any hypertrophy of the left ventricle, nor with any increase in its work. The increase in the area of cardiac dullness toward the left was found to be due to the upward displacement of the diaphragm, and the consequent displacement of the heart in an upward and outward direction. Comparative outlines made before and after labor demonstrated a rapid return to the normal position. A striking feature frequently observed was an increase in the extension of the dullness toward the left in the second and third interspaces and distinct pulsation in the same area. In the absence of evidence of retraction of the lung, and in view of the fact that the pulsation was marked, the phenomena are ascribed to distension of the conus arteriosus and root of the pulmonary artery. The frequent presence of a systolic murmur, most clearly audible in the same area, is considered as further substantiation of this view.

The position of the right border of the heart seemed on the average too far to the right, and this fact, in conjunction with the conditions present at the root of the pulmonary artery, appeared to indicate that during the later months of pregnancy there is probably some continuous dilatation of the right ventricle, though this is apparently of slight degree. Such a state of affairs is readily explained by the increased difficulty in the pulmonary circulation due to the upward displacement of the diaphragm and pressure on the lungs.

The separation of the abdominal recti muscles observed in multiparæ materially lessens the tendency to displacement of the diaphragm, and diminishes in corresponding degree the displacement of the heart during pregnancy. After delivery the diastasis may occasion downward displacement of the apex of the heart, and the contrast before and after labor may be quite as pronounced as in primiparæ, though the first position occupied may not have been far from normal. Later, if the separation of the muscles is not considerable and the normal tone of the abdominal wall is regained, a restoration to the normal occurs on the part of the heart and its apex.

As a rule, no material increase in the blood pressure was found before or after labor, although during labor a notable increase in the blood pressure was sometimes present.

EDDYISM AND PUBLIC HEALTH.

It is sometimes said, by those charitably inclined people who are ready to find excuses for others, that Eddyites scarcely deserve to be condemned so unsparingly

as they often are, since at most they harm only themselves. This, of course, does not take into account that the most faithful members of the sect insist on exposing their families to whatever danger they themselves may incur because of their disbelief in disease and in modern medical methods. A case recently occurred in Connecticut, in which once more it has been made very clear how much risk to the community believers in the Mrs. Eddy cult may invite by their refusal to recognize the necessity for hygienic precautions and to obey sanitary regulations.

The occurrence was at Stamford, and it involved the death of one child and the exposure of many persons to diphtheria. In one of the public schools, a little boy, scarcely more than ten years of age, was noticed by his teacher to be suffering from headache, and his flushed face indicated that he had fever. He was sent home at once, with the thought, of course, that he would be properly cared for. No physician, however, was summoned to see the boy. The mother was a fervent believer in the principles of Eddyism, and a "healer" was sent for. The child evidently was very ill, but no report of his condition was made to the authorities. By the end of the week, rumors had reached the neighbors that the child was suffering from a contagious disease and, as no precautions were being taken to prevent its spread, the health authorities of the town were informed of the suspicions. In spite of protest on the part of the mother, a health officer forced his way into the house. He found the little boy almost in the last stages of diphtheria, while a brother and a sister were suffering from the same disease in a rather virulent form. After these discoveries, the board of health insisted on a physician being called, but the first little patient died scarcely twenty-four hours later. The other children, we believe, are well on the way to recovery. It was found that a child of the healer was also suffering from the disease.

Here, then, is a flagrant example of how much danger to the community may result from even one person insisting on not obeying the legal regulations that are enacted for the sake of public health. Of course, Eddyism is an unfortunate delusion, and one finds it hard to blame the poor misguided victims for actions for which they are not quite responsible. This is an attitude of mind, however, that the followers of the cult would be the first to resent. Under the circumstances, therefore, the only thing that can be done is to insist on punishment, to the fullest extent, for violation of sanitary laws. Unfortunately, as the death of the little patient in this case did not take place until some twenty-four hours after a physician had been called, and as the physician was, therefore, in a position legally to sign the death certificate, no prosecution of the parties involved will be instituted by the Connecticut authorities. This is a sad state of affairs.

It is evident that further and more stringent legisla-

tion is required in many of our states with regard to such conditions as this. Such legislation can only be obtained after proper education of the public mind. It is the plain duty of physicians to bring the details of cases like this to the attention of those who can be influential in procuring such legislation, and by this means help to stamp out an evil that threatens to endanger many others besides the unfortunate victims of the Eddyite delusion.

WHISKY PREFERENCES.

Julia Marlowe, the actress, announces to the public that she likes her whisky with a little bitter in it. At least, the newspapers are publishing her photograph with the following testimonial: "I am glad to write my endorsement of the great remedy, Peruna, as a nerve tonic. I do so most heartily.—Julia Marlowe." Perhaps it will not be deemed wholly flippant if it is noted that those who take their whisky straight, as a "nerve tonic," do not usually write testimonials thereof.

IS IT HERESY FOR AN EDDYITE TO HAVE SUPERFLUOUS HAIR REMOVED?

In our medicolegal items is mentioned a curious case recently decided by the Supreme Court of Michigan. It appears that the plaintiff, a believer in Eddyism, sought and obtained instruction in the art of mental healing. The defendant stood high in the cult, but the pupil found himself unbenefited by the teaching, and present and absent healing in his hands a failure. In other words, he found the instruction of the professed profitless. Hence the suit to recover the money paid to the instructor. It appeared from the testimony that the defendant had suffered from hypertrichosis, and had employed a physician to remove the superfluous hair from her face. This, it was claimed, showed belief in disease, and, therefore, lack of faith in Eddyism, which rendered the defendant practically an impostor and vitiated her instruction as a teacher of Eddyite healing. The decision, however, was for the defendant, since two years had elapsed between the material treatment and the instruction of the immaterial to the plaintiff—a sufficient time, the court held, to allow her to qualify as an Eddyite instructor—and, moreover, the superfluous hair on the female face might be considered as a facial blemish rather than as a disease, and did not necessarily imply such a lack of faith as would make the individual incompetent to impart to others the secrets of the mysteries of practical Eddyism. Since both parties to the suit acted on the theory of the truth of Mrs. Eddy's teachings, the decision was made on that assumption. Eddyism is evidently a pretty slippery proposition.

GINGERISM.

According to a London cable dispatch, the use of essence or strong tincture of ginger as a stimulant is becoming dangerously popular among society people in Great Britain. In some cases very large quantities

are said to be used, even as much as a pint daily. The fact that ginger is a well-known domestic remedy is very likely the starting point of its usage in cases of mental and social strain accompanied with gastric disturbances, but the habit becomes a cumulative one and fully as dangerous as the cocaine, morphin and other drug habits which it is often desired to avoid. This constitutes a special danger; the subjects at first consider that they are taking a harmless remedy, which they have known as such from childhood days. The fact that essence of ginger is often nearly of full alcoholic strength renders the drug excessively dangerous, and the further fact that it may be obtained from druggists or grocers by anyone at any time is an additional special peril. The consequences of the ginger habit, beside those from the alcoholic contents, are generally aggravated gastric disturbance and general systemic disorder. The habit is said to be more common among women than men, but accurate statistics are hard to obtain. We have not yet heard of the vice as a common one in this country, but it probably exists, and the reported cases of wood-alcohol poison from the use of essence of ginger indicate a still more insidious peril of the habitual use of the drug. It is well to be warned on these points, and to be on the lookout for possible concealed habits that may be both individual and social dangers.

THE PSYCHOLOGY OF RAILROAD ACCIDENTS.

An eastern railroad president claims that certain railroad accidents are due to temporary psychologic aberrations that may occur even in the coolest and most experienced under special circumstances, without any specially obvious inciting cause. There is, beyond question, truth in this view, but it should not be taken as exonerating railroad companies and high railroad officials from responsibility. It is not very long since an accident, costing a number of lives, occurred from an apparent disobedience or neglect of certain orders. It was shown that some of the train hands, at least, had been on continuous duty for a considerable length of time beyond the usual term of duty, and lack of necessary rest and sleep was very naturally suggested. Railroad work is often very exacting, and there is too frequently caused a degree of mental and physical strain that is inconsistent with competency adequately to meet emergencies. The human machine overtaxed is as dangerous as any other worn-out or weakened part of the railroad machinery. An engineer or dispatcher, whose nervous system has been strained almost to the breaking point, may be as much a source of danger as a weakened or broken bridge. Modern requirements of speed and close connections of fast trains render such a possibility more than ever a matter to be guarded against. There is, moreover, in the human machine the added difficulty that defects involving nervous accuracy can not always be so easily detected as can defects in mechanical appliances. The greater is therefore the danger in requiring special stress and strain in railroad employes, and the more serious the responsibility of those who permit it.

INDOOR HUMIDITY.

We have examined with unusual interest a copy of an article which Dr. Henry Mitchell Smith read before the Brooklyn Medical Society. Dr. Smith calls attention anew to the radical error in the arrangements for heating in common use to-day, namely, the absence of provision for supplying moisture needed in the air. He declares that in heating buildings we have failed to appreciate the full importance of the fact that our sensations of temperature depend not on the heat that is received from outside sources, but on the rapidity with which the body heat is lost. Radiation from the body is much more rapid when the air is lacking in moisture. To supply this moisture is a measure both hygienic and economic. On the latter point of view he quotes an authority as saying that "25 per cent. of the cost of heating is expended in raising the temperature from 60 to 70. So if we can keep comfortable at a temperature of 65, we shall have saved at least 12.5 per cent. of the total cost of heating." Relative to the above temperatures, Dr. Smith cites the results of an elaborate series of experiments, in which he found that a temperature of 65 degrees, when the air contained a proper amount of moisture, was warmer and more comfortable than a temperature of 72 or 74 degrees, with only half enough humidity. Dr. Smith has so repeatedly demonstrated this fact that he declares that it should be a cardinal rule that if a room at 68 is not warm enough for any healthy person it is because the relative humidity is too low, and in such case the procedure is to raise the relative humidity, not the temperature. Dr. Smith recommends that every household should have a hygrometer, and that water should be evaporated in rooms in sufficient amount to secure a relative humidity of about 60 per cent. In the absence of the hygrometer, a simple test will be to evaporate a sufficient amount of moisture to make the room comfortable at a temperature of 65 or 68 degrees. Dr. Smith suggests that the increase of catarrhal and other diseases in the winter time, including pneumonia, may be ascribed in some measure to the difference in the humidity between indoor and outdoor air. Not only is the dryness of the air conducive to hyperactivity of the glandular structures, but the passing from dry indoor air to moist outdoor air, and vice versa, is a severe strain on the mucous membranes. These facts are of great importance to the physician. For him to regulate the ventilating and heating apparatus of his patients' homes will be a tremendous task, and yet many affections can not be controlled until this important aid to health is properly looked after.

THE INFLUENCE OF INTESTINAL BACTERIA ON THE PROPERTIES OF THE BLOOD SERUM.

The study of the absorption of bacteria or bacterial products from the intestinal canal has both an academic and a practical interest. Although it is known from the work of Nuttall and Thierfelder that the presence of bacteria in the intestinal canal is not necessary to life, the practical fact remains that bacteria in enormous numbers are always present in this situation. Whether these bacteria are of any use in the economy—and it is

conceivable that their products might aid in the digestive process—is still unknown. On the other hand, there seems good reason to believe that bacteria which are normal inhabitants of the gastrointestinal tract, and which, under normal circumstances, do no harm, may, under certain conditions, become pathogenic. This certainly seems to be the case so far as the colon bacillus is concerned, and, as is well known, this organism inhabits the intestines in enormous numbers. It seems strange from what we know of the process of immunity that a resistance on the part of the body to an organism which is so constantly present in large numbers is not developed. Can it be that the colon bacillus (taking this as a standard type of intestinal bacterium) does not get into the circulation under normal circumstances? Even if this be the case, is it possible that its products even are not absorbed? It seems likely from the work of Adami and his pupils that colon bacilli do get into the portal if not into the general circulation, and this suggests that the colon bacillus and its products may undergo certain changes in the liver which prevent the formation of immunizing substances. The subject is one which may be attacked experimentally, and recently Telitshkin¹ has endeavored, by feeding young and also adult rabbits with cultures or toxins of the typhoid bacillus, to clear up some of the problems connected with it. This author finds that adult rabbits which are fed on large doses of typhoid bacilli develop in their blood agglutinins, fixatives and sometimes precipitins. The sera of such rabbits do not, however, possess any preventive properties. Similar but much feebler results were obtained by substituting filtrates of typhoid cultures or dead typhoid bacilli for the live cultures. In very young rabbits no results were obtained, perhaps because no absorption of the bacteria took place, or perhaps because the organism of very young animals is not capable of forming agglutinins and similar substances. If these experiments are applicable to the human being they explain why we are susceptible to colon infections, notwithstanding the fact that we constantly harbor the colon bacillus. There still remain many points along this line of investigation to be cleared up.

Medical News.

ARKANSAS.

Illegal Practitioner Fined.—Dr. Clement L. Katz, Morrison Bluff, has been fined \$25 at Paris, for practicing medicine without a license.

Smallpox.—Ward, Lonoke County, reports about 20 cases of smallpox three miles north of the town.—Many cases are reported around Butlerville.—In these two neighborhoods there are said to have been 8 or 10 deaths from the disease.

Building for Doctors.—Work will be commenced in a few days on the new three-story office building which is to be put up by the Medical Building Company of Little Rock, at a cost of \$50,000, and is designed for the use of physicians and dentists.

Hot Springs "Drummers" Must Go.—The following commissioners have been designated by the secretary of the interior to take up and regulate the practice of medicine at Hot Springs: Drs. William H. Barry and Samuel E. Steele and Hon. Charles D. Greaves.

1. Annales de l'Institut Pasteur, vol. xviii, No. 9.

Asylum Annexes Ready.—The two annexes to the Arkansas State Lunatic Asylum, Little Rock, which have been erected at a cost of about \$140,000, will be ready for occupancy this month. These additions will increase the capacity of the institution from 672 to 1,022 patients.

CALIFORNIA.

Golden Wedding.—Dr. and Mrs. Charles L. Anderson, Santa Cruz, celebrated their fiftieth wedding anniversary, October 31.

Personal.—Dr. and Mrs. Charles E. Hablutzol, San Jose, have returned after a six months' tour of Europe.—Dr. Robert C. Howe, Orland, was seriously burned about the face and neck by the explosion of a bottle containing nitric acid and alcohol.

—Dr. George F. Shiels, a trustee of the San Francisco Polyclinic since its inception, has left San Francisco and will locate in New York City.—Dr. J. Coplin Stinson has resigned from the San Francisco Board of Health.

In Charge of Hospitals.—The board of directors of Redlands Hospital, which was opened November 1, consists of Dr. Christopher A. Sanborn, president; Dr. Hoell Tyler, vice-president; Dr. Gayle G. Moseley, secretary, and Drs. J. E. Payton and Charles E. Ide.—Drs. Charles D. Ball, John L. Dryer, James R. Medlock, Francis M. Bruner, John G. Berneike, Howard S. Gordon, John Weirly, James F. Boyd and Willella H. Waffle have been chosen directors of the Santa Ana Hospital Association, and Dr. Dryer has been elected president; Dr. Bruner, vice-president; Dr. Ball, secretary, and Dr. Gordon, treasurer, of the board.

Propositions for the Legislature.—At a conference of the health officers of the various counties and municipalities of the state, held at San Francisco October 29, the association resolved to submit the following five propositions at the next session of the legislature:

First.—That the State Board of Health be given power to control matters throughout the state and make regulations and punish offenders instead of being merely an advisory body.

Second.—That a State Board of Statistics be created and maintained.

Third.—That a State Registrar of Vital Statistics be appointed.

Fourth.—That a state bacteriological laboratory be established in San Francisco.

Fifth.—That county health officers be appointed on salaries.

ILLINOIS.

Personal.—Dr. John A. Pratt, Aurora, has returned from Europe.—Dr. Anrellus T. Bartlett has retired after 40 years of practice in Virden.—Dr. George W. Hall has returned to Chicago after spending several months in Europe.

Smallpox.—Smallpox has developed at La Grange. One of the patients is an Eddyite who objected to vaccination after she had visited a friend who had the disease.—Several cases are reported at Orland.—Alton reports two cases.

To Examine Staff Candidates.—The board of physicians to examine candidates to serve on the staff of Cook County Hospital is made up as follows: Surgery—Drs. Arthur D. Bevan, John B. Murphy, Louis L. McArthur; gynecology—Drs. Ferdinand Henrotin, Enilius C. Dudley and Henry Banga; obstetrics—Drs. J. Clarence Webster, Joseph B. DeLee and Charles S. Bacon; medicine—Drs. Otto Schmidt, Frank S. Johnson and William E. Quine; children's diseases—Drs. Frank B. Earle, John C. Cook and Alfred C. Cotton; skin, venereal and contagious diseases—Drs. James Nevins Hyde, Frank H. Montgomery and Joseph Zeisler; eye, ear, nose and throat—Drs. T. Melville Iiardie, William H. Wilder and E. Fletcher Ingals; nervous diseases—Drs. Hugh T. Patrick and Harold N. Moyer; pathology and pathologic chemistry—Drs. Ludvig Hektoen, Robert H. Harvey and F. Robert Zeit, and x-ray—Drs. Joseph F. Smith and Oliver S. Ormsby. Dr. Hugh T. Patrick has been elected chairman of the board. The examinations were to begin November 18 and to continue until all places are filled.

Chicago.

Fined Twice in One Week.—Dr. Adolph Brendecke was fined \$100 and costs for selling cocaine. Less than a week before he was found guilty of a similar offense and fined \$50 and costs. He says he will appeal from both decisions.

The Week's Deaths.—For the week ended November 12, 413 deaths were reported, equivalent to an annual mortality rate of 11.17 per 1,000. The rate for the previous week was 11.36, and for the corresponding week of 1903, 13.45 per 1,000. Pneumonia caused 57 deaths; consumption, 47; violence, 36; heart diseases, 33; intestinal diseases, 26, and Bright's disease and cancer, each 25.

Pneumonia Again Leads.—For the first time since the week of May 28 the deaths from pneumonia exceeded those from consumption; there were 57 pneumonia and 47 consumption deaths recorded during the week—an excess of 21.2 per cent. of pneumonia. During the intervening five months there were 1,188 deaths from consumption and 685 from pneumonia—an excess of 73.4 per cent. of consumption deaths.

IOWA.

Hospital for Mason City.—The Sisters of Mercy of Dubuque have received an offer from Mason City to establish a hospital there. The committee agrees to provide \$50,000 if the sisters will furnish \$30,000.

Tuberculosis in Iowa.—It was stated that in 1900 the deaths from tuberculosis in Iowa outnumbered the deaths from all other contagious diseases. A recent investigation indicates that there are about 8,000 cases of tuberculosis in the state.

Temporarily Blocks Vaccination Law.—In the District Court at Iowa Falls, November 12, Judge Richards granted a temporary injunction restraining the school board of that city from preventing pupils from attending school unless vaccinated in the manner prescribed by the State Board of Health, thus allowing those treated by the internal method to attend school.

KENTUCKY.

Medal for State Board.—The Kentucky State Board of Health has been awarded a silver medal at the Louisiana Purchase Exposition for its exhibit of literature on the prevention of disease.

Physician Wins Suit.—Dr. Thomas T. Cleaver, Lebanon, was given a verdict of \$7,500 against the Louisville and Nashville Railroad Company in the Circuit Court, October 18. Dr. Cleaver was injured last spring while driving across the railroad track in front of an incoming passenger train.

Personal.—Dr. Walter F. Boggess, Louisville, has resigned from the chair of practice of medicine in the Kentucky School of Medicine and has accepted the chair of practice of medicine and physical diagnosis in the Hospital College of Medicine.—Dr. Walter A. Lackey, first assistant physician of the Western Asylum for the Insane, Hopkinsville, has resigned to enter private practice.

Will Run No Risks.—Despite the report from the members of the Board of Health of Christian County that in their opinion the smallpox situation was well under control, the State Board of Health, which met in Louisville October 29, ordered Dr. James B. Jackson, Hopkinsville, chairman of the county board of health, to hold weekly meetings of his board until the state board is satisfied that all danger is passed. Christian County has been infected with the disease for the past six months, and it has spread to neighboring counties. While the situation is not one to give cause for undue alarm, the state board expressed the opinion that the disease should be thoroughly stamped out before winter sets in.

MARYLAND.

Baltimore.

Personal.—Dr. Augustus G. Pohlman has resigned as instructor of anatomy at the Johns Hopkins Medical School to accept an appointment as assistant professor of anatomy in the University of Indiana.

Plans for Johns Hopkins.—On November 11 President Remsen explained "the Homewood plans" for the Johns Hopkins University. The present needs of the university require only an administration building, a lecture hall, a library and four laboratories. When the move will be made is uncertain, but Dr. Remsen thinks it now feasible. The board of architects has chosen the plan of a Baltimore firm—one of the five which competed—pictures of which were thrown on a screen. Dr. Remsen recommends that the buildings be simple and comparatively inexpensive, but representative of a high style of architecture.

The Smoke Evil.—In an address before the Good Government Club, Dr. Howard A. Kelly condemned the smoke evil. "If we allow such a condition to go on," he said, "unchecked, and are content, like the people of Cincinnati and Pittsburg, to let our clothing, our streets, our houses, as well as our lungs, be insulted by this filth, then must ensue not only an injury to health, but what I consider an even greater evil, the lowering of the moral tone of the community. . . . You can not, day by day, breathe particles of coal dust or any other form of

dirt, without enormously enhancing your chances of tuberculosis and other pulmonary diseases; and with the lungs once clogged in this way, the powers of resistance to disease are lessened and the chances of recovery diminished." A bill passed one branch of the city council about a year ago for the arrest of this evil, but failed to pass the second branch. As a result of this meeting an address will be sent to the city council asking that this ordinance be revived and made a law.

MASSACHUSETTS.

The Massachusetts Sanatorium for Consumptives at Rutland has a capacity for 325 cases, to be increased to 400. They report 48.97 per cent. of cases cured, 43 per cent. improved, and only 7.9 per cent. unimproved.

Farewell Banquet to Dr. Collins.—The physicians of Haverhill, on October 31, tendered a banquet to Dr. William D. Collins, who, after 27 years in that city, is about to remove to Cambridge. After the banquet a silver loving-cup, suitably inscribed, was presented to Dr. Collins.

Massachusetts Charities.—Massachusetts has 463 charitable corporations, who spend \$5,320,000 per year, occupy property valued at \$17,725,000 and have invested funds totaling \$23,147,000. Of 382,537 beneficiaries during the year, 40,399 paid, 96,989 paid part, and 245,149 paid nothing.

Diphtheria on the Wabash.—The United States receiving ship *Wabash*, stationed at the Charlestown Navy Yard, has been invaded by diphtheria. A large number of mild cases have appeared, the vessel has been quarantined and patients have been removed to the Naval Hospital, Chelsea.

Irregular Practitioner Punished.—Charles J. Stuart, Grafton, who claimed to be a medical electrician, was found guilty of violation of the registration laws of medicine, was fined \$100, and sentenced to three months in the house of correction. On his appeal he was remanded to the Superior Court under bail of \$500.

Boston Deaths.—During the ten weeks ending Nov. 5, 1904, there were reported to the Boston Board of Health 1,946 deaths. There were reported 486 cases of diphtheria, with 32 deaths; 123 of scarlet fever, with 5 deaths; 390 of typhoid fever, with 46 deaths; 48 of measles, with 2 deaths, and 374 of tuberculosis, with 200 deaths. There were 162 deaths from pneumonia, 7 from whooping cough, 180 from heart disease, 43 from bronchitis and 61 from marasmus. Of the decedents 502 were under 1 year old, 635 under 5 years old, and 393 over 60 years old.

Asylum Report.—The Northampton Insane Hospital reports for the year ended September 30, 732 patients, an increase of 60 during the year. During the year 333 were admitted and 273 discharged. The patients come mostly from the western counties. The causes noted in order of frequency are heredity, intemperance, senility, congenital causes and organic diseases of the brain. The total expenses were \$145,125. The superintendent urges the establishment of colonies in the western part of the state to relieve the overcrowding which has resulted from taking all the pauper insane to state hospitals as now required by law.

An Academy of Medicine in Boston.—The movement toward the development of an academy of medicine in Boston takes form this winter in the promulgation of a plan for a series of meetings at the Boston Medical Library. The schedule has been prepared and sent to members of the Boston Medical Library and of the Suffolk district of the Massachusetts Medical Society. Refreshments are to be served each evening. All physicians will be welcome and it is expected that many will attend outside of these societies. The program is as follows:

November 16, Nephritis: Pathology, Prof. W. T. Councilman. Clinical Examination of Urine, Prof. E. S. Wood. Diagnosis, Dr. Richard C. Cabot. November 30, Prosis of the Abdominal Organs with Special Reference to the Kidney: Discussion, December 7. The Humane Treatment of Malignant Disease from a Surgical Point of View, Dr. John C. Munro. December 21, Nephritis: Medical Treatment, Prof. F. Pfaff. Surgical Treatment, Dr. Paul Thorndike. Prognosis, Dr. Frank Wells. January 4, General Treatment of Appendicitis: Discussion, January 11, Medical Charity, Dr. Geo. W. Gay. January 25, A Study of Objective Methods of Diagnosis of the Stomach in a Medico-surgical Clinic with Report of Cases, Dr. H. F. Hewes. Results of Surgical Treatment of Benign Disease of the Stomach, Dr. J. G. Mumford. February 1, Results of Operative Treatment of Cancer in and About the Mouth: Discussion, February 11, Physiological Economy of Nutrition, Prof. R. H. Chittenden. New Haven, February 15, Recent Work on Etiology of Disease, Prof. W. T. Councilman. March 1, The Surgery of Renal and Ureteral Calculi: Discussion, March 8, The Present State of Opinion Concerning Sewer Gas and Its Effects, Prof. Wm. T. Sedgwick. Nine Years' Experience in the Treatment

of Diphtheria with Antitoxin at the South Department of the Boston City Hospital, Dr. John H. McCollom. March 11, Open. April 5, Cerebral and Spinal Surgery: Discussion.

MICHIGAN.

Personal.—Dr. Elmer D. Gardner, Hancock, has accepted the position of head physician of the Louisiana Lumber Company and will locate at Clark, Caldwell Parish, La.

Smallpox at University.—Seven cases of smallpox were discovered November 14 among the students at the University of Michigan, Ann Arbor, six in the engineering and one in the law department. The health officer considers the disease under control.

Hackley Hospital Open.—Hackley Hospital, Muskegon, the latest gift of Charles H. Hackley to the city, was formally dedicated and opened November 17. The hospital, aside from its endowment, has cost more than \$200,000, occupies four city blocks, is built on the pavilion plan, is fireproof, 204 by 250 feet, and three stories in height.

Must Add to Curriculum.—High school graduates in Michigan can not enter the medical schools of the state because their standard does not come up to that of the state university. The deficiency is in biology, mathematics and physiology. The medical schools call for less geometry and a semester of trigonometry instead; a more extended course in physiology, and for zoology in addition to botany.

NEW YORK.

Fire in Children's Hospital.—A fire occurred in the Day Nursery and Children's Hospital at West Brighton, S. I., causing a loss of \$8,000. Fortunately, the children were not in the building when the fire occurred.

School Inspection.—The inspection of the schools of Rochester began October 17 under the direction of the Rochester Public Health Association. The following five physicians have been designated by the association as medical inspectors: Drs. Samuel H. Rosenthal, Charles R. Witherspoon, William E. Dake, Frank T. Bascom and Michael L. Casey. Each of these will be put in charge of, and be held responsible for, the health of three schools.

Albany Alumni Meet.—The Central New York Alumni Association of Albany Medical College held its fourth annual meeting and banquet at Syracuse, September 28. Dr. Eli Van de Warker, Syracuse, officiated as toastmaster.—The annual meeting of the New England Branch of the Albany Medical College Alumni Association was held in Springfield, Mass., October 20. Dr. Albert Vander Veer delivered an address on "Recent Progress in Surgery." Dr. Thomas D. Crothers, Hartford, Conn., was elected president; Dr. Alva E. Abrams, Hartford, vice-president; Dr. Walter G. Murphy, Hartford, secretary, and Dr. Alfred H. Hoadley, Northampton, Mass., treasurer.

New York City.

Hospital for Ruptured and Crippled.—The report for the year just ended showed that more than 45,000 cases were treated in the hospital and outdoor department during the past year.

New French Hospital Open.—The French Benevolent Society has opened its new hospital on West Thirty-fourth Street, M. Jusserand, the French ambassador, and Mayor McClellan conducting the exercises.

St. John's Guild.—At the annual meeting of this association a plea was made for more funds. During the past season the Floating Hospital carried 27,826 babies and mothers, and the Seaside Hospital accommodated 2,256.

Annex for Consumptives.—The New York Post-Graduate School and Hospital has been given an adjoining house, which is to be converted into a hospital for the treatment of consumptives, and has been promised \$6,000 yearly for its maintenance.

Montefiore Home.—The annual report of this institution shows that 889 patients had been cared for during the past year, but the resources were not half equal to the demands made on it. A strong appeal for funds for a larger building was made.

Contagious Disease.—There were reported to the sanitary bureau for the week ended November 5, 344 cases of tuberculosis, with 150 deaths; 504 cases of diphtheria, with 23 deaths; 178 cases of scarlet fever, with 9 deaths; 91 cases of typhoid fever, with 10 deaths; 70 cases of measles, with 5 deaths; 72 cases

of variella, 2 cases of smallpox, and 5 deaths from cerebro-spinal meningitis.

The Air of the Subway.—Because of the comments of several physicians and the announcement of Prof. Adolph Spicer, chemist at Cooper Union, in regard to the condition of ventilation in the subway, Commissioner Darlington is about to make an investigation. Professor Spicer announced that after testing the subway air he had found it lacking in oxygen and that passengers had to breathe much more rapidly than above ground. Dr. Darlington has authorized Prof. Charles F. Chandler of Columbia University to make the tests for the Board of Health and to report.

PENNSYLVANIA.

Personal.—Dr. John W. Coffin, Beaver Falls, for 10 years major-surgeon of the Tenth Infantry, N. G. Pa., has resigned and will locate in El Paso, Texas.

Bequest to Chester Hospital.—The Chester Hospital has received a gift of \$15,000 from A. O. Deshong, to be used exclusively for the equipment of a laundry for the institution.

First Hospital for Consumptives in Western Pennsylvania.—Through the generosity of a resident of Oil City, western Pennsylvania will have its first modern hospital for the treatment of pulmonary tuberculosis opened November 21. The hospital is located on a large farm about three miles from Oil City, and at an elevation of 1,600 feet. At present 15 patients will be accommodated. Both charity and pay patients will be received. The treatment will be the same as that which has been so successfully carried out at White Haven, Pa. Application for admission can be made to Dr. Harvey E. Kirschner or Dr. Frank McCarthy, Oil City.

Philadelphia.

Smallpox at League Island.—One case of smallpox was discovered among the marines on the battleship *Alabama* at League Island. The patient was transferred to the Municipal Hospital and every effort is being made by the medical staff of the yard to prevent the further development of the disease. There are nearly 700 enlisted men on the battleship.

Personal.—Dr. Harry C. Deaver sustained a Colles' fracture October 29 by being struck with the crank of his automobile.

—Dr. Alfred Gordon was elected instructor of neuro-pathology and psychiatry in the Jefferson Medical College, vice Dr. William R. Pickett, resigned.—Dr. D. Forrest Harbridge has been elected visiting ophthalmologist to the Chester City Hospital.

Dinner to Dr. Cullen.—Dr. Wilmer Krusen gave a dinner in honor of Dr. Thomas Cullen of Johns Hopkins University, November 10. Among those present were Drs. Edward E. Montgomery, John G. Clark, Samuel Wolfe, Henry J. Walcott, Jr., of Springfield, Mass., J. Thompson Schell, Elmer E. Brown, I. Newton Snively, Charles S. Barnes, John C. Applegate and Frank C. Hammond.

Bequests.—By the will of Emma M. Thompson \$9,988 is divided equally between the Philadelphia Home for Incurables and the Children's Hospital.—By the will of Anna H. Wilsbach the Hospital of the Protestant Episcopal Church, the Episcopal Home for Consumptives, and the Pennsylvania Hospital receive \$6,000 each, and the Howard Hospital \$800.—By the will of Sallie Tuston the Methodist Episcopal Hospital receives \$500.

Alumni Election.—The annual meeting of the Philadelphia Alumni Association of the Medical Department of the University of Pennsylvania was held November 12. The following officers were elected: President, Dr. Jay F. Schamberg; honorary vice-president, Provost Harrison; vice-presidents, Drs. De Forest Willard, Edmund Holmes, John Marshall, O. H. Davidson and Joseph Gibbs; treasurer, Dr. Herbert B. Carpenter, and secretary, Dr. B. Franklin Stahl.

Health Report.—The records for the week show a rather large increase in the death rate, due largely to pneumonia and Bright's disease. The deaths from all causes during the week numbered 423, an increase of 37 over those of last week and 47 over the corresponding period of last year. There was a decided increase in scarlet fever, the whole number of cases reported being 105, as compared with 73 for the preceding seven days. Three deaths resulted from traumatic tetanus, 35 from disease of the kidneys, 70 from diseases of the lungs other than tuberculosis, and 52 from tuberculosis. In all there were 229 cases of contagious disease, with 13 deaths, as compared with 217 cases and 13 deaths for the preceding week.

TEXAS.

New Hospital at Temple.—The Santa Fe Employees' Hospital Association will erect a three-story brick hospital building at Temple, to cost \$24,000.

Wolff's Successor.—Governor Lanham has appointed Dr. J. H. Florence, Dallas, now at Aransas Pass, quarantine officer at Brownsville to succeed the late Dr. Arthur S. Wolff.

October Quarantine Fees.—The receipts of the State Health Department from quarantine fees for the month were as follows: Galveston, \$2,182; Sabine Pass, \$847; Brownsville, \$22; Aransas Pass, \$5; Velasco, \$2, and Pass Cavallo, \$2; total, \$3,060.

New Building for Medical Department.—The trustees of Southwestern University have decided to erect a new building at Dallas for the medical department of the university, to cost from \$60,000 to \$75,000 and to be ready in time for the opening of the college year in September, 1905.

Colleges Consolidate.—The Dallas Medical College has consolidated with the Baylor University College of Medicine, and the new institution will be known in the future as the Dallas College of Physicians and Surgeons (Medical Department of Baylor University). The combined matriculation will number 250 students. The new consolidation carries with it membership in the Southern Association of Medical Colleges. The majority of the members of each faculty will have places provided in the new institution.

GENERAL.

Southern Medical College Association.—This organization will hold its next annual session in the Hillman Hotel, Birmingham, Ala., December 12.

To Study Epilepsy.—The fourth annual meeting of the National Association for the Study of Epilepsy, etc., will be held in the medical library of the Fenway, Boston, November 22. The association invites all persons interested in the welfare of epileptics and in charity work generally to attend the meeting. The preliminary program which we have received indicates that the meeting will be an instructive one. The secretary of the association is Dr. William P. Spratling, Sonyea, N. Y.

Southern Surgical and Gynecological Association.—The seventeenth annual meeting of the Southern Surgical and Gynecological Association will be held at Birmingham, Ala., December 13-15. There will be reduced rates on all railroads of the Southeastern Passenger Association. The secretary of the association is Dr. W. D. Haggard, Nashville, and the chairman of the committee of arrangements, Dr. John D. S. Davis, Birmingham. The preliminary program is a very interesting one and covers the whole field of work of the association.

Consumption of Spirits, Beer and Wine.—The Department of Commerce and Labor, through its bureau of statistics, has published the following table, which shows per capita the consumption of the three kinds of beverages in the following countries:

Countries	Gallons.		Wine.
	Spirits.	Beer.	
United Kingdom	1.38	35.42	.39
France	2.51	7.48	34.73
Germany	2.11	30.77	1.93
Italy	.34	.20	31.86
Russia	1.29	1.13	...
Belgium	1.42	56.59	1.25
Sweden	2.13	8.83	.15
United States	1.33	18.04	.48

It is seen that France shows the heaviest consumption of the most concentrated beverage, spirits, viz., 2.51 gallons per inhabitant. The United States is well-nigh at the end of the list of spirits-drinking countries. Belgium stands at the head of the nations in the matter of per capita consumption of beer, its per capita consumption being 56.59 gallons. Second in order is the United Kingdom with 35.42 gallons, while Germany, which shows the largest absolute figures of consumption, in the matter of per capita consumption, takes third place with 30.77 gallons. The United States follows with 18.04 gallons, while Italy has .20 gallon. The consumption of wine may be said to be concentrated in two countries chiefly, France and Italy, both the absolute and per capita consumption showing that wine in these countries is a common article of consumption rather than an article of luxury, used only by the favored few. The figures of per capita consumption of wine in these countries—34.73 gallons in France and 31.86 gallons in Italy—are almost identical with those shown for beer by the United Kingdom and Germany. The consumption of wine in the other countries is relatively insignificant.

Transportation Rates to Cuba and Panama.—Dr. H. L. E. Johnson, Washington, D. C., in charge of transportation arrangements for the American Public Health Association at Havana, Cuba, and the fourth Pan-American Medical Congress, at Panama, January, 1905, writes that the only rates obtainable are the winter tourist rates for 1905, which apply either at Tampa or Miami, with stop-off privileges and limitation to May 31. Round trip from Montreal, Canada, to Tampa or Miami will be about \$107.50; Portland, Maine, \$103.50; Boston, \$96.50; New York City, \$86.50; Philadelphia, \$82.50; Pittsburg, \$78.40; Washington, D. C., \$76.50; St. Paul, \$84.60; Chicago, \$69; St. Louis, \$59; San Francisco, via New Orleans and steamer, one way, \$78. The Transcontinental Passenger Association grants nine months' tourist rate, about one and one-third regular fare, round trip, about 2 cents per mile. From California common points to Chicago and return \$110, plus tourist rates from that point to Havana. To St. Louis, Memphis, New Orleans and return, \$102, to which add tourist rate to Havana, for example, San Francisco to New Orleans and return, \$102, plus transportation by ship to Havana and return. From North Pacific common points and return, to Chicago, \$110; St. Louis, \$102; Memphis, \$111.60; New Orleans, \$117. From these points, for example, from New Orleans add the boat rate to Havana and return. Ward lines out of New York and return, \$75 round trip, meals and berth; one way, \$40. Diverse routes returning can be arranged. A special ship is promised, if 25 members take passage via New York, at a special rate of \$60. (Rates subject to change.) For a combination trip to Panama the Di Giorgio Steamship Company of Baltimore offers a trip with meals, berths and no extra expenses, for \$130, for the trip of about 26 days, provided at least 50 persons take passage. The steamship *Athos* will leave Baltimore December 24, 1 p. m., touching Jamaica and arriving Panama January 1. After adjournment of Pan-American Medical Congress, leave Panama January 6, evening, due Havana, January 8, evening. After adjournment of American Public Health Association, leave Havana January 13, arriving Baltimore, January 17. The ship will be for the exclusive use of the party. Full information will be furnished by Mr. Ralph F. Nolley, agent, 103 Park Avenue, Baltimore, or Dr. H. L. E. Johnson, chairman of transportation, 1821 Jefferson Place, Washington, D. C. The Panama Railroad Steamship line, of New York and Panama, advise trip to Panama and return direct, cabin, \$150 to \$200, according to location. Ship leaves New York every Tuesday. General office, 24 State Street, New York City. C. C. Van Riper, agent. These ships do not touch at Cuba or Havana going or returning. Panama can be reached via New Orleans by the United Fruit Company's steamers.

CANADA.

To Limit Tuberculosis in Montreal.—The Montreal city council will pass a by-law prohibiting spitting on the public walks, etc., with the aim of preventing the spread of tuberculosis.

Toronto New Consumption Hospital.—The National Sanitarium Association reports 40 patients received into its new consumption hospital near Toronto. The physician in charge is Dr. Allan H. Adams. The institution is free and advanced cases are being accepted. This hospital will be maintained by a per diem allowance from Toronto patients, by a government grant and by private subscription.

Toronto General Hospital Report for October.—This hospital reports: Patients in hospital September 30, 244; admitted in October, 229; births, 7; discharged, 212; deaths, 23; remaining in hospital October 31, 245. The death record includes ten cases brought to the hospital in a dying condition. Over 900 extra patients received advice and treatment in the outdoor departments, and nearly 200 cases received first aid at the emergency branch.

Vaccination Popular in Montreal.—The annual health report of Montreal shows that out of 90 persons who had smallpox last year, not one had been vaccinated during the past five years. Montreal is now a much better vaccinated city than it was a few years ago. The health department now has the co-operation of all schools and factories in the city in order to enforce vaccination. Civic officials who are at present going around the schools vaccinating report that they meet scarcely any opposition, whereas two years ago over 1,000 children refused to attend school because they had to submit to vaccination.

Ontario Physicians Transferred.—Dr. R. W. Bell, second assistant physician at the Asylum for the Insane, London, Ont.,

has been made medical inspector of the Ontario Board of Health. His position at London has been filled by Dr. W. C. Herriman from the Kingston asylum. Dr. McNaughton of London asylum has been transferred to Kingston. Dr. W. P. St. Charles of the Mimico asylum has been appointed relieving officer to public institutions in Ontario. Dr. George M. Biggs has been appointed assistant at Mimico. Dr. W. T. Wilson, third assistant at the Hamilton asylum, has been transferred to London asylum.

Caring for Insane in Jails in Ontario.—For a number of years the jails throughout the province of Ontario have had to do service in housing some of the insane of the province, the government claiming insufficient asylum accommodation. The cry against this housing insane people with criminals has been effective, and the government is removing all those suitable for asylum treatment. Each jailer is now required to make a special report to the government each month on the insane people under his charge, and a similar one to the superintendent of the asylum in his district. Thus it is sought to avoid the unnecessary detention of any insane in the county jails.

Annual Health Report of Montreal.—The mean annual death rate for the past eighteen years for the city of Montreal, leaving out that for 1885, the year in which the great smallpox epidemic prevailed, was 24.77 per 1,000, while the rate for 1901 was 23.25, and that for 1902, 22.58 per 1,000. The rate for 1903, 20.21 per 1,000, is 4.56 less than the mean rate for the preceding eighteen years; 3.04 per 1,000 and 2.37 per 1,000 less than 1901 and 1902 respectively. Tuberculosis caused less deaths than in preceding years. Before 1900 the number of deaths was 692; in 1901, 647; in 1902, 644; while in 1903 the number was 633. In 1903 there were 2 deaths caused by smallpox, or 8 less than in 1902; 77 by measles, or 7 less than in the preceding year; 24 by scarlatina, or 40 less than in 1902, 21 less than in 1901, and 108 less than in 1900. The deaths by diphtheria and diarrhea can not be compared, as they have been classified according to the new international system. Typhoid fever caused 90 deaths, or 4 more than in 1902. Bronchitis caused 224 deaths. Pneumonia, including bronchopneumonia, caused 528 deaths, or 16 less than in 1902.

FOREIGN.

Defective Teeth in the British Army.—In future men who are suffering from defective teeth will not be accepted as recruits until the decayed teeth are replaced with artificial ones. Men who would otherwise be discharged from the army for this cause will now have their teeth attended to, a certain sum being deducted from their pay for this purpose.

Pension for Finsen's Widow.—A bill has passed the Danish lower house, presented by a cabinet minister, awarding a pension of nearly \$1,000 to Finsen's widow. This is three times the pension given the widow of any state official. A subscription list is being circulated also to raise funds for a memorial to Finsen, signed by all the cabinet ministers, members of the legislature and editors of the country, besides many of his patients.

Official Denunciation of Quackery in Bavaria.—A recent official notice issued by the Bavarian government urges physicians and medical societies to watch for swindling ads. published by irregular practitioners and to institute legal proceedings against them. It concludes with the remark that the authorities must bear in mind that quack practices have become a serious evil in public life, to the injury of the interests of the public and of the medical profession, and that efforts to reduce this evil promote the public welfare.

Infant Mortality in Berlin.—The last summer was an unusually hot season in Europe, but the infant mortality in Berlin was kept below the average by vigorous efforts to insure a good milk supply. The total number of deaths during the summer months of children less than a year old was 4,425 in 1900, 4,454 in 1901, and 3,522 in 1904. About 60,000 circulars on the care of infants were distributed, and 48 veterinary surgeons formed a volunteer force to supervise conditions in dairies. The total infant mortality for the year will probably range about 10,000, but in 1900 it was 11,762. The population of Berlin is about 1,900,000.

Quacks in Mexico.—An editorial in the last *Escuela de Medicina*, xix, No. 19, states that nowhere in the world do quacks have such absolute liberty to ply their trade as in Mexico. No one interferes with them in any way, and the lay press teems with their advertisements. The editorial makes a solemn appeal to the government to protect the pub-

lic against their practices. It has grappled with the questions of drunkenness and gambling, and no one has complained that the freedom of the individual is incompatible with legislative restrictions on these vices. "Why should there be any more outcry if the government should seek to protect the people against the swindling practices of the quacks?" Several flagrant instances of the latter are cited.

LONDON LETTER.

Yellow Fever Expedition to the Amazon.

The Liverpool School of Tropical Medicine proposes to dispatch a second yellow fever expedition to the Amazon to investigate still further this disease. It may be remembered that the late Dr. Myers was selected by the school with Dr. Herbert Durham to undertake an expedition to Para to investigate the disease a few years ago. They were both attacked by the fever and Dr. Myers died. The expedition will probably start at the end of the year.

Correspondence.

The Alma Sanitarium and Dr. Butler.

CHICAGO, Nov. 11, 1904.

To the Editor:—As former medical superintendent of the Alma Springs Sanitarium, Alma, Mich., I desire emphatically to deny certain reports to the effect that there were unpleasant and unsatisfactory relations existing between the sanitarium company and myself. I have nothing but commendable words to say of the institution, its management and of Dr. Raymond C. Turck, its present medical superintendent and business manager. He is a well-qualified physician and surgeon, and the institution is everything that is claimed for it.

Geo. F. BUTLER, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

SECRET METHODS OF TREATMENT.

EL PASO, TEXAS, Oct. 29, 1904.

To the Editor:—Kindly tell me through your columns what, if any, standing the "Ensor" treatment for inebriety has with the medical profession. I understand it is a secret system of treatment, and therefore inimical to the best interests of our profession. 2. Would a doctor hired by the company to administer this treatment, and who is giving the treatment, knowing it to be a secret form of treatment, i. e., administering drugs the nature of which he is ignorant, be eligible to membership in an affiliated society of the American Medical Association, a county society, for example?

X. Y. Z.

ANSWER.—1. We know nothing of it. 2. Not if the members of the county society to which he applies do their duty to themselves and to the profession.

TENTS AND HOUSES FOR CONSUMPTIVES.

LOWELL, IND., Nov. 10, 1904.

To the Editor:—Where may I find plans for an adequate frame building for the outdoor treatment of a tubercular patient? Where may a suitable tent be obtained for the same purpose?

A. J. WILLIS.

ANSWER.—An illustrated description of a frame building for consumptives appeared in THE JOURNAL, May 7, 1904, p. 1232; an excellent tent was fully described and illustrated in THE JOURNAL, Dec. 26, 1903, and methods of adapting porches for this purpose are illustrated in the *Illinois Medical Journal* (Springfield), October, 1904. Further, some tents are mentioned in the report of the Maryland Tuberculosis Exposition, described in THE JOURNAL, Feb. 6, 1904, p. 391. You ask for plans. None of the above gives what are called architects' plans. Such are probably unnecessary because of the simplicity of the building. Any carpenter competent to take charge of the erection of such a building can draw sufficient diagrams.

PRIVATE PRACTICE BY SURGEONS OF THE ARMY, ETC.

To the Editor:—1. Is a medical officer of the United States Army or of the United States Public Health and Marine-Hospital Service legally qualified, without having complied with the special medical

laws of the state or territory wherein he may be stationed, to engage in private practice? 2. Is it customary to treat such officers as legally qualified practitioners and to allow them to engage in private practice without undergoing the examination? 3. Is such an officer eligible to membership in an affiliated society without having complied with such state or territorial laws? X.

ANSWER.—1. No, unless the laws of the particular state make an exception in such cases. 2. Yes, this custom is very general in states whose laws do not provide for the case. When a physician leaves one of the services he is, we suppose, treated as an ordinary physician, subject to examination. 3. Officers of the medical departments of the Army, of the Navy and of the Public Health and Marine-Hospital Service are eligible to membership as such.

DURATION OF LICENSE TO PRACTICE.

CHICAGO, Nov. 9, 1904.

To the Editor:—1. Does a license to practice in Indiana, granted in 1895, entitle the holder to practice in that state now without an examination? 2. Give address of secretary of the American Confederation of Reciprocal Examining and Licensing Medical Boards.

T. ANSWER.—1. Yes. 2. Dr. L. D. Harrison, Sault Ste. Marie, Mich.

BOOKS ON CLIMATOLOGY.

ROCHESTER, N. Y., Nov. 13, 1904.

To the Editor:—Kindly inform me of the names and where I may obtain the latest and best books on climatology?

A. C. REMINGTON.

ANSWER.—This query was answered in THE JOURNAL, March 19, 1904, p. 784.

Marriages.

BURTON WELLES, M.D., Toledo, Ohio, to Miss Edna Myers of Tiffin, Ohio, November 1.

BENJAMIN DORES PARISH, M.D., to Miss Helen Griffith, both of Philadelphia, November 16.

EVERETT H. BUTTERFIELD, M.D., Ottawa, Ill., to Miss Letitia Rothwell, in Chicago, November 3.

FREDERICK L. OSGOOD, M.D., to Miss Blanche M. Osgood, both of Saxton's River, Vt., October 26.

CLARENCE B. WEAN, M.D., Lorain, Ohio, to Miss Edith Anna Griswold of Kinsman, Ohio, October 12.

FRANK CLIFFORD CARLE, M.D., Garrison, Iowa, to Miss Georgia Wilson of Weltman, Iowa, October 7.

ORA K. MCKITTRICK, M.D., to Miss Susette Harper of Plainville, Ind., at Terre Haute, Ind., November 3.

BRUCE B. EVERALL, M.D., Monona, Iowa, to Miss Myrtle Trumpler of Des Moines, Iowa, November 16.

HARRY JACOB JONES, M.D., North English, Iowa, to Miss M. Gertrude Downing of Wellman, Iowa, November 9.

CLARENCE JOSEPH MCCUSKER, M.D., Portland, Ore., to Miss Clare Alena Campbell of West Newton, Iowa, October 26.

Deaths.

DeWitt Clinton Wade, M.D. Albany (N. Y.) Medical College, 1860, of Holly, Mich., a member of the American Medical Association; given an honorary degree by the University of Michigan in 1902; local surgeon of the Grand Trunk Railway; superintendent of the Holly Hospital; member and acting president of the Oakland County Medical Society; member of the Michigan State Medical Society, died in a hospital at Flint, Mich., from appendicitis, after operation, November 4, aged 68.

William H. Huntington, M.D. University of Vermont, Burlington, 1881, a member of the American Medical Association; for several years brigade surgeon in the Vermont National Guard, and surgeon general on the staff of Governor Stickney; president of the Vermont State Medical Society in 1900, died at his home in Rochester, Vt., from appendicitis, November 7, after an illness of three days, aged 47.

James Anthony Dibrell, M.D. Department of Medicine University of Pennsylvania, Philadelphia, 1870, a member of the American Medical Association and vice-president in 1901; twice president of the Arkansas Medical Society; a member and once president of the Little Rock Medical Society; for 15 years physician to the Arkansas Deaf Mute Institute; one of the founders of the Medical Department of the University of

Arkansas, dean since 1884, and professor of anatomy in that institution; secretary of the State Board of Health from 1879 to 1881; vice-president of the Sanitary Council of the Mississippi Valley, and one of the foremost surgeons of Arkansas, died at his home in Little Rock, November 12, from pneumonia, after an illness of one week, aged 58.

Charles H. Potter, M.D. Baltimore Medical College, 1898, a member of the American Medical Association; formerly connected with the Johns Hopkins Hospital; who had made a specialty of microscopic photography for medical works in which his reputation was international, and more recently was in charge of the micro-photographic department of the Tuberculosis Exposition held in Baltimore, died suddenly at his home in Baltimore, November 9, aged 50.

Abner D. Kimball, M.D. Rush Medical College, Chicago, 1860, assistant surgeon in the Forty-eighth and later in the Ninety-ninth Indiana Volunteer Infantry; some time president of the Grant County (Ind.) Medical Society; chief surgeon at the National Home for Disabled Volunteer Soldiers at Marion, Ind., died at his home in that place, November 11, from diabetes, aged 65.

Henry E. Allison, M.D. Dartmouth Medical College, Hanover, N. H., 1878, medical superintendent of the Matewan State Hospital for the Insane, a member of the American Medicopsychological Association and Medical Society of the State of New York, died at his home from Bright's disease, after a long illness, November 12, aged 53.

W. S. Noblitt, M.D. Hospital College of Medicine, Louisville, who, after a controversy with the local board of health, secured a license to practice by order of the Supreme Court, died at his home in Honolulu, Hawaii, October 19, from typhoid fever, after an illness of one month, aged 36.

Charles H. Ludlow, M.D. Medical College of Ohio, Cincinnati, Ohio, 1902, who was found insensible at Hyatt Station, Ind., November 9, having been drugged, sandbagged and robbed of \$5,000, died from concussion of the brain at his home in Covington, Ind., November 10.

Thomas L. Laliberte, M.D. Laval University Medical Department, Quebec, 1876, a member of the American Medical Association; prominent as a physician and politician, died at his home in East Minneapolis, Minn., November 5, after an illness of five months, aged 53.

Augustus George Holloway, M.D. Cleveland Medical College, 1854, assistant surgeon in the Fifty-first and One Hundred and Ninety-seventh Ohio Volunteer Infantry in the Civil War, died at his home in Deatur, Ind., November 4, after an illness of 18 months, aged 75.

D. Morrow Barrere, M.D. Miami Medical College, Cincinnati, 1878, a member of the American Medical Association, a prominent practitioner of Dayton, Ohio, died at his home in that city from pneumonia, November 5, after an illness of ten days, aged 54.

Frederick Lefew, M.D. University College of Medicine, Richmond, Va., 1900, a member of the Medical Society of Virginia and the Roanoke Medical Society, was stabbed in the breast two weeks ago, and died at his home in Roanoke, November 15.

Jacobs Pollatsek, M.D. Royal University, Buda Pesth, Hungary, 1878, some-time quarantine officer at Cairo, Egypt, died at the Harbor Emergency Hospital, San Francisco, presumably from poison self administered, November 6, aged 63.

Charles G. Cruickshank, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1876, local surgeon for the Santa Fe system, died suddenly from heart disease at his home in San Marcial, N. M., October 12.

Caleb F. Farrar, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1846, an officer in the Confederate service during the Civil War, died at his home in Kingston, Miss., November 3, aged 80.

Littleton R. Tull, M.D. McDowell Medical College, St. Louis, Mo., 1848, died at his home in Carrollton, Mo., where he had practiced for more than half a century, November 6, after an illness of several months, aged 83.

Frederick A. Treacy, M.D. College of Physicians and Surgeons, Chicago, 1901, a member of the American Medical Association, of Lewistown, Mont., died at Helena, Mont., from tuberculosis, October 21, aged 30.

J. Wallace Collins, M.D. Denver (Colo.) College of Medicine, 1888, formerly county physician and health officer of Teller, surgeon in the national guard, died at his home in Victor, Colo., October 31, from apoplexy.

Charles N. Branch, M.D., Jr. Medical College of Ohio, Cincinnati, 1891, of Anderson, died from tuberculosis at Wickenburg, Ariz., where he went for his health two years ago, October 29, aged 32.

Franklin S. Whaley, M.D. Berkshire Medical College, Pittsfield, Mass., 1844, who retired from practice about ten years ago, died recently at his home in Compton, Cal., aged 85.

Frederick Schade, M.D. University of Tübingen, Germany, 1852, a retired physician of St. Louis, died at his home in that city, October 18, from heart disease, aged 79.

William Bray, M.D. Iowa, 1886, of Dubuque, Iowa, died at Mercy Hospital in that city, November 8, from typhoid fever, after an illness of three months, aged 46.

Guilford H. Gunter, M.D. Department of Medicine of the University of Pennsylvania, 1881, died at his office in Camden, N. J., November 5, from uremia, aged 50.

Cassius L. Gurney, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1878, died suddenly at his office in Doon, Iowa, from apoplexy, November 5, aged 62.

Rufus A. Shimpoch, M.D. Long Island College Hospital, Brooklyn, N. Y., 1860, died at his home in Gold Hill, N. C., October 30, from Bright's disease.

Cassius W. Hare, M.D. Medical College of Virginia, Richmond, 1886, died suddenly from apoplexy at his home in Brentsville, Va., November 10.

John William Knight, M.D. Albany, (N. Y.) Medical College, for many years a practitioner of Walpole, N. H., died at Farmington, N. H., aged 82.

John Kerr, M.D. Western Reserve Medical College, Cleveland, 1848, died at his home in Cedar Falls, Iowa, November 8, after a brief illness, aged 85.

Henry L. Shireman, M.D. Toledo (Ohio) Medical College, 1885, died at his home in Nazareth, Pa., from paralysis, November 5, aged 63.

David A. Wood, M.D. Cleveland Medical College, 1872, died at his home in Norwalk, Ohio, after a long illness, October 30, aged 72.

J. Milton Welch, M.D. Ohio, 1878, died at his home in Los Angeles, Cal., November 6, after an illness of four months, aged 70.

William H. Oliver, M.D. University of Victoria College, Coburg, Ont., 1866, died at his home in Chicago, November 9, aged 80.

H. B. Pittman, M.D., died at his home in Hillsdale, Pa., October 26, after a lingering illness, from dropsy and paralysis, aged 69.

William H. Gardner, M.D. Bellevue Hospital Medical College, New York City, 1873, died at his home in Rockwood, Pa., October 29.

George Walton, M.D. New York University, New York City, 1873, died at his home in St. Louis, Mo., November 8, aged 55.

Arthur Young, M.D. Rush Medical College, Chicago, 1853, died at his home in Prescott, Wis., October 20, aged 75.

John B. Wilson, M.D. Ohio, 1853, died at his home in Mansfield, Mass., October 31, aged 71.

Nathan M. Smith, M.D., was shot and killed in a quarrel in Washington, Kan., October 31.

Charles W. Arnold, M.D. Ohio, 1850, died at his home in East Townsend, Ohio, October 26.

Thomas C. Quinn, M.D., died at his home in New Vienna, Ohio, October 30, aged 75.

William Kean Foltz, M.D. Ohio, 1859, died at his home in Akron, Ohio, November 9.

Deaths Abroad.

P. Tillaux, M.D., professor of clinical surgery at Paris, president of the Académie de Médecine, co-editor of the *Tribune Médicale* and author of a popular manual of topographic anatomy, died at Paris, October 20, aged 70.

C. Milone, M.D., professor of anatomy at Buenos Ayres since 1884, when he left a similar position in Rome to make his home in Argentina, died at Buenos Ayres, September 30, aged 60.

M. Bartels, M.D., one of the most prominent physicians in Berlin and author of several important medico-anthropologic and ethnologic works, died at Berlin, October 22, aged 61.

C. H. Huppert, M.D., professor of medical chemistry at Prague until 1901, died there October 19, aged 73.

Book Notices.

FOOD INSPECTION AND ANALYSIS, for the Use of Public Analysts, Health Officers, Sanitary Chemists and Food Economists. By Albert E. Leach, S. H., Analyst of the Massachusetts State Board of Health. First Edition. First Thousand. Cloth. Pp. 787. With 120 Figures and 40 Full page Half-tones. Price, \$7.50. New York: John Wiley & Sons. London: Chapman & Hall, Limited. 1904.

The fact is generally familiar to those concerned with public health matters that Massachusetts was the pioneer in establishing, some twenty years ago, a practical system of food and drug inspection. It is also universally recognized that the Massachusetts State Board of Health has in various ways given a powerful impetus to sanitary work of all kinds. Its activity has been displayed both in the original investigation of scientific problems and in the promotion of the publication of books and monographs dealing with the various undertakings in which it has been engaged. The present work on food inspection and analysis must rank as one of the most important that has issued from its laboratories. The book deals with the following topics: Food analysis and state control; the laboratory and its equipment; food, its functions, proximate components and nutritive value; general analytical methods; the microscope in food analysis; milk and milk products; flesh foods; eggs, cereals, legumes, etc.; tea, coffee and cocoa; spices; edible oils and fats; sugar and saccharine products; alcoholic beverages; vinegar; artificial food colors; food preservatives; artificial sweeteners; canned vegetables and fruits products; flavoring extracts. Considerable attention is devoted to the use of the microscope in food analysis. Well-chosen figures illustrating the microscopic structure of powdered tea, coffee, cocoa and the spices appear in the text, and a valuable set of photomicrographs (40 plates) is appended to the volume. The book is no mere literary compilation. The methods that it details have been mastered rather than copied, and we are given the full benefit of a wide, first-hand laboratory experience. It is not too much to say of the work that it takes its place at once as the authoritative standard in the English language.

A MANUAL OF GENERAL EXPERIMENTAL PATHOLOGY, for Students and Practitioners. By Walter Sydney Lazarus-Barlow, B.A., B.C., M.D., F.R.C.P., Director of the Cancer Research Laboratories of the Middlesex Hospital. Second Edition. Cloth. Pp. 736. Price, \$6.50 net. Philadelphia: P. Blakiston's Son & Co. 1904.

During the five years that have elapsed since the appearance of the first edition of this book, the advancements in pathology, particularly along certain lines, have made it necessary to practically rewrite much of the work, and this is what the author has done. The greatest changes are in the chapters on the pathology of the blood, on inflammation and on the pathology of infection and immunity. The need of a more uniform classification of the varieties of leucocytes is apparent, as the terms applied to the same kind of cell by different writers are confusing to one, not perfectly familiar with the subject. The greatest advancements in the future are to be hoped for along clinical lines, hence "The Pathology of the Blood Plasma" forms a very interesting chapter. The modern conception of infection and immunity as set forth by Ehrlich in his side chain theory is well presented. The various theories concerning the etiology of carcinoma and sarcoma, about which so much interest has centered of late, are clearly stated, and while the author leaves the matter still an open question, it is plain that he leans toward the non-parasite side. The illustrations are few in number, only 33, but the clearness of the text makes up largely for the deficiency. The general makeup of the volume is good.

HEALTH, STRENGTH AND POWER. By Dudley Allen Sargent, A.M., Sc.D., M.D., Director of Hemenway Gymnasium, Harvard University. Illustrated. Cloth. Pp. 276. New York and Boston: H. M. Caldwell Co.

This very readable book discusses the universal need for exercise, how and where it should be taken, what kinds are best for all ages and ends with a complete system of fully illustrated movements for individual use without apparatus. They will not particularly interest the athlete or the one who already has access to means of exercise; to one of sedentary habits they are to be recommended. The author's competency to speak on the subject leaves nothing to be desired. He adds

excellent advice as to bathing and food. Although an enthusiastic advocate of athletic sports for women, he cautions that their standards should be carefully maintained far below those of men and highly competitive matches avoided. The latter, he says, develop women away from some of their most desirable feminine qualities. In speaking of golf as a valuable sport for women he refers to its power in making the waist and abdomen more fit for the requirements of child birth. The publishers have made the book very presentable. Either they or the author are responsible, however, for the ancient spelling: "vigour," "odour," "favour," "labour," which look very odd in this country.

DISEASES OF THE NOSE AND THROAT. By D. Braden Kyle, M.D., Professor of Laryngology and Rhinology, Jefferson Medical College, Philadelphia. Third Edition. Thoroughly Revised and Enlarged. With 175 Illustrations and 6 Chromo-lithographic Plates. Cloth. Pp. 669. Price, \$4.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

This edition of this very valuable work contains a number of important additions to the previous ones. The chief changes made are in the chapters on "Keratoses," "Epidemic Influenza" and "Correction of Nasal Deformities by the Paraffin Method." "Hay Fever" and "Septal Deformities" are treated more fully than in the last edition. Of special interest is the consideration of the chemistry of the salivary and nasal secretions. The author believes that much can be determined in regard to the chemistry of the tissues by an examination of a physiologic secretion such as the saliva and that much may be accomplished in the cure of certain diseases by correcting abnormal chemical conditions, notably hyperacidity and hyperalkalinity, the former of which he usually overcomes by free administration of benzoate of soda and the latter by boric acid. It is impossible to do justice to his views in a brief space, consequently the reader is referred to the article with the promise that a careful perusal will more than repay him.

THE THEORY AND PRACTICE OF INFANT FEEDING, with Notes on Development. By Henry Dwight Chapin, A.M., M.D., Professor of Diseases of Children at the New York Post-graduate Medical School and Hospital. Second Edition, Revised. With Numerous Illustrations. Cloth. Pp. 312. Price, \$2.25. New York: Wm. Wood & Co. 1904.

The first portion of this book differs somewhat from other books on infant feeding. Dr. Chapin has made comparative studies of the digestive tracts of young animals and concludes therefrom that the digestive system of each animal is particularly suited to its natural food and that as the digestive tracts of young animals must be, in a general way, like that of their parents, the milk of one animal is not suited for the young of another species. Dr. Chapin considers that the trouble caused by the substitution of some other milk in infant feeding is probably due to the difference in the digestive system. In part 2 Dr. Chapin gives simply and practically the various methods of testing milk, etc. Part 3, on "Practical Feeding," comprises the care and diet of the mother and directions for preparing infants' food. Part 4, "The Growth and Development of Infants," contains tables of measurements and weight of infants at different ages. The book is comprehensive and practical.

THE MOTHER'S MANUAL. A Month by Month Guide for Young Mothers. By Emelyn Lincoln Coolidge, M.D., Visiting Physician of the Out-patient Department of the Babies' Hospital, New York. Illustrated. Cloth. Pp. 262. Price, \$1.00 net. New York: A. S. Barnes & Co. 1904.

Among "mothers' guides" this book may be distinguished by its simplicity. Some matters seem to the young mother too simple to ask the physician or even a lay friend about and so she blunderingly worries along—unless she possesses a book which, like the one discussed, tells every little detail. The book is almost too full and may tempt some mothers to depend on home treatment too much. We certainly do not approve of the mention in such a book of preparations containing 17 and 20 per cent. of alcohol with the statement that they are of value between meals for infants and children with marasmus, etc., especially in view of the danger that the mother will take into her own hands the prescribing and administering of them. On the whole, however, Dr. Coolidge brings out very clearly at what times the mother should call a physician, how she should carefully follow his advice and that she should be

ware of patent medicines, which "have no place in the household."

A TEXT-BOOK OF HUMAN HISTOLOGY. Including Microscopic Technic. By Drs. A. A. Böhm and M. von Davidoff, of Munich, and G. Carl Huber, M.D., Professor of Histology and Embryology in the University of Michigan, Ann Arbor. Second Edition, Thoroughly Revised and Enlarged. With 376 Original Illustrations. Flexible Cloth. Pp. 525. Price, \$3.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

The second edition of this valuable text-book on histology appears in a form which is a great improvement over that of its predecessor. Although the text has been added to and the number of illustrations increased by 26 new plates, the volume is only half the thickness of the first edition, owing to the light paper and the flexible cover. The additions to the text are found chiefly in the sections dealing with histologic technic, but there is also a new section on the hemolymph glands, giving the results of Warthin's researches. The section on neuroglia is also enlarged. The new illustrations, many of them from Sobotta's atlas, show a tendency toward realism which is highly to be commended in a book designed for students.

CLINICAL DIAGNOSTIC BACTERIOLOGY, Including Serum Diagnosis and Cyto diagnosis. By Alfred C. Coles, M.D., D.Sc., F.R.S. Edin. With Colored Plates. Cloth. Pp. 237. Price, \$2.75 net. London: J. and A. Churchill. Philadelphia: P. Blakiston's Son & Co. 1904.

As is indicated in the title, this book is intended for the use of the clinician, but it inclines strongly toward the laboratory rather than the clinical side of diagnosis. The author has endeavored to place before the reader the methods of examination best adapted for practical diagnostic purposes, and has also included an account of some research work made by him on the acid-fast bacteria. Unfortunately for the practitioner too much space (about one-third of the book) is devoted to this subject, although it will prove of interest to the research worker. Such bacteriologic examinations as involve elaborate investigation, such as cholera and glanders, have been omitted entirely; and, judging from its omission, we presume the author included the typhoid bacillus in this class, an opinion to which we wish to take exception. There is also a short account of serum diagnosis and cyto-diagnosis, but not sufficient to be of more than passing interest.

HAND-BOOK OF PHYSIOLOGY. By W. D. Halliburton, M.D., F.R.S., Professor of Physiology, King's College, London. Nineteenth Edition, with Nearly Seven Hundred Illustrations, Including Some Colored Plates. Cloth. Pp. 901. Price, \$3.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

Considerable changes in the arrangement of the exercises have been made in this edition. A new first lesson on the detection of the elements contained in substances of physiologic interest has been added, and the fats, which were somewhat meagerly treated in former editions, have now been made the subject of a separate lesson. Many new exercises have been inserted in other places, and the advanced lessons on milk, pancreatic digestion, muscle and Kjeldahl's method have been rewritten, bringing the work abreast of advances in science without detracting from its value as a serviceable and practical laboratory guide.

A COURSE IN QUALITATIVE INORGANIC CHEMISTRY. By Arthur L. Green, Ph.D., M.D., Ph.D., Dean and Professor of Chemistry, School of Pharmacy, Purdue University, and Charles E. Vanderkleed, Ph.C., B.S., A.C., Analytical Chemist with the H. K. Mulford Co. Fourth Edition. Cloth. Pp. 158. Lafayette, Ind.: Arthur L. Green.

This little book is a well-arranged laboratory manual, one which will be received with a full measure of appreciation by the student. It is provided with a thumb index, part of which can be used from before backward and vice versa.

Miscellany.

Syme's Staff.—In Dr. Parker Sym's article on Prostatic Obstruction in *THE JOURNAL*, November 5, page 1381, a typographical error made "Syme's staff" read Sym's staff.

Legible Type on Labels.—Mr. W. Bodeman of Chicago, president of the State Board of Pharmacy, in the *Practical Druggist*, calls the attention of manufacturers to the small type in

which it is customary to print the dose stated on bottles of hypodermic tablets, granules, small pills and similar goods. He says that it requires a microscope in some cases to distinguish between 1/3 and 1/8 grain, or between 1/10 and 1/100 grain, and thinks the figures should be large and distinct. He also calls the attention of manufacturers of synthetic preparations to the desirability of stating on each package the solvent of the chemical, its dose and whether or not it is hygroscopic.

Rhythmic Nose-Pulling as a Resuscitating Measure.—Young ladies will not consider it so genteel to faint, now that Panyrek of Prague has announced that vigorous pulling of the nose should be tried as a means of reviving persons in a faint or asphyxiated from any cause. He explains its effect as due to reflex stimulation of the vasomotor nerves of the cortex and the centers of respiration and circulation by the energetic, rhythmical movements of the nose upward and downward, repeated several times. The sudden stimulation of the sensory nerves thus effected is reflected to the vasomotor nerves above and the respiratory and circulatory centers. The principle is somewhat similar to that of rhythmic traction of the tongue, which is now a widely adopted means of resuscitation.

Jamaica as a Health Resort.—Dr. E. E. Lewis, in a recent issue of the *Journal of Balneology and Climatology* advocates the claims of Jamaica as a health resort. He says that the tradition attaching to Jamaica as an unhealthy station is rapidly being dissipated, and the pretensions of this beautiful island to be regarded as a health resort are meeting with many advocates. Of the total area of the island more than half is 1,000 feet above sea level. Cool nights, a temperate wind—"the doctor" as it is termed—and an equable climate go far to commend Jamaica to both the sick and the well. Mineral springs at Bath, some forty-five miles from Kingston, possess the same mineral constituents (but in larger quantities) as those of Aix-la-Chapelle, Baresges and Bagnères de Leuchon.

Open-Air Treatment for Tubercular Children.—The *American Journal of Nursing* states that the open-air treatment of tuberculosis is being tried at the Children's Hospital, Boston. A shack, twenty by forty feet, lighted by ten windows which open like a transom, has been built at Wellesley Hills and connected by a covered passageway with the temporary building used as the convalescent home of the Children's Hospital. The windows are kept open day and night. The children sleep in flannel night gowns, flannel night caps, woolen bed socks and between blankets. In the daytime they wear flannel underwear, dresses, sweaters and woolen hoods. There has not been a case of sore throat or cold in the head and the appetites of all have improved. The children are those who have been treated in the hospital for tubercular disease of the joints and bones, and tubercular empyema and peritonitis.

Anatomic Proof of Healing of Military Tuberculosis Under Tuberculin.—Spengler of Davos writes to the *Zft. f. Hyg. und Inf.-Krankheiten*, XLVII, 1, to describe a healed case of military tuberculosis of the lungs. The patient was a consumptive belonging to a tuberculous family. In 1890 there was a military dissemination of the tuberculosis over the hitherto exempt portions of the lungs. He was treated by tuberculin in stages, the "Etappen-Tuberculin" treatment, and was apparently completely cured after the sixth series of injections, which closed in August, 1904. He succumbed a few months later to a brain affection, probably an abscess. Examination of the lungs alone was allowed. The lung process had entirely healed. Each single nodule was found enclosed in a wall of connective tissue or surrounded by a rampart of leucocytes. Not a trace of tubercle bacilli could be discovered.

Alcohol Dressings for Superficial Lesions.—A. Puhf of Hanover lauds the Salzwedel method of alcohol applications as the simplest, cheapest and best method of treating cutaneous superficial wounds, inflammations of connective tissue, swollen glands, furuncles, inflamed periosteum and bursa, and also for deep lying lesions, inflamed joints, glands and body cavities. He finds that 40 to 50 per cent. alcohol displays much

the strongest bactericidal power. Fluid alcohol does not penetrate deep into the tissues, but applied in the form of compresses covered airtight the fumes of the alcohol have great penetrating power. He writes from an experience of 117 cases thus treated. Leutz has always found the alcohol dressings an effective mode of treating chilblains. A piece of gauze folded in eight thicknesses is moistened with 70 per cent alcohol, applied to the part and covered with a piece of perforated oiled silk or rubber tissue, the whole held in place with a bandage.

Effects of Deprivation of Salt on the Nerves.—Vincent has been making a systematic study of hyperchloridation and hypochloridation in various nervous affections. He found that 12 to 15 gm. of salt taken by hysterics in addition to their usual food, invariably aggravated their nervous symptoms and caused an outbreak of symptoms in the latent cases. Diarrhea and vomiting were sometimes noted, much relieving the patients by the evacuation of the excess of salt. It seems to affect latent hysteria in the same way as alcohol, lead, mercury or other poisons, aggravating pre-existing morbid nervous tendencies. Claude has been studying the effect of deprivation of salt in health, and has become convinced that the intake of salt has a much greater influence on the nutrition than has been hitherto recognized. Cramps, dyspeptic troubles, lassitude and incapacity to work were noted during the five days of hypochloridation, while the restoration of the usual modicum of salt rapidly restored conditions to normal. Their research was reported to the Paris Soc. Méd. des Hôp., July 8, and they theorized to explain the effects observed, advocating a trial of transient deprivation of salt in certain nervous affections, especially in hysteria.

Lumbar Puncture in Headache of Bright's Disease.—Legrain quotes P. Marie and cites a case from his own experience to demonstrate the benefit liable to be derived from lumbar puncture in case of the persisting headache of advanced Bright's disease. It has also proved beneficial in the headache of lead poisoning. In a communication to the *Progrès Médical*, XXXII, 44, he reiterates that lumbar puncture may be repeated without danger several times in succession at intervals of two to four weeks. It causes no disturbance if done aseptically, with a fine, sharp needle, the subject reclining for two or three hours afterward. His patient was a worker on copper, 56 years old, the diagnosis being uremia with vertigo and epileptiform seizures followed by transient cerebral disturbances. An attack of almost intolerable headache recurred every day, or rather night, sometimes as many as two or three in the twenty-four hours. After failure of all other measures about 12 c.c. of cerebrospinal fluid were withdrawn by lumbar puncture. There was no hypertension, the fluid escaped a drop at a time, the patient seated. Seven punctures were made in all, the patient clamoring for them when the headache became unendurable. Each was invariably followed by subsidence of the pain for two days at least. The amount of fluid withdrawn ranged from 12 to 15 c.c. The epileptiform seizures became much less frequent after the second puncture. As the cerebrospinal fluid in this case never showed signs of abnormal pressure, the benefit from the punctures must be ascribed to its extra toxicity. In the other cases on record the fluid escaped under pressure and the relief from pressure was evidently a factor in the benefit derived.

Veratrum Viride in Puerperal Eclampsia.—Dr. René de Coctret eulogized this method of treatment of puerperal eclampsia in a communication to the Congress of French-Speaking Physicians at Montreal in June. He says that he has never had a mishap from its use, but has found it decidedly beneficial. He insists that it is free from danger, even when large doses are given, provided the patient is kept in the horizontal position. He uses the fluid extract or tincture, and always by hypodermic injection. The dose varies according to the pulse. With a pulse of 120 or over, he gives, at once and without fear, from 20 to 25 drops of the fluid extract; with a pulse of 100 he gives 20 drops. If the pulse is below 100 he never

gives less than 10 drops for the first dose. About thirty-five minutes are required for the drug to exert its principal action and slow the pulse. The pulse must be reduced below 60 to control the convulsions. Even at 60 they sometimes reappear. If the pulse is not down to 56 or 50 by the end of thirty-five minutes, a further injection of 5 to 10 drops should be made. It is truly astonishing, he remarks, the way in which the pulse drops and the convulsions cease in response to the injections. When the convulsions are frequent and keep up before the drug has had time to work, he gives a few whiffs of chloroform as a convulsion commences, to tide the patient over this interval. She must be kept under the influence of the veratrum, that is, the pulse must be kept under 60, for twelve to twenty-four hours. If the pulse becomes too slow, 25 to 30 beats, a stimulating injection, preferably of morphin, one-fourth of a grain, will accelerate it at once. The Italians have lately been using veratrum viride in eclampsia with equal confidence and good results, especially the Florence school.

Ligature of Subclavian Artery in Aneurism.—De Garay was the first surgeon in Mexico to extirpate the sac in treatment of aneurism, his first case dating from 1893. The aneurism in this instance was in the femoral artery. He has since perfected a method of ligating the subclavian artery which he has successfully performed in 3 cases of traumatic aneurism of the axillary artery. It is a modification of the Lisfranc technique and he describes it in detail in the *Escuela de Medicina*, XVIII, No. 17. He advocates it as a less serious operation than extirpation of the sac, while the results show that it is harmless and answers the same purpose. He reaches the subclavian artery by a vertical incision 5 to 6 cm. long, about 1 cm. inside of the center of the clavicle, supplemented by a short perpendicular incision, thus forming an L, avoiding the external jugular vein. The inner lip of the incision is then detached back to the margin of the sterno-mastoid. The aponeurosis is then incised, or cut with scissors, below the omohyoid muscle, without opening the sheath of the subclavian vein. By this means the external jugular may be safely drawn to one side of the field of operation and the subclavian vein is protected by the fascia. It is advisable to remove any ganglia and fatty tissue obstructing the view. He commences by outlining the external jugular, making his incision inside of it, and thus leaving it undisturbed in the flap, while the subclavian vein is likewise undisturbed in its sheath, neither coming into view during the operation. The field is well exposed, and the space between the scaleni, the nerves passing to the brachial plexus, etc., are readily recognized. The subclavian artery can then be easily ligated, no forceps being required in his 3 cases nor the slightest inconvenience encountered, even in the cases of much tumefaction of the axillary artery. The pains were reduced almost at once, and the member did not grow cold nor exhibit signs of gangrene in any instance. The wound was 6 cm. deep, but rapidly healed. The ligature thread fell off the tenth day.

The Surgical Conscience.—At the meeting of the Montreal Medical Society of March 22, Dr. Coytex-Prevost of Ottawa delivered an address, but instead of recounting his successes as a surgeon, he reviewed the fatalities in about a thousand operations. Fifty-nine deaths in all, the patients succumbing notwithstanding or on account of the operation. The largest percentage was in cases of acute obstruction of the intestines, and the extensive ravages found in apparently the mildest cases now impel him to operate without delay. The lesson he has learned from the 10 fatal cases of appendicitis is to operate in every case seen before the end of the third day. He discusses whether the too tardy operation hastened the fatal termination or whether the final result would have been the same under expectant treatment. He remarks that the number of cases of appendicitis seems to be increasing every day and it alone is almost enough to support the medical man. Guided by experience we will soon be able to reduce to zero the mortality of operative statistics. Then will come the golden age of abdominal surgery, but the general practitioner will then feel justified in operating, and the gynecologic specialists will become the victims of the application of a sort of Monroe doc-

trine. It is to be hoped, however, he added, that a few women will still be left weary of their ovaries or sighing for the restitution of relaxed organs. He concluded his review of the tombs in his practice by confessing that his hesitancy and trust in expectant treatment had cost lives, and that he deserved to be stoned, "let that surgeon cast the first stone who does not carry around with him a little cemetery in some corner of his memory." His address is published in the *Revue Médicale du Canada* of the corresponding date. We have not learned of his having been stoned to death as yet.

State Boards of Registration.

COMING EXAMINATIONS.

New Mexico Board of Health, Santa Fe, December 5. Secretary, R. D. Black, M.D., Las Vegas.

Ohio State Board of Medical Registration and Examination, Columbus, December 13-15. Secretary, Frank Winders, M.D., Columbus.

State Medical Examining Boards of Delaware, Wilmington and Dover, December 13-15. Secretary, P. W. Tomlinson, M.D., Wilmington.

The Medical Examining Board of Virginia, Richmond, December 13-16. Secretary, R. S. Martin, M.D., Start.

Board of Medical Examiners of Maryland, Baltimore, December 14-17. Secretary, J. McI. Scott, M.D., Hagerstown.

Missouri State Board of Health, St. Louis University, St. Louis, December 19-21. Secretary, W. T. Morrow, M.D., Kansas City.

Iowa State Board of Medical Examiners, Capitol Building, Des Moines, December 21-22. Secretary, J. F. Kennedy, M.D., Des Moines.

Oklahoma Medical Examining Board, Guthrie, December 28. Secretary, E. E. Cowdrick, M.D., Enid.

AMERICAN CONFEDERATION OF RECIPROCATING EXAMINING AND LICENSING MEDICAL BOARDS.

Semi-Annual Meeting, held in St. Louis, Oct. 25, 1904.

The President, Dr. W. A. Spurgeon, Muncie, Ind., in the Chair.

This report is concluded from THE JOURNAL, November 5, page 1407. In that issue the schedule of questions for examination was referred to as having been unanimously adopted. It was so adopted, but by a later motion was held over until the next meeting for further consideration. The same action—postponement for a later final action—was taken in the case of the following committee reports:

Uniform Entrance and Graduation Requirements.

The committee on uniform entrance and graduation requirements recommended as a minimum entrance requirement to medical colleges a legitimate and duly accredited high school diploma, or its equivalent, and that such credential be simply treated as a credential of identification, and that its acceptance shall be dependent upon a certain number of credits, the same to be determined later. The committee recommended further that a medical diploma in the future be simply treated as a matter of identification, and that the medical course must consist of at least four thousand hours; that the division of subjects under this limit shall be in hours multiples of twenty-five; that no college shall be recognized that falls below this standard over 25 per cent. in any one branch, or over 10 per cent. in the total.

Advanced Standing.

The committee on advanced standing suggested that graduates in dentistry and veterinary medicine, and holders of baccalaureate degrees, or equivalent, from a reputable college or university may be given time credits not exceeding one year, provided that the applicant has had at least 40 hours in physics, 144 hours in chemistry, 24 hours in osteology, 292 hours in anatomy, 124 hours in histology, 85 hours in embryology, 145 hours in physiology and 46 hours in materia medica; and provided that the applicant for such time credits satisfies the professor in charge of the various subjects as to his proficiency in the subjects for which he seeks time credit. Further, that in case of transfer of students from one medical school to another, the dean of the recipient institution must secure an official statement from the school from which the student comes

as to the latter's educational and moral status, and no student shall be advanced to a higher class in his own school or any other medical school who has more than two conditions in his previous year's work, these conditions to be removed before the end of the school year on which the student enters. But no student shall be permitted to enter the fourth year until all conditions of the third year shall have been removed.

The committee on uniformity of forms also reported and was continued to report further at the next meeting, to be held in Indianapolis, on call of the secretary. The present incumbents in office were re-elected to serve for the ensuing year. The secretary is Dr. B. D. Harrison, Sault Ste. Marie, Mich.

The following states were represented at the meeting:

- Indiana.—W. S. Spurgeon.
- Michigan.—Wm. Bell and B. D. Harrison.
- Wisconsin.—J. B. Stevens, W. T. Saries, L. F. Bennett, A. P. Andrews, F. P. Klahr, J. R. Currens and F. A. Forsbeck.
- Kentucky.—J. N. McCormack and C. A. Mayer.
- Iowa.—J. A. McIlveen and J. H. Sans.
- Nebraska.—B. F. Bailey.
- Illinois.—G. W. Webster, J. A. Egan and W. H. Hipp.
- Ohio.—H. F. Beebe and S. B. McGarran.
- Colorado.—S. D. Van Meter.
- Kansas.—O. F. Lewis and C. E. Johnston.

Louisiana October Report.—Dr. Felix A. Larue, secretary of the Louisiana State Board of Medical Examiners, reports the written examination held at New Orleans, Oct. 21-22, 1904. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number examined was 25, of whom 17 passed and 8 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Medical College of South Carolina	(1901)	92.6
University of the South, Sewanee	(1904)	78.8
Med. Dept., Tulane Univ.	(1904) 66.6, 51.4;	(1899) 91.2
Laval University, Montreal	(1893)	80.6
Med. Dept., Columbian Univ., Washington, D. C.	(1904)	86.4
Woman's Med. Coll. of Pennsylvania	(1888)	87.4
University of Michigan	(1904)	82.4
University of Tennessee	(1904)	81.4
Nat. Med. Univ., Chicago	(1904)	88.2
Maryland Medical College	(1904)	76.8
Kentucky University	(1903) 75,	(1904) 82.4
Memphis Hospital Medical College	(1899)	77.0
Bellevue Hospital Medical College	(1898)	86.4

FAILED.

Univ. of the South, Sewanee	(1903) 67.2,	(1904) 59.8,	73.73
University of Louisville	(1902)		67.6
Memphis Hospital Medical College	(1900)		66.0
Flint University	(1902) 63.6,	(1904)	67.0

Montana October Report.—Dr. William C. Riddell, secretary of the Board of Medical Examiners of Montana, reports the written examination held at Helena, Oct. 4-5, 1904. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number examined was 20, of whom 15 passed and 5 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Trinity Medical College, Toronto	(1903)	81.6
University Medical College, Kansas City, Mo.	(1903)	76.0
University of Michigan	(1904)	83.2
Kentucky University	(1904)	78.3
Detroit College of Medicine	(1904)	73.1
Northwestern University	(1904)	78.3
University of Illinois	(1904)	75.9
College of P. and S., New York	(1904)	87.5
Imp. Alexander's Univ., Pilsand	(1894)	*78.2
Queen's Univ., Kingston, Ont.	(1903)	75.4
Rush Medical College	(1903) 86.3,	(1902) 85.6
St. Louis College P. and S.	(1895)	†76.6
Bellevue Hospital Medical College	(1894)	79.8
College of P. and S., Kansas City, Kan.	(1904)	75.2

FAILED.

Hahnemann Medical College, Philadelphia	(1901)	66.4
New York University	(1893)	41.9
Kansas City Medical College	(1895)	47.7
Howard Medical College, Washington, D. C.	(1892)	57.1
Dunham Medical College, Chicago	(1901)	63.6

* Second examination. †Third examination.

The Public Service.

Army Changes.

Memorandum of changes of stations and duties of medical officers, U. S. Army, week ending Nov. 12, 1904:

Williamson, L. P., asst.-surgeon, leave of absence extended fifteen days.

Owen, Wm. O., surgeon, left Fort Logan, Colo., on thirty days' leave.

Swaney, Verne E., asst.-surgeon, relieved from duty at U. S. Army General Hospital, Presidio of San Francisco, and ordered to Fort Mackenzie, Wyo., for duty.

Rutherford, Henry H., asst.-surgeon, relieved from duty at Fort Mackenzie, Wyo., and ordered to the U. S. Army General Hospital, Presidio of San Francisco.

Phillips, Jno. L., surgeon, ordered to take charge of the office of the chief surgeon, Department of the East, during absence of Col. Valery Havard, chief surgeon.

Hammond, Thos. E., surgeon, relieved from duty at the Louisiana Purchase Exposition, St. Louis, and ordered to Fort Assiniboine, Mont., for duty.

Metcalfe, K. F., asst.-surgeon, sick leave of absence extended thirty days.

Brown, Polk D., Johnson, Charles W., and Warriner Benjamin B., contract surgeons, Sorber, Ord M., and Tignor, Edwin P., contract dental surgeons, called on the *Sherman* November 1 from San Francisco for Philippine service.

Werthenbaker, Clark I., contract surgeon, ordered from his home at Cleveland, Ohio, to Madison Barracks, N. Y., for duty.

Smith, Rodney D., contract surgeon, granted leave of absence for three months.

Guttrud, Alwin M., contract surgeon, granted an extension of one month to his leave of absence.

Nash, Francis S., contract surgeon, granted leave of absence for four months.

Woods, Oscar W., contract surgeon, returned to duty October 31, at Vancouver Barracks, Wash., from leave of absence for two months.

Truheoltz, Clarence A., contract surgeon, left General Hospital, Fort Bayard, N. M., November 5, on leave of absence for two months.

Dade, Waller H., contract surgeon, granted leave of absence for one month on account of sickness at the expiration of his present leave of absence.

Reagles, James, contract surgeon, left Fort Yellowstone, Wyo., November 7, for duty at Fort Keogh, Mont.

Adair, George F., contract surgeon, left Fort Du Pont, Del., November 9, for his proper station, Fort Wadsworth, N. Y.

Merrick, John N., contract surgeon, granted leave of absence for two months.

Turner, Samuel S., contract surgeon, granted leave of absence for four months.

Navy Changes.

Changes in the medical corps of the Navy, week ending November 12, 1904:

Lewis, D. G., medical inspector, detached from the *New York* and ordered to the *Chicago*.

Furlong, F. M., P. A. surgeon, detached from the *Chicago* and ordered to the *New York*.

Brown, E. M. asst.-surgeon, detached from the *New York* and ordered to the *Chicago*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ending Nov. 9, 1904:

Williams, L. L., asst.-surgeon general, granted leave of absence for eight days from November 7.

Metzch, F. C., surgeon, granted leave of absence for two days from November 5.

Blue, Rupert, P. A. surgeon, detailed to represent the service at convention of League of California Municipalities at Santa Ana, Cal., November 16-18.

Clark, Tallaferra, F. A. surgeon, on being relieved at Baltimore, Md., by Asst.-surgeon J. W. Schereschewsky, to rejoin station at Philadelphia.

Anderson, J. F., P. A. surgeon, granted leave of absence for seven days from Nov. 9, 1904, under Paragraph 191 of the Regulations.

Billings, W. C., P. A. surgeon, to proceed to St. John, N. B., for exclusive duty in connection with inspection aliens.

McIntire, C. B., P. A. surgeon, granted extension of leave of absence for twenty-three days from November 7.

Schereschewsky, J. W., asst. surgeon, on completion of examination to determine fitness for promotion to the grade of P. A. surgeon, relieved from duty at the Immigration Depot, New York, and directed to proceed to Baltimore for exclusive duty in connection with the inspection of aliens.

Safford, M. V., A. A. surgeon, granted leave of absence on account of sickness for four days from October 21.

Rehrig, A. M., pharmacist, Department letter of Sept. 1, 1904, granting leave of absence for thirty days, amended to read twenty-five days from Sept. 12 to Nov. 7, 1904.

Miller, Chas., pharmacist, granted leave of absence for fourteen days from November 10.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Nov. 11, 1904:

SMALLPOX—UNITED STATES.

Illinois: Chicago, Oct. 30-Nov. 5, 28 cases, 2 deaths; East St. Louis, Aug. 15-Oct. 20, 200 cases, 25 deaths.

Louisiana: New Orleans, Oct. 30-Nov. 5, 1 case.

Michigan: Oct. 30-Nov. 5, at 50 places, present; Detroit, 1 case.

Minnesota: Oct. 25-31, Hennepin Co., 8 cases; Todd Co., 1 case.

Missouri: St. Louis, Nov. 1-7, 7 cases, 1 death.

New York: New York City, Oct. 30-Nov. 5, 6 cases.

Ohio: Canton, Oct. 16-22, 3 cases; Toledo, Oct. 23-29, 1 case.

Pennsylvania: Philadelphia, Oct. 30-Nov. 5, 2 cases.

Wisconsin: Milwaukee, Oct. 30-Nov. 5, 22 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Oct. 16-22, 4 cases.

Brazil: Pernambuco, Sept. 30-Oct. 13, 43 deaths; Rio de Janeiro, Oct. 3-9, 236 cases, 115 deaths.

France: Paris, Oct. 16-22, 7 cases, 1 death.

Great Britain: Bradford, Oct. 9-22, 4 cases; Oct. 16-22, Manchester, 3 cases; Newcastle-on-Tyne, 17 cases, 2 deaths; Nottingham, 6 cases, 1 death.

Italy: Catania, Oct. 2-8, 1 death.

Italy: Catania, Oct. 21-27, 1 death; Palermo, Oct. 16-22, 1 case, 5 deaths.

Russia: Moscow, Oct. 23-29, 4 cases; St. Petersburg, Oct. 19-25, 5 cases, 1 death; Warsaw, Oct. 29-26, 19 deaths.

Turkey: Constantinople, Oct. 17-23, 10 deaths.

West Indies: Barbados, Oct. 25, 2 cases on British bark *Endenado*, from Rosario.

CHOLERA.

India: Bombay, Oct. 5-11, 7 deaths; Madras, Oct. 2-8, 6 deaths.

Russian Empire: Saratov Province, Saratov, Sept. 27-Oct. 7, 18 cases, 9 deaths; Trans-Caspian District, Sept. 25-Oct. 2, 11 cases, 5 deaths; Trans-Caucasia, Baku, Sept. 28-Oct. 11, 191 cases, 114 deaths.

Turkey: Sept. 27-Oct. 3, 233 cases, 160 deaths.

YELLOW FEVER.

Brazil: Rio de Janeiro, Oct. 3-9, 1 case.

Cuba: Havana, Oct. 26, 1 case from American S. S. *Havana* from Mexico.

Mexico: Tuxtitepec, Oct. 23-29, 47 cases, 12 deaths; Merida, Oct. 23-29, 1 case.

PLAGUE.

Africa: Port Elizabeth, Oct. 2-8, 1 case.

Australia: Brisbane, Sept. 10-24, 1 case, 1 death; Perth, Sept. 5-24, 4 cases, 1 death; Sydney, Sept. 12-26, 2 cases, 2 deaths.

Brazil: Rio de Janeiro, Oct. 3-9, 43 cases, 15 deaths.

Egypt: Oct. 1-7, Alexandria, 4 cases, 2 deaths; Port Said, 1 death.

Formosa: Sept. 1-30, 4 cases, 3 deaths.

India: Bombay, Oct. 5-11, 71 deaths; Karachi, Oct. 3-9, 12 cases, 13 deaths; Madras, Oct. 1-7, 1 case.

Peru: Oct. 1, Arica, present; Eten, present; Pacasmayo, present; Sept. 25 Oct. 1, Callao, 1 case; Lima, 11 cases.

Straits Settlements: Singapore, Sept. 22-28, 2 deaths.

Society Proceedings.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, Oct. 6, 1904.

The President, Dr. Richard C. Norris, in the Chair.

The Intermediate Repair of the Cervix.

DR. BARTON COOKE HIRST declared that experience has demonstrated that intermediate repair after the fifth day gives the best results. This fact dictates the time for the repair of all the pelvic injuries, if the cervix must also be repaired. To give special attention to the community at large Dr. Hirst recommended that the poorer classes be confined in well-appointed and intelligently managed hospitals, and that the wealthier classes be attended by their family physicians under the supervision of a specialist, who could deal with complications in labor, examine the patient during the puerperium, repairing whatever damage has been done, and make the final examination at the end of the puerperium.

The Immediate Repair of the Pelvic Floor and Perineum.

DR. EDWARD P. DAVIS said that when the uterus is well contracted, when inspection of the cervix reveals no laceration with bleeding, and when torn vessels in the posterior segment of the pelvic floor are not bleeding, that persistent hemorrhage is caused by a laceration of the vulva or anterior segment of the pelvic floor, and that on inspection a positive diagnosis can be readily made. Treatment may be expectant or by suture. Lacerations of considerable extent are apt to cause prolapse, etc., and primary closure by fine or medium sized chromicized catgut is satisfactory. If in extensive laceration high up it is impossible to close the entire laceration, one or two sutures of medium sized catgut buried deeply enough to include the fascia will prevent prolapse. Lacerations of the posterior segment of the pelvic floor are divided into tears of the pelvic floor and tears of the perineum. To recognize injuries to the pelvic floor requires especial care; the patient must be placed on the back or side at the edge of a bed or table, the labia separated and the pelvic floor raised for inspection.

If the laceration of the posterior segment be considerable and the condition of the patient bad, operation may be delayed

24 to 36 hours. The most important stitches in closing lacerations of the pelvic floor are those placed at the highest points in the tears in the sulci. In repairing the perineum, the operator should begin near the anus and bring together the skin edges and underlying fascia with silkworm-gut stitches, taking a considerable portion of tissue, but without tension. The perineum should be brought together up to the point where the posterior vaginal wall begins. If the pelvic floor sutures are continued on the perineum, the posterior wall of the vagina will be brought downward and protrusion of the vaginal mucous membrane will result. If the stitches are drawn too tightly they will cut; if sufficient tissue be not included in the stitches, only superficial union may occur. In complete tears, the rectum may first be closed by continuous suture of No. 1 chromicized catgut, prepared to last ten days, the stitches passed into the connective tissue, turning the mucous membrane into the bowel. A careful approximation will turn but little mucous membrane into the intestine and secure good application for the stitches. The fascia and sphincter muscle of the bowel may then be accurately closed and then the pelvic floor and perineum as in an incomplete tear. Chromicized catgut No. 2, prepared to last ten days, has given good results in the sulci of the pelvic floor and where but one stitch was required in the fascia and muscle of the sphincter of the bowel. For closing the anterior segment of the pelvic floor and the rectum, No. 1 catgut of the same sort has been useful. In the skin perineum, silkworm gut has given satisfaction. In complete tears, the free use of salt solution on the mucous membrane of the bowel tends greatly to prevent infection. Where there is edema, the application of hot sterile compresses or irrigation with hot sterile salt solution may be useful. Vaginal douches should be avoided, because they may carry infective material from the perineum to the cervix. The after-treatment consists of surgical cleanliness so applied as least to disturb the tissues and parts which are healing. The use of the catheter after this operation should be as brief as possible and its employment should cease after two or three days. After complete tears the rectum must be kept quiet for 48 hours, and after that daily movements of softened fecal matter should occur. After the operation for complete tear, fistula may remain between the vagina and rectum for some time. Fluid may pass between these cavities. If care be exercised in aseptic precautions and saline flushing, these fistulae will close spontaneously and their presence will delay convalescence but slightly. Where partial union occurs, as soon as the first stitches have been removed, a good result can often be obtained by curetting thoroughly the unhealed parts of the laceration and by inserting stitches a second time. In estimating the success of an immediate operation we must take into consideration whether the vaginal walls are completely or very nearly in apposition and without prolapse, whether there is good control of the sphincter of the bowel, and the patient free from pain, especially when using a closet or commode, or when moving about, and whether there is discharge from the sutured tissues.

DISCUSSION.

DR. E. E. MONTGOMERY said that the possibility of infection must influence the procedure, whether it be immediate, intermediate or of a later date. He would want to know something of the methods of the attending obstetrician before he would resort to immediate repair of cervix, vagina or perineum. In a number of cases of laceration of the pelvic floor, where the immediate repair was made, and in which aseptic precautions had not been employed by the attendant, sepsis developed and it was necessary to remove sutures to give the patient a chance for recovery. In a case seen in consultation, he found that there had been a bilateral laceration of the cervix into the lateral fornices to the peritoneum. A laceration of the perineum to the sphincter had been repaired. As a result the tissues were bathed with a lot of decomposing material and there was high fever. Instead of hysterectomy, he advised removal of the perineal sutures, the entire cavity irrigated and packed with gauze. A few hours later there was a temperature of 106; but there was subsequent recovery. In other cases the im-

mediate repair of the perineum has been followed by much necrotic tissue between the sutures, no union ensuing and the necrotic tissue giving rise to danger from absorption of the putrescent material. Objection is sometimes made to immediate repair of the cervix from the fact that the parts are so relaxed that the sutures have to be tied firmly, and, owing to the rapid involution, become loosened, and union does not result. In the majority of primæ gravida laceration of the cervix occurs. In a series of examinations made at the Philadelphia Hospital, in the great majority of cases the laceration had healed spontaneously. The acid secretion of the vagina causes the more rapid disappearance of the catgut than is evident in other parts of the body. In some cases, catgut prepared for a short time has been absorbed too soon, and there is stretching of the parts and formation of cicatricial tissue. In operations on the vagina and perineum the operation should include every laceration in the genital canal, otherwise there will be danger to the patient from the accumulation of material in the vagina giving rise to septic processes.

DR. JOHN G. CLARK quoted Dr. Dickinson as advocating waiting five days for the repair of all lacerations of the cervix, except in the three following classes: 1, those in which there is a profuse hemorrhage from the laceration; 2, those in which there had been bilateral incisions; 3, those in which the cervix is low in the vagina and may easily be reached at the time of the perineorrhaphy. There must first be taken into account the time when injuries to the perineum are sutured. Dr. Clark urged that careful operative technic is the keynote of the situation. For several years the consensus of opinion has been in favor of immediate repair. Considering the bad surroundings under which these operations are necessarily performed and the uniformly good results following, Dr. Clark believes that a general departure from this custom is not justifiable. If under unfavorable conditions these results follow, there may be expected even more perfect healing following the treatment described by Dr. Davis. If it were admitted that the perineum should be at once repaired, then the cervix should be either immediately repaired, or, if deferred, at a more remote day after the puerperium is completed. All have seen cases in which healing occurs most satisfactorily when left alone. If primary healing is not satisfactory the more remote trachelorrhaphy is so good, that to break into a woman's early convalescence and throw her house into turmoil six days after her labor, by operating at a time when the milk secretion is fairly established and the baby nursing well, is not justified by the surgical exigencies of the case.

In the discussion of the immediate repair before the American Gynecological Society, Clifton Edgar and Cragin of New York, Williams of Baltimore, Craig of Boston, and Wakefield of San Francisco all opposed the immediate repair of a lacerated cervix. Cragin admitted that it might be done by skilled hands successfully, but that he could not sanction this teaching to students. Dr. Clark had no doubt that these injuries, if repaired in a well-equipped maternity hospital, would do well, yet the vast number of labors occur in private houses, in the majority of which there are no facilities for repairing a lacerated cervix. It would be ideal to have all women confined in maternity hospitals, or if in private houses to have an expert in consultation, but the domestic environments of the parturient woman are usually such that this will never be the case, consequently these operations must be considered from the standpoint of the conditions under which they will usually be performed. If the immediate or five-day repair were generally to be adopted, not only would the morbidity, but also the mortality of puerperal cases overbalance the good which this procedure might do, if solely confined to the hands of the specialist.

DR. STRICKER COLES said that for the last ten years he has closed all lacerations of anterior and posterior vaginal walls and in the cervix, if the tear were large, immediately after labor. He has not had to delay in a single case for 24 hours, for he prepares for it before delivery. The stitches should be placed at the uppermost part of the tear, but should not be placed too far down, as the lumen of the cervix will be nar-

rowed and the flow of lochia retarded. His results with immediate closure of the perineum, pelvic floor and anterior vaginal wall have been most satisfactory, even when the tear was complete. He emphasized the importance of bringing muscle to muscle, and to do this with the buried suture it is often necessary to bring the retracted ends into direct apposition. He tries to obviate the swollen and edematous condition of the parts, which largely causes the objection to immediate closure by watching his cases and not allowing the tissue to become devitalized by prolonged pressure. The healthy epithelial cell is the best barrier to sepsis and he endeavors to protect and keep its continuity. He wonders whether sepsis will not be more frequent when raw surfaces are left exposed for five or ten days, and what will be the effects of an operation at this time on the mother's milk. When done immediately the operation takes a very few minutes, causes the patient no inconvenience and only slight pain, and gives almost as good a result with the cervix and equally as good with the perineum, pelvic floor and anterior vaginal wall.

DR. E. P. BERNARDY said that his results have been very good, without elevation of temperature. Everything should be properly prepared, even at the bedside of the patient. While 25 per cent. of lacerations of the cervix heal spontaneously, the other 75 per cent. are either operated on, or the patients live with lacerated cervixes. Dr. Bernardy stitches lacerations of the perineum immediately after the birth of the child and he cited one case seen in consultation, in which there were used twenty-two stitches in the vagina and perineum, and in which on the ninth day the patient left her bed entirely well and without a sign in perineum or vagina that there had been a laceration. In cases in which the parts are mutilated and black and blue an attempt should be made to bring the tissues to normal condition by douching with warm saline solutions before stitching, when the results invariably will be good.

DR. GEORGE M. BOYD said that he thinks it would be bad teaching to tell the average family doctor, who must be an obstetrician, to sew up every cervix. The average maternity is not sufficiently careful to repair injuries after labor.

DR. O. HOPKINSON, JR., said that in his experience, tears had been bilateral and the anterior lip much larger, edematous and more easily reached than the posterior. He cited one case in which a man with little experience in the repair of the cervix, tried to pull the posterior lip down even with the anterior, with the resultant giving way of the tissues. Immediate repair of the cervix should be done by some one with experience. He believes it safer, except in the presence of hemorrhage, to leave it alone for five or more days.

DR. THEO. A. ERCK stated that he places stitches for laceration of the perineum at the termination of labor. All have seen and operated on cases in which the result of the primary repair was a failure, and he suggested the substitution of silk-worm gut, so that the operator will see the result during the removal of the stitches.

DR. RICHARD C. NORRIS thought that the intermediate operation must be considered from two view-points: 1. Its practicability; 2. its results. It is the experience of most men that the immediate operation for laceration of the cervix, unless done for the special indication of hemorrhage, is not justifiable. When the intermediate repair is chosen and an examination is made on the sixth, seventh or eighth day of the puerperium, the cases of spontaneous healing of the cervix will be found to be pretty well advanced, and the experienced surgeon will not operate; if spontaneous healing has not occurred the experienced surgeon will operate at this time. Operation on the cervix, after the sixth or seventh day, has been quite as successful as in a later operation. If equally satisfactory union follows an intermediate operation, what advantage can accrue to the patient by delay? In many cases, while the wound in the cervix unites, the uterus undergoes chronic interstitial changes, and there has been evolved a train of symptoms which often persist, but which would not exist if the cervix had been repaired at an early date. If it can be demonstrated that better results will follow an immediate operation for repair of the pelvic floor and perineum than can

be obtained by the intermediate operation, then the immediate operation should be done, and the advantage of the intermediate cervix repair must be abandoned. If it can be demonstrated that the operation on the perineum has no disadvantages by being delayed and that equally good results can be obtained, then the combined intermediate repair of both cervix and perineum will be the ideal treatment. If the obstetrician has not conducted the labor with the highest grade of asepsis and antiseptic he had better not operate immediately or after a few days. It should be determined by actual experiment whether it is any detriment to the patient to allow the perineum and pelvic floor to remain unrepaired for six or eight days. There would not be so many secondary operations if the average physician did not neglect at once to repair these cases, and yet patients so neglected seldom have serious infection. If the average practitioner gets bad results in the primary operation, he will get bad results in the intermediate. He had better do the best he can with the immediate repair of the perineum, and when the patient is convalescent send her to a gynecologist for reasonably early repair of the cervix. As time goes on the new generation of physicians will be prepared for clean surgical and obstetric work, and the intermediate operation on both the cervix and pelvic floor will gain in popularity with the profession. Among the more intelligent class of private patients, appreciation of the ultimate gain will offset the natural objections on the part of the patient and her family to an anesthetic and a formal operation following so closely the anxiety of the confinement.

DR. B. C. HIRST agrees with Dr. Norris that the question can not be decided by theorists, but only by men with large practical experience. His experience coincides with that of Dr. Norris. Until three and a half years ago he believed it a bad plan to attempt too much in the way of repair, but he happened to see Lusk's statement in regard to the repair of the cervix and one or two articles advocating primary repair, and determined to try it. As a result of that trial, for three and a half years, in an experience comprising more than 150 cervical operations alone in the University Maternity, beside a number in other hospitals and private practice, he is in a position to recommend the procedure. Fifty or sixty years ago the average practitioner was not able to use the forceps. An old graduate told him that when he left the university fifty years ago to settle in the country he took an obstetrical forceps with him, and an old practitioner, having a case of adherent placenta, sent for him to bring those "new-fangled instruments" and see what he could do with them. Dr. Hirst believes that in the near future the majority of physicians in general practice will do this work well or they will not do it at all. In the University Maternity he said that they demonstrated more than 50 cervical operations every season, done usually at the end of a week, to a class of about ten men each, so that each man acts as assistant in about five cervical operations. He believes that these students ought to be prepared to do this work as it should be done. Dr. Hirst said that he at first thought the immediate operation was the better one and he had tried it in 40 or 50 cases, but had found that there was too large a percentage of fever after the repair of the cervix immediately. After the intermediate operation this tendency was not observable. Dr. Hirst disagrees with Dr. Dickinson if the latter is quoted correctly as saying that if the perineum must be repaired then the cervix should be immediately repaired. There is no harm whatever in letting the perineum go to the end of a week.

DR. E. P. DAVIS said that he has not noticed the absorption of No. 10 catgut alluded to by Dr. Montgomery in puerperal cases. It seems to him that the reaction of the lochial discharge is not the same as that in the vagina of a woman not parturient. By immediate repair he would understand repair within an hour after the expulsion of the child, not 12 or 24 hours. In a certain class of cases the results have been satisfactory. The cases are watched through the entire labor and the tissues are not allowed to become nodular, edematous nor bruised. After delivery the entire genital tract up to the internal os is inspected for lacerations. Lacerations of the cer-

vix more than one-quarter of an inch long and of the pelvic floor and perineum are closed. He has seen no fever following this procedure. He has seen a number of very satisfactory unions in the cervix and, of course, a very high percentage of unions in the pelvic floor and perineum. Those cases were in good hands, and the operation was practically immediate. The so-called intermediate, or five or seven-day operation, is on trial. Is obstetrics to be done as a makeshift, a disagreeable necessity by the practitioner, to eke out his living; or, is it to be a surgical specialty? Many cases will fall into all sorts of unskillful hands, and in such hands, the least interference the better; but, if obstetrics is to take the place of a surgical specialty, then the students will develop an individual aptitude for practice, and some will take up medical work; others will do surgical work, and those students will be competent to perform operations on the genital tract, whether it be done within an hour, in ten or twelve days or in two or three weeks, and the work will go to those men.

CLEVELAND ACADEMY OF MEDICINE.

Twentieth Regular Meeting, held Sept. 16, 1904.

The President, Dr. G. W. Crile, in the Chair.

The Surgical Treatment of Paralytic Deformities with Demonstration of Cases.

DR. WALTER G. STERN presented three cases of severe paralytic pes varus caused by paralysis of the tibialis anticus and posticus muscles. One was operated on by grafting the tendon of the extensor proprius hallucis into the tendon of the tibialis anticus just below the annular ligament, with the result that the flat-foot has disappeared. The patient constantly holds the foot straight or slightly inverted and can actively invert the foot, when, at the same time, he extends it. Through active massage, exercise and gymnastics, the patient can invert the operated foot almost as well as the sound one, and the tendon of the extensor hallucis has hypertrophied. The second case showed still more hypertrophy of the ingrafted extensor hallucis. In this case it could easily be mistaken for the tendon of the tibialis anticus. The third case had, in addition, a paralysis of the first two tendons of the extensor digitorum. This case was operated on according to the plan of Hoffa. The extensor digitorum was shortened, all the tendons being united in one, the extensor hallucis was inserted into the tendon of the tibialis anticus and the peroneus brevis was cut off from its insertion at the fifth metatarsal and brought around behind the tendo Achilles and firmly sewn into the periosteum of the scaphoid. This operation gave an ideal result, patient can actively invert and evert, pronate and supinate the foot, and has in addition a moderate amount of extension in the toes. Two cases of paralytic pes equino-varus were cured by lengthening the tendo Achilles, and inserting one-third of it into the tendons of both peronei muscles. The tibialis anticus was divided, one-half being sewn into the paralyzed extensor digitorum, the other half being lengthened. The entire extensor hallucis was brought over and sewn into the periosteum of the cuboid. Both operations were preceded by forcible correction by means of the Thomas wrench and tenotomy of the plantar fascia and tendons. The result in both cases is such that the feet are permanently in a valgus position and can actively be flexed, extended, inverted and everted. One case of Volkmann's ischemic paralysis of the wrist was straightened by lengthening the flexor tendons, and inserting the cut tendons of the palmaris longus and flexor ulnaris into the extensor communis digitorum by means of artificial tendons of silk. The hand was dressed in a hyper-extended position. The patient can now hold the hand straight and slightly flex and extend the fingers.

The object sought by these operations is not to add new muscle power, but to distribute the power left to the member so as to bring the parts into a condition of stable muscle equilibrium. Lange's teachings were closely followed, but not to the exclusion of the sound principles of the Nicoladoni-Vulpus method. These cases show that flexor tendons can

learn to act as extensors and vice versa, and that when the proper after-treatment is employed comparatively weak tendons may be made to hypertrophy when called on to do the work of a more powerful muscle. Silk was used in sewing the tendons and for the artificial tendons, and silkworm-gut for the skin. The member should always be held in an over-corrected position for at least eight weeks. This is best done by means of a plaster cast. Failures from tendon transplantation may be attributed to the following reasons: 1. Lack of after-treatment. This is a very prolific cause. Davies' report of 38 cases operated on in Boston lacks the important mention of after-treatment, and their failures may be due to this one factor alone. 2. Inflammation. Hemostasis and asepsis must be absolute. Silk should be boiled on three successive days, and catgut should be tabooed. Inflammatory reaction which would be harmless in a laparotomy will cause adhesion of the transplanted tendons and failure. Extensive mutilation should be avoided, as Senn has shown that repair begins from the tendon sheath. 3. Lack of sufficient muscular tension. All paralyzed muscles lose tone and elastic tension, and therefore all transplantations must be done under sufficient tension to allow the muscles to work. This tension is rendered latent and harmless by holding the limb in an overcorrected position for eight weeks. 4. The use of weak or paralyzed muscles. This can not always be foretold. Electrical reactions in children are extremely uncertain. Muscles may simply be overstretched and not paralyzed. Cutting into the muscles is not always a safe guide, as the color depends on the relative amounts of healthy muscle, fat and regenerated muscle fiber in that particular spot.

Some Common Errors in Obstetric Practice.

DR. R. E. SKEEL said that patients themselves are frequently responsible for poor work, because of unwillingness to pay for adequate attention and nursing. Proper ante-partum examinations are still neglected in spite of text-book advice, with the result that eclampsia occurs unnecessarily. Malpresentations are not discovered until labor is well under way, and disaster, in the way of maternal or fetal death, often occurs. Neglect of scrupulous aseptic technic is fostered by the fact that Nature's own efforts frequently overcome infection before systemic absorption takes place, and it would be better if a definite minimum amount of septic material in the vagina were invariably followed by reaction. In that event every attendant would use the proper precautions to prevent its introduction. Most frequent failures in asepsis are due to too great faith in chemical antiseptics and the belief that infected cases can be handled with impunity if the hands are washed in bichlorid solution. The development of the aseptic conscience will be followed by better results, as it will lead to the use of rubber gloves, infrequent vaginal examinations, and in the future to resort to the sharp knife and clean incision more frequently, and the heavy, bungling instruments with the traumatism which they produce will be less often seen. Fetal death is often caused by premature operative interference in cases of difficult labor, due to close adaptation of the fetal head. Conditions, not hours, should count in the indication for operative termination of labor. Pelvic floor injuries are overlooked or badly repaired by efforts to minimize their importance and sew them up immediately after the close of labor. This is much better done if deferred for twelve or twenty-four hours, and perfect results can be obtained at this time. Exact diagnosis of any post-partum elevation of temperature is necessary in order to treat it intelligently. Great harm is done by failure to recognize that persistent temperature without apparent cause is usually due to infection. More harm is done by trying to treat all such infections when recognized by the intra-uterine douche. Diagnosis of the treatment may be applied. Peritonitis, postabortion or postpartum seems to be managed most successfully by simple incision and drainage. Pryor's incision and iodoform gauze pelvic drain work well in nearly all early cases, although a number will need secondary removal of the diseased organs. The laity still fails to recognize that a competent nurse is almost as important as a com-

petent physician, and the so-called experienced nurse whose chief assets are her unbounded confidence in her douche bag and her consuming desire to wash the baby is altogether too much in evidence. By proper education and insistence on the part of the physician this defect can be overcome in time, but, at the present, conditions among the masses of people are anything but satisfactory.

DISCUSSION.

DR. F. S. CLARK emphasized the importance of the preparation of the attendant and the patient before examinations were made; the methods are usually careless and the field is a more difficult one to keep clean than the surgeon's operative field. Clipping the vulvar hair was important, and care in inserting the examining fingers so as to avoid contact with the surrounding parts.

The cut end of the cord should be antiseptically dressed at once; usually this is not done for an hour or more, and cord infections are more frequent than is generally supposed.

Trichinosis.

DR. SHULER reported a case of trichinosis in a girl aged 10. The swelling of the eyelids was marked, and he regards this as a very important symptom. The patient was flushed, delirious and had a high fever, but no albuminuria. Subsequently he saw several other cases in the neighborhood infected from the same source as the original one.

Intussusception.

DR. R. E. SKEEL reported a case of acute intussusception in a child of 11, who had for a week some abdominal pain, for which he had been given cathartics with satisfactory results as regards the bowel movements. On examination there was slight resistance on the right side of the abdomen, but no elevation of temperature, the pulse was normal and there had been no bloody stools. The next night he had more pain and vomited once or twice, and next morning a characteristic sausage-shaped tumor was found extending across the abdomen into the left iliac region. An operation was performed; the invagination had begun at the cecum immediately above the appendix, and extended to the sigmoid. Reduction was easy, as few adhesions were present. A gangrenous spot was found at the tip of the invagination, and this was closed with sutures; the sutures prevented a tendency to reinvagination, noted when the condition was at first reduced. The case recovered satisfactorily.

Adrenal in Collapse.

DR. YARIAN reported the successful use of adrenalin with saline solution in the collapse of an infant suffering from digestive troubles.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting, held Oct. 20, 1904.

Dr. Andrew H. Smith in the Chair.

Primary Malignant Neoplasms of the Lung and Pleura.

DR. ISAAC ADLER delivered the Wesley M. Carpenter Lecture. He said that the treatment of malignant neoplasms of the lung and pleura is almost entirely neglected in the literature. Dr. Adler has seen ten cases, in all of which the diagnosis made during life was confirmed at the autopsy. Primary malignant disease of the lungs and pleura probably is much more frequent than is generally supposed. Organs which are so often affected by secondary deposits are rarely the seat of primary ones. It is difficult to determine whether tumors of the lung arise in the epithelium or in the endothelium. The endothelium has a very strong tendency to proliferate and it is difficult to distinguish a neoplastic growth from proliferation. In primary epithelioma of the pleura this structure becomes very much thickened, especially the costal pleura, which becomes hard and lacks its normal glossy surface. The diagnosis must be decided by the microscope.

The proportion of males to females is about 5 to 1 and the right side is more often involved than the left. It is less frequently found in children than in adults. Wolff of Munich in

20,160 autopsies found primary cancer of the lungs in 46 cases. Carcinoma was found in 211 cases, sarcoma in 22, endothelioma in 24; 10 cases were mixed and the remainder he was unable to classify. The majority of cases of carcinoma originated in the bronchi and had a tendency to ulceration. They formed large tumors in the mediastinal spaces where adhesions were readily formed involving the pericardium and other nearby structures. There was frequently a tendency to hemorrhage. It was exceedingly difficult to diagnose between carcinoma and sarcoma, the essential feature of the former being the character and behavior of the epithelial cells.

Sarcoma of the lung occurred in massive tumors while softening and degeneration with the formation of cavities rarely occurred. Extensive papillary growths of the pleura often occurred and it was quite common to find cancerous erosions of the blood vessels which caused metastasis. The retroperitoneal lymph nodes and the mesenteric and inguinal glands were frequently involved. Metastasis occurred 87 times in the liver; in 49 instances the kidneys were affected and frequently the pericardium also. The heart was sometimes affected by direct proliferation. In 27 cases metastasis occurred in the brain. Certain nerves, the diaphragm and peritoneum were also frequently involved.

Heredity, habits and occupation do not seem to be predisposing factors. If traumatism has any influence it is probably as a stimulant to neoplastic growth. Dr. Adler thinks that these growths and tuberculosis may exist at the same time. In 37 cases there was no expectoration and in 158 cases the character of the expectoration gave no aid in diagnosis. The sputum in many cases contained gangrenous masses. Death may be due to hemoptysis. Dyspnea was frequently noted. Pain was noted as an early symptom in 128 cases, and this was considered an indication of the extent of the pleural involvement. Pleuritic effusion was of common occurrence and an examination of the exudate may aid in diagnosis. In examining the chest flatness was noticed in some cases; in others, tympanitic sounds were elicited. At times intense dullness with a woody resistance in the upper part of the right or left lung associated with abolished voice and breathing sounds, not extending to the apex, presented symptoms which were pathognomonic of this affection. The one absolute sign is the finding of tumor elements in the sputum. There is a great difficulty in making a diagnosis between tumor and tuberculosis. Syphilis and aneurism must also be differentiated. The x-ray is of value in making a diagnosis.

CALIFORNIA ACADEMY OF MEDICINE.

Meeting held in San Francisco, Sept. 27, 1904.

The President, Dr. T. W. Huntington, in the Chair.

Value of the X-Ray in the Diagnosis of Certain Headaches.

DR. C. M. COOPER described the case of a woman with severe periodic headaches for which no cause could be discovered until the x-ray showed a marked osteosclerosis of the cranial bones with obliteration of the diploë and of the sutures.

DISCUSSION.

DR. H. C. MOFFITT described a similar case in which the headache had for years been regarded as a functional condition until the x-ray showed a thickening in the bones of the cranium. One year later double optic neuritis developed. In a second case an osteoma of the skull was demonstrated by the use of the x-ray.

DR. GEORGE BLUMER stated that he had performed an autopsy on a case very similar to those described by the preceding speakers and had found an enlarged pituitary body without any other signs of acromegaly except the thickened cranium.

Use of the Iodids.

DR. C. M. COOPER stated that he had seen several cases in which the continuous use of iodids in large quantities had given rise to a slight exophthalmos and a von Graefie phenomenon. In a case of gummatous meningitis, by using a com-

bination of the iodids, with thyroid extract, he had obtained a better result than by the use of iodids alone.

DISCUSSION.

DR. EVANS stated that he had administered iodin in this manner and not only obtained good therapeutic results, but had been able to demonstrate the iodin in the urine in considerable quantities and for a long time after ceasing the administration of the drug.

Malignant Papillary Growth of the Colon.

DR. L. W. ALLEN stated that the patient began to complain of burning sensations in the abdomen and attacks of vomiting about the middle of May, 1903. He became very constipated and passed blood in the stool. He rapidly lost in weight; 42 pounds in ten weeks. Physical examination about August 1 revealed a large mass in the right ileocecal region extending up under the ribs. He continued to lose weight during the next month, but seemed to recover the loss in the next six months, and on April 13, 1904, he came under Dr. Allen's care. A mass the size of a small orange, which was freely movable and not tender, could be felt in the right iliac fossa. Owing to the low percentage of hemoglobin, operation was postponed until June 13, and a tumor of the ascending colon was discovered. The transverse colon was divided near the hepatic flexure and the end of the distal portion turned in. The ileum was divided near its termination and a lateral implantation of the end of the ileum on the side of the transverse colon was made. Finally the ascending colon and cecum were removed. The patient recovered from the operation. Pathologically the growth proved to be a malignant papilloma.

Effects of Bile on the Ester-splitting Properties of Pancreatic Juice.

DR. HEWLETT made a preliminary report on the effect of bile on the action of the pancreatic lipase. It has long been known that bile assists in the digestion and absorption of fats, but the nature of this action has never been fully worked out. The addition of bile to pancreatic juice will increase the action of this secretion many times on certain esters (ethyl butyrate, ethyl acetate, amyl acetate, triacetin), as much as forty times being observed in certain instances. This action was due, in part at least, to the lecithin contained in the bile. The lecithin acts as a zymo excitator and not by converting a proferment into an active ferment.

DISCUSSION.

DR. OPHULS called attention to the somewhat similar action of lecithin in activating the hemolytic substance present in cobra venom as has been shown by Kyes.

A New Analgetic, Stovain.

DR. DUDLEY TAIT stated that many substitutes for cocain have been proposed, yet none has as yet replaced it. Stovain¹ is a drug which promises to come into general use. The experiments of the Paris surgeons would seem to indicate that stovain is as effective as cocain as an anesthetic, and is only one-third to one-half as toxic. It is possibly somewhat more fleeting in its effects. When dropped into the conjunctival sac it will induce anesthesia, but here it is inferior to cocain, being more painful and at the same time less analgetic. It causes hyperemia of the tissues instead of anemia. This may be disadvantageous when it is used as a local anesthetic, but is probably of advantage when it is used for spinal anesthesia. The use of stovain as a spinal anesthetic is not followed by such bad effects as are liable to follow the use of cocain. Possibly it may prove to be of use in high spinal anesthesia. It is possible to introduce a needle into the sixth intervertebral space without injuring the cord, provided one pays sufficient attention to the sense of resistance offered by the ligaments and the dura. The anesthesia resulting from an injection of cocain at this point is complete, but the method is attended with a certain amount of danger on account of the depressing effects of the cocain.

1. A description of stovain may be found in THE JOURNAL, PAGES 575 and 636.

Travel Notes.

CEYLON.

FROM AUSTRALIA TO CEYLON—ISLAND OF CEYLON, ITS CLIMATE, PEOPLE, DISEASES—COLOMBO GENERAL CIVIL HOSPITAL—CEYLON MEDICAL COLLEGE—CEYLON LEPER COLONY—LEPER BUDDHIST CELEBRATION—KANDY GENERAL CIVIC HOSPITAL.

(Concluded from page 1497.)

NICHOLAS SENN, M.D.
CHICAGO.

SOYSA BACTERIOLOGIC INSTITUTE, COLOMBO.

Since its opening this institution has undertaken work of diverse character, and is now supplying a long-felt want in the colony by its researches in bacteriologic analyses of tissues, secretions, blood, etc., so indispensable to scientific diagnosis of diseases. The acting director, Dr. S. C. Paul, F.R.C.S., is consulted by government medical officers and private practitioners for reports on specimens submitted to him on bacteriologic and allied subjects.

CITY OF COLOMBO.

The city of Colombo is an important port and the largest city in the island. It has a very mixed population of 128,000. More Europeans live here than anywhere else in Ceylon. The steamers anchor some distance from the wharf. It has excellent streets, the so-called red streets, a bright red from the color of the soil, electric lighting and electric tramways. The Grand Oriental Hotel, near the wharf, is the best hostelry in the island. Every room has an electric fan—a great comfort to the traveler throughout the entire year. The rooms of the hotel are never locked, as stealing and robbery are almost unknown. The crowd of chamber-men and servants are always ready to wait on the guests and understand to perfection the system of exacting a substantial tip. At the present writing the temperature in my room, in spite of the faithful fan, registers 91 degrees F. The air is thoroughly saturated with moisture, which is accountable for the oppressive sensation of heat that every newcomer experiences.

The Cinnamon Gardens is the city park and is a lovely place. The drives along the coast are beautiful and disclose at every turn the luxuriant vegetation of this wonderful island. The native policemen are courteous and devoted to their duties. They are fully impressed with the responsibility and dignity of their office, and cross and recross their beats with a keen eye for any evildoers. The city has a museum, free library and many charitable institutions for the sick and poor.

THE GENERAL CIVIL HOSPITAL.

This hospital is made up of numerous one-story brick-and-mortar pavilions connected by roofed colonnade, cemented walks which impart to the whole complex of buildings a fine architectural appearance. The snow-white walls and pillars and the red tile roofs are in strong and beautiful contrast with the perennial green surrounding the buildings inside and outside of the large square court which they inclose. The income from pay patients is not large, but the government appropriations are liberal. All of the employes are salaried, including physicians, internes and nurses. Dr. Thomasz, one of the two attending surgeons, receives 4,000 rupees a year. He conducted me through the different wards and showed me many interesting surgical and medical cases. The nursing is in the care of thirteen Anglican sisters and a number of women nurses, graduates from the Lady Havelock Hospital. A corps of native men and women act as helpers. The wards are airy, well lighted and furnished plainly but comfortably.

Echinococcus, so common in Australia, is not seen here; on the other hand, elephantiasis is quite common. Dr. Thomasz has operated on a number of cases of scrotal elephantiasis with success. The natives are not very good subjects for prolonged major operations, as they are very liable to inordinate

slough. Chloroform is used as a general anesthetic, and in several thousand anesthetics only two deaths occurred. The operating room is old and not up to modern requirements. The equipments and appliances also leave much to be desired. Asepsis has not succeeded here as well as could be desired and the many failures to obtain primary wound healing have finally led to the abandonment of buried absorbable sutures of any kind. Silk is used almost exclusively and the sutures are removed from three to seven days after the operation. The same practice is followed in the Kandy General Hospital. In the outdoor department I watched an interne dress two recent wounds. He did not remove his coat, and a basin with some antiseptic solution was relied on in performing primary disinfection. Not much time or effort was expended in preparing the wounds for suturing, and I have little doubt that the sutures rather retarded than assisted Nature's efforts in repairing the wound.

Ovarian tumors are quite common, but myofibroma is rare among the native women. Women the subjects of ovarian cysts of enormous size frequently enter this hospital for operation. Little operating is done in the country villages and patients usually do not seek medical advice until they are much inconvenienced from the size of the tumor. Prostatectomy is performed by the suprapubic route. Stone in the bladder is not of frequent occurrence. Tuberculosis of the lungs is quite common, as during one year, 1901-1902, 956 cases were admitted to the different hospitals. Surgical tuberculosis is much less prevalent, as during the same year only 60 cases of tuberculosis of the glands of the neck were treated, 32 of lupus and only 5 cases of tuberculosis of the joints. I did not see a single case of spinal deformity among the thousands of people I saw in Ceylon and only one case of ankylosis of the hip and 2 cases of ankylosis of the knee joint, and very few cases of tuberculosis of glands of the neck or its remote result, scarring of the neck. Only 12 cases of snakebite are reported for one year, of whom 2 died.

SEPTIC THROMBOPHLEBITIS OF THE SPERMATIC VEINS.

Dr. Thomasz a few years ago described a form of septic thrombophlebitis occurring in young men the subject of varicocele; the immediate cause is usually an injury of some kind which induces the thrombosis. When this has taken place the pus microbes find in the obliterated lumen of the veins a favorable soil for their reproduction, which leads very rapidly to prenia and death. The disease pursues a very acute course and is nearly always fatal unless an early radical operation is performed, which must also include the testicle on the affected side.

CEYLON MEDICAL COLLEGE.

The Ceylon Medical College was formally opened on June 1, 1870, with one principal and three lecturers. The first intent of the school was to be "simply an elementary school." The faculty was increased three years later and in 1888 it became a regular medical college with power to license in medicine and surgery. Lady students were admitted to the college for the first time on May 5, 1892. The one-story building of the college, with library, lecture rooms and laboratories, was erected at the expense of the late Susew de Soysa. The dissecting room is a separate building as well as the laboratory for physiology and pathologic chemistry. The clinics are given in the General Civil Hospital, opposite the college building. The course of study embraces five years. The teaching force consists of 32 professors, lecturers, demonstrators and assistants. T. F. Garvin, M.B., C.M. Aberdeen, is lecturer on surgery, and H. G. Thomasz is clinical lecturer. Physics, biology and elementary zoology are included in the primary branches. All the specialties are included in the faculty. The present attendance of students is about 120. The students are given ample opportunity to serve in the hospital as dispensers and dressers, and the clinical material for instruction is very large, including practical obstetrics in the De Soysa Lying-in Hospital. The school has also a department for apothecaries. The standards for admission and graduation correspond with those of the medical schools of the United Kingdom. The fee for the whole

course in advance (to be paid in one sum at the commencement of the first college year), is 800 rupees (\$250). A number of prizes and medals have been established by friends of the institution. At the close of the session 1901-1902 the school graduated 26, the following year only 9 candidates. Part of the entrance and professional examinations are conducted in the Tamil and Singhalese languages, of which the student must have a fair knowledge.

LEPER ASYLUM AT HENDALA.

I visited this institution, which by the carriage drive is ten miles distant from Colombo. The road leads through a series of native villages, rice fields, marshes and strips of primeval forests and dense jungles. The colony is located on seventeen acres of land enclosed by a stone wall. The numerous one-story buildings of brick and mortar are connected by roofed cement walks. The entire settlement, exclusive of physicians, numbers 360, of whom there are only 69 women. The youngest patient is only 6 years old. One of the patients, a man 60 years of age, has been here for thirty years. He is afflicted with the anesthetic form of the disease, is totally blind and has lost all of his fingers and toes. The disease has cured itself, but has left the patient a helpless, shapeless mass of flesh. It appears that the anesthetic and tubercular forms of the disease occur about with the same frequency. The institution is well managed and the nurses and two resident physicians do all in their power to render the existence of these hopelessly

Leper Asylum at Hendala.

diseased victims as comfortable as possible. The patients appeared to be content with their fate and the humane restraint that is practiced. The law of segregation came recently in force, but the authorities find it difficult to carry it out with the strictness for which it is intended.

LEPER BUDDHIST CELEBRATION.

The day I visited the asylum was the annual celebration to the memory of Buddha. It was a gala day, the walk leading from the entrance to the little Buddha temple was decorated with palm leaves. The procession was formed outside of the gate. There was no elephant to draw the shrine of Buddha perched on a rude cart, but a little humpbacked bullock answered the purpose very well, and he performed his part of the celebration with credit to his kind. A brass band and a band with native instruments headed the procession, then came the shrine followed by a number of bronze-colored yellow-robed priests, and lastly the Buddhist lepers in all stages of the disease. Explosives were thrown against the stone wall, where they exploded with a terrible report, emitting at the same time a blue-black smoke which enveloped the slowly moving procession. The bombardment, with the ear-splitting music of the native band, imparted to the whole affair a weird appearance. When the procession entered the temple silence was restored, and only the murmurings of the priests could be heard outside of its sacred walls.

CITY OF KANDY.

This little city of 20,000 inhabitants, the former residence place of the kings of Ceylon, has degenerated into a dilapidated mountain village. It is located in a valley in the subalpine region, surrounded by verdant hills and nestled around a little artificial lake of the same name. It is accessible from Colombo by rail, the road passing the first fifty miles through rice fields, marshes, then ascending for thirteen miles in a zigzag line to the height of 1,600 feet above the level of the sea, and then through a valley nine miles in length, when the little city suddenly comes into view. The beauty of Kandy and its environments have been greatly exaggerated by sentimental writers. The town is noted for the Temple of the Tooth, an old, crumbling pile of stones which contains in its most interior and not accessible part a tooth of the famous prophet. I happened to be in the city on the day when the Buddhists turn out in masses to do honor and homage to their deity—Buddha.

THE ANNUAL BUDDHA CELEBRATION.

For three days the little city was packed with a seething mass of humanity. In many places standing room was scarce. The great event took place at 9 o'clock Saturday evening, August 27. The procession, headed by a band of native musicians and three elephants abreast with their riders, was made up of 24 other elephants, an army of chiefs gorgeously arrayed, and bareheaded yellow-gowned priests, dancers with faces disfigured by white stripes, screaming and yelling boys and the faithful followers of the god of whom at least one tooth had remained to testify that he once inhabited this earth; the tooth that was carried in the procession in a shrine carefully guarded. The most solemn celebrants were the 29 magnificent elephants, who marched with slow, thoughtful steps, their sly little eyes peeping through small holes in their masks of royal red, casting a glance now and then on the sea of humanity on either side of the road. The great mass of people who took an active part in this celebration and the enthusiasm aroused when the hiding place of the tooth of Buddha came into view showed only too clearly that this deity has not lost his influence and power among the natives of Ceylon.

BOTANICAL GARDEN.

The botanical garden four miles from Kandy is the most interesting spot in this part of the subalpine region of Ceylon. It comprises thirteen acres of land, included in a horseshoe bend of the Mahaveli ganga. Every known variety of palm can be found here, as well as specimens of nearly all trees and shrubs of the tropics. I saw here a clove tree (*Eugenia caryophyllata*) at least forty feet high, an ebony tree (*Diospyros ebenum*) and a nux vomica tree of about the same dimensions. The towering palms, the dark walks cut through the otherwise impenetrable jungles, and the gorgeous flowers, of trees, shrubs and plants, make this spot a real paradise on earth, a great contrast to the dilapidated city of Kandy.

KANDY GENERAL CIVIC HOSPITAL.

This is a very pretty, comfortable, clean, well-managed general hospital, built on the same plan as the Colombo General Hospital. It is located outside of the depressing influences of a formerly famous, now crumbling city, in a little vale surrounded by green hills on all sides. The snow-white one-story pavilions and the connecting, roofed cement walks lined with square columns of the same color, around a central square ornamented with jack and botrees, palms and flower-beds, give it the very picture of isolation, comfort and peace. The 243 patients inside of its walls enjoyed the blessings of careful nursing and the benefits of excellent surgical and medical skill.

Dr. James William de Hoedt is the physician and surgeon in charge, ably assisted by a woman house surgeon, Miss Winifred Nell, L.R.C.P. and S. E. Dr. Nell is not only a very competent physician, but at the same time a skilled naturalist, as I had an opportunity to learn during the visit we made together to the botanical garden. The nursing staff is in charge of an Anglican sister, Sister Eustacia Mary, a well-trained nurse and charming lady. I found here a number of interesting emergency cases and the usual predominance of ankylostoma,

malaria and enteric fever. There have occurred here in the small maternity ward recently five cases of puerperal tetanus, all recovered. This hospital has a remarkable record in the treatment of tetanus, 13 cases without a death. Buried sutures are not employed, silk is used exclusively and the sutures are always removed. Chloroform is the favorite anesthetic and biniodid of mercury is largely relied on in hand and surface disinfection.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Jaundice.

Porter, in the *Medical Record*, gives the following suggestions for the treatment of this condition:

DIETETIC.

The author recommends that the different classes of food-stuffs be given in quantities that will not overtax the digestive functions nor exceed the oxygenating capacity of the system. In some patients the exclusive use of skimmed milk or butter-milk is most valuable. This is to be followed as soon as possible by the use of unskimmed milk, beef tea, plain meat broths, and raw eggs may be added to the diet as soon as the patient can tolerate them. Later, as soon as the system will digest them, soft cooked eggs and beefsteak may be allowed. Last of all, bread is added to the diet, in the form of dry toast or plain wheat bread which is from twenty-four to forty-eight hours old. Fruit and many other vegetable foods it is advised to void in all forms of intestinal indigestion, as these articles are prone to cause acidity and fermentation.

ATTENTION TO THE BOWELS.

It is indispensable in the successful treatment of jaundice that from one to three free movements of the bowels should be secured daily. The cathartics and antiseptics work best when combined with the bile and pancreatic extract and should be administered before each meal. For direct action on the liver the author recommends calomel in varying doses. Calomel may be given alone or in combination with arsenic, bichlorid of mercury and ipecac. Hygienic conditions must be given proper attention. These patients should have access to plenty of fresh air and light; a sojourn in the country is often of very great benefit.

In the treatment of jaundice the continuous use of sodium phosphate has found favor with many clinicians. This drug may be administered in doses of from one dram to one-half ounce three times a day, best given before meals. It should be given over a period of considerable time. Even after the jaundice has disappeared it is advisable to continue its use in small doses.

Vomiting.

Lemoine, in *Nord. Medical*, for Sept. 15, 1904, says that he has found the following mixture valuable in the vomiting of pregnancy, and also in various cases of gastritis:

R. Mentholig. iss	30
Tincturæ opii	
Tincturæ belladonnæ	
Tincturæ hyoscyami, Æ.m. xv	1
Alcoholis	32/3 20
M. Sig.:	Five drops in a little water every hour.	

Striæ Atrophicæ of Pregnancy.

The *Journal des Praticiens* recommends the following ointment, which may be of use in preventing the above condition:

R. Tincturæ nucis vomicæ
 Tincturæ calisayæ, āā.....m. lxxv 5 |
 Lanolini
 Petrolati, āā.....32/3 20 |
 M. Sig.: To be applied by massage for ten minutes every evening.

Typhoid Fever.

Hackett, in the *Medical Record*, describes his treatment of typhoid fever and calls it a specific treatment. It consists of the administration of mercury in the form of blue mass and calomel. The author believes that mercury is absorbed, taken up by the circulation and distributed throughout the body; by this means the mercury comes in contact with the typhoid bacilli and destroys them.

OUTLINE OF TREATMENT.

Blue mass in doses of from one to two grains is given every three hours from the time the patient comes under observation until the constitutional symptoms of mercurialism are noticed, such as soreness in the gums. An initial dose of five or ten grains of calomel is given, to be followed in a couple of hours by a seidlitz powder or two drams of Rochelle salts, unless hemorrhage or grave diarrhea is present. If constipation persists, five grains of calomel may be given once every day. Whether the bowels are constipated or loose, the rule is to give an alkaline cathartic during the fever; for example, a seidlitz powder or a teaspoonful of Rochelle salts. For restlessness and lack of sleep the author recommends an opiate which likewise quiets peristaltic action. If necessary, an enema of glycerin and water may be used to bring about a stool. For hemorrhage, morphin should be given hypodermically.

DIET.

Water and milk, equal parts to make a tumblerful, is given ice cold every two hours. If the stomach rebels after a fair trial, give some light farinaceous gruel or peptonized milk. Water is given freely. Watermelon has proved harmless and is a great source of comfort to the patient. The author has found that the mercury obviates to a degree the necessity for cold baths to reduce temperature.

As a result of this treatment he gives the following conclusions:

"1. In all cases of typhoid fever mercury is well borne by the system; it requires more mercury to get the constitutional symptoms of tenderness of the gums when typhoid fever is present than under any other circumstances.

"2. As the system becomes impregnated with mercury the bacilli gradually disappear, so that when the system is impregnated with mercury to the extent of a slight soreness of the gums the bacilli are no longer active. This is signified by a gradual reduction of the temperature to normal and a rapid convalescence.

"3. With the use of mercury the patient's blood is in a more healthy state; mercury maintains the red corpuscles of the blood, and accordingly the system does not fall into that state of grave anemia so common to the disease under other or no treatment.

"4. The patient may begin taking solid food as soon as the temperature is normal without danger of relapse. This I attribute to the healthy condition of the blood due to the action of the mercury in the system.

"5. A few days after the beginning of the administration of mercury in the treatment of typhoid fever the tongue becomes gradually moist. The breath gradually becomes less fetid, indicating a more healthy condition of the stomach, and there is a desire on the part of the patient to take the nourishment described. The stools also gradually lose their fetid odor. I have not had a dry tongue continue beyond three or four days after treatment was instituted since I began the use of mercury in this disease.

"6. The temperature of the patient treated with mercury in typhoid fever does not become subnormal after fever drops. The reason I ascribe for this is twofold: (a) We get control of the disease before the patient falls into a very low physical condition, and (b) the mercury increases the red corpuscles of the blood, tending to maintain the physical standard.

"7. It is unnecessary, unpardonable and unscientific to salivate a patient when using mercury in the treatment of typhoid fever, but I have yet to observe any ill effect of the slightest nature from the use of mercury in the system to the extent only of the soreness of the gums."

Diet in Typhoid Fever.

Henry, in the *New York Journal of Medicine*, says of the diet in typhoid fever that he gives nothing but water for from one to two or even more weeks, depending on the condition of the patient. Large quantities of water are given internally. After about a week, with everything going well, the patient is allowed every three hours a little orange or grape juice expressed fresh from the fruit. After all symptoms of bowel trouble have disappeared, the morning temperature normal and the tongue clean or clearing, food in very small quantities is allowed. The author states that he is not particular as to the kind of food allowed, but says: "I do not allow milk, soups, broths, or fresh foods or their extracts of any kind. As preferred by the patient, the most of the cereals or breakfast foods may be given, as well as the breadstuffs and about all kinds of fresh fruits. I allow the patient to eat but once in six hours, and for a number of days but one kind of the articles selected at a meal. Beginning with but a very small quantity at first, the amount can be gradually increased from day to day. Whatever is taken should be most thoroughly masticated; the dryer foods, such as toast or bread, should be chewed until they become quite fluid in the mouth, and the softer breads worked over in the mouth for some time, to insure thorough insalivation. I usually advise giving the fruit juice for some time after solid foods have been resumed."

The following formula is recommended for use in excessive tympany in typhoid fever:

R. Olei terebinthinæ3i 4 |
 Olei olivæʒiv 120 |
 Emulsi asafoetidæ q. s. ad.....ʒviii 480 |
 M. Sig.: Shake well; use as a rectal injection.

Medicolegal.

Weight to Be Given Expert Opinions.—The Supreme Court of North Carolina says, in re Peterson's Will, that where the expert states precise facts in science as ascertained or settled, or states the necessary and invariable conclusion which results from the facts stated, his opinion is entitled to great weight. Where he gives only the probable inference from the facts stated, his opinion is of less importance, because it states only the probability. Several eminent judges and authors express the opinion that the rule, even as limited, is not sound, and should be rejected. Certainly, in view of the wide divergence and often irreconcilable opinions expressed by medical experts in respect to mental capacity on personal knowledge of conditions and hypothetical questions, the principle should not be extended beyond the limits herein prescribed. This case presented a striking illustration of the danger of undertaking to prescribe any rule for weighing the testimony otherwise than by the opportunities for knowing the facts on which their opinions are based. Of the four intelligent physicians examined, two expressed positive opinions that the testator had sufficient mental capacity to make the will, and two with equal confidence expressed opinions exactly to the contrary. It would seem that the safer rule would be to permit the entire evidence to go to the jury, to be weighed and considered by them in the light of all the other evidence on the question.

Is It Heresy for an Eddyite to Have Superfluous Hair Removed?—The Supreme Court of Michigan says in the case of Meyer vs. Knott that it was novel (not to say unique). The defendant was a teacher of Eddyism, and was in February, 1901, first reader of the First Church of Christ, Scientist, of the city of Detroit. The declaration alleged that on Feb. 14, 1901, the defendant falsely represented to said plaintiff that she (the defendant) was then a conscientious believer in and

practitioner of the principles of "Christian Science," and "mentally and morally qualified and competent to give class instruction in Christian Science mind healing"; that the plaintiff agreed to pay and did pay the defendant \$100 for instruction, which was given; that by reason of the defendant not being a sincere and faithful believer in and practitioner of Christian Science, the plaintiff received no benefit from the instruction given him, wherefore he sought to recover the money paid and compensation for the time spent in the attempt to learn to "cure disease through the power of Christian Science mind healing." On the trial it appeared that the defendant had, two or three years prior to the contract with the plaintiff, had superfluous hair removed from her face by a physician by electrical treatment, and, as the plaintiff was able to call medical experts who testified that the superfluous hair was known to pathology by the name of "hypertrichosis," and was a disease, and as Eddyism is opposed to material treatment for disease, the Supreme Court says that it follows that one who has superfluous hair removed is not a true believer in, and adherent and practitioner of, the principles of Eddyism. But the court goes on to say that, apart from the consideration that this departure from the true faith, if it be such, occurred two years before the contract with the plaintiff, thus leaving ample time for the defendant to mature her belief, the court deems it sufficient answer to the plaintiff's contention that, if it be conceded that superfluous hair is a disease, it is also regarded by many as a facial blemish. Some conceal it as well as they may by the use of face powder: some have it removed. The defendant, because her little son teased her about the appearance of this superfluous hair, caused hers to be removed. This was not done as a treatment for disease, but as a means of making herself more presentable. The court thinks this did not tend to show that the defendant was guilty of fraud in holding herself out as a teacher of Eddyism. The court takes pains to add that it is to be understood that both the plaintiff and the defendant proceeded on the theory that Eddyism, as taught by Mrs. Eddy's book, "Science and Health," is true, and that it had therefore determined the case on that assumption. (Judgment for defendant was affirmed.)

Wisconsin Doctrine as to Privileged Communications.—The Supreme Court of Wisconsin says, in *re Hunt's Will*, that its decisions on the statute (section 4075, Revised Statutes of 1898) giving privilege of secrecy to all information acquired by physician from patient in attending latter professionally, necessary to enable prescription for such patient, have eliminated from consideration very many of the refinements and distinctions with which some other courts have limited, if not emasculated, similar statutes. Thus the privilege under the Wisconsin statute is not confined to communications made by the patient, but extends to all information, however derived by the physician in the course of professional attendance and for the purpose specified. Neither are the words "necessary" or "prescribe" to receive any technical or unduly restricted meaning. Further, this court has held that the privilege is created for the protection of the patient, and is personal to him; and has in the plainest terms repudiated the doctrine supported by some authority elsewhere that others can in any degree waive the privilege. In *Boyle vs. Northwestern Relief Association*, 95 Wis. 312, this construction was announced, although its application was merely to deny right of waiver to physician. In *Bruendl's Will*, 102 Wis. 45, right of waiver was contended for in behalf of the heirs of the decedent, who offered the physician's testimony, and the whole subject was argued and considered fully, whereon it was said: "The legislature has decided wisely that public policy requires such measure of restriction on the freedom of the physician to testify or of others to demand testimony." While the decision in that case turned on other considerations, the above remark was made with deliberation, and in response to full discussion. The court adheres to that view, and holds that no one, save the patient himself, can effectively consent to withdrawal of this mantle of secrecy which the statute has cast about the information which the physician needfully ac-

quires in and for professional treatment. Nor does the court agree with the contention that the statute has no application to a contest over the probate of a will. It says, among other things, that, as to physicians, its attitude, as already pointed out, is adverse to any power to waive the secrecy of professional information, and is also adverse to the grounds asserted by other courts, notably Iowa (*Winters vs. Winters*, 102 Iowa, 53), viz., that the "statutes are for the protection of the patient while living and of his estate when dead." Whether this last idea may be correct as to communications to attorneys with reference to property transactions, it certainly is not true with reference to the sheltering of information acquired by attending physicians. The purpose of that statute is personal. It is to protect the patient himself from disgrace or chagrin. Its effect on property rights or estate is only incidental. Such reasons do not cease on the death of the patient. His memory and good name are still subject to injury by publication of information necessary to proper treatment by his physician, and apprehension of such enforced publication after his death may well result in reluctance or unwillingness to make those disclosures necessary for preservation of life or health which it is the policy of the statute to encourage by assurance of their secrecy. The authorities supporting admissibility of attorneys' testimony as to the transaction of preparing and executing a will, which do not rest on a right of waiver of privilege in the legal representatives, do rest on grounds wholly inapplicable to the physician's testimony. The real ground, albeit not very clearly, declared in some of them is that the very transaction itself evinced an intention and desire on the part of the testator that the attorney should disclose what transpired, and therefore he himself had waived the statutory and common law seal of secrecy. Obviously no such purpose can be ascribed to the disclosures made to a physician for purpose of treatment by him because at or about the same time the patient prepares and executes a will. There is no rational connection between the two things; no probability that the patient expects or wishes his physician to publish to the world acts perhaps indicating parietic or other conditions, which might blacken the patient's good name and memory, or threaten the peace of mind of his descendants. Wherefore, after considering all the arguments urged or suggested in authorities cited, the court says that it is constrained to adhere to the views heretofore maintained by it that section 4075 is to be enforced according to its words, with no exceptions, save in the presence of a clear waiver of the privilege of secrecy by the patient himself; and that, after his ability to make such waiver is terminated by death, the physician's lips are forever sealed under all circumstances.

1. See abstract in THE JOURNAL of October 8, page 1078.

4. **Chronic Dyspepsia.**—The conditions revealed in the case reported by Reed were such as are found, with but slight variation, in all patients who insist on medicinal and dietetic treatment and realize little, or, at best, only temporary benefit from it. They are generally variously treated for "chronic dyspepsia," "gastralgia," "painful digestion," gallstones," "di-

lated stomach," "cardialgia," etc. Many of them, if left alone develop into cancer. The only rational treatment is rest and drainage. The only way absolute rest can be given to an ulcerated pylorus is to close it, while the only way drainage can be affected is to divert the food current. In the case cited, Reed performed a gastroenterostomy and a supplementary duodeno-duodenostomy three inches below the union to the stomach; the bile current was cut off from the stomach by plicating the proximal segment of the duodenum between the two artificial openings; complete occlusion of the pylorus was also affected by plication. The patient made an uneventful recovery.

6. **Genu Recurvatum.**—Cone reviews the pathology of this condition and reports one case for the purpose of adding more proof to the idea that the pathology is that of a displaced tibia due to a bending forward of the epiphysis on the diaphysis of the femur. Also, to indicate that if taken early and properly modeled and firmly fixed, the chances for a cure are much greater and much time is saved.

8. **Cancer of the Larynx.**—Semon urges the importance of early diagnosis of laryngeal cancer. The attention of the general practitioner should be drawn to the fact that there are no more promising cases for radical operation than those in which the disease is at first manifested by obstinate hoarseness, occurring, without any apparent cause, in middle-aged and elderly persons. The clinical diagnosis ought, whenever possible, to be confirmed by microscopic examination before a radical operation of any kind is undertaken. This, however, should only be done if the patient previously consents to immediate radical operation being undertaken in the event of the microscope confirming the diagnosis. The microscope is by no means infallible in these cases, and should its evidence be negative or inconclusive, microscopic examination should either be repeated, if necessary, several times, or, if the clinical symptoms do not warrant postponement, exploratory thyrotomy should be undertaken. The intralaryngeal method is unsuitable for the radical removal of malignant new growths of the larynx. Sub-hyoid pharyngotomy, apart from being applicable in a very small number of cases only, is still *sub judice* with regard to its advisability in such cases. Thyrotomy, if undertaken in suitable cases and at a sufficiently early period, and if performed on the lines which experience has shown to be successful, is a perfectly ideal operation in intrinsic cancer of the larynx. Hemi-laryngectomy comes into question only when, after opening the larynx it is found that mere thyrotomy will not suffice. When performed it may be accompanied by removal of the tributary lymphatics even if, apparently, not diseased. Semon advocates that total laryngectomy should be reserved for extrinsic, and for those cases of intrinsic cancer in which both sides of the organ are affected and in which the disease has proceeded too far to be eradicated by milder measures. When performed it should be accompanied by the removal of the laryngeal lymphatics on both sides of the neck.

9. **Thyroidectomy for Exophthalmic Goiter.**—Mayo prefers thyroidectomy to cervical sympathectomy in treating exophthalmic goiter surgically. He says if it were possible to eliminate more of the hopeless and yet operate on medium and severe types of the disease, the results of thyroidectomy would justify the operation and compare favorably with those obtained by other methods. His own cases show marked improvement of all who survived the operation. Of these, 50 per cent. made a very early recovery, especially of the severe

symptoms—tachycardia, nervousness and tremor; 25 per cent. did so after several months, and 25 per cent. were improved, yet suffer from irregular recurrence of some of the major symptoms. He says if the condition of the patient is fair, operate, but if the pulse is from 130 to 160, or if it suddenly fluctuates in tension and rapidly, if there is anemia, with swelling of the feet, the patients are placed on the belladonna treatment for several days. The more severe types are also given x-ray exposures in addition, which is continued for from 2 to 6 weeks.

14. **Splenomedullary Leukemia.**—When Cheney began the use of the x-ray in the treatment of this case the red blood corpuscles numbered 2,508,000; the white cells, 120,000; hemoglobin, 47 per cent. Throughout the course of the treatment the static machine and the street current were used and a "soft" or low vacuum Queen's tube. The duration of the treatment was usually from twelve to fifteen minutes. The tube distance was 10 inches, except in a few instances, when it was only 8 inches. The site of exposure usually was the splenic tumor, either directly in front or on the left side. Whenever there was any skin reaction the x-ray applications were made over the long bones—thighs and legs in particular, the sternum less frequently. At first daily exposures were made but because of intolerance of the skin Cheney adopted the plan of giving them every other day. During the nine months the patient was under treatment he received in all 144 applications. The effect on the patient's general condition was good. He improved in health, gained in weight, felt none of his old symptoms of weakness, dyspnea and abdominal distress. From a symptomatic standpoint he is well. However, the size and contour of the splenic tumor has not changed materially. The white cells fell as low as 45,000, but most of the time fluctuated between 70,000 and 90,000, the fluctuations apparently being dependent on the regularity or irregularity of treatment. The red cells gradually increased until they numbered 4,000,000, and they have never fallen below that point. The hemoglobin likewise has markedly improved, remaining stationary at 75 per cent. No bad effects were observed, except the dermatitis.

16. **Conveyance of Yellow Fever.**—Carter lays down the proposition that yellow fever is conveyed from the sick to the well by a mosquito host, the *stegomyia fasciata*, contaminated by feeding on the sick man; and, in nature, it is only thus conveyed. That this is the only method of conveyance, the argument is: 1. The analogy of other diseases conveyed by living hosts. 2. That the facts observed of the natural propagation of yellow fever agree with this theory. 3. That measures based on this theory have given the very results which they should have given if the theory were true. 4. No other natural method of conveyance is proven.

17. **Endotracheal Medication.**—Richardson believes that in intratracheal injections we have a valuable method of treating many of the inflammatory and infective diseases of the lower respiratory tract. The method is simple, safe and practical. The success in making the injections depends in no small measure on the selection of the syringe. The one which he has found most satisfactory is Shradel's. It consists of a glass barrel enclosed in metal and having a spiral spring attached to the piston. When the syringe is filled with the liquid for injection, it is relieved of its contents by gentle pressure with the index finger on a small spring that allows the liquid to flow out slowly or quickly, according to the will of the operator. The canula is about 8 inches in length and is of the proper curvature for its introduction and passage through the larynx. The selection of the medicaments is also of paramount importance. He has made most use of the volatile essential oils,

eucalyptus and thyme, combined with menthol, camphor, creosote, iodoform, or orthoform, with sterilized oil as a vehicle. The injections should be given daily, one or two drams of the liquid being injected at a time. The diseases treated have been bronchitis, bronchial asthma, tracheitis, bronchiectasis and pulmonary tuberculosis. Its greatest field of usefulness is in the treatment of bronchitis. The mixture which has proved the most beneficial in this class of cases is 5 per cent. campho-menthol with eucalyptus and thyme and sterilized olive oil, or a highly refined bland petroleum. No other treatment gives such prompt relief in the so-called "winter cough," chronic bronchitis of alcoholics, and the acute attacks which so often follow dissipation. As to tuberculosis, intrapulmonic injections have not proved to be all that was hoped for in the beginning. In most cases nothing more than temporary relief was afforded. The injections have no specific effects. Richardson believes, however, that they are a means of alleviating the local and general symptoms of the disease in many cases, better than by the internal administration of drugs.

- 18 *Treatment of Lateral Curvature. Edward H. Bradford.
 19 Fractures of the Radius in Starting Automobiles. E. B. Lund.
 20 Three Cases of the Association Neurosis, with Remarks on Its Genesis. John E. Donley.

18. Treatment of Lateral Spinal Curvature.—The object of Bradford's paper is to present simple principles and methods of treatment for lateral curvature without structural changes, which can be adopted without demanding elaborate preparation or outlay. The methods vary in the rigor of application according to the severity and urgency of the case. The simplest method for the application of a constant force is one applied with precision and in such a manner that it will stretch the curved and distorted ribs and not the other portions of the spine. When, however, any alteration in the shape of the bones has taken place, the use of a stronger correcting force is necessary. For this purpose, nothing is as efficient as the fixed plaster jacket applied with the patient in a corrected position, or in a position as nearly corrected as is possible for the patient to endure. It is necessary that judgment should be used in the use of corrective force, and a certain amount of skill is required in order that jackets put on will be borne by the patients. It is undesirable that the first jacket should be applied with a distressing amount of force. Windows can be cut in the plaster, allowing respiration in the portions of the spine which do not need pressure, but in any event the application of a plaster jacket, if any corrective force is used, should be employed only when it is possible to watch the patient for twenty-four hours after the application. In most jackets, it is necessary that the bandage should be applied above the shoulders. It is rarely necessary to include the head, though in the most severe upper curves this would undoubtedly be desirable. Repeated applications of the jacket are necessary if much correction is expected. The greater the amount of structural change and the older the patient, the less the amount of practical correction which can be expected. Fixed plaster jackets should not constitute a method of treatment any longer than is absolutely necessary. They should be followed as soon as possible by removable corsets and by the use of gymnastics. Removable jackets can be made either of plaster, leather, celluloid or of cloth, reinforced by properly applied steel bands. These removable corsets should be regarded as applicable when the danger of increasing growth has passed, or when the greatest amount of correction has been obtained. That form of removable plaster jacket which is most within the reach of the general practitioner can readily be made if a plaster jacket is removed from the patient and a cast is poured into the jacket, thus making a mold; around this a plaster jacket may be applied, reinforced by bandages, which are rolled in a mixture of dextrin and plaster of paris. A jacket made in this way requires a longer time to harden than the ordinary bandage, but it is somewhat more elastic and durable. If split and arranged with lacing it will serve as an adequate jacket to a faulty position.

25. Massage in Diseases of the Joints.—Norstrom reviews the progress made by massage as a therapeutic measure in the treatment of various forms of arthritis. He says that where formerly the surgeon tried to prevent bed sheets from coming in contact with the joint on account of the fear or pain or still more serious consequences, we now perform effleurage, instituting systematic extension and flexion. The dictum of absolute rest has given way to that of allowing the patient to walk. Acute processes, instead of contraindicating massage, are now taken to indicate its use. Immobilization is neither necessary nor useful. In acute arthritis massage yields rapid and positive results. Even after the first treatment the pain and tumefaction often are diminished and a permanent cure is arrived at in a very few days. Massage will also cure a certain number of cases of chronic arthritis. In tuberculous affections of the joints, however, it may be a factor in contributing to serious general disturbances. In ordinary hydrarthrosis, Norstrom has always succeeded in causing a disappearance of the liquid and nearly always in preventing its reappearance, probably by modifying the secreting surface. The application of massage in the course of a rheumatic affection is often interrupted by the occurrence of relapses of varying intensity. It is useless to interrupt the treatment unless the relapses are real acute or subacute attacks, when massage ought to be stopped and salicylate of sodium administered for some days, before the massage is taken up again. It is desirable, in order to secure a permanent result, to supplement massage—simultaneously or when the massage treatment is over—which is better—by general treatment in the form of thermal baths. It should never be forgotten that rheumatism is a general disease and that the effects of massage are purely local. In gout he uses massage only when the attack has subsided and when the arthritis, or tenosynovitis, or bursitis with effusion, remains and shows very little tendency to become absorbed. Massage is useless in arthritis deformans, except in so far that it diminishes the muscular atrophy. Sometimes, too, massage may be applied with profit in the accompanying effusion of the joints, probably of rheumatic nature. The manipulations employed in chronic arthritis are generally effleurage and friction. Tapotement is only used when the arthritis assumes a torpid character and when it is necessary to provoke reaction and revive the vitality of the tissues. No hope of success from the use of massage in gonorrhoeal arthritis is entertained so long as a discharge persists. After the cessation of the urethral discharge, the patient should be advised to have recourse to massage. In hyperplastic granular synovitis massage should be avoided because its use favors the absorption of a product containing a specific element.

29. Convergent Strabismus.—Reber's study has led him to draw the following conclusions: 1. Esotropia is most likely to manifest itself before the end of the third year. 2. It can not yet be said whether any of the various reasons assigned by parents for the appearance of strabismus have aught what-

ever to do with it. Whooping cough may be related to it. 3. Heredity certainly plays a part in bestowing on some children a congenitally deficient visual apparatus. 4. The degree of deviation will average about 30 in a large number of cases. It is in no special way bound up with the degree of refractive error. 5. The amblyopia of esotropia is presumably an amblyopia ex anopia, the present day evidence being against Schweigger's theory of a congenital amblyopia. 6. The degree of amblyopia increases with the length of time elapsing between the appearance and the time of treatment; especially is this true after the seventh year. 7. Improvement may be expected in the amblyopic eye in from 50 to 60 per cent. of cases by properly adjusted glasses. This improvement varies from 20 per cent. to ninefold betterment. 8. While a defectively developed fusion apparatus has much to do with the genesis of esotropia, the influence of hypermetropia and its allied states seems almost as important as in the days of Donders. 9. The part played by astigmatism is no little one. 10. There seems to be no special relation between the degree of refractive error and the degree of deviation. 11. Hypermetropic conditions of from 1 to 4 diopters seem most commonly associated with esotropia. 12. A very high degree of hypermetropia does not necessarily exclude strabismus. 13. If taken before the fifth year, there is no reason why the strabismus should not be cured by non-operative methods in 70 per cent. of cases. This percentage will, in all probability, be increased to 80 per cent. in the next ten years. 14. The results of non-operative treatment in children, if adhered to with any persistence, are infinitely better than any "scissors" statistics thus far offered.

31. **Chronic Dysentery.**—There is no doubt in MacDonald's mind that all chronic cases of dysentery, and most acute ones, should be operated on. The cecum is the home and head center of the germ, whatever one there is, and he believes that operation will, in the future, be just as common as wiring a fractured bone. The operation advocated by him is an inguinal colostomy, the cecum being opened. The edges of the abdominal wound are whipped with a continuous suture fastening the peritoneum to the skin; the cecum is then sutured to this, care being taken that the suture passes only through the peritoneal and muscular coats of the bowel. The wound is then packed with iodoform gauze and the patient returned to bed. Two days later the cecum is opened and potassium permanganate irrigations are begun. A large tube with shoulder is placed in the inguinal wound, and the anus is made patulous by a similar process. Three gallons of a 1 to 10,000 solution is passed through the bowel twice daily. There is some difficulty in closing the wound. MacDonald objects to the old semi-circular flap inasmuch as that leaves two weak places in the abdominal wall instead of one; but if the gut is closed carefully and then dissected back far enough to get to the peritoneal surface of the bowel, and use a Lembert's suture, the closure becomes easy. The permanganate solution should be hot and plenty of it used.

45 Imperforate Anus, with Report of a Case. Wm. F. Stucky.

46 Mental Hygiene. Mary Lawson Nef.

42. **Feeding with Essential Fat of Tubercle Bacillus.**—MacDonald claims to have discovered that hydrous cholesterol fat (wool fat) gives the essential tests of the tubercle bacillus. The importance of the discovery is that when patients are fed on it there is a marked increase in weight and a favorable influence on the progress of various chronic wasting diseases. More than half a pound has been administered daily, with excellent results, both in health and disease. About half of the tubercle bacillus consists of fat, which explains the historic therapeutic value of the latter. The author details a number of chemical experiments and confirmatory tests, together with clinical results, to prove his findings.

45. **Imperforate Anus.**—An examination of Stucky's case showed the entire perineum to be smooth with the exception of a small spindle-shaped bleb slightly darker than the surrounding integument, at the posterior margin of and running into the scrotum. No fluctuation nor bulging could be seen. An incision about half an inch long was made at the normal site of the anus. This was increased in depth to one inch without encountering the rectum. It was then decided to cut into the small bleb, hoping that it might have some connection with the bowel. The result was the escape of a small amount of gas, but no meconium. This point proved to be the termination of the rectum, which organ was almost straight, lacking both the curve in the direction of the hollow of the sacrum and coccyx and the curve in the opposite direction near the anus. Although no fecal contents had escaped, no obstruction could be found higher up. A piece of small rubber tubing was introduced and fastened with silk sutures, and the first incision closed with interrupted silk sutures. An hour later the child was given one-half teaspoonful of castor oil, which resulted in a copious action of the bowels. There was no infection, and the wound healed by first intention. The tubing was removed on the sixth day and the silk sutures two days later. The anus began to take on a natural appearance and the stools were normal. No further trouble was experienced with the intestinal tract, but after a few days of apparent improvement in strength and vitality, the patient began to decline steadily and finally (seventeen days after birth) succumbed to marasmus.

Archives of Electrology and Radiology, Chicago.

47 *A Large Fibrosarcoma Treated by Roentgen Radiation. Clarence Edward Skinner.

48 Electric Resonance. Karl G. Frank.

47. **Fibrosarcoma Treated by Roentgen Radiation.**—The tumor in the case cited by Skinner was situated in the lower part of the abdominal wall in the region of a cicatrix, the result of a laparotomy performed three years before, for what was regarded as a fibroid tumor of the uterus. The fibrosarcoma was the size of a cocoanut, filling up the entire iliac fossa, extending nearly to the umbilicus, and two inches beyond the median line to the left. The tumor was very firmly fixed and seemed to involve the abdominal wall. Microscopic examination showed it to be a fibrosarcoma. Erysipelas toxins were used for ten months. During the first two months the growth decreased more than half in size, and for a long time thereafter, while there was no decrease, there was no distinct growth. Later on, the influence of the toxins seemed to have become lost, and there was a slow but gradual increase in size. X-ray applications were then begun, and were administered by means of a tube giving rays of high penetration and backing up a spark of from four to six inches, excited by a machine having 12 thirty-two inch revolving plates, for the first seven months, and by a machine of the same type having 16 revolving plates thirty-two inches in diameter, for the rest of the time. The anode was placed nine inches from the patient's skin and the duration of the application was fifteen minutes. The tube was focused on the middle of the anterior surface of the tumor at one seance, on one side at the next, on the other side at the third, and so on, treating these different

areas successively. One layer of thin toweling was interposed between the source of the rays and the patient's skin, and the face, chest and thighs, below the level of the pubis, were shielded by tin foil, gauge No. 22. The patient received 136 applications within 739 days, the applications being given on an average of every 2.5 days at the beginning of the treatment, then, later on, one in five days, fifteen days and thirty-seven days. Twenty-eight months after beginning the treatment, the patient had increased considerably in weight and the tumor had entirely disappeared. Among the conclusions deduced by Skinner are the following: 1. Roentgen radiation sometimes brings about the entire disappearance of large, deeply located, malignant neoplasms, which have been proven to be hopelessly lethal in their tendency under any other management, and simultaneously restores the patient to apparently perfect health. 2. The fact that it sometimes accomplishes this result, taken in connection with the size of the malignant mass in the case just cited demonstrates that the lack of satisfactory influence which attends its employment in so many cases is not due to weakness, inherent in the remedy itself, nor to mere thickness of the tissues intervening between the pathologic focus and the source of rays, but to some at present undetermined factors. 3. There is probably a direct and intimate connection between systemic toxemia and the disappearance of malignant growths under Röntgen radiation as indicated by the uniform occurrence of sudden diminution in the size of the tumor immediately following each onset of toxic symptoms during the later course of the case reported. 4. The application of the Roentgen rays to a malignant growth belonging in the same class as the one described should be persisted in as long as the patient's condition will permit, even if no benefit is observable. 5. There is a vast difference between the therapeutic effect of the rays derived from a tube excited by a static machine and those derived from a coil-excited tube, and the difference between the rays derived from these two sources will sometimes constitute the difference between success and failure in the management of deeply located malignant processes.

- 49 Hip and Shoulder Amputations. Myles F. Porter.
 50 Broken Links in the Chain of Surgical Asepsis. Walter B. Chase.
 51 *Vagino-fixation for Retrodeviation of the Uterus, with a Report of 120 Cases. L. R. Garrigues.
 52 The Up-to-date Treatment of Fractures. H. L. Stickney.
 53 A New Brace for Fracture of the Thigh. J. F. Myers.

51. **Vaginal Fixation of Retrodeviation.**—Garrigues presents the results obtained in 120 cases, the uterus being examined seven weeks after operation. Of 78 extra-peritoneal operations, 16 cases were examined and found normal at periods varying from three months to two and a half years. Among the 42 cases operated on by the intraperitoneal method one recurrence was found; 9 were examined at periods varying from three months to two years after operation. Of these 120 cases, 12 became pregnant; of this number 2 aborted, and 1 aborted but later bore a child normally. The rest bore children at term without artificial aid or unusual pain. The patients are all reported to be well since their confinement. There were no deaths following the operation, nor was the bladder wounded. Garrigues' technic may be described, briefly, as follows: Make a longitudinal incision through the vagina extending from 1.5 cm. below the meatus urinarius to well below the bladder. Two flaps are dissected to the sides with the handle of the scalpel, and the forefinger gradually inserted under the bladder to separate this organ from the uterus, which is held antverted with a sound, and pulled down with a bullet forceps. As the finger is pushed higher it penetrates between the uterus and its peritoneal covering, and the latter is seized with hemostatic forceps and incised. The adnexa are then palpated and freed from adhesions, if they are slight. If the adhesions are dense and the adnexa diseased, the fundus must be delivered through the incision. The adnexa are then ligated and excised, cysts broken, subperitoneal fibroids excised, adhesions torn, etc. The uterus is replaced by traction on the cervix and gentle pressure on the fundus. In closing

the peritoneal cavity, care must be taken to approximate the peritoneal edges so as to get only sero-serous adhesions. This is done by passing a medium sized sharply curved needle armed with silkworm gut through the vagina near the urethral end of the vaginal incision, through the peritoneum, the fundus of the uterus, the other side of the peritoneal incision, and finally through the vagina again and tying the suture. It is important for the ultimate result of the operation to insert the suture at about right angles to the tip of a sound introduced into the uterus. A second suture is introduced slightly below the first, but similar in other respects. The rest of the open peritoneum is united with a running catgut suture, and the vagina with interrupted silkworm gut. All cases are first everted to avoid septic complications. When the anterior vaginal wall is short, a transverse incision just above the cervix is made instead of a longitudinal one, and the vaginal sutures inserted so that the two ends of this incision are united, thus lengthening the anterior vaginal wall. Garrigues lays particular stress on the use of the transverse incision in cases of congenital retroflexion as, in his opinion, the large number of failures reported to permanently correct by various operations the malposition of the uterus in these cases is due to the short anterior vaginal wall pulling the cervix forward and hence the fundus backward. Should the vagina be too narrow to work through to advantage, an oblique vulvovaginal incision is first made, which is subsequently sutured. If an operation on the cervix is required it is performed before the fixation so as not to strain the sutures holding the uterus in place. Should a cystocele exist, a semilunar portion of the vaginal wall is cut away from each side of the longitudinal incision before suturing. After the operation there remains a uterus freely movable in all directions except into retroflexion. The suture material should never be silk, as it often carries infection from the vagina and thus causes a very tight fixation. Silkworm gut is best on account of its dense nature and unirritating properties. The sutures are left in seven weeks, the patient going home in the meantime, and are then removed. The operation is a safe one; the results are durable; no scars are left; the ovaries and tubes can be operated on conveniently if found diseased; the plastic work so frequently required can be readily performed, and there is no difficulty with gestation if the method is well chosen.

Journal of Nervous and Mental Disease, New York.

November.

- 54 President's Address, at Thirtieth Annual Meeting of the American Neurological Association. Frank R. Fry.
 55 *Purulent Myelitis: Focal and Disseminated. Joseph Collins.
 56 *Hallucinations. Wm. A. White.

55. **Purulent Myelitis.**—Collins reports a case of an unmarried woman, 25 years old, who, shortly after an attack of influenza, complained of parasthesia and pain in the left leg and back. Three months later she had to stop work because of weakness of the left leg. The pain and weakness continued to grow worse and nine months after the onset of her illness the right lower extremity became involved. The leg felt cold, there was a burning sensation in the knees, the legs felt stiff, and there was a constant sensation of burning in the lower part of the abdomen. Examination revealed exaggeration of the knee and ankle jerks, patellar and ankle clonus and Babinski jerk; anesthesia on the anterior surface of the left thigh, anesthesia and thermoanesthesia on the outer side of the same area. On the posterior surface there was less disturbance of sensibility than on the anterior. On the inner and outer surfaces of the right thigh there was complete loss of sensibility. On the anterior surface of the right thigh there was still some sensitiveness. Two months later there was complete paraplegia, the left leg being spastic, the right flaccid. Loss of both plantar jerks, knee and ankle jerks present, left greater than the right. Anesthesia, thermo-anesthesia, and some analgesia of both lower extremities from the crests of the ilia and a line drawn around them downward. Just above this line there was a belt of hyperesthesia two inches wide. There was some tenderness at the tenth dorsal vertebra. Death ensued fourteen months after the onset of the illness. At the autopsy no evidences of syphilis were found.

The viscera and other structures of the body revealed no focus from which the abscess of the cord took its origin. The entire lower end of the spinal cord was flooded with thin creamy pus. No abscess cavity was detected until after the cord was sectioned, when a longitudinally placed cavity was found in the sacral region, chiefly in the posterior portion of the gray and partly also in the white matter. It reached from the lower end of the cord about one inch upward. Numerous extensive disseminated purulent foci were found throughout the entire cord. A diagnosis of syphilitic spinal paralysis was first made and, naturally, when the paraplegia was not yet complete, such a diagnosis was quite as tenable as any other. Moreover, there was apparently no attributable cause for a starting point for the abscess formation, save possibly the attack of influenza. The final diagnosis was reached only by exclusion. The onset and course of the disease, its clinical manifestations and the findings at autopsy are of considerable interest.

56. **Hallucination.**—White narrates ten cases illustrating how phenomena, as ordinarily experienced, can graduate into a true hallucination, and arrives at the following conclusions: 1. Hallucinations are false perceptions. To have a false perception there must be something to perceive, and that something is in the environment and can only enter as a factor into the mental life through the intermediation of sensation. Ideas can not be perceived. 2. Hallucinations are secondary sensations either arising in the same sensory field, in which case they may be described as illustrations in the sense of Esquirol, or arising in other sensory fields, in which case their secondary character is quite clear. 3. The mental state in illusions and hallucinations is identical. 4. Given the sensory elements, the falseness in their perception is due to central derangement.

 59 *Granuloma Fyrogenicum* (Botryomycosis of French authors). M. B. Hartzell.

58. **Erysipeloid.**—The observations made by Gilchrist in his cases are as follows: The incubation period varied from three hours to two days, in the majority of cases the latter. The duration of the disease was about a week, although in many cases it was only three or four days, and in a few extended from ten days to two weeks. In practically all the cases the disease occurred on the fingers or hands, there being only two cases where the lesions appeared on the soles of the feet. The history is practically always that of a bite or injury from a crab. The part bitten becomes red, swollen, painful, hot and accompanied by a throbbing sensation. The lower border of the eruption presents a distinct line of demarcation and is slightly raised. The disease extends slowly from finger to finger, finally encroaching on the back or palm or both sides of the hand. The characteristic slightly raised margin retains its definite bright red outline wherever it advances, but usually presents a rather more acute inflammatory aspect than the enclosed area. A particularly characteristic feature of this dermatitis is that suppuration never occurs, neither do any papules, vesicles nor pustules form on the surface, unless, as very rarely happens, pus organisms infect primary lesions. Desquamation does not follow. There are practically never any constitutional symptoms, except, perhaps, a slight pain extending up the arm. Careful bacteriologic examination failed to reveal the presence of any micro-organism. The disease is differentiated from erythematous eczema by the character and location of the lesion. In eczema also there is intense itching, whereas erysiploid is accompanied by pain, which is relieved by firm pressure. Erysipelas, on the other hand, is unusual on the hands alone or on the fingers, and it is accompanied by constitutional disturbances. The treatment in these cases consisted of thorough disinfection of the injured part with bichlorid solution, then a carbolic acid solu-

tion varying in strength from 1/20 to 1/30 was injected hypodermically at the growing margin of the disease, and finally the affected portion was dressed with iodoform ointment. Unna's salicylic acid plaster was also used. At first 50 per cent. was applied in strips to the diseased portion, and also well beyond the growing edge of the patch. In many cases one application was sufficient to cure the affection. The results of various methods of treatment have shown that the salicylic acid plaster of the strength of 25 per cent. is the best remedy, although plain adhesive plaster is frequently efficacious. After removal of the salicylic plaster, at the end of three days, the skin is white and sodden. A simple ointment is then prescribed.

 61 *Pruritus Considered from a General Standpoint. H. E. Ménage.
 62 *A Preliminary Note on a New Clinical Method as an Aid in Diagnosing Renal Impairment. A. C. Eustis.

61. **Pruritus.**—The one remedy which has proven most useful in Menage's experience in the treatment of pruritus is cannabis indica. The initial dose should be small, 5 drops three times a day, well diluted and given after eating and increased gradually until 20 or 30 drops are taken at a dose. Next, in the order of his preference, are camphor monobromate, valerian, musk and castoreum, given separately or combined in pill form in full doses. Locally he uses a combination of carbolic acid, menthol, camphor and chloral. He has also used the galvanic current with good results in a few obstinate cases of localized pruritus. The current should be applied with as much intensity as the patient will and can stand. In general pruritus currents can not be used in any such strength, and in such cases the electric bath with the sinusoidal current, as suggested by Oudin and Bisserie, is the one worth trying.

62. **Diagnosis of Renal Impairment.**—Eustis' method is based on the nitrogen content of the blood and is carried out as follows: Twenty cubic millimeters of blood are sucked up after pricking the ear, in the Gower hemoglobinometer pipette and transferred to a test tube, preferably one six inches long. The pipette is washed out with distilled water into the same test tube and 1 c.c. of concentrated sulphuric acid is added. The mixture is then boiled and small crystals of potassium permanganate are added from time to time, until the black color caused by the charring of the sulphuric acid has entirely disappeared. A water-white solution is thus obtained in a few minutes. After cooling, the acid solution is diluted to 100 c.c. in a Nessler jar and 2 c.c. of Nessler's solution are added. A yellow color is produced, varying in intensity with the amount of ammonium sulphate present. By comparing the color obtained with the color produced by known amounts of a standard ammonium chlorid solution, after the addition of the same amount of Nessler's solution, the nitrogen in the 20 cm. of blood can be ascertained. The standard ammonium chlorid solution used is made by dissolving .314 grams of C. P. ammonium chlorid in 100 c.c. of water. Five cubic centimeters of this solution are diluted with distilled water, sufficient to make 500 c.c. Each cubic centimeter of the dilution contains .01 mg. of ammonia or .008 mg. of nitrogen. By multiplying the number of cubic centimeters of standard ammonia solution required to produce the same color as obtained with the blood by .008, and this result by 5,000, we obtain the milligrams of nitrogen in 100 c.c. of blood. Comparisons of the colors should not be made until the solutions have stood twenty minutes. Thirty minutes in all are required for the entire operation, provided the solutions needed are at hand. Examinations of the blood of 18 normal and healthy individuals have given Eustis a reading of from 40 to 80 mg. of nitrogen per 100 c.c. of blood, and usually they were below 40 mg. Variations in color of less than 1 c.c. were not noted, and he took 40 mg. as his normal. In all cases of nephritis he obtained a high content of nitrogen in the blood, while in those cases in which there was no renal impairment the nitrogen content was low. Three cases are cited in which the diagnosis

was made from the blood finding alone. From the cases observed Enstis concludes that if the blood of a patient shows a nitrogenous content below .50 mg. of nitrogen per 100 c.c. of blood there is no renal impairment. If the blood shows a nitrogen content of from 120 mg. to 140 mg. per 100 cc., there is partial renal impairment. If the blood shows a nitrogen content of 200 mg. to 100 c.c. of blood, the patient is suffering from uremia. Recommending the method are the short time required for its performance, the small amount of blood needed, its simplicity and its applicability in doubtful cases of uremia.

5. **Chronic Appendicitis.**—A new method of closing certain wounds is described by Bell and the term "autorrhaphy" is applied to it. This method, or a modification of it, can be utilized to close wounds in the abdominal wall and wherever aponeurotic tissue of sufficient strength is available. A fairly long skin incision is made, rather lower and nearer the an-

terior superior iliac spine than is indicated in the text-books. It is the most convenient incision for reaching the appendix at once and it also gives better strands of the aponeurosis of the external oblique which are to be utilized in closing the wound. In a chronic case or in the "quiescent" period of an intermittent case, the best and usually adopted method of separating the muscles in the direction of the fibers should be employed. When the aponeurosis of the external oblique is reached it must be very carefully cleared of its fascial investment, in order that the fibers may separate easily when required later. This done, a clear interfibrous space is found and opened for the whole length of the wound with the knife. The divided aponeurosis is then raised and undermined for about half an inch throughout the length of the incision on either side of its division. Next, the internal oblique is divided in the ordinary way in the direction of its fibers and the transversalis fascia and peritoneum in the same direction; as a rule, quite a small opening is required in order to deliver and remove the appendix. The object of the operation being successfully accomplished, the divided external oblique aponeurosis is seized on the side nearest the umbilicus and an interfibrous space sought for about one-sixteenth inch from the edge. This space is opened with the point of the knife, and the handle or a blunt dissector used to split the isolated strand up to the ends of the original incision. This divided strand is removed with knife or scissors, and is threaded on one of the special needles with a large eye, or it is seized at one extremity by a modified Cleveland needle forceps and then passed through the internal oblique and transversalis muscles and the peritoneum on either side of their division and tied. As a rule, one suture is quite sufficient to close the innermost layers, but should another be required it can be obtained in the same way and from the same side as the first. Next, two other strands are separated in the same way, one on each side of the incision through the external oblique, that on the umbilical side being freed at the lower end of the wound while the other strand—on the side nearest the anterior superior iliac spine—is freed at the top end of the incision. The external oblique is then laced up from either end of the incision, the strands meeting and being tied in the middle. The skin may then be closed with an ordinary or with a wire subcutaneous suture. The advantages of the method are obvious. No foreign material need be introduced into the abdominal wall. Instead of irritating sutures in the sensitive muscles, living material is used which belongs to the part and will go on living. There is little danger of sepsis.

6. **Congenital Hypertrophic Stenosis of Pylorus.**—Nicoll holds that the appropriate treatment of hypertrophic stenosis of the pylorus is to "burst up" the thickened pyloric ring by forcible over-stretching from within, as one does in obstinate urethral stricture. He is decidedly in favor of a combination of Loretta's operation with gastroenterostomy. This has been completely successful in several cases. In one case, however, no relief was obtained, and the patient died six days after operation; in another case apparent cure was followed by a return of the vomiting at the end of two months. The operative procedure adopted by Nicoll may be stated thus: Open the stomach, within easy reach of the pylorus; pass the dressing forceps through the incision into the stomach, and gradually force them through the contracted pylorus; stretch the pylorus until the peritoneal coat slightly ruptures. Then decide the further course of the operation by the infant's general condition. If collapse be imminent, close the stomach and abdomen rapidly by suture, regarding the operation as a temporary measure merely. If, however, the child's condition permits, complete the operation by a gastroenterostomy, making use of the incision already made in the stomach wall. He believes that the thickness of the pyloric wall renders pyloroplasty unsuitable in this instance.

8. **Operations for Varicose Veins.**—The method employed by Kennedy in dealing with varicose veins of the leg is to remove in every case the internal saphena in the thigh up to a point within one and a half or two inches of its termination at the

saphenous opening, whether the vein in the thigh appears to be varicose or not. When the vein has been removed from the thigh its removal is continued downwards into the leg and the prominent varices are also removed as far down as they extend, together with any prominent tributary in the leg. The total length of vein removed varies from sixteen to twenty-one inches, so that the internal saphena is almost entirely removed. In no case does the slightest untoward result follow the operation; and with the exception of two cases, which had a history of syphilis, the long wounds all healed up perfectly by first intention. A reaction on the circulation of the leg need not be feared, for the vein which is removed lost its function of returning blood long before the operation was undertaken. The results in every instance have stood the test of time. Patients examined at the end of periods ranging up to five years were found to be not only free from symptoms, but also from any recurrence of dilated veins.

15. **Treatment of Injury and Acute Infection.**—The ideal treatment of general peritonitis, according to Ballance, is continuous irrigation, or the continuous bath treatment so successfully employed in acute suppuration in joints. He has twice endeavored to carry out this treatment with baths of normal saline solution, but, unfortunately, both cases were unsuccessful. One was a case of duodenal ulcer which had perforated two days before operation. The other was a case where general peritonitis had occurred from a first attack of appendicitis; the operation was not performed until the seventh day. Both patients lived forty-eight hours. In both, the intestines were allowed to float out through the single long incision into the bath of saline solution. So rapidly did the purulent matter escape into the bath that several assistants were required to keep the bath water even approximately clean. At the necropsies the abdominal cavities were absolutely clean. Ballance suggests that it would probably be better after dealing with the local cause of the peritonitis rapidly to insert three or four drainage tubes through reasonably small openings in various situations and then at once to commence the bath treatment. This would obviate manipulation of the intestine which causes so much shock.

17. **Wreck of the Australia.**—Incident to the investigations following the wreck of the steamer *Australia*, the following regulations were adopted by the marine board of Victoria for the visual requirements of those who propose to enter the pilot service: 1. Vision to be 6/6 in each eye without glasses. 2. The total error of refraction is not to exceed 1 D., and of this astigmatism is not to exceed 0.5 D. This estimate is to be made by retinoscopy with the eye under the influence of a mydriatic. 3. The pupillary reflexes are to be normal. The fundus to be free from disease, the visual fields to be normal and the balance of the ocular muscles is to be normal. A candidate is to possess binocular vision. 4. Color vision is to be normal, as tested by colored wools and colored discs. 5. If during the course of service the vision deteriorates, the pilot must retire from the service. 6. If the pilot should be concerned in any accident, he should at once undergo re-examination. 7. The pilots are to be examined annually and must retire at 60 years of age. (See item concerning Health of Pilots in THE JOURNAL, November 5, page 1357.)

18. **Clinical Study of Actinomyces.**—Knox reports three cases of actinomyces occurring in two boys and their sister

who had been in the habit of visiting in the country on a farm for several years in succession. The first patient developed her serious symptoms at the farm in the shape of an attack of pleurisy with high temperature. The two boys had adenoids for years. All three patients had had trouble with their teeth. They all suffered from colds in the head and congested throats at variable periods, and they all had some glandular trouble. In the case of the girl several of the swellings developed into abscesses, which contained the characteristic fungus. One boy improved after his faulty teeth were attended to and the adenoids removed. The other two patients responded to iodids and a marked improvement in health was noted. Knox concludes that the infection in these cases occurred through the mouth, probably through the carious teeth. An early examination of expectoration or pus is the only certain method of diagnosis; in fact, an early diagnosis can only be made by the aid of the microscope. Surgical measures should be instituted at once if the lesion is superficial. It is the most rational and effective treatment. Iodid of potassium appears to be a specific in early cases, but the remedy must be pushed to its extreme limit. It appears that patients suffering from actinomycosis are very tolerant to this drug. One of Knox's cases took, on an average, 103 grains daily without exhibiting any undue symptoms.

23. **Antistreptococcus Serum in Infection.**—Anderson has made use of antistreptococcus serum in two cases of streptococcal infection with good results. To achieve the best result the following factors seem necessary: 1. That where the infection is "single" and polyvalent serum is obtainable possessing the "immune" body, it should be applied as soon as the illness is recognized, the object being to inject before much toxin is formed. 2. That the serum should be as fresh as possible. 3. That in those cases in which the serum is doing good there is no danger in administering an excess, and that in those cases where there is no apparent benefit there is no evidence to show that it does harm. 4. That since the serum acts mainly by increasing phagocytosis and since, in certain cases, very little antidote is formed, the administration of the serum should be continued for some time after apparent recovery, until its action is quite complete.

25. **Treatment of Embolism and Phlebitis.**—Reynier takes issue with Lucas-Championnière in regard to the treatment of phlebitis with exercise and massage. He reaffirms the necessity for repose and for even exaggerated prudence in the treatment of phlebitis, old or recent. Immobilization at first, and afterward careful refraining from any exaggerated fatigue, repose at the slightest suspicion of pain or edema—"these measures will protect better than massage or movement against embolism, the Damocles' sword always over our heads."

27. **Diverticula of the Appendix.**—Lejars gives illustrations of the diseased appendix in a number of cases in which diverticula of varying shapes and sizes were discovered. They are probably the result of the formation of an abscess in the wall, the neck opening into the lumen of the appendix being comparatively narrow. When the abscess is evacuated the cavity persists, forming a recess liable to harbor microbes, the thinness of the walls inviting perforation. These diverticula may explain recurrences of appendicitis and the perforation in apparently mild cases. The frequent localization of these diverticula on the adherent margin of the appendix may explain likewise certain cases of subperitoneal iliac suppuration orig-

inating in the appendix. He has had occasion to operate in one case of deep phlegmon under the iliac peritoneum, combined with an intraperitoneal iliac phlegmon. The origin of the trouble may be ascribed to perforation of the meso-appendix consecutive to perforation of the adherent margin of the appendix, probably the result of suppuration in a diverticulum at this point.

29. **Lipoma of the Breast.**—Out of the 18 cases found in the literature 5 were men. The affection is essentially benign, and a single lipoma is readily shelled out. In case of multiple, deforming tumors, ablation of the breast may be necessary. In a personal case described the breast "resembled a bag full of oranges," and was excised. The other breast was entirely normal.

30. **Fat Embolism After Forceful Straightening of a Stiff Joint.**—De Quervain has had a case of threatening fat embolism occur after forceful straightening of an ankylosed knee and ankle consecutive to osteomyelitis of the tibia. The straightening was done with the utmost care and the minimum of force, and yet, thirty-six hours later, symptoms developed suggesting fat embolism—bloody sputa, dyspnea, rapid pulse, temperature of 40 C. and frequent vomiting. A large amount of fat in the urine confirmed the diagnosis, but the case terminated in the recovery of the patient, a lad of 13. Search in the literature revealed 10 similar cases, all fatal. It is probable that fat embolism has occurred more frequently than these statistics would indicate, but has escaped attention in the cases with favorable outcome. The joint requiring straightening was always the knee or ankle in the cases on record. There is a specially large proportion of cancellous tissue in these joints, much more than in the wrist and elbow. They are further distinguished by the fact that the bone has to be compressed in straightening them, the more, the greater the deformity. In 7 out of the 11 cases several joints had been straightened at one time, both knees in 4 instances. The long immobility of the joint entails atrophy not only of the muscles but of the bone itself. The true bone substance becomes substituted by adipose tissue. This substitution of fatty marrow for the bone facilitates its compression during the maneuver, but also supplies an abnormal amount of fat. Compression of any bone long condemned to inactivity shows astonishing softness of the bone tissue while a reddish juice escapes, like an emulsion of blood and fat. In all the cases above mentioned the joint had been immovable for a year at least, with one exception, in which the ankylosis was only of five months' duration. He describes the three ways in which fat embolism might be induced by forceful straightening of an ankylosed joint, and adds certain points useful for prophylaxis. If the patient exhibits signs of the lymphatic diathesis which Payr regards as a factor, it is better to err from excess of caution rather than the reverse. The physician should refrain from straightening more than one joint at a time. He should bear in mind the possibility of osteoporosis resulting from the long inaction of the parts. A further important aid is afforded by radiography, comparing the stiff with the normal joint. If the bone is discovered to be abnormally porous it is better to abandon the idea of forceful straightening even of a single joint, and apply more gradual measures. They are liable to be more effectual the more pronounced the osteoporosis.

34. Blood Count in Gynecologic Affections.—Pankow relates the particulars of his study of the blood count in a large number of patients at the Jena gynecologic clinic. He has become convinced that repeated finding of more than 10,000 leucocytes always indicates a suppurative affection in the adnexa if other causes can be excluded.

37. Pure Septicæmia.—Kneise reports a case in which the heart, liver and kidneys were found studded with streptococci the fourteenth day after spontaneous delivery, but there had been no chills and no evidence of local reaction could be found anywhere in the tissues. He thinks that this kind of puerperal infection—general affection with dissemination by way of the blood—should be called pure septicæmia. The subject in this case was a woman of 32, a vii-paræ, who had been examined *in partu* fifteen times by the midwife.

43. Birth in Isolated Uterus.—Kurdinowsky nourished with Locke's fluid the isolated uterus of rabbits. He was able in this way to keep the uterus and its appendages "alive" for nearly fifty hours in one instance. Each contraction of the uterus was registered with a Ludwig kymograph. The phenomena observed establish that the uterus—entirely independent of the influences of the cerebrospinal nervous system—is capable of accomplishing the birth function. Another result of the research described is that adrenalin was found to exert a much more energetic action on the contractions of the uterus than any of the drugs supposed to be specific for this purpose. This fact suggests further study of adrenalin in this line.

44. Aseptic Healing of Tissue Necrosis.—Burkhardt concludes from the experimental research described that tissue which becomes crushed or cauterized during an aseptic operation scarcely ever induces a suppurative exudation. This is more liable to follow cauterization. The suppuration is always benign and generally becomes spontaneously absorbed. Absorption of necrosed tissue the size of a bean required a few months before it was complete. The inflammatory exudation and deposit of fibrin that follow implantation of a crushed or cauterized scrap of muscle in the musculature of a healthy rabbit never progressed to an actual abscess in the absence of infection, but it produces a place of lesser resistance and may complicate and delay healing.

49. Intrahepatic Cholelithiasis.—Beer discovered stones in the liver in 6 out of 72 cadavers with evidences of cholelithiasis, noted during the examination of the liver from 250 cadavers. Intrahepatic concretions apparently require three factors for their production, stagnation of bile, cholangitis and a tendency to stone formation. It is possible that stones lurking in the liver may explain certain cases of supposed reformation of gallstones. The stone may induce inflammation in the liver or may pass into the gall bladder or bile duct and continue to increase in size. Consequently Kehr's plan of draining the hepaticus has, besides its other advantages, that of preventing trouble from this source. It should not be restricted to the severer cases, but should be applied in the mild ones, especially those with a history of occlusion of the bile duct and cholangitis. A stone in the liver may entail the most serious consequences and the formation of such a stone should be prevented at almost any cost. When lithiasis and cholangitis are once determined an operation before the second month would avert all danger from this source.

52. Treatment of "Double Bladder."—Fagenstecher mentions the various drawbacks to different modes of treating diverticula of the bladder, and describes his own technic. Extirpation of the diverticulum is the best means of relief, but it is always a difficult operation on account of the reimplantation of the ureter which is usually necessary. For this reason the sacral route is preferable. He cured a patient by this means, although a fistula into the bladder required some time before it spontaneously healed. His article is a comprehensive study of the cases on record of congenital diverticula of the bladder, vesica duplex and bipartita, and hour-glass bladder. His case is the first on record in which a large congenital diverticulum was successfully operated on by the sacral route.

55. Resection of Epididymis on Account of Tuberculosis.—To the 166 cases on record Bogoljuboff adds 12 from his own experience. The results of resection are better when it is total than partial. A large majority of the patients are permanently cured and recurrence in the testicles is rare. Resection of the epididymis, supplementing excision of a tuberculous focus in the testicle, is frequently successful. Potencia coeundi does not seem to be impaired by resection of the epididymis on one or both sides, and the testicle retains its normal functions. Resection of the epididymis on one or both sides may in some cases have a favorable influence on existing tuberculous processes in the prostate or seminal vesicles, leading to complete and permanent recovery. This occurred in 19 out of 45 cases. Lung processes were improved in 8 out of 32 cases. Tuberculosis of the testicles usually starts in the epididymis, where it remains circumscribed for a long time before it invades the testicle. The prognosis is equally good after resection of the epididymis and vas deferens and anastomosis. This was done in all but 2 of the personal cases described. The technic of this intervention was mentioned in THE JOURNAL, xlii, page 1455.

57. Implantation of Flaps to Fill Bone Cavities.—In 2 cases of osteomyelitis with extensive loss of substance, von Mangoldt induced regeneration of the bone by implantation of unpunctuated flaps of periosteum and bone taken from the tibia. A number of radiograms show the progressive growth of new bone. The subjects were boys of 8. The flap for one was 7.5 cm. long by 2 cm. wide, and for the other 10 cm. long.

60. **New Illuminator for Operating Rooms.**—To avoid the heat and the vitiation of the air from ordinary lights in an operating room Krönig and Siedentopf have devised an illuminator on the principle of the lantern used for throwing pictures on a screen. The lantern stands outside the room, and the shaft of light enters through an opening in the wall, strikes a mirror in the ceiling and is reflected down on the operating table. The intensity of the light can be regulated and it can be moved to various points as needed. The parts are illuminated with 20,000 candle power, a light so intense that for ordinary purposes it is shaded and the full strength is used only when inspecting cavities. The details of the illuminator can be easily understood from the illustrations. Some of them are reproduced in the last *Centralblatt f. Chirurgie*, No. 42.

65. **Roentgen Dermatitis.**—In the case described the findings indicated an obliterating endarteritis. The patient was a physician who had had occasion to work with the Roentgen rays for three years. A chronic ulceration developed at the base of one of the finger nails, and the pain became so severe that the finger was finally amputated two years after the ulceration developed. The history and the literature on x-ray burns are added.

71. **Carcinomas in Digestive Tract.**—The material reviewed includes 66 cases of cancer in the stomach, 22 in the colon and 212 in the rectum. The malignancy of the various kinds of cancer differs widely, so that exploratory excision should always precede operation. The writers describe the unicentric growth, anatomic findings, etc., of the various forms, and remark that the mode of growth of cancers in the digestive tract excludes a parasitic etiology. It seems to be possible that non-cancerous cells may be deported from the cancerous organ. The article is illustrated with 16 plates and 117 cuts in the text. Gastric cancer spreads along the inner wall of the stomach; cancer in the colon remains limited to a circumscribed spot, while cancer in the rectum spreads little inside the rectum, but has a tendency to involve early the pararectal tissue.

72. **Surgery of Spine.**—One of the 4 cases described was an extradural lipoma causing compression of the spinal cord, one was a tuberculous meningitis, another spondylitis and another a sarcoma in the pia. The focus was freely exposed and excised and the patients with the lipoma and the tuberculous spondylitis were permanently cured. Every progressive tumor in the spine should be operated on, as the outcome is otherwise fatal, but the prospects of success are not always certain. Only a few tumors in the spine are capable of being radically removed. When the cord is involved the growth is inoperable. But when a lipoma, fibroma, psammoma, echinococcus or exostosis has developed and compresses, but does not encroach on, the cord, success may be counted on. Mere diagnosis of the segment affords no information as to this point. The first symptoms of a surgical spinal affection may be restricted to simple bladder disturbances. The pains are often taken to be sciatica or intercostal neuralgia.

 83 Studies of Pns. C. Posner.—Esterstudien.

76. **Chemistry of Albumin.**—We have learned that the albumin molecule is composed of a number of organic groups which can be easily separated, but which retain their separate identity. The albumin molecule is thus like a large vessel which contains various organic compounds resulting from the vital activity of the organism. The vessel contains sometimes more of certain of these compounds than of others. The proteids contain usually three times as many atom groups as the proteins and the latter are thus simpler in their composition and easier to study. They have been found hitherto only in the spermatozoa of fishes. The varying composition of the albumin molecule probably corresponds to varying physiologic purposes. Experiments on dogs showed that phosphorus intoxication causes chemical changes in the albumin bodies in the liver. Certain compounds in the albumin molecules diminish in quantity, while others increase. The large amount of nuclear substance in young, growing tissues is an important factor in these variations. Kossel long ago called attention to the genetic connection between nuclein and hypoxanthin and xanthin, adenin and guanin, and his later research has shown that uracil, thymine and cytosin belong in the same series of nuclein derivatives. The different arrangement of the carbon and nitrogen atoms in these and in arginin and the imidazol ring suggests that this grouping is a means or by-product in these synthetic processes.

77. **Action of Quinic Acid on Lime Metabolism.**—Oberndörffer has been studying on his own person the elimination of lime under the influence of ingested acid. He reviews the experiences of Rumpf and others which have established the possibility of thus influencing the output of lime, and gives the details of his own experiments. He preferred to use quinic acid, and found that the elimination of lime in both stools and urine far surpassed the amount of lime ingested. All but 4 per cent. was eliminated through the stools. The phenomena observed indicate that the quinic acid is eliminated in combination with the lime, and by way of the intestines. He has not attempted to apply to the sick the data thus learned from a healthy subject, but the results observed certainly encourage further research in this line of possible therapeutics for arteriosclerosis, etc.

79. **Action of Lead on Uterus.**—Lewin mentions that professional lead poisoning is more common among women than men. In Vienna 26.4 per cent. of the women, and only 6.9 per cent. of the male employes in the type foundries, and 80 per cent. of the women making lead foil capsules are victims of lead poisoning. He has been examining 81 such women, and found that out of 123 pregnancies there are only 14 living children. Lead poisoning in the father alone leads to equally direful consequences. In 7 such married couples, with 32 pregnancies, there was abortion in 11 cases, and only 5 of the children survived to the third year, and 3 of these died soon after. Lewin comments with approval on the regulations in France which exclude women from trades using phosphorus, arsenic, chromates, etc. He thinks that the state should interfere to prevent this wholesale slaughter of the innocents and inevitable decay of the worker.

80. **Test Diet in Diagnosis.**—Strauss regards the use of the Schmidt and Strassburger test diet as a great progress in the diagnosis of the intestinal functions. He uses a diet made up from the hospital kitchen: 1.5 liter milk, 80 gm. scraped meat, 200 gm. soft mashed potato, 2 eggs, 40 gm. butter, and soup made with 40 gm. oatmeal, .25 liter bouillon, and 6 zwieback, each 18 gm. The aspect and smell of the stools on this uniform test diet and the interval before they appear are important points for the diagnosis. When a healthy subject takes the

test diet, marked off with carmin, the first stained stools appear in about 15 to 25 hours. An interval of 10 to 15 hours was observed in his experience only in colitic processes, especially when the lower part of the colon was involved. An interval of 3 to 5 hours was noted only in conditions accompanied by excessive peristalsis. Study of the mucus content and of the reaction of the stool is more reliable than after a single test meal. A still further means by which the test diet can be utilized is for determination of the tolerance for certain articles of food. For this he repeats the test diet, marking it off with charcoal, giving twice or four times the amount of meat, potato or butter, or reducing them in like proportions. Careful study of the subjective findings at the same time will aid in selection of an elective diet. He prefers for the fermentation test a large, graduated reagent glass with a rubber cover allowing the passage of a U-shaped tube. This shows the intensity of the fermentation during given periods, and also the amount of carbonic acid generated. He gives the details of the standard technic he has adopted for this test. The microscope shows the amount of digestion of fat and utilization of starch, and the aloin test will reveal "occult" bleeding. He further ascertains the amount of indican. This differentiates a "putrid" from a "bland" diarrhea.

82. **Elaboration of Glycuronic Acid in Man.**—Wohlgemuth describes the case of a physician who swallowed by mistake .75 gm. of cocain and then took amyl nitrite, followed by nearly a pint of brandy. Artificial respiration was kept up for several hours with inhalation of oxygen, and camphor was given subcutaneously. In two weeks the patient was fully restored. The urine contained large proportions of grape sugar at first and later of glycuronic acid. These findings suggest that the cocain and alcohol had injured the organism to such an extent that its power of oxidation was temporarily reduced. It was incapable of oxidizing the sugar produced and also the glycuronic acid elaborated after the elimination of the cocain and camphor. Wohlgemuth thinks that this case supplies the missing link in the demonstration of the primary origin of glycuronic acid.

84. **Radium Treatment.**—Werner and Hirschel report the experiences at Czerny's clinic with 22 patients exposed to the action of 10 mg. of radium bromid. The cases included 5 of carcinoma, 1 of melanosarcoma, 2 of nevus, 5 of angioma, 7 of lupus, etc. The radium was always applied to the part in a capsule, fastened with adhesive plaster, from five to thirty minutes at a time. No effect was apparent in the malignant tumors, but in the benign and in the tuberculoides the results were extremely satisfactory, and no recurrence has been apparent five to ten months after treatment. In lupus the exposures were longer, to a maximum of three hours. After these long exposures it was noticed that the nodules showed a more marked specific reaction than the epidermis, while with fractioned exposures the skin reacted more. It proved possible to cure a nodule by a single long exposure, without necrosis of the skin in some instances. This and other facts which they cite seem to suggest that inadequate treatment does harm instead of good, and that the ideal results should be sought by longer, un-fractioned exposures. In malignant disease, especially, the rule should be to treat radically with the rays or not at all.

87. **Progress in Treatment of Eclampsia.**—Glitsch reviews 40 communications that have been published recently in regard

to the treatment of eclampsia. Chloral by rectal injections seems to be useful, as is also the rinsing out of the stomach to remove toxic substances eliminated by this route.

93. **Medical Publications.**—Kohn comments on the multiplicity of current medical periodicals, Germany alone possessing 240, with a constant influx of new ones. He says that writing and research are not at all in proportion, so that there is no reason for so many journals. Many issues can be laid aside unread without fear of having missed something that is new and of real interest. As soon as some one subject assumes more than usual prominence a journal is devoted to its exploitation. Ere long, without any actual need for it, other journals appear, devoting themselves to the same line of thought. Kohn mentions that there are in Germany to-day 7 journals on gynecology, 5 on ophthalmology, 6 on pediatrics and 3 taking up the subject of prevention of tuberculosis, when one journal in each of these special fields would be more than sufficient to chronicle actual advances. Why then, he asks, is the market flooded with so many journals which are bound to react unfavorably on the progress of medicine. He condemns simultaneous publication of an article in a number of journals; the desire to write when there is nothing to write about; re-writing, with slight changes, of the same article so as to have an excuse for its publication, and appending to an article a lengthy but useless bibliography, a custom much in vogue at the present time. Many journals are kept alive by the advertisements alone; others by the desire of young men to appear before the public in print; others by articles written to please the editor or for some other extraneous reason. The consequence of all this flood of "periodical literature is that readers, because of lack of time or for financial reasons, content themselves with the reading of abstracts and do not attempt to keep up with the endless procession of current literature. This is necessarily superficial, and leads to superficial reasoning, while an error in an abstract is perpetuated in other works based on it. As a remedy Kohn suggests that all teachers and research workers restrain their assistants and students from writing until they have a definite result to present, and to keep them from "padding" the articles, and physicians should not be ever ready to "favor" a young editor with an article just to help out, or to lend the weight of their name and authority to the exploitation of the journal.

94. Treatment of Hyperacidity of Stomach.—Von Noorden has witnessed extremely favorable results from forced feeding supplementary to the ordinary measures, in cases of acid gastric catarrh and ulcer. In hyperacidity in poorly nourished subjects, he has also found forced feeding useful in conquering the existing hyperacidity. It sometimes cures without any other measures. In 3 cases of hyperacidity described there were no subjective disturbances. In 3 others the hyperacidity was accompanied by obstipation. The secreting processes were restored to normal in these cases by curing the obstipation, which was accomplished by laxative mineral waters and dieting. He regarded the hyperacidity as merely secondary, and the results of treatment on this basis confirmed its correctness. In case of gastric ulcer his measures are very strict for eight or ten days. He then rapidly pushes the nourishment, sometimes reaching 3,500 to 4,500 calories a day by the end of the second week, making extensive use of fats. He is convinced that this accomplishes as much as the Leube technic, while it has the advantage that it invigorates and restores the patient more effectually. As a rule, he gains 10 to 15 pounds on this treatment when previously reduced.

99. Treatment of Hemorrhoids.—Proebsting attributes the disturbances of hemorrhoids to retention of feces in and around the sphincter. He thinks that the best treatment is by cleansing rectal injections after defecation, preferably with cold water, although tepid water can be used if cold is not tolerated. He teaches his patients how to make "the toilette of the anus" with a small bulb syringe, and many have been entirely relieved of all hemorrhoidal disturbances by this simple measure.

100. Disinfection of Biliary Passages.—Kuhn's announcements in regard to the efficient sterilization of the biliary passages with the salicylates was summarized in these columns, page 1095.

101. Hyperacidity in Incipient Gastric Cancer.—Ziegler has observed 5 cases in which uncomplicated hyperchlorhydria with normal motor functions preceded the development of a cancer of the stomach. He is convinced that carcinoma should be suspected when hyperacidity exists rebelliously to all the usual measures, such as regulating the diet, lavage, bismuth, atropin, alkalies, etc. The diagnosis is almost certain when motor disturbances become superposed on the hyperchlorhydria. A repugnance to meat generally accompanies the hyperchlorhydria. The subjects are usually past the age when the latter is most common.

105. Digestive or Alimentary Hypersecretion in Stomach.—Strauss remarks that the determination of this condition requires consideration of a number of circumstances. There is evidently a close connection with hyperacidity and ulcer, and it seems to be more frequent in cases with dilatation of the

stomach than without. It has no direct connection with motor insufficiency, although it may outlast it, but in this case merely as an expression of the irritation of the mucosa from stagnating stomach contents. The etiology of the "digestive" hypersecretion is liable to be multiple, and removal of the cause is the first indication in treatment. When induced by gastropnoia, forced feeding may prove more useful than bandages, as it relieves the general asthenia and may restore normal conditions throughout. When dependent on a hernia, surgical treatment of the latter is indicated. Symptomatic treatment should be the same as for hyperacidity. Milk is useful, but a strict milk-vegetarian diet is required only when the manifestations of general neurasthenia or obstipation predominate in the clinical picture. Improving the intestinal functions frequently improves at the same time the hyperacidity or "digestive" hypersecretion. The Carlsbad cure is particularly useful for this purpose.

109. Polymyositis.—The postmortem findings in the case described showed numerous hemorrhages and interstitial inflammatory processes throughout the muscles involved. There were also inflammatory processes in certain joints. There was a history of preceding grippe.

114. Reduction of Sensibility of Myocardium by Digitalin.—Through all Brandenburg's experimental research one phenomenon was constantly observed, namely, that a small amount of digitalin injected under the skin temporarily diminished the response of the heart muscle to stimuli of various kinds, while it increased its contractility. He discusses the clinical significance of this fact. Among other points brought out is that digitalin is contraindicated in cases in which the irregularity of the pulse is due to morbidly increased automatic action of parts of the heart which normally do not develop movement stimulus. This class of cases includes certain forms of pulsus bigeminus in neurasthenic subjects. Digitalin in such a case would only exaggerate the morbid tendency of the heart muscle to independent action at the atrio-ventricular boundary.

117. Rare Complications of Dysentery.—The complications were urethritis, double conjunctivitis, rhinitis and severe iridocyclitis. The Shiga bacillus was agglutinated strongly even at 1 to 320.

122. Tetany with Dilatation of Stomach.—Only 42 cases are known of tetany in connection with dilatation of the stomach. Richartz describes another case. It was remarkable for the facts that the tetany developed after lavage of the extremely dilated stomach, and that it vanished completely after removal of a colloid carcinoma in the stomach. At the laparotomy several cherry stones were found in the stomach and 80 plum stones. The patient had not eaten any plums for a year or so, and asserted that it had been many years since she had been in the habit of occasionally swallowing a plum stone.

125. Vasodilating Measures in Chronic Nephritis.—Edel summarizes the aims of therapeutics in chronic interstitial nephritis as, 1, the reduction of the blood pressure by vasodilating measures, such as rest in bed, warm and carbonated baths, amyl nitrite and nitroglycerin; 2, permanent strengthening of the heart by suitable exercises, and, 3, systematic measures to restore tone to the nervous system. The albuminuria diminishes with decreasing blood pressure. Mountain climbing is particularly useful as an exercise to strengthen the heart, both by the muscular exercise and by the dilatation of the vessels in the muscles and skin, but high altitudes should be strictly avoided. Nervous influences, emotions, etc., affect the blood pressure by contracting the arteries. It is not improbable that the heart itself may suffer from this cause. These nervous influences should be counteracted by tranquilizing the patient, reassuring his alarm at the discovery of the albuminuria. Obesity should be reduced. Seven patients treated on these principles were much improved.

126. Boas-Oppler Bacilli as Sign of Cancer.—Heichelheim announces from an experience with 6 cases of gastric carcinoma that the long thread bacilli can be most easily discovered in the dark brown clots of blood in the stomach content. Re-

peated findings of blood clots in the stomach contents, with unusually large proportion of free HCl, speak for cancer, and the diagnosis is almost positive when the thread bacilli are very numerous. If they are scanty the diagnosis should be cautiously formulated.

133. Intercurrent Diseases During Imprisonment.—Avendano presented this article at the last Latin-American Congress. He urged a conference to agree on uniform measures in case of intercurrent diseases affecting criminals undergoing sentence. Provision should be made, he thinks, for the execution of the sentence to be suspended during a serious intercurrent disease or insanity, until the subject has recovered under treatment in a hospital or other safe place. The time of the duration of the disease should be deducted from the period for which he was sentenced. His final plea is that small prisons should be erected at various points in each country, instead of large central prisons, in order that the prisoners may live in the climate to which they are accustomed.

136. Simple Mode to Determine the Coagulating Power of the Blood.—Biffi gives an illustration of a simple apparatus which consists of an ordinary test tube, about 20 to 25 cm. long and 4 cm. in diameter. The stopper of the tube has two openings, one holds a thermometer which projects nearly to the center of the tube. A glass rod passes through the other hole, just projecting into the tube, but carrying a platinum wire .5 mm. thick and 10 cm. long. This wire is bent into five small, round loops, each 3 to 4 mm. in diameter. This takes up the wire so that the lower end reaches downward only a little below the thermometer, each just above the middle of the tube, which is filled half full of water. A drop of blood is drawn from the finger, and each of the five loops is touched to the blood, which rapidly spreads out and fills each loop. The stopper is then replaced in the test tube and the time noted, the temperature of the tube being kept at 68 to 77 F. At certain intervals the glass rod is pushed downward through the stopper, just far enough to bring one of the loops under the surface of the water. If the blood has not coagulated it diffuses into the water. Again the rod is pushed down after a similar interval, and so on, until the blood has completely coagulated, when it no longer diffuses, but shows as a firm round disc in the loop below the surface of the water. In normal conditions coagulation is complete in seven to ten minutes. Biffi has compared the findings with those of the more complicated apparatus for determining the coagulability of the blood, and found that they paralleled each other with great precision. He calls the instrument the hemogelometer.

PRACTICAL MEDICINE SERIES OF YEAR BOOKS. Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued

Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-graduate Medical School. Vol. VIII. Materia Medica and Therapeutics, Preventive Medicine, Bacteriology, Anatomy, Legal Medicine, Forensic Medicine. Edited by George F. Butler, Ph.D., M.D., Henry B. Favill, A.B., M.D., Norman Bridge, A.M., M.D., Daniel H. Brower, M.D., Harold N. Moyer, M.D., July, 1904. Volume IX. Physiology, Pathology, Bacteriology, Anatomy, Legal Medicine. Edited by W. A. Evans, M.S., M.D., Adolph Gehrmann, M.D., William Healy, A.B., M.D. August, 1904. Vol. X. Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M.D., Hugh T. Patrick, M.D. September, 1904. Chicago: The Year Book Publishers.

THE MEDICAL NEWS VISITING LIST, 1905. Weekly (Dated for 30 Patients) Monthly (Undated for 120 Patients per Month); Perpetual (Undated, for 30 Patients Weekly per Year); 60-Patients (Undated, for 60 Patients Weekly per Year). The Weekly, Monthly and 30-Patient Perpetual Contain 32 Pages of Data and 100 Pages of Classified Blanks. The 60-Patient Perpetual Consists of 256 Pages of Blanks Alone. Each in One Wallet-shaped Book, Bound in Flexible Leather, with Flap and Pocket. Pencil and Rubber, and Calculator for Two Prices, \$1.25. Pamphlet Index, 25 cents extra. By mail, postpaid, to any address. Philadelphia and New York: Lea Brothers & Co.

A TEXT-BOOK OF PRACTICAL THERAPEUTICS; with Especial Reference to the Application of Remedial Measures to Disease and Their Employment on a Rational Basis. By Hobart Amory Hare, M.D. Professor of Therapeutics and Materia Medica in the Jefferson Medical College, Philadelphia. With Special Chapters by Drs. G. E. de Schweinitz, Edward Martin and Barton C. Hirst. New (10th) Edition, Much Enlarged, Thoroughly Revised and Largely Rewritten. With 113 Engravings and 4 Full-Page Colored Plates. Cloth. Pp. 908. Price, \$4.00 net. Philadelphia and New York: Lea Brothers & Co., 1904.

A TEXT-BOOK OF PHYSIOLOGICAL CHEMISTRY. By Olof Hammarsten, Professor of Medical and Physiologic Chemistry in the University of Upsala. Authorized Translation from the Author's Enlarged and Revised Fifth German Edition. By John A. Muelcke, Sr., Professor of Chemistry and Physics and of Physiologic Chemistry in the New York University and Bellevue Hospital Medical College. Fourth Edition. Cloth. Pp. 703. Price, \$4.00. New York: John Wiley & Sons, 1904.

A TREATISE ON BRIGHT'S DISEASE AND DIABETES, with Especial Reference to Etiology and Therapeutics. By James Tyson, M.D., Professor of Medicine in the University of Pennsylvania. Second Edition, Illustrated. Including a Section on the Ocular Changes in Bright's Disease and in Diabetes. By George E. de Schweinitz, M.D., Professor of Ophthalmology in the University of Pennsylvania. Cloth. Pp. 908. Price, \$4.00 net. Philadelphia: P. Blakiston's Son & Co., 1904.

A TEXT-BOOK OF QUANTITATIVE CHEMICAL ANALYSIS BY GRAVIMETRIC, ELECTROLYTIC, VOLUMETRIC AND GASOMETRIC METHODS. With Seventy-two Laboratory Exercises, Giving the Analysis of Pure Salts, Alloys, Minerals and Trades. By E. F. Johnson, Col. Olsen, M. M. B. L. Professor of Analytical Chemistry in the Polytechnic Institute of Brooklyn. Cloth. Pp. 513. Price, \$4.00 net. New York: D. Van Nostrand Co., 1904.

THE PRINCIPLES OF REFRACTION IN THE HUMAN EYE BASED ON THE LAWS OF CONJUGATE FOCI. By Swan M. Burnett, M.D., Ph.D., Professor of Ophthalmology and Otolaryngology in the Georgetown University Medical College. Illustrated with 25 Original Diagrams. By Charles F. Prentice, M.E. Cloth. Pp. 65. Price, \$1.00 net. Published by the Keystone, the Organ of the Jewelry and Optical Trades, Philadelphia, 1904.

THE ART OF COMPOUNDING. A Text-book for Students and a Reference Book for Pharmacists at the Prescription Counter. By Wilbur L. Scoville, Ph.G., Formerly Professor of Theory and Practice of Pharmacy in the Massachusetts College of Pharmacy. Third Edition, Revised and Enlarged. Cloth. Pp. 337. Price, \$2.50 net. Philadelphia: P. Blakiston's Son & Co., 1904.

ACCIDENTS AND EMERGENCIES. A Manual of the Treatment of Surgical and Medical Emergencies in the Absence of a Physician. By Charles W. Dulles, M.D., Fellow of the College of Physicians of Philadelphia. Sixth Edition, Thoroughly Revised and Enlarged. With New Illustrations. Cloth. Pp. 208. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co., 1904.

MULTIPLE PERSONALITY in Experimental Investigation Into the Nature of Human Individuality. By Boris Sidis, M.A., Ph.D. (Harvard). Author of the Psychology of Suggestion and Psyche pathologic Researches, and Simon P. Goodhart, Ph.B. (Yale). M.D. Cloth. Pp. 456. Price, \$2.50 net. New York: D. Appleton & Co., 1905.

A COMPEND OF MEDICAL LATIN. Designed Expressly for Elementary Training of Medical Students. By W. T. St. Clair, A.M., Professor of the Latin Language and Literature in the Male High School of Louisville, Ky. Second Edition, Revised. Cloth. Pp. 131. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co., 1904.

SURGICAL EMERGENCIES. THE SURGERY OF THE ABDOMEN. Part I. Appendicitis and Other Diseases About the Appendix. By Bayard Holmes, B.S., M.D., Professor of Surgery in the University of Illinois. Paper. Pp. 349. Price, \$2.00 net. New York: D. Appleton & Co., 1904.

DRUGS IRRITANT TO THE KIDNEYS, AND HENCE TO BE AVOIDED IN IMPAIRED KIDNEY FUNCTION.*

TORALD SOLLMANN, M.D.

Professor of Pharmacology, Western Reserve University,
CLEVELAND, OHIO.

The title of this paper really covers two distinct subjects: the study of renal irritants, and the question whether the use of these should necessarily be condemned in the presence of nephritis. I shall reverse this order, and discuss in the first place the question:

Is the use of drugs which irritate the kidneys to be prohibited when the renal functions are impaired?

THE GENERAL PROBLEM.

This common opinion, that renal irritants should be avoided in renal diseases, seems to be based rather on *a priori* conceptions, than on direct experiments or observations. Basing ourselves on analogy, on the common experience of inflammatory processes in other regions which have been better studied, we are doubtless justified in accepting this as a general rule. If it causes us to err at all, the error is apt to be on the safer side. But, after all, may there not be important exceptions to this general rule? Have we not many instances in which an irritant agent acts favorably on an inflammatory process in other situations? Are we correct in assuming that this may not occur in the case of nephritis? Were this the case, and should it be proved that every renal irritant causes a further injury to the inflamed kidney tissue, it would not, even then, necessarily follow that every renal irritant should be proscribed. The injury to the kidney is not the direct source of danger in nephritis, but the immediate danger lies rather in the secondary results of this injury, viz., the retention of deleterious substances in the body. It is quite conceivable that a drug might be immensely useful by leading to the excretion of these substances, even if it did so at the expense of some further slight injury to the kidney. It need scarcely be said that its field of usefulness would be very limited; but were we to exclude irritants altogether from the treatment of inflamed conditions, we should have to dispense with all forms of stimulation. Is not rest the first desideratum in the treatment of inflammation, and is not every extra work thrown on the inflamed organ injurious to it, and therefore every stimulant contraindicated? Nevertheless, we often risk this lesser direct evil for the greater indirect benefit which experience has taught us to expect. And so, in

the case of the kidney, if we condemn on *a priori* grounds and without qualification every form of irritation, we must also condemn by the same reasoning every form of diuresis. On the other hand, we must not fall into the error of supposing that only those drugs are to be avoided in nephritis which irritate the kidneys, or which stimulate them to overwork. Dangers quite as grave may arise from the retention of deleterious substances introduced under the disguise of medicines. The danger of a constant administration of potassium salts, digitalis, etc., under conditions when they can not be excreted, lies even more in their general toxicity than in any direct effect on the kidneys. A recent work on the effect of salts in nephritis¹ also suggests that drugs which are indifferent to healthy kidneys may become irritant in nephritis. Finally we are confronted with the question: Are we justified in assuming without direct proof that the drugs which are capable of producing nephritis, are really renal irritants in the therapeutic doses? It is quite reasonable to suppose that doses which are indifferent to healthy kidneys may become irritant in nephritis; but there must evidently be a limit to this, and the question as to whether our therapeutic doses lie above or below this limit can only be answered by experiment.

SPECIFIC PROBLEMS FOR ANIMAL EXPERIMENTS.

It is evident, from these considerations, that the problem can only be solved when we are in possession of considerable experimental material—most of which is, unfortunately, still wanting. We should know in the first place whether a drug is capable of producing nephritis at all, and to what anatomic lesions it gives rise. This portion of the problem has been studied quite well. The next experimental question concerns the effect of these nephritic poisons on the composition of the urine, and here our knowledge is already very deficient. All the nephritic poisons give rise to urine which contains proteids, casts, renal epithelium and often leucocytes; in some cases blood or hemoglobin and its derivatives are excreted. The quantity of urine is increased by small doses and diminished by larger quantities—and there our information generally stops.

The effect of different doses on the constituents of the urine—which is most important from a therapeutic standpoint—has scarcely been studied except in the case of a few diuretics. It has been shown that glomerular nephritis (as produced by cantharis) greatly lessens the renal excretion of water, and diminishes or abolishes the diuretic effect of fluids, saline diuretics, caffeine and phlorrhizin,² and that the molecular concentration of the blood serum therefore tends to increase,³ whereas

those nephritic poisons which act only on the tubular epithelium (chromate) have less effect. It has been shown by several investigators that all nephritic poisons and diuretics (except water) tend to break down the chlorid regulating mechanisms in the rabbit, but not in the dog. This is about the extent of our experimental knowledge of the subject. Evidently, there is a large field for pharmacologic investigation, which would necessarily have to be done on animals. Researches along this line could scarcely fail to yield important additions to our knowledge of the drugs, of nephritis and of the physiology of the kidney. These results, obtained with toxic doses on healthy kidneys, could not, however, be applied directly to the question of the effects of therapeutic doses on diseased kidneys.

CLINICAL INVESTIGATIONS.

For this purpose we must know the effect of therapeutic doses on metabolism, and on the excretion of the urinary constituents, both in healthy kidneys and in the various forms and stages of nephritis. We must also know, by direct experiment and not merely by *a priori* reasoning, the modifications which these therapeutic doses introduce into the nephritic process itself. As a preliminary to this, we also must have an accurate knowledge of the chemical data of the various forms of nephritis. We already know that there are considerable differences in the reaction of the various classes of animals to drugs—witness the different effect of caffeine on rabbits and dogs, the different behavior of the chlorid regulating mechanism in these animals toward nephritic agents. These facts indicate that experiments on the lower animals could not be applied directly to man, although they would be valuable for orientation, and as pharmacologic data. But direct experiments on healthy human subjects and on nephritic patients are the surest way to a successful solution of these problems. I would not be understood as advocating indiscriminate experimentation on patients. I am only pleading for the thorough scientific study of those instances in which drugs, such as calomel, digitalis, potassium and anesthetics would be conservatively administered in any case.

METHODS OF INVESTIGATION.

The methods of study are sufficiently indicated by the preceding considerations. They would comprise a thorough and accurate investigation of the constituents of the urine before, during and after the administration of the drug. This would bear in most cases particularly on the total quantity of urine, its molecular concentration, and the percentage and daily quantity of the nitrogen, chlorids, and proteid. The more factors are determined in a given case, the greater its value; but too great multiplicity of observations tends to inaccuracy; or at the best, restricts the number of cases which can be observed. For this reason further refinements, such as the separate determination of albumin and globulin, of the various nitrogenous metabolites and of the salts; also the effect on the excretion of salts and other drugs introduced into the body, would form proper subjects for later investigation.

The subject of the greatest immediate importance is, beyond doubt, the effect on the proteid of the urine; for this is the only quantitative index which we have of the course of the nephritis. The percentage of the proteid is especially important. Emerson⁴ has again shown the reliability of this factor. It need scarcely be mentioned that the general conditions, such as diet and salt in-

come, must be kept perfectly uniform. It may not be superfluous to dwell on the fact that these observations, to be of any value, must be made with chemic methods of sufficient accuracy. The so-called rapid clinical methods of quantitative estimation are generally worse than useless for scientific purposes. Results which are not reliable are necessarily misleading. I am well aware that investigations of this character consume time. Considering the many possible types of nephritis, it would probably be necessary to dispose of a considerable number of such studies before generalization would be safe. But from the great importance of the subject I feel convinced that the results would in the end justify all the cost.

SYNOPSIS OF LITERATURE.

It is therefore a source of astonishment to find how little work has been done in this direction. There is an excellent paper by Emerson⁴ which may well be taken as a general model for this work. This research, small as it is to the entire subject, already indicates that diuresis produced by the administration of water or diuretic does not increase the percentage of proteid in acute or chronic nephritis, and may even diminish it; it also demonstrates the value of a milk diet and rest in bed; and establishes some other valuable data, surely not an unpromising showing for a single and comparatively simple research.

Emerson's results agree very well with those obtained by me⁵ in a case of "physiologic" albuminuria. The subject had a persistent albuminuria, amounting to 0.32-1.19 gm. per liter, or 0.2-0.9 a day; without any other symptom of nephritis or abnormality whatsoever.* Various drugs were tried, in therapeutic doses; none of these produced changes exceeding the normal variations; the only positive result was obtained with a very large dose (31 gm.) of potassium acetate, which produced a free diuresis and lessened the per cent. of proteid, without altering its daily quantity. Smaller doses (4 and 11.7 gm.), as also therapeutic doses of potassium nitrate, 4 gm.; caffeine, 0.6 gm.; urea, 2.1 gm.; digitalis, 1 c.c. of tincture; nitroglycerin, 3.3 and 3.9 mg.; strychnin, 6.5 mg. and water had no certain effect on the albumin.

There are also a considerable number of observations on the effect of water and salts on the composition of the urine in health, and a few studies of their effects in nephritis. I shall only consider the latter. Kövesi and Röth-Schulz⁶ state that the administration of water, which ordinarily increases the quantity of urine and lessens its molecular concentration (depression or freezing point), does not have this effect in acute and sub-acute nephritis; the divergence from the normal result is less in cases of contracted kidneys. They propose this as a diagnostic test for kidney insufficiency. Koeppe⁷ arrives at the same result. It is also well known that a diseased kidney can not secrete urines with a molecular concentration much higher than that of the blood,⁸ especially when the tubular epithelium is involved. Some important contributions to this subject of the effects of salts and water on nephritis have appeared quite recently, stimulated by the observations of French clinicians on the effect of salt on nephritic edemas. Mohr and Dapper⁹ obtain the important result that a moderate

limitation of water (to 1½ liters per day) leads to a diminution of nephritic edema, without diminishing the excretion of metabolites (nitrogen and phosphates); but an excessive reduction, whilst it may lessen the edema, also impairs the excretion.

With chronic contracted kidney, the reduction of water causes generally a temporary increase of the albuminuria, but this soon returns to the previous degree. Mohr¹⁰ and von Kozięzkowsky¹¹ find that some cases of nephritis show a retention of chlorid, while others do not have this tendency.

I would also cite the studies of Castaigne and Rathery,¹ who cite numerous cases in which albuminuria was caused, in some, by administering sodium chlorid, in others by withholding this salt. They also found that doses of salt which did not cause albuminuria in normal rabbits, increased an already existing renal albuminuria.

While this list of investigations dealing with quantitative determinations of the effect of nephritic and diuretic drugs is perhaps not quite exhaustive, yet it is fairly so; and this illustrates the paucity of our positive knowledge of the subject, which I have emphasized earlier in this paper.

THE PHARMACOLOGY OF NEPHRITIC POISONS.

In the absence of these experimental data, it is not possible for me to treat of the subject as I would wish to do, i. e., from the standpoint of the effect of nephritic drugs in nephritis. I must content myself in presenting to you what is known concerning the effects of toxic doses. This study has more interest for the pharmacologist than for the practicing physician, but it is not devoid of importance to the latter, since it will serve to point out to him which drugs should be held in suspicion and which therefore require investigation.

A very large number of the most commonly used drugs must be placed in this class. Everyone is familiar with the fact that most substances act as irritants if they are brought in contact with tissues, in sufficient concentration. It is also well known that the conditions for irritation are peculiarly favorable in the kidney; partly because the concentration is increased during the excretion of the substance, and also because the renal cells are peculiarly delicate and subject to injury. To emphasize the latter fact, we need but recall the comparatively small variations from the normal which give rise to albuminuria; and that clamping the renal artery for a very short time causes a very persistent impairment of the renal functions.

A drug, to be classed as a nephritic poison, must possess the following qualities: 1. It must be capable of causing irritation. 2. It must be capable of being absorbed. 3. It must be capable of injuring the kidney in doses which are smaller than those which will produce acute death through its other actions. 4. In some cases the nephritis is not so much due to the direct effect of the drug on the kidney as to the breaking down of the blood-corpuses, and other tissue changes.

The more important nephritic poisons may be grouped as follows, according to the tissues which they may affect: 1. Tubular epithelium primarily; stroma secondarily; metals, aloin, coal tar products, alcohol and anesthetics, oxalates. 2. Glomeruli primarily; tubules only with larger doses; cantharidin, arsenic. 3. General irritants; essential oils. 4. Only irritant under special conditions; Caffein, neutral salts of alkalies.

5. Affecting kidney secondarily: Poisons destroying blood; chronic poisons (alcoholism, morphinism).

For convenience of study I have divided the nephritic drugs into several large classes, according to their chemical affinities.

GROUPS OF METALS.

All metals, so far as they have been studied¹² cause a nephritis when they are absorbed into the body in sufficient amount. This has been actually observed with the following: Aluminium, antimony, arsenic, beryllium, bismuth, cadmium, cerium, chromium, cobalt, copper, lead, manganese, mercury, nickel, phosphorus, platinum, silver, tungstan, uranium and zinc.

Owing to the emetic effects and the small absorbability of most metals, the nephritis results only when corrosive doses are taken, or if the salts are injected directly into the veins or subcutaneously. Mercury, arsenic and chromates are notable exceptions. Nephritis may also arise in the course of chronic poisoning by any metal.

The anatomic and functional effects are alike for all metals, with the few exceptions which will be noted presently. The finer details have only been studied on the more important metals; but there is every reason to suppose that the others conform to the same type.

Anatomic Changes.—The anatomic changes are at first confined to the epithelium of the convoluted tubules, which show cloudy swelling, disintegration of the nuclei and impaired staining qualities, and often fatty degeneration. If the dose is very large, and in chronic poisoning, the inflammation extends to the connective tissue, which shows round-cell infiltration, cirrhosis and other changes.

Urine.—The urine is moderately increased by very small doses; larger doses diminish its quantity to total suppression. It becomes albuminous and often bloody, and contains leucocytes, renal cells and numerous casts.

The clinical phenomena of this nephritis need not be discussed.

SPECIAL METALS.

Arsenic.—This produces a specific paralysis of capillaries, which is most pronounced in the glomeruli. Hellin and Spiro,² experimenting on rabbits, found the space of Bowman's capsule all but obliterated by the swollen capillaries. In addition to this, arsenic has the usual metal effect, the epithelium of the convoluted tubules being affected in various degrees, while the straight tubules escape almost unchanged. Albuminuria appeared within ten minutes after the hypodermic injection of 10 mg. per kilogram.

Phosphorus.—This causes the same fatty degeneration in the kidney which it produces in other organs.

Bismuth.—This is said by Langhans¹³ to act differently from other metals, and more like cantharidin; small doses causing a strong glomerular nephritis, with comparatively little change in the tubular epithelium. The stroma, however, is affected quite early.

Chromates and Bichromates.—These have been used extensively in experimental work, to produce an almost purely tubular nephritis.² The epithelium of the convoluted tubules may undergo total necrosis. The glomerular epithelium and the straight tubules are unaffected, or at most suffer very late. The urine becomes albuminous, scanty and contains numerous casts and

sometimes blood. Very small doses cause a slight diuresis in rabbits.¹⁴ Chronic poisoning ends with extensive interstitial nephritis. (Rabbit, 30 mg. per kilogram, subcutaneous.)

Iron.—Tyson warns against the use of excessive doses of iron in chronic nephritis, but not apparently because of any action which it might have on the kidney. I could find no reports of nephritic phenomena referable to iron.

Mercury.—Kobert¹⁵ claims that large doses cause occlusion of the renal tubules by calcareous deposits. Otherwise the phenomena of large doses of mercury are those typical of all metals. Its principal interest lies in the effects of small doses, which have such a wide application in therapeutics.

CALOMEL DIURESIS.

A most important action in the present connection is the calomel diuresis. The diuretic effect of calomel in cardiac dropsy is said to have been well known to the physicians in the latter half of the eighteenth century, but it was forgotten, and practically rediscovered by Jendrassik in 1886.¹⁶ He found it effective mainly in cardiac dropsies, in which it produced results far greater than could be obtained with digitalis or caffeine. The urine was often increased to 7 or 8 liters a day. The absolute amount of urea and chlorids was also greatly increased. To obtain the best effects, 0.2 gm. was given from 4 to 5 times a day, until a slight mercurial stomatitis was produced. If this did not prove effective from the start, the remedy was discontinued; it also seems wise to intermit it occasionally. The bowels may be regulated by opium. Jendrassik remarks that the calomel appears relatively or quite ineffective when the heart disease is uncomplicated by dropsies; it was also ineffective in pleuritic exudates, in nephritic effusions, and in healthy individuals. This report gave rise to extensive trials of the drug. The results of these were summarized by Jendrassik in 1891,¹⁷ together with further observations and experiments of his own. His previous conclusions concerning the best method of administration, and the usefulness of calomel in cardiac dropsies seem to have been generally confirmed, as also the relative insufficiency in non-dropsical heart disease, in pleuritic exudates and in normal individuals. It seemed to be slightly diuretic in the latter, but the action can never compare with that seen in cardiac dropsies. It was often found effective in hepatic ascites, but failed frequently. It gave good results in some cases of nephritic edema, but in most instances gave no result; it seemed impossible to predict what it would do. Wood¹⁸ states that "in chronic parenchymatous nephritis with alarming decrease of urine, calomel is one of the most efficient diuretics known."¹⁹

The theoretical objections to the use of so powerful a renal irritant as mercury in nephritis, was early emphasized, especially by Cohn,¹⁹ and supported by some clinical observations. It was claimed that there is a very marked tendency to mercurial symptoms, and that the nephritis is often made worse. The greater number of observers, however, hold the opposite view, viz., that calomel does not render the nephritis worse, whether it has a diuretic action or not. This is defended by

Jendrassik, and by Henck.²⁰ Schild²¹ reports 3 cases, in which he claims that a diuretic effect was obtained, together with a lessened per cent. of albumin; the daily output of protein being unchanged.

Briefly, it seems certain that the doses of calomel which are advocated have never produced albuminuria in normal individuals, but the question of their effect on an existing nephritis is not sufficiently investigated to admit of a decisive answer. Great conservatism in its employment is therefore indicated.

MECHANISM OF THE CALOMEL DIURESIS.

Jendrassik showed that the effect is due to the mercury of the calomel, for other insoluble mercurials have a similar effect, although they are not so useful by reason of their side actions. He also tried to determine the mechanism of this mercury action by experimental means. He passes rather lightly over the opinion held by most of his contemporaries, that the calomel acts by irritating the renal epithelium. Perhaps his strongest argument is based on a few hemoglobin estimations; he argues, quite correctly, that a diuresis produced by renal irritation should concentrate the blood; direct observation showed that it was more dilute. This result, if correct, would indicate that the diuresis is merely the secondary result of an absorption of the exudate. In view of the importance of the subject, it is to be regretted that these hemoglobin estimations have not been repeated. The fact that calomel is only effective in edema, naturally favors the idea that it acts on the exudate, but the absence of effect with the exudates of pleurisy and hepatic cirrhosis speak even more strongly against it. Jendrassik himself points out that the effect is not obtained through change in the general circulation, so that this explanation for its selective effect in cardiac dropsy falls away.

The subject was in this unsatisfactory condition when Cohnstein²² undertook its investigation. He experimented on rabbits, by the hypodermic injection of solutions of calomel in hyposulphites of sodium, and of silver and platinum. A very moderate diuresis occurred with small doses, but this failed to set in if the animals were deeply chloralized. (It will be recalled that caffeine gives a good diuresis under these conditions.) This result brought him to the conclusion that the calomel diuresis is caused by a vasomotor action, originating in the medulla.

The question seems to have been abandoned until Vejux-Tyrode and Nelson²³ in 1903 repeated Cohnstein's work, with very different results. They attribute the difference to the hyposulphite used by Cohnstein. The experimental data in the paper are so scanty that it is not possible to form an independent opinion as to whether this is the most likely explanation or whether the dosage and other conditions could not have influenced the result. They employed the caseinate of mercury; intravenous injections sometimes gave a slight and very short diuresis, but more often none. Subcutaneous administration was more often successful; deep anesthesia did not alter the result, as claimed by Cohnstein. When an artificial ascites was produced by the injection of saline solution into the peritoneal cavity the calomel often caused a greater diuresis.

They arrive at the conclusion that the mechanism of

the calomel diuresis is too complicated to be explained by the known data—a conclusion in which we must concur, unsatisfactory as it is.

SERIES OF BENZOL DERIVATIVES.

We are probably safe in assuming that all coal tar products are capable of producing nephritis. This has been demonstrated in the case of phenol, cresol, creosote, salicylates, salol, resorcin, pyrogallol, anilin and the dyes (methylene blue), picric acid, antipyrin and saccharin; and doubtless of many others. With the greater number, albuminuria occurs only with very large doses, quite beyond the therapeutic limits. Smaller doses cause a diuresis without albumin. It may be doubted whether the coal tar products, in therapeutic doses, need be counted among the possible nephritic poisons; but some suspicion is justified. Acutely toxic amounts produce a diminished and albuminous urine, with casts, and often with blood or hemoglobin and methemoglobin. The anatomic findings consist in a profound degeneration of the tubular epithelium. This is well illustrated by Hesselbach.²⁴ The changes become interstitial in chronic poisoning.

VOLATILE OILS.

There can be no doubt that all essential oils and the substances containing them, may irritate the kidneys, in part directly in the course of their excretion and, in part also, by producing a hyperemia of the pelvic viscera. All these substances are diuretic in therapeutic doses, and the diuresis is attributed to their irritant action. Even these doses must therefore be regarded with suspicion, especially in acute nephritis. Larger doses result in diminished and albuminous urine. This has been observed in the case of turpentine, juniper, cubeb and thymol. Savin, and probably the other ebolic oils, produce in addition a hemorrhagic condition.

DIGITALIS GROUP.

All the members of this group (the digitalis principles, strophanthus and squills) in therapeutic doses, cause a diuresis, especially in cardiac disease. LeNoir and Camus²⁵ have shown that the main effect is on the water and chlorids, that the action appears on the day following the administration and persists for some time. Overdoses, on the other hand, diminish the urine and render it albuminous and often bloody.

In view of the known irritant action of these drugs, their effect on the urine has also been referred to a varying degree of irritation of the renal cells. This has never been proved, and it seems more likely that the effects are mainly secondary to the circulatory changes; the diuresis to an improvement of the renal circulation and to the hydremia following the absorption of edemas; the anuria from overdoses being referred to tetanic contracture of the renal arterioles. It remains to investigate whether the ordinary doses are at all irritant in nephritis.

CANTHARIDIN.

This poison is one of the most powerful and one of the most selective of the renal irritants, a fact which makes it especially interesting to the pharmacologist, and especially useful for experimental purposes.

Richter and Roth³ have shown that even a moderate degree of cantharidin nephritis prevents the compensating action of the remaining kidney when the other has been excised and that it lessens the excretion of organic metabolites, and therefore raises the molecular

concentration of the blood. Hellin and Spiro² also show that it prevents caffeine and phlorrhizin diuresis completely. Cantharis should always be avoided in renal disease, at least until further investigations have been made. Its therapeutic indications are, however, so limited that the occasion for its use in nephritis rarely arises. The anatomic lesions produced by cantharidin have been quite thoroughly investigated. The earlier literature (from 1880 to 1882) is quoted by Mürset.²⁶ This has been confirmed in every point by Hellin and Spiro and Richter and Róth: Small doses act entirely on the glomeruli, which are enormously dilated; numerous leucocytes are found in Bowman's capsule. The urine becomes albuminous within half an hour after subcutaneous injection. The smallest doses increase its amount, while larger doses diminish it. The epithelium of the convoluted tubules is only affected by larger doses, and rather late in the course of the poisoning. The interstitial tissue escapes entirely in the acute intoxication, and is but slightly changed even in the subacute form.

ALOIN.

This has also a purely experimental importance. Cushny states, without citation of his source, that it does not irritate the kidneys in man, nor in the dog or cat. The anatomic lesions in rabbits have been investigated especially by Mürset;²⁶ they are practically the same in acute and chronic poisoning, and consist mainly in degeneration of the epithelium of the convoluted tubules. This loses its striations and staining qualities, and the nuclei disappear. The glomerular epithelium is but slightly altered, and the glomerular vessels show no lesions. These observations are confirmed by Hellin and Spiro.² The urine may be increased or diminished and contains proteids, leucocytes, casts, crystals and blood.

PHLORRHIZIN.

The importance of this glucosid is also mainly experimental, but it has some practical significance from its use as a diagnostic test of kidney insufficiency. Its administration leads to glycosuria and diuresis. There can be no doubt that the glycosuria is of renal origin; there are as yet, however, no facts to show what influence its renal action has on the course of nephritis.

Of the anthelmintics, both santonin and male fern are capable of producing parenchymatous nephritis: santonin also causes hematuria.

CATHARTIC PRINCIPLES.

The irritant cathartics may be supposed to act on the kidneys directly by their irritant action, and indirectly by the pelvic hyperemia. The cathartic resins have sometimes given rise to nephritic phenomena. I have found no reports of nephritis from rhubarb, senna, cascara, and other emodin containing drugs. From their relation to aloin, they are open to suspicion. I have also failed to find reports of renal irritation from croton oil.

ALCOHOL.

The irritant effects of large doses of alcohol on the kidney are too well known to require discussion. They rarely lead to an acute albuminuria in healthy subjects, but even moderate doses may occasionally be unfavorable in an existing nephritis. The fatty degeneration and cirrhosis which chronic alcoholism produces in the kidneys need not be considered in this place.

²⁴. Hesselbach in Kobert's Lehrbuch, p. 230.

²⁶. Mürset: Arch. f. Exp. Path. und Pharm., 1885, vol. xix, p. 310.

CHLOROFORM AND ETHER.

These drugs have a peculiar importance, since their administration as anesthetics is often urgently indicated during the course of nephritis. There can be no doubt that overdoses produce acute parenchymatous nephritis and that even the amounts which are required in the course of a short operation may be very distinctly unfavorable to nephritic patients. There are innumerable observations bearing on this point, but very few possess the required degree of scientific accuracy. The urine is rarely examined for a sufficient period before and after the operation, and even the proteid estimation is usually not quantitative, or is made by inaccurate clinical methods. We are therefore unable to estimate the dangers of an ordinary anesthesia. (The recent studies of Munro²⁷ seem to indicate that they have been exaggerated). Nor is it possible to give a decisive opinion as to the relative danger of chloroform and ether. This would seem to be an urgent problem for clinical experimental investigation.

Chronic chloroform poisoning leads to the same changes as chronic alcoholism. The other inhalation anesthetics, as also the hydrocarbon hypnotics (chloral, urethane, hedonal, etc.), may be supposed to produce analogous effects, although there has not been opportunity for actual observations with all of these drugs. Sulfonyl is especially apt to cause nephritis, with extensive necrosis of the tubular epithelium.

IODOFORM AND UROTROPIN.

Iodoform is also capable of producing albuminuria and hematuria. Even its local use on large open surfaces has been known to produce these phenomena of renal irritation.

Urotropin is another substance which has caused nephritis through changes in the tubular epithelium. The urine is apt to contain blood cells as well as the serum proteids. Formaldehyd would probably produce similar effects.

ALKALOIDS.

The majority of alkaloids are so slightly irritant and are used in doses so small that there can be little question of nephritic action. The albuminurias which are seen late in the course of the various drug habits are doubtless secondary phenomena, and not due to direct irritation. The only alkaloids which could be suspected of acting directly on the kidney are those which are markedly irritant, like veratrin, or which are given in very large doses, as quinin. There seem to be no reliable observations on the renal effects of veratrin. The data as to quinin are also scanty. According to Kobert, instances of hemoglobinuria and persistent albuminuria have been observed after large doses of this drug. The caffeine group (including caffeine, theobromin and theophyllin) occupies a peculiar position among the diuretics, in that these drugs appear to stimulate the renal epithelium without any of the usual phenomena of irritation. Although the investigations into the mechanism of their action are not closed, the known facts are all in favor of the view that the diuresis results from a direct stimulation of the cells, mainly or solely those of the convoluted tubules and that any action which they may have on the general and renal circulation is inconstant, and therefore of secondary importance. The evidence is equally clear that they do not irritate the kidneys.

Pouchet and Chevalier²⁸ have indeed made the statement that theocin (theophyllin) in large doses injures the epithelium of the convoluted tubules and glomeruli. This, however, relates merely to theocin, and needs confirmation. The only other fact in favor of an injurious action is that caffeine, like all other diuretics, breaks down the chlorid-regulating mechanism in rabbits. Even this phenomenon is absent in dogs and in man.²⁹

The changes which caffeine produce in the urine have been extensively studied. It increases not only the excretion of water, but also that of all the solids, and particularly of urea; the percentage of the latter remaining practically unchanged, notwithstanding the diuresis.³⁰ Caffein or theobromin would, therefore, seem especially to be indicated to secure the excretion of metabolites when this is deficient in nephritis. The only danger would lie in the increased work which they must necessarily put on the kidneys. The observations of Emerson⁴ and of Sollmann and McComb⁵ show that the percentage of albumin is not increased, and that, therefore, no injury was caused in these cases. On the other hand, the usefulness of these drugs is lessened by the fact that they can not act if the tubular epithelium is greatly changed² and their action does not seem to be sustained well on continuous administration.²⁵

OTHER PURIN BODIES.

Clinical observations seem to indicate that other purin bodies—such as are formed in the course of metabolism, or which exist in the extractives of meat—do not share the harmlessness of caffeine. The experimental data are still too scanty to make their discussion profitable.

NEUTRAL SALTS OF ALKALIES.

The chlorid and acetate of sodium or potassium, as also glucose and urea, secure a diuresis, in which the absolute amount of metabolites and salts is increased, while their concentrations in the urine is diminished—excepting the salt which has been administered. Similar results are secured by drinking water copiously. The mechanism of this action is not yet completely elucidated, but I incline to the opinion that the diuresis is mainly the result of physical causes, such as the increased quantity and the dilution of the blood, changes in its molecular concentration, and the different resorbability of the various ions. It would take us too far to enter deeply into this subject; but I believe that we may assume that the vital stimulation plays but a subordinate rôle in the process, and that irritation does not occur at all under ordinary conditions. Much interest has been aroused recently by the statement—made especially by French clinicians—that the withholding of sodium chlorid results often in the disappearance of nephritic edema. It would seem that this requires further confirmation and study. It is quite conceivable that this supposed deleterious action of salt does not depend on its direct action on the kidney, but that the withdrawal of the salt leads indirectly to the absorption of the effusions since they can not exist in the absence of salt. Were this the case, the result of salt-withdrawal would be mainly symptomatic. The experiments of Castaigne and Rathery¹ seem to indicate, however, that salts may have an irritant action. The entire subject demands further investigation. In the meantime there can be little doubt that these diuretics may be extremely

useful by removing metabolic poisons. Their efficiency in the removal of poisons introduced from without has been abundantly confirmed, and they must have a similar usefulness for removing toxic substances produced within the body. It is almost superfluous to emphasize that substances which are themselves toxic (such as lithium or potassium) should not be administered in nephritis; so that the choice is practically restricted to sodium chlorid and acetate. The useful eliminative effect of the former was shown very strikingly in experiments on the salt-poor milk diet of typhoid fever.³¹ The salts incidentally cause an increased formation of metabolites, but this is more than counterbalanced by their increased excretion.

IONS WITH SPECIFIC ACTIONS.

A few ions have specific actions and must be considered separately:

Nitrates.—It has always been held that potassium nitrate is especially diuretic, and that the greater diuresis is based on a specific irritation of the renal cells. This opinion needs further proof. The evidence of deleterious action is more positive in the case of acids, large doses of which have given rise to albumin, and even to blood in the urine.

Chlorates.—These are also strong irritants, the urine becoming charged with casts, hemoglobin and methemoglobin. It is not known how far this action is direct and how much is due to the changes in the blood.

Oxalates.—The oxalates occupy a peculiar position. They form insoluble crystals in the course of their excretion, and these block up the renal tubules of the cortex. They also have a direct irritant action on the epithelium,²⁷ producing a vacuolar degeneration in the convoluted tubules. The glomeruli are but little affected. The stroma shows a slight focal round-cell infiltration. The urine becomes diminished in amount and contains a small amount of proteid, some renal epithelium and casts, and quantities of crystals of oxalate. The nephritic changes seem to occur only with very large doses, and it is doubtful whether they have any therapeutic importance.

Fluorids.—These have been but little studied. J. B. MacCallum³² has recently shown that the injection of calcium salts causes serious interference with the secretion of urine. But it is questionable whether this ion can be absorbed sufficiently to produce this action from the alimentary canal.

THE ETIOLOGY AND PATHOLOGY OF GOUT.*

THOMAS B. FUTCHER, M.B. (TOR.).

Associate Professor of Medicine, Johns Hopkins University,
BALTIMORE.

THE ETIOLOGY OF GOUT.

In a consideration of the etiology of gout we must group the causative factors under two headings—(1) the predisposing etiologic factors, and (2) the actual disturbances of metabolism causing the disease.

During the fifteen years since the opening of the Johns Hopkins Hospital, from May 15, 1889, to May 15, 1904, there have been 54 cases of gout admitted to Dr. Osler's wards. These were out of a total of 17,100 medical admissions, or 0.31 per cent. Occasional reference to

these cases will be made in the following discussion of the etiology and pathology of the disease.

I. THE PREDISPOSING ETIOLOGIC FACTORS.

(a) *Heredity.*—There is no doubt but that hereditary predisposition plays a very important part. Scudamore states that out of 523 gouty patients 309, or 59 per cent., gave a history of the disease in the parents or grandparents. Garrod found that the predisposition was inherited in 50 per cent. of his hospital patients. Among his private cases, however, he believed that the tendency was inherited in 75 per cent. In our series there were only 7 cases, or 12.9 per cent., in which a definite history of gout having existed in the parents or grandparents was obtained. In addition to these, 10 patients gave a history of "rheumatism" in their ancestors. In contrast to the rich, poor patients rather resent the implication that their parents or grandparents had gout, preferring to call the arthritic manifestations rheumatism. Fifty of our 54 cases belonged to the poorer classes and were admitted to the public wards, only 4 patients being treated in the private ward. There is a strong probability that in most, if not all, of the 10 cases giving a history of "rheumatism" in the ancestors, the arthritic disease was actually gout. Putting the most liberal interpretation on these cases and considering them all instances of gout, it would make a total of 17 cases with gouty ancestors, or only 31 per cent. It would appear, therefore, judging from this series, that gout in this country in the majority of cases is acquired or "freehold" and not inherited or "copyhold." to use the classification of old Sir William Browne. Although it is of rare occurrence, infants at the breast have been known to suffer from gout.

(b) *Age, Sex and Race.*—Gout is rare in infancy and childhood. This is illustrated by Scudamore's statistics of 515 cases. Only 4 occurred before the age of 17, the youngest being 8 years old. There were but 13 in the first two decades. When gout appears in very young individuals it is nearly always inherited. In our series the ages of the patients on first admission to the hospital, according to decades, were as follows: 1 to 10 years, no cases; 11 to 20, 2 cases; 21 to 30, 3 cases; 31 to 40, 11 cases; 41 to 50, 15 cases; 51 to 60, 15 cases; 61 to 70, 6 cases; 71 to 80, 2 cases. The largest number of cases occurred in the fifth and sixth decades, each decade having the same number of cases; that is, there were 15 cases between 41 and 50 years and the same number between 51 and 60. The youngest patient was a boy of 17 years, and the oldest a man of 76. The initial attack in the latter case occurred at the age of 48. General statistics show that the initial attack makes its appearance most frequently in the fourth decade, that is, between the ages of 30 and 40.

Males are more liable to the disease than females. Women appear to possess a relative immunity. Of 80 cases collected by a special commission of the French Academy, 78 were in males and 2 in females. In the medical wards of St. Bartholomew's Hospital there were 124 cases of gout admitted in 14 years, and, of these, 100 cases were males and 24 females. In the Johns Hopkins series there were only 2 females out of the 54. When gout occurs in the female it is nearly always inherited. In the two cases in women in our series there was a definite history of inherited gout in both instances. The relative infrequency of gout in the female is undoubtedly due in large part to the fact that they are much less liable to be exposed to the contributory etiologic factors to be mentioned later.

32. J. B. MacCallum: Univ. Cal. Publ. Physiol., 1904, vol. i, p. 51.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Entler, Solomon Solis-Cohen and O. T. Osborne.

The disease is relatively much more frequent in the white than in the colored race. It occurred in two negroes in our series. The diagnosis which was made clinically was substantiated postmortem by finding sodium biurate deposits in the cartilages of the big toe joints, scrapings from which showed the characteristic needle-shaped crystals of sodium biurate.

(c) *Alcohol.*—Alcohol has always been considered a most potent etiologic factor in gout. In fact, it probably ranks at the head of the list in importance among the predisposing causes. Fermented liquors, such as wine, particularly port and sherry, beer, ale and porter are much more injurious than the distilled liquors—whisky, brandy, rum and gin. Some other factor must play a part other than the quantity of alcohol itself. In Scotland, where whisky is drunk, gout is very much less prevalent than in Southern England, where beer is the chief beverage. It has not been shown that the greater acidity of the fermented beverages, nor the contained sugars and saline matters are responsible for their greater potency in causing gout. The use of fermented beverages, particularly beer, appears to be the chief etiologic factor in the production of this disease in the United States as elsewhere. The lighter beers of this country are considered less potent than the heavier beers of England and Germany. Fifty-two of our 54 cases used alcohol. Concerning the other two there were no data as to their alcoholic habits. Three of the 52 cases used whisky alone. Forty-nine had been beer drinkers for years. Most of these had also used whisky in moderation or to excess. Only two gave a history of the use of wine.

(d) *Food and Exercise.*—The food undoubtedly plays a large part in the production of gout. We have long been taught that meats, and particularly the red meats, are especially to blame, and are most injurious to the gouty individual once the disease is established. This statement must be accepted with some reservation. Sydenham stated the case clearly when he said: "Great eaters are liable to gout, and of these the ostive more especially. Eating as they used to eat when in full exercise, their digestion is naturally impaired. Even in these cases, simple gluttony and the free use of food, although common incentives, by no means so frequently pave the way for gout as reckless and inordinate drinking." From the food standpoint it is the over-eating, combined with the taking of insufficient exercise, that does most harm. Neither the quality of the food nor its quantity does so much harm as the fact that it is "unearned by muscular exertion," as Ewart puts it. Gout is not confined to the rich, however. Dr. Osler says: "In England the combination of poor food, defective hygiene, and an excessive consumption of malt liquors makes 'the poor man's gout' a common affection." These were the conditions which largely prevailed in our series, as 50 of the 54 cases belonged to the laboring classes.

(e) *Effect of Lead Poisoning.*—Musgrave, Huxham and Falconer (1772) had previously called attention to the association between lead poisoning and gout, but it remained for Garrod to show the importance of lead as an etiologic factor. He found that one in four, or 25 per cent. of the gout cases that came under his care in hospital practice, had at some period of their lives been affected with lead, and for the most part had followed the occupations of plumbers or painters. Garrod's percentages have in general been confirmed by the observations of others. Of our 54 cases there were only 2 patients who presented definite evidences of lead intoxication. One was admitted for

an acute attack of lead colic. The other was a young man, aged 28, who was admitted during an attack of arthritis of the left knee, and it was found that he had a definite "blue line" at the margin of the gums. It is of interest that this patient stated that his father died of "painter's colic." Both of these cases of lead gout were in painters. It would seem that undoubted saturnine gout cases are less frequent in this country than in England. Although there were only two cases of gout where it could be positively stated that lead poisoning co-existed, yet there were in all nine patients whose occupations exposed them to possible lead infection. Six of these were painters and three were tinnners. Thus in 9, or 16.6 per cent. of the cases, lead was probably an important etiologic factor.

How lead acts in predisposing to the development of gout is still an open question. Garrod showed that the blood of patients suffering from lead poisoning contains an excess of uric acid. He pointed out that they were also especially liable to develop chronic nephritis, and drew the conclusion that the increased amount of uric acid in the blood and the frequency of gouty manifestations were caused by the lowered power of the diseased kidney to excrete uric acid. The majority of subsequent observers have supported this view. Sir Dyce Duckworth and Lancereaux both held that the lead acts injuriously through its effects produced on the nervous centers, Duckworth asserting that "this malign influence evoking such trophical changes in the entire vascular system and in the kidneys, as are prone to be produced by the morbid condition which we recognize as gout in its most comprehensive aspect."

(f) *Occupation.*—The workers in lead, painters, plumbers and tinnners, are particularly liable to the disease. Six of our series were painters and three were tinnners. There were three bartenders. The opportunity for free indulgence in malt liquors by the latter renders them especially prone to gout.

II. THE ACTUAL DISTURBANCES OF METABOLISM CAUSING GOUT.

With the possible exception of diabetes mellitus, the metabolism of no disease has so frequently been the subject of research, notwithstanding which there is still the greatest possible difference of opinion as to the actual chemical disturbances causing the disease. It seems safe to say that gout is due to defective metabolism of the nitrogenous foodstuffs ingested and of the nitrogenous products of tissue change. Defective oxidation is probably in part responsible for these metabolic disturbances.

For decades, nearly all students of gout have held that the disease is due to disturbances in the formation or elimination of uric acid. In recent years evidence has been accumulating to show that the manifestations of gout are not entirely due to disturbances in uric acid metabolism, but possibly also to the toxic effects of certain closely allied nitrogenous compounds. Until further evidence is brought forward, however, we are forced to conclude that uric acid is, in large part, either directly or indirectly responsible for the gouty manifestations, and it is this organic compound which must chiefly occupy our attention in a consideration of the etiology of the disease.

(A.) URIC-ACID METABOLISM UNDER NORMAL CONDITIONS

To appreciate the metabolic disturbances in gout it is important that we should fully understand the physiology of uric acid and its closely allied compounds. Such a consideration will also enable us to familiarize our-

selves with the names of various nitrogenous compounds frequently used in gout discussions, the number of which is unfortunately being gradually added to.

Uric acid has the empirical formula $C_5H_4N_4O_3$ and the structural formula

It is not necessary for our purpose to consider the various views that have been held regarding the formation of uric acid in man. To avoid prolonging the discussion unnecessarily, it is sufficient to say that the generally accepted view at the present time is that uric acid is derived from the nuclein resulting from nuclear destruction. At least four other nitrogenous compounds are known to be derived from nuclein. These are xanthin, hypoxanthin, adenin and guanin, and they constitute the so-called nuclein bases. These, with uric acid, are derived from the nuclei of the leucocytes and from the nuclei of the tissue cells throughout the body; also from the nuclear material of the ingested food. In addition to these there are several other compounds which are closely related in structure. They all contain carbon, hydrogen and nitrogen, and in most cases also oxygen. These closely related nitrogenous compounds, with their formulæ, are as follows:

- | | |
|-----------------------|-------------------|
| 1. Uric acid..... | $C_5H_4N_4O_3$ |
| 2. Xanthin..... | $C_5H_6N_4O_2$ |
| 3. Hypoxanthin..... | $C_5H_6N_4O$ |
| 4. Guanin..... | $C_5H_7N_5O$ |
| 5. Adenin..... | $C_5H_7N_5$ |
| 6. Heteroxanthin..... | $C_6H_6N_4O_2$ |
| 7. Paraxanthin..... | $C_7H_8N_4O_5$ |
| 8. Episarxin..... | $C_7H_8N_4O_5(?)$ |
| 9. Carnin..... | $C_8H_9N_5O_3$ |
| 10. Epiguanin..... | $C_8H_9N_5O$ |

These ten compounds collectively were given the name alloxuric bodies by Kossel and Krüger, whereas the last nine constitute the alloxuric bases. The term "alloxuric" was applied to them because each is made of an alloxan and a urea nucleus. Emil Fischer¹ has shown in many ways that there is a close relationship between uric acid and the various other members of this group. He has further demonstrated that it is possible to prepare a number of them synthetically, one of the most remarkable discoveries in physiologic chemistry in recent years. He finds that they are all derived from a combination $C_5H_4N_4$, called "purin," having a carbon-nitrogen nucleus, the "purin nucleus" as basis. Purin, according to Fischer, has the formula

and the different purin bodies are derived therefrom by the substitution of the various hydrogen atoms of byhydroxyl, amid or alkyl groups. In order to signify the different positions of substitution Fischer has proposed to number the nine members of the purin nucleus in the following way:

In observing the structural formula of uric acid given above it will therefore be seen that uric acid is 2, 6, 8 trioxypurin. Xanthin, accordingly, is 2, 6 dioxypurin; hypoxanthin is 6, oxypurin; adenin is 6, amidopurin, and guanin is 2 amido—6, oxypurin, etc., etc.

In order to make clear certain terms frequently used to designate the ten nitrogenous compounds tabulated above it may be said that they are collectively called the alloxuric or purin bodies; whereas, those from 2 to 10

inclusive are termed the alloxuric, purin, nuclein or xanthin bases. Hence it will be seen that the alloxuric or purin bodies comprise uric acid together with the alloxuric, purin, nuclein or xanthin bases.

The close relation between uric acid and the xanthin or nuclein bases and their common derivation from nuclein is shown by the following scheme:

Experimentally this has been clearly shown by Horbaczewski. This observer found that by adding some oxidizing substance, such as fresh blood, to spleen pulp or spleen nuclein, and then keeping the whole at a constant temperature of 45 C. for several hours, he obtained a certain amount of uric acid. If, on the other hand, no oxidizing agent were added and only heat applied, he was unable to obtain any uric acid, but secured an identical amount of nuclein or xanthin bases as indicated by the nitrogen contained in each. He believes that the uric acid is not formed from the alloxuric bases as an intermediate step, but that all alloxuric bodies are derived from the nucleins—the uric acid when cleavage precedes an oxidation, and the alloxuric bases with cleavage without oxidation.

The feeding of nuclein to man and dogs is followed by a marked increase in the excretion of uric acid. Horbaczewski, who advanced the theory that uric acid was derived mainly from the nuclein of the leucocytes, thinks that the increase in the uric acid after nuclein ingestion is not due to the nuclein directly, but to the nuclein derived from the increased number of leucocytes produced by the nuclein. An amount of proteid not containing any purin or nuclein bases but containing the identical quantity of nitrogen does not produce a similar rise in the excretion of uric acid, as has been demonstrated by Schmoll and Kaufmann.

The purin bodies from which uric acid is mainly derived come from two sources, and for this reason Burian and Schur have termed them the "endogenous" and "exogenous" purins. The "endogenous" purins are those derived from the nucleins of the body, whereas the "exogenous" purins are those introduced with the ingested food. So also we speak of "endogenous" and "exogenous" uric acid when it is derived from these respective sources. By use of a diet free from purin bodies (such as milk, eggs, butter, cheese, white bread, rice, sago and fruits) it has been possible to estimate the quantity of nuclein derivatives or purin bodies which arise solely as a result of cellular processes. The results of various investigators show that the endogenous purins excreted in the urine in twenty-four hours varies from 0.10 to 0.20 grams expressed in terms of nitrogen. The quantity of endogenous purin which appears in the urine only represents a certain percentage of the whole amount of nuclein decomposed in the body. The remainder is transformed by the liver cells and excreted as urea or as bodies intermediate between purin bases on the one hand, and uric acid and urea on the other. Allantoin constitutes one of these intermediate bodies. Of the total purin bodies of the urine, nine-tenths are present as uric acid and one-tenth as xanthin or purin bases.

According to Hammarsten we can not say anything positive in regard to the organ or organs in which uric acid is normally formed. The liberation of the purin

1. E. Fischer: Berichte d. deutsch. chem. Gesellsch., vol. xxx.

bodies from the cells in the case of the endogenous purins and the absorption from the intestinal tract in that of the exogenous purins lead to their presence in the lymph and ultimately in the blood stream. In the tissue spaces it is probable that the purin bodies are to a slight extent oxidized into uric acid, but the liver is in all likelihood the organ in which these waste products are eliminated. The purin bodies leave the liver in some form of uric-acid organic combination or as intermediate bodies between uric acid and urea. Burian and Schur have shown that the uric acid resultant from the intake of exogenous oxypurins varies from 40 to 60 per cent. of their total purin content. In the cat and dog, however, the percentages are considerably lessened, and allantoin is met with in large quantities. Allantoin results from a further decomposition of uric acid. Sir Alfred Garrod, Luff and Latham hold that the final formation of uric acid takes place in the kidneys. Zaleski after extirpating the kidneys of snakes and v. Schröder after extirpating these organs in birds have shown that there is an accumulation of uric acid in their blood and tissue. These experiments show that the kidneys of birds and snakes are not the only organs producing uric acid, and Hammarsten states that no direct proof of the formation of uric acid in the kidneys has up to the present been demonstrated.

Form in Which Uric Acid Circulates in the Blood.—There is still considerable difference of opinion as to the form in which uric acid circulates in the blood under normal conditions. Uric acid is a dibasic acid, and as such may be represented by the formula $H_2(C_5H_2N_4O_6)$. It thus has two atoms of replaceable hydrogen. According to Bence-Jones and Sir William Roberts, it forms three groups of salts and for the purpose of illustration sodium may be indicated as the replacing metal. The salts are as follows: (1) Neutral sodium urate, $Na_2C_5H_2N_4O_6$. (2) Biurates or acid sodium urate or sodium biurate, $NaHC_5H_2N_4O_6$. (3) The quadriurates in which a metal takes the place of one-fourth of the displaceable hydrogen of two molecules of uric acid loosely combined, such as $NaHC_5H_2N_4O_6$, $H_2C_5H_2N_4O_6$, the sodium quadriurate.

The neutral urates are purely laboratory compounds, and under no circumstances occur in the human economy. The biurates do not occur physiologically. It is important to remember, however, that this is the form in which uric acid is deposited about the joints and in tophi in gout. Free uncombined uric acid never occurs in the tissues or blood, either under physiologic or pathologic conditions. Sir William Roberts holds that the uric acid circulates in the blood as the loosely combined, readily soluble quadriurate and in this view he has had many supporters. The general view at present is that uric acid or its combinations cannot be demonstrated in the circulating blood of normal individuals by the methods now available, although Abeles claims to have found traces in human blood under normal conditions. The inability to demonstrate uric acid in normal blood is believed to be due to its being in loose organic combination with some other purin product which consequently prevents its precipitation by the usual reagents. Minkowski holds that the uric acid is in combination with the purin base, nucleotin-phosphoric acid, and that it is in this form that it circulates in the blood. This side of the subject still requires investigation.

Daily Excretion of Uric Acid.—The amount of uric acid eliminated in the urine daily by a healthy adult of average weight, and on a mixed diet, may be said to

range between 0.4 and 1.0 grams. Hammarsten gives 0.7 gram as the average daily excretion in the urine. It may be repeated here that of the total purin or alloxuric bodies eliminated in the urine, nine-tenths are present as uric acid and one-tenth as purin, alloxuric, xanthin or nuclein bases. The ratio of uric acid to urea varies considerably with a mixed diet, but is on an average 1 to 50 to 1 to 70. The exact form in which uric acid is eliminated in the urine has not been definitely ascertained, but Bunge and later Rüdel suggested that it is here also excreted in loose combination with some other organic substance. They hold that this combination is easily broken up and the uric acid is then set free. It may then either remain free or enter into combination with the sodium, potassium or ammonium contained in the urine.

(To be continued.)

EDITOR'S NOTE: The remainder of the paper of Dr. Fletcher will appear next week with the paper of Dr. Hutchinson and the discussion.

THE RATIONAL APPLICATION AND VALUE OF SPECIFIC TREATMENT FOR TUBERCULOSIS.*

EDWARD R. BALDWIN, M.D.
SARANAC LAKE, N. Y.

Tuberculin and antitoxic serum are, strictly speaking, the only real specifics related to tuberculosis. I shall, therefore, restrict my observations to these and endeavor to present some thoughts on their rational use, limitations and value in the light of our present knowledge of their effects. I must state at the outset that my personal experience with these methods is for the most part confined to laboratory and experimental observations. Whatever may be thought by some of the value of such observations, it must be remembered that man has not been found an exception among animals in the application of the general principles worked out by animal experimentation.

In order to formulate some ideas about the propriety of employing tuberculin as a treatment, one should first consent to an unprejudiced investigation of its utility and danger. Ignorant haste, both in its use and condemnation, characterizes the history of tuberculin treatment, for it is only since the problems of immunity in general have been successfully studied that we have had other than empirical ideas about its action. Even now the local reaction is not fully explained, though this was recognized from the first as most peculiar, and to it Koch attributed its healing properties. More recently the immunization of the patient has been an object in view in addition to the healing of ulcerations, both of which have proved to be possible by experimental investigation. The principles involved in this immunization are the same as those now known and used for many other purposes where the injection of a foreign substance excites the tissues or cells of an animal to produce a specific antagonism to it. In the case of tuberculin it is now known that this acquired antagonism or tolerance may be expressed by the production of an agglutinating or coagulating substance in the serum which acts on the bacilli by clumping them or on solutions of tuberculin by forming a precipitate. In this way an explanation

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Sells-Cohen and O. T. Osborne.

is given of the gradual diminution of the local and general reaction when tolerance is acquired to tuberculin by all the tissues, for we may understand that it becomes bound or combined before reaching the general circulation or periphery of the tubercles where the cells appear to be especially sensitive to its presence.

In fact, v. Behring's¹ recently expressed opinion as to the cause of the local reaction is in line with this explanation. He thinks that the smallest blood vessels around the tubercles secrete coagulating or agglutinating antibodies, which act on the soluble substances derived from the tubercle bacilli. Thus there follows the intravascular coagulation, capillary engorgement and extravasation of red and white blood cells which characterize a typical local tuberculin reaction. This theory is the more plausible because quite marked febrile reaction may occur in tuberculous subjects from other causes without typical local congestion about the periphery of the tubercles, such as are produced by tuberculin. This I believe to be an important distinction between true tubercula reactions and those so-called reactions produced by other substances. The independence of a fever reaction from a local one is thus possible in so far as that fever may occur without the usual signs of hyperemia about tuberculous foci, though the reverse is not generally true. It is well known that under certain conditions a hyperemia produced intermittently about tuberculous and other ulcerations favors cicatrization. Whether or not mild temperature or local reactions are necessary, they seem to hasten the healing according to most observations. We therefore have two possible ends of importance attainable by tuberculin. We may succeed in fortifying the patient artificially against the specific poison and at the same time under this stimulus aid in healing an otherwise sluggish tuberculous ulcer.

During the process of immunization against tuberculin a certain degree of immunity is obtained against the disease, but after the injections have reached a maximum dose, beyond which there is no local reaction and no increase of agglutinative power in the blood, it is useless and generally harmful to proceed further. This biologic law of maximum cell stimulation is a more or less general one, and it has been found that two or three months is the period within which this occurs. This is confirmed by clinical experience with tuberculin treatment. It is decidedly more rational to give several courses of treatment, with intervals, as recommended by Petruschky,² should one not be sufficient for healing. Experience has shown that a high agglutinating power in the blood is generally coincident with heightened resistance to the disease, but not invariably so, and, after the cessation of the injections, the specific resistance both to the poison and to the disease is gradually lost. The condition of the individual undergoing an immunization against tuberculin should obviously be such that his cells are not already overburdened by the effects of the disease, for to add to this would simply mean more poisoning, an irrational and inexcusable thing. This fact precludes the safe treatment of most of the advanced and progressive cases of pulmonary tuberculosis, though not necessarily excluding certain chronic cases in good nutritive condition.

During a tuberculin reaction, and for a time afterward, the so-called serum complement is found to increase, and leucocytosis also is present. Their exact relation to tuberculosis may be regarded by analogy as favorable, though not understood in many respects.

Concerning the danger that the bacilli may be scattered during the local reaction, much has been asserted, but little proved. In fact, except when first given in doses that were reckless in the extreme and to patients with progressive disease, I know of no reliable evidence that this result actually occurs. Even the oft-quoted opinion of the late Professor Virchow during the first tuberculin craze was said to have been greatly modified by its author in later years. The isolated instances in which the disease is alleged to have been lighted up into activity by tuberculin, used either for diagnosis or for treatment, always lack complete proof that these relapses would not have occurred without tuberculin. The question is thus reduced to a matter of opinion. Nevertheless, it must be remembered that the conditions are such during a violent local tuberculin reaction as to favor the scattering of tubercle bacilli, because the blood and lymph streams are then much more active about the tubercles. It would seem reasonable that considerable danger of spreading the infection with the formation of few foci would exist at such times. The experimental evidence and the clinical experience of those who have had most opportunity to form unbiased opinions are, however, decidedly against this view. Moreover, it would seem that even if bacilli were set free by the reaction they must quickly die and disappear without producing new foci of disease. Otherwise a prolonged fever reaction and other indications of fresh disease would be common. The actual effect of tuberculin in suitable cases is distinctly favorable, judging from the absence of fever after the reaction, lessened expectoration, and cicatrization of ulcers.

Having mentioned the chief points concerning the physiologic action and dangers from the use of tuberculin, we may be able to form some rules for its clinical application. It should be evident at once that all forms of acute tuberculosis are to be excluded from this treatment both on account of the danger of increasing the load for the already poisoned cells, and of the possible extension of the disease either from the increased inflammation or from the decreased resistance. For similar reasons patients with extensive or advanced lesions complicated with other infections, renal or intestinal disease, are to be excluded. There would then remain as suitable for treatment only early, localized, apyretic cases, with some arrested or quiescent ones of longer standing which have good nutrition. Some more advanced or chronic cases which still have good resisting powers have been very successfully treated by tuberculin in spite of some fever. As a rule, however, it can not be recommended on rational grounds for such cases.

The form of its administration has been the subject of various modifications, but at present, with the object of immunization in view, the most rational preparation would seem to be the emulsions of the entire substance of the bacillus unaltered by heat. It must be said that these emulsions are more difficult of absorption, and may not be entirely sterile without the addition of some chemical germicide, if not heated. The various extracts of tubercle bacilli in use all produce the specific local reactions, and possibly some increased resistance to the disease, although there is reason to think that the poison is somewhat altered by heat in its preparation. It is, after all, difficult to say that one preparation has any superiority over another from clinical results thus far obtained. The dosage, intervals between the injections and careful observations of temperature and other symptoms require so much care that its use is practically confined to institutions, while the restrictions under which it seems safe

1. Deutsch. med. Woch., Sept. 24, 1903.

2. Berlin. klin. Woch., Dec. 18-25, 1899.

to give it are so many that its value is thereby considerably limited.

The active immunity or heightened specific resistance to be obtained by tuberculin, however short in duration, is an ideal object in the therapy of tuberculosis, for it might tide the patient over a sufficient time to complete the healing of an open tuberculous ulceration, which is a menace of reinfection or mixed infection so long as it remains open.

The results in simple sanatorium régime are so good in patients who are favorable from the beginning that I should question the wisdom or desirability of tuberculin treatment for a routine in such cases, although there is evidence that relapses are somewhat less common after its use. Whether this is due to any prolonged immunity is doubtful, judging from the return of tuberculin susceptibility after cessation of treatment. I am more inclined to the idea that the cicatrix may be somewhat stronger after tuberculin.

When a patient fails to recover under the usual hygienic-dietetic treatment after a reasonable time—for example, in six months or a year, according to the amount of ulceration—there is great danger that the disease will be chronic in spite of otherwise favorable factors, such as a normal, or practically normal, temperature and general health. I think physicians who have much experience in health resorts and sanatoriums recognize what may be described as arrested and uncompleted cases, whose physical signs do not indicate extensive ulceration, yet continue to have expectoration with bacilli as practically their only symptom. It is in these cases that the use of tuberculin seems to me most rational and safe. They have much to gain if the ulcer can be healed, and, if one may judge from the statistics that have gradually been accumulating, more persons may be healed with its aid than without it.

It is not too much to hope that the future may bring us further improvement in the application of an immunizing therapy for tuberculosis.

In many papers that have appeared in this country the terms "tuberculin" and "serum" treatment seem to mean one and the same thing to the writers. Since antitoxic serum is generally intended in "serum" treatment, it should be so stated. When serum is assumed to have active immunizing properties, of course the synonymous meaning given would be correct.

Antitoxic serums for tuberculosis were much vaunted several years ago, and the good effects obtained in this treatment were ascribed to the direct neutralization of the tuberculous poisons. Some experimental evidence was produced which led to this belief, but it rested solely on the fact that a minimum reacting dose of tuberculin could be inhibited by serum from an animal immunized against tuberculin in its various forms. No clinical proof of such effects in lowering a pure tuberculous fever has been given that is at all satisfactory nor does experiment indicate that serums neutralize the poisonous effects of the disease in the animal. A possible explanation of the antagonism to tuberculin when an anti-tuberculous serum is mixed with it before the injection is that a precipitation may take place which prevents the absorption of the tuberculin. This has been demonstrated to be possible in some of my own experiments, but by no means constitutes proof of antitoxic power comparable to that of diphtheria antitoxin. On the whole, one is led to think that the good results reported in sero-therapy for tuberculosis are due neither to a direct nor indirect antitoxic power. Indirect production of antitoxin implies a specific stimulus from the serum acting on the cells of the

patient under treatment; in other words, either tuberculin in the serum or a hypothetical bactericidal power, neither of which is thus far proved. If there is any other manifestation of antitoxic activity that does not exhibit itself by reducing the temperature, I am confident that it must be very weak. A critical estimate of the clinical results of anti-tuberculous serum treatment produces the impression that the favorable results may be accounted for by the non-specific stimulus given to the tissues, which may aid nutrition. Moreover, two reasons appear to me obstacles to any successful serum therapy in tuberculosis: First, the difficulty of its reaching the seat of the poison, which is in the bacillus itself, lodged in caseated tubercles, and for the most part exerting its effects locally. Second, the serum injections excite antibodies against themselves when repeatedly administered even in small amounts, as will any serum alien to the animal injected.

While we ought to be alert for any addition to the therapy of tuberculosis, it is too often forgotten that the maintenance of a high nutritive condition in the patient is a prerequisite for their usefulness, and in the final analysis most of the benefit derived from them will depend on this factor.

DISCUSSION.

DR. V. Y. BOWDITCH, Boston, said that when tuberculin first appeared he used it in several cases, including cutaneous and pulmonary tuberculosis. The results were *nil*. He then decided to wait for further instruction from Koch before experimenting further, but, yielding to the opinion of those whose judgment he respects, he has used it several times at the Sharon and the Rutland sanatoria, but never in private practice. He has always felt uncertain as to the results. In most of these cases he has used it where he had a suspicion of tuberculosis in order to confirm the diagnosis, chiefly to satisfy the "doubting Thomases" who would perhaps challenge the results. He had two cases in which 10 mg. failed to give any reaction, but in which blood spitting occurred later, whether due to the use of tuberculin or not he was unable to say. In other cases there was no reaction to 10 mg., yet tubercle bacilli were found in sputum ejected just before the injection was given. He has had one or two cases that have seemed to make a decided improvement after a diagnostic dose was given, but whether this improvement was *post hoc* or *propter hoc* it would be impossible to say; he regards it simply as a coincidence. As to the number of relapses in cases where the disease has become arrested, he forms his opinion largely on what Dr. Trudeau said to him at one time, that the number of patients who relapsed after the use of tuberculin is slightly less than in those in whom it had not been used. If there had been any decided effect from its use, it seems that the number of the former should be very much less in order to carry much weight. Dr. Bowditch agrees with Dr. Baldwin in regard to the necessity of carrying on these clinical observations in institutions. There seems to be much uncertainty about the observations made by physicians in this matter, especially in dispensary practice. Patients who have gone away and come back with a history of headache, malaise, etc., after the use of tuberculin have been recorded as having had a reaction, a conclusion which seems quite unwarranted and not scientific. In reports of cases which have been using certain vaunted methods of treatment it frequently happens that the value of improved hygienic surroundings alone has been scarcely taken into account. In his opinion no special method of treatment can be fairly tried until after hygienic methods have been fully tested first and found wanting. Dr. Bowditch said he had only used one serum, and in that case the results were absolutely negative. He could not see what good it would do to give patients hypodermic doses of tuberculin before they leave an institution to see that they do not react, because specific resistance to the tuberculin has, after a time, become weakened or lost.

Dr. J. W. Foss, Phoenix, Ariz., stated that he had had considerable experience with advanced cases of pulmonary infection which had been considered hopeless. In this class of cases there is usually a mixed infection. In the cases showing streptococci infection in the lungs he has used streptolytic serum for the past two years with most satisfactory results. One of his earliest cases was a physician whose case was considered absolutely hopeless. He had a well-marked mixed infection of the lungs, consisting of streptococci pyogenes, staphylococci, tubercle bacilli and pneumococci. He was given the serum and in three months had gained 28 pounds. This was over two years ago. He is still living and attending to his duties as railroad surgeon, and considers himself well. It is the opinion of Dr. Foss that this treatment is very valuable in a large percentage of cases in mixed infection of the lungs which have hitherto been looked on as hopeless. In his examination he always looks for the streptococcus pyogenes, and if his patient is not doing well he uses this treatment. He has observed that when there is a persistent excess of amorphous urates in the urine that the case usually terminates fatally. He has had cases of well-marked mixed infection showing a rapid progress of the disease in the lungs. After giving the serum, expectoration and cough entirely ceased within a few months. He usually gives 20 c.c. at the first dose, followed by 10 c.c. daily, injected subcutaneously in the back or abdomen, never in the limbs. His cases have required from 140 to 320 c.c. of the serum. All cases have a reaction more or less severe, consisting of urticaria, edema, pain in the joints and a small percentage of the cases have had cyanosis. He has never had any serious results from the use of the serum.

Dr. EDWARD O. OTIS, Boston, asked Dr. Foss if he referred to the use of antistreptococcal serum in these cases of mixed infection, and if he made any difference between the treatment of those with streptococci and those with both streptococci and staphylococci, and whether he does not find both of these organisms in the advanced cases along with tubercle bacillus. Dr. Otis said that he had had but little experience with antistreptococcal serum, and then with no results, but he has used tuberculin in over 150 cases for purposes of diagnosis, without any bad results. After remarking that pulmonary tuberculosis was treated either principally by drugs, by a combined drug and outdoor treatment, principally outdoor, and by treatment with the various antitubercle sera, he said that by the latter alone we have not as yet been able to eliminate or obtain immunity from the bacilli. He thinks that for the present the best treatment is the hygienic and dietetic treatment, with very few drugs. His own experience leads him to place very little confidence in any drug whatever. He has used large amounts of creosote, for example, and is convinced that it has very little effect except possibly on the digestive organs. The results are best when we rely on the dietetic and hygienic treatment. When such good results are obtained by it as we find at Rutland, we should be encouraged, especially as the climate of Rutland, Mass., is not an especially good one.

Dr. R. C. NEWTON, Montclair, N. J., called attention to work done by the New York Board of Health. Dr. Herrold of this board, guided by the fact that the antitoxic serum from horses that have been immunized from diphtheria will cure diphtheria, concluded that horses that had been immunized by injections of cultures of the toxins derived from cases of tuberculosis and mixed infections, would furnish a serum that could be used against human tuberculosis. The experiments with this serum have thus far given promising results. One case is now practically well and another case is doing very well. The cases are, so far, too few from which to draw any positive conclusions. Dr. Herrold's idea is that it is the effect of the mixed poisons, and not that of the tubercular infection alone that is to be overcome by the serum, and that every tubercular patient should receive the serum in repeated injections from a healthy immunized horse. He gets the horse to the point where it will no longer react, and then he begins injecting the serum into the patient. Dr. Newton said that we are in duty bound to thoroughly test any plan of treatment which may by

any possibility prove to be valuable in the treatment of this disease.

Dr. JOHN H. LOWMAN, Cleveland, said that those who have reported the best results from tuberculin are those who have used it in the very smallest doses. It is claimed that the smallest number of relapses and the highest percentage of cures are obtained in Silesia, and that he was very much interested, in making a tour of these institutions in Germany, to find that those who used the tuberculin treatment were those who had graduated in Koch's laboratory. Dr. Lowman said that the cases in Cleveland have been advanced cases. In diagnostic cases the serum treatment has been satisfactory. It has been used in bone cases, in Pott's disease, in chronic pleurisy. He has used it in several cases to detect the character of the pleurisy. He has not been able to completely satisfy himself as to the real value of this substance, even from the diagnostic standpoint.

Dr. LAWRASON BROWN, Saranac Lake, N. Y., said that, at the Adirondack Cottage Sanitarium tuberculin has been used since 1890, when Koch first announced his discovery. In all, about 160 cases have received it. One of the immediate results of tuberculin treatment is that the percentage of patients who have lost their bacilli is greater than the percentage of such in the total number of cases (1,500). The ultimate results show that the tuberculin treated cases have fewer relapses. These results may be criticised because many of the cases were carefully selected, and many who received tuberculin remained a much longer time under hygienic-dietetic treatment. At first the old tuberculin of Koch was used in selected cases, but lately the bacilli have been used in emulsion containing the entire substance of the pulverized tubercle bacilli. The whole question of secondary infection is one much involved at present. It is difficult to determine from the sputum whether or not secondary infection is present.

Dr. J. H. ELLIOTT, Gravenhurst, Canada, stated that in his sanitarium experience most of the cases admitted have been advanced cases, and for this reason he has not used tuberculin for diagnostic purposes, because the diagnosis has been only too evident. In one or two cases lately, however, it has been used and with good results. He has afterward found tubercle bacilli in the sputum of some patients, and has wondered whether or not the appearance of the tubercle bacilli might have been the result of the tuberculin injection. But as they disappeared in a short time under treatment, the patients were not injured by it. All who are engaged in sanitarium work find a class of cases where after marked improvement the patient remains stationary. The bacilli remain and the case does not further improve. He has used the antistreptococcal serum in a small number of cases with sufficient results to encourage its further use. The examination of the sputum in this respect seems rather faulty. A streptococcus serum is used, but we can not say whether or not the serum is from the same variety of streptococcus as that in the patient. In some cases it has been necessary to discontinue the use of the serum on account of a rash, or severe joint pains. One case of pelvic suppuration with multiple abscesses and alarming symptoms yielded very rapidly to antistreptococcal serum injections.

Dr. J. W. Foss said in reply to Dr. Otis that he has found staphylococci in the sputum in many cases associated with streptococci. They usually disappear after treatment with the serum. It is his opinion that the improved condition of the patient after the elimination of the streptococci may be responsible for this result.

Dr. EDWARD R. BALDWIN said that at the present day we know that laboratory methods in diagnosis are somewhat overrated. For instance, Widal's test, when it was first introduced, was thought to be decisive, but now it is mixed up with paratyphoid and other diseases, and requires much laboratory experience in order to interpret the results. While the diagnosis of tuberculosis by the use of tuberculin is of great value, there is frequently some idiosyncrasy which impairs the value of the result, and the best estimate as to its value places it at about 75 per cent. There are also a certain number of cases which will not react. If persons react to minute doses of tu-

tuberculin, it is probable, in more than 75 per cent. of cases, that they have tuberculosis in some part of their body. Such large doses as were given by Koch's directions (up to 10 mgr.) are rarely required in the diagnosis of pulmonary tuberculosis. Dr. Baldwin thinks that the whole condition of the patient should be taken into consideration in the matter of diagnosis. If tuberculin is given it should only be in the most minute dosage. It should not be given on any consideration to a patient whose temperature at night is 99.5 nor to one who has not been under observation for some weeks. Therefore its field in diagnosis is very narrow. It is a very unpleasant experience to have a bad result attributed to the use of tuberculin. The best method, in his opinion, is the diagnosis by exclusion. He is quite certain that the tuberculin reaction can be obtained in healed tuberculosis except in those cases where the tubercles are wholly fibrous or calcified. In other words, in the greater number of persons who have had tuberculosis, this reaction may be obtained. He mentioned a patient who took tuberculin as a treatment until he no longer reacted to large doses, and was healed. That was six years ago. Recently tuberculin was again administered and a reaction occurred. Therefore, in Dr. Baldwin's opinion absence of reaction is no sign of a cure, because the susceptibility gradually returns. He has known unfavorable symptoms to occur after treatment with antidiphtheritic serum, antitetanic serum, and other kinds. These symptoms are very alarming and are liable to deter a physician from any kind of serum treatment. They may be explained on the ground that they are due to thrombosis in the minute capillary vessels and not to any specific ingredients in the serums. Dr. Baldwin agreed with Dr. Lowman that there is a great deal of what might be called the personal element with regard to the tuberculin treatment in Germany. Professor Koch has a great many critics and a great many enemies in his own country. The Berlin and Vienna schools are not always harmonious. We can not but admire the absolute thoroughness with which the Germans do their work; but we can not admire the personalities they indulge in, which are condemned by the scientific world, in Germany and in this country alike. With regard to the Adirondack Sanitarium cases and the results from tuberculin treatment, they can be criticised on account of the early character of the cases. Of course it would be of more convincing value if tuberculin should not be used in the treatment of pulmonary tuberculosis, until other methods have been given a fair trial.

INJURIES TO THE RECTUM CAUSED BY GYNECOLOGIC EXAMINATIONS.*

HOWARD A. KELLY, M.D.
BALTIMORE.

Unfortunately, all risk to our patients is not incurred solely in the course of our aggressive modern methods of operating, as experience shows that the preliminary examination itself may even be a source of danger. The injury done by a gynecologic examination may fall on the structure which is being examined, or on the enveloping structures which constitute the wall of separation between the object and the examining fingers, occasioned by the effort on the part of the examiner to overcome the resistance offered by the barrier to palpation and the sense of touch.

The injury thus incurred may be due either to the delicate nature of the tissues examined, rendering them liable to damage from the slightest violence, or to an unduly rough examination such as we too often witness, or to both of these factors combined. The examiner may in this way rupture, intra-abdominally, a thin-walled papillary ovarian cyst, and so become respon-

sible for the dissemination of its contents over the previously sound peritoneum. He may rupture, as I have seen done, a vascular cystic sarcoma of the ovary in which the malignant elements had hitherto remained confined within the cyst walls.

I have seen an extrauterine pregnancy ruptured by an examination, and I have heard of one ruptured in this way, from which the patient died. Pelvic abscesses, too, are not infrequently spread abroad by unwise handling in the effort to make an accurate diagnosis; operators of large experience in diseases of the vermiform appendix have observed the disappearance of a well-defined collection of pus immediately after an unduly zealous palpation. In the hospital in which I was a resident twenty-two years ago, one of the attending physicians ruptured a liver abscess in this way, and distributed its contents through the abdomen, with a fatal result.

Lesser injuries, such as the rupture of the thin-walled large graafian cystic follicles, by the operator or by his assistants, in the course of an examination made just before an operation, have doubtless repeatedly been noted and verified within a few minutes at the operation by other operators as well as by myself.

These injuries, however, are all intra-abdominal and confined to collections of fluid within more or less thin-walled cysts or limiting membranes; injuries to the intervening structures, which separate the examining fingers from the object of the examination, are far less common.

The enveloping walls which are subjected to pressure in the course of a gynecologic examination are the strong musculotendinous and cutaneous walls of the abdomen, the tough musculomembranous vagina, and the more delicate musculomucosa of the rectum.

The only injuries I have ever seen sustained by the abdominal wall have been done to the capillaries, as evidenced by little effusions of blood under the skin, which subsequently pass through the characteristic color changes. I have never seen a distinct hematoma, or an abscess produced in this way. Sometimes the too long finger nails abrade the skin, and these lesions might easily become avenues of infection.

I have not yet seen any injury done the vagina by the examining fingers, although I have witnessed many cases of perforation of the uterus by a sound, and in one instance perforation and death by a dilator loaned to a physician; it is not my purpose, however, to dwell on injuries due to instrumentation.

Of all the avenues of investigation of the pelvis, it is the rectum which is the most delicate, and, I believe, the most liable to serious injury. I desire to report briefly four cases in which the coats of the bowel were actually perforated by the examining finger, which was thrust through the rectum and into the peritoneal cavity. All of these injuries have occurred in my own personal experience in my hospital practice within the past fifteen years, not in the hands of inexperienced students, but in the course of an examination made by a competent assistant, and once my own finger was responsible.

CASE 1.—Mrs. J. S., a married white woman, 52 years old, was etherized for dilatation and curettage for an excessive menstrual flow. During an examination of the pelvis by the rectum, the finger was pushed through the bowel into the abdominal cavity.

An incision was at once made posterior to the cervix in the vaginal vault, through which a vertical rent was found in the rectum 4 cm. above the cervix and 13 cm. from the vaginal ori-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

fice; this was closed with fine black silk sutures, and recovery followed without any ill effects.

CASE 2.—Mrs. E. W., a married white woman, 63 years of age, who had a cystitis. At an ether examination made in order to determine the condition of the pelvic organs, which were found normal, the finger was pushed through the rectum into Douglas' cul-de-sac. The opening into the peritoneal cavity was at once exposed by an incision in the vaginal vault back of the cervix, and repaired with fine silk sutures. An iodoform gauze drain was brought out through the vagina. Recovery followed, complicated by a fecal fistula, which closed spontaneously.

CASE 3.—Mrs. C. J., white, aged 58, had a large left ovarian cyst, widely adherent to the intestines and omentum, weighing, with the contents, 15,000 grams. During the rectal examination, which I made before the anesthetic was given, my finger was pushed through the rectum into the peritoneal cavity. As the abdomen was about to be opened and the rent was sufficiently plugged by the tumor filling the pelvis, I made the abdominal incision and removed the tumor, and so exposed the rectal tear, which was closed with fine silk sutures. There was no soiling of the peritoneum apparent, and no drainage was used. She made an uneventful recovery.

CASE 4.—Mrs. L. L., white, aged 28, suffering from excessive menstruation, was anesthetized August 25 for curettage and diagnosis. In the course of the rectal examination the index finger was pushed through in the peritoneal cavity. A piece of gauze was passed through the opening in the rectum and brought out at the anus, but as there was a manifest peritonitis coming on the next day, the abdomen was opened and the rectum closed with fine silk sutures and the pelvis drained. She made a slow recovery, leaving the hospital forty-five days later.

I think the cause of these injuries lies in the age of the patients (in three averaging about 57 years) and the weakened muscular tone of the bowel. In one it is significantly noted that the patient was very stout. In such cases not only is a greater effort made to reach the deeper seated structures in an examination, but the tissues are far more friable.

I believe the proper treatment is, in all cases, to open the peritoneum at once and carefully suture the rent from the peritoneal side. It would be better to use two layers of fine silk sutures rather than one. A washed-out iodoform gauze (Saenger) drain should be inserted through the vaginal vault. If the opening is accessible, the posterior vaginal cul-de-sac is the most convenient avenue by which to reach the tear, unless the abdomen is about to be opened, as in my case of ovarian tumor. If, however, the perineum and vagina are rigid and contracted, and the rent awkward to reach, it would be wiser to make an abdominal incision and sew it up in that way through the superior strait; in either case the operator must be skillful in sewing at a distance with long instruments. It is of the utmost importance that the sutures should be well placed, penetrating the thick coats of the bowel as far as the mucosa and securing accurate apposition. After such an operation the patient ought, as a rule, to receive no other food than albumin water for from five to seven days. The anal orifice should be thoroughly dilated, and if a rectal tube is tolerated it will serve to carry off gases and keep the parts at rest.

In order to avoid such injuries in the future, I would suggest that the rectal examination be made with the utmost gentleness, constantly bearing in mind the possibility of a rupture of the bowel, especially in stout elderly women. It is well to empty the bowel before the examination, and if the patient is then placed in the knee-breast posture and a speculum introduced, so as to secure a maximum air distension, on returning her to the dorsal position the rectum will be found expanded and holding a much wider and closer relation to the structures in the posterior pelvis.

An important point, not sufficiently emphasized, is that the examiner should avoid the natural impulse to invaginate the wall of the rectal ampulla on the end of the finger, pushing it to a point higher up in the pelvis. This error will not occur if, after introducing the finger into the ampulla, the next step made is that of seeking out the so-called "third sphincter"—that is to say, the rectal valves behind the cervix. The finger ought to be introduced between these distinct anatomic structures and then up into the pelvis, where the bowel lies in its natural relation in contact with the posterior surface of the uterus and the left broad ligament.

It is important, too, that the wrist and the fingers should be at ease and flexible during the examination. If the whole arm is made rigid in the effort to push in the perineum in order to gain a few centimeters in finger length, the hand also is apt to become rigid and the tactile sense impaired, and the movements less under control. I avoid this rigidity of the arm by resting my elbow against my hip and pushing the arm in from the hip and so setting it at ease. I trust this brief presentation of these few cases will serve the more important purpose of eliciting the experiences of many of the gynecologists who are here, as I feel sure an important new chapter will be written concerning the injuries produced in the course of gynecologic examinations when all the facts are known.

DISCUSSION.

DR. THOMAS S. CULLEN, Baltimore, mentioned two cases of injury to abdominal structures resulting from a vaginal examination. In one case there was a myomatous uterus, two of the nodules were sessile and one pedunculated. On opening the abdomen, after several students had examined the patient, he found about 200 c.c. of free blood in the abdomen. The pedunculated myoma had been partially torn from its uterine attachment and there was free oozing. Such an accident is liable to happen even when the utmost care is used. The slightest traction during operation is liable to partially separate a myoma from the uterus. As the abdomen was opened immediately after the examination the slight hemorrhage was of little consequence. Had there been merely an ether examination without operation the bleeding might in a short time have produced alarming symptoms or possibly have occasioned death. Several years ago Dr. J. W. Williams told Dr. Cullen of a case in which he made a vaginal examination and found pus tubes. Four or five hours afterward the temperature rose to 105 F. and the pulse became rapid. On opening the abdomen he found that one of the pus tubes had collapsed. The pelvis was full of free pus and acute peritonitis had already commenced. After removal of the tubes the patient made an excellent recovery.

DR. F. F. LAWRENCE, Columbus, Ohio, said that this paper emphasizes two points: first, that palpation, to be of value, must be light; second, to be other than that means great danger to the patient and great anxiety to the surgeon, not only in the cases mentioned, but in others. He has twice seen most disastrous results follow unnecessarily vigorous examination in strangulated hernia. In one case the manipulation resulted in perforation of the bowel above the neck of the sac intraperitoneally, with the escape of a large amount of the intestinal contents into the free peritoneal cavity. The result was fatal. Dr. Lawrence recently saw a case of extra-uterine pregnancy in which an unruptured tubal pregnancy was diagnosed. A relative of the patient was anxious to satisfy himself that an operation was justified and made a rather vigorous examination. In two hours the pulse went up to 140. The abdomen was found to be full of blood, and only the most vigorous efforts saved the patient's life. Injury to tissues other than the rectum are also to be considered. A rectal examination must be made even more delicately than a vaginal examination.

DR. GEORGE EREY SHOEMAKER, Philadelphia, said that he could add one case of rupture of an appendiceal abscess by the hydrostatic pressure of an enema. The woman was in collapse when he arrived. Her physician had attempted to move the bowels. The nurse had placed the bag at least four feet above the level of the patient. The patient gave a sudden outcry and went almost immediately into collapse. Her condition being absolutely hopeless, he declined to operate. No postmortem was allowed, but undoubtedly the pelvis was full of pus because of rupture of the abscess into the peritoneal cavity.

DR. H. G. WETHERILL, Denver, said that there is another way in which injuries to the rectum may occur, incident to obstetric operations; as the head is descending and receding rather rapidly, he has seen the second finger thrust into the rectum and recession prevented in that way. This is a practice which should not be sanctioned under ordinary circumstances, not only on account of the risk of injury to the rectum, but because of the danger of infection.

DR. CHARLES P. NOBLE, Philadelphia, reported a case of rupture of a cyst of a graafian follicle on the examining table. This was followed by syncope, but no other ill results. He has had a number of similar cases, both in the office and in the operating room. The only serious case occurred in his clinic recently. The diagnosis was in question, whether a suppurating ovarian tumor, or a tumor, plus a pelvic abscess. One of the assistants, a very competent and careful man, made an examination and ruptured the abscess, a very serious situation, as the patient was profoundly prostrated at the time. Immediate celiotomy was performed with a fatal result.

DR. SAMUEL M. BRICKNER, New York City, asked Dr. Kelly whether he obtains as good results from a rectal examination by placing the patient in the dorsal position, after first placing her in the knee-chest position, as on the side. Dr. Brickner also has had a case of ruptured graafian follicle cyst. He examined by vagina and found a very small cyst. He asked one of his assistants to examine her. The young woman had been married recently and there were a number of raw edges on the vagina, which were painful, so he asked him to examine by the rectum, which he did. He made hard pressure over the abdomen, but said that he could not feel the tumor. Dr. Brickner examined, but failed to find it again. She had severe pain in the abdomen, so he operated at once and found that the cyst had been ruptured. The patient recovered.

DR. H. A. KELLY said that the treatment of such an injury is an important matter. A patient in one of our inland towns who had a rent in the rectum caused by a proctoscope died. The best plan is to open the posterior cul-de-sac, sew up the rent and put a small drain into the peritoneum. If the physician is about to perform an intra-abdominal operation at once the wound may be closed through the superior strait and then drained below, but in all cases it is well to put in a drain.

THE TREATMENT OF OTITIC SEPTICEMIA.*

B. ALEX. RANDALL, M.D.
PHILADELPHIA.

The distinction which has been made between perforative and non-perforative inflammation of the middle ear or between its purulent and its catarrhal form is usually well grounded, and coincides with the differences of septic or non-septic involvement. Like all rules, however, this has its exceptions, and cases lacking all evidence of purulency can go on to the most serious results in a way that justifies us in urging that every case of middle ear inflammation shall at first be dealt with as though the outlook was serious in the extreme. Several of the most important deaths which have oc-

curred in my experience have been in cases where tympanic symptoms were moderate, trivial or even apparently absent, yet meningitis or intracranial purulency developed with fatal results. This question, therefore, of the septic character of a tympanic involvement must at times be inferred, in spite of the symptoms, rather than by their aid, and in all cases there is reason that we should adopt, beside the local treatment, general measures looking to a forestalling of such dire possibilities.

GENERAL TREATMENT.

Rest in bed, with protection by compress and bandage of the whole aural region, bloodletting, purgatives, restricted diet, and heat or cold externally, are generally insisted on, and their value is well known to all who have employed them. In spite of all these and the free drainage by incision of the suspicious drumhead and of the edematous upper back wall of the canal—"internal Wilde's incision," which has rationally displaced almost entirely the older cut through the mastoid periosteum—we may have vague yet disquieting symptoms of variable fever, pain, headache, nausea, and possibly twitchings verging on convulsions. Of course, it is easy to be radical, and, if permitted, to chisel the mastoid and even explore the intracranial cavity or the cerebrum itself; but the rational demands for this are often lacking. The conservative man can not feel justified in urging this against opposition, especially if he has employed it vainly in a previous series of cases, in which the absence of findings to justify the exploration has left him of the opinion that recovery, if achieved, has been in spite of his intervention rather than because of it.

The absence of localizing symptoms may be such as to leave the steps of intervention utterly indeterminate. Evidence of sepsis may be present in the steeped temperature-chart, and yet the signs of even phlebitis of the jugular or lateral sinus may be lacking, or the irritative symptoms of meningeal involvement may leave us in doubt as to whether anything more than irritation is present. In such cases radical intervention will not always be accepted, even if the aural surgeon feels impelled to offer it. It is here that we may still hope for benefit from medicinal means, and mercurials, salines and sweatings may do much to eliminate the toxic materials from the system and to prevent the occurrence of the serious lesions which threaten.

Hypodermoclysis.—In addition to these, the latter days have given us great help in the employment of hypodermoclysis or enteroclysis. The value of the first of these is too well assured to need much urging, especially with any one who has employed it. Yet those who have not employed it will look with some hesitation to its demand for strict asepsis, and will regard it as a surgical procedure which few physicians, fewer trained nurses and no others can possibly undertake, while patients or friends will refuse it on the score of its painfulness and its unknown possibilities of evil. Yet it should be feasible to sterilize a fountain syringe by boiling and a large hypodermic needle by alcohol and to boil the water and its due proportion of salt, permitting the giving of such injections at any bedside without risk and with minimum trouble.

Enteroclysis.—The enteroclysis, on the other hand, is a familiar matter to every household, and will be readily accepted in many cases where the other might be absolutely rejected. Its value may be less, as its action is certainly slower and less striking; but it is so

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

easy of performance that the patient will rarely make the least objection, and it can be repeated with most gratifying results again and again in cases where the occurrence of high fever has marked some complication, but study fails to indicate the seat of the trouble. It has seemed fair to assume in such instances that the condition is as yet a mere toxemia, whether by absorption from the ear, the intestines or some other part; and vigorous use of the high saline enema has been followed by prompt fall of temperature and disappearance of all disquieting symptoms.

Lumbar Puncture.—In the severer cases where meningeitic symptoms are present but without localization, and operative opening of the skull seems premature and haphazard from lack of localizing indications, there is great aid to be gained from lumbar puncture. This does not mean that the milder measures with free catharsis and all medicinal aids should be neglected. These should be freely employed; but in addition to these puncture of the lumbar canal, if done with fair anatomic knowledge and a clean needle, should be harmless, yet frequently valuable. This value is not merely in the diagnostic aid afforded by the study of the fluid drawn off—its therapeutic value is equally great, although often overlooked. Marked convulsive attacks may cease wholly under its relief of tension, stupor and other evidences of brain pressure may lighten and pass away, and the main credit for the gain will properly belong, in many of the cases, to the lumbar puncture. Its real therapeutic rather than merely diagnostic value points to its repeated employment, many times a day if urgent symptoms demand; and it is this rather than other points as to its use on which I feel that I can insist. The antitoxic effect of quinia, permanganate of potash and other drugs is probable but not proved; and the antistreptococcal serum seems to work in other hands, if we may believe reports, but it is apt to prove barren in our own hands.

Glycogen, either by the mouth or hypodermically, has claims made for it equal to those which can be urged for the most potent remedies, but it remains to be proven how often it will equal or approach such expectations. It has seemed valuable in my hands, and I can commend its further employment.

CONCLUSION.

I especially wish to urge the frequent and full employment of enteroclysis in these cases of otitic toxemia as a remedy potent and general in its effect, while almost ridiculously simple in its employment. The temperature may be warm, medium or cold, as the inclination or condition of the patient dictates. The amount must vary from two or three ounces in the infant to a pint in some adults, in accordance with the capacity of the bowel. The introduction must be slow with slight pressure—a foot of elevation of the reservoir is enough—and the perineum may need to be supported for many minutes after the withdrawal of the tube if retention is to be secured. Even if much of the fluid is lost, its flushing of the lower intestinal tract is of great importance, and the amount of absorption is generally greater than might appear. Quinia and other medicaments may be added to it, or the nutritive materials if other means of feeding are unsatisfactory. But with all this simplicity, it is probably as efficacious as most of our possible interventions; and in the vague, indeterminate cases, where surgery must wait for clearer indications, it may often forestall serious complications and prove the means, not brilliant but real, of saving life.

PLASTIC OPERATIONS FOR THE CLOSURE OF POSTAURAL OPENINGS FOLLOWING RADICAL AND MASTOID OPERATIONS.*

EDWARD BRADFORD DENCH, M.D.
NEW YORK CITY.

It occasionally happens that after either a simple mastoid operation or after the radical operation for the relief of chronic suppurative otitis media, that an opening of considerable size remains behind the ear. Some operators advocate that such an opening be left in the majority of cases of radical operation for the relief of chronic suppurative otitis media, in order that all parts of the middle ear may be freely open to inspection. As the radical operation is now performed, however, most surgeons prefer to close the posterior wound completely, and to secure all subsequent drainage through a sufficiently patent external meatus. It also occasionally happens that a permanent opening remains behind the ear in cases operated on for acute mastoiditis. This occurs only in those cases where the destruction of bone has been very extensive, and usually where, after the operation, large sequestra have been exfoliated. When these openings occur, either by accident or design, the surgeon is frequently called on at a subsequent period to operate for the relief of the deformity.

Quite a number of cases of this character have presented themselves to me for operation. As no two cases exactly resemble each other, it is almost impossible to lay down any definite line of procedure which is applicable to every case.

The simplest procedure is that of Trautmann, who advises circumscribing the entire fistula by means of an incision through the soft parts. The integument is then dissected up along this circular line of incision on all sides, so as to form two semicircular flaps which are folded inward into the opening. The raw edges of these flaps come together, the cutaneous surfaces of the flaps meeting in the external auditory canal. The raw edges of the flaps are united by means of fine catgut sutures. Occasionally silk sutures are used, and in this event they are introduced so that the knots will lie in the lumen of the meatus. This procedure closes the opening, and the next step is to undermine the skin for a considerable distance, starting from the margins of the circular incision. The skin being undermined in every direction, this circular incision is completely closed by means of sutures, and is thus converted into a linear wound. The posterior opening is thus entirely obliterated.

This procedure answers very well for openings of small size. For the larger openings, however, the Mosevig-Moerhof operation is the one ordinarily chosen. In this operation the margins of the opening are freshened, and the anterior and posterior margins of the wound split into two flaps, the lower or interior flap having its cutaneous surface directed inward toward the meatus, while the outer or external flap has its cutaneous surface presenting outward. A tongue-shaped flap is then dissected up from the skin of the neck, sufficient in size to completely fill the posterior opening. This flap is dissected from below upward, its pedicle representing the lower margin of the opening it is desired to close. This tongue of skin is then folded upward

* Read at the Fifth-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Maknen, George L. Richards and John F. Barnhill.

on itself and secured to the internal flap made by splitting the margins of the opening, by means of fine catgut sutures. The skin is then extensively undermined along the lines of incision made in cutting the tongue-shaped flap, and also along the lines of the original opening, the anterior and posterior margins of which were split. This undermining of the skin enables the surgeon to completely cover and bury the tongue-shaped flap which is fitted into the posterior opening, and to convert the entire wound into a linear wound, easily closed by interrupted sutures. Both these procedures are simple enough in a typical case. Unfortunately, these cases are, as before stated, atypical.

In a case that came under my observation a large permanent opening had been left after a radical operation had been performed. The result of this operation had not been entirely satisfactory, as there was still some offensive discharge from the middle ear. I was called on to relieve the suppuration which still remained in the tympanic cavity, and also to close the posterior opening so as to remove the unsightly deformity. The case was operated on twice, the first operation having for its purpose the relief of the suppuration. I simply repeated the radical operation already performed, removing what carious bone remained, and lining the entire tympanic cavity by means of skin grafts.

Ten days after this operation I closed the fistula in the following manner: The external auditory meatus had been much contracted as the result of the first radical operation. This was, therefore, enlarged in the usual manner, by cutting a large, tongue-shaped flap from the concha, dissecting out the cartilage, turning the tongue of integument secured from the concha upward and backward into the posterior opening, and securing it in place by sutures. An incision was then made from the upper margin of the posterior opening, just behind the line of auricular attachment. This incision extended down to the periosteum, but not through it. The integument was then dissected up from the underlying soft tissues, forward over the posterior surface of the auricle and backward over the skull for a considerable distance, throughout the entire extent of the opening which it was desired to close. The margins of this opening were then pared so as to present a raw surface. From the lower border of the original postaural fistula two slightly divergent incisions were made down the neck, mapping out a tongue-shaped flap of sufficient size to be folded upward, and to completely fill the opening behind the ear. The pedicle of this flap was placed at the lower margin of the opening which it was to close; the flap was turned upward into the wound, and held in position by catgut sutures. Anteriorly, this flap was attached to the tegumentary tongue, which had been turned backward into the wound from the concha. Posteriorly, the flap was attached to the periosteum which had been dissected up from the superficial portion of the bony cavity of the mastoid. After this flap had been secured in position, the margins of the wound in the neck, left after dissecting up the tongue-shaped flap, were undermined, both anteriorly and posteriorly. It was then found possible to draw the soft structures together so as to completely close the wound, and to bury the tongue-shaped flap which had been inserted into the opening behind the ear. The raw surface of this flap, therefore, lay in contact with the raw surface made by drawing the tegumentary edges of the wound together, while the cutaneous surface of the tongue-shaped flap formed a portion of the lining of the external audi-

tory meatus. The wound healed throughout by first intention, and the result was perfect.

In a second case, in which a radical operation had been done, together with excision of the internal jugular vein and exploration of the cerebellum, I was able to close the large opening without taking the tongue-shaped flap from the neck. This case presented many difficulties, as the original wound had healed by granulation, and over the region where the cerebellum had been exposed, the resulting cicatricial tissue was very thin. The external auditory meatus was first enlarged by a plastic operation, performed in the usual way, a tongue-shaped flap being cut from the auricle, the cartilage being dissected out and the flap turned upward and backward so as to enlarge the meatus. An incision was then made upward from the upper margin of the opening which I desired to close, for a distance of about an inch in the line of auricular attachment. A similar incision was made in the line of auricular attachment downward from the lower margin of this opening. The anterior margin of the opening was then freshened by means of scalpel and scissors, and the integument dissected up from the posterior surface of the auricle. This undermining of the integument was also continued anteriorly throughout the extent of the two incisions first described. An incision was now made about the posterior margin of the opening. Great care was necessary in making this incision in order to avoid opening the dura. The dura was avoided by making the incision well inside of the opening, so that the knife came in contact with the bony wall. By means of a periosteum elevator and with the scalpel, the soft structures surrounding this opening posteriorly were dissected up. Of course, they could not be undermined for any distance backward for fear of opening the dura. By careful dissection, however, I was able to get a short flap of cicatricial tissue. The anterior flap had been so thoroughly undermined that it could be sutured to this short posterior flap without any tension, thus closing completely the posterior opening. The result, in this case, was excellent; the wound healed perfectly by primary union, and there is now scarcely any scar.

It is worth while to remember, in speaking of these plastic operations, that when the skin covering the posterior surface of the auricle is undermined, it can be pulled backward for a considerable distance. I have been surprised, in all of these cases, at the amount of skin that could be obtained from the posterior surface of the auricle. In this last case, no one who saw the operation believed that primary union would occur on account of the cicatricial character of the tissue of the posterior flap; there was not even a stitch abscess, however.

In another case a large permanent opening was left after an ordinary mastoid operation. The greater portion of the posterior wall of the external auditory meatus had been removed at the time of operation, and the drum membrane could be seen in position through the large posterior opening. In this case I simply circumscribed the opening by an incision through the soft parts. With a small periosteum elevator, the lining of the bony cavity was carefully dissected up, above, behind and below. The tissue was very thin, but fairly well nourished. This lining of the bony cavity was then gently lifted out, carried forward and attached to the freshened margins of the meatus. The skin of the posterior surface of the auricle was undermined and the skin adjacent to the posterior margin of the wound

was treated in the same way. The wound was then completely closed by sutures. The result in this case was entirely satisfactory, the wound healing by first intention throughout.

In still another instance a small fistula remained behind the ear after a radical operation, and suppuration from the tympanum had not been entirely relieved by the previous procedure. The discharge seemed to come from a small spot in the region of the eustachian tube where cicatrization had been imperfect. In this case, prior to closing the posterior opening, I curetted out the deepest part of the tympanic cavity through the enlarged external auditory meatus, but found very little softened bone. I therefore inserted a skin graft over the area which had been denuded by the sharp spoon, and held it in place by cotton pledgets. The posterior opening was then closed by undermining the skin in front and behind the fistula after the edges of this had been thoroughly freshened. The wound behind the ear was closed by mattress sutures, so as to bring large raw surfaces in contact. The healing was by first intention, and the discharge from the ear absolutely cured.

I would also call attention to the fact that in cases of a large permanent posterior opening, following either the radical or the mastoid operation, the normal entrance to the meatus usually becomes very much contracted. In one case recently seen, the fibrous canal was absolutely obliterated by cicatricial tissue. In these cases it is necessary to enlarge the meatus considerably by means of a plastic operation—the one which I prefer being that usually employed in the performance of the radical operation—that is, the cutting of a tongue-shaped flap from the concha, dissecting out the cartilage and turning the tegumentary conchal flap upward and backward on itself, so as to secure a very patent meatal orifice. Where the formation of this flap leaves a raw conchal margin of any extent, healing is much facilitated and subsequent contraction of the meatus hindered by covering the cut margin with a Thiersch graft. Even where a very large meatus has been formed at the time of operation, the subsequent cicatricial contraction will narrow this considerably. It is always well, therefore, to make the meatus very patent at first, in order to allow for this subsequent contraction.

CONCLUSIONS.

It is always difficult to describe a plastic operation, and I am afraid that the descriptions in the above cases have not been very clear. Cases which apply for relief of such conditions as those above described are frequently met with in a large operative practice, and I have reported the cases in detail because for some time I was rather skeptical as to the advisability of attempting to close these openings, and was uncertain as to what the results would be. The outcome, however, in these cases has been so satisfactory that I think the surgeon should always urge operative interference for the relief of these deformities, as the results obtained seem almost invariably to be satisfactory. In only two instances, one of which is reported above, have I been obliged to use the tongue-shaped flap from the neck. In all the other cases the opening behind the ear was satisfactorily closed by dissecting up the skin from the posterior surface of the auricle. As the operation is much simpler where the tongue-shaped flap is not used, and can be performed much more rapidly, this procedure should always be preferred to the more extensive one.

DISCUSSION

ON PAPERS OF DRs. RANDALL AND DENCH.

DR. NORVAL H. PIERCE, Chicago—We must always remember that, no matter what general treatment we pursue, the object aimed at is the evacuation of the toxic foci about the ear. It is true that in cases which we see almost constantly there is great difficulty in differentiating between toxemia, septicemia and pyemia. If we were able to differentiate between septicemia and pyemia in aural disease it would be of great aid to us in operation, because in the majority of instances pyemia is the accompaniment of thrombosis of the larger blood vessels. There is not very much doubt that pyemia can occur from thrombosis of the veins within the mastoid process itself. There is postmortem evidence of this fact, and it is in these cases that we can do most in external medication, and it occurs mostly in children whose bones are highly vascular. I am sure Dr. Randall would never advise in any case where there is fever and other accompaniments of pyemia, to rest entirely on external medication; it is at the beginning of this process that you have the best chance. As to lumbar puncture, if Dr. Randall meant to say that his canula remains in the spinal canal for an hour, the spinal fluid must run very slowly in Philadelphia. It does very little good in septic meningitis, but is followed by brilliant results in serous meningitis, but that is not a septic condition *per se*. Whenever we get pus in the spinal fluid by puncture, it is a strong contraindication to operation. When mercurials help, it is not because of relief of the local symptoms, but because the intestinal canal is relieved of its toxic contents. Antistreptococcal serum in my hands has invariably been followed by disappointment. I have never seen a case followed by good results in any way. In the winter of 1902 I subjected ten cases of mastoid inflammation in the very first stage to high saline injections. This was retained and the method given a thorough test. All these came to operation except one. Pus was found on operation, and this method abandoned. Dr. Dench has been very fortunate in having his patients recover so nicely. I have had cases where I found postauricular openings a year afterward. It is a question which cases should be closed and which should not.

DR. S. MACCUEEN SMITH, Philadelphia—Our idea in the early operation is to prevent septicemia, which is more important than treatment by any method. Last December I presented a paper before the Aural Section of the Academy of Medicine of New York City, in which I reported two cases of metastatic abscess of the liver following suppurative disease of the middle ear. In these cases the Austrisch serum was of no use at all. I believe that those of us in the past who have waited for the external classical symptoms before operation were justified; but in recent years, since the advent of epidemics of gripe, those who wait for the classical symptoms before opening the mastoid will lose many of their patients. When acute otitis media continues for some days with a discharge, and especially if there is swelling over the posterior and superior wall, and these symptoms do not rapidly improve, the only rational procedure is the mastoid operation. In more than sixty cases operated on in a period of about thirty days, in not one was the diagnosis wrong. Some of the cases with the least symptoms showed the greatest amount of decay of the mastoid.

DR. W. SOHIER BRYANT, New York City—I think lumbar puncture is used altogether too seldom in these cases.

DR. D. MCAULIFFE, New York City—This class of cases was alluded to some years ago by Koenig, and his views were disputed by Jansen. They are too rarely looked for where a thrombosis is not suspected. In the last few months I have had two cases of this type of pyemia. One had symptoms of meningitis at the first visit and was put on the table pulseless; I punctured the cerebrum and cerebellum, but found no pus. I saw nothing to indicate meningitis, but found fluid in the lateral sinus and the jugular collapsed. This was practically a moribund collapse, but that was the only thing to prove a jugular bulb thrombosis. The patient died. Another case developed temperature and showed symptoms of sinus thrombosis,

but exploration gave no evidence. This patient also developed pyemia and died. In these cases I think the infection was carried to the jugular bulb.

DR. H. O. REIK, Baltimore—When we more commonly employ the proper measures for carefully studying the pathologic condition of the blood we shall probably classify these cases better and succeed in reducing the mortality. Careful and frequent blood counts and bacteriologic investigations will help us very materially. I am very sorry to hear the antistreptococcal serum so strongly condemned, and that without a word of reservation. I remember that Dr. Welch of the Johns Hopkins University, in the early days of these serums, called attention to the fact that we used the word streptococcus too broadly, and that it really covered not one but a variety of organisms. The serum from any one of these streptococci may counteract the effect of that organism, but not the effect of other streptococci, and so, if we can succeed in distinctly classifying the varieties of this organism, we may hope that in the future we may secure an antitoxin for each, if not one of a general form. In the line of treatment, and as having some bearing on the question of hypodermoclysis, I wish to mention briefly some work which has been recently done in Baltimore. A furor was created a year or two ago by the reports of the employment of formalin intravenously in septicemia, and know that the further use of it was not very encouraging. Dr. Joseph Hume of Baltimore was at that time experimenting in the same line with nitrate of silver. His first case was one of general septicemia following an operation for appendicitis, and after the case had been abandoned as hopeless he succeeded in saving the patient's life by the intravenous injections of silver nitrate, using it, I believe, in the strength of 1/5,000 and injecting from 300 to 700 c.c. at a time. His work has not yet been published, but I know of a number of cases in which he has used it with excellent results. This is still in the experimental stage, and its dangers are fully recognized, but his work is very encouraging.

DR. G. L. RICHARDS, Fall River, Mass.—We sometimes get a little too radical. Now and then we may possibly reinfect a case and intensify the danger of a fatal result. A certain degree of surgical conservatism may be proper at times. I do not think Dr. McAllister's first case was helped by the very extensive operation he did.

DR. J. A. STUCKY, Lexington, Ky.—In what class of cases are we justified in doing exploration? I would like to emphasize the importance of early operation in doubtful cases.

DR. G. HUDSON MAKUN, Philadelphia—I would like to report a case of deformity in which there had been no mastoid operation, a deformity of the external auditory canal. The posterior walls of both canals and the auricles have fallen downward and forward so that, instead of canals, there are only slight slits on either side. The deafness, I think, was due in part to this collapse of the walls. During conversation the man takes hold of the auricle and pulls it upward and outward, and thus increases his hearing powers. Has any operation been devised for the relief of this condition? The man is 45 years old.

DR. E. B. DENCH, New York City—We all meet cases of otitic pyemia, and any contribution from a man like Dr. Randall is of great value. There seems to be one point to which the discussion leads: Let us not have aural suppuration to treat, but let us eliminate it. More and more do I find my views becoming radical in this direction. An ear which is the seat of chronic suppuration is as dangerous as an appendix which is the subject of recurrent attacks. Unless there is some contra-indication, I would advise that all chronic suppurating ears be treated by radical operation to prevent later septic developments, which may be insidious, as in the case reported. I think most of you will bear me out in the statement that, with an acute inflammation of the middle ear, when seen early, we seldom get systemic infection. What we must do in order to cut these cases out is to treat cases of chronic suppuration by radical operation during the interval period. I have never used saline injections, but for a short period they may be of value in stimulating the heart and flushing the kidneys. The dorsal cavity should be washed out, just as the peritoneal cavity is

washed out. But no method of that kind will enable us to treat septic meningitis. I do not regard lumbar puncture as of any value in purulent meningitis.

DR. J. HOLLNER, Chicago—Accurate indications are most important for surgical procedures. The tendency in otology at present is to operate too much. In operating we destroy the cellular structure of the mastoid process, and whether that has no influence on the hearing is a question about which I want to see some carefully prepared statistics extending over many years before I consider it settled. Four patients were in my care a short time ago on whom immediate operation was urged by well-known colleagues, yet every one was cured by from three to ten treatments without operation. As to the question whether or not to close the retro-auricular opening in radical operations, I have one experience which teaches me that we can not make rules which apply to all cases. A boy had to be operated on a second time because in one cell which was too far back to be reached from the meatus, cholesteatomatous material had gathered; had there been a retro-auricular opening this would not have occurred.

DR. R. C. MYLES, New York City—The percentage of cases in which operation is indicated has not been determined, and it is generally admitted that in every ten cases nine did not require operation, but the tenth needed it so badly that it was better to operate on the other nine rather than to have missed the tenth. In any given case operation may be refused, brain abscess results and the patient dies. On the other hand, it must be admitted that many of the cases operated on will end fatally. Accidents must, therefore, always be taken into consideration. These are the two sides of the question, and what we now desire is the statistics of the cases in which operation is indicated—what percentage come to operation and what proportion get well without it.

DR. A. B. RANDALL—I would warn the gentlemen listening to the results obtained by a skillful operator that they must not expect to obtain equal results often. A man sometimes does his work too well, if he makes success seem too easy. The matter of closing these posterior wounds is of the utmost difficulty and extreme care must be used. I am sorry that the cerebrospinal fluid moves so slowly in Philadelphia, but where I have used lumbar puncture in serous meningitis I have continued it so long as I could get drippings of the fluid. Just as in brain abscess, it makes a difference if we spend even an hour in evacuating the fluid from the cranium. This little irrigating spatula is used in that class of cases needing heroic help, where there is pus in the fluid when drawn by lumbar puncture. The only thing, then, to be done is free irrigation by opening the cranial cavity and the dura and thus giving them the only chance they have for life. As to the lungs, I did not think it was necessary to say to this Section that they must retain their medical perceptions and training. Dr. William F. Norris, in the days of my training, used to make us look at the medical aspect of every case when we were studying eyes. I constantly have cases referred to me for operation where with suppuration of the ear, symptoms point to deeper trouble. Recently a child brought after the mastoid trouble had healed, with mild meningitic symptoms, following a reduction of his renewed suppuration, showed only a manifest pneumonia of one lung, with empyema following. As the genuine Credé salve sometimes has a heavy coat of mold on it when imported, I have hesitated to use it. To those of you who are acquainted with my hospital work when I send a patient in and ask that he be ready for operation in thirty minutes, the expectation that I wait long for an operation will seem rather surprising. I pass in Philadelphia as rather a bloodthirsty man, not being very hard on the trigger as to operation when I see the necessity for it, or think there is greater danger in waiting than in going ahead. Where the patient is well studied as to blood count, condition of the lungs and every medical aspect, with evidence of a toxic condition, intestinal perhaps, yet not clear, we must do something to relieve while awaiting developments as to what and where any intervention is to be done. It is under such circumstances that I urge the value of saline injections and at times lumbar puncture.

DR. E. B. DENCH—Replying to Dr. Makuen's question, I do not know that any operation has been devised for correcting a sinking posterior wall, but such an operation would seem very easy. Operation on a drooping ear has frequently been done, and a modification of that could be devised that would lead to a patulous canal, and I would advise it. It would not injure the drum membrane. In the matter of closing these posterior openings, I always have the external canal sufficiently open so that I can inspect the entire interior, and the patient is in no danger whatever from absorption of the products.

THE PALLIATIVE TREATMENT OF ACUTE MASTOIDITIS AND ITS LIMITATIONS.*

PHILIP HAMMOND, M.D.

Assistant in Otolaryngology, Harvard University; Assistant Aural Surgeon, Massachusetts Charitable Eye and Ear Infirmary.
BOSTON.

The appropriate treatment for the inflamed mastoid is a vexed question, occupying much the same position with reference to otology at the present time that the treatment of the inflamed appendix held in abdominal surgery a few years ago.

Aurists differ but little as to the treatment of the acute abscess formation in the middle ear, but when it becomes apparent that the mastoid process is involved the greatest diversity of opinion exists as to the method of procedure which shall be employed.

A few years ago conservatism in the treatment of mastoiditis was absolute, and the operation of perforating the cortex rare. During the past decade great changes have taken place in our attitude toward this disease, until to-day the tendency is almost toward the opposite extreme.

I am well aware that much has been written of recent years on the subject of treatment of acute mastoiditis versus operation, still the presentation of actual results must always be of value.

The present paper embodies conclusions obtained from a study of 50 consecutive cases taken from hospital record during a period extending over six months, and sufficiently remote to insure against the possibility of subsequent relapse and operation on the cases reported as cured by treatment.

Although these cases were taken in order of sequence, none was considered where the conditions were such that immediate operation was performed, nor, on the other hand, were there any simple acute inflammations of the middle ear without mastoid complication, as all were admitted to the hospital with the distinct diagnosis of acute mastoiditis.

Immediately on entering the hospital free incision of the drum was made in all cases where there was not already a sufficiently good opening. This was usually carried out under the influence of a general anesthetic, nitrous oxid gas being preferred. Rest in bed for the first day or so, the continuous use of the Leiter coil, cleansing of the auditory canal and attention to the alimentary tract comprised the treatment following the paracentesis.

Of the cases subjected to this treatment, 30 resulted in recovery with disappearance of mastoid symptoms; 17 came to operation during the stay in the hospital, and 3 patients who were discharged apparently relieved subsequently returned for operation.

Inquiry showed that three cases had had previous at-

tacks of acute suppuration; the aural history in the other cases was negative. The duration of the acute inflammation previous to admission to the hospital varied from one day to one month, the average length of time being about six days. All but six of the cases had discharge from the ear on entering, either from spontaneous perforation or following paracentesis. Three of the six patients with intact drums came to mastoid operation.

Mastoid tenderness in some degree was present in all but three of the cases. Some were very tender throughout the whole mastoid, while some exhibited simply localized tenderness on very firm pressure over the antrum or tip of the process. Swelling and edema of the canal wall was noticed in 19 of the 50 cases, and was followed by operation in 10.

The average length of time the continuous cold coil was worn was slightly over forty-eight hours, the shortest period being twelve hours and the longest seventy-two hours.

The chief factors taken into account in deciding to operate were a continuance of purulent discharge from the ear, with tenderness or swelling, or both, of the mastoid tissues, lasting for some days in spite of the treatment.

In several of the cases where there was persistent tenderness of the mastoid the appearance of a slight swelling in the canal was the signal for operation, and in one case there was apparently a slight beginning facial paralysis at the time of intervention.

Acute purulent infection of the bone was found in all the cases on which operation was performed, accompanied by granulation formation, and generally by softening of the bone. In four cases there was absorption of the inner table of the skull, with the purulent contents of the mastoid lying in contact with the lateral sinus, and in one there was an extradural abscess.

CASES WITHOUT MASTOID TENDERNES.

It is interesting to note that of the three cases without mastoid tenderness two came to operation. One had had several attacks of earache with apparent recovery during the preceding three months. The drum was intact, red and bulging; there was no swelling of the canal, or over the mastoid, but there was intense pain. Paracentesis was followed by a week of relief, but at the end of that time there was a return of the pain, with swelling over the mastoid. Operation showed diseased bone, with extradural abscess from streptococcus infection. The other had an acute earache of only five days' duration. After nine days in the hospital the symptoms subsided and the patient went home. Three weeks later he returned with profuse discharge from the ear and slight edema over the mastoid. Operation showed extensive destruction of the cortex, large pneumatic cells filled with pus and granulations, and pus lying free on the surface of the lateral sinus.

The comparatively large number of recoveries (60 per cent.) following the treatment is also interesting. As contributing causes to this we must reckon, first, on the admission to the hospital at the earliest possible moment after establishing the diagnosis, although there were many cases which applied for relief after the disease was well established; in the second place, to the free tympanic drainage insisted on in all cases.

DRAINAGE THROUGH THE DRUM MEMBRANE.

Spontaneous perforation of the drum rarely furnishes an adequate opening for drainage, and often leads to a false sense of security, for many times examination shows that the discharge comes from a bulla which has

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

ruptured, leaving the membranum tympani intact. This objection of insufficient opening also applies often to the small punctured wounds of the drum. The operation of incising the drum, although slight, is very painful, and unless performed under the influence of an anesthetic is necessarily hurried and more or less incomplete.

The method of providing for the escape of secretion from the ear following the evacuation of the tympanic cavity also merits attention. When the drum is opened early the discharge is largely serous and readily drains through an aseptic wick, which not only serves to perform this function, but also acts as a safeguard against the introduction of infective material through the external canal. It is only when the discharge becomes so thick that it will not readily pass through such a wick that syringing should be employed.

There is a noticeable absence of fatality in these cases, notwithstanding that five had penetration of pus to the surface of the dura. In none of these latter cases was there any particular elevation of temperature, nor did any of them have chills. The only indication of the seriousness of the process was the existence of unquestioned mastoid disease, continuing for days without improvement.

The presence of edema of the posterior canal wall is one of the best guides to the condition of affairs within the bone, even in the absence of mastoid tenderness. Patients who are apparently convalescing from an acute inflammation of the middle ear should be closely observed for the appearance of this sign. It is the one symptom which is in no way masked by the use of the ice coil, and as such is of the utmost importance.

THE USE OF THE LEITER COIL AND ICE-BAG.

Coming to the use of the coil, it would seem that we have in it an appliance of the greatest value in conjunction with other forms of treatment. In default of the coil, the ice-bag devised by Dr. Sprague has given good results, and is often better adapted to use in private practice.

Considerable difference of opinion exists as to the length of time during which cold applications may be made to the mastoid, and apparently no rule can be formulated that will fit all cases. The local tenderness of the bone may disappear within a few hours under the cold treatment, or it may exist for days, gradually diminishing. Persistence of mastoid tenderness, with a serous or mucous discharge from the canal, does not necessarily call for interference, as under such circumstances an expectant policy may be pursued with safety. With steady decrease in the amount of tenderness, and no swelling of the canal or severe pain, we may place reliance in the use of the coil for a period even longer than the maximum reported in these cases. The patient should be under competent supervision, however, so that the slightest change in the physical conditions may be detected immediately.

USE OF LEECHES.

One method of treatment formerly much in vogue consisted in the use of leeches, and without doubt they are of value in properly selected cases. With marked tenderness of the mastoid due to intense congestion of the bone, and where the inflammation has not yet advanced to the stage of pus formation, three or more leeches applied to the surface of the mastoid may afford almost immediate relief. Objections to their use are the uncleanliness of the method and the masking of the tenderness, as the leech bites may be sensitive for some days.

THE BEST TIME FOR SURGICAL INTERVENTION.

The question of the most appropriate time for surgical intervention is one in which experience must play a large part. Undoubtedly many of the cases which eventually recover when left to themselves contain pus, but this by no means should establish a precedent for allowing cases to go on without operation. Where tenderness of the mastoid exists for days, even in slight degree, with abundant purulent discharge from the ear, or where after once subsiding, the tenderness returns, operation is undoubtedly expedient, even if not absolutely necessary.

Under no circumstances should attempts at prevention of operation be continued where edema has already appeared in the region of the mastoid, as with this condition the amount of damage inside the bone may be merely conjectured, and surgical interference becomes imperative.

DISCUSSION.

DR. R. W. SEISS, Philadelphia—I think we often lose sight of a very important fact in mastoid disease. Every pathologist of note will agree that every case of sharply acute purulent middle ear disease is a case of mastoid disease. We know that most of them get well without difficulty under a little treatment. Out of 600 cases I have had 35 operations, and there were but 5 deaths. Two of those I operated on died; another was transferred to a colleague and died; two others were transferred to general surgeons. None of the patients not operated on died. I doubt very much if quite as many mastoid cases did not get well a century ago as recover under advanced modern surgery.

DR. E. B. DENCH, New York City—My house surgeon found out by investigations two years ago that about 90 per cent. of cases of staphylococcus infection got well without operation. I am sorry to register myself as a radical man, but I am more and more inclined to operate early in mastoid disease than I was in the early days. I believe suspicious cases do better if operated on. I have given up the use of ice, and do not think I shall use it again, for I have seen a number of cases in which the superficial tenderness improved and subsequently the cases came to operation, and I found very extensive involvement, such as extradural abscess, brain abscess, etc. It seems to me it is dangerous, because it masks the symptoms. I fully agree as to the importance of the symptom of the sinking of the canal wall; also that tenderness is misleading in many cases. It depends on the temperament of the patient. What does Dr. Hammond mean when he says the wick drain guards against infection of the secretion from without? It seems to me it would favor this.

DR. KASPAR PISCHEL, San Francisco—I am delighted to hear a man of Dr. Dench's experience speak against the ice-coil. Hot applications relieve the patient just as much without masking the symptoms. Besides, heat will help absorption if that is still possible, or hasten outward perforation if the mastoiditis is advanced beyond the possibility of absorption.

DR. G. L. RICHARDS, Fall River, Mass.—In the last two or three years the class of preparations consisting mainly of glycerin and clay have come up, and, if you take many of these mastoid cases and put on a thick covering of such a preparation and cover it with absorbent cotton, it will take up and remove a lot of the serum and it does not mask the symptoms. It will not take away the continuous pain, so it has advantages over the ice-coil. You can put one of these applications on in any family or tenement and leave it on for from twelve to twenty-four hours. Its use should be accompanied by a free incision of the drum membrane. I have had good results from their use, especially in the first stages. With reference to Dr. Dench's question about the wick, at the New Orleans session last year a paper was read on this subject. The wick is put in at the moment of the incision of the drum and maintained there until it shows signs of being purulent. It prevents the germs from entering because on the outside is a pledget of absorbent cotton, which is removed as often as it becomes moist.

DR. S. H. LARGE, Cleveland, Ohio.—I recently used the ice-coil on a patient with mastoiditis, accompanied by considerable pain. After twenty-four hours the pain had entirely disappeared, even pain on pressure, but forty-eight hours later he developed cerebral symptoms. The mastoid cells and antrum were opened and pus was found in large quantities. In this case the ice-bag certainly masked the symptoms and came near causing a fatal result to the patient.

DR. C. H. BAKER, Bay City, Mich.—Dr. Seiss mentioned one important point, namely, the fact that the mastoid is involved in every case of middle ear inflammation with extensive discharge; therefore, I think the statistics of recovery hinge not only on cases classed as mastoid but on cases of middle ear inflammation as well. The percentage of five deaths in 600 cases would be perhaps nearer the truth than five in thirty-five. The difficulty which most often prevents success consists in getting the patients and their families to consent to what we think is the right thing to be done. We can not always control them and are not allowed to do what we know is the proper thing, and must, therefore, resort to the measure which is next best. I have adopted hot irrigations in great quantities where I can not operate when I think the patient needs it. That means not the use of water a little warm, but water as hot as the skin will bear it and from two to four gallons of it. This is repeated every hour or two and has prevented a number of cases from coming to operation.

DR. S. F. SNOW, Syracuse, N. Y.—The limitations in acute mastoiditis are not always well marked, for in uncomplicated cases we can often give considerable latitude. We must be limited in conservatism when handling subacute or chronic cases because we can not then depend on free intercommunication from cell to cell. A point to be insisted on is free tympanic drainage if we are to rely on conservative methods. Free tympanic drainage is, to my mind, an all-important matter. I never feel safe in applying cold unless the drainage is free. I think the incision should begin at the bottom of the drum and go upward, cutting through to the bone, as the knife comes out along the superior wall of the external canal.

DR. D. McAULIFFE, New York City.—I think the retrogression of symptoms in mastoid disease depends largely on the stenosis. If it extends long enough to allow the septic process to penetrate the cells the case is one for operation. The application of ice is known to diminish the temperature of bone at least five degrees. If maintained longer than twenty-four hours it diminishes tissue resistance. Where the condition began as catarrhal mastoiditis, the application of ice would have an important influence. We can not draw the line sharply between catarrhal and infected mastoiditis, and time is necessary for the development of bacterial infection.

DR. PHILIP HAMMOND—I do not wish to appear as the champion of conservatism, and fully agree that the palliative treatment of acute mastoiditis is of no value where the disease has penetrated to the stellate cells of the mastoid. It seemed to me it would be of importance to tabulate a group of cases which were not selected, and I chose hospital cases for that purpose. Just how many cases were operated on during the time these cases were accumulating I do not know. More than 300 mastoid operations were done within three months' time. I believe that in many acute cases the patients die, though possibly I may be wrong in saying "many." I saw one within the past few months with acute suppuration of the middle ear of ten days' duration, with no mastoid tenderness, but with swelling of the canal and great pain, and just before I was called he passed into coma. In this case the cortex of the mastoid was tremendously thickened, and the only symptoms pointing to mastoid disease were the intense pain, and the edema of the canal. It seems to me this swelling of the canal wall should be recognized as early as possible and early operation advised. At the present time we are not taking cultures in all cases, but four or five years ago records were made of all acute cases, and the results bore out Dr. Dench's statement. Dr. Richards has ably answered the question as to the dangers and advantages of the wick in drainage. The results achieved at the infirmary are confirmatory of the value

of this method. Some cases treated in this way healed without going on to suppuration. We use carbolyzed glycerin in the treatment of various affections of the external canal, but never to put in the wick for drainage purposes.

A CASE OF BILATERAL TUBERCULOSIS OF THE MIDDLE EAR IN AN INFANT.*

DUNBAR ROY, M.D.

Clinical Professor of Eye, Ear, Nose and Throat Diseases in the Atlanta College of Physicians and Surgeons.

ATLANTA, GA.

Whether the case here reported is one of primary or secondary tuberculosis of the middle ear must be left as an open question, just as it has been done in the few cases of this nature previously reported. In studying the history of this case, however, I feel just as warranted in calling it one of primary as I would one of secondary tuberculosis, chiefly on account of the age of the patient and the early manifestation of the middle ear trouble before any other physical signs of involvement.

The statement of Friedrich contains a great deal of truth when he says: "It is difficult, if not impossible, from the clinical point of view, to decide whether one has to deal with primary tuberculosis of the bone with secondary involvement of the tympanic cavity, or with the opposite condition."

Patient.—Baby C., 6 months old, was brought to me from a nearby town on Nov. 15, 1903, suffering with a discharge from both ears. The parents appeared healthy, this being their first child.

Family History.—The father's side gave an excellent family history, while that of the mother showed a tuberculous line of antecedents. A brother and sister had died of pulmonary tuberculosis, and a brother was at present afflicted with the same malady.

Present Illness.—The birth of the child was normal, and there was no trouble manifested until six weeks previously, when the left ear began to discharge. This was treated by the family physician without any result, and two weeks ago the right ear began to discharge. The little patient had also had considerable cough and apparently breathed through the nose with difficulty. There was absolutely no history of syphilis.

Examination.—Left ear: There is absolutely no swelling over the mastoid or around the ear. Considerable purulent discharge from the auditory meatus, and very offensive in odor. This was thoroughly cleansed away, when two-thirds of the canal was seen filled with granulation tissue, which bled freely if touched with any force. No necrosed bone could be felt, although there was every evidence of its existence. The canal was at no point swollen.

Right ear: Discharge slight but purulent. Very little odor. The same granulation tissue was encountered, but less in amount. No necrosis discoverable. The baby was exceedingly fretful.

The nasopharynx was explored with the finger, but very little adenoid tissue was found. No abnormality in the nasal cavities could be seen to account for the difficulty in breathing. There was slight signs of a facial paralysis on the left side. Temperature was normal. The baby nursed without difficulty, but slept only at intervals. While the patient was in my office some of the deep secretions and granulation tissue were taken by Dr. Claude Smith, pathologist, and the examination showed a large number of tubercle bacilli. An examination of the chest disclosed numerous râles indicative of a bronchitis.

Treatment and Result.—The treatment at the beginning was expectant and tentative. The canals were kept cleansed, and

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. H. Henson Maknen, George L. Richards and John F. Barnhill.

with the nasal punch forceps as much of the granulation tissue as possible was removed each day, followed with applications of guaiacol in alcohol. Syrup of the iodid of iron was administered internally, and the chest rubbed nightly with terebene in olive oil. Two days after the beginning of the treatment the patient seemed to rest easier at night and was less fretful. The discharge, however, did not cease, and the granulations seemed to sprout daily. On November 20, five days after the beginning of the treatment, the patient appeared brighter than usual and the facial paresis less marked. The next day, the weather being bad, the father reported that the baby appeared drowsy and that the eyes had a peculiar look.

On the following day, November 22, in consultation with two other physicians, the following condition was noted: No change in the objective appearances of the ears. The baby appeared drowsy and took absolutely no notice of anything around. Both eyes were turned in, and the pupils were contracted. No difficulty with the respiration, and the baby nursed from the mother as usual. The temperature was rather subnormal. There were no signs of a spasm. A radical operation was discussed, but considered inadvisable on account of the lack of any focal lesion, and the fact of an evident tubercular bronchitis. The baby gradually grew weaker and died four days later. The temperature never went above 101 F., and there were two spasms during the last hours, but limited to no portion of the body. Unfortunately, a postmortem could not be obtained.

This case presents many interesting features. The age of the patient and the bilateral involvement of the ears with the same clinical features was certainly a remarkable condition. Repeated examinations showed unmistakably the tuberculous nature of the process, and I do not think that we could differentiate the primary source of infection. To me the line of treatment most proper to pursue afforded the chief point of interest. I considered from the very beginning the question of a radical operation through the mastoid. On the other hand, this latter had never shown the slightest signs of involvement, which in infants is very easy of occurrence because of the anatomic structures. The operation was discussed with the parents, but they were unwilling to submit the baby to the same unless I could assure them of its success. They clung to the idea that it was only a discharge from the ear and would get well of itself. Such a promise as that I, of course, could not make, so adopted the next best plan, and that was to clean out the tympanic cavity as best I could through the auditory canal. This proved a failure, just as I had anticipated, and it only proved to me the futility of any such an operative procedure. Nor did I think that much could be accomplished by a radical operation, for the patient was evidently marked with disseminated tuberculosis.

I have been unable to find just such a similar case on record, and for this reason I feel that the detailed description of the above case is not without interest.

Quite a little has been written on tuberculosis of the middle ear, but nearly all of this has been confined to cases of adults who were at the time suffering most usually with the pulmonary form. Such patients, suffering with suppuration of the middle ear, would naturally be suspected of having a localized tubercular process of this organ. However, there is a marked lack of unanimity among otologists as to the frequency of this condition, due largely to the uncertainty of their methods of diagnosis.

One naturally supposes that a tubercular condition would be diagnosed by the presence of tubercle bacilli in the secretions or in the surrounding tissues, yet we find close observers like Bezold and Hegetschweiler who "depend on the macroscopic appearances of the clinical picture and neglect bacteriologic examinations."

It is a well-known fact that to find tubercle bacilli in a discharge from the middle ear it is always best to take some of the granulation tissue deep in from the focus of suppuration, and for this reason many observers have often failed to find tubercle bacilli because they have examined only the superficial secretions.

In looking up the literature on tuberculosis of the middle ear I find that there is a great difference of opinion both as to its frequency, its objective and subjective symptoms. For instance, Friedrich says: "It would appear that tuberculosis in the ear is usually secondary. The few cases so far recorded as primary are open to criticism, and for the present we have no proof of a primary tubercular osteomyelitis of the mastoid process."

Grimmer, in writing on this subject, says that probably 65 or 70 per cent. of cases of suppurative otitis media with neighboring bone lesion, in children under 5 years, are tuberculous; in older persons not more than 16 per cent. of similar cases are tuberculous. My own observations do not agree with this percentage, for tuberculosis in any part of the body is certainly a more serious condition than the above statement would admit. The usually good results obtained in the treatment of suppurative otitis media in children is an argument also against this statement.

Milligan also states in an article on this subject that "primary tuberculous disease in and around the middle ear is of rather frequent occurrence." I can not believe that there are many otologists who will agree with this statement.

MODE OF INFECTION.

As to the mode of infection in these cases, it is generally agreed that the infection takes place by one of the following three ways: 1, the eustachian tube, from the nasopharynx and its mucous membrane wall; 2, the blood or lymphatic system; 3, externally through a perforation in the drum membrane.

PREDISPOSITION.

Experience and observation lead me to believe in an inherited predisposition on the part of the patient for the development of tuberculosis in any part of the body, and more especially in the tympanic cavity. If there should be this "inherited predisposition" and the ear should become inflamed, then the localized lowered vitality will afford an excellent ground for the growth of a tuberculous process. The fact that E. Fränkel states that the danger of infection from the post-nasal space is not very great is certainly significant, for among fifty autopsies on tuberculous patients he found tuberculosis of the postnasal space ten times, and yet in none of these was the middle ear involved. That an infection may take place, however, as the result of the presence of the tubercle bacilli without this inherited predisposition, I do not deny, but I must confess that I am a weak believer in this mode of infection.

CLINICAL MANIFESTATIONS.

Writers vary as to the clinical symptoms of this disease, but nearly all agree as to the absence of pain as one of the most common. In chronic middle ear suppuration of all kinds this symptom is also present, hence it is by no means peculiar to tubercular ulceration.

Grimmer, in his excellent article referred to, gives the following symptoms as characteristic of tuberculous otitis: 1, painless onset of the discharge from the ear; 2, two or more perforations of the drum membrane; the presence of pale edematous granulations; 3, creamy pus discharge; 4, facial paralysis coming on at a very early

stage; 5. bare bone which may be felt through the meatus.

Friedrich says that "granulations and polypi are not present as a rule," and yet in my own case I have never met with such exuberant granulations as those which filled the auditory canal. Bone necrosis and rapid exfoliation of the same are held as prominent symptoms of this condition, but these also show variations.

After all, I think we must agree with Milligan, who says: "The best and most reliable means of establishing the tubercular nature of the disease is by means of properly conducted inoculation experiments."

The all-important point of this paper is to elicit a free discussion as to the proper line of treatment after a certain diagnosis has been made. If the tympanic cavity is involved, and secondarily or even primarily the mastoid also as evidenced by necrosis or fistulae, then the proper surgical procedure is clear.

On the other hand, if only the tympanic cavity is involved and granulations exist in the cavity, extending also freely into the auditory canal, if there is no other discomfort beyond a discharge from the canal, if the case is in no wise chronic in character, shall we treat the condition through the auditory canal or shall we make the radical operation through the mastoid immediately?

CONCLUSIONS.

My own experience leads me to the following conclusions:

1. If there is free drainage of the tympanic cavity through the auditory canal: if there are no granulations present and no symptoms of facial nerve paralysis; if the mastoid does not show, and has never shown any signs of involvement, and if there are no extensive areas of necrosis, I would treat the condition expectantly through the auditory canal.

2. If there is facial paralysis and extensive granulations extending out into the canal; if the mastoid shows or has shown involvement, whether tubercular or not, and the patient shows vitality enough to stand the anesthetic, I should propose the radical operation immediately.

During the last four years I have had three cases where there were extensive granulations springing from the middle ear and sides of the auditory canal and which almost entirely filled this latter. There was absolutely no history of involvement of the mastoid. In all of these I undertook to remove the granulations through the canal much to my regret, and they taught me the important lesson that the radical operation was the only one to be considered. The man who undertakes to treat profuse granulation tissue through the auditory canal will come to grief, and I am firmly convinced that the radical operation will prove to be the most conservative.

DISCUSSION.

Dr. C. M. COBB, Boston—So far as my experience goes, when the infection of tuberculosis gets in the lymph current it goes with the current and not against it. The infection from the tonsil goes down through the neck and not up through the face. The lymph glands evidently stop some of the infection or they would not become inflamed. If it is absolutely certain that we can remove every particle of diseased tissue and all the bacilli, the operation is justifiable; but the patient is much more rapidly infected through the blood current than through the lymph current. The condition will become rapidly worse with a raw surface. My experience in operating on tubercular meningitis has been pretty bad. This result has been so invariable that I generally refuse to help operate on such cases. The patients apparently do not live as long as

they would if left alone. What can be accomplished is through the treatment with iodoform. I do not think it is safe to use the curette for the granulations unless the patient is having symptoms of retention of pus.

Dr. B. A. RANDALL, Philadelphia—The cases in which we can prove the tubercular character of inflammation of the middle ear are rare. I have placed a number of specimens in the hands of our best investigators and they were unable to prove the presence of tuberculosis from cultures from the tissue; yet from the clinical standpoint it was unmistakable. I have had some very good results in cases where I was sure of the condition. While operating on a child six months of age for removal of polypoid tissue from the auditory canal, I found a tiny piece of loose bone in the upper back part of the tympanum. I caught it with the forceps and when withdrawn discovered that it was half of the stapes, which had been exfoliated. There was slowness of the movement of the face on that side, but not full paresis. The glands were much involved and I urged their enucleation, although the child was not of known tubercular history on either side. It was the only child and it was very important not to imperil life. On these grounds, radical intervention was refused and I curetted the tympanic cavities and from time to time twenty-seven glands and left the family physician three or four others to treat in this manner. The adenoid tissue in the pharynx was slight. A few weeks ago he walked into my office, a hearty little chap of 8, and when I saw him I felt glad I had done as I did. It was a cure, but whether of a tubercular process or not I can not say. The cultures were negative. All possible of the infected tissue in these cases must be eliminated. If we have in the middle ear, and especially in the mastoid, evidence of tubercular involvement, we must deal with it radically. With a family history of tuberculosis and typical appearance of the child, I have had good results, though I have not followed them for many years to confirm the outcome. I believe it is our duty to do radical work on these cases.

Dr. DUNBAR ROY—It was an interesting and important case to me, because of its being the only child. The question of doing the radical operation was discussed and the opinion of another excellent aurist was obtained. He suggested doing a double operation on both mastoids immediately, but the child being almost moribund, this was abandoned. My experience in dealing with these cases through the auditory canal has been very unsatisfactory. However, I would not again treat granulations through the auditory canal, but would go into the mastoid immediately and do a radical operation.

THE NEW OPHTHALMOLOGY

AND ITS RELATION TO GENERAL MEDICINE, BIOLOGY AND SOCIOLOGY.

GEORGE M. GOULD, M.D.
PHILADELPHIA.

(Concluded from page 1549.)

Again the critic may justly ask: "Have none, then, recognized and spoken out this much unrecognized truth?" Oh, yes, many and good men have done so. There is a vast quantity of literature produced by clinicians of the best character and professional standing, and it is astonishingly convincing and cogent. It is unfortunately scattered, and hence, in part ignored by too many physicians. The last weighty utterances are Dr. Zimmerman's study,⁶ and especially since they are from England, the excellent reports of Dr. Snell,⁷ and Dr. Pronger.⁸ Hundreds of others might be cited, the testimonies, *e. g.*, of such good professional journals as the *Cleveland Medical Journal*, the *St. Paul Medical Journal*, the *Lancet*, the *Pacific Medical Journal*,

6. N. Y. Medical Journal, Nov. 21, 28, 1903.

7. The Lancet, April 30, 1904.

8. Slight Errors of Refraction and Their Influence on the Nervous System, Harrogate, R. Ackrill, 1903.

matical precision to accurate unity and brilliant action of every muscle of the body. Similar perfection of eye and motion has been evolved in every higher animal of the world, and in every savage, and in every child. Your horse avoids all stones and knows, unconsciously, every inequality of the ground before and beneath him by the like mechanical unity. Watch little children in play barely missing obstacles and dangers which would mean injuries and perhaps death, with swift unconsciousness. The history of savagery and of civilization is all there and is of the same nature. See with unbelievable accuracy if you would succeed, is the first verse of the biologic decalog. That is the physiologic Logos which became the biologic flesh.

But see inaccurately and you die, is the antithesis, and the animal which failed to obey perished, inevitably and quickly. The savage did the same, your horse that stumbles is useless, your playing child that hits its leg or trips becomes, at least, a very different child, and a very different man or woman from the others who do not make these visual and co-ordinating blunders. Such are the backward scholars in school and, in large part, they are your failures in life, society's expensive degenerates, defectives, and dependants. They are rapidly increasing in number with every step in civilization, because every such step means the entangling difficulty of added near vision.

All of which—and this is the heart of the matter—Darwin, a martyr to bad eyes himself, failed to see, and all of which no evolutionist has since caught sight of. And yet it has been one of the large controlling conditions of the evolution process. For not only has this unity of mathematic optics and physiologic function been the inescapable method of success in the struggle for existence, but it has been the chief mechanism whereby the so-called unfit have been thrown out of the count. Visual imperfection has been, and is increasingly becoming one of the dominating causes of the exclusion of the ontogeny from the propagating phylum. This is the fundamental distinction which differentiates the laws of biologic evolution and survival of those with and those without vision. It is the key which will unlock and reveal many of the profound mysteries of heredity and descent which to-day are tormenting the different schools of evolutionists and biologists. Open the door and walk into the long-closed ancestral hall and the mystery of forbear and aftercomer is revealed. How and why we are here is at once plain. None could have been, and we could not now be the link between the phylum of the past and that of the future, except on the condition of seeing well. Those not allowed to become such parental links were largely those who saw too inaccurately to compete in the beneficent but summary process.

Note well, however, two things: The most perfect organism in the past world of animal and man was useless without, first, this perfection of visual function, cerebral co-ordination, and muscular response; and, second, the attainment of this optical mechanism was far more transcendently difficult than any other physiologic task. To attain transparency and nourishment of cornea, lens, vitreous humor, and retinal end-organs, to superpose the images of the two eyeballs, to respond to the almost nothing of stimulus, to transmit to brain, to manufacture sensation, to dominate all other cerebral function, instigate and direct all motion—where is the end of the marvellous task! The end is in failure to do any one of these things, and to make that inch-in-

diameter eyeball of a spheric perfection which shall not vary by 1/300 of an inch from the normal. The end is not to have prevented conjunctivitis, traumatism, keratitis, iritis, glaucoma, cataract, retinitis, and other multiform diseases, prone especially to occur in the astoundingly complex and refined organism. The pathology of animalian evolution has therefore been in large part the pathology of vision. The organism otherwise perfect except as to an infinitesimal visual part is thrown out by this optical necessity. The mechanism *par excellence* of the exclusion of the unfit is thus made clear.

To this now add the consummating and crowning function of vision—the creation of intellect. Psychology, history, and biology unite to demonstrate that the objectivation of the $\psi\chi\theta$ of civilization is almost uniquely by means of vision. The greatest task of all human history was the creation of the letters of the alphabet. It was so difficult that only one race did it, and within one or two milleniums all others have come to a knowledge and use of civilization only through the adoption of the invention. No writing and printing, no civilization. But the letters of the alphabet are conventionalized symbols of pictures, or things seen. Add to this that language itself is of identic origin. There has been no speech except to express the result of ocular function. Almost all psychology is summarized as handlings, co-ordinations and deductions of visual images, of these and of the motions made possible by sight. Thus every cerebral function, perception, appereception, feeling, most of it, and willing, that which is effective, surely reasoning and judgment—all spring originally and constantly, are bound up with, dependent on, and interdependent with vision.

There is something more than mere imagery and fancy which analogizes the course and phases of these developmental stages to the way of water-flow in the world. Decidedly optical are the sun, cloud, rainfall and snowfall on the uplands and mountains whence spring the crystal streams and rivulets of physiology. In them, optics become function and action, physics become physiologies. The lower falling brooks become discolored and morbid when they reach the homes and degradations of man—physiology becomes pathology. But the stream broadens into the large river of biology with the commerce, the health and unhealth of a continent, until finally the Mississippi sweeps to the mothering ocean of sociology where sail and steam the navies of the world.

Thus all routes and efforts lead to man, all biology ends in sociology. Our striving is for human betterment; because all medicine is pre-eminently philanthropic. The beclouded or befogged mariner orients himself by means of an optical instrument, and as the sun and the sun's winds bear the sun-made clouds back to the faraway mountains again, so vision and optical eyes and instruments again complete the morbid and therapeutic circle, the cure which is always beginning and never complete.

My contention is that here is a great means of civilization. It is a profoundly important thing that the hopeful Carlyle of the "Characteristics" should have become the pessimist of "Shooting Niagara and After." It is civilization's tragedy that Nietzsche should have had havoc played with his mind by eyestrain; that Huxley should have been driven from work at the height of his powers; that DeQuincey should have been an opium eater; that Darwin should have been able to work but two hours a day with his eyes, and Parkman

but a few minutes; is it not a sad thing that George Eliot and her books, Symonds and his great opportunity, Twain and his great scholarship should have suffered as they did? Is it not a pathetic source of social misery that 10 or 20 per cent. of eyes are incapable of sewing, typewriting, book-keeping, lathe-work, studying, draughting, and a still sadder thing that their owners have no knowledge of the fact, and that they should suffer until "break down" comes? Is it not an awful thing that from 40 to 60 per cent. of all school children are sickly? That suicide is increasing, insanity and epilepsy incurable, hospitals multiplying—and taxes, and prisons, and war, and want? A certain, perhaps a large, per cent. of all these backward school children, epileptics, prisoners, insane, hysterics, neurasthenics, dyspeptics, have such eyes that glasses correcting their optical defects would bring them much relief, would often have prevented much or all of their tragedy. And the proof is this: Put any pair of such spectacles on any one of us, and within an hour there would be headache, giddiness, vomiting or intense suffering. The cynics and skeptics of "eyestrain exaggeration" can be speedily converted whenever they are earnest enough to try a simple experiment on themselves. It is a truth awful in its significance that in civilized countries there are millions of people who are good products of the evolutionary mill, who have sound minds and good bodies, but who are partial or complete failures, always with intense personal suffering, simply because of an infinitesimal malcurvature of the cornea, a too long, or a too short eyeball, no greater than the thickness of a sheet of thin paper. It is the little thing that, overlooked by others, makes or mars all undertakings, all sciences, and all cosmic proceeding. The compass guides the ship, and without it there would be no civilization as we see it. Without vaccine virus there would be a different world, there could hardly be civilization, and yet it was a generation after farmer Jesty inoculated his family from the teats of the cows in the field before even Jenner dared do the same, and before the best of the profession would have anything to do with it; and to-day there are perhaps a million antivaccinationists in America! When Pasteur had demonstrated what Villemin and Davaine had before said was true, the bacterial origin of some diseases, history records that, "the doctors, in the great majority, were violently opposed to the germ theory of diseases. They answered experimental proof with oratory. The less excited among them urged temporizing. The surgeon Chassaignac warned Pasteur that laboratory results should be brought out in a circumspect, modest, and reserved manner, etc." In 1843 Dr. O. W. Holmes conclusively showed that puerperal fever was contagious. We ignored the fact. In 1846 Semmelweis of Vienna independently proclaimed that puerperal fever was due to inoculation by nurse, midwife, or doctor, and that this contagion could be prevented. For this bravery and clinical acumen Semmelweis was persecuted by his medical brethren, turned out of his professorship and ruined. In the Paris Maternité Hospital in 1856, 64 women died of the disease out of 347 admitted. In 1864, out of 1,350 cases, 310 died. At last in 1874 Fournier and Budin introduced the "new" views of Pasteur and Lister, and in spite of what Dr. Roux calls the "tyranny of medical education," they were accepted, and puerperal fever disappeared. Would it not have been an inestimable gain not to have persecuted Semmelweis, and instead, to have examined and tested his

theory? In 1888 Dr. G. Martin stated that "migraine" was due to astigmatism and published proofs. In 1903 and 1904, the *Medical News* likens those who say the same thing to Dowie and Mrs. Eddy, and the leaders of the New York Academy of Medicine call a special meeting in order to snuff out of existence the advocate of such a senseless theory. And yet migraine is due to eyestrain as any one can prove whenever he wishes, and as thousands of patients will testify whenever asked. Migraine is peculiarly a disease of civilization, increased with every added hour of near-work with the eyes; and civilization is enormously increasing that constant strain of near-work with eyes evolved during millions of years for a different function.

There is hardly an instance in all history of a great and beneficent medical discovery that was not either ignored or hated and scorned by the official leaders, and by the great part of the entire profession. It was so with vaccination, with anesthesia, the germ-theory of disease, Mendelism, thoracic percussion, ovariotomy, antiseptics in surgery, the etiology of yellow fever and malaria, the serum treatment of diphtheria, Pasteur's antirabies inoculations, the humane treatment of the insane, etc.

Now the amazing fact about all of this is its ease of proof or disproof, the passionate hatred with which was rejected a possible source of relief of human suffering, the harmlessness of the trial, the utter forgetting of the patient, the supreme interest in the prejudice. Vaccination is harmless and its protective effect easily demonstrated. To tap the chest with the finger is a very simple proceeding and the sounds elicited are easily recognized. It is not difficult, if so minded, for the nurse, midwife, and doctor, to be clean, and thus test if puerperal fever is contagious. The physicians who clamored against railway travel because it would make passengers sick, giddy or insane, and said if the foolish would build railways board fences must be built above the height of the cars—these physicians could have got on the cars and disproved their theory. The opposers of the theory of circulation of the blood might at least have tested the theory by pricking their finger. The prejudice against rabies inoculation, the diphtheria antitoxin, the mosquito-theory of malaria, and yellow fever, etc., which resulted in untold deaths and delay of scientific progress, could have been easily tested. It is childishly simple to test the power of astigmatism to produce or cure migraine, and yet many prefer not to make the test.

There are probably not a half dozen hospitals or ophthalmic clinics in the world outfitted with a trial-frame or set of test lenses that would enable even an expert refractometer to diagnose ametropia with the perfect accuracy which is necessary to cure morbid ocular reflexes. But those set to do refraction work in the public clinics are not expert. They are the students and learners. Hence nine-tenths of the glasses prescribed in these institutions are not correct. Ophthalmic surgery and inflammatory diseases are all that interest, and these would be largely preventable by the refraction that is neglected and misdone.

Even in the institutions for the blind, it has been found that some of the inmates are not blind, and that their remnants of vision may be so vastly improved as to make these dependents self-supporting. In every school of the world at least 20 per cent. of the pupils are suffering from ill-health due to imperfect eyes, and yet pedagogics, except infinitesimally and incipiently, does not know and does not care. The teachers and profes-

sors in preparatory schools, colleges, universities, technical and other schools, pay little or no attention to the ventilation of the rooms, or to the refraction of the eyes of their students. These are constantly breaking down in health, or in study, from migraine, etc., and the general scholarship is vastly depreciated because of the neglect of the eyes. An official and resident expert refractonist would make a university outdistance its rivals more than does all its "athletics."

In every asylum for the insane some patients are there because of bad eyes—and if only a few are curable of the chronic disease, many could be relieved of the headaches, gastric, and other nutritional diseases which burden the attending physicians and the taxpayer. In one great institution for epileptics, a little experiment with glasses, imperfectly executed in many ways, showed a greater percentage of cures, a greater reduction in the number of seizures, than by all other methods of cure combined that had been tried in the institution. And yet the official report characterized the experiments as "disappointing," and sneered and misrepresented it. Epilepsy, it has been demonstrated, is in many cases due to ametropia; many cases could be prevented by proper glasses in the child, or during the early history of the case. In the chronic, severe and hopeless cases it may not be always or even frequently curable. The conditions of the glass-treatment are exceptionally difficult to carry out, and often can not be done at all, especially if conscience and sympathy are absent. The improved general health, freedom from headaches, etc., would make it at least a saving of money for the state to pay an expert resident oculist. This, apart from the humane consideration. Nobody can rightly estimate the number of degenerates, paupers, defectives, and dependents, loaded on the producers and taxpayers because reading, writing, sewing, study, handicrafts, etc., are impossible to a person with disqualifying astigmatism. Neglect of the fact greatly increases the tax rate, and makes the philanthropic miserable.

Why does the truant school boy exist, and why does he so often develop into the young criminal? If the majority of these, as Dr. Case of the Elmira reformatory finds, have an ocular defect that makes vision impossible for any continued reading, writing, or hand-work, does not the fact modify all penalty? If the sewing-girl can not possibly sew, or do any such kind of eye-work, what alternative is often left her except crime? Sociology is very frequently another name for ophthalmology.

And if even to-day, in the city, the poor can not be fitted with a simple device to make their lives happy and independent, how is it with the other half or three-quarters of the people who live in small towns and in the country supplied only with the itinerant criminal spectacle-peddler? The farmers and their families now waste most of their evenings and their winters, and then the sociologist blames them for their vile country newspaper and their unprogressiveness.

Philosophers and thoughtless critics bewail the literary pessimism of the age. It is indeed a pitiable and a pitiful fact. In a time when comfort and possibility of education and of enjoyment have suddenly increased a hundredfold, why the strange phenomenon of vastly increased skepticism, mental suffering, hopelessness and melancholy? Who have set the fashion? Certain powerful, but in some respects morbid, literary geniuses. Who were they? Those almost without exception who

were great sufferers from physical disease. Of what disease? Simply of "migraine." Without a thought of the class to which they may belong, make a list of the literary pessimists of the last century, and another list of the optimists. The pessimistic or gloomy writers and artists were almost entirely great sufferers from eyestrain and from its result, migraine. They were, for instance, Nietzsche, the two Carlyles, de Maupassant, George Eliot, Wagner, Tchaikowsky, Chopin, Symonds, Tolstoi, Heine, Leopardi, Schopenhauer, Turner, Obermann, Thomson (the younger), Poe, and many others. Others that partially or wholly conquered the "migraine" of eyestrain, by opium, or by renouncing ocular near-work, by walking, etc., are Mrs. Browning, DeQuincey, Coleridge, Beethoven, Parkman, Whittier, Margaret Fuller, Browning, Huxley, Spencer, Taine, Darwin, Lewes, Hugh Miller, Southey.

The optimists, the cheerful, hopeful, encouraging, loving, and helpful ones, were, a few and at random, Goethe, Mozart, Verdi, Ruskin, Wordsworth, Ste. Beuve, George Sand, Emerson, Lowell, Longfellow, Hawthorne, Kant, Scott, Brontë, Dumas, Voltaire, Gibbon, Macauley, Mommsen, and a host of others.

In not one of the lives, or writings, of these last will you find a hint of eyestrain or migraine, hardly even of ill-health. Note also that the pessimists are mostly atheistic and materialistic, while hardly one of the healthy optimists is so. One may also remember the tendency to despair and even suicide in those who suffered the most from migraine. It is exactly so in private practice to-day. Pessimism and atheism are an expensive tax on the natural vitality, a danger to the public health, a brake on the wheels of the progress of civilization. If we care naught for the personal and preventible sufferings of these great workers in humanity's cause, nothing for those of the literary and other laborers tremendously increased by the very nature of their tasks, we at least should consider the welfare of the generations that follow us. As the creation and perfection of vision has been the condition of past biologic evolution, so its normalization and the avoidance of its pathogenic results is one of our highest professional duties and ideals.

TYPES OF CHILDREN.*

W. S. CHRISTOPHER, M.D.

CHICAGO.

For many years—indeed, since the advent of the more exact scientific methods in medical research—it has been, to say the least, unfashionable to refer to "diatheses" and "temperaments." It is not difficult to find why these terms have dropped into disuse, and the reasons are good. Not only are the general terms themselves illy defined, but the attempts made to differentiate their subdivisions and parts are equally inchoate and confusing. They become, therefore, an easy refuge for inexact thinking, a condition obnoxious to modern medical methods. And yet we owe so much to the fathers, and have such great reason to admire the genius with which they brought to light many fundamental truths when surrounded by vicious methods of reasoning and faulty, inexact and incomplete methods of investigation, that it becomes a duty to give respectful attention to and make careful investigation of their dicta, even when adherence to them is withheld. Even so recently

*Address before the Ohio State Pediatric Society, Cleveland, 1904.

as my own student days, and more recently still, the old woman's practice of giving teas to new-born babies was laughed at. Now we know that the kidneys of the newly born are very frequently the site of a uric-acid infarction, and that if we would prevent some of the pain of the new baby we must supply it with fluid, and we know that this fluid should be sterile. The herbs from which these teas are made are probably without any value for the purpose for which they are given, but the fact that they are administered as teas insures sterilization of the liquid. That a practice involving such a combination of important truths should have become so firmly established as to have become a custom, and that when the actual reason for its verity was utterly unknown, has long impressed me as but little short of wonderful, and has forced me to give respectful attention to the beliefs of the old practitioners. A very similar instance is the universal custom of giving a daily bath to the new-born baby, a custom carried out even among people who do not always taken even an annual bath. It is not difficult to mention numerous customs of long-established practice, whose *raison d'être* is of very recent discovery. It is such well-established facts which induce us, nay force us, to go back and examine carefully the old doctrine of the diatheses and temperaments of our forefathers.

Trousseau accepted Littré and Robin's definition of diathesis, which was as follows: "Diathesis is a general tendency, in virtue of which an individual becomes the subject of several local affections similar in their nature." This definition is broad enough to include syphilis, and what has been called the "strumous" diathesis—in other words, tuberculosis. But if diathesis includes the chronic infections it ought also to include the acute ones. This would make it almost synonymous with sickness. It is clear, therefore, if the term is to have any use, that the infections should be excluded from it, at least to the extent of refusing to consider infecting agents as direct causes of diathetic manifestations. So also should there be excluded all causes of morbidity which act from without the body, such as geographical and climatic conditions, occupations and social relations. In other words, it would seem just to limit the causes of the so-called diathetic manifestations to nutritional factors. Even the influence of heredity should be considered only in its nutritional relations.

Nutrition is a very comprehensive process. It has to do not only with the foodstuffs, but with their digestion and absorption. It has to do with the so-called internal digestion, or elaboration of absorbed material by such great organs as the liver, the thyroid, the thymus, the adrenals and the pancreas. It has to do with assimilation after all this preparation, and with disassimilation and the modifications of the end products of the metabolism, and as well with the intoxications produced by these end products, and with their excretion.

To me it seems clear that the processes which we speak of as diathetic, when we allow ourselves this liberty, all center around and have their chief origin in the great elaborating organs, especially the liver, the pancreas, the thyroid and the adrenals, while influenced also by each of the other features of the nutritional process.

In this sense diathesis can be expressed as the prevailing type of metabolism of the individual. This means that every individual has some diathesis, and, in some instances, I hope to show, has more than one.

The study of this metabolism, so far as the clinician is concerned, must be approached first through the urine, that great metabolic resultant.

The study of the urine in this connection requires an examination into the relations of urea, uric acid and the other alloxuric bodies, sugar and its congeners, the acidity, the inorganic salts, particularly the phosphates, the oxalates, as well as some other substances of very infrequent occurrence. My own study of the urine as related to diathetic states has been limited to urea, acidity and sugar. With these, for practical purposes, indican must be included, although being generally an expression of intestinal putrefaction, is not really a metabolic product. I am perforce compelled to limit my remarks on this occasion to my own line of observations.

Some seven or eight years ago I began to make occasional determinations of the acidity of urine, and, finding some very interesting things, finally adopted the plan of determining the acidity of every sample of urine brought into the office, and the further plan of having all office patients bring urine nearly every time they came, and not infrequently having them send specimens between their visits.

The method employed to determine the acidity was this: 10 c.c. of the urine, together with a few drops of an alcoholic solution of phenolphthalein, were placed in an evaporating dish and decinormal solution of sodium hydrate run in from a burette until the faintest possible permanent red of the phenolphthalein was noted. The number of c.c. of the $N/10$ soda solution used was then recorded as the index of acidity. At the same time the so-called percentage of urea was determined by a Doremus' ureometer, or other form of nitrometer, as well as a rough colorimetric determination of the indican. Later I began to use the safranin test for sugar, originally recommended by Crismer. This latter test has proven very interesting to me. Safranin is one of the coal tar dyes. I have always employed the water soluble safranin prepared by Grübler. A 1/10 per cent. aqueous solution, which is blood-red in color, was the one used. When heated with sugar in the presence of an alkali the safranin is changed to a leuco-compound and the color disappears. This leuco-compound is, however, very readily reoxidized by free oxygen, so that the slightest agitation, even a bubble rising, will cause some return of the red color. Great care must, therefore, be employed in using it quantitatively. In applying the test a series of test tubes is taken, into each of which is put 1 c.c. of urine, 1 c.c. of normal sodium hydrate, and varying quantities of the safranin solution, viz., 1 c.c. in the first tube, 2 c.c. in the second, 3 c.c. in the third, and so on. These tubes are then placed in a beaker containing glycerin and carefully heated to 180 to 190 F., a thermometer being placed in the glycerin to determine the temperature. The number of tubes in which the safranin is decolorized is recorded as the safranin index. Nearly every urine will reduce some safranin. The reaction must, therefore, not be confounded with the ordinary copper tests for sugar, nor must a urine which reduces safranin be considered what is generally understood as a diathetic urine. I have found over 90 per cent. of all urines I have examined to give a positive reaction to the safranin test. If, therefore, it shows sugar, it can only mean the so-called physiologic sugar which is now generally admitted to be present in normal urine, but in quantity too small to be shown by the ordinary tests. What is the evidence that safranin shows sugar and nothing else? 1. It is reduced by sugar; 2. it is not reduced by uric acid or creatinin; 3. I have personally determined that the safranin reducing substances found in non-diabetic, as well as that found in diabetic, urine can be gradually and in the end completely removed by

mixing the urine with yeast and subjecting it over several days to a temperature favorable to the growth of the yeast plant. This does not absolutely prove that nothing found in urine but sugar can reduce safranin, but it does put it on a better basis than any other sugar test of which we have knowledge. The unreliability of Fehling's was very well shown by some experiments which I conducted in conjunction with Dr. Julius Eichberg of Cincinnati. We found that a solution of glucose in pure water of the strength of 1 to 1,000,000, reduced Fehling's reagent and produced a precipitation of cuprous oxid, while a solution of glucose in urine of a strength of 1 to 500 failed to reduce Fehling's reagent. A solution of the same strength, however, of which half of the diluent was this same urine and the other half water, did reduce Fehling's. We are forced to conclude from this that urine apparently normal contains something which prevents the ordinary Fehling's reaction. Whatever the nature of this interference may be, it evidently occurs in varying degrees in different urines, as I have found a urine with a safranin index of 14 which failed to show sugar either by the copper or the phenylhydrazin

teresting conditions. The average of each of the items of examination, viz., urea percentage, acidity index and safranin index was determined for each year of life and for each sex separately. The number of urinalyses for each year up to 14 was sufficiently large to secure fairly accurate norms, as shown by the regularity of the resulting curves which are here reproduced.

A study of the development of urea excretion, as expressed by percentage, shows the following:

1. This percentage is very low in the first year of life, being considerably less than 1 per cent.
2. In the second year of life it increases very rapidly to a little less than 2 per cent.
3. It then increases more slowly to 3 years of age (the fourth year of life) when it reaches its maximum, about $2\frac{1}{4}$ per cent.
4. From this time on it runs a fairly constant course, with some tendency to decrease, up to puberty, when it is about the same as in the second year of life.
5. As to the sexes, the curve for girls parallels that for boys, but is lower than the masculine curve, except in the first year of life, until the age of 12 is reached, when it crosses it.

As will be seen from the chart, the safranin curve parallels the urea curve with singular fidelity, except that the feminine curve crosses the masculine curve at 11 years instead of 12.

The acidity curve also follows the urea curve generally, but is more irregular, a condition due first to the fact that acidity itself is a very complex result, and next, this factor was much interfered with in many of these urinalyses because of the free administration of alkalis.

Until further work is done on these lines we can accept these curves as expressing norms, with which the conditions found in any individual child can be compared to determine its variations from the normal, just as we compare the measurements of the individual child with anthropometric norms to show vagaries in growth which go so far in explaining some morbid states. It is for the special purpose of calling attention to deviations from the chemical norms, as expressions of diathetic conditions, that I have called attention to the norms themselves. I wish to deviate for a moment to refer again to the crossing of the curves of the two sexes in these three chemical factors at the ages of 11 and 12. The curves of the sexes representing growth in stature cross at 11 years, so do those of height sitting, while those of weight cross at 12 years, the same years at which the urea, acidity and safranin curves cross. Hence these norms of chemical factors illustrate the profundity of the processes of puberty, in a direction, I believe, not hitherto shown.

In using the foregoing norms it must be remembered that the variations in the urine of a child from day to day are often very considerable, and consideration of a single urinalysis is liable to be very misleading.

To determine the minimum number of observations necessary to establish with some degree of significance the average safranin index of an individual, the following study of these urinalyses was made. A list was made of all individuals under 21, of whose urine ten or more examinations were made; also of the number of examinations of each, and of the average safranin index of each individual. There were altogether 77 individuals (both sexes) with 1,559 urinalyses, making an average of 20.3 examinations for each. The average of all their safranin indices was 1.82. The average safranin index of all urines examined, adults excluded, was

Chart 1.—Normal urea, safranin and acidity curves. Solid line, boys; dotted line, girls.

test, while ordinarily a urine with a safranin index of 5 will show sugar by the copper test. It has also been shown that phenylhydrazin does not always precipitate all the sugar present in a given urine. On the whole, I think we are safe in saying that the safranin test for urinary sugar stands on at least as reliable a basis as any other test for this purpose, and is quite as free from legitimate criticism as most other tests in biologic chemistry.

The special value of the safranin test to the clinician is its applicability to the determination of the quantitative variations in the physiologic sugar of the urine.

One year ago I took all of my recorded urinalyses, which showed the urea percentage and the acidity and safranin indices, and for which I could determine the age and sex of the children, and subjected them to a somewhat critical analysis. This review¹ of these analyses, some 3,500 in number, revealed some rather in-

1. The Safranin Test for Sugar in the Urine of Children.—THE JOURNAL, A. M. A., June 20, 1903.

1.81. Of the 77 individuals, 11 had exactly ten urinalyses, and the average safranin index of these 11 was found to be 1.81. This would indicate that for a given individual not less than ten examinations should be

made to determine his average safranin index. Of the 77 individuals with ten or more examinations, 11 had a safranin index between 2 and 2.5; 11 had an average safranin index between 2.5 and 3; with 2 the average index was between 3 and 3.5, and with 4 it was 3.5 or more; the maximum was 3.92.⁷³¹

Lewis G. was under observation from Sept. 7, 1900, to Oct. 9, 1902, from the age of 19 months to the age of 44 months. During this time 78 urinalyses were made, in all but 4 of which the safranin test was made. Chart 2 illustrates his urinalyses. These examinations gave an average urea percentage of 2.27, average acidity index of 4.82, and an average safranin index of 3.92. The average of the norms for the three years in which his age fell are urea percentage 2.02, acidity index 4.04, and safranin index 2.02, indicating throughout a concentrated urine of high acidity and very high safranin index. A consideration of the chart illustrating this boy's urine leads to the following conclusions, which are also in harmony with observations made on other patients:

In general, safranin and acidity parallel each other. Occasionally a high acidity will be found to precede a high safranin by a day, and begin to drop the same day that the safranin index reaches its maximum. In general, a high safranin does not last more than two or three days; high acidity not infrequently persists longer, and may occur independently of the safranin reaction. High safranin very rarely occurs independently of high acidity.

A few extracts from this boy's clinical history are now in order:

He had jaundice neonatorum and has always been pale and sallow. Was brought Sept. 7, 1900, for painful micturition. His urine then showed acidity 6.2, urea 1.7, ind. +, saf. 3. He was put on kal. bicarb., gr. 4, kal. nitrat., gr. 1, and vin. colch. sem., gt. 1, every two hours. This will hereafter be called his alkaline mixture. One week later the urine showed acidity 1.4, urea, 0.9, indican +, and safranin 1. Urination was less painful. Alkali continued. Ten days later he had some fever, with putrid stools and a canker sore, which quickly yielded to calomel. On October 19 his urine gave a safranin index of 10½ and also reduced bismuth and Fehling's test. Nov. 1, 1900, trouble again, with putrid bowel contents. Jan. 23, 1901, urinalysis: sp. gr. 1.023, acidity 7.2, urea 2.6, indican absent, safranin 8. Was given pulv. Doveri, gr. 1/10 t. i. d., and one week later urine showed sp. gr. 1.026, acid 5.8, urea 3.2, indican absent, safranin 2½.

In June he was brought in with the statement that he had had in March a grip attack which particularly affected the bowels, producing a mucous discharge which lasted for five or six weeks. After some improvement for two weeks the condition returned and was present at the time of his visit. His urine then showed acidity 7.2, urea 4.8, indican +, and safranin 12. He was put on his alkaline mixture and the bowel symptoms promptly cleared up and his disposition was much improved and his sleep became quieter. He was still taking the medicine when he was brought in on Aug. 5, 1901, at which time his urine showed acidity 2.3, urea 1.8, indican absent, safranin 2½. During the fall he continued in fairly good health, but was on the alkaline mixture much of the time. He would occasionally have slight attacks of putridity of bowel contents, requiring calomel, once or twice showed slight jaundice, and much of the time presented a geographical tongue. When he finally dropped out of observation he was in much better condition, showed less autotoxemia, and his urine ran close to the normal.

The accompanying table shows the average urea and acidity and safranin indices, with the average age of all cases up to April, 1903, for whom 10 or more urinalyses were made and whose average safranin index

Chart 2.—Safranin, acidity and urea curves of Lewis G. Solid line, urea; dotted line, safranin; broken line, acidity.

was above the normal for the age. For convenience, parallel columns show norms. This table is intended to illustrate the general peculiarities of the urine of children presenting abnormally high safranin reactions. Arrangement is in the order of the safranin indices:

TABLE 1.

No.	Name	Sex	Age	Aver. Acid	Norm. Acid	Aver. Urea	Norm. Urea	Aver. Saf.	Norm. Saf.
1	T. E. F.	M	5 9	5.30	3.84	2.55	2.10	2.06	1.87
2	E. R. F.	F	4 7	3.35	3.23	2.09	1.84	2.08	1.75
3	H. I. M.	M	6 2	10.21	3.95	5.66	2.25	2.23	1.90
4	R. K. M.	M	11 0	1.95	3.69	1.21	2.04	2.27	1.69
5	D. M. F.	F	2 7	5.49	3.59	2.48	1.85	2.29	1.73
6	M. S. F.	F	5 8	3.75	3.38	1.99	1.92	2.29	1.57

Nos. 16, 21 and 23 were typical instances of high safranin. Of 24 cases showing excess safranin, 20 also had high acidity, illustrating very well the general association of these two phenomena. The table also illustrates that both high acidity and high safranin may occur independently of each other, indicating difference in origin.

The history of Lewis G. (Case 24 in the table) gives a fair view of the clinical course of a well-marked case of the saccharin diathesis. It is impossible to review in detail the clinical histories of these patients, beyond a comment or two on a few of them:

CASE 22.—Aimee M. Has always been a well-developed and well-nourished child, with an appetite that has needed curbing and with a tendency to minor skin eruptions, canker sores in the mouth and gingivitis. Often troubled with putrid bowel contents.

CASE 11.—Walter G. Was a difficult baby to feed, and from the age of 16 months for three years had persistently elevated temperature ranging in the morning from 99 to 99.5 (rectal), to 100 to 101 (rectal), in the evenings, and most of the time in apparently very good health and gaining regularly in weight. Since last fall this boy's temperature has been normal most of the time. Another boy in the same family seems to be about to follow in the older brother's footsteps.

CASE 20.—William S. At 21 months had a convulsion and two weeks later another. No fever. Urine showed acidity 6.0, urea 2.0, safranin 3, no indican. Put on alkalis, with prompt improvement in general conditions. Three months later another convulsion. During the next year, two more convulsions. None since.

CASE 21.—Ralph W. Was a difficult baby to feed, who did badly on milk, especially uncooked milk, and well on beef juice.

CASE 12.—Dorothy C. A delicate, nervous, sensitive child, continuously under weight. Subject to periods characterized by malaise, lack of appetite and marked languor. In each of these periods urine always highly toxic, i. e., showed high acidity and high safranin. Each spell quickly dissipated by alkalis. Twice she had slight jaundice. This child's urine was a perfect indicator of her feelings. Deficiency of weight was always a feature. Under the influence of alkalis, with the consequent improvement of general conditions, her weight would always increase.

CASE 23.—Russell B. Had bronchitis which was very persistent, and subject to exacerbations. Promptly relieved by alkalis.

CASE 10.—Harold O.C. This boy's autotoxemia was associated with diarrhea, headache and slow gain in weight.

Melvin I. At 2½ years of age suffered much with "dyspepsia," characterized by abdominal pain and undigested food in feces. Urine at this time highly toxic. Later some eczema. Under alkalis and colchicum he made rapid improvement in digestive symptoms and gained rapidly in weight.

Cyclical vomiting, or as I personally prefer to call it, recurrent biliousness, is always accompanied by high acidity, but not always by high safranin. For purposes of illustration, I present two recent and typical cases:

Anna J., age 7 years. Has been troubled with recurrent biliousness for two years past. Last attack began on the 6th inst., and lasted 30 hours, during which period she vomited thirty-five times. The urinalyses were as follows:

	May 7.	May 8.	May 9.	May 10.
Acid	6.8	9.1	3.2	4.4
Urea	1.8	3.2	3.0	2.8
Indican	+	+	0	+++
Albumin	0	0	0	0
Safranin	2	2	1	6

Treatment.—Soda bicarbonate, calomel, and enemata of plain water.

Eldon V., age 2 years. Subject to recurrent biliousness. Commenced vomiting on the 7th and vomited about ten hours. Urinalyses as follows:

	May 8.	May 9.
Acidity	14.7	1.3
Urea	3.0	0.7
Indican	0	++
Albumin	0	0
Safranin	5	0.5

In this second case it is interesting to note that even after complete recovery the urine contained large quantities of indican.

A case unique in my experience, associated with toxic urine, was the following:

Bonna B., age 21 months. This child, brought in from Emporia, Kan., presented the most marked choreic movements that I have ever seen. The condition had been present for several weeks at the time I saw her, in consultation with Dr. G. M. Gafford, and the choreic movements were so severe as to require chloroform narcosis to produce sleep. The single sample of urine obtained before she died showed acidity 9.4, urea 1.6, indican 0, albumin 0, safranin 3.

Several times I have met what was symptomatically meningitis, apparently due entirely to autotoxemia. The most striking instance was the following:

Gretchen J., age 8 years. This child had been sick two days when I first saw her, there being present fever, intense headache and persistent vomiting. I found also opisthotonos, photophobia, irregular pulse and Cheyne-Stokes respiration. Her urine showed an acidity of 18. She was given two teaspoonfuls of baking soda during the next twenty-four hours, and at the end of that time all symptoms had ceased. The soda was then stopped and in another twenty-four hours all the symptoms had returned. On resorting again to the baking soda the situation was again controlled and complete recovery ensued.

(To be continued.)

CONSTIPATION IN INFANTS.*

J. ROSS SNYDER, M.D.
BIRMINGHAM, ALA.

Complete digestion embraces a three-fold function—viz., conversion, absorption and evacuation. There is a conversion and an absorption of the nutrient element of food, and following there is an evacuation of the refuse.

The successful performance of these several divisions of the digestive function is dependent on each other, on

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

the character of food ingested, and on certain secretions and motions of the organs involved.

If the food be of such character, or if it be so contaminated, that it over-stimulates secretions or exaggerates peristalsis, the lower bowel responds to the excitation and a diarrheal condition results.

On the other hand, if the secretions are not properly elaborated or if the mechanical movements of the bowel are insufficient to propel the contents of the intestine along its canal, the products of ingestion will be retained beyond that period necessary for all purposes of conversion and of absorption. This constitutes constipation; which may be defined then as a condition in which the products of food are retained in the bowel after they have lost all nutritional value and have become, therefore, foreign matter.

Constipation, it is true, is only a relative term, but it expresses a condition no less definite than that conveyed by the opposite term—diarrhea.

To determine the existence of either, the knowledge of just how many stools are normally evacuated during the day is of secondary importance to the knowledge of what character and volume the normal stool should be.

There are certain anatomic differences in the digestive tract of the infant compared with that of the adult, which are usually recited as predisposing the former to constipation.

The intestinal canal is relatively longer in the infant than in the adult. It contains a larger number of loops and coils and its caliber is relatively smaller. The infant's abdominal cavity, whose walls are yielding, is forced to accommodate a larger number of coils of intestines because of the undeveloped condition of the pelvis. The peristaltic movements are slight because muscular structure is undeveloped. The walls generally are thinner and weaker in the infant than in the adult.

Now it is well to know of these peculiarities, but the knowledge should furnish us with something better than an opportunity to nag at nature. As is very often the case, naked facts, such as are here furnished by the anatomists, have forced a false conclusion.

It is not by accident that an infant evacuates a smooth, yellow, homogeneous mass, thinner and relatively two or more times bigger by volume than the irregular sausage-shaped mass of varying color, which the adult normally passes. This difference in the character of the infant's stool is just what we should expect after considering the difference between his diet and the diet of the adult.

The infant's food is uniformly liquid, and its composition is more or less constant. Relatively the baby partakes of this more bountifully than does the adult of the long and interchangeable list of articles (liquid, semi-liquid, and solid), which goes to make up the latter's diet.

Nature is only able to perpetuate herself by conserving energy. Therefore she does not give to the infant a fully developed digestive tract, but she does give him that which is wonderfully adapted to his natural food and that which his natural food is capable of developing.

Because a great many constipated mothers have constipated babies, some have thought that they have seen another expression of hereditary influence. Constipation in the mother, however, or its causes, will produce just the changes in her milk that renders it constipating of itself. Her own baby is the one most likely to suffer, because he is the one most likely to be nursed. However, any other baby would suffer the same inconvenience on the same diet.

So far as the infant is concerned, the real causes of constipation are to be found only in the errors of hygiene or in errors of diet. Over-crowding, lack of sunshine, lack of fresh air may so interfere with the digestive processes and with the normal development of the child that irreparable injuries are produced.

The pernicious habit, not only prevalent among the poor and ignorant, but too often seen in homes where intelligence is otherwise perceptible, of so bundling and wrapping the infant with clothes that a heavy weight is placed on the abdomen and the normal exercise of limbs and abdominal muscles is prevented, is accountable for a large number of constipated babies. A too tight or resisting diaper may also be a factor in its production.

ERRORS OF DIET.

Errors of diet, to which constipation may be traced, are found in the method of feeding, in the composition of food or in both. Irregularity in the time of feeding and overfeeding usually accompany each other. The former interferes with the rhythm of the various stages of digestion, including bowel evacuation.

Distention from overfeeding materially affects bowel tone and embarrasses muscular activity. Insufficient nourishment will cause constipation immediately, by furnishing too little bulk of waste matter to supply the degree of resistance necessary to excite peristalsis; mediately by depriving the child of the necessary nutriment for development. Nourishment furnished in a too concentrated form will act very much in the same way.

Fat is normally supplied to the infant in excess of the nutritional needs proper. It is always found in considerable quantities in the normal stool and to its presence is due the soft, mushy consistency of the feces. Being nature's own laxative, it does not impair bowel tone or muscular activity, but only strengthens and develops them. A deficiency of fats in the food then will usually very promptly result in constipation.

The proteids, on the other hand, are almost all absorbed in their passage through the digestive tract. They are found in the feces in but slight quantities.

Now, if proteids are ingested in quantities much above the absorbing capacity of the bowel, the excess will form an unexpected residue. The same thing will result if the proteids are in a form illy suited to the absorbing function of the particular bowel into which they enter. In either case the residue is adventitious matter, difficult to propel, obstructing the bowel, weakening its tone, and producing constipation. If these errors of too low fat and too high proteid occur in the same milk, the result is all the more quickly evident and obstinate.

For the performance of the evacuating function a stimulus to peristalsis is necessary. Besides the fats already mentioned, this stimulus is furnished by bacterial fermentation, the acids, and the gases of the intestinal contents.

Strassburger's experiments have shown that the feces of constipation are almost free from bacteria, while normal feces abound in them. Two varieties of bacteria are constantly present in the intestinal tract of the infant. In the upper part of the small intestine the *Bacterium lactis aerogenes* is found in great numbers. It decomposes milk sugar, on which it depends for its growth, with formation of lactic acid and certain gases. As you note, these products of decomposition are some of the very forces acting as stimuli.

In the lower portion of the small intestine and throughout the large intestine, is found the *Bacillus*

coli communis, which, though depending on the secretions for its growth, when grown still further stimulates peristalsis and intestinal secretions. Ordinarily then, these bacteria are not only non-pathogenic, but are even desirable for furthering the performance of bowel functions. Because the one is directly and the other indirectly dependent on sugar for growth, a deficiency of this ingredient in food may result in constipation.

It has been found that farinaceous food will decrease the number of bacteria present, and it is as much by this property as by the residue it leaves, that this class of food has been found constipating to a great many children.

For the most part, constipation following the use of sterilized milk is due to the changes produced by heat on the proteids, whereby they are rendered less absorbable. Heat, however, produces several other changes in milk, which reinforce this constipating effect of the proteids. It changes at least a part of the sugar to caramel. It also destroys the chemical union between the mineral salts and the proteids. This union is not an arbitrary arrangement on the part of nature, but is essential to proper assimilation and distribution of those parts entering into it.

The importance of the mineral salts in furnishing constituents to the blood and in facilitating absorption, secretion and excretion is now generally accepted.

I hope that, without taxing your patience, I have entered sufficiently into the etiologic details to assist in offsetting certain misconceptions as to the gravity of the significance of the disorder and the importance of early treatment.

In the course of our care-taking of children, we are wont to be so concerned with the more distressing and imperative symptoms coincident with other digestive disturbances that we give slight, or at most secondary consideration to the more insidious, but after lapse of time, none the less undesirable digressions from the normal, which, so far as we are warned against them, have their beginning in a condition of constipation.

IMPORTANCE OF PROPER FEEDING.

For a long time text books on the diseases of children either ignored the subject entirely or gave to it only a cursory, paragraphic mention. Present writers give to it some of the space which it deserves. But that there is still no inclination to give to the subject full consideration, can not be better illustrated than by pointing out to you that in the series of papers on infant feeding, read before this section last year, not only did the subject fail to win title, but was not specifically mentioned either in the papers or in the discussion.

There is a too general impression in the professional, as well as in the lay mind, that constipation need be interfered with, not for what it stands for, but only when it produces undesirable and uncomfortable symptoms of its own.

Too often the practitioner feels that his obligation to the child ends after he has found, by accident or experiment, a food which agrees with it. In ordinary acceptance, food which agrees means no more than one which does not provoke vomiting or excite diarrhea.

In fact, so unsure of their methods, so fearful of exciting diarrhea are some who are attempting infant feeding that they regard constipation as a desirable, rather than an undesirable condition.

It goes without saying that the members of this section have a better understanding, but when we consider

the effect of what is said and of what is left unsaid here on that great body of physicians which looks in this direction for guidance, are we not, after all, responsible for their misconceptions?

We must teach that the baby must be carried, not dragged, through his infancy, and that he must be placed on the threshold of childhood in condition to enjoy his existence, which can be only after he has been furnished with all the nutriment necessary for his normal development.

Constipation does not cause rickets, nor scurvy, nor inanition, nor chronic indigestion, nor marasmus, nor anemia. Constipation, however, is the result of that which, if persisted in or allowed to be neglected, will cause one, and may cause any of these nutritional diseases. When we can gain a general recognition of the significance of constipation, preventive medicine will have taken a stride forward.

TREATMENT OF CONSTIPATION.

The treatment of constipation in the infant is then something more than the treatment of the condition itself. There is no more intelligence displayed in simply securing daily evacuations with medicinal stimulants and excitants of the bowel than there is in checking a diarrhea only to allow the absorption of the poisons producing it.

If the disorder is one resulting from unhygienic conditions, no amount of castoria or of castor oil or of nuxvomica will better those conditions in the least.

If the diet is too high in proteids, the most liberal administration of salts, of suppositories or of enemas will not lessen the percentage of those proteids by the smallest part of a fraction.

The treatment of constipation is not a difficult thing if the condition is treated early and dealt with intelligently. A knowledge of the relationship between the feces and the ingesta and of an abnormality in the first pointing to the abnormality in the latter is prerequisite. Have we the right to attempt infant feeding at all without this knowledge?

General recommendations, such as are found in some text books, for the use of cream, of oatmeal, etc., are misleading and only show how carelessly the subject has been handled by otherwise capable authors.

Rational treatment denies routine in these cases, and demands primarily the finding of the cause. The cause, when found, suggests its own correction, which is the treatment of constipation in the infant.

If, however, the condition is neglected while the child is yet a young infant, treatment becomes an altogether different and more difficult question.

Before the contents of the bowel alone were at fault, but to this has now been added changes in the bowel structure itself, which can not be corrected by simply controlling the diet. It is for such cases that medicinal treatment is necessary, but even here great caution must be observed against abuse.

If the constipation is not of very long standing, atony of the bowel may be overcome, after correcting the diet, by an endeavor to establish habit. The simplest way of accomplishing this is by holding the child at regular hours, preferably after the morning and evening bottles, on a chamber in such a posture as to favor an evacuation. For the success of this method, regularity in feeding, because it favors rhythm in the stages of digestion, is necessary. If the bowel still remains obstinate a stimulus should be given. At the same time it should be recognized that this is unnatural and foreign

and that not only must it be slight as possible, but it must be withheld at the earliest possible moment.

Because no better method presents, I frequently advise the insertion, while the child is in posture, of an ordinary clinical thermometer, well oiled and used only for the purpose. Beside its simplicity and frequent success, it impresses the mother with the foreign nature of such a stimulus and the more readily does she dispense with its use. Soap and glycerin suppositories are to be avoided if possible. Massage ought never to be practiced on the young child.

This paper is intended as a plea for the early correction of constipation and will not, therefore, outline any treatment for the neglected cases of this disorder.

DISCUSSION.

DR. THOMAS S. SOUTHWORTH, New York City, said that the first step in the treatment of constipation in infants is to understand the underlying conditions. With nursing infants, the care of the mother and the regulation of her diet are important in relation to the constipation of the child.

DR. ISAAC A. ABT, Chicago, stated that the use of over-fatted food, especially cream, which is commonly regarded as desirable in the treatment of constipation in infants, has actually been found at times to produce constipation and has led to the formation of scybala. The late Dr. Earle once made the statement that children were often constipated because the food they received was so perfectly assimilated that there was very little residue. Dr. Abt believes that constipation in infants may be due to a variety of causes. First, to the food itself; second, to the nature and quantity of the residue, and third, to a lack of muscular tone in the bowel. It may be the result of an atonic condition of any section of the bowel, or it may depend on a simple tonic constriction of the sphincter. Dr. Abt believes this is a frequent condition in infants. We have all seen cases where the mere introduction into the anus of a fever thermometer, or the point of a syringe or a bit of greased paper, has given rise to a stool of perfectly normal consistency. All that is necessary in these cases is the relaxation of the sphincter muscle.

DR. J. R. SNYDER believes that such children are underfed and that a child should have an amount of food in excess of the actual nutritional needs. The best way to determine the cause of constipation is by a close inspection of the stools. This will disclose just what the stool lacks.

PERINEPHRITIS IN CHILDREN.*

WISNER R. TOWNSEND, A.M., M.D.,
NEW YORK CITY.

The term perinephritis is used by most writers to describe an inflammation in the tissues surrounding the kidney. Schmid,¹ Prior,¹ Puky,¹ Senator¹ and Israel² would limit it to those cases where the disease originates in the fibrous sheath of the kidney. When it begins in the fat tissues they prefer the term paranephritis, except Israel, who designates such cases as epinephritis. Kuster³ limits perinephritis to an inflammation of the anterior peritoneal covering of the kidney, and calls all others paranephritis. Under paranephritis Israel classes all inflammations beginning in the retroperitoneal tissues.

This diversity of nomenclature rather tends to con-

fusion than clearness, and in this paper all cases are spoken of as perinephritis.

Perinephritis is not of frequent occurrence. Nieden,⁴ in 1897, could only find records of 166 cases. Of these, 23 were under 15 years of age, the youngest being five weeks old. Gibney,⁵ in 1876, reported 9 cases, and in 1880 increased the total to 28. The ages varied from 1½ to 15 years. In 16 there was suppuration; in 12 no suppuration. In 19 cases no cause was found; in 8 a cause was given. Fenwick,⁶ in a report on 76 cases, speaks of 4 in children under 10 years of age, and of 9 between 10 and 20 years, the youngest being 14 months old. He excluded from his list all of Gibney's cases, because none of them had been verified by postmortem findings. Kuster³ rejects 16 of Nieden's list, and adds 80 cases, making a report on 230. Of these, 24 were under 10 years of age, 17 between 10 and 20.

Johnson,⁷ in an experience of nine years in Roosevelt Hospital, saw but one case in a child, a perinephric abscess in a boy of 10, following a fall, not complicated by a kidney lesion. Israel,² in a report on 43 cases, speaks of one in a patient 12 years old. The 6 cases reported in this paper were all that were seen in children at the Hospital for the Relief of the Ruptured and Crippled, New York City, during the years 1894-1903, when 3,689 patients were treated in the indoor department, all under 14 years of age.

In no instance in the 6 cases reported from the Ruptured and Crippled Hospital was a correct diagnosis made by the attending physicians who first saw the patients, but all of them were sent to the clinic to have either spinal or hip braces applied. Gibney and others state that an erroneous diagnosis is made in over 50 per cent. of the cases seen. Only in rare instances should any difficulty arise in correctly interpreting the symptoms in a case of beginning perinephritis. After an abscess has formed the diagnosis is usually very easily made.

CLASSIFICATION.

In a consideration of perinephritis, the most simple classification is the division into primary and secondary, acute and chronic. Other classifications have been made, but they are unnecessarily elaborate. The best is that of Schmid,⁸ who speaks of direct and indirect infections, with various subdivisions.

Under primary are classed all cases where the disease originates in the tissues about the kidney, the fibrous capsule, the fatty or areolar tissue, the fascia over the quadratus lumborum or psoas, the fascia about the diaphragm or in the peritoneum in front of the kidney.

The secondary comprises all diseased conditions of these parts following or secondary to diseases in other parts of the body.

Acute and chronic are used in the ordinary acceptance of the term. Fenwick⁶ would add to the acute and chronic a latent type, to include those in which no physical signs are present pointing to suppuration near the kidney, or in which they are masked by more prominent manifestations of illness in other parts. In this class would be placed many of the pyemic cases.

ETIOLOGY.

In most instances the etiology is obscure, but in many a definite cause is supposed to exist. Exposure to cold, a strain or sprain, a blow, a wound or fall on the side, constipation, excessive exercise of any kind, jarring of the body, overexertion, simultaneous infection of the perinephric tissues with other infections are among the causes that have been held to produce primary perinephritis.

The secondary may follow infection of any part of the body, and has been seen in all forms of kidney lesion, especially in pyonephrosis, pyelitis and stone in the kidney, or after operations on the kidney, ureters, bladder or urethra. It may follow or occur in typhoid and other fevers, in pneumonia, empyema, abscess of the lung or pleurisy, after the ulceration of a stone through the gall bladder or the rupture of an echinococcus cyst, in appendicitis or inflammations of neighboring organs within the thorax or pelvis, or after injuries of the kidneys,⁹ etc. The acute cases come on suddenly, and most of the primary cases are of this character.

PATHOLOGY.

The pathology is an inflammation of the parts. Among the bacteria which may be found are staphylococci, streptococci, pneumococci, typhoid, tubercle or colon bacilli. Eighty per cent. of the primary cases end in abscess, and in the secondary an abscess is always found.

Where no abscess occurs the inflammation subsides more or less rapidly, and no trace may be left except, in occasional instances, a thickening of the part.

SYMPTOMS AND PHYSICAL SIGNS.

Symptoms.—The first symptom of primary perinephritis is usually pain, which may be very severe in character. It is most frequently felt in the region of the kidney near the vertebrae, but may be referred to the terminal filaments of the nerves and felt in the axillary line or even in front of the body. It may intermit and be mistaken for a neuralgia or lumbago, or extend downward and simulate a sciatica. Occasionally it is felt in the distribution of the anterior crural or obturator nerves. If constant it may be severe or dull in character, and pressure about the region affected generally increases it. As movements of the body tend to aggravate the pain, the spine is generally held rigid, and it is due to this fact that so many of the cases are at first mistaken for Pott's disease. A spine held stiffly often misleads the careless examiner, as the position assumed may tend to bring into prominence the spinous processes of the vertebrae, but to the careful observer this "position curve" is very different from the kyphosis of Pott's disease, the curvatures due to rhachitis or the beginning cases of rotary lateral curvature.

When psoas contraction occurs either before or after an abscess has formed or within the psoas muscle, flexion of the thigh results, and attempts to straighten the lower extremity cause pain, due to tension on this muscle, which may be referred to the hip, spine or pelvis. Very young children can not locate it definitely, and even those older are often uncertain where it is felt. This drawing up of the thigh by contraction of the psoas causes lameness and tilting of the pelvis, with consequent bending of the body to the affected

side. This accounts for these cases being mistaken for beginning hip-joint disease, and the true condition overlooked.

As the disease is of an inflammatory type, chills or rigors, followed by fever and septic temperatures, are among the first symptoms, and are often severe in character, and produce rapid depression of the vital forces. Rigors, septic temperatures and great general depressions, where a definite cause is not known, should suggest an examination for a perinephritis, even if other symptoms are absent.

Constipation is the rule, and its causation is variously ascribed to the patient's desire to avoid the pain of moving the body necessary to open the bowels, to pressure from the abscess on the intestinal tract, or to pressure on the sympathetic nerves. Diarrhea is very exceptional, and may be an early sign of pyemia. Vomiting is often present at the onset, but is of no special significance.

Examination.—A physical examination of the loins may show a dull note on percussion in the hypochondriac region over the affected area, and this is apt to increase as the abscess enlarges. The colon on the left side is in front of and on the right side to the inner side of the tumor, and over this a tympanitic percussion note may be elicited.

Abscess Formation.—With the formation of an abscess we have a tumor which may be felt, even when small, and which usually follows certain lines in coming to the surface.

It either points near the spine or in the hypochondrium or simulates a psoas abscess,¹⁰ which may be described as consisting of four parts: 1, A somewhat narrow channel at its upper part in the psoas sheath; 2, a dilated sac in the iliac fossa; 3, a constricted neck under Poupart's ligament; 4, a dilated sac in the upper part of the thigh.

All psoas abscesses do not, however, pursue this course. The matter may leave the muscle above the crest of the ilium, and tracking backward, may point in the loin (lumbar abscess); or it may point above Poupart's ligament in the inguinal region; or it may follow the course of the iliac vessels into the pelvis, and, passing through the great sacrosciatic notch, discharge itself on the back of the thigh; or it may open into the bladder or find its way into the perineum.

It may burrow upward and pass through the pleura and lungs and be discharged through a bronchus,¹¹ or burrow downward and open into the vagina or intestinal tract.

The pus may have a fecal odor without any connection existing between the abscess and the bowel, as gases in debilitated patients may pass through the bowel wall. When a perforation of the kidney has occurred, a urinary odor may be noticed in the abscess.

Urine.—The urine may be of high specific gravity, high color, and may contain albumin and casts, indications of involvement of the kidneys, such as occurs in course of inflammations in other parts of the body. It is transient in character, not a permanent kidney lesion.

Blood.—The blood count shows an increase in the leucocytes, such as is found in abscess formation in other parts, and in many inflammatory conditions. If tubercular in character, there will be no leucocytosis unless sepsis also exists.

11. Loumeau: Jour. de Med. de Bordeaux, vol. xx, No. 41.

RELATION OF AGE AND SEX TO THE DISEASE.

The disease affects the sexes in about equal proportion and the same is true of the side affected. There is no reason why bilateral perinephritis may not occur in children, but I have found no recorded cases. Secondary bilateral cases have been reported by Turner,¹² Rayer,¹ Rosenstein,³ Hitz,³ and others in adults.

DIFFERENTIAL DIAGNOSIS.

The most common errors are to mistake perinephritis for beginning osteitis of the spine, Pott's disease, osteitis of the hip or hip-joint disease, or for acute osteomyelitis of the vertebrae. The absence of kyphosis, the rapid onset, the location of the pain, the rapid formation of abscess, high leucocyte count, with high temperatures, are symptoms rarely found in beginning Pott's disease, and the differential diagnosis is rarely difficult.

In hip-joint disease all motions are limited, in perinephritis only extension, and all are possible if the thigh is flexed. In hip-joint disease there is atrophy of the hip. An abscess rarely occurs in early stages, but if present, it is apt to be near the joint, not near the spine. The onset of hip-joint disease is usually slow, and the first symptom is generally lameness, the leucocyte count is not increased until suppuration occurs, and pain is apt to be referred to the knee or hip. In but rare instances will any difficulty be found in making a proper diagnosis.

From psoriasis in some cases a positive diagnosis can not be made. The principal points to remember are that psoriasis is more rare, abscess is infrequent, pain is apt to extend along the course of the psoas and iliacus and to be felt in front rather than behind, and that psoas contraction or thigh flexion is a very early symptom. Undoubtedly some of the reported primary cases of perinephritis where no suppuration occurs are cases of psoriasis, although suppuration may occur in inflammation of muscle.

In acute infectious osteomyelitis of the vertebrae, the pain is felt in the spine, most severely in the affected area, with local spinal tenderness. The last symptom is of great value, and is absent in perinephritis. With involvement of the nerve root within the spinal canal, we have lancinating pains which extend in front. These are usually more severe than the pain in perinephritis, but this symptom may be misleading. Dural symptoms may appear early, and pressure on the cord cause compression symptoms. These are absent in perinephritis. The septic symptoms would be the same in both.

The abscess tumor may be mistaken for an enlarged spleen, liver or kidney, or for an aneurism or appendicitis, but proper study of the symptoms will rarely leave one in doubt as to the true condition that exists.

The treatment should be based on the conditions present. If seen early, rest in bed, tonics, laxatives and mild stimulation are indicated. If an abscess is present, prompt surgical interference is demanded. Failure to promptly open a collection of pus may mean death from sepsis or burrowing into other parts, with formation of sinuses and long delay in recovery and serious complications.

A study of the reported cases in the literature clearly shows that the tedious convalescence, the formation of abscesses in other parts secondary to the perinephritis and the deaths were largely due to failure in making an

early diagnosis and to indefinite surgical procedures after the diagnosis had been made.

In the cases treated at the Hospital for Ruptured and Crippled Children, no deaths have occurred. In primary perinephritis the death rate should be very low, if cases are properly treated; in secondary it will depend on the primary site of and character of the infection.

Watson⁹ found perinephritic abscess the cause of death in 56 of 81 fatal cases of subparietal injury to the kidney treated expectantly, but in 99 uncomplicated cases treated by operation other than nephrectomy, in 21 cases of perinephritis there was but one death. The cause of perinephritis and the treatment both influence the mortality rate.

REPORT OF CASES.

CASE 1.—Male, aged 13; admitted to hospital Nov. 27, 1903. Family history negative. Was perfectly well up to two weeks ago.

History.—In July he had a chair pulled from under him, slightly injuring his back, but he fully recovered. In September he fell from a bicycle, but did not hurt himself. Two weeks before admission he lifted a heavy box and the next day suffered intense pain in the back and had a chill. The pain was excruciating and paroxysmal in character and confined to the right side of the spine. About a week later it extended downward toward the hip and was felt in front of the abdomen. He was constipated and the bowels were finally moved by the use of salts. After the chill he had fever, and three days later was delirious. A physician who was called at this time was unable to make a diagnosis, but pronounced it hip joint disease when one week after onset the thigh became flexed and was held constantly in that position. After the first few days vomiting was present and persisted, until after admission to the hospital. Boy lost flesh rapidly and had a daily chill and fever for over two weeks.

Examination.—On admission, rectal temperature was 101 degrees, pulse 88, respirations 18. He was pale and evidently suffering pain. The right thigh was flexed on the abdomen; extension beyond 90 degrees was impossible. No disease of hip or spine made out. Deep pressure in region of kidney caused pain.

Urine amber color. Sp. gr. 1020. No sugar or albumin. Abdomen retracted, no signs of peritonitis. Leucocyte count 14,000.

Treatment.—Treatment was rest in bed and milk diet.

Result.—Symptoms gradually subsided. Leucocyte count December 5 was 7,500. Flexion of thigh had disappeared, and on December 12 he was discharged cured.

Feb. 15, 1904, he was seen in the out-patient department and was perfectly well; could walk or run as any other boy, and was gaining flesh rapidly.

CASE 2.—Male; aged 6½; admitted to hospital July 22, 1903. Family history negative. Has had none of the diseases of childhood.

History.—Was perfectly well until one week before admission, when he complained of pain in the left side, very severe in character and worse at night. No cause known. Had chills, followed by fever; lost flesh; appetite failed. The family physician first made a diagnosis of malaria, then of hip disease, and sent the patient to the hospital for a brace.

Examination.—Examination on admission showed general condition poor; rectal temperature, 102.8 degrees. A large, fluctuating tumor was easily made out in the lumbar region, presenting two inches to the left of the spine, midway between the crest of the ilium and the last rib.

Treatment.—Abscess was opened, careful examination made and no disease of spine was found.

Result.—August 19, discharged cured. February 14, 1904, seen at his home; was perfectly well.

CASE 3.—Male; aged 11 years; admitted to hospital, Oct. 29, 1902. Family history negative.

History.—The first symptom noticed was pain in the back near the spine; the child held himself bent over when he walked. He lost weight and had chills, followed by fever. No cause known. The family physician made a diagnosis of hip disease and sent him to the hospital for a brace.

Examination.—Examination on admission showed boy in poor physical condition. The left thigh was flexed on the abdomen, and could not be extended beyond 90 degrees. No evidence of disease of spine or hip. In left ilioacostal space a fluctuating tumor was easily made out.

Treatment.—This was opened, drained, and patient was discharged cured on November 24. February 15, 1904, seen at his home; was perfectly well.

CASE 4.—Female; aged 6 years; admitted to hospital Nov. 12, 1903. For two weeks prior to admission she had pain in the back, with chills, followed by fever. No known cause. The family physician sent the child to the hospital for a brace for Pott's disease.

Examination.—On admission the rectal temperature was 104 degrees; there was incontinence of urine, sensitiveness to pressure in the right lumbar region, marked stiffness of the lumbar spine. Pain was increased when the child bent to either side. Bowels regular; no tumor felt.

Two days later the parents removed the child from the hospital. At that time the temperature was lower and the general condition improved.

February 12, 1904. Seen at her home and condition found to be perfect.

CASE 5.—Female; aged 3; seen in out-patient department Sept. 27, 1901.

History.—For two weeks had been complaining of pain in the back and walked lame. No cause known. Had chill, followed by fever.

Examination.—A fluctuating tumor was found to the left of the spine in the lumbar region; marked psoas contraction; thigh held flexed on abdomen; constipation; passes but small quantities of urine daily. Temperature in axilla 100 degrees.

Treatment.—Three days later at the hospital the abscess was opened, and one month later entirely healed. Feb. 15, 1904. Seen at home; perfectly well.

CASE 6.—Female; aged 5 years; admitted to hospital Dec. 5, 1898.

History.—In July she was run over by a wagon, but the superficial wounds healed, and she was apparently well, but two months ago she began to get lame.

Examination.—General condition was poor; abdomen prominent, also third and fourth lumbar vertebrae. Muscular spasm and rigid spine. Distinct abscess was found in the right pelvis, psoas contraction; thigh flexed on abdomen.

Treatment.—December 18, aspirated, and two ounces of greenish pus were withdrawn; December 22, aspirated and seven ounces withdrawn. Temperature, 100 to 102 degrees.

December 26, abscess was opened, and on Jan. 17, 1899, a counter opening was made between the ribs and pelvis and free drainage established between this and the opening in front.

Dec. 26, 1899. Posterior opening was closed; one into the pelvis in front still discharging.¹³

DISCUSSION.

DR. R. B. GILBERT, Louisville, mentioned two cases in which this condition was mistaken for disease of the vertebra, and said that the knowledge of the facts in regard to perinephritis in children should aid in the diagnosis of this condition, which is so frequently overlooked.

DR. A. JACOBI, New York City, considered that Dr. Townsend did not lay sufficient stress on the possibility of constipation being a cause of the condition in children, just as it is in the adult. It is due, not so much to the pressure produced by the dilated colon, but to the stagnation of the feces, producing inflammation of the colon and subsequent infection. Dr. Jacobi has no doubt that in the adult Dr. Townsend has seen many

just such cases. In some cases that have come under Dr. Jacobi's observation, obstinate constipation of many years' duration was the cause, or one of the causes, of the perinephritis. He could only recall four cases of this condition in young children, two in children perhaps 2 or 3 years old, the other two in older children. In the latter cases the perinephritis was on the right side; in the younger children on the left side. Constipation takes place in very young babies particularly about the left curvature, just in or above the sigmoid flexure; particularly in those which he has described as "congenital constipation," which depends on an exorbitant length of the sigmoid flexure. In older children, in whom the ascending colon is longer than in the newly born, the constipation may take place in the right curvature, and this happened in the cases that came under his observation.

DR. W. R. TOWNSEND said that he had recently seen two cases of perinephritic abscess in children and both had been mistaken for hip-joint disease.

Clinical Notes.

RESPIRATORY PITCH.

A. J. STEVENS, M.D.

MALDEN, MASS.

Those who write their opinions on medical subjects, unsupported by reasons or experiments which can be put to the proof by any competent person, and those who write the "one consecutive case" articles may usually be considered bores. My justification for asking a hearing is based on something more definite than personal opinion, something which can be confirmed by evidence sufficient to prove a case in the courts. As a preliminary I will ask the reader's indulgence in the relation of a personal experience which may have a certain value to those interested in auscultation.

Thirty-six years ago the teaching as to the pitch of respiratory sounds was the same as that of to-day. At that time it was my privilege to receive instruction in auscultation under a talented pupil of Dr. Austin Flint. Through personal experience of pulmonary disease my interest in becoming expert was great, but my first experience as a pupil was discouraging. The current teaching as to pitch did not coincide with the evidence of my ear.

After referring to my instructor a number of patients in whose chests the expiratory sounds were lower than the inspiratory, and being told that I was in error, I feared for some time that my peculiarity would be fatal to proficiency as a diagnostician in pulmonary diseases. I had confidence in my ability to detect slight differences in pitch, but that confidence did not carry me to the extent of setting up an unsupported opinion against that of the experts in the profession. After many discouraging attempts to master the subject, I learned that ability to detect morbid sounds was not lessened by inability to define the pitch in the terms of the accepted authorities.

After thirty-five years, in which auscultation has been practiced daily, and the correctness of early impressions in this particular have been confirmed, it is a satisfaction to read what Dr. Quimby stated in his paper in THE JOURNAL, Oct. 1, 1904. The following evidence is worth considering, and any physician can multiply the tests to any desired extent on the same lines. Musicians use the term "positive pitch" to designate a faculty which seems incredible to one who does not possess it. Those persons who have it can, unaided by any sense except that of hearing, name any note sounded on a piano. The evidence of persons having "positive pitch" should have great weight in settling the question of the pitch of respiratory sounds.

Several of my patients and friends have this faculty, and having tested their ability to hear and describe the sounds heard through a stethoscope placed over the trachea and also over different parts of the chest, and finding their evidence unanimous, that inspiration is of higher pitch than expiration, it seems to me that an unbiased jury would render a verdict in

13. Since the above was written the author has seen two additional cases in children of 3 and 4 years of age, one mistaken for hip-joint disease, the other for spinal disease. Abscesses were opened and drained and both cases made perfect recoveries.

accordance with the evidence, without hesitation. Doubtless many physicians are proficient in auscultation whose sense of hearing would not enable them, either from natural defects or erroneous training, to decide this question correctly. A better foundation can be laid on truth than on error, and more men will become expert in auscultation when to every factor is assigned its correct position and value than when an error complicates the problem. It would seem that a correct settlement of this question is not only of interest but of importance, and that it may be settled to the satisfaction of all by the kind of expert testimony cited.

RHEUMATISM TREATED BY VENESECTION AND HYPODERMICOLYSIS.

C. G. HARRIS, M.D.
FESTUS, MO.

A man, aged 26, English, bricklayer by occupation, has had rheumatism at varying intervals since he was 15 years old. His father is in good health, but drinks a good deal. Mother is extremely "nervous." The patient complained of lameness and rheumatic pains which had persisted for the last four months. The right shoulder, wrist, knee and ankle joints were swollen and painful. Temperature was 103, pulse 96. His tongue was heavily coated and his breath bad. He complained of headache. The urine was of dark red color, high specific gravity and acid in reaction. Calomel and saline cathartics were given to clean out the intestinal tract. As the usual anti-rheumatic remedies failed to give relief and anodynes seemed to have no effect on the pain, venesection was performed and about twelve ounces of blood were withdrawn. Following this, two pints of normal salt solution were injected beneath the skin of the breasts. All pain (except a slight soreness) had disappeared in less than two hours. Temperature dropped to normal and pulse to 80. Two hours later the pulse was 72. Recovery was uneventful and so far (four months later) there has been no recurrence.

New Appliances.

A SUPPORT FOR PATIENTS SUFFERING WITH WEAKNESS AND PAIN AFTER THE ARREST OF TUBERCULOSIS OF THE SPINE.

JOHN JOSEPH NUTT, M.D.

Assistant Attending Surgeon, Orthopedic Department of Cornell Dispensary,
NEW YORK CITY.

The relief from weakness and pain, which sometimes remain persistently after all the acute symptoms of tuberculosis of the spine have disappeared, may severely tax the ingenuity and skill of the orthopedist. Because of this fact, this apparatus is presented with the hope that it may be of value to the profession. No originality is claimed, except for the ensemble of its parts, which are taken from well-known braces and applied to a leather corset. This combination, however, proved so serviceable in this instance that others may profit by copying it, in whole or in part.

Patient.—S. F., aged 27, of Caracas, Venezuela, had developed Pott's disease during early childhood. Until his tenth year he was so weak and sickly that he was not expected to live. He then began to improve, and for the following eight or ten years enjoyed comparatively good health.

History.—During the past ten years he has suffered a great deal from pain and weakness, and three years ago he was forced to give up every form of exercise. After several months in bed he gained enough strength to sit up and walk about to a limited extent. The actual canterly had been applied at frequent intervals during the last year and gave slight but temporary relief from the pain. He had also been placed in a Sayre's suspensory apparatus a number of times last winter; with just what object is not known.

Examination.—Physical examination showed a most pronounced kyphos in the lower dorsal region. No symptoms of an acute process could be found, although it seems highly probable that there had been an exacerbation of the disease about three years ago. The heart and lungs appeared to be normal.

Figure 1.

Figure 2.

He came to New York because he still suffered from pain and weakness. The pain was felt on either side of the kyphos and along the costal borders, especially the right. This pain was not usually present while lying down, but became more marked the longer the time he remained in an erect position. He could

walk but a few moments without being compelled to rest, and even standing quickly fatigued him.

Diagnosis.—A diagnosis was made of intercostal neuralgia and weakness from deformity. It seems probable that the vertebrae, though ankylosed, had been too far disintegrated to form a spine of sufficient strength to support the well-developed shoulders and chest.

Treatment.—A plaster-of-paris jacket was applied with the patient in extension, and, by giving some relief, gave encouragement. A stronger plaster was then applied, but did not fill all the indications. After considerable study and experiment-

Figure 3.

ing, the apparatus here shown was devised and applied. (Figs. 1 and 2.) The patient wore it to St. Louis on a visit to the Fair, and on his return pronounced it very successful.

He had been able to walk about for several hours at a time without once sitting down. Except for a slight change in the leather beneath one shoulder, no alterations were made.

As it was difficult to get sufficient leverage to obtain the necessary support, the crossed straps were used extending from the ends of the pelvic band to the upper part of the crutch on the opposite side. (Fig. 3.)

A NEW INHALER FOR NITROUS OXID ETHER SERIES.*

SAMUEL IGLAUER, B.S., M.D.
CINCINNATI.

Purpose.—The advantages of nitrous oxid as a preliminary to ether are well known and require no particular commendation. Suffice it to say that nitrous oxid followed by ether combines the elements of safety, rapid and pleasant narcosis, avoidance of the stage of struggling and excitement, and a great reduction of the quantity of ether necessary for the induction and continuation of the anesthesia. Various apparatus have been devised for this series. Many, however, are rather cumbersome, complicated and expensive.

Construction.—The inhaler which I have devised for the administration of nitrous oxid and ether consists of a closed metallic face-piece, provided with an inflatable rubber cushion, accurately fitting it to the patient's face. On top of the face-piece is a detachable glass and metal ether-container, from which a visible supply of ether may be fed in definite quantities as desired. (Modification of Brown's ether container.) Within the face-piece is a wire basket for the gauze, on which the ether is allowed to flow.

An L tube telescopes at one end with the face-piece. To the other end of the tube is attached a large rubber bag for the nitrous oxid gas. To prevent the gas from escaping until de-

sired, the tube contains an obturator valve, controlled by a small lever, which projects through the air slot in the tube. This is the only valve in the apparatus, and acts simply as a cut-off.

A large ring for the thumb enables the anesthetist to hold the face-piece, and to support the angle of the patient's jaw with one hand. On the side of the face-piece are two openings, through which air may be admitted or ether poured, if desired. If the ether-container be removed, the ether may be poured from a bottle, directly on the gauze.

Use.—To use the inhaler, first, loosely fill the wire basket with gauze.

Second, fill the ether-container with ether (about one ounce).

Third, inflate the gas bag with nitrous oxid from a cylinder containing the gas. (This cylinder must have key, yoke and tubing, which may be obtained at any supply house.)

Fourth, apply the inhaler to the patient's face and instruct him to breathe through the mouth. Admit air through the air slot, until the breathing is regular and the patient reassured.

Fifth, now turn the lever freeing the gas and shutting off the air. Allow the patient to breathe the gas back and forth into the bag. In about forty to sixty seconds nitrous oxid narcosis will ensue.

Sixth, at this time allow from two to three drams of ether to flow on the gauze. The patient now breathes a mixture of nitrous oxid, ether and carbon dioxide from his own lungs.

Seventh, admit a breath or two of air if the patient becomes cyanosed or if the breathing is stertorous.

Eighth, allow ether to flow on the gauze from time to time until ether anesthesia is established. This usually requires three minutes.

Ninth, remove the large rubber bag and slide on the smaller one (provided with the outfit), continuing the anesthesia with the closed or Clover method, air being admitted from time to time as necessary. By removing the bag we can change to the open method if desired.

For the administration of nitrous oxid alone the inhaler is provided with a three-way valve, modified after Goldan's. The inhaler may be used for ethyl chlorid by closing all the vents except one, through which ethyl chlorid may be sprayed on the gauze. For ethyl bromid, all vents are closed, and after pouring the bromid directly on the gauze, the inhaler is applied to the patient's face until anesthesia ensues.

The inhaler combines the qualities of lightness, compactness, convertibility with simple construction. The metal parts may be sterilized by boiling, while the rubber parts are best cleansed with alcohol.

* Demonstrated before the Section on Surgery and Anatomy at the Fifty-fifth Annual Session of the American Medical Association, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

CHEMISTRY OF AMYLOID.

Before the era of aseptic surgery, amyloid disease was one of the commonest conditions met with by hospital physicians and surgeons, but now that chronic suppuration has become rare, the frequency of amyloid has been greatly diminished. Still, one sees it occasionally, especially in old syphilitic cases, or in connection with advanced tuberculosis; the clinician recognizes the enlarged liver and spleen, and looks for the characteristic pale urine with its large amount of albumin; the pathologist, even more frequently, demonstrates the presence of amyloid at autopsy, finding the waxy liver and the sago spleen, or, in sections, using the iodine reaction or the methyl-violet test.

Since its discovery by Virchow, amyloid has been an ever-interesting puzzle to medical men, and there have been many speculations as to its origin and nature. On account of the iodine reaction which it yields, Virchow was inclined to regard it as a carbohydrate, looking on it as a sort of animal cellulose, but analyses, at first crude (Friederich and Kekulé, C. Schmidt), but later more exact (Kühne and Rudneff, Modrzejewski), have demonstrated that amyloid is more of the nature of an albuminous substance. Oddi's discovery in 1894 that amyloid contains chondroitin-sulphuric acid, a substance known to be an important constituent of cartilage, and Krakow's proof of the firm union of this acid with the albuminous part of the amyloid molecule, probably in the form of an ester, led many to hope that the question of amyloid formation might be quickly solved. It seemed rational to suppose that a general metabolic disturbance, causing the cachexia and marasmus preceding the amyloid degeneration, resulted in the transportation of chondroitin-sulphuric acid into the diseased organs, where it accumulated, irritated the tissues and caused the formation of amyloid. Experiments (Oddi, Kettner) undertaken in support of this hypothesis yielded, however, entirely negative results, and there would seem, therefore, much more to be expected from a study of the albuminous part of the amyloid molecule, especially as the chondroitin-sulphuric acid component is relatively small. Unfortunately, up to this year we have remained practically ignorant of the essential nature of the albuminous part of amyloid, the only observations earlier made having been those of Modrzejewski, through which the presence of leucin and tyrosin in the molecule was made probable.

In view of the great progress now being made in albumin chemistry, thanks to the initiative of men like Kossel, Fischer and Hofmeister, it is not surprising that attention has recently been redirected to the structure of the albuminous part of amyloid. Neuberg, in Orth's laboratory, has carefully examined purified amyloid by the most modern methods, and has arrived at some highly important and interesting results. The details of the research are chemically too abstruse to be presented to the average medical reader, but the general results must be interesting to all. To put these most briefly, it may be said that Neuberg has shown that amyloid varies in constitution according to its origin; that it belongs to the more basic albumin bodies, being very rich in diamino-groups and relatively poor in monamino-nitrogen; that it is absorbable; that contrary to the views of Herxheimer and of Schrötter, it is chemically as different from fibrin and elastin as it conceivably could be; that, in opposition to Tschermak's opinion, it is far removed in constitution from the ordinary body-albumins; and, finally, that it resembles most closely in the analytic figures and in its internal constitution that particular group of albumin bodies known as histones.

We are justified in believing, as a result of Neuberg's investigations, that amyloid results from the transformation of albumins in the body in the way that more acid molecules are transformed into more basic ones through the introduction, gradually, perhaps, of an increasing number of diamino-groups. Just as there is, as Miescher demonstrated, a gradual increase in the basic properties of the albumins in the developing testicle with culmination in those very basic substances, the protamins, so a somewhat similar metamorphosis may, Neuberg thinks, under certain pathologic conditions, lead, in the liver, spleen and kidney, to the formation of amyloid.

These results are, of course, still very far from clearing up the obscure questions connected with the origin of amyloid. They do represent, however, a good step forward in our knowledge of its nature, for, though hydrolysis indicates that the amyloid molecule is far more complex than that of a relatively simple protamin, it seems likely that a "protamin nucleus" occupies a very dominant position in it. It is now highly desirable that those who have the opportunity to do so should examine different amyloids varying in their age and origin, with the hope of gaining an insight into the exact stages of metamorphosis through which the albumins from which amyloid arises pass.

BORIC ACID AS A FOOD PRESERVATIVE.

At the meeting of the New York Academy of Medicine, held November 17, Dr. H. W. Wiley, the chief of the Bureau of Chemistry of the United States Department of Agriculture, made a formal preliminary re-

1. Neuberg, C.: Ueber Amyloid. *Verhandl. d. Deutschen pathol. Gesellsch.*, Jahrg. 1904, No. 1, pp. 19-32.

port with regard to the effect of boric acid and borax when used as preservatives in food. So much has been said in the newspapers pro and con on this subject that it is very interesting to have the definite results of the government investigation given by the investigator in charge. The report is a model of judicious and temperate weighing of the elements of a difficult problem, and the conclusions are not emphasized, but rather suggested. They are eminently calculated to do honor to those who have had the investigation in charge, and will doubtless prove definite landmarks in our knowledge of this extremely important subject.

According to the German investigators, borax and boric acid, given in large doses, always cause severe nausea and vomiting, and their use is followed by great depression, and, of course, by loss of weight and strength. Such marked effects were not found by the American investigators, either when the boron derivatives were given in large doses over short periods, or in small doses over long periods. Dr. Wiley points out one possibly important reason for this difference of opinion, in the fact that the German investigators were asked to make their studies with the definite purpose of justifying the German Government in certain legal measures that had already been enacted, for the exclusion from Germany of foodstuffs preserved by means of boron compounds. The problem is not so easy of solution as might seem at first sight, and the bias inevitably created in the investigator's mind by the previous action of his government would undoubtedly prove sufficient to turn the scale of judgment and vitiate the value of his experimental conclusions.

The main results that were found were first an inhibition of the elimination of nitrogen; that is, the men under observation who were taking boric products excreted less nitrogenous material than they did while taking the same amount of food of the same nature, in a preliminary set of observations, before the administration of these substances was begun. In a word, the boron derivatives prevent the tissues of the body from breaking down, and so prevent them from keeping in that renewed youthful condition which the frequent reproduction of cellular tissues insures. If all the tissues can be kept young, then there is no senility. If worn-out tissues are prevented from breaking down, however, then senile change is advancing. Hence the use of these food preservatives can not be otherwise than inimical to health. On the other hand, more phosphoric acid is excreted than is normal for the amount and character of food taken. This means that the bones are being disintegrated.

A very interesting phase of the investigation was that which showed that wherever albumin, not nephritic but physiologic, was present in the urine of the individuals on whom the observations were made before the ingestion of boron products was begun, it was increased to a notable degree during the time of administration. A curious commentary on this is the fact

that the boric acid and borax are excreted, not through the feces, as might be expected, but almost entirely through the kidneys. At least 80 per cent. of the amount ingested can be found in the urine, while the remaining 20 per cent. is excreted in the perspiration.

In the discussion it was pointed out that in recent years there has been a marked increase in the number of cases of nephritis in this country, and that it is not at all unlikely that the free use of such preservatives in food has been an important factor in this sad state of affairs. Certain it is that with the strain that is put on the kidneys by the tendency, so marked in modern life, to overeat, especially of nitrogenous material, the extra effort required for the excretion of such foreign materials as the boron compounds is likely to work serious harm if continued over long periods.

The conclusions, then, while not absolute, are very definite. All metabolism is disturbed by the constant use of such food preservatives. All the individuals experimented on lost weight. As was pointed out in the discussion, small doses of boric acid constitute one of the best antifatals that we have, and the only one that has sustained its reputation in the hands of conservative observers. To permit its general use, then, is to invite evil. While it is not a serious poison, it is a dangerous substance. Laws should be so constructed that all food materials in which such preservatives are employed must bear a label to that effect. There may very well be times when the slight danger involved in the temporary use of such preserved foods may be preferable to the greater risk of consuming food materials that have begun to spoil. Consumers must be allowed to choose for themselves in this matter. Physicians, however, must certainly take the side that it is better to avoid such suspicious substances than to run the risk of metabolic disturbances, with possible nephritis at the end, that may follow their prolonged use.

THE PROPHYLAXIS OF MALARIA.

Since it has been demonstrated that the malarial fevers are due to an animal parasite transmitted from one person to another through the intermediation of certain mosquitoes, it can be comprehended that the only connection between malaria and bad air resides in the fact that emanations from decomposing vegetable matter take place under conditions that favor the propagation of the intermediating mosquito. In view of the facts as they have been demonstrated, it should be scarcely, if at all, more difficult to eradicate malaria than it has been possible so to do with yellow fever in Havana. Indeed, the task should be even simpler, inasmuch as in quinin we possess a specific remedy against the disease that has also considerable prophylactic value.

The means of prevention based on the known facts must consist (1) in the vigorous treatment of all individuals suffering from malarial fevers, thus eliminating sources of infection; (2) in destruction of the parasite-

bearing mosquitoes; and (3) in case of failure to destroy the mosquitoes, in protecting healthy persons from their bites. A most interesting discussion on this subject was held in the Section of Tropical Diseases at the meeting of the British Medical Association, recently held at Oxford, and was participated in by a number of experts, who spoke authoritatively from personal observation.

Dr. J. W. W. Stephens¹ laid emphasis on the fact that only certain species of anopheles acted as the intermediate host and carrier of the malarial parasite, and that the species varied in different localities. In conformity with this fact, the measures to be employed for the eradication of the breeding places of the pathogenic mosquito will vary in accordance with the species and its individual habits. In contradiction of a somewhat prevalent fallacy Stephens and Christopher found that the normal flight of anopheles is a matter of only some hundred yards and not miles; and the intensity of infection and the danger therefrom grow gradually less as the distance from the breeding grounds increases, disappearing ordinarily at a distance of about one mile.

The methods of prophylaxis to be enforced are (1) antilarval; (2) mechanical; (3) medicinal, and (4) segregatory. The first consists in systematic drainage, as a result of which the breeding places of the larvæ are removed. Petrolage, or the covering of the surface of collections of water with petroleum, can be considered only as a temporary expedient and not as an ultimate means of eradication. Mechanical prophylaxis consists in the use of wire screens, mosquito netting, veils, gloves and similar means of preventing the access of mosquitoes to both the sick and the healthy. Medicinal prophylaxis consists in the administration of quinin in suitable dosage to individuals exposed to the danger of infection with malaria. Finally, separation of the sick from the well has been recommended in tropical countries, with the object of avoiding such exposure.

Only by the intelligent application of the foregoing measures is it possible to diminish on any large scale the prevalence of the malarial fevers and evidence is not wanting of their practical efficacy.

THE FUNCTION OF THE CECUM AND APPENDIX.

The large amount of study which has been applied to the vermiform appendix in the last ten years has had to do, in the main, with the surgical aspects of this organ. It is true that the widespread recognition of the importance of this structure in human pathology has led to a restudy of its anatomy and pathology, but the physiology has been greatly neglected. In his recent Huxley Lecture Macewen² calls attention to these facts: He states that, as a rule, the appendix is de-

scribed as a rudimentary organ, and that some writers regard even the cecum as a useless inheritance derived from our prehistoric ancestors. He comments on the modern tendency to regard organs whose functions we do not fully understand as useless organs, and the resulting idea that it is of benefit to remove such organs, even when not diseased, when they are exposed by operations done for other purposes. He suggests the improbability that Nature has constructed our bodies so faultily that it is necessary for us to patch and trim them, as is often suggested and occasionally done. He then attempts to show that the cecum and appendix have useful functions, and are not the useless structures that the appendectomaniacs would have us believe.

He considers the subject first from the comparative view-point, and shows that the relative importance of the stomach and the cecum in the digestive process is determined by the kind of food on which the animal lives. In carnivorous birds and animals, most of the work of digestion is done by the stomach, and the cecum is small or rudimentary; in herbivora, on the other hand, the cecum is enormously developed, and in certain species, the solipeds, the cecum is the chief digestive organ. This suggests, Macewen states, that man, who is both carnivorous and herbivorous, should possess not only a stomach, but also a cecum, and this is indeed the case. The relatively small size of the cecum in man can be explained by the fact that the vegetables which he consumes are soft and relatively easily digested.

Observations on human beings which bear on the function of the cecum and appendix have been obtained as a result of injury or of operation, and are necessarily somewhat fragmentary. The effects of fecal fistulæ occurring at various levels in the intestines have shown in a general way that the nearer a fistula is to the stomach the more pronounced are the symptoms of malnutrition. Where a fecal fistula is situated just above or in the cecum, provided in the latter case that the opening be large, a certain amount of interference with nutrition results. In patients in whom the cecum has been removed the digestive processes are practically never normal, and all of these cases have to live on a special diet. In the few cases in which an opening in the cecum has existed which was large enough to allow of easy inspection, certain interesting occurrences have been observed. It has been noted that certain definite movements occur in the cecum as a result of stimulation by food, and it has also been noted that one or two hours after the introduction of food into the stomach there is a considerable secretion of mucus by both the cecum and the appendix. Then, too, it has been noted in such cases that the ileocecal valve allows only the intermittent passage of the chyme, a circumstance which would favor its admixture with the cecal and appendiceal secretions. Anatomically, the situation of the valve opening just above the appendiceal opening, the dependent situation of the cecum, and

1. British Med. Jour., Sept. 17, 1904, p. 629.

2. *Ibid.*, Oct. 8, 1904.

the presence of large numbers of follicles of Lieberkühn in the cecum and appendix, all speak for something more than a mere mechanical action.

The bearing of these facts on appendicitis Macewen merely touches on, and in this part of his paper he really brings out nothing which we had not already learned empirically. The relation of appendicitis to digestive disturbances and the preventive measures which logically suggest themselves were already sufficiently obvious. The first part of the paper, however, is very suggestive, and should be read by the surgeons and gynecologists, and especially by those who advocate removal of the normal appendix, whenever an opportunity offers.

MEDICINE AS APPLIED SCIENCE.

It can scarcely be too often emphasized that the science of medicine consists almost entirely of applications of the principles and methods of other sciences, natural and mental, to the study of disease. The principles of natural science, especially, form the skeleton on which the great masses of medical facts are hung. Medical men sometimes forget that it is the methods of physics and chemistry that they are using every day, and that it can scarcely be otherwise in their work. Everyone knows, when he stops to think of it, that physics and chemistry are more fundamental or basal sciences than biology, just as mathematics is a science more fundamental than physics.

The ophthalmologist, fitting a pair of spectacles or examining a fundus, and the microscopist, making his observations through the wonderful instruments with which we are familiar, have to be reminded that their work is largely applied optics. The clinician percussing the chest or listening to the sounds of the heart, is seldom conscious that he is working in the field of applied acoustics; nor does he realize that he is performing a simple experiment in hydrostatics when he makes a blood-pressure reading, or that he is making a physical measurement when he takes a patient's temperature. Analyses of the urine and stomach juice are now such distinctly medical operations that their relations to purely chemical procedures are often lost sight of. In an applied science, such as medicine, except that part of it which deals with problems of coordination, which wholly is, the applications have to be made from sciences which are more fundamental, more nearly primary or elementary, more all-inclusive, and these are, in progressively more fundamental sequence, biology, chemistry, physics, geometry, mathematics, and, finally, that wider conception, the science of manifoldness.

Considering the origin of "their own methods," one would scarcely expect physicians to deplore the recommendation of new lines of research by biologists, physicists and chemists. But they sometimes do, and the explanation probably lies in the fact that the practical

man is pre-eminently conservative in his tendencies. He is seldom the first to try new methods or to cast aside old ones; so far as the practical man is concerned, Pope's famous lines need scarcely have been written. Farmers were a long time giving up the sickle to welcome the reaper; printers have resisted for an unconscionable period the introduction of the linotype machine. Manufacturers fought the principle of "community of interest" until they were forced to accept it; engineers preferred the training of apprenticeship until the graduates of the technical schools began to capture all the prizes in the shape of advanced positions. Should anything arise which would discourage work along biologic, chemical and physical lines in medicine, so that no new applications of these sciences would be attempted, it would be interesting to know whence the streams of medical research could take their spring. A war between medicine on the one side and biology, physics and chemistry on the other would be impious in its nature; the fifth commandment of the decalogue would be definitely disobeyed.

THE ACTION OF THE X-RAYS IN LEUKEMIA.

Our attention has been called to the editorial under the above title, which appeared in these columns November 12, to the effect that it carried the impression that the Senn case was the first one recorded. We lost sight of the earlier recorded cases to which Dr. Pusey called attention in *THE JOURNAL*, July 23, 1904. We refer to this error on our part so that it may not be repeated by others who may take our editorial statement as correct.

UNCORRECTABLE MISTAKES.

It seems to us rather a curious decision or opinion of the attorney general of Iowa that a medical certificate obtained through misapprehension can not be revoked. A certain osteopath received a certificate from the Board of Medical Examiners while the board was under the impression that the institution from which he obtained his diploma was one of those recognized by the board. When the mistake was discovered it was proposed to revoke the certificate, but the power to do so was denied by the attorney general. The case will probably be a warning to other boards to scrutinize credentials, especially in this class of cases.

MYOCARDITIS IN CHILDHOOD.

Inflammatory and degenerative processes involving the myocardium are generally thought of in connection with mature or advanced life, but when it is considered that the muscular wall of the heart may be affected in the course of various infective disorders it will be clear that the conditions referred to may occur likewise in children, although often the underlying cause may remain obscure. Attention has been called to this matter by Dr. George Carpenter,¹ who has recently reported a case in which uncomplicated myocarditis developed in a

girl in her eighth year and was attended with signs of cardiac failure and terminated fatally. No etiologic factor could definitely be ascertained, although it was suspected that the condition had succeeded on an unrecognized diphtheria. The child presented a cyanotic appearance. The pulse was weak at the wrist and the first sound of the heart was not good, while the second at the left base was accentuated. The urine contained a large amount of albumin. Death resulted and post-mortem examination disclosed the existence of fatty degeneration of the myocardium.

A PHYSICIAN WITHSTANDS A MOB.

It is refreshing to learn that a Georgia physician is by himself alone more effective than a whole company of militia in foiling a lot of would-be hangmen. His conduct is in notable contrast to that of many cowardly public officials, whose failures at such times have brought dishonor on their names and on the reputation of their states. In this instance a murderer, himself badly wounded, lay in a hospital. A mob, bent on vengeance, was met at the hospital door by the surgeon-in-charge, who announced his intention to shoot any one who attempted to enter. The mob reconsidered its threat and finally dispersed. We do not know that it is the custom of Georgia physicians to be prepared to meet such emergencies, but it is satisfactory to know that when the occasion occurred one was not found wanting. The physician in this case upheld the best traditions of his profession as a life saver, and should receive the thanks of his brethren and of the community generally. It is a pity that public officials, sheriffs and the like in some portions of the country have not the pluck and regard for their obligations of this physician. He is undoubtedly in his proper place, but otherwise we should recommend the State of Georgia to put him in charge of its militia. At any rate, the latter can profit by his example.

VITAL STATISTICS.

Bulletin fifteen of the Department of Commerce and Labor of the Census Bureau contains a discussion of the vital statistics of the twelfth census, which ought to be a reminder to our state authorities and health boards of their failures of duty in this regard. Only three or four states give approximately correct records of births and deaths and about seven states of deaths alone. The value of such figures is almost incalculable and the Census Bureau has in its last enumeration endeavored to give us some facts that will make up for the deficiencies above mentioned. While the tables are not strictly accurate, they are suggestive in many ways, as well as of value for comparison with other available data. As regards municipal sanitary statistics the figures are more useful, as many cities give fuller, though far from complete, data than do the rural communities surrounding them. They are encouraging as showing in many of these cities a progressive general lowering of the death rate during the past ten years. The figures also show what has been observed elsewhere, that while

tuberculosis has decreased its mortality, pneumonia has become progressively a more fatal disorder—a fact which was first brought prominently before the public by THE JOURNAL. The increase of cancer is also a notable fact, pointed out by the census statistics, and deserves—as it is receiving—the careful attention of sanitarians. While the census figures have as a whole only a relative importance and are useful mainly for comparison, they are suggestive and worthy of study.

ANTIVACCINATION AND INTERNAL VACCINATION.

Opposition to vaccination, as well as to other like sanitary requirements, sometimes takes on queer phases. In Latin-American countries, where revolutions are a specialty, it may break up the government, as was apparently attempted the other day in Brazil.¹ In this country the methods are different. The antivaccinationists sometimes find their best resource in the courts of law, and the public health has to go by the board—as shown by legal decisions in one or two states. It is astonishing how ready judges sometimes are to decide medical questions of which they can not have, as their decisions show, any real knowledge. A rather odd development of the antivaccination activity is shown in the contention of the Iowa homeopaths in favor of the internal administration of the virus as a prophylactic against smallpox. We do not know how universal in that school is the faith in this method, but we can hardly believe that an educated homeopath would advocate it. A little education of the public ought, it seems, to serve to make it unpopular. We have all heard of the man who mistook a vaccine point for a toothpick, and of the consequences which he suffered for his mistake. When taken internally, antitoxin and vaccine are usually digested and thus destroyed, but one can easily see what may happen where any internal abrasions or ulcerations exist. The results would probably not be comfortable, and might be excessively dangerous. Probably, however, our homeopathic friends are using it in "high potency," in which case, of course, there will result only negative harm. It will be interesting to observe how the courts decide the Iowa dispute.

THE CHARITY WORK OF PHYSICIANS.

The calculation has been made that the value of the free medical and surgical services, given in one Philadelphia hospital during a year and calculated according to the usual rates of compensation, amounted to \$500,000. Supposing it to be only half this amount, which is probably nearer the truth, it is a large sum. This is the contribution of a limited number of physicians—probably forty or fifty—to charity. This is only one of the hospitals of a large city. If the hospitals of the whole country were taken into account, the aggregate

1. "Military and naval detachments have been called on to restore order. Thus far seven persons have been killed and thirty others wounded. It is believed that the opposition to vaccination is only a pretext for disorder and that the disturbances are really instigated by discontented politicians."—Cabled news item from Rio Janeiro.

gate amount given by physicians to charity would rise up well into the millions. If the dispensary services were also reckoned in, to say nothing of the private charity practice of which nearly every medical man has his share, the figures would be still more formidable. If any other occupation in life can make a similar showing of unrequited service it has not yet been heard from, and it is probably safe to say it will not be found. This, too, is service done for the public as well as for the individual, and makes the hospital physician, as it were, a sort of unrecognized quasi public official. Of course, it may be said that those who do this work derive a certain advantage from it, in that they obtain additional experience and reputation, and are thus aided in building up a really remunerative practice. That such motives influence them to a certain extent need not be denied, but it does not alter the fact that the public is the gratuitous recipient of a vast amount of unpaid-for service exacted from a class that is by no means the best remunerated otherwise. There is, moreover, a genuine altruistic motive in many of the cases, as well as a scientific ambition to contribute to the sum of human resources against disease. There are few people who have as much sense of responsibility in their work or to whom the success of the work is of more importance than conscientious physicians. Hence the desire to extend their observations and to gain additional experience by hospital practice. Even private charity practice is not always due to pure benevolent impulse—though we believe that this enters more or less into its motives in most cases—but it may be actuated by the same reasons as those given above; these, however, are creditable in themselves. We have no reason to blush for the record of the medical profession, and while self-praise is morally unhealthy, an occasional reminder of its well-doing is not always amiss. We need not fancy ourselves all William McClures nor coddle ourselves in the contemplation of our own excellencies, but it is well worth remembering that our profession is one that deserves respect, and to let this fact make us the more anxious to keep our profession thus respectable.

Medical News.

GEORGIA.

Convict Physician.—Dr. L. F. Harvin, Atlanta, who is serving a life sentence for murder, has been made physician of the West Holmes and Coffey convict camps, near Valdosta.

Ill and Injured.—Dr. Abner W. Calhoun, Atlanta, is seriously ill with ptomain poisoning.—Dr. J. William Anderson, Clinton, is critically ill at his home.—Dr. W. Monroe Smith, Atlanta, was seriously injured in a runaway accident November 2.

A Brave Physician.—Dr. E. B. Elder, house physician at the Macon Hospital, defeated the plans of a party of men who supposedly wanted to lynch a wounded murderer in the hospital, by confronting the party, informing the members that they could not enter the hospital and emphasizing his statement with a revolver.

ILLINOIS.

Protest at Proposed Removal.—Members of the Sangamon County Medical Society lodged a violent protest November 14 against the proposition to remove the office of the *Illinois Medical Journal* from Springfield to Chicago.

Hospital Opened.—The remodeled St. Joseph's Hospital at Paris, which has accommodation for thirty patients, and already has applications from twenty patients, was formally opened November 19. The hospital is under the charge of the Benedictine Sisters.

Cost of State Charities.—The report of the State Board of Charities shows that the per capita expense of maintenance at the various state hospitals for the quarter ended September 30 was as follows: Illinois Charitable Eye and Ear Infirmary, \$45.63; Hospital for Insane Criminals, Chester, \$60.40; Illinois Hospital for the Incurable Insane, Bartonville, \$33.02; Illinois Western Hospital for the Insane, Watertown, \$35.56; Illinois Southern Hospital for the Insane, Anna, \$35.94; Illinois Central Hospital for the Insane, Jacksonville, \$34.41; Illinois Eastern Hospital for the Insane, \$32.44, and Illinois Northern Hospital for the Insane, Elgin, \$37.60.

Warning to the Public.—A German with various aliases, among them Hans von Unwerth, Dr. A. J. Roeder, Dr. Troebner, Dr. Erosius, is asking people in Chicago and Evanston to aid on the plea that his wife recently died and left in his care three small children, and that he is without work. He has twice recently given the address "224 Sixty-third Street," which has been found to be false. From the description furnished the Bureau of Charities believes he is an impostor known to have operated in this city in other years, and therefore announces that he is about 5 feet 10 inches tall, weighs 135 to 140 pounds, has blonde hair, blue eyes, small hands, pale smooth face, and wears a light gray suit. He claims to be an engineer, a linguist, a musician, etc.

Chicago.

Donation to Memorial Institute.—Mr. Otto Young has donated \$100,000 to the endowment or building fund of the McCormick Memorial Institute for Infectious Diseases.

Addition to Hospital.—Through the munificence of Mrs. R. H. McElwee of Lake Forest, the capacity of the Mary Thompson Hospital for Women and Children will be doubled. She bears the entire cost of the erection of a new three-story addition, to contain an operating room, wards and private rooms.

More Deaths.—Although there were 470 deaths from all causes reported during the week ended November 19, or 66 more than for the week previous, the mortality rate is still satisfactorily low. The excess was caused chiefly by Bright's disease, from which 23 more deaths occurred, and by bronchitis, consumption and pneumonia, from each of which there was an increase of 9 deaths.

Must Pay for Bread Pills.—A Chicago medical "institute" dispensed considerable alleged advice and medicine through central Illinois and took promissory notes in payment in many cases. An injunction secured by 194 of the victims to prevent collection of the notes on the ground that they had been deceived with bread pills and sugar pills has been dissolved in Moultrie County and the case is appealed to higher courts.

Increase in Communicable Diseases.—Except typhoid fever, all the contagious and infectious diseases show an increase in the number of cases reported over those of the previous week—diphtheria from 85 to 92; scarlet fever, 27 to 31; smallpox, 12 to 21; chicken-pox, 1 to 7. The number of new typhoid fever cases reported was only 7 as against 12 the previous week. Total number of all contagious and infectious cases reported, 166, was 15 per cent. more than during the previous week and 55 per cent. more than for the corresponding week of last year.

Staff Examinations for County Hospital.—The recent order of the Cook County Board reducing the number of the attending staff of Cook County Hospital and requiring all applicants for position on the staff to submit to an examination, thereby placing them under civil-service rules, has been productive of much in the way of hard feeling and dissension. A board to conduct the examination was named, consisting of 42 individuals, 38 of whom belonged to the regular school, 2 to the homeopathic and 2 to eclectic. A number of practitioners, chiefly of the homeopathic and eclectic schools, filed a petition November 17, asking an injunction restraining the county authorities from placing members of their profession at Cook County Hospital under civil service. The granting of this injunction stopped the plans for the examinations, which were to begin November 18. In spite of this injunction the president of the Board of County Commissioners has received applications from more than 600 physicians who are desirous to take the examination. The latest development is a petition signed by a number of physicians asking the commissioners to rescind their original motion calling for the examination.

INDIANA.

Anonymous Gift.—An unknown benefactor has presented \$1,000 to the Home Hospital, Lafayette, to be applied toward the purchase of new equipment for the institution.

Anti-Spitting Ordinance Wanted.—The Fort Wayne Medical Society decided, November 8, to inaugurate a crusade against tuberculosis and to attempt to secure an ordinance against spitting on sidewalks and in public places. A committee to map out the details of the crusade will be appointed, to consist of eight practicing physicians, seven citizens and the executive heads of the various charities organizations of the city.

No Osteopaths Licensed in the State.—It is stated that the action of the Elkhart County Medical Society in having one of its members file a criminal complaint against an osteopath for practicing without a license, has brought out the fact that none of the 40 osteopaths in the state has secured a license, because the license requirements provide that all applicants must be graduates of schools of four-year courses while osteopathic schools have but three-year courses.

October Sickness and Death.—The most prevalent malady in October was tonsillitis. Typhoid fever maintains the same position of second place it occupied in September. The order of prevalence was: Tonsillitis, typhoid fever, bronchitis, diarrhea, scarlet fever, influenza, pneumonia, diphtheria, pleuritis dysentery, inflammation of bowels, cholera infantum, measles, puerperal fever, whooping cough, cerebrospinal meningitis. Diphtheria and scarlet fever appeared in epidemic form in several places. The severest outbreak occurred in the Miami County Orphan Asylum at Mexico, where there were 56 cases, with 3 deaths. Antitoxin was freely used and all known precautions were rigidly enforced. Smallpox increased as compared with the corresponding month of last year, the increase in cases being 60, and the increase in deaths 17, but the area invaded was less. Two deaths from hemorrhagic smallpox occurred. Both cases were diagnosed as typhoid fever. The total deaths numbered 2,702, an annual rate of 12.3 per 1,000. The rate for October, 1903, was 12.0. Of the total deaths 12.5 per cent. were of children under 1 year of age, and 25.5 per cent. were over 65. Some important causes of death were: Pulmonary tuberculosis, 334; typhoid fever, 164; diphtheria, 17; scarlet fever, 11; whooping cough, 16; pneumonia, 113; diarrheal diseases, 204; influenza, 4; puerperal fever, 6; cancer, 103; violence, 148; smallpox, 18. The city death rate was 15.4 per 1,000; the county rate, 10.1 per 1,000.

KANSAS.

Diphtheria.—For October and up to November 15, 80 cases of diphtheria, with 11 deaths, have been reported. Of the cases 27 occurred in Topeka, with 3 deaths, and 22 in Wichita, with 2 deaths.

Meffert Decision Affirmed.—The Supreme Court of the United States, on November 14, affirmed the decision of the Supreme Court of Kansas in the case of Dr. William M. Meffert of Emporia, Kan., whose license was revoked by the state medical board on the charge of improper conduct. The state courts sustained the validity of the act.

Contagious Diseases.—During the quarter ended September 30, 109 cases of diphtheria, with 24 deaths; 168 cases of scarlet fever, with 18 deaths; 353 cases of typhoid fever, with 82 deaths, and 173 cases of smallpox, with 3 deaths, were reported to the State Board of Health. Since receiving the quarterly reports epidemics of diphtheria in Lyon and Jewell counties have been reported, and 6 cases in Labette County; 50 cases of typhoid fever in Crawford County; 2 cases of smallpox at Neodesha and 3 cases in Kiowa County.

Kansas City Will Be Sanitary.—The council of Kansas City has passed an ordinance submitted by the Wyandotte County Medical Society, which gives the mayor power to appoint the members of the Board of Health, which is to consist of two regular practicing physicians and one veterinary surgeon, each to be a graduate of a reputable school. The mayor is to select the three members from six physicians and three veterinary surgeons to be recommended by the Wyandotte County Medical Society. The members of the board are to serve without pay and will hold office for two years.

MARYLAND.

Endows Hospital Ward.—George W. Navy of Baltimore has endowed the Baby Memorial ward in the new Cambridge Hospital.

Cambridge Hospital.—The Cambridge Hospital was dedicated November 17. A steamer was provided for the Baltimore guests and a very large number of physicians attended. Lunch and supper were provided for them on the boat by the authorities. The exercises were held in the open air in front of the building. Addresses were made by Judge Henry Lloyd, president of the board of directors, by the governor and by Dr. Howard A. Kelly. The building was then inspected. To date it has cost \$70,000, and about \$5,000 more will be needed for furnishing. The funds were provided by the state, county and individuals, the largest individual donation being \$30,000 by the late John E. Hurst of Baltimore. The cornerstone was laid May 26, 1903. The hospital began in a rented house in December, 1898, and has hitherto been known as the "United Charities Hospital," the name now held having been suggested by Mr. Hurst. The building is of brick, in colonial style, with three stories and basement. It is 136 feet long and 51 feet wide in the center, with wings 36 feet wide. There are porches at the front and ends. The operating room is on the third floor. There is steam heating and lighting, and there are accommodations for 60 patients, 16 rooms being provided for private patients. Dr. Thomas S. Cullen is the visiting surgeon and Dr. Henry O. Reik, specialist in diseases of the eye and ear. The local staff consists of Drs. Bruce W. Goldsborough, John Mace, Guy Steele and P. E. Hines.

Baltimore.

Martenet Memorial.—A window in memory of the late Dr. Jacob Fussel Martenet has been placed in Appold M. E. Church.

Bequests.—The late Dr. Charles H. Potter left \$20,000 in reversionary bequests to the Presbyteryian Board of Relief for Disabled Ministers and the Widows and Orphans of Deceased Ministers.

Personal.—Dr. Henry R. Carter, United States Marine Hospital Service, chief quarantine officer of the Isthmian Canal Commission, arrived in Baltimore from Panama November 17 and started the next day on his return with his wife and children.—Dr. Lloyd Noland, who was appointed one of the resident surgeons at Panama by the canal commission, has taken up his residence on the isthmus.—Dr. Daniel Jenifer has been appointed assistant physician at Bayview Asylum.

MICHIGAN.

Unlicensed Practitioner Fined.—"Dr." B. H. Ling, Germfask, was found guilty of practicing medicine without a license and was fined \$10 and costs, with the alternative of 60 days in the county jail.

To Educate Nurses.—The will of the late Elbridge M. Fowler, who recently died in Pasadena, Cal., gives \$10,000 to Grace Hospital, Detroit, to aid in the work of educating worthy young women to become nurses.

Cocain Kills Student.—Douglass M. Graves, a student at the Detroit College of Medicine, died at his boarding house in Detroit, November 9, from an overdose of cocaine, to the use of which he is said to have been addicted.

October Mortality.—The total number of deaths for October was 2,565, corresponding to an annual rate of 12.0 per 1,000. This rate was lower than that for September (12.7), and also lower than that for the corresponding month of the previous year (12.5). There were 483 deaths of infants under one year of age; 152 deaths of children aged 1 to 4 years, and 789 deaths of elderly persons aged 65 years and over. Important causes of death were as follows: Tuberculosis, 229; typhoid fever, 67; diphtheria, 27; scarlet fever, 3; measles, 4; whooping cough, 9; pneumonia, 109; diarrhea and enteritis, under 2 years, 168; cancer, 146; accidents and other violence, 195. Deaths from pulmonary tuberculosis and pneumonia increased for October as compared with the preceding month, but there was a large diminution in the number reported from diarrheal diseases. Typhoid fever showed a very slight increase over September. There were two deaths reported from smallpox during the month.

NEBRASKA.

Neal Hospital Sold.—Neal Hospital, Nebraska City, has been sold to the Sisters of Charity, who will open it as a public hospital early next year.

Ira Reinstated.—Dr. George W. Ira, resident physician at the Santee Indian Agency, who in the course of the policy of reduction in expenses of Indian offices was removed from office in July last, has been reinstated.

Council Bluffs, Not Omaha.—Health Commissioner Dr. John B. Ralph, Omaha, notifies us that the item "Disease Closes School" in THE JOURNAL of November 12 is incorrect, as Omaha has no Bloomer school, and Council Bluffs has a school of that name. Omaha has an increase in the number of cases of diphtheria as compared with last year, but it has not been thought necessary to close any school buildings on account of the disease.

NEW YORK.

A New Assignment.—Dr. Robert C. Lamb, who has been superintendent of Dannemora State Hospital for four years, has been appointed superintendent of Matteawan State Hospital, vice Dr. Henry E. Allison, deceased.

Criticism of Secretary Resented.—The authorities of the Post-Graduate School and Hospital, of Beth Israel Hospital, Babies' Hospital and of Lebanon Hospital have resented the criticisms which Robert W. Hehberd, secretary of the State Board of Charities, is credited with having made that these institutions were deficient in fire protection, sanitation, provisions and facilities for recreation. Mr. Hehberd says there was no censure of institutions intended, but that attention had been called to some defects. A list of institutions that would receive reports of inspection had been read, and the inference might have been made that they were the subject of censure.

Buffalo.

Personal.—Dr. Floyd S. Crego has sailed for Europe.—Dr. Edmond E. Blaauw has returned from Europe.—Dr. Stephen Y. Howell has returned from Florida.

Much and Severe Typhoid.—Many additional cases of typhoid are appearing and the individual cases show a severe form of infection, with numerous hemorrhages and other complications.

Polyglot Medical Journal Club.—A new club known as the Medical Journal Club has been formed, which will meet monthly, abstract and discuss interesting papers as they appear in the leading medical journals of all countries and in all languages.

October Health.—The monthly report of the Department of Health for October shows a death rate of 14.24 per 1,000 per annum. The following were the principal causes of death: Consumption, 36; cholera infantum, 11; cerebrospinal meningitis, 6; diphtheria, 7; typhoid fever, 19; debility, 43; cancer, 27; apoplexy, 7; meningitis, 7; cardiac dilatation, 8; endocarditis, 6; myocarditis, 7; valvular disease of the heart, 25; bronchitis, 11; pneumonia, 39; appendicitis, 3; gastroenteritis, 8; diabetes, 4; nephritis, 21, and violence, 32. The total deaths were 451, as compared with 442 for October, 1903.

New York City.

Bequests.—Under the will of the late Mrs. Sarah B. King, Mt. Sinai Hospital will receive \$10,000 and Montefiore Home \$5,000.

Award Declared Inadequate.—Dr. J. Harvie Dew, who sued the estate of Oliver W. Buckingham for \$55,000, has been awarded by the referee \$10,000 for continuous services for five years and \$10,000 for providing a home for the patient for three years. Dr. Dew says he will appeal, as the award is inadequate.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 12, 362 cases of diphtheria, with 27 deaths; 299 cases of tuberculosis, with 154 deaths; 201 cases of scarlet fever, with 8 deaths; 100 cases of typhoid fever, with 21 deaths; 59 cases of measles, with 3 deaths; 77 cases of varicella; 1 case of smallpox, and 11 deaths from cerebrospinal meningitis.

Report on Subway Air.—The preliminary report of Dr. Chandler of Columbia University to Health Commissioner Darlington has been made public. The conclusion reached is that the air of the subway is entirely satisfactory, that there is no cause for complaint in the present and no need for alarm as to conditions in the future. The analyses of 50 samples of air taken at various stations and under various atmospheric conditions show that the average percentage of oxygen is 20.55. This percentage shows that carbon dioxide is not present in any appreciable quantity. The Board of Health will continue investigations for some time to come before passing final judgment on this matter.

OHIO.

Personal.—Dr. Wylie McLean Ayres, Cincinnati, sailed from New York November 15 for a stay of three months in Switzerland.—Dr. Alvin H. Carr, Reading, was attacked by high-waters near Pleasant Ridge November 13 and severely injured.

Thirty Years Old.—At the thirtieth annual meeting and banquet of the Mahoning Valley Medical Society, held at Youngstown November 21, Dr. Roswell Park, Buffalo, was the guest of honor and read a paper on "Diseases of the Gall Bladder and Bile Ducts."

Post-Graduate School Opens.—The Cincinnati Polyclinic and Post-Graduate Medical School opened with a reception at the new building, 911 Race Street, November 22. The following make up the staff: Surgery—Drs. Henry A. Ingalls, Travis Carroll, Herschel D. Hinckley and Earl Harlan. Medicine—Drs. Frank L. Ratterman and William E. Kiely. Ophthalmology—Drs. Oscar W. Stark and Theodore A. Christen. Rectal Diseases—Dr. Louis J. Crouse, and Laryngology, Otolaryngology and Rhinology—Drs. Adolph Morgenstein, William C. Harris and Thomas V. Fitzpatrick.

Condemns Political Methods in State Institutions.—The following resolutions were adopted at the first meeting of the Tenth Council District of the Ohio State Medical Association, held in Columbus, November 15:

In view of the notoriety recently given the Ohio Hospital for Epileptics at Gallipolis, Ohio, be it

Resolved, That this association condemns all political methods in dealing with the benevolent institutions of Ohio and calls on the chief executive to uphold all competent and worthy medical officers of the state, and not to permit the interference of any person for political reasons; and further, that this association will not support any administration that so misuses the benevolent institutions; and be it

Resolved, That a copy of these resolutions be sent to Governor Myron T. Herrick and to the superintendent of the Ohio Hospital for Epileptics.

PENNSYLVANIA.

Personal.—Dr. J. M. Brown, Huntingdon, head of the relief department of the Philadelphia division of the Pennsylvania Railroad, had a cerebral hemorrhage November 14 and is critically ill.

Dr. Care Reinstated.—By order of the judicial council of the Medical Society of the State of Pennsylvania, to which he appealed, Dr. James R. Care, Norristown, who was expelled from the Montgomery County Medical Society three years ago for the alleged offense of having written a letter criticising the Charity Hospital, has been reinstated to all rights and privileges of the society.

Railroad First-Aid.—Medical boxes to be used for first aid to the injured by the Pennsylvania Railroad are being sent out to various points from Altoona. The boxes are wooden and oblong. Each is sealed, with written instructions on the outside. Inside is a tin box securely sealed, with further instructions. When the inner box is once opened it must not be used again, but must be returned to Altoona that it may be fumigated and additional materials inserted. The box contains rubber bandages, compressors and other materials used for first-aid to the injured.

Philadelphia.

Bequest.—By the will of Eliza W. S. P. Field, the Maternity Hospital of the university receives \$4,000 in trust.

Faculty Changes in the University.—The trustees of the university have made Dr. Leo Loeb assistant professor of pathology and Dr. Philip S. Stout, assistant demonstrator of pathology.

Report of Jefferson Maternity.—The twelfth annual report of the Jefferson Maternity Hospital shows that 304 patients were treated during the past year, and that 136 children were cared for. The receipts for the year were \$6,411.12 and the expenditures \$4,582.50, leaving a balance of \$1,828.62, of which \$1,000 was transferred to the building fund.

Mütter Lecture.—The Mütter lecture on surgical pathology for 1904 will be delivered in the hall of the College of Physicians of Philadelphia, at Thirteenth and Locust streets, Friday, December 2, at 8:30 p. m. by Dr. George H. Monks, Boston, on "Studies in the Surgical Anatomy of the Small Intestine and Its Mesentery." Physicians are cordially invited to be present.

Health Report.—Diphtheria continues to increase despite the efforts of the authorities. This week's record of new cases revealed 119, an increase of 42 over the preceding week. The

major portion of the sufferers are school children. The total number of cases of contagious diseases reported was 249, with 18 deaths, as compared with 239 cases and 10 deaths for the previous week. Deaths from all causes numbered 401, a decrease of 22 from those of last week and a decrease of 8 over the corresponding period of last year. Diseases of the respiratory tract caused 124 deaths.

"Test Case" Fails.—Dr. J. A. McKee was arrested on the charge of issuing a false certificate of vaccination. It was alleged that he had given a certificate without examining the arm of a patient whom he had successfully vaccinated three years before. The health authorities, who caused his arrest, asserted that the law requires that individuals must be vaccinated every two years. On account of the indiscriminate issuance of vaccination certificates the health authorities used this as a "test case." It was found, however, that no specific two-year law of vaccination had been established, and the accused, therefore, was discharged.

GENERAL.

Trachoma in Honolulu.—The health authorities in Honolulu are taking measures to combat the outbreak of trachoma and Dr. W. L. Moore has been appointed special medical examiner of schools.

Yellow Fever in Cuba.—Yellow fever is said to have broken out in Cuba. The cases now reported are the first since the disease was stamped out during the American occupancy of the island in 1900.

Funds for the Study of Tuberculosis.—The National Association for the Study and Prevention of Tuberculosis, which has its headquarters in the United Charities Building, New York City, has issued an appeal for contributions to a fund of \$50,000.

Pan-American Congress.—Dr. Henry P. Newman, American secretary of the section on gynecology and abdominal surgery of the Pan-American Medical Congress, is in the South with headquarters at the New St. Charles Hotel, New Orleans. He writes that arrangements for getting to Panama from that port are ideal. Dr. Rudolph Matas, 2255 St. Charles Avenue, New Orleans, is American secretary of the section on general surgery. He writes that, by a change of schedule, the steamer of the United Fruit Company will sail from New Orleans Wednesday, December 28, in time to reach Colon Monday, Jan. 2, 1905, in time for the congress. The rate for the round trip on this boat is now \$50, half the regular rates. Dr. Newman states that the southern physicians are enthusiastic over this meeting and he thinks that it will be a great success.

The Pneumonia Commission.—The commission organized under the authority of the Department of Health of New York City to investigate pneumonia has secured the co-operation of hospitals in Baltimore, Washington, Chicago, St. Louis, Kansas City, San Francisco, Buffalo, Helena, Minneapolis, Denver and twenty other cities equally scattered and in Montreal, Canada. These hospitals will carry on the field work and will report on specially prepared blanks. The laboratory work will be carried on in Boston, Philadelphia, Saranac Lake and at three laboratories in New York City. Twenty thousand cases will be studied in the six months which began November 1. The central laboratory will be at the headquarters of the Department of Health of New York City. The commission will study the occurrence and virulence of the pneumococcus and the organisms related to or resembling this in the human mouth in health and in disease; the evidence of variation in virulence of the pneumococcus; the occurrence of the pneumococcus in children's hospitals, homes and asylums, with a study of the bacteria of mouths before and after an outbreak of pneumonia; the vitality of the pneumococcus under various conditions; the study of mouth disinfection and the study of the air in public places, especially in reference to its dust content. The first six months of this year showed a death rate of 19.6 per cent. of the total number of deaths due to pneumonia. The same period in 1903 showed a death rate of 16.5 per cent. due to this cause. The commission will probably make an examination of subway workers and surface car men with the object of ascertaining the effects of these employments on the health of these men.

CANADA.

Vaccination in Lumber Camps.—Lumbermen are said to be guarding against possibilities of smallpox outbreaks by compelling their men to be vaccinated before going into the camps.

One concern, which has already sent 300 men into camps in its New Ontario limits, required them all to be vaccinated.

St. John Vital Statistics.—There were 751 deaths in the city of St. John, N. B., during the year ended Oct. 31, 1904, as compared with 777 for the previous year. Tuberculosis caused 108 of the number, 19 more than in 1903. There were 100 cases of diphtheria reported, with 11 deaths; scarlet fever, 58 cases, 2 deaths; measles, 67 cases, 1 death; typhoid fever, 20 cases, 6 deaths; smallpox, 1 case, no death.

FOREIGN.

Tuberculosis a Reportable Disease.—The United States Public Health and Marine-Hospital Service reports that the Birmingham (Eng.) city council authorized the health officer to request physicians to notify the health department of all cases of phthisis which came under their observation in Birmingham. The council has no authority to compel this notification, but by promising that the information would be confidential, the system has been successfully carried out. As a supplementary step, a tuberculosis inspector will be appointed, at a salary of £100 (\$486) per annum.

Russian Quarantine Regulations.—From the public health reports we learn that the Russian Board of Medicine has elaborated regulations to be put in force in case the cholera epidemic should spread as far as Moscow. For this purpose the town is divided in sections, and all the cases, should the disease appear, are to be carefully registered and all dwellings are to be disinfected. It has been decided to make experiments with anticholeric lymph, and to distribute among the population pamphlets containing directions as to the precautionary measures to be adopted in order to check a spread of the epidemic. The towns of Baku and Saratow are declared to be infected with cholera.

From the Seat of War.—A telegram from Professor Zoega von Manteuffel, dated Mukden, October 19, says: "We have passed through the greatest battle the world or history has ever known. We are alive and well." An official dispatch states that during two weeks in October Mukden received 775 wounded officers and 27,887 wounded privates, 168 sick officers and 3,224 sick privates. After they had been duly cared for and fed they were forwarded to hospitals beyond. General Trepow adds to his report a few words of appreciation of the tireless devotion of the surgeons. The quarters where the wounds were dressed were frequently under fire. The authorities have ordered another lot of physicians in Russia to report at the seat of war. This leaves a large district in Russia temporarily without medical aid. A large consignment of antidyenteric serum has recently been forwarded to the active forces.

Smallpox in India.—Smallpox is endemic in the Bombay presidency, according to the last report of the United States Public Health and Marine-Hospital Service. There being no jurisdiction over the movements of infected persons, either by road or boat, in Lind province, the disease spreads readily. In a very severe outbreak in the town of Malegao there was great opposition to vaccination on the part of a class of local weavers, and great difficulty in obtaining early notification of the disease from neglect on the part of the people in reporting cases. Parents in the jungle districts of Kanara and Dharwar object most strongly to vaccination, especially of infants under one year of age; thus many children escape vaccination permanently. The preventive measures were those habitually adopted, viz.: On the notification of outbreaks, vaccination and revaccination is offered to the people, and as much vaccination work performed in and around the affected area as possible. Isolation and disinfection methods are at present impracticable. Owing to notification being non-compulsory, frequently the only intimation received by the deputy sanitary commissioner is the return of deaths from smallpox, by which time the disease has obtained a firm hold on the village. In the city of Bombay notification is compulsory and vaccination is required before the age of six months. Disinfection of quarters where cases have occurred is regularly carried out.

Medical Organization in Belgium.—The Federation of Medical Societies in Belgium held its annual meeting October 27. The president, Dr. Merville, editor of the *Gazette Méd. Belge*, remarked in the course of his address that one of the federated medical societies was in the habit of sending to the office of the Federation a copy of all the programs, notices, etc., sent by its secretary to its members. He commented on the value of the information thus obtained, the central office being thus kept in touch with what is going on in this local society. He

suggested that each of the local societies should instruct its secretary to place on its mailing list the names of the secretaries of all the other local societies. The extra expense and trouble would be trifling in comparison with the benefits to be derived by being thus kept in touch with each other. In many instances this interchange of ideas would prove an inspiration and stimulation and the research of one might supplement that of another, instead of several working on the same task. The assembly adopted the following resolution among others: "The surgeon shall present a global bill for every operation, the amount including the sums to be paid to his aids and to the attending physician for their intervention in the operative act. The physician attending the patient afterward and giving the after-care shall present his account separately." In the discussion beforehand Dejaque remarked that the lay press might comment on this resolution in a way to travesty the upright intentions of the medical body, and he urged those physicians who had entrée to the lay editorial sanctums to place the matter in the proper light. The president suggested that the officers of the Federation might take the initiative in the matter, and his suggestion was approved.

LONDON LETTER.

Dairyman Held Responsible for Typhoid Germs in Milk.

A verdict given against the Aylesbury Dairy Company, one of the largest firms engaged in the sale of milk in London, is of far-reaching importance, applying, as it does, an old principle in law to a new set of circumstances. In July last year there was an epidemic of typhoid fever in Ealing, a London suburb. Among the victims was a woman who died. She had partaken of milk supplied by the Aylesbury Dairy Company. Her husband, believing that the milk was the source of the disease, sued the company for damages. His counsel pointed out that the company, in their advertisements, guaranteed that their milk was free from disease germs. He also proved that part of the company's supply was drawn from a farm where there had been a case of typhoid fever. If the milk had been polluted then he contended that there had been a breach of warranty. There was some difference in the expert evidence as to the contamination of the milk. Dr. Thresh, examiner in state medicine at the University of London, said that there was a suspicion as to the milk, but the proof was far from conclusive. Evidence was given that in June, July and August, 1903, 21 cases of typhoid fever occurred in this suburb and in 12 the milk was supplied by the defendants. For the defense it was shown that elaborate precautions were taken by the company to insure the purity of the milk. The judge instructed the jury that if a purveyor sold food injurious to health he was liable. The jury found a verdict for \$530, the amount of expense to which the woman's husband had been put. It is thought by health officers that the decision will do much good by making dairy companies more particular.

Identification by Teeth Casts.

A dentist has called attention to the value of teeth casts in identification—a means which does not seem to have previously been used. He relates the following example: A gentleman went to Africa to shoot big game. Soon a newspaper report appeared that he had been murdered by the natives. His property was large, but probate would not be granted on the basis of the newspaper report. His brother went to Africa and was shown the spot where the murdered man was said to be buried. The skeleton was found and brought to England. But how could it be identified? The probate court remained inexorable. It occurred to a relative that the man had consulted a dentist and the skull was brought to him. He had supplied the missing man with a set of artificial teeth and kept the cast of his mouth. Comparison of this with the skull at once proved his identity beyond doubt and probate was granted forthwith. The dentist insists that, as in the case of finger prints, no two persons' mouths are alike and that a mouth may be identified by a cast taken years ago even though teeth have subsequently been destroyed or the gums lost, as in a skeleton.

Plague in Natal.

Mr. Ernest Hill, health officer of Natal, has issued a report on the outbreak of plague in that colony. The first case occurred in Durban on Dec. 4, 1902, and the last in the same town on Aug. 15, 1903. In all there were 221 cases, of which 162 were fatal—a mortality of 73 per cent. Of this number 201 cases, with 145 deaths, occurred in Durban alone. The disease was principally spread by infested rats and mice. High value is attached to Haufkine's method of preventive inoc-

ulation and some good results were apparently obtained from Yersin's serum. The report gives the results of some valuable bacteriologic researches by Mr. Watkins-Pitchford, assisted by Dr. L. G. Haydon. Some of the most notable experiments were those concerning the vitality and virulence of the plague bacillus. Rodents were confined in boxes carefully protected from all possibility of outside contamination. The boxes were first infested by rats suffering from the disease; when these died healthy rats, after the lapse of a month, were introduced and contracted the disease. When two months elapsed before the introduction of another batch of healthy rats the experiments proved negative. Attempts to transmit the disease to the domestic animals, after the method of Professor Simpson in Hong Kong, proved negative. It is concluded that the strain of bacillus used in Hong Kong has a wider pathogenic range than that used in Natal, and that domestic animals did not in the latter place play a part in the transmission of the disease. The writers insist on the untrustworthiness of microscopic appearances in the diagnosis of plague. To come to a trustworthy conclusion cultural characteristics and the virulence of the organism must be tested.

Correspondence.

The Passing of the Red-Light Treatment of Smallpox.

PHILADELPHIA, Nov. 16, 1904.

To the Editor:—In May, 1903, I published in THE JOURNAL¹ an article in which the value of the red-light treatment of smallpox so stoutly championed by Finsen, was questioned. The theoretical objections to the acceptance of Finsen's claim were discussed in detail and the unfavorable results of the treatment of two cases of smallpox in a well-equipped red-light room were given. Finsen replied to this article and criticised the methods employed and the deductions drawn.

Since this time Dr. Nelson D. Brayton² of Indianapolis published the absolutely negative results obtained in the treatment of 300 cases of smallpox in red-light wards. In the *London Lancet*, July 30, 1904, there appears an article³ on "The Red-Light Treatment of Smallpox," by Dr. T. F. Ricketts, medical superintendent of the Smallpox Hospital of the Metropolitan Asylums Board, and J. B. Byles, assistant medical officer of the Joyce Green Hospital. These men, who have had large experience in smallpox, treated 13 cases of smallpox in a thoroughly equipped red-light room. Seven of the cases were placed in the room on the second day of the eruption; no objection can, therefore, be made that the cases were received too late. Suppurative fever and suppuration were not prevented. The authors state, "We can not agree that the treatment has any of the merits which have been claimed for it." Indeed, these English physicians of experience rather regarded the red light as harmful. "We thought the treatment had an unfavorable effect on the general condition of the patient. The tendency to mental symptoms (delirium, headache, restlessness, etc.) seemed more marked." In concluding the authors said: "We venture to appeal to Dr. Finsen, who has done so much for suffering humanity, to cease to lend the weight of his authority to support a method of treatment which, if it is inefficacious, must necessarily be inhuman."⁴

During a visit to Copenhagen this summer I was told by Dr. Reyn of the Light Institute that the Empress of Russia had given instructions to have the red-light treatment thoroughly tested in one of Russia's smallpox hospitals.

Dr. Finsen has recently died and a noble and useful life has been cut short. Finsen's work in the application of actinic rays of light to the treatment of skin diseases, particularly lupus, entitles him to a prominent place in the history of medicine. The use of red light or, rather, the exclusion of actinic rays of light in the treatment of smallpox, will soon be forgotten.

1. May 2, 1903, p. 1183.

2. July 25, 1903, p. 233.

3. Abstracted in THE JOURNAL, August 20, '04, p. 573.

4. EDITOR'S NOTE.—Finsen's reply to the report of Ricketts and Byles is reviewed in this issue of THE JOURNAL, foreign abstract 12, p. 1665.

Finsen was obviously deceived, as were likewise some other physicians who used the red-light treatment in smallpox, through inexperience with this disease and a consequent inability to distinguish between the natural course of smallpox of different degrees of severity and a modification the result of treatment. I was shown this summer a temperature chart of one of Finsen's published cases of smallpox. There was distinct secondary fever beginning on the sixth day of the eruption; this had not been interpreted as such, but had been attributed to a parotitis. Physicians with the largest experience in smallpox are agreed that there is no known remedy which can abort or modify the course of the variolous eruption. The liability to error in interpreting the value of therapeutic agents is especially great in those diseases which from time to time vary greatly in severity.

JAY F. SCHAMBERG, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ANTIKAMNIA FOR THE PUBLIC.

DR. W. W. GOLDEN, secretary of the West Virginia State Medical Association, has forwarded us a letter, circulars, etc., which were handed him by a non-medical friend and which he asks us to publish. We have on several occasions called attention to the fact that the medical profession has been doing its share to help the antikamnia people to bring their various combinations to the attention of the public. Of course, to use physicians for this purpose is a cheap way of advertising, as newspaper rates are pretty high, especially when a firm attempts to cover the whole country. With over 100,000 physicians as agents, without pay, the expense of promotion is minimized immensely. We can not but admire the Antikamnia Chemical Company in the wisdom they have shown; their method of "promotion" is an excellent one, and others are following their footsteps. The following is the letter referred to:

St. Louis, U. S. A., Oct. 17, 1904.

Mr. H.:—We are pleased to enclose a sample of "Antikamnia Tablets" for Pain. A sample of something good is a "good thing" to keep about the house, or, for convenience, in your pocket or purse. Antikamnia Tablets will relieve all headaches, muscular pains, neuralgias, the grippé, insomnia and women's aches and ills, where sell them in any quantity or in our regular "Vest-Pocket Boxes" as below.

Sincerely yours,
The Antikamnia Chemical Company,
Frank A. Ruf, Prest. and Treas.

On the letterhead are such legends as the following: "Vest-Pocket-Boxes," "Sent direct by mail on receipt of 25 cents, if your druggist can not supply them," "Order a 'Vest-Pocket-Box' of 'Antikamnia Tablets' so as to have them on hand in time of Pain." Stuck to the letter is an artistic picture of a poor wretch evidently suffering from neuralgia of the face with a hint that antikamnia is for facial neuralgia. From the circulars accompanying the letter we clip the following:

"There are numerous important uses for Antikamnia Tablets, of which many may be uninformed. Before starting on an outing, everybody, and this includes tourists, picknickers, bicyclers, and, in fact, anybody who is out in the sun and air all day, should take a five-grain Antikamnia Tablet at breakfast, and avoid entirely that demoralizing headache which frequently mars the pleasure of such an occasion. This applies equally to women on shopping tours, and especially those who invariably come home cross and out of sorts, with a wretched 'sightseer's' headache." The nervous headache and irritable condition of the business man is prevented by the timely use of a ten-grain dose. Every bicycle rider, after a hard run, should take a bath and a good rub-down and two five-grain Antikamnia Tablets on going to bed. In the morning he will awake minus the usual muscular pains, aches and soreness. As a preventive of the above conditions, Antikamnia is a wonder, a charming wonder, and one trial is enough to convince."

They quote, or rather misquote, from an article by Dr. John H. McIntyre, published in THE JOURNAL of the American Medical Association some thirteen years ago, the object evidently being to make it appear as though this journal endorsed the use of antikamnia. The pathetic part of the whole matter comes from the fact that directions are given for the use of antikamnia and codain in practically every disease to which flesh is heir; there is no hint anywhere, so far as we can discover, of the danger accompanying the use of acetanilid and codain.

USE OF SUGGESTION—THE STATUS OF THE LIBERAL HOMEOPATH.

NEW YORK CITY, Nov. 14, 1904.

To the Editor:—Can you advise me whether the consensus of professional opinion is for or against the recommendation, to suitable patients, of such therapeutic methods as mental science or Christian Science? In other words, should we consider solely the welfare of the patient or should we consider how the recommendation of a certain measure, while beneficial to one, may, through our having recommended it, work harm to others. 2. Kindly tell me if homeopathic medical colleges are to-day teaching homeopathy. 3. Is not a man a fraud who claims to be a homeopath and yet does not practice homeopathy? J. J. N.

ANSWER.—The answer to this query naturally divides itself into two parts. For instance, certain patients may be benefited by the application of the therapeutic methods of mental healing, etc., while it might be highly inadvisable to place those patients in the care of such individuals as in a given locality happen to be practicing "mental science," etc. In other words, it may be proper, and even desirable, in a given case that the physician himself apply the methods of the healers or else refer the patient to a physician experienced in the application of suggestion. As the exponents of the various "healing" cults are ignorant of the natural sciences on which modern medicine is based, and as they are always either self-deluded or dishonest, it is difficult to imagine circumstances that would justify the reference of a patient to one of them. 2. Homeopathic colleges still teach some modification of homeopathy. In many of them the subject occupies only a small portion of the curriculum. 3. This is a question of casuistry. How many people are that they "claim to be"? If the man who "claims to be a homeopath and yet does not practice homeopathy," at the same time believes himself to be a homeopath, it would be using unadvised strong language to call him a fraud. If he deliberately pretends to be what he knows he is not, he, of course, is a fraud. The charitable attitude under any such circumstances can do us no harm.

CURE OF INGROWING TOENAIL.

MEXICO, Nov. 11, 1904.

To the Editor:—I have a patient who has been troubled for two years with an ingrowing toenail. The nail has been taken off twice by physicians in the States, but the condition is gradually growing worse. The nail extends down into the tissue at least one-quarter of an inch, only the side next the second toe being affected. There is a continual discharge of pus and small pieces of nail have several times come out of the bottom of the toe. Naturally the man is much discouraged from the previous results and wants the very best thing done this time. Kindly give your best opinion. I have treated several cases before by the various methods commonly used, but I have not had good results in this case. W. J. E.

ANSWER.—Failure followed the removal of the nail because the matrix was not removed with the nail. A very successful and satisfactory way of treating ingrowing toenails is to remove that part of the nail which becomes imbedded in the flesh together with its portion of the matrix. Under local or general anesthesia begin at the free border of the nail and cut longitudinally, extending through the nail to the root, removing only that portion of the nail which is giving rise to the trouble. After removing this portion of the nail cut out a wedge-shaped piece, including all of the matrix, back to the root, which has been uncovered. The wedge should include all of the tissues down to the phalanx. The tissues then fall together and primary union usually results. If care be taken to remove all the matrix back to and including the root, the relief will be complete as well as permanent.

DURATION OF LICENSE TO PRACTICE.

CRAWFORDSVILLE, IND., Nov. 21, 1904.

To the Editor:—On page 1662 of THE JOURNAL, Nov. 19, 1904, in reply to question asked by "T," you state that a license issued to practice medicine in 1895 in Indiana, "entitles the holder to practice medicine in Indiana without an examination." You are in error in this statement. Any license issued prior to March 8, 1897, confers no legal right to practice medicine in any of its branches in Indiana. All licenses issued prior to March 8, 1897, were revoked by the present law. Please make correction.

W. T. GOTT, M.D.,
Secretary of the Indiana Board.

INTERNAL VACCINATION.

OHIO, Nov. —, 1904.

To the Editor:—Kindly give through your Queries and Minor Notes columns the value of the internal administration of antitoxin, both as a preventive and a curative measure. VERTAS.

ANSWER.—So far as known the internal administration of antitoxins has no preventive and curative effect because the digestive juices destroy the antitoxins before they can be absorbed. See editorial in this issue.

EPIDURAL INJECTIONS.

CAMPELLSPORT, WIS., Nov. 12, 1904.

To the Editor:—Please explain Cathelin's epidural injections.

F. H. RUSSELL.

ANSWER.—Cathelin's epidural injections are injections of cocaine outside the dura between it and the vertebral arches. This method has been claimed to be less dangerous than the subarachnoid method. It has been found useful not only for Anesthesia, but also in urinary incontinence and night pollutions. Numerous articles dealing with the method have been abstracted in THE JOURNAL, vol. xxxvii, pp. 150 and 793; vol. xxxviii, p. 1282; vol. xli, pp. 287 and 399.

WANTS A SKELETON ARTICULATED.

GRAND JUNCTION, COLO., Nov. 15, 1904.

To the Editor:—Where can I send a skeleton to have it articulated?
DR. U. S. ABBOTT.

Marriages.

RAYNOR S. FREUND, M.D., Butte, Mont., to Miss Sue McLanahan, at Butte.

HERBERT FOX, M.D., to Miss Emma Louise Gaskill, both of Philadelphia, November 9.

LOUIS BROWN, M.D., St. Louis, Mo., to Miss Mabel Martin of Peoria, Ill., November 15.

EYERETT W. GOULD, M.D., to Miss Alice E. Williams, both of New York City, November 10.

CHARLES W. BAILEY, M.D., to Miss Josephine Ida Groesbeck, both of Hebron, Ill., November 3.

T. SNIVELY DUNNING, M.D., Columbia, Pa., to Miss Elizabeth Christina Nittinger, November 9.

TULLY O. HARDESTY, M.D., Kampsville, Ill., to Miss Kathryn Killum of Winfield, Mo., September 20.

WILLIAM H. GREEN, M.D., Farnhamville, Iowa, to Miss Bertha Marohn, at Des Moines, Iowa, November 9.

FRANK WINFIELD LAIDLAW, M.D., Hurleyville, N. Y., to Miss Sylvia Coddington of Loch Sheldrake, N. Y., October 26.

PHILIP STANLEY CHANCELLOR, M.D., Santa Barbara, Cal., to Miss Emma Elise Matthiessen of La Salle, Ill., November 23.

Deaths.

Henry Munson Lyman, M.D.

Dr. Henry M. Lyman, for many years a professor and senior dean of Rush Medical College and one of the most prominent practitioners of the west, died at the home of his daughter in Evanston, Ill., November 21, after an invalidism of four years, aged 68. The cause of his death was angina pectoris. Dr. Lyman was born in Hilo, Hawaiian Islands, Nov. 26, 1835, and was graduated from Williams College, Massachusetts, in 1858, as valedictorian of his class. He commenced the study of medicine at Harvard University Medical School, Boston, but graduated—again as valedictorian—from the College of Physicians and Surgeons in the City of New York, in 1861. After a short term as interne in Bellevue Hospital, he entered the Army and served as acting assistant surgeon from 1862 to 1863, being on duty in the military hospitals of Nashville, Tenn. In 1863 he established himself in practice in Chicago, paying especial attention to diseases of the nervous system. From 1871 to 1876 he was professor of chemistry in Rush Medical College; from 1876 to 1877, professor of diseases of the nervous system; from 1877 to 1879, professor of physiology and of nervous diseases, and from 1889, professor and emeritus professor of the theory and practice of medicine in the same institution. He was also professor of medicine in the Northwestern University Woman's Medical School from 1880 to 1888. He was attending physician to Cook County Hospital, Chicago, from 1867 to 1876, and to the Presbyterian Hospital from 1884 until his retirement. He became consulting physician to St. Joseph's Hospital in 1890. Dr. Lyman's society affiliations included the Chicago Pathological Society, of which he was president in 1876; the Illinois State Medical Society, the American Neurological Association, of which he was president in 1892-1893; and the Association of American Physicians, of which he was president in 1891-1892. His chief contributions to the literature are his works on "Artificial Anes-

thesia and Anesthetics," published in 1880; "Insomnia and Other Disorders of Sleep," in 1886; a "Text-Book of the Theory and Practice of Medicine," in 1892, and numerous articles in the literature.

T. M. Drown, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1862, died in St. Luke's Hospital, Bethlehem, Pa., one week after an operation for an intestinal tumor, November 16, aged 62. Dr. Drown served as surgeon in the Civil War and subsequently studied in the School of Mines at Freiberg and the University of Heidelberg and became, in 1869, instructor in metallurgy in Harvard University; from 1874 to 1881 he was professor of analytical chemistry in Lafayette College. In 1885 he filled a similar position in the Massachusetts Institute of Technology, becoming president of Lehigh University in 1895. Dr. Drown was one of the charter members of the American Institute of Mining Engineers and its secretary for 13 years.

Duncan Campbell MacCallum, M.D. McGill University, Montreal, 1850, M.R.C.S. England, 1851; demonstrator of anatomy at McGill University, 1854 to 1856; professor of clinical surgery, 1856 to 1860; professor of clinical medicine and medical jurisprudence, 1860 to 1868; professor of midwifery and diseases of women and children, 1868 to 1883, and emeritus professor thereafter; a frequent contributor to the medical literature; one of the founders of the *Medical Chronicle*; visiting physician to the Montreal General Hospital from 1856 to 1887, and then consulting physician; in charge of the University Lying-in Hospital from 1868 to 1883 and afterward its consulting physician, died November 13 at his home in Montreal after a short illness, aged 80.

Francis M. Casal, M.D. Rush Medical College, Chicago, 1864, a member of the American Medical Association, formerly of Pittsfield, Ill., died recently at his home in Santa Barbara, Cal. At a meeting of the Santa Barbara County Medical Society, of which Dr. Casal was one of the oldest and most beloved members, held November 9, resolutions of sorrow at his death and sympathy with his household were unanimously adopted.

James L. Bryan, M.D. University of Maryland, Baltimore, 1849, a veteran of the Mexican War; for about 32 years school commissioner of Dorchester County, Maryland, and largely instrumental in establishing the school system there after the war; who gave up practice and founded the Cambridge Military Academy, died at his home in Cambridge, November 6.

William McClellan Reber, M.D. Jefferson Medical College, Philadelphia, 1863, a prominent physician and citizen of Bloomsburg, Pa., died at Wilkesbarre City Hospital from peritonitis November 18, aged 61. He was a member of the American Medical Association and of the state and local medical societies.

W. H. Carter, M.D. College of Physicians and Surgeons, New York City, formerly in the United States Navy and a member of the Kansas legislature in 1882, died at his home near Cottonwood Falls, Kan., November 13, from Bright's disease, aged 60.

Hunter A. Bond, M.D. Bellevue Hospital Medical College, New York City, 1891, first assistant physician at Manhattan State Hospital, member of the Medico-Psychological Society, and of the Medical Society of the County of New York, committed suicide at Petersburg, Va., November 14.

William R. Gibson, M.D. University of Edinburgh, Scotland, for 15 years a practitioner of Bradford, Pa., died at the State Hospital for the Insane, Warren, where he had been a patient for about eight months, November 7, aged 49.

Edward Thomas Gagen, M.D. King and Queen's College, Ireland, 1880, formerly of Baker County, Oregon, committed suicide at his apartments at Los Angeles October 31, while dependent on account of heart disease, aged 46.

Thomas S. Hopkins, M.D. Medical College of the State of South Carolina, Charleston, 1845, a Confederate veteran, at one time surgeon at Andersonville prison, died at his home in Thomasville, Ga., November 12, aged 87.

John W. Hensley, M.D. Rush Medical College, Chicago, 1867, formerly secretary of the Illinois State Medical Society, died at his home in Peoria November 14, from paralysis after an illness of ten days, aged 68.

James J. Healey, M.D. College of Physicians and Surgeons in the City of New York, 1872, once president of the Essex North Medical Society, died at his home in Newburyport, Mass., November 11, aged 56.

Thomas S. Duckett, M.D. Jefferson Medical College, Philadelphia, 1836, who represented Prince George County in the legislature in 1845, died at his home in Bladensburg, Md., November 12, aged 89.

Lewis Washington Knight, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1847, died at his home in Nashville, Tenn., November 2, after an illness of six weeks, aged 88.

James P. Burchfield, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1862, of Clearfield, Pa., died at Williamsport, Pa., November 8, after an illness of two days.

James Poulson, M.D., an ex-Confederate soldier, for a number of years a practitioner of Texas, who retired several years ago to the eastern shore of Virginia, died at Onancock, November 15, from an acute affection of the throat, aged 65.

G. S. Mostellar, M.D. Medical Department Illinois College, Jacksonville, a surgeon in the Mexican War, died at the home of his son in Pittsburg, Kan., November 11, aged 82.

George Henry Jefferson, M.D., one of the oldest physicians of Trigg County, Kentucky, died at the home of his son in Linton, November 2, from heart disease, aged 73.

Mell R. Hackedorn, M.D. Bellevue Hospital Medical College, New York City, 1870, died at his home in Galion, Ohio, November 16, after an illness of two days, aged 58.

Isaac F. Cowan, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1860, died at his home near Metuchen, N. J., November 10, aged 80.

Marion L. Amick, M.D. Cincinnati College of Medicine and Surgery, 1869, died at his home in Cincinnati November 15, after an illness of two weeks, aged 61.

William A. Huddleston, M.D. Atlanta (Ga.) Medical College, 1880, died at his home in Wetumpka, Ala., November 8, from lung disease, after a long illness.

Benjamin Franklin Keith, M.D. Rush Medical College, Chicago, 1858, died at his home in Edwardsport, Ind., November 5, from Bright's disease, aged 79.

William Ratliffe Brandon, M.D. New Orleans School of Medicine, 1857, died at his home in Como, West Feliciana Parish, La., November 2, aged 70.

Charles E. Daniels, M.D. Illinois. 1876, a pioneer physician of South Dakota, died at his home in Milbank, November 13, from apoplexy.

Jerome T. Whelpley, M.D. Illinois, 1887, one of the oldest physicians of southern Illinois, died at his home in Cobden, November 10.

J. M. Browder, M.D. Cincinnati College of Medicine and Surgery, 1889, died at his home in Celina, Ohio, October 25, aged 74.

William F. Van Kirk, M.D. Jefferson Medical College, Philadelphia, 1868, died at his home in Grafton, W. Va., November 12.

L. P. Jones, M.D. Tulane University, New Orleans, recently killed his wife and then shot himself, at his home in Benjamin, Texas.

Thomas H. Cooper, M.D. Detroit College of Medicine, 1898, of Orion, Mich., died at his early home in Canada November 1.

Benjamin F. Sides, M.D. Jefferson Medical College, Philadelphia, 1872, died at his home in Furniss, Pa., November 17.

John Hawes, M.D. Louisville Medical College, 1893, died at his home in McBean, Ga., November 12, from typhoid fever.

Alicia Jane Howard Koch, Ohio, 1865, died at her home in Indianapolis, November 12, after an illness of six months.

W. K. Dangeliewicz, M.D., died at his home in Shamokin, Pa., November 1, after an illness of four weeks, aged 60.

A. J. Hodge, M.D. University of Nashville Medical Department, 1874, died recently at his home in Cuero, Texas.

Lyman W. Henry, M.D. Indiana, 1897, of Burnettsville, Ind., died at Battle Creek, Mich., October 29, aged 87.

B. C. Cook, M.D. Medical College of Georgia, Augusta, 1857, died at his home in Long Cave, Ga., October 11.

William B. Bolton, M.D. Illinois, formerly of Canton, Ill., died at Cuba, Ill., November 10, aged 79.

T. C. Conklin, M.D. Illinois, 1888, died suddenly at his home in Farmington, Ill., November 9.

J. D. Drane, M.D., died at McCool, Miss., October 13.

Book Notices.

THE MEDICAL NEWS VISITING LIST, 1905. Weekly (Dated for 30 Patients); Monthly (Updated for 120 Patients per Month); Perpetual (Updated for 30 Patients Weekly per Year); 60-Patient (Updated, for 60 Patients Weekly per Year). The Weekly, Monthly and 30-Patient Perpetual Contain 32 Pages of Data and 160 Pages of Classified Blanks. The 60-Patient Perpetual Consists of 272 Pages of Blanks Alone. Each in One Wallet-shaped Book Bound in Flexible Leather, with Flap and Pocket, Pencil and Rubber, and Calendar for Two Years. Price, \$1.25. Thumb-letter Index, 25 cents extra. By mail, postpaid, to any address. Philadelphia and New York: Lea Brothers & Co.

PHYSICIAN'S POCKET ACCOUNT BOOK. By J. J. Taylor, M.D., 4109 Walnut St., Philadelphia. Containing Obstetric, Vaccination and Death Records and Cash Accounts. 4 1/2 x 6 3/4 Inches. Over 244 Pages. Leather. \$1.00. Also bound in manila boards with separate leather case. Price of case and two manila books, \$2.00. Subsequent manila books to use in the case, 60 cents each; two for \$1.00; three for \$1.40. Also large size for desk or office use, \$4.00. Philadelphia: Published by the Author.

THE MEDICAL RECORD VISITING LIST OF PHYSICIANS' DIARY FOR 1905. New Revised Edition. Bound in Flexible Leather, with Flap and Pocket, Pencil and Rubber. Price, \$1.25. New York: Wm. Wood & Co.

These three are neat, compact and well-bound pocketbooks for the recording of the names of patients and the services rendered day by day for a year. The two visiting lists contain in addition the usual summaries, the comparisons of scales, urinalysis rules, guide for emergencies, dosage and obstetric tables, etc. The pocket account book is especially devoted to the keeping of physician's accounts in ledger form and is so arranged that it shall be a book of original record, each patient's name being in a separate place. The two visiting lists are spaced by days and each day's record is by itself.

TEXT-BOOK OF HUMAN PHYSIOLOGY, Including Histology and Microscopic Anatomy, with Especial Reference to the Practice of Medicine. By Dr. L. Landis, Professor of Physiology and Director of the Physiological Institute in the University of Greifswald. Tenth Revised and Enlarged Edition. Edited by Albert P. Brubaker, M.D., Professor of Physiology and Hygiene in the Jefferson Medical College. Translated by Augustus A. Eshner, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic. With 324 Illustrations. Cloth. 17, 1927. Price, \$7.00. Philadelphia: J. P. Blakiston's Son & Co., 1904.

This is the fifth English and the tenth German edition of this work. The part devoted to the circulation is complete: abnormal conditions, abnormalities in the heart sounds, murmurs, etc., are contrasted with the normal condition. Directions are given for transfusion of blood. The action of the ductless glands and the influence of their secretions on the circulation are only briefly mentioned. The pituitary body is not mentioned at all in connection with acromegaly. Electricity in relation to physiology is discussed at some length, as are the methods of making blood examinations and urinalysis. The section on the physiology of the organs of special sense is complete and practical.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN, For the Use of Students and Practitioners. By James Nevins Hyde, A.M., M.D., Professor of Skin, Genito-urinary and Venereal Diseases, Rush Medical College, Chicago, and Frank Hugh Montgomery, M.D., Associate Professor of Skin, Genito-urinary and Venereal Diseases, Rush Medical College, Chicago. Seventh and Revised Edition. Illustrated with 107 Engravings and 34 Plates in Colors and Monochrome. Cloth. Pp. 938. Price, \$4.50. Philadelphia and New York: Lea Brothers & Co., 1904.

The fact that seven editions of this work have been demanded is sufficient evidence of its high standard. The new chapters added on general pathology of the skin, radiotherapy and phototherapy, as well as the chapters on some of the rarer skin diseases, add materially to the value of this volume over preceding editions. The bibliographic references show evidence of the most careful research of dermatologic literature and are of great value to dermatologists. The revision and enlargement which this edition has undergone brings it up to date and keeps it in the front rank as a text-book for both students and practitioners.

PRACTICAL DIETETICS WITH REFERENCE TO DIET IN DISEASE. By Alda Frances Pattee, Graduate Boston Normal School of Household Arts. Second Edition, Revised and Enlarged. Cloth. Pp. 312. Price, \$1.00. Published by the Author, 32 W. 39th St., New York City, 1904.

The second edition of this practical little work on dietetics shows evidence of careful revision. It possesses value to the physician as a reference book, to the nurse as a text-book and handbook and to the housewife who wishes to exercise care in the matter of diet. It is simple, brief and practical.

Miscellany.

Indexing of Current Medical Literature Abroad.—In Russia the *Russkii Vrach* makes a specialty of carrying the complete index of the prominent medical journals of the world, with a line or two of descriptive text with each title, but no abstracts in this department. In Germany the *Deutsche medizinische Wochenschrift* follows this plan, but has recently inaugurated the system of classifying the titles by subjects, and thus it is impossible to learn the actual contents of any one journal except by going over the entire list. Unless very ably edited, as in this *Wochenschrift*, this system would cause many mistakes, as an improper classification would cause the title to be lost. The *Münchener medizinische Wochenschrift* follows practically the system in use in THE JOURNAL, but restricts it to German periodicals. It is supplemented by semi-occasional reviews of current literature in France, England and eastern and southeastern Europe, abstracts being given of the articles deemed important, but no mention of the titles of other articles. This does not differ materially from the system followed in THE JOURNAL, by which the foreign journals not included in the Index are reviewed and abstracts of the important articles are published as Miscellany. In France the *Semaine Médicale* aims to publish the bibliography of the leading articles in current periodical literature, giving the titles alone, classified, but as it devotes only a given amount of space to it and uses large type, there is not room for a complete list. A number of the specialist journals abroad publish a full index of articles on their specialty, the *Annales de Dermatologie* having adopted the convenient device of printing the classified bibliography on the back of the advertising pages and in the shape of cards, which can be cut out and arranged in a card catalog without further ado. The *British Medical Journal* and the *Lancet* make no attempt to index periodical literature, the former devoting merely four pages in each issue to abstracts without any attempt at system even in these. The German periodical literature is overwhelmingly larger than any other. This is due in large part to the fact that when a Russian, Japanese or Scandinavian physician has a communication to make to the world of science he sends it to some German periodical at the same time as he publishes it in his home journal. Physicians in the Latin countries of both continents send their communications to the French journals in the same way. The publishing facilities of the larger journals are so superior to those of the home periodicals that the communication generally appears complete in the former, while it is still dragging as a serial through the latter or has not yet seen the light, or it may be published simultaneously in two or more countries to obtain a wider circle of readers. A number not long ago of the *Deutsche med. Wochenschrift* is a striking example of this cosmopolitanism. The issue for June 9, No. 24, contains 12 original articles—one each from Russia, England, Norway, Holland, Hungary, Roumania, Egypt, Poland, Colombia, two from Italy and one from New York—the contributions of a single month.

Treatment of Bright's Disease by Restriction of Salt.—Widal's communication last year on the effects of "dechloridation" in kidney disease was rapidly followed by others demonstrating the benefits of the same measure in certain cases of cardiac edema and in heart affections in general. Huchard called attention to the fact that the polyuria induced by digitalis is accompanied by polychloruria, and Merklen found further that the polychloruria induced by this drug vanished with the edema. The action on certain ascitic effusions of therapeutic restriction of the intake of salt has also been established. Vincent, Laufer, Liossier and Hayem have since published accounts of its favorable action in certain cases of hyperchlorhydria. Jaquet has reported a favorable influence on the coryza of albuminuric subjects, and Ravant has recently published that its action is most beneficial in certain cutaneous affections accompanied by exudation. Widal bases this mode of influencing Bright's disease on the discovery that in certain cases the kidneys become more or less impermeable to sodium

chlorid. Under normal conditions an average of 15 gm. a day is ingested, and almost the entire amount is eliminated by the kidneys. In some of his tests he found that 30 gm. of sodium chlorid were thus eliminated through the kidneys in twenty-four hours. When the kidneys become impermeable to the sodium chlorid its retention in the tissues attracts the water into them by physical affinity. The kidneys may develop this partial or total lack of permeability for sodium chlorid long before any of their other eliminative functions are impaired. It is detected by daily determination of the chlorids in the urine, a very simple task, not necessitating the elaborate technic of analysis of the different chlorids, etc. The balance between the salt ingested and that eliminated through the kidneys is thus easily determined. The salt with which the food is seasoned is weighed beforehand each day, and the patient is weighed every morning at a given hour after having urinated. The amount of salt in meat, vegetables, unsalted bread, etc., amounts to about 1.5 gm. If 10 gm. of salt are used for seasoning he is thus taking 11.5 gm. He is weighed every morning, and if he increases in weight constantly or variably water is evidently being retained in the tissues to hydrate the salt not eliminated by the kidneys, and edema may be expected soon. If by restricting the amount of salt ingested to 5 gm. the patient's weight remains stationary, it is evident that his kidneys are able to eliminate this amount of salt. By testing the patient thus from day to day it is possible to establish the salt balance and watch it gradually return to normal. The efficacy of milk in kidney disease is due to its lack of salt, but it is no longer necessary to "burn the house down to get roast pork." The desired result can be attained by a diet as varied as the subject may desire, provided it contains only the proper amount of salt which his kidneys are able to eliminate at the time. The capacity of eliminating salt varies with the condition of the kidneys, and treatment by reduction of the intake of salt, of course, acts only on this element of the kidney affection. It does not pretend to cure the entire syndrome, as the chloruremia is by no means all the uremia. The physician may, however, rest assured in every case that this alimentary restriction of salt is perfectly harmless and without any inconveniences for the subject with Bright's disease. There is always enough salt naturally in the various articles of food to suffice for the physiologic needs of the organism. The amount taken above this is from an acquired taste, and is actually an abuse of this substance. A healthy man can tolerate this extra amount without harm, but any one with kidney disease should pay unceasing attention to the salting of his food, and should always avoid an excessive amount, as he never knows at what moment it may become exceedingly injurious to him. The above is a summary of Widal's address presented at the first meeting of the newly organized Société de l'Internat. at Paris, April 28, bringing the subject of dechloridation—of which he is the father—down to date.

State Boards of Registration.

COMING EXAMINATIONS.

New Mexico Board of Health, Santa Fe, December 5. Secretary, R. D. Black, M.D., Las Vegas.

Board of Medical Registration of the State of California, San Francisco, December 6. Secretary, Charles L. Tisdale, M.D., San Francisco.

Ohio State Board of Medical Registration and Examination, Columbus, December 13-15. Secretary, Frank Winders, M.D., Columbus.

State Medical Examining Boards of Delaware, Wilmington and Dover, December 13-15. Secretary, P. W. Tomlinson, M.D., Wilmington.

The Medical Examining Board of Virginia, Richmond, December 13-16. Secretary, R. S. Martin, M.D., Stuart.

Board of Medical Examiners of Maryland, Baltimore, December 14-17. Secretary, J. McP. Scott, M.D., Hagerstown.

Missouri State Board of Health, St. Louis University, St. Louis, December 19-21. Secretary, W. T. Morrow, M.D., Kansas City.

Iowa State Board of Medical Examiners, Capitol Building, Des Moines, December 21-22. Secretary, J. F. Kennedy, M.D., Des Moines.

Oklahoma Medical Examining Board, Guthrie, December 28. Secretary, E. E. Cowdrick, M.D., Enid.

Arkansas October Report.—Dr. J. P. Runyan, secretary of the State Medical Board of the Arkansas Medical Society, reports the written examination held at Little Rock Oct. 11, 1904. The number of subjects examined in was 7; the total questions asked, 70; percentage required to pass, 75. The total number of persons examined was 20, of whom 15 passed and 5 failed. Among those who passed were 4 undergraduates and one person who did not give year of graduation. Among those who failed there were 2 who did not give date of graduation, 1 undergraduate and 1 not specified who attained a grade of 10. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Maryland.....	(1879)	79	
Arkansas University.....	(undergraduate)	75	
Baltimore Medical College.....	(1898)	83	
Med. Dept. Vanderbilt University.....	(1901) 91,	1891	76

University of Michigan.....	(1904)	84.78	

College.	PASSED.	Year Grad.	Per Cent.
Howard University, (1903) 68.47.....	(1904) 73.72, 71.69,	69	
University of Maryland.....	(1904)	52.75	
University of Virginia.....	(1904)	72.59	

The general average for all representatives of the Columbian University at the July examination was 86.6; for all representatives of Georgetown University, 87.4.

At the October examination the total number examined was

19, of whom 17 passed and 2 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Columbian University, New York City.....	(1901)	88.50	
Columbian University, (1904) 91.60, 81.85, 83.16, 87.53, 84.12, 91.19, 84.12.			
Georgetown University, (1902) 88.04, (1903) 86.75, (1904) 94.56, 91.06, 80.66			
Howard University.....	(1904)	79.04	
National University.....	(1903)	93.013	
Rush Medical College.....	(1901)	87.569	
University of Michigan.....	(1902)	89.094	

College.	PASSED.	Year Grad.	Per Cent.
Georgetown University.....	(1904)	67.544	
Woman's Medical College of Pennsylvania.....	(1904)	73.944	

The general average for all representatives of Columbian University, at the October examination, was 86.6; for representatives of Georgetown University who passed, 88.2.

Washington Report for January and July, 1904.—Dr. C. W. Sharples, secretary of the Washington State Board of Medical Examiners, reports the examinations held January and July, 1904. The total number examined was 182, of whom 135 passed and 47 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Coll. of P. and S. of San Francisco.....	(1891)	81	
Cooper Medical College.....	(1850)	77	
McGill University.....	(1902)	86	
Toronto Univ. Med. Faculty, (1892) 71, (1899) 84, (1903) 91			
Trinity Medical College, (1897) 80, (1901) 83, (1902) 81, (1903) 75, 82, (1904) 81.			
Colorado School of Med. (State Univ.).....	(1903)	73	
Gross Medical College.....	(1896)	79	
Univ. of Georgetown.....	(1891) 81, (1897) 77, (1903) 78, 80		
Atlanta Coll. of Eclectic Med. and Surg., (1889) 72, (1894) 82			
Univ. of Heidelberg, Germany.....	(1903)	82	
Univ. of Amsterdam, Holland.....	(1887)	83	
American Med. Missionary Coll.....	(1900)	81	
Beane Coll. of Eclectic Med. and Surg., (1888) 78			
Coll. of P. and S., Chicago, (1878) 89, (1892) 82, (1902) 84, (1903) 76, 81, (1904) 88.			
Northwestern Univ. Med. School, (1887) 92, (1896) 83, (1902) 84, (1903) 92, (1904) 78, 84, 85, 87, 87.			
Rush Medical College, (1890) 70*, (1896) 75, (1894) 78, (1899) 89, —; (1901) 80, (1902) 83.84; (1903) 78, 86.			
The Chicago Homeopathic Med. Coll., (1894) 82; (1902) 85, (1904) 82, 83.			

College.	Year Grad.	Per Cent.
Indiana Medical College.....	(1902)	83
Univ. of Iowa Med. Dept.....	(1875) 75; (1904) 83

The following questions were asked:

NERVOUS DISEASES.

1. Name three prominent symptoms of locomotor ataxia. 2. Of what condition is choked disc (optic neuritis) the most prominent and most valuable symptom? 3. What is aphasia? Also state in a general way with the function of what part of the brain its presence indicates. What part of the cerebrum is defective? 4. Make a differential diagnosis between the "Status Epilepticus" and uremic convulsions. 5. What are the two most prominent symptoms of Meniere's disease? 6. Give in general terms the prognosis of the following diseases, for ultimate recovery (but not as regards life and death): (a) migraine, (b) chorea, (c) locomotor ataxia, (d) infantile palsy, (e) cerebral palsy of infancy, (f) paralysis agitans. 7. Give the symptoms of the acute stage (or onset) of infantile palsy. 8. What is the result of apoplexy and the prognosis of the condition? 9. What facial condition is often associated with mastoid disease, and why? 10. What is sciatia? Give its etiology and symptoms.

MATERIA MEDICA.

1. Describe the action of digitalis on the heart and on the kidneys. 2. What are diuretics? Give names and doses of five. 3. Give the method of action of sulphate of zinc and apomorphia, in producing emesis. 4. Give the minimum and maximum doses for an adult of—(a) tincture of opium, (b) tincture of belladonna, (c) fluid extract of colchicum root, (d) fluid extract of gelsemium, (e) powdered digitalis, (f) extract of hyoscyamus. 5. What ratio does hypodermic dosage bear to that by the mouth? What ratio does rectal dosage by the mouth? 6. Illustrate the action of each. 6. What are two indications for the administration of strychnin? Indicate the proper dose. 7. Give the symptoms of carbolic acid poisoning and the treatment of the same. 8. What is the indication for Fowler's solution? How does it act? Why and why? 9. Name four preparations of mercury, their doses and therapeutic indications. 10. Name five hypnotics and their doses.

MEDICAL JURISPRUDENCE.

1. Differentiate in a blood stain: (a) mammalian, 1., menstrual, 2. hemorrhage, (b) human, 2. What is atelactasis, how demonstrated, and what does it prove? 3. What is *contre coup*? 4. Bullet wound: Describe point of entrance and point of exit. 5. What is the difference in appearance of: (a) antemortem contusions and lacerations, (b) postmortem contused and lacerated wound. What is the cause of difference? How demonstrate that death was caused by: (a) carbolic acid, (b) strychnia, (c) arsenic. 7. A stain is supposed to be caused by spermatic fluid. Give full demonstration. 8. Describe burns of various degrees. 9. Differentiate eruption caused by croton oil from that of measles, smallpox or other eruptive diseases. 10. Outline your method of performing a postmortem examination of the thorax.

ANATOMY.

1. Inferior carotid triangle: (a) boundaries, (b) contents, (c) relation of vessels. 2. Popliteal space: (a) boundaries, (b) contents, (c) relation of contents. 3. Describe origin and distribution of great sciatic nerve. 4. Give the nerve supply of the hand. Describe shoulder, knee or hip joint. 6. Describe the anterior abdominal wall. 7. Locate and describe the thyroid gland, with its most important relations. 8. Locate four of the principal motor centers in the cerebrum. 9. What structures would be seen on a cross section of the body at the level of the twelfth dorsal vertebra? 10. Describe the gall bladder and the bile ducts. Give their relations.

OBSTETRICS.

1. Name the bones of the pelvis. Give the diameter of the inlet and of the outlet. 2. What are the symptoms of pregnancy? Describe etiology; symptomatology and management of threatened abortion. 3. Give management of the normal antipartum parturient and the puerperal period. 4. What is prolapsus funis? How would you manage the same? 5. What is hydrocephalus? How would you recognize and manage the same? 6. Describe the placenta previa and your method of managing the same. 6. Give etiology, symptoms and management of a case of puerperal eclampsia. 7. How would you manage a case of retained placenta? 8. What do you understand by glass concretion of the management? How is it recognized and how overcome? 9. What is phlegmasia alba dolens? Give symptoms, etiology and management. 10. Differential diagnosis between pregnancy and pelvic tumor.

PRACTICE.

1. What is chronic bronchitis? Give its causes. 2. Name the normal pulmonary sound in auscultation of the different regions of the thorax. 3. Name the variations of the voice, sound in pathological conditions of the lungs and their causes. 3. What are complications, prognosis and treatment of acute rhinitis? What is chronic

rhinitis and its pathologic anatomy? 4. Give causes and diagnosis of gastric ulcer. 5. Define hyperchlorhydria (hyperacidity), causes, symptoms, diagnosis and treatment. 6. Define Argyll-Robertson pupil and name the disease in which it is one of the diagnostic symptoms. 7. What is angina pectoris, its causes and with what conditions is it associated? 8. What are the varieties of aneurism of the aorta? Give symptoms and diagnosis. 9. What are the symptoms and physical signs of aortic regurgitation? When uncompensated? 10. What are symptoms, diagnosis and treatment of leucocythemia?

DISEASES OF THE EYE AND EAR.

1. Give diagnosis, treatment and prognosis of trachoma. 2. Give diagnosis and treatment of chalazion. 3. Describe the mechanism of accommodation, and how is accommodation measured? 4. Give etiology, prognosis and treatment of glaucoma. 5. Give causes and diagnosis of sympathetic ophthalmia. 6. Describe the normal appearance of the membrana tympani. 7. Give the diagnosis and treatment of acute otitis media. 8. Give cause, symptoms and treatment of eczema of the auditory canal. 9. What are the symptoms and treatment of necrosis of the ossicles? 10. Give diagnosis and treatment of aural polypus.

CHEMISTRY.

1. Describe and fully explain the chemistry of Fehling's sugar test. 2. Name three chemical tests for albumin. 3. Distinguish between ionic and ous terminations. 4. Give formula of nitrate of silver and test for same. 5. What is an acid? Give names and formulae of three used in medicine. 6. Write a chemical equation. 7. Define specific gravity. 8. Give difference between chemical and mechanical compounds and an example of each. 9. Give a simple method of estimating the amount of uric acid in urine. 10. Roughly estimate the total amount of solids in urine.

DISEASES OF WOMEN.

1. Define dysmenorrhoea; give common causes. 2. Differentiate between uterine fibroids and carcinoma of the uterine body. 3. Give diagnosis and treatment of specific vaginitis. 4. Describe operative treatment of perineal fistula. 5. Give the technical operation for the relief of retroversion. 6. How would you prepare the abdomen for celiotomy? 7. Give diagnosis of hydro-salpinx. 8. Give causes and treatment of severe uterine hemorrhage. 9. Give symptoms and treatment of cystocele. 10. How do you treat an incomplete abortion?

ELECTRIC MATERIA MEDICA.

1. What are the properties of lobelia inflata? (b) What tissues are influenced by it? (c) When is it indicated? 2. What are the five indications for remedial agents? (b) What classes of agents would you give to meet them? 3. Name five diaphoretics? (b) Name five diuretics. (c) Name five hepatics. 4. Give treatment you would employ in a case of emphysema of the chest of three months duration in a child of ten years old. 5. Give treatment of a case of acute pleuritis with effusion. 6. Give treatment for catarrhal gastritis. 7. What agents would you employ in cerebrospinal meningitis? 8. Give symptoms and treatment of capillary bronchitis. 9. What would constitute the course of treatment of articular rheumatism? 10. Name five vegetable nontoxic nerves.

SURGERY.

1. How would you prepare the patient and field of operation for a laparotomy? What physical conditions would contraindicate general anesthesia? 2. Define a benign and a malignant tumor. Name three types of each. Give prognosis and frequent location of each of the latter. 3. Give prognosis and treatment of a non-united fracture of a long bone. 4. Give prognosis and treatment of penetrating wounds of the abdomen. 5. Give the etiology and pathology of the so-called hip joint disease. Give the symptoms and treatment of an incipient case. 6. Differentiate between an intracapsular fracture of the femur and a dislocation of the head of same. 7. Give symptoms and diagnosis of fracture of the base of the skull. 8. At what age of infancy would you advise an operation for talipes; also cleft palate. 9. Give differential diagnosis between backward dislocation of the ulna and fracture of the humerus near the condyles. 10. Give the differential diagnosis between inguinal hernia and hydrocele.

DISEASES OF CHILDREN.

1. Give the best method of preparing cow's milk for a child one month old. How often do you feed and how much do you give at a time? 2. Give the symptoms and course of cerebrospinal meningitis. 3. Give the etiology, symptoms, course and treatment of infantile atrophy (marasmus). 4. Give etiology and treatment of tetanus neonatorum, and how is it prevented? 5. Give the etiology, symptoms and treatment of acute gastroenteric intoxication. 6. In a normal child what are the indications for weaning? 7. Describe the appearance of the tongue and pharynx in scarlet fever. Give three common sequelae of scarlet fever and the means of prevention of each. 8. Give the differential diagnosis between diphtheric and follicular tonsillitis. 9. Give the complications and sequelae of follicular tonsillitis. 10. What is your opinion of the condition sometimes called membranous croup?

PREVENTIVE MEDICINE.

1. How is the infection of yellow fever disseminated, and how may it be prevented? On what does the infection of anthrax depend, and what is the method of prophylaxis? 3. What is glanders? How is it disseminated? What is its prophylaxis. 4. What is the source of infection of bubonic plague, its mode of distribution, and its prophylaxis? 5. Scarlet fever? Give (a) method of dissemination? (b) are fomites dangerous in scarlet fever? If so, what would be the period of infection, if not disinfected?

PHYSIOLOGY.

1. Name the functions of the Rolandic region, and the order of its subdivisions, from above downward. 2. Describe and give the function of: (a) Red blood cell, (b) leucocyte, (c) fibrin. 3. Give the physiology of the fetal circulator. 4. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration? What is meant by tidal, complementary, reserve and residual air? Give volume of each normally. 5. Name digestive ferments. Give complete digestion of starch, protein and fat, and the products of the final circulator. 6. Name the different types of respiration?

through the heart. What is cause of first heart sound? Of second heart sound? 3. What do you understand by metabolism? 10. Give the functions of the tracts of the spinal cord as seen in a transverse section of the cervical region. Of the dorsal region.

HISTOLOGY.

1. Classify and describe ciliated epithelia, and give location of each. 2. Describe a cross section of long bone. 3. How does heart muscle differ from voluntary muscle in structure? 4. Describe the lymph glands. 5. Describe the wall of an artery. 6. Give structure of a cross section of fallopian tube. 7. Does the nerve sheath or investing membrane cover the nerve axis at its termination?

HOMOEOPATHIC MATERIA MEDICA.

1. Differentiate between the mental symptoms of hyoscyamus and stramonium. 2. Describe eye symptoms requiring argemone nitricum. 3. For what kind of troubles would you give *viola odorata*? 4. Give three remedies most frequently required in diphtheria, with indications for each. 5. Give three characteristic indications for muriatic acid. 6. What is the chief field of action for *agaricus muscarius*? 7. Differentiate between *cannabis indica* and *cannabis sativa*. 8. For what is *bariata caru* used? 9. Give three most important remedies for diabetes mellitus. 10. What is the chief characteristic for *cuprum metallicum*?

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Nov. 19, 1904:

Leach, Charles, asst.-surgeon, sailed for Tokyo, Japan, on special detached duty.

Porter, Ralph S., asst.-surgeon, granted fifteen days' leave of absence.

Smart, Robert, asst.-surgeon, granted one month's leave of absence about November 21, with permission to apply for fourteen days' extension.

Appel, A. H., surgeon, ordered to return to Manila, P. I., for assignment to duty.

George, James, asst.-surgeon, left Fort Sheridan, Ill., with Troops I and K, Eleventh Cavalry, en route to Fort Des Moines, Iowa.

Wolven, F. Homer, contract dental surgeon, granted leave of absence for two months.

Kellogg, Preston S., contract surgeon, granted leave of absence for one month.

McMillan, Clemens W., contract surgeon, granted an extension of ten days to his leave of absence.

Brewer, Isaac W., contract surgeon, granted leave of absence for one month.

Bell, Leonard P., contract surgeon, granted an extension of one month to his leave of absence.

Whipney, Jean C., contract dental surgeon, granted an extension of one month to his leave of absence.

Branch, Frederick D., contract surgeon, relieved from duty at Fort Ethan Allen, Vt., and ordered to duty at Fort Wood, N. Y.

Hansen, Morris J., contract surgeon, granted an extension of one month to his leave of absence.

Havard, Valery, asst.-surgeon general, sails on special detached duty for St. Petersburg, Russia.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Nov. 19, 1904:

Young, R. M., asst.-surgeon, detached from the *Oregon* and ordered home.

Webb, U. R., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered home.

Mayers, G. M., asst.-surgeon, detached from the *Raleigh* and ordered home.

Hoen, W. S., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *Oregon*.

Dykes, J. R., asst.-surgeon, detached from the *Rainbow* and ordered to the Naval Station, Cavite, P. I.

Cowan, J., pharmacist, retired, detached from the Naval Station, Port Royal, S. C., and ordered home.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Nov. 16, 1904:

Gassaway, J. M., surgeon, granted leave of absence for four days from November 23.

Young, G. B., P. A. surgeon, granted leave of absence for one month, or so much thereof as may be necessary on account of sickness.

Grubbs, S. B., P. A. surgeon, granted leave of absence for six days from November 14.

Anderson, J. F., P. A. surgeon, granted extension of leave of absence for the seven days from November 16.

Currie, D. H., P. A. surgeon, to proceed to Merced, Cal., for special temporary duty.

Steuer, E. M., asst.-surgeon, granted leave of absence for four days from Nov. 9, 1904, under Paragraph 191 of the Regulations.

Hallett, E. B., A. A. surgeon, granted leave of absence for two days from November 23.

Stegurs, H. H., A. A. surgeon, granted leave of absence for thirty days from December 2.

Cook, B. J., A. A. surgeon, granted leave of absence for eighteen days from November 19.

Davis, H. E., pharmacist, Department letter of Oct. 13, 1904, granting leave of absence for fifteen days from Oct. 26, 1904, amended so that said leave shall be for twelve days only.

BOARD CONVENEED.

Board convened to meet at the Marine Hospital, Port Townsend, Wash., Nov. 21, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon J. H. Oakley, chairman; P. A. Surgeon D. E. Robinson, recorder.

PROMOTIONS.

Asst.-surgeon Dunlop Moore commissioned as P. A. surgeon, to rank as such from June 4.

Asst.-surgeon Carroll Fox commissioned as P. A. surgeon, to rank as such from July 27.

Asst.-surgeon Matthew K. Gwyn commissioned as P. A. surgeon, to rank as such from August 8.

Asst.-surgeon Chas. W. Yoge, commissioned as P. A. surgeon, to rank as such from July 27.

REMOVAL.

C. E. D. Lord removed from the position of asst.-surgeon in the Public Health and Marine-Hospital Service, Nov. 15, 1904.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Nov. 19, 1904:

SMALLPOX—UNITED STATES.

Illinois: East St. Louis, Nov. 5-12, 8 cases, 1 death.

Michigan: Detroit, Nov. 6-13, 3 cases; at 50 places, Oct. 29-Nov. 5, present.

Missouri: St. Louis, Nov. 5-12, 13 cases, 1 death.

New York: New York City, Nov. 5-12, 1 case.

Ohio: Cleveland, Nov. 6-12, 1 case.

SMALLPOX—FOREIGN.

Austria-Hungary, Prague, Oct. 22-29, 13 cases.

Brazil: Bahia, Oct. 8-15, 11 cases, 3 deaths; Para, Oct. 1-21, 29 cases, 4 deaths.

France: Lyons, Oct. 22-29, 3 cases.

Great Britain: Leeds, Oct. 22-Nov. 5, 4 cases, 1 death; London, Oct. 22-29, 1 case.

Russia: Moscow, Oct. 15-22, 2 cases.

Turkey: Oct. 22-29, Alexandretta, 1 case; Beirut, present; Constantinople, Oct. 23-30, 20 deaths.

YELLOW FEVER.

Cuba: Santiago, Punta de Sal, Nov. 8, 1 case.

Mexico: Coatzacoalcas, Oct. 29-Nov. 5, 3 cases, 2 deaths.

Venezuela: LaGuayra, Oct. 22, present.

CHOLERA.

Persia: Tabris, Sept. 27-Oct. 2, 209 deaths.

Turkey: Bagdad and vicinity, Sept. 17-Oct. 1, 272 cases, 216 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Nov. 11, 1 death.

PLAGUE—FOREIGN.

Brazil: Bahia, Oct. 8-15, 3 deaths.

Egypt: Alexandria, Oct. 8-14, 2 cases, 1 death.

India, Karachi, Oct. 8-16, 9 cases, 11 deaths.

Mauritius: Aug. 5-Sept. 8, 31 cases, 20 deaths.

Medical Organization.

NEW ORGANIZATION WORK IN INDIANA.

BY J. N. M'COORMACK.

In accordance with plans made by the council of the Indiana State Medical Society, I have recently, as the representative of the American Medical Association, visited and addressed meetings of the county society officers and representative members in nine of the thirteen council districts of that state.

As this is in a measure an extension of my duties in organization work, evolved as a seeming necessity in lieu of something better, which is probably to be adopted in other states, and as the experience was as interesting and instructive to me as it could have been to any of the others participating in these gatherings, and as the account may be made of practical value to others, it may be proper that the results of the trip and the impressions gained, go before the profession of the entire country.

The itinerary was so planned by the council that it was easy to go from district to district in regular order, and with the least possible travel and expense, but the place of meeting within the district, and all details as to arrangements, were left to the discretion of the individual councilor. In some districts two meetings were held, one at one end of the district in the afternoon and another at the other end in the evening, but

usually some central and easily accessible place was selected and but one meeting held.

The date being fixed by the council, when the place was decided on, the councilor would send a cordial invitation to every reputable physician in the district, whether a member of his home society or not, to attend and take part in the meeting. This invitation was supplemented by special efforts on the part of officers of county societies looking to the same end, and the telephone was often effectively used on the eve of the meeting. In such invitations physicians were informed that the meeting was solely in the interest of the county society and of the individual physician, and that after my talk on the necessity, methods and advantages of organization, all present would be invited to make criticisms and ask such questions as would make the meeting a practical consultation between those informed and interested, as to the conditions and needs of the profession in each county. As a result of these combined efforts the attendance was large in some districts, and in all of them it was fairly representative, and I was able in a personal way, and with more or less effect, to reach the profession in nearly every county.

It was soon found here, as in other states, that the plans, purposes and possibilities of such a real and comprehensive organization of the profession as would make each county society an active, living force for the practical every-day benefit of every doctor and individual within the jurisdiction had been realized by few even of the officers, and sometimes only imperfectly by the councilor himself. When these were unfolded and made plain to them, and they learned what had actually been done elsewhere by a union of all the forces at the command of a harmonious profession, the interest and enthusiasm were most encouraging.

The criticisms and inquiries were abundant and intelligent, and often very far-reaching and instructive. These indicated clearly that while a society existed in nearly every county, many, probably a majority, existed only in name, the meetings being infrequent, the attendance small and irregular—and the influence on the profession and community unimportant. It was nearly always easy to detect the obstacles in the way of complete organization, as they were usually on the surface, and the remedy often indicated itself on a frank statement of the conditions. In some instances the county officers, and especially the county secretary, were not active or tactful, and in a few instances the councilors had fallen short of their duty.

On the other hand, many strong, and some almost ideal, county societies were discovered which had done better work than those in any other state so far visited by me. At Valparaiso, as an adjunct to the county society, a regular post-graduate course of instruction had been carried on for three nights of each week during the whole of last winter, and they had just completed arrangements for a similar course for the present season. This included an excellent course in anatomy, with demonstrations on the cadaver, and a practical course in chemistry. The society had become incorporated so that it could legally obtain ample anatomic material from one of the state prisons. It is hardly necessary to say that there was little trouble in maintaining the interest and attendance in such a society.

The society at Michigan City had worked out another problem which confronts the profession in many sections of this country. As a result of the dissensions which had come down to them as an inheritance from their forbears, fees had been so reduced as to seriously impair the usefulness of the profession. Even with those in most active practice the income was so small as to interfere with equipment and progress. Two years ago the profession was so organized that every licensed physician in the city, after full and patient consideration and conference with lay friends, agreed to a fair and equitable schedule of fees, which at once put them on a well supported basis, the night fees being placed high enough to prevent such calls except when actually necessary, and I was informed in the presence of the entire faculty that in the entire two years not a complaint had been made in or out of the profession, either in regard to this action or in carrying it out. Of course, this was not done as a society, but it was the direct outgrowth of the harmony and spirit of co-operation made possible by organization, and the benefits both to the profession, which was better supported, and to the community, which was better served—were so evident that there was no trouble in keeping up the attendance and interest in that county society.

The advantages of a district society, meeting annually, for an interchange of opinions and plans, was well illustrated in these two counties. Although adjacent to each other, neither

one knew what the other was doing along the lines here outlined until they were brought together to meet me. Each expressed the intention of taking immediate advantage of the experience the other had gained, and the representatives from the other counties had the benefit of all of it plainly set forth as in practical operation. If the councilor district societies meet only once a year, half-way between the meetings of the state societies, and merge their proceedings into those of the county societies for that month, and have no dues, they have a distinct and useful place in our plan.

The hospitality of the Indiana physicians was constant and most gracious. Dinners, lunches or smokers for all in attendance were provided everywhere, and at South Bend an elaborate banquet was arranged. At Muncie a most pleasant innovation was made by the invitation of the wives and daughters of physicians to the dinner.

All in all the visit, while exacting and laborious, was a profitable and instructive one to me, and must result in good. I have since gone on similar itineraries which have been arranged for me in Wisconsin and Kansas, after which the other four districts in Indiana will be visited, as well as two or three counties in that state where special difficulties have been encountered.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Southern Surgical and Gynecological Association, Birmingham, Ala., December 13-15.

Western Surgical and Gynecological Association, Milwaukee, Wis., December 28-29.

American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Oct. 19, 1904.

The President, Dr. John E. Murphy, in the Chair.

Diabetes.

DR. EDWARD F. WELLS said that this disease is characterized by hyperglycemia and glycosuria, probably due to hypoglycolysis, from insufficiency of the pancreatic internal secretion. Glycosuria and diabetes are not synonymous. He mentioned the alimentary, nervous, renal, adrenal and diabetic forms of glycosuria. The essential cause is insufficiency of internal pancreatic secretion.

DISCUSSION.

DR. ARTHUR R. ELLIOTT stated that definite lesions of the pancreas have been found in 50 per cent. of cases of diabetes which have come to autopsy. Several authors have reported instances of undoubted pancreatic diabetes, in which there was no emaciation, but exceptions to the rule are so rare that Dr. Elliott reported two cases.

CASE 1.—C. M., a schoolgirl, aged 21, consulted him in April, 1903. In November, 1901, sugar was first discovered in the urine; intense thirst, polyuria, polyphagia and menstrual irregularity were the symptoms at that time. The patient's normal weight was 142 pounds, and during the first eighteen months which elapsed after the discovery of the glycosuria, she gained eighteen pounds, attaining a maximum of 150 pounds, in spite of a strict dietary. When she consulted Dr. Elliott her weight was 148, she was of firm musculature, possessed a high color, well-rounded body curves and looked the picture of health. She complained of polyuria, excessive thirst and appetite, fatigue, dryness of skin and mucous membranes. There were numerous small furuncles and troublesome pruritus vulvæ; urine 82 ounces; specific gravity, 1.036; 3 per cent. sugar; diætic acid and acetone were present. The patient remained under observation until a few days before her death from diabetic coma, December, 1903. During the period the glycosuria fluctuated between 1.5 and 3 per cent. Acetone and diætic acid were constant urinary ingredients, betaoxybutyric acid being first positively demonstrated in May, 1903. At no time did the body weight suffer, and at the time of the patient's death stood at 142. No autopsy was procurable.

CASE 2.—F. E., at the time of consultation, was passing 136

ounces of urine, containing 6 per cent. of sugar. There were traces of acetone, but no diacetic acid. Her normal maximum weight is 160 pounds, which, at the time of consultation, was reduced to 141. Regulation of the diet caused a rapid elevation of the body weight to 155 pounds. The patient has been under continuous observation for six months. Sugar elimination ranges between 1 and 2 per cent. on a limited starch diet (100 grams per diem). For the past two months acetoneuria has been pronounced and diaceturia pretty constant; coma prodromes have once or twice developed. Despite the serious nature of the case and the probability of an early termination, the patient's weight has risen to 155, and she has the appearance of being in excellent health.

DR. JAMES B. HERRICK referred to the common teaching that a saccharine urine is one of high specific gravity. As a result many insurance companies direct their examiners to test for sugar only when the specific gravity is over 1015 or 1020. One should not fall into this error, but should remember that many a urine in true diabetes may for days and weeks at a time have a specific gravity of no more than 1018 or 1020. There are conditions under which the urine may have a much lower specific gravity than this and still be a saccharine urine. Von Noorden calls attention to the fact that preceding the period of glycosuria there is frequently a period of polyuria without sugar, and also following the period of glycosuria, when sugar is disappearing from the urine, there may still be an increased quantity, but of low specific gravity. If we happen to catch a patient just as the glycosuria is coming on, in the period of preglycosuric polyuria, or just as glycosuria is disappearing, we may find that a urine of low specific gravity contains sugar. Furthermore, the drinking of large amounts of water lowers the specific gravity, so that the patient may pass urine containing considerable sugar which still has a specific gravity of 1018 or 1020. Chronic interstitial nephritis, which occurs in the course of diabetes, lowers the specific gravity of the urine, and if a patient presents himself with the cardiovascular changes of this condition, with albumin and casts in the urine, the urine being of low specific gravity, we may carelessly forget to examine for sugar, so that we should make it a routine practice, even when we find a urine of low specific gravity, to test for sugar.

There is a certain type of diabetes that has a peculiar periodicity about it. He believes that we occasionally see sugar disappear from the urine spontaneously, even though the patient is rather careless as regards diet. The importance of recognizing this fact is seen when a patient consults a physician and says he has diabetes, and has been treated for it, and when one examines the urine he finds it sugar-free. It is easy for one physician to say that the other practitioner was mistaken in regard to the diagnosis, and to tell the patient that he is not suffering from diabetes. There is occasionally an unexplained periodicity about glycosuria as a part of true diabetes, just as in certain cases of nephritis for days at a time albumin is absent from the urine.

DR. FRANK BILLINGS stated that since studying Opie's contributions, not infrequently he has been able to elicit a history in these patients of disease of the gall tracts. He believes that there is a place for the surgeon in the treatment of diabetes, and specially in that form of the disease associated with the presence of gallstones in the gall tract, or a continued infection of the gall tract which can be removed by drainage. He agrees with Dr. Wells and others that "once a diabetic, always a diabetic," but he does not agree that this necessarily means that we should give a prognosis to patients of early death, because a patient, when once acquainted with his condition, may, by rigidly adhering to the hygienic treatment mapped out by his physician, live longer than his neighbor who has no diabetes. Two years ago von Noorden brought out as a therapeutic food test a combination of starches, chiefly in the form of oatmeal, of fats in the form of butter, and albumin in the form of egg albumin. For an individual weighing 150 pounds, von Noorden advises the use of 300 grams of oatmeal, to be mixed with 250 grams of butter, and 100 grams of egg albumin, the oatmeal to be steamed or boiled, and while hot to

have the butter intimately mixed with it, and finally the whites of a sufficient number of eggs to measure about one hundred grams or three ounces to be mixed with them. One would think this mixture would be unpalatable to the patient, or indigestible, but the speaker said the contrary is true. So far he has used it in hospitals and private practice on seven patients, and no complaint has been made that it was disagreeable to the palate or dissatisfied them. Immediate improvement occurred in five; in two there was no improvement. In all apparently the conditions as to acidosis, presence of diacetic acid and acetone in the urine, were rather increased than decreased. In five of the patients not only was the acidosis increased, but the per cent. of sugar was either diminished or became immediately almost absent. A young man from the West, who suffered from diabetes, passed 3,000 c.c. of urine in twenty-four hours with 2 per cent. of sugar, but within thirty-six hours from the time he began the meal the urine was without a trace of sugar. While there was in the first twenty-four hours a little reaction with the appearance in the urine of a trace of sugar, still, while the patient was under observation in the hospital for ten days, the urine was practically sugar-free.

Dr. Billings placed a child on this diet early in June of this year; until September the sugar entirely disappeared from the urine and the child gained nine pounds in weight. After being two months on this diet she began to complain and wanted something else to eat. The mother allowed the child bread in place of oatmeal, with egg and a light diet, and immediately the sugar began to appear in the urine. The child was again put back on the von Noorden diet, and the sugar disappeared. Not only has he used it since von Noorden's announcement for a therapeutic test, but as a steady diet for a month longer in some individuals, with not only the disappearance of the sugar, but improvement in the nutrition of the patient.

The good physician watches his patients carefully, measures the urine, and if he finds that on a rather strict diet the patient is losing weight, he adds to the diet something which will enable the patient to increase in weight rather than to continue a diet which means less sugar, but less in weight of the individual, for invariably as an individual decreases in weight there is coincidental with it, but not related to it in any way, acidosis and increase in diacetic acid and acetone, and consequently the case passing on toward coma.

DR. ALFRED C. CROFTAN said that a radical change of front has occurred within the last few years in regard to the administration of carbohydrates and sugars in diabetics. Many cases of acetonuria, diabetic and otherwise, will stop excreting acetone and its precursors and congeners, if a certain amount of carbohydrate is given. In cases of severe acidosis, particularly in patients who have been on a carbohydrate free diet for a long time, it is good practice, in impending coma, to give sugar. He goes further than that, and in extreme cases of coma, in which one is resorting to hypodermic or intravenous injections of sodium bicarbonate and alkalis, he has been in the habit of injecting directly into the veins, together with carbonate solution, a sugar, preferably levulose, and he believes in some cases that the recovery from the coma was due in part to the administration of this carbohydrate. He does not believe, however, that the statistics of the von Noorden diet are so favorable as those mentioned by Dr. Billings. In his experience he has had some good results, and one bad one, and believes the poor result was attributable in part to the administration of the oatmeal. After stopping the oatmeal, sometimes a large amount of acetone is found in the urine which is out of all proportion to that found in any other disease accompanied by acetone. One need not be afraid of this. Not only oatmeal, but any of the ordinary starches, such as potatoes, rice or bread, can be utilized largely in this sense, provided care is taken to give a particular carbohydrate alone. He warns patients to take either oatmeal alone, or potatoes or rice alone, but not to take rice and oatmeal together, or oatmeal and potatoes together. The same effect is produced in some cases by the single administration of one carbohydrate.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, held Oct. 26, 1904.

The President, Dr. Roland G. Curtin, in the Chair.

Typhoid Fever Complicated by Appendicitis.

DR. MOSES BEHREND reported a case of typhoid fever of a rather severe type; in the third week of the disease the patient developed symptoms of perforation which at operation were found to be those of appendicitis. He recovered from an operation and ten days afterward was tapped for pleurisy with effusion. About fourteen days after this he developed pneumothorax. The patient made a fine recovery.

DISCUSSION.

DR. L. J. HAMMOND said that he thought that the case illustrating the fact, now generally admitted, that appendicitis occurring in the course of typhoid fever is entirely coincident, and in no way connected with the typhoid process, and that the majority of cases of appendicitis occurring in the course of typhoid fever are recurrent attacks. Given a case of typhoid fever with the early symptoms of pain, rigidity and other symptoms of appendicitis, one should suspect the presence of a large amount of adhesions, and if the symptoms are severe the surgeon is justified in operating at once. The removal of the appendix, breaking up of adhesions and liberation of the coil of intestines will lessen the possibility of typhoid perforation.

DR. W. H. TELLER considers that notwithstanding the fact that the mucous coat presented all the symptoms of typical catarrhal appendicitis, the condition was that of preperforative typhoid, with involvement of the peritoneal covering of the appendix by extension and not a case of pure appendicitis.

DR. J. ALLISON SCOTT stated that there are several varieties of inflammation of the appendix in typhoid fever. Reviewing the literature of the perforation of the bowel, and collecting statistics of the hospitals of London and suburbs and of the Pennsylvania Hospital, he has found 382 cases of perforation, seventeen of which were in the appendix alone and due to ulceration from within. There is another type, in which during the course of the typhoid fever, or during the convalescence, acute inflammations of the appendix have been set up, not due to ulceration within the appendix, but from the appendix becoming gangrenous and perforating in the ordinary form of appendicitis. Dr. Scott is inclined to believe that if cases of perforation of the bowel are studied carefully it will be found that the appendix is involved more frequently than is thought.

DR. ASTLEY P. C. ASHHURST believes that there are several varieties of appendiceal inflammations during typhoid fever. That they may be distinguished by the different symptoms he does not think is possible. In the early stage of typhoid fever there may be constant pain, vomiting and a certain amount of shock, with rigidity over the appendix. At operation there may be found infiltration of the appendix and an appendicitis, the probability being that these are only typhoid lesions in the appendix. Later, the same conditions may be present through perforation of ordinary inflammation of the appendix. The inflammation, he believes, will so obscure the typhoid lesions that to distinguish one from the other would hardly be possible.

DR. BEHREND declared his belief that the case was one of pure appendicitis, due to the extension of the inflammation resulting from a case of pure typhoid fever. As interesting facts connected with the case Dr. Behrend stated that of five nurses connected with the case, one contracted typhoid fever and recovered while another contracted appendicitis and died from peritonitis. The patient's wife contracted typhoid fever and recovered.

The Trend of Modern Prescription Writing.

DR. M. CLAYTON THRUSH read a paper on this subject which will be printed in full in THE JOURNAL.

DISCUSSION.

DR. S. SOLIS-COHEN asked what Dr. Thrush meant by "therapeutic incompatibility." Aconite and digitalis, or nitroglycerin

and strychnin are to a certain extent incompatible, yet under some circumstances may be given together. He also asked the meaning of the expression "proprietary preparation." Squibbs' ether, he said, is a proprietary preparation, and so is antikamnia, yet there is a considerable difference between the two.

DR. THRUSH replied that by therapeutic incompatibility he meant the combination of those ingredients which from a therapeutic standpoint were directly antagonistic, and in which the action of the drugs would be particularly antagonistic. He had met two instances in which aconite and digitalis had been used, but he felt that it had been done for a certain object. The question of proprietary preparations was one considerably confused in the minds of all. His reference was to those preparations of which the chemical or pharmaceutical composition is known, but which are dispensed by some particular chemical manufacturer, who has a copyright for that preparation which no one else can use.

The Relation of the Physician to the Bureau of Health.

DR. S. W. NEWMAYER said that in the word "co-operation" are gathered all the duties of the physician to the bureau of health. There should be no need of legally calling some physicians to account for failure to report cases of contagion in order to set an example to other physicians. He made a plea for a more accurate and an earlier diagnosis by laboratory methods, and for a postgraduate course in the clinical diagnosis of the more common communicable diseases. The bureau of health, he believes, should have under its supervision a series of lectures and demonstrations by competent teachers, which physicians should be invited to attend. It should be compulsory for all medical students to attend lectures on contagious diseases and to see cases in the city hospital. There should be given to each graduating class one or more lectures on the duties of a physician to the bureau of health, explaining what diseases to report and the best means to protect the public. To lessen the mortality from tuberculosis there should be a practical and concerted plan of education, as well as a report of cases of tuberculosis. Every physician should impart the principles of domestic hygiene to those to whom he is called in his daily work. The consideration of simple lessons on contagious diseases should be borne in mind by physicians having the revision of school text-books. To lessen the infant mortality, largely caused by impure milk and improper food, the physician, trained nurse and even the public should be taught a few practical and simple tests for impurities in milk.

DISCUSSION.

DR. EDWARD MARTIN, director of public health, said that the desire of the bureau of health is to help the medical profession, to act as its agent, and not as a foreign intervention. The bureau asks the help of the profession and is ready to give its assistance in return. He referred to the corps of young men instructed in the work, every man of which had been a hospital resident, had had a special course in contagious diseases and, in other directions, had been fitted for the work. Dr. Martin said that one can not teach all men tact and judgment; one can make many men wise, but can not make all men sensible. The underlying spirit of every man in the corps, however, he said, is to help, and to stand by the profession, and not to interfere.

DR. RANDOLPH FARIES stated that many cases of contagious diseases are never reported, because the families can not employ a physician. These usually come under notice by accident. The solution of this problem is of vital importance.

DR. KATE W. BALDWIN said that she would be grateful for the solution of this problem; many such cases appear at the dispensaries and it is almost impossible to make cultures and to watch the patients. They have no family physicians, and they are frequently found playing with other children in the alleys, and are found to have diphtheria.

DR. ANDREW A. CAIRNS said that it is contrary to the methods of the bureau of health for a medical inspector to examine a patient. The only examination required is at the termination of the disease, when the inspector is to see all cases before ordering fumigation; any mistakes between the medical inspec-

tor and the attending physician should be corrected as early as possible.

DR. HENRY BEATES said that he thinks it possible to devise some ethical means to establish the proper relation of the physician to the bureau of health.

DR. ANDREW A. CAIRNS stated that there are only two diseases on which the bureau of health requires the medical inspectors to make diagnoses: smallpox and chicken-pox, and that if a medical inspector makes himself obnoxious it is not done under orders.

DR. WALTER S. CORNELL referred to the methods of disinfection of houses and of the giving of antitoxin at the hands of the bureau of health.

DR. HENRY BEATES pointed out as important the need for some rule or law by which a responsible physician, the moment he is in contact with an infectious disease, can control the family until the board of health can act.

DR. I. VALENTINE LEVI said that the fact that the board of health should carry out the disinfection, unless the physician obtain special permission to do so, has been the source of much trouble between the medical inspector and the physician. The family physician tells the family to burn some sulphur and that the board of health will not need to do anything, and when the medical inspector appears and insists that the house be disinfected he gets all kinds of beautiful appellations. In one instance the medical inspector was reported to the central office as doing everything possible against the medical profession. He felt that the physician should tell the patients that the house must be disinfected by the board of health, unless he orders otherwise.

DR. S. SOLIS-COHEN regards as important the question of what is to be done with patients suspected of having diphtheria, until a culture is made. He believes it the duty of the physician, whether in his office or in the dispensary, to disinfect the throat promptly when there is any question in diagnosis. His experience with the board of health and its inspectors leads him to declare that there need be no trouble if both sides are willing to act as human beings who recognize their own liability to make mistakes. Occasionally an officious or tactless inspector has done or said something in the household of a patient to which he felt he could take reasonable objection, but he has always found that communication with the superiors of such a man has been the means of having him so instructed that he does not repeat the error elsewhere. He believes that each physician should be prompt and unsparing in the direct report to the chiefs of the bureau of health, of any dereliction, or seeming offense, on the part of their inspectors. Sometimes it will be found that the physician has been misinformed by the patients. He feels that the bureau of health is deserving of all the support and advice that can be given by the medical profession.

DR. JAY F. SCHAMBERG agreed with Dr. Cohen that there are many instances in which both patients and physicians are misrepresented. He knows that the average ability of the members of the board of medical inspectors in the detection of contagious diseases is of a very creditable standard, and is bound to increase. He believes that the medical profession has full confidence in the bureau of health, and that the subject should be approached with a little more charity on both sides.

Travel Notes.

XVII.

MADRAS MEDICAL COLLEGE AND GOVERNMENT GENERAL HOSPITAL.

NICHOLAS SENN, M.D.

CHICAGO.

CALCUTTA, INDIA, Sept. 17, 1904.

India with its 300,000,000 inhabitants has only four medical colleges, located at Madras, Calcutta, Lahore and Bombay. All of these medical schools are in affiliation with the respec-

tive universities. On recommendation of the medical faculties the universities confer the degrees, but the medical schools receive no financial aid from the universities and set their own standards of requirements for admission and graduation. All the medical schools are patterned after those of the United Kingdom as to requirements for admission, graduation and methods of teaching. From information obtained from different sources I find that the great stumbling block of the Indian medical student is language. A knowledge of Latin is a *rara avis* and the meaning of ordinary English words is hard for them to express and comprehend. The teachers find this imperfect knowledge of the English language the greatest drawback in ingrafting their ideas into the minds of the students. The number of medical students in the different institutions at the present time is about 2,000. Very few Mohammedans study medicine; the great majority of students are Hindus and Parsees. The Hindus are said to be the brightest students. The classes have increased in size very rapidly during the last few years, so rapidly, indeed, that space and equipment in all of the schools have become entirely inadequate. From what I have seen of the students in the different medical colleges I have become impressed with their lively, cheerful dispositions and their earnest devotion to their work. The teaching force, as a rule, is inadequate in number in all the schools, and in consequence the men are overworked. I will give only one striking instance of this kind. Lieutenant-Colonel Dimmock of Bombay is director of the Jamsetjee-Jeejeebhoy Hospital, principal of Grant Medical College, and professor of obstetrics, gynecology and diseases of children. Enough work for five men under ordinary circumstances. The men of the Indian medical service who are engaged in medical teaching are overworked and underpaid, and they are the men who do more for India than any other class of men.

MADRAS MEDICAL COLLEGE.

The Madras Medical College was originally established as a medical school in 1835 (Fig. 1). The classes received their instruction at first in rooms adjoining the quarters of the surgeon general of the general hospital. The main building of the school was opened in 1836 and then consisted of four apartments—a theater or lecture room, a library, a museum and a laboratory. The school commenced with a teaching force of seven, 10 medical apprentices and 11 native medical pupils. Private students were first admitted in 1838. They obtained, in common with government students, a free education. In 1851 it became a college, and in 1857 it was placed in the list of affiliated institutions. The buildings were altered and enlarged in 1867. In 1885 separate anatomic buildings were erected, to which were added a theater with a dissecting room for the pupils of the hospital assistant department and a museum in 1887-88. Separate buildings for biologie and hygienic laboratories followed. In 1875 the college admitted on its rolls three new classes of students—viz., candidates for the degree of licentiates in medicine and surgery, for the new grade of civil apothecary, and female students. The system of free education for the students of the college department was abolished a year before this department had been closed, in order to allow the professors to devote themselves to the teaching of subordinates for the service of government. For the second time the hospital assistant department was transferred to the auxiliary medical school at Rayapuram in 1903. The principal of the college at the present time is Lieut.-Col. J. Maitland, M.D., I.M.S., F.M.U. The teaching staff consists of 23 professors and assistant professors, and the number of students is 400. Major G. G. Gifford, I.M.S., is professor of surgery, and Miss V. Adams, M.B., lecturer in midwifery to female students. The calendar of the college for 1904-1905 contains the following regulations:

DRESS—FOR NATIVES ONLY.

1. The typical dress.—Turban, a long or short coat buttoned up to the neck, trousers, socks and English shoes. Underclothing according to choice, but where the material of the coat is not washable, e. g., tweed, a linen collar should be

worn, and, if the coat does not button up to the neck, collar and tie must always be worn, whatever the material. The Parsee hat and Burman head cloth are, for the purposes of these regulations, to be regarded as turbans.

2. Modifications permissible. (a) Students who wear a "tuft" or who shave the scalp, must wear a turban which must conceal the tuft when it is present. (b) Students who dress their hair after the European fashion may wear caps, but indoors, if their dress is otherwise European, the cap

cepted by the syndicate as equivalent thereto. The course of training for this class extends over five years, and the fees charged for tuition are:

	Rupees.	
For the first year of study.....	100	(\$32.00)
For the second year of study.....	155	(49.60)
For the third year of study.....	155	(49.60)
For the fourth year of study.....	100	(32.00)
For the final year of study.....	100	(32.00)

Or if paid in one sum on joining college, 500 rupees, equivalent to about \$160.

The course for the L.M. and S. degree extends over four years and the fees charged for the whole course if paid in advance amount to 470 rupees (\$150). The candidates for these degrees are obliged to pass only three examinations. The first examination includes one course in each of the following branches: Anatomy, physiology, chemistry, practical chemistry, practical pharmacy, histology. The second includes one course in medicine, surgery, materia medica and therapeutics, general pathology, practical pathology and bac-

Fig. 1.—Madras Medical College and Government General Hospital.

must be removed. (c) A cap when worn must be black and may have a lace border, but not otherwise decorated—and no caps are allowed to be worn on ceremonial occasions, such as prize distribution, etc. Mohammedans may be allowed to wear the fez on ordinary occasions, but not at ceremonial observances. (d) Any student may wear a dhoti or mundu; he must then go barefooted indoors or wear socks and European shoes. The latter are recommended, as the feet are apt to get soiled or inoculated with septic matter either in the hospital wards, dissecting rooms or out-patient rooms.

Fig. 2.—Another view of Madras Medical College and Government General Hospital.

3. All articles of dress, whatever the material, must be clean.

This dress regulation must certainly interest our American students, as even with these restrictions the sight of a class of students of the medical colleges of India is a very much checkered and picturesque one, probably made up of more colors than the checkered coat of Joseph. The candidates for the M.B. and C.M. section must have passed the first examination in arts of this university, or an examination ac-

Fig. 3.—Chondrosarcoma of humerus and scapula. Successful interseapular amputation performed by Captain Niblock, I. M. S. of Madras.

teriology, hygiene, practical hygiene, medical jurisprudence, minor surgery. The third and final examination includes mid-wifery and diseases special to women and the newborn child, ophthalmology, mental diseases and operative surgery. The examination test for the degree of M.B. and C.M. is much more severe. Provision is made for the education of military pupils for the Indian subordinate medical department, colonial apprentices, apothecaries, male and female, and chemists and druggists. As an inducement for diligence on the part of the students the Madras Medical College offers annually nine medals, eleven prizes and ten scholarships.

MADRAS GOVERNMENT GENERAL HOSPITAL.

This institution is intimately connected with, and in fact is, the clinical part of the Madras Medical College (Fig. 2), all of the attending physicians and surgeons being members of its faculty. The hospital is made up of a number of two-story pavilion buildings around a capacious square court orna-

mented with tropic trees, shrubs and flowers. The buildings harmonize with each other. It can accommodate 450 patients. The amount and variety of clinical material in this institution is simply enormous. The operating theater, while not up to all of the modern requirements, is one of the best in India. Chloroform is the routine anesthetic. The favorite suturing material is silk and silkworm gut, as the use of absorbable sutures has given rise to many disappointments. Binioid of mercury is the favorite antiseptic for hand and surface disinfection and sterilized gauze is used for dressing wounds. I found a great many emergency cases in this hospital, fractures and accidental wounds, as well as a number of cases of abscess of the liver recently operated on. Among the most important cases was a man who was admitted into the hospital a few days previously with a strangulated inguinal hernia of four days' standing. Professor Giffard performed the operation. The bowel was gangrenous. Enterectomy was done, the continuity of the bowel restored by suturing and the pa-

Fig. 4.—Elephantiasis of the scrotum weighing 61 lbs. Photograph used by courtesy of Captain Niblock, I. M. S.

tient is recovering without having shown any untoward symptoms since the operation. Although inguinal hernia is met with quite frequently in Madras, femoral hernia is very rare, only one case being admitted to the hospital during the past 20 years. (Giffard.) Elephantiasis of the scrotum is very frequently operated on in this hospital (Fig. 4). Lieut.-Col. Maitland has performed this operation 160 times with most excellent immediate and remote results. Stone in the bladder is very common in this part of India. Crushing is the favorite operative procedure. Many surgeons, among them Professor Giffard, prefer to perform the operation through a median perineal incision instead of the urethra and in case the stone is too large to be removed by this method it is extracted either whole or in fragments through a suprapubic incision.

CARCINOMA IN INDIA.

An unusual number of cases of cancer of the mouth find their way into this hospital and its frequency is attributed by

the surgeons to betel chewing. Two pathologic forms are distinguished, the papillomatous and ulcerative, the latter being much more malignant and pursuing a very acute course. Capt. W. J. Niblock, I.M.S., surgeon Government Hospital, has contributed a very important article to the literature of "Cancer in India," published in the *Indian Medical Gazette*, May, 1902. The paper is based on the clinical records of this hospital. He has the following to say regarding betel chewing as a cause of carcinoma of the cheeks and jaws: "On looking at Table 1A one can not avoid being struck very forcibly by the enormous number of patients shown as admitted for carcinoma of the cheek and jaws. Carcinoma of the cheek alone accounts for almost one-third, and carcinoma of the cheek, jaws and tongue taken together for more than one-half of the total admissions. The cheek is the part most commonly affected in Hindus and Mohammedans, males and females. The disease affects the buccal surface of the cheek, generally commencing opposite the teeth of the lower jaw and spreading with varying rapidity. The frequency of carcinoma in this situation is, in my opinion, due to the chewing of 'betel,' a common habit in this country, and indulged in, I believe, by almost all classes of natives. 'Betel,' as used in the Madras presidency, is said to be made up of the following parts: (a) The essential constituents, viz., 'betel' leaf, areca nut, and caustic lime (chunam). (b) Condiments, such as cloves, nutmeg, cardamoms, eubeds. Dry powdered cocoanut and oil are also sometimes added. The above components are mixed in varying proportions, rolled up in a betel leaf, and placed in the mouth. They are then chewed and rolled about by the tongue and cheek for a period varying from 10 to 30 minutes and then spat out."

I can testify from observation to the universal use of betel both in India and Ceylon. Carcinoma of other parts of the body appears to be more rare than in our country. The tables of Capt. Niblock show, for instance, that 513 cases of carcinoma of the mouth were admitted to the General Hospital during 10 years, 1892-1901, and only 44 cases of carcinoma of the breast and 19 of the lip. Concerning the latter location he says: "Epithelioma of the lip, it will be noted, is comparatively rare, and, so far as my experience goes, affects both lips with equal frequency. The rarity of carcinoma in this situation is no doubt explainable by the fact that smoking from a pipe (or at any rate a clay pipe) is not indulged in by natives of this country." The comparative frequency of carcinoma of the upper lip referred to by Capt. Niblock stands almost isolated as a clinical observation and constitutes a very important contribution to the topography of carcinoma as it is observed in India. Hundreds of cases of carcinoma of the lower lip have come under my observation and only a single case of carcinoma of the upper lip (Fig. 3).

ABSCESS OF THE LIVER.

In visiting any of the large hospitals in India one is sure to find a few cases of abscess of the liver, and yet Capt. W. J. Niblock says the disease is not so frequent as is generally supposed. (Notes on operations for abscess of the liver, ascites, and gallstone. *Indian Medical Gazette*, November, 1903.) In looking through the reports of the Madras General Hospital, he found that, during the ten years, 1893-1902 inclusive, only 154 cases were operated on and during the last three years the average annual admissions were at the rate of 63,591. Of the 154 cases recorded, 21 were shown to be multiple, all of whom died. There were 53 deaths among the 133 other cases, several of which were, however, probably multiple, as some of the surgeons who performed the operations made no distinction between single and multiple abscesses in their records. Capt. Niblock reports the result of 29 cases of abscess of the liver operated on by himself from March 25, 1899, to Sept. 21, 1903. All the patients were males, their ages ranging between 14 and 70. The racial distribution was as follows: Hindu, 29; Eurasian, 3; European, 5; Mussulman, 2. Out of the 29 cases five were multiple, all of whom died. Among the remaining 24 there were six deaths, that is, the mortality was 25 per cent. All of the abscesses con-

taining less than 20 ounces of pus at the time of operation recovered. In the treatment of this affection the author of the paper emphasizes the importance of a preliminary exploration of the liver by means of a long needle and syringe.

His directions for exploring the liver are as follows: "If a distinct prominence be felt or seen, the needle is first introduced at that situation. Where no such prominence exists, the needle is usually introduced into the liver through the ninth or tenth intercostal space. After the liver has been pierced, the piston of the syringe is drawn back for an inch or so, leaving a vacuum. Should pus now enter the syringe, the latter is detached, leaving the needle sticking in the liver to act as a guide. If no pus be found, the needle is gently pushed upward, inward and slightly backward, this being the most likely direction in which to strike pus. It is gradually withdrawn if no pus is found, and reintroduced in another direction. Five or six different parts of the liver are thus carefully explored before the case is sent back with a negative result." The exploration is made under an anesthetic and if pus is found the operation is performed at once. After resection of about two inches of the ninth or tenth rib in the axillary line the liver is exposed by an incision. If adhesions are present the liver is incised at once; if there are no adhesions a strip of gauze is carefully packed all around the proposed line of the visceral incision. Sutures are never used, as they tend rather to favor than prevent the escape of pus into the serous cavities. With a small scalpel the capsule of the liver is incised. If the abscess is deeply situated a sinus forceps is pushed through the liver substance into the abscess, followed by the index finger and the needle is then withdrawn and one or two Keith's glass drains inserted. After evacuation of the pus one or two large fenestrated rubber drains are substituted for the glass drains and a large aseptic absorbent dressing applied. Washing out of the cavity with antiseptic solutions is abstained from, although the operator has seen good results from the use of a solution of quinin, 1 in 60 to 1 in 80, as advised by Capt. L. Rogers, I.M.S.

The nursing in the Madras General Hospital is in charge of 28 trained female nurses, 51 male ward attendants and 21 female ward attendants. Twelve female nurses resigned during the year and gave their reasons for this step as follows: Left to be married, 6; left to train as midwife, 1; retired on pension, 2; retired on account of ill health, 2; retired for private reasons, 1.

The amount of available clinical material of this hospital is something enormous. During the last year the institution cared for 60,842 out-patients and 7,177 in-patients. The total number of deaths that occurred in the hospital was 644. Among the most frequent causes of death we find malaria, 48; dysentery, 46; tuberculosis, 83; diseases of liver, 38; diseases of the urinary organs, 40. Cholera is credited with 5 deaths. Only 5 deaths occurred from septic diseases acquired in the hospital. They were as follows: One case of sapremia, 1 case of septic peritonitis after enterectomy, 1 case of erysipelas after operation on tubercular glands of the neck, 1 case of cancrum oris occurring in a patient suffering from malaria, and 1 case of gangrene of the leg following the puerperal state in a debilitated woman.

Forty-eight deaths occurred in cases of septic diseases acquired outside of the hospital, namely, 16 from tetanus, 9 from cancrum oris, 9 from cellulitis, 3 from gangrene, 2 from sloughing after extravasation of urine, 1 from sloughing of scrotum, 1 from sloughing phagedena of the penis, and 7 from septicemia (two puerperal).

The total number of operations performed was 6,281, with a mortality of only 1.9 per cent. Among the more important operations were 43 for elephantiasis of the scrotum, with one death; 8 suprapubic cystotomies for stone, with 4 deaths, 1 death following a median perineal operation and 2 litholapaxies, with 1 death; 61 operations for hemorrhoids without mortality, 7 by ligature, 3 by excision and 51 by clamp and cautery; 10 operations for extravasation of urine, with 1 death; 700 operations for hydrocele by tapping, tapping with injection, incision and eversion of sac, excision of parietal

part of sac and incision and drainage; 31 castrations without a death; 5 operations for prolapse of the rectum, with 1 cured, 2 relieved and 2 deaths; 26 operations for strangulated hernia, with 9 deaths, and 102 radical operations, with 3 deaths; 31 operations for abscess of the liver, with 3 deaths, and 15 exploratory punctures of the liver, with 1 death from hemorrhage; 6 exploratory laparotomies, with 2 deaths; 3 operations for intestinal obstruction, with 2 deaths; 5 excisions of the appendix, with 1 death, and 5 incisions for appendiceal abscess, with 1 death; 6 amputations of the thigh, with 1 death, and 10 amputations of the leg, with 1 death.

A few of the operations are of sufficient interest to entitle them to a more extended notice here.

ANEURISM OF COMMON AND EXTERNAL CAROTID ARTERIES.

The patient was a Hindu, aged 22 years. The pulsating swelling was first noticed a year ago and measured three inches in diameter at its widest part. Patient suffered from severe pain in the region of the swelling and on the right side of the head, slight dysphagia, paralysis and wasting of the right side of the tongue. The common carotid was ligated below the omohyoid, October 20. The pulsations in the swelling facial and temporal arteries ceased at once and never returned. The swelling steadily decreased in size, but as the progress was too slow to satisfy the patient it was later incised at his urgent request, the coagulated blood removed and, as no hemorrhage attended the operation, the wound was sutured without making provision for drainage and healed by primary intention.

HYDATID CYST OF TIBIA.

Operator, Captain Niblock. The patient, a Hindu ryot, aged 30, was admitted to hospital for a tumor of the upper end of the right tibia. He gave a history of the swelling commencing seven months before and gradually increasing; also of indefinite pain and weakness in the leg for two years. Pain never severe. The tumor on examination was hard, smooth, and fairly regular in outline, no eggshell crackling. The tumor was diagnosed as possible myeloid sarcoma, but on being incised it was discovered to be a hydatid cyst, containing about 10 ounces of fluid. The cyst wall was removed thoroughly and the bony shell of the cyst broken and turned inward so as to partially fill the cavity. He left the hospital cured in four months.

RHINOSCLEROMA.

The patient was an Eurasian, 21 years old, fireman by occupation, resident in India since birth, spent most of his time at Bhunda Ekhand, Jhansi. Admitted on July 30, suffering from most typical rhinoscleroma, affecting nose, palate and pharynx. No history of any member of his family ever having suffered from a similar complaint nor has he ever seen the disease in any other person. Three years ago he first noticed a small hard pimple on the skin of the right side of the nose about the middle; at the same time he suffered from occasional attacks of epistaxis. The hemorrhage stopped entirely after six months and has never recurred. The growth slowly but steadily extended until the greater part of his nose became affected, and then involved the upper lip, soft palate and pharynx. Captain Cornwall, I.M.S., isolated the bacillus, from which he made pure cultures and also rhinosclerum, which was tried without success. Large doses of carbolic acid and iodoform administered internally proved likewise useless. Partial excision and applications of formalin, and more recently the x-rays, have been tried, under which treatment the disease appears to have become stationary.

There are no gynecologists connected with the Madras General Hospital, the attending surgeons being in charge of all surgical cases regardless of sex. The hospital has nine private rooms, for which the patients are charged from 2 to 5 rupees a day (.64 to \$1.60).

Bubonic plague cases occasionally find their way to Madras, but the sanitary precautions are so stringent that the disease has never gained a foothold here. Every stranger who arrives at Madras by boat or railway is kept track of by the police for 10 days, the maximum limit of the period of incubation of bubonic plague.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Yeast.

Wainwright, in the *Central States Medical Magazine*, discusses the therapeutic application of yeast and quotes liberally from the French observers, who have experimented extensively with yeast in the treatment of various conditions. The author gives the following description of the physiologic action: Yeast is not sensibly affected by micro-organisms. It is found necessary, in order to provide the most advantageous medium for the development of yeast in the digestive tract, to give a liberal supply of sugar with yeast. After ingestion it is found that the motor activity of the stomach is decreased, that the production of hydrochloric acid is retarded, but that pepsin is present in sufficient quantities.

Large quantities produce diarrhea, vomiting, fever and coma. This is probably due to the evolution of carbonic acid gas and the poisonous effects of this gas. In animals abdominal distension and asphyxia are observed. Among the diseases attributed to the effects of alcoholic fermentation are dilatation of the stomach, acute gastrointestinal catarrh and chronic gastritis. It is recommended that yeast is efficacious in the acute and chronic forms of gastroenteritis of adults, in dysentericoid enteritis, and also in the gastrointestinal troubles accompanying typhoid fever, and likewise in gastroenteritis of children. The following method of the administration was used:

About a dessertspoonful of fresh yeast dissolved in from 50 to 60 grams (two ounces) of boiled water. After the administration of a purgative this was introduced, at a temperature of 98 F., through a rectal tube, into the bowel, and caused to be retained as long as possible. The yeast was introduced three times daily. Subsequently, for convenience sake, a teaspoonful of dried yeast was used in place of the fresh preparation.

Yeast has been used in cases of glycosuria with very great amelioration in the symptoms and distinct reduction in the amount of sugar excreted. In habitual constipation very favorable results have been obtained by the use of yeast. Either fresh yeast, simply dried at a temperature of 86 F., or yeast the vitality of which has been destroyed by an hour's subjection in an oven to a temperature of 298 F., was used. The dose of the former is 7½ grains, to be taken per os twice or thrice daily; of the latter 3½ grains.

The favorable action is said to manifest itself from the second day, and to continue for some time after the cessation of the treatment.

Some flatulent distension and occasionally slight colic may occur, but these are said to be avoided, or, at least, diminished, by the use of the sterilized yeast. The results of the use of yeast in furunculosis have not always been satisfactory. Some cases of pneumonia are reported as cured. Favorable results are reported in the treatment of otitis externa furunculosa with beer yeast.

Kempf, in the *Indiana Medical Jour.*, says that yeast poultice is one of the best antiseptic applications for various septic conditions such as gangrene, ulcers, erysipelas, eczema, and as an application for infected tissues after extensive injury. The poultice is prepared by taking a quart of beer yeast and mixing it with one pint of finely sifted cornmeal. The mixture is then placed near a fire until it rises. With the dough thus formed two ounces of finely powdered charcoal is incor-

porated. The writer reports six cases with very excellent results.

Eczema.

Leeds, in a communication, gives the following formula, which has given good results in the treatment of this condition:

R. Pulv. sulphuris	ʒiv	16
Cupri sulphatis	ʒiii	8
Hydrargyri oxidi rubri.....	ʒi	4
Vasellini albi	ʒvi	120

M. Sig.: Apply every night, allowing it to remain ten minutes, then remove with warm, soft water and castile soap.

Chronic Nephritis.

Moore, in the *Clinical Review*, recommends the following, which has given him excellent results in increasing elimination and overcoming the drowsiness of impending uremic coma:

R. Sodii benzoatis	ʒiv	16
Tincturæ limonis	ʒi	30
Aquæ dest., q. s. ad.....	ʒvi	180

M. Sig.: Tablespoonful in half glass of hot water on arising in the morning, or as required.

Acne Vulgaris.

Hunt, in the *Jour. of Med. and Surg.*, outlines the treatment of this condition as follows: Prolonged bathing in hot water will effect a cure in the less severe cases. The water should be soft and the applications should be made with a soft sponge. The water should be as hot as can be borne and the sponge applied to the face at least five minutes, moderate pressure being used. This bathing should be done night and morning. After sponging, the face should be dried with a soft towel and bay rum applied freely. In the more severe cases the following may be used:

R. Saponis viridis	ʒiiss	45
Alcoholis	ʒi	30
Spiritus odorati	ʒiii	8
Aquæ dest., q. s. ad.....	ʒvi	180

M. Sig.: Rub into the skin at bedtime and wash off in the morning. If this proves too stimulating it may be omitted for a day or two and some mild oil used on the skin. The inflamed and unsightly follicles should be opened and contents expressed.

Hygiene in Maternity.

Hanson, in an article on this subject in the *Columbus Medical Journal*, recommends that the following articles of diet should be avoided during the pregnant state: Soup made from vegetables growing under ground; salt pork, with or without beans, in any form; boiled dinners, ham, veal, duck, liver, kidneys, hash, meat-mixed salads, corned beef; any canned meats or soups, mackerel, dried fish or salt meats, except codfish; bananas, tapioca, breakfast cereals, mince pie, suet pudding, fruit cake—in fact, any kind of cake; tea or coffee, and especially if they have been boiled.

Ringworm.

The *Clinical Review* recommends the use of formalin in this affection and states that it is best given with glycerin in the following formula:

R. Formalini	m. v	30
Glycerini	ʒiii	8

M. Sig.: Apply locally.

Remove all grease from the scalp, or part affected, by turpentine, followed by soap and warm water. Then apply the above solution, and continue the application several times for about an hour, so as to allow an opportunity for the preparation to penetrate into the deeper parts of the diseased follicles.

Bronchitis.

Yeo recommends the use of antimony for this condition, and states that it should be given in small and frequent doses early in the disease, when the membrane of the bronchial tubes is dry and tumid, and the skin is hot and dry and the pulse hard. It is well to combine antimony with other diaphoretics. From 10 to 20 minims of the wine of antimony may be used for adults, and from 5 to 10 minims for children. The following combination is advised:

R. Vini antimonii3ii	8
Spiritus etheris nitrosi5iv	16
Liq. ammon. acetatis3ii	60
Tincturæ camphoræ comp.3ii	8
Aquæ dest. q. s. ad.5viii	240

M. Sig.: Two tablespoonfuls every three or four hours.

Bisulphid of Carbon in the Treatment of Tuberculosis.

Professor Coronilas of Athens, Greece, discussed this subject recently before the Chicago Medical Society. His results and conclusions are based on the observations made in Greece and France since 1892 of cases treated by this method. The point he especially emphasized was that the hypodermic use of this remedy exerts a favorable influence on the white corpuscles. The use of the same remedy by intratracheal instillations is also recommended. The author has treated 66 cases, including pulmonary tuberculosis, in several stages; lupus, spondylitis, anal fistula and tuberculous peritonitis. His conclusions are as follows:

1. That the bisulphid of carbon as administered by him has no disagreeable results.
2. It has a strong action against the bacillus tuberculosis.
3. Because of its parasitic antizymotic, antiseptic and inoffensive action it is capable of penetrating all tissues and in this manner cures tuberculosis.
4. It should not remain unknown, but should take its place in therapeutics as one of the specifics of our time capable of doing immense service to suffering humanity.

Diarrhea.

Scott, in the *Central States Med. Magazine*, states that the following combination has proved valuable in the treatment of acute diarrhea of adults:

R. Benzonaphtholgr. ii	12
Bismuthi salicylatisgr. v	30
Resorcinigr. ii	12

M. Ft. Chart No. i. Sig.: One such powder every three hours.

Tonsillitis.

The *Med. Times and Hospital Gazette* recommends the following formula:

R. Tincturæ guaiaci ammon.	
Tincturæ cinchonæ comp., aa.3vi	24
Sodii chloridi5ii	8
Pulv. acacia	
Aquæ dest., aa q. s. ad.3iv	120

M. Sig.: Shake well. Add teaspoonful of mixture to wine-glassful of water and use as a gargle three times daily.

Medicolegal.

Criticisms of Questions for Medical Experts.—The Court of Errors and Appeals of New Jersey says that, in the malpractice case of Shoemaker vs. Elmer, where it awarded a new trial, after judgment for the defendant, the only assignments of error of importance related to the admission in evidence, over objection, of three questions propounded to the expert medical witnesses called by the defendant. One question was: "Now, from the statement made by Dr. Elmer as to what the patient said to him as to the cause of the injury, what he said he did in discovering what the injury was, and the treatment as testified to by him, was what he did to discover the cause of the injury and his treatment in conformity with or a departure from the rules of practice of the medical profession?" Another question was: "From the statements as made by the defendant in your hearing as to the plaintiff's statement of the cause of the injury, and his (the defendant's) statement as to what he did to determine the injury and what he did in the treatment of it, was there any want of skill or bad treatment, or malpractice by the defendant?" The court thinks each of these questions inadmissible. It says that they were clearly objectionable, even under the cases relied on by the

defendant to sustain them. Neither of these two questions was limited to, or solely predicated on, the statements made by the defendant in his testimony in the cause. The first question was broad enough to permit the expert to base his reply solely on facts which he might have learned from the defendant off the witness stand, or on those he might have heard him testify to in the cause at the trial, or both. The second question was also broad enough to permit the witness to base his reply either in whole or in part, at his pleasure, on facts derived from the defendant's statements made as a witness or otherwise. Neither of these questions needed further comment. There is no rule of evidence governing the admission of expert testimony which could make these questions thus framed admissible. The third question was somewhat more restricted. It was: "Doctor, from the symptoms and the particulars of the plaintiff's condition and the treatment by the defendant, as testified to by the defendant, do you see any evidence of bad treatment or malpractice, according to the rules laid down in practice by the medical faculty?" To sustain the admissibility of this question, Twombly vs. Leach, 11 Cush. (Mass.), 397, was cited. The court says that case did appear to give support to the admissibility of this question; but it does not commend itself to the court's judgment, and is clearly unsupported by authority. This question was a hypothetical one. It was asked of an expert who was expressing an opinion on facts testified to by another person. The question was so framed that it was not possible to tell which of the facts testified to by the defendant must be taken by the witness as the basis of his opinion. The question permitted the witness to determine what part of the defendant's evidence he would adopt and which reject in reaching his conclusion. It afforded the opposing party no opportunity to object to the assumptions of fact on which the opinion of the witness was asked. Expert evidence should be carefully guarded. It is sufficiently dangerous when carefully circumscribed. It becomes altogether too unreliable when the basis of it is indefinite. The question on which the opinion is expressed should be so clear that the jury will not be left in any doubt about what the actual facts are on which the witness is expressing an opinion. A question should not be so framed as to permit the witness to roam through the evidence for himself, and gather the facts as he may consider them to be proved, and then state his conclusion concerning them. An attempt was made, and the court says it was supported by some authority, to differentiate where the testimony used or the basis of the question is the testimony of but a single witness and is uncontradictory. But the court states that it is unable to see why that should be so. Whether it is contradictory, or involves a different interpretation by different minds, is always problematical. For the expert to remember all the material facts testified to by a single witness, which are to be the basis of his opinion, may be as difficult as to call to mind all the material facts testified to by several witnesses. There should be no loosening of the rule as to the admissibility of this class of evidence. It is undoubtedly very important evidence in many cases, when given strictly within the rule, and its usefulness should not be impaired by raising a doubt as to just what force such evidence should have in the cause. The jury, to estimate properly the opinion expressed, should have the means of showing exactly on what the opinion is based. This court agrees with the view that a medical witness, who has been present during the whole trial and heard all the evidence, should not be permitted to express an opinion on the evidence as heard by him, but that his testimony should nevertheless be taken on a hypothetical question, stating the facts claimed to be established and which are to form the basis of his opinion.

Excessive Sexual Demands as a Ground for Divorce.—The Supreme Court of Iowa says, in *Ridley vs. Ridley*, that when the plaintiff was married she was 54 years old and a widow, and the defendant was nearly 68 years of age and a widower. They lived together about two months, when the plaintiff left the defendant, and thereafter brought this suit, alleging that her life was endangered by the defendant's excessive sexual demands on her. With regard to the evidence, all that the

court says is that the plaintiff testified as to the frequency of the demands, and that the defendant did not deny her statement, nor did he claim that "age had withered his desire." Neither was there a serious question as to the effect on the plaintiff's health. It probably was true that these excesses did not directly affect her lungs, and cause the attack of pneumonia which she suffered after she left the defendant; but that they produced a weakened physical condition, which more readily yielded to that disease, may fairly be inferred. The plaintiff did not claim that she resorted to physical violence to restrain the defendant's ardor, but she protested and resisted as strongly as she could without resorting to extreme force. And the court says that to entitle a wife to maintain an action of this nature it does not apprehend that it is necessary to prove that she engaged in an angry controversy or resorted to extreme physical force every time that she declined the embrace of her husband. If such were the case, the wife's life would be doubly endangered at such times. So, while this was not an extreme case, the court thinks that the plaintiff was entitled to a divorce under the evidence, and affirms a decree in her favor.

Violation of Practice Act One Continuous Offense.—Section 4 of the Kentucky act of May 10, 1886, regulating the practice of dentistry, provides that "any person who shall, in violation of this act, practice dentistry or dental surgery in the state of Kentucky, for fee or reward, shall be subject to indictment by the grand jury of the county in which the offense is committed; and, on conviction, shall be fined in the sum of not less than fifty dollars nor more than two hundred dollars for each offense." The question was raised, in *Wilson vs. Commonwealth*, whether or not the offense denounced by the statute is of such continuous nature as to subject the violator to only one conviction for the whole period of time next before the institution of the prosecution, or is it of such a character as that each act of practice constitutes a separate offense? The Court of Appeals of Kentucky says that it is apparent, upon very slight consideration, that if each time an unregistered dentist pulls a tooth he is subject to a fine of from \$50 to \$200, in a short while these would aggregate so large a sum as to make payment impossible, and, as a result the defendant might lie in jail a large part of his life. Such a conclusion is not to be reached, unless constrained by the very letter of the statute. We are not without high authority, as well as sound reason, against the cumulative construction. So the court decides against it, or that the offense denounced by the statute is of such continuous nature as to subject the violator to only one conviction for the whole period of time next before the institution of the prosecution. The first case cited on the subject is the English one of *Apothecaries Co. vs. Jones*, 1 Q. B. 89, where the court says that there was involved an act similar in principle to the one here under consideration. The apothecaries act of 1815 (55 Geo. III, c. 194, sec. 20) provided that "any person who shall act or practice as an apothecary without a certificate is liable to a penalty 'for every such offense.'" The defendant had practiced as an apothecary without a certificate, and given medical advice and supplied medicine to three different persons at different times on the same day, and it was held that the words "act or practice as an apothecary" were directed against an habitual or continuous course of conduct, and that the defendant was not guilty of a separate offense in attending each of the three persons, and was only liable to one penalty.

5 *The Results of Treatment of Carcinoma by the Roentgen Ray. J. N. Scott.

1. **Transudates and Exudates.**—Miller presents the results of his investigations into the general characteristics of exudates and transudates, the methods of determining the tuberculous character of serous fluids, the prognostic value of the findings, the present knowledge of cytodiagnosis and his personal observations in examination of fluids obtained from 93 different patients. He concludes that the color of the fluid, its reaction, and the size of the erythrocytes are of little diagnostic value. Nucleoalbumin is usually more abundant in exudates than transudates; however, many exudates fail to show more than a faint trace. On account of the constancy of the salts present, the specific gravity and amount of albumin bear an intimate relation. Fluids from different body cavities of the same individual, or fluids of the same origin in different individuals or successive tapplings of the same cavity may show marked variation in the amount of albumin, probably explained by the permeability of the capillaries, the degree of irritation of the serous surface, the condition of the patient's blood, the tension of the fluid, the amount of absorption taking place, and possibly the blood pressure. Methods of estimating the bulk albumin, as Esbach's or Purdy's, are not applicable to serous fluids. Reuss' formula is the most accurate, simple method for determining the amount of albumin in serous fluids. The diagnostic value of the specific gravity, or amount of albumin is greatly lessened by the frequent presence, simultaneously, of several processes. A hydremia, as a result of anemia or transudation from pressure may lower the specific gravity of an inflammatory fluid. Secondary inflammation, high tension of the fluid, or resorption taking place, may increase the specific gravity of a transudate. At present there is no reliable method for determining the tuberculous character of a serous fluid. The specific gravity of a fluid, when taken for successive tapplings, may be of prognostic value. Epithelial cells in sheets are not infrequently present in fluids of inflammatory origin. The predominance of lymphocytes may be associated with a long-standing simple pleuritis, a hydrothorax or a tuberculous pleuritis. The presence of relatively large numbers of neutrophils in pleuritic fluids may be associated with an acute, simple, or secondary tuberculous pleurisy. The presence of numerous cells, chiefly neutrophils, suggests an acute simple pleuritis. The presence of numerous lymphocytes, with few, if any, neutrophils, indicates that the process is probably a tuberculous one. In ascitic fluids there is little that is characteristic. Neutrophils are usually more abundant in fluids due to portal stasis from cirrhosis than in tuberculous peritonitis. An eosinophilia in one body cavity may occur along with a neutrophilia in another. A study of the cellular elements in fluids from the pleural or abdominal cavities is of comparatively little diagnostic value, either in differentiating transudates from exudates, or in determining the character of the latter.

5. **Roentgen Ray in Treatment of Carcinoma.**—Scott obtains his current from two 12-inch Fessenden machines connected in series to give a 20-inch spark, and a mechanical break of his own construction, consisting of a copper disc with four fans, which revolve and make contact with a copper brush. The break is made under alcohol. This gives a clean, sharp break. It is operated by a motor with a rheostat which gives three speeds of break, one 500 per minute, one 1,000, and one 2,000. He operates a machine of 110 volts direct current through a graduated rheostat in series with coil. He keeps an ampere and volt meter in circuit. To protect himself and parts of the patient not being treated, from the effects of the ray, he uses a metallic box, which he described several years ago. He begins with daily exposures if the case is serious; if not, every other day. Ordinarily the anode of the tube is placed 8 inches from the part to be treated, raying for six minutes, if exposures are daily, and eight minutes if every other day. In a given case he tries to carry out the same technic all through the treatment, regulating the number and duration of the exposures by the reaction obtained. He uses a vacuum corre-

sponding to the depth of growth being treated, employing a self-regulating tube with a small amount of metal in the anode. The cases which respond best are those of slow growth, whether the growth is primary or secondary to an operation. His best results have been obtained in the treatment of recurrent growths of the breast, next primary growths of the breast, then the uterus, stomach and intestines. He cites the following statistics: Cancer of the uterus, 14 cases; two patients well for two years, one had been operated on with recurrence, the other had not. Considerable relief was obtained, lessened hemorrhage and general temporary improvement, in 8 other cases. The remaining 4 either discontinued treatment or there was no apparent improvement. Primary carcinoma of the breast, 11 cases; 4 are well at the end of two years or longer. In 15 patients treated immediately after operation, there has been no recurrence after two years in 10. Of 38 recurrences after operation, 8 are well at the end of two years.

8. Therapeutic Fasting in Typhoid Fever.—Harbin says that fasting and a restricted diet are indicated in the treatment of typhoid fever because of pathologic conditions, and that such treatment will, to a great extent, eliminate the dangers of sthenic cases. In fact, the proper food management of a case will well-nigh shield it from every danger incident to the course of the disease. What the patient loses in food is more than compensated by a lessened degree of toxemia. Surplus food causes accumulations in the intestine, augments the toxemia, causes diarrhea, and increases the risk of hemorrhage. There always is a greater degree of toxemia in cases complicated by severe gastrointestinal disturbances. Different individuals are affected differently by the specific toxin, robust young adults being more susceptible, while the extreme of ages and the anemic are less so. The author employs cocoa, coffee, egg albumin, peptonoids, and broths of beef, mutton, chicken, oysters, etc., in prescribed amounts, to be given only after the patient has fasted from twenty-four to forty-eight hours. Gelatin is a valuable adjunct in the dietary of the typhoid by adding to the relish of the various liquids, lessening the nitrogenous waste and preventing hemorrhage. A teaspoonful three or four times a day, is ordered, dissolved in a little hot water, and added to any liquid nourishment. When used, emaciation is less rapid. It should be used as a routine in all cases to prevent hemorrhage. In very aggravated cases of diarrhea it may increase tympany, but in these cases it may be used on alternate days in small quantities. Since beginning its use, Harbin has not had a case of intestinal hemorrhage. Milk should be absolutely forbidden, except diluted with from 2 to 5 parts of coffee, cocoa, broths or hot water, because then the danger of curd formation is slight. This plan of dietetic treatment should be continued until the active symptoms are controlled. Fasting in late stages and convalescent stages will cause fever. Nearly all recrudescences are due to dietetic errors. Fasting and restricted diet greatly enhance the effect of hydrotherapy. Harbin reports 45 consecutive cases of typhoid, treated according to his method, without a death. Since using the treatment he has had a mortality of only 3.4 per cent.

10. Formol-Iodin.—In order to increase the tensile strength of catgut, Stone suggests the following modification of the Claudius method: Submerge the raw commercial catgut in an aqueous 4 per cent. formalin solution for from thirty-six to forty-eight hours; then wash in running water for from ten to twelve hours to free the excess of formalin, and then sub-

merge in the iodine solution recommended by Claudius, for eight days before using. The gut should be loosely wound on glass spools and put in the formalin solution. When in the running water, strands from ten to twelve inches long are cut from the spool and put into the iodine solution. The addition of 5 per cent. boroglycerin solution or of glycerin, to the iodine solution, improves the pliability of the catgut without in any way lessening its tensile strength. The boroglycerin, or glycerin, should be sterilized in a container surrounded by boiling water for one-half hour on three successive days. The material is left in the iodine or iodine-glycerin solution until ready for use, when it is removed with sterile forceps, threaded and placed in sterile water. Stone says that catgut so prepared has the tensile strength of silk. It is pliable, not too elastic, knots well, and seems to be the ideal in every way.

11. Strophanthus in Lobar Pneumonia.—Am Ende emphasizes the value of strophanthus in the treatment of lobar pneumonia, to be given immediately on the establishment of a diagnosis; the dosage to vary according to circumstances. In his experience it has brought about a favorable termination of all cases on the fifth day. One case is cited where minimum doses of strophanthus were administered every hour with full doses of aromatic spirits of ammonia, with the result that within about twenty hours the well developed symptoms of the first stage had all disappeared and the patient returned to work four days later.

- 15 Plastic Operations for Resection of the Nasal Septum and Excision of Septal Spurs. A Review. George H. Powers, Jr.

14. Resection of the Cecum.—Every surgeon doing abdominal work, says Scudder, should be familiar with the technic of this operation. The abdomen should be opened by that incision which will render most easily accessible the parts to be operated on. An incision in the right linea semilunaris is satisfactory in most instances. The oblique incision parallel to and above the crest of ileum is also a convenient one. The parts being well exposed, an incision is made through the posterior parietal peritoneum at the outer side of the cecum and ascending colon. The colon is freed from its bed until the hand passes beyond its inner border behind the peritoneum. The branches of the ileo-colic artery are divided and ligated with fine silk by the use of a Cleveland needle. All mesenteric vessels to the cecum and to the ileum, so far as it is decided necessary to remove the ileum, are likewise ligated. This leaves the parts of the bowel to be removed entirely free. A rubber covered clamp is placed on the distal portion of the ascending colon. A clamp without rubber cover is placed near it on the ascending colon. The bowel is divided, between the clamps, sufficient space being left on the proximal end of the ascending colon to permit of the placing of a purse-string suture. The distal divided end of the colon is closed by an over-and-over continuous Pagenstecker linen suture. This suture closes the colon and checks all bleeding from the mucous membrane. The rubber covered clamp is then removed. The closed end of the colon is pushed within the purse-string suture, which is drawn taut and tied, three or four interrupted mattress sutures being then placed over the dimple formed by the puckering purse-string suture. The clamped cecum is held with gauze by an assistant, while two clamps are placed on the ileum, a rubber covered clamp being placed on the proximal portion. The clamp without the rubber cover being placed tightly on the portion to be removed. The ileum is divided obliquely so as to preserve by a good circulation the integrity of the bowel opposite to the mesenteric attachment. A point is selected on the ascending colon or transverse colon at which the divided ileum is anastomosed to the colon. After transverse division of the bowel it may be longitudinally divided opposite the mesenteric attachment, the corners thus formed being rounded off. This gives a larger opening and one less likely to be subsequently constricted. The portion of transverse colon where the

anastomosis is made is isolated by means of the rubber covered clamp, thus checking hemorrhage and occluding the bowel. The suture used is the Pagenstecker linen thread with a straight No. 6 milliner's needle. A bit of omentum is fastened as a plastic over the line of suture. The operation is done practically extraperitoneally, the abdominal cavity being protected by gauze. The parts are washed carefully with salt solution and the abdomen is closed, with the exception of one small wick to the retroperitoneal attachment of the ascending colon. If there is need for speed in finishing the operation, the Murphy button may be used to advantage.

18. **Water and Bright's Disease.**—The observations presented in Carter's paper were undertaken with the object of determining the influence of dry and moist climates on the amount of water consumed and the amount given off as urine, and whether or not there is any relation between the prevalence of Bright's disease and the climatic conditions. A careful study of his table of comparison of mortality rates and climatic conditions of different cities shows that there is no relation between the degree of humidity or length of the warm summer season, and the mortality from Bright's disease; nor does the latter bear any relation to the general mortality rate. For instance, in Denver and Boston the conditions of temperature are very similar while there is a wide difference in the humidity, but the proportion of deaths from Bright's disease is practically the same. There appears to be no doubt that Bright's disease is more prevalent in Galveston than in most cities, but it seems highly improbable that the climatic conditions have anything to do with this. Carter believes that there are two causes which seem more plausible than any of the explanations usually given: (1) the excessive use of meats in a climate in which proteins can not be so readily metabolized as in a colder climate; and (2), the failure to recognize and properly manage mild acute infections.

20. **Cicatrization.**—In four cases of ulcerations of traumatic origin which proved stubborn to the usual treatment of curing and canterizing, Kollischer made the rather surprising observation that disagreeable symptoms, such as irritation in the bladder region, frequency of urination and occasional tenesmus, persisted, although the urine was cleared up perfectly and repeated and careful cystoscopic examination proved with absolute certainty that the ulcers had healed and that complete epithelialization of the defects had taken place. It occurred to Kollischer that the persistence of a number of quite large blood vessels in the neighborhood of the healing ulcer might have something to do with the sensation of irritation of which the patients continued to complain even after the ulcers had healed. Therefore, he obliterated these vessels with the pointed galvanocautery of his operative cystoscope, and after the eschar was thrown off, usually within a week, the symptoms had entirely disappeared and the patients were well. The appearance of these vascular loops is similar to the cicatrization loops which appear running to the ulcers in the cornea.

 28 *Observations on a Series of 10 Cases of Disability of the Shoulder Joint. Harold W. Jones and Nathaniel Allison.

23. **Hodgkin's Disease.**—Shoemaker's patient was given daily exposures to the x-ray for a period of ten minutes during six days. The high vacuum tube was used, the entire body being exposed. The abdomen, left side and back were alternately treated. The glands began to diminish in size at the end of a week, and at the time of death, which occurred sixteen days after the commencement of the treatment, they were only about one-third their original size. The spleen decreased gradually, and on the day of death it had receded to the costal border. Although the patient developed symptoms of toxemia during the treatment, Shoemaker believes that death may have been but the ordinary termination of the disease. However, he says that in connection with the x-ray treatment of these cases we must bear in mind that there may not be time enough for the procedure to produce any benefit; that there is danger of an x-ray burn, and finally, the danger of a rapid disintegration of the new growths with the production of toxemia.

25. **Experience in Anesthesia.**—Magaw's method for producing anesthesia is the drop method, both for chloroform and ether, but otherwise does not differ from that usually employed. The statistics given are very meager and merely show that out of 11,000 anesthetics there has never been a death, nor has artificial respiration been resorted to in six consecutive years. Her patients are all anesthetized in the operating room while they are being prepared for the operation, thus securing a more rapid surgical narcosis with the use of less anesthetic. Magaw finds the method safer and more satisfactory in every way.

28. **Disability of the Shoulder Joint.**—Jones and Allison describe ten cases having a uniform symptom—complex, and notwithstanding the fact that the original diagnosis varied from paralysis to dislocation, they feel justified in placing them in the same class. In each case, the affection was ascribed to a trauma, although the injury in most cases was a very trivial one, such as reaching upward and backward to press an electric button in the street car; "bruising" the shoulder slightly; "straining" the shoulder while reaching for something, etc. The affection in each case ran a definite course and the authors believe that the lesion was probably circumarticular rather than intra-articular. In the acute stage, fixation afforded complete relief from pain, and, in the majority of instances, freedom from subsequent disability. In the chronic stage, the disability due to the fibrous ankylosis was greatly relieved by manipulation under an anesthetic. The end result depends entirely on the patient's willingness and ability to follow out the exercises which constitute the aftertreatment. About ten weeks' time is required for complete relief from the disability.

 37 *Report of a Case of Tetanus Treated with Antitetanic Serum: Recovery. E. E. Montgomery.
 38 Autointoxication and Its Treatment. (To be continued.) Heinrich Stern.

33. **Leprosy.**—Lieberthal reports two cases of leprosy, one of the tubercular variety, the other of the maculo-anesthetic or nervous type. The first case was reported some years ago, the

clinical diagnosis being confirmed by the microscopic demonstration of lepra bacilli in the nodule. The second case is a recent one, occurring in a Chinaman 34 years of age. About ten years ago, without any preceding symptoms, he noticed a discoloration of the skin on the anterior and bilateral aspects of the lower two-thirds of the right limb. The color became lighter and simultaneously the sensibility began to diminish. Gradually the light color changed to brown, which became more decided as time went on. About two years ago he noticed a reddish flat pimple on the left forearm, just below the elbow, which gradually increased in size. In this area the sensibility gradually diminished until now no perception remains. At present, the face is covered with an eruption of lentil to bean-sized irregular spots of a dirty brown color, smooth and shiny; infiltrated and slightly raised. The trunk and upper part of the arms show a copious crop of pinkish, non-infiltrated spots of the same size as those on the face and moderately desquamating. Small red papules resembling syphilides were found on the back and elsewhere. Sensibility was wanting in all the affected parts, although the back of the chest, as well as the inner aspect of the right humerus was hyperesthetic. Nowhere did the area of anesthesia correspond to the distribution of a certain nerve. The soles of the feet and the palms of the hands showed normal perspiration, but were without secretion of sebum. Of the accessible nerves, the ulnars, as well as the crurals, were thickened and slightly hyperesthetic. There was no weakness nor atrophy of the muscles. The superficial as well as the deep reflexes were intensified. The glands above and below Poupart's ligament were enlarged. The mucous membranes of the nose, mouth and throat were perfectly normal. The blood and skin lesions were examined for bacilli without result.

34. Adrenal Tumor.—The case reported by Holmes manifested only the most benign symptoms and the local findings were so obscure that it was impossible to make a correct diagnosis. The abdomen was opened on the left border of the left rectus muscle. The capsule of the tumor was carefully incised and the peritoneum thus liberated was sewed to the parietal peritoneum of the laparotomy wound, thus shutting off completely the peritoneal cavity from the field of operation. The tumor and the kidney, to which it was attached, were delivered through the incision and the tumor carefully enucleated. No large blood vessels were severed, but the oozing from the cut surface of the cortex of the kidney could only be arrested by bringing the capsule on one side against the capsule on the other by three mattress stitches. The kidney was allowed to fall back into its normal position. With the exception of the development of a periappendicular abscess in an old appendicitis scar, the patient made an uneventful and rapid recovery. A microscopic examination of the tumor showed that it was a typical adrenal growth. Holmes emphasizes that this case shows the possibilities of an extraperitoneal operation even for the removal of a very large tumor, although it is possible only when the tumor has slowly grown into the tissues of the mesocolon, and the ventral or right peritoneal surface of the colon has become greatly hypertrophied or enlarged, and the blood vessels of the colon so distorted that a long incision would not, in any way, vitiate the blood supply of this large duct. The results of the operation also show, says Holmes, the necessity of taking advantage of every opportunity to completely remove a neoplasm, no matter how grave the prognosis may be at the time of operation.

37.—Tetanus Cured by Antitetanic Serum.—Montgomery reports a case of tetanus in a boy, aged 14, following an injury of the foot. Ten days after the receipt of the injury the patient began to develop stiffness in the muscles of the jaw, which increased gradually and extended to the other muscles of the body. Thirty-six hours afterward Montgomery administered 20 c.c. of antitetanic serum, 5 grains chloral hydrate and 10 gr. sodium bromid. Within an hour after the administration of the serum the spasms ceased and the muscular rigidity was less pronounced. A second injection of serum, given eighteen hours later, was again followed by general improvement, lasting about twelve hours, when the dose of the serum

was repeated. The patient received in all 140 c.c. of serum and at the end of the second week was so far convalescent that he could be removed to his home.

- 45 *The Cycle Method of the Treatment of Syphilis. Noah E. Aronstam.
- 46 The Diagnosis of Modified Smallpox. Charles A. Hodgetts.

45. Cycle Method of Treatment of Syphilis.—Aronstam describes the so-called "cyclic" method as consisting of the systematic administration of mercury in variable, changeable and alternate forms, with slight intermissions, wherein tonics and eliminatives are exhibited. The advantages of the method are: 1. It never salivates the patient. 2. No untoward after-effects are discernible. 3. Gastrointestinal disturbances are obviated. 4. Consecutive mercurial dermatoses are not apt to appear. 5. Its greater efficacy, promptness and permanency. 6. It is systematic and thorough. 7. The danger of recrudescence is minimized. 8. The tardy or tertiary phenomena are held in abeyance. Metallic mercury, in the form of mercury and chalk, should be given the preference in the commencement of treatment. It can be administered in doses of from 2 to 5 grains *ter in die*, in conjunction with nuxvomica and hyoscyamus to prevent griping, and some of the easily assimilable iron preparations, if anemia coexists, as follows:

- R. Hydrarg. cum creta, gr. 63.....gm. 4.15
- Extr. nucis vomice, gr. 5.....gm. 0.30
- Extr. hyoscyami, gr. 7.....gm. 0.42
- Ferri lactatis, gr. 20.....gm. 1.30
- M. et it. cap. No. 21. One, *ter in die*, 2 hours after meals, and should be continued for 7 days, after which a bitter tonic in combination with belladonna and arsenic in a vehicle of wine of kola is to be exhibited for about three days.

The author makes use of the subjoined prescription:

- R. Tr. nuc. vom., dr. 1.....c.c. 4.0
- Tr. quassie, dr. 3.....c.c. 12.0
- Tr. belladonnæ,
- Liq. pot. arsenitis, aa. dr. 1.....c.c. 4.0
- Vin. kola, q. s. oz. 4.....c.c. 120.0

M. Sig.: Dr. 2, twice after meals with water. The three days of intermission are termed the short period of repose. In contradistinction to the long period of intermission, to be delineated in detail later on.

The protoiodid of mercury is the form next to be employed. It can be given in doses of from gr. 1/6 to 1/4 t. i. d., either alone or in combination with the tartrate of iron and ammonium. The length of time of administration is one week, to be followed by the tonic mentioned above for three days. Mercuric iodid, gr. 1/12 to 1/8, t. i. d., is then exhibited in the same manner as above, with a similar period of intermission wherein tonics are used. Next, inunctions of mercurial ointment, or, what is better, mercury vasogen (which is said to be metallic mercury with a partially oxidized hydrocarbon base of neutral reaction) may be employed. The most appropriate time for its application is the hour of retiring, and it should be continued for twelve consecutive evenings on twelve separate regions of the body, beginning with the right arm and then the left arm, anterior thorax, abdomen, right thigh and inguinal space, left thigh and inguinal space, right leg, left leg, both hands, both feet, lumbar and sacral regions, and dorsal and cervical areas in the order named, two grams of the ointment being used for each inunction. A warm alkaline bath is ordered immediately on the completion of the course and a three days' tonic repose granted. Fumigation with calomel in 15-grain doses is the next form utilized. Fumigation should be ordered every alternate day for one week, followed by another short period of repose and the administration of tonics and eliminatives. The "mixed treatment" consists of the simultaneous use of the bichlorid or biniodid of mercury and sodium or potassium iodid, preferably the sodium salt. The method is the same as used in the other procedures. When the eliminative treatment is used the patient is put on sodium or potassium

iodid in ascending doses for one week, beginning with one minim of a saturated solution three times a day, and increasing by one minim each subsequent day. If the iodids are not well borne the syrup of hydriodic acid may be substituted, or the potassium iodid may be given in solution by rectum, a few drops of tincture of opium being added to allay rectal tenesmus. The iodid may also be given in conjunction with vegetable alteratives such as stillingia, rumex, lappa, sarsaparilla. This is followed by a three-days repose and tonic treatment. After this, simple or alkaline baths daily for a week are advised, especially the various sulphur spas. All treatment is then suspended and the patient permitted to enjoy a two-weeks rest, when the above method is resumed. Aronstam insists on the strictest observance of general hygiene and appropriate diet. Balneotherapy, either simple or medicated, should supplement the treatment and should be encouraged. After the elapse of the first eighteen months under the above systematic specific medication, a month's repose is granted, after which iodid, in the form of the sodium or potassium salt, is administered in ascending doses for one month; the vegetable alteratives may be used in combination with the iodid. The iodid is given in gradually increasing doses, two or three hours after meals. A period of intermission, which should not exceed one month, is then allowed. Mercury and chalk is then prescribed for ten days, followed by a bitter tonic for four days. For the next two weeks all treatment is suspended and the patient is ordered to take frequent baths, simple or medicated. The subsequent cycles are similar to the preceding, except that the form of mercury is varied to correspond with the classification of mercurial administration outlined above. Aronstam describes many a favorable and permanent outcome to this method, and very few, if any, cases of recurrence have come to his notice. He believes this method to be vastly superior to the old unsystematic and irregular régime.

47. *Bacillus Pyocyaneus* Septicæmia.—Eastman and Keene report a case of septicæmia caused by *Bacillus pyocyaneus* following injury in a runaway accident. The clinical features were not such as would lead to a correct diagnosis, this resting entirely on the bacteriologic findings. There was every evidence of profound intoxication—a very high pulse rate, with a temperature usually subnormal. Probably the most marked feature, and certainly one of diagnostic value, was the marked nervous involvement, a complete loss of sensation in the fingers, leading to a diagnosis of traumatic hysteria. Finally, the patient could not move her left arm or leg and had great difficulty in swallowing. The finding of blastomycetes in the local ulcer at once cleared the diagnosis and explained the failure of the wound, incident to an operation performed for the relief of

pressure of the musculo-spiral nerve, to heal. The authors have been unable to find any report of another similar instance of a combination of blue pus bacillus infection with blastomycetic infection. Evidently the wound became infected with blastomycetes primarily and with *Bacillus pyocyaneus* secondarily. Thorough antiseptic measures eventually proved effective in combating the infection.

48.—See abstract in THE JOURNAL of July 2, page 70.

51. Fracture of the Base of the Skull.—A very thorough and painstaking study of the clinical and pathologic records of 50 cases of fracture of the base of the skull lead Walton to conclude that in the majority of the cases fractures resulted from an impact received in the horizontal plane of the skull, whether on the frontal or the occipital region or on the side of the head. While certain of the basal fractures extended from the vertex, there was no suggestion of the *contre-coup* of earlier writers. The line of fracture tended to enter the fossa nearest the point of impact and to extend in the general direction in which force was applied. In traversing the base of the skull, the lines of fracture tended to follow the lines of least resistance, and in 22 of the 50 cases these lines corresponded more or less accurately to those indicated by Rawling, who claims that the sella turcica is implicated in 70 per cent. of cases; that the line of fracture is extremely liable to follow a suture, either causing its separation or cutting across it irregularly. In Walton's cases the sella turcica was implicated in 36 per cent. The petro-occipital and masto-occipital sutures furnished common lines of least resistance. Fractures extending across the base tended to run parallel to the petrous portion of the temporal bone and through the sella turcica. Certain blows on the occiput tended to cause a line of fracture extending to the jugular foramen or across the petrous bone. The portion of the petrous bone containing the auditory apparatus showed itself peculiarly liable to fracture, more often transversely than longitudinally. In 7 cases, 14 per cent., the fracture was limited to the base, after vault impact in the horizontal plane. Neither Rawling's theory of transmitted force nor the theory of bursting fracture of von Wahl and others, says Walton, suffices alone to explain these cases. The results of experiments with bodies of simpler structure would suggest that the bursting principle predominates in pure compression of the skull and the principle of transmitted force in case of blows, while both play important parts in case of falls. The orbital fossa was implicated in 21.4 per cent. of the cases of orbital fossa fracture. Inequality and immobility of pupils, or both, furnish the most frequent and unfavorable sign of fracture of the base. In the 44 cases in which the pupils were recorded they were normal in only 13. Walton believes that injury to the cerebrospinal tract in its intracranial part is a more probable cause of the Hutchinson's pupil and the other pupillary changes than injury to the third nerve or to the cortex, though no single lesion explains all cases. He also found that the reflexes may be lessened or lost in fracture of the base, as in any case of violent jarring of the brain. On the other hand, they may be increased even to spasticity, probably through direct pressure on the pyramidal tract, as by hemorrhage. It is probable, he says, that the initial result of the impact in all cases is a tendency toward lessening or loss of the reflexes. Profuse and persistent bleeding from the ear does not suggest middle meningeal hemorrhage. None was found in the case of profuse and persistent bleeding and, conversely, hemorrhage from this artery occurred eight times without, and once with only slight bleeding from the ear.

52. Ligation of Both Common Carotids.—Thomas reports the case of a man, aged 32, the victim of a sarcoma of the upper jaw, which was so situated that radical removal was impossible, but which caused so much distress that some relief was urgently called for. After studying the case carefully it was decided that the only justifiable operation was ligation of the common carotid artery. Because of previous difficulty in inducing general anesthesia the right common carotid was ligated under local anesthesia by the Schleich method. There were no cerebral symptoms at the moment the ligature was tied nor

subsequently. The wound healed by first intention. A slow but positive improvement followed the operation and the mass diminished perceptibly in size. Two months later, however, a recurrence of the symptoms necessitated ligation of the left common carotid, which was done under cocaine anesthesia. By the following morning the patient had passed into a condition of coma; the muscles of the neck were rigid, the hands twitched and the breathing was stertorous. Death followed shortly after.

55.—See abstract in THE JOURNAL of September 3, '64, page 697.

57. Treatment of Stump in Appendicectomy.—Seelig details the results of his investigations undertaken to discover if it were not possible by a combination of clinical, experimental and pathologic methods, to determine on a rational method of dealing with the appendix stump. As the result of this work he found that a simple ligation of the appendix, ablation of the organ distally to the ligation, and cauterization of the stump, is the simplest and safest method of dealing with the diseased vermiform appendix. Of course, he says, there will always be cases where the judgment and ingenuity of the operator must regulate the method of procedure. Yet, in the main, the fact holds good that in the ordinary run of both acute and interval appendicitis cases the method mentioned is the most rational. Whether the cauterization be done with the actual cautery or with pure carbolic acid makes no material difference. Seelig prefers the actual cautery because the heat exerts a bactericidal action at some distance from the point of application of the incandescent platinum, whereas the acid acts only on the surface. Moreover, by dividing the appendix with the cautery, the escape of feces and the consequent infection of the operation field is guarded against. The disinfected stump is dropped back into the peritoneal cavity. Sections of experimentally ligated appendices showed that the mucosa is not brought into contact with mucosa, as is stated by Dr. Morris, but is crowded back for fully one-eighth of an inch on both sides of the ligation, and so crowded back as to close off the lumen completely and thus prevent the germs in the appendicular lumen from attacking the so-called line of "compression anemia." Moreover, the stump is quadruply fortified, in that it is covered over by: 1, the pulpy lymphoid tissue; 2, a thick layer of the resistant submucosa; 3, a layer of muscularis; 4, a layer of serosa in addition to being shut off by the infolding of the mucosa. He has never encountered a perforation in a case where the ligation was applied about an appendix in a non-gangrenous and not too friable area. He satisfied himself by bacteriologic experiments that disinfection of the stump either with pure carbolic acid or with the actual cautery is thorough. The opportunity presenting itself, Seelig examined postmortem the cecum of two patients who had been operated on according to his method. In both instances that portion of the cecum where the longitudinal striæ meet to mark the site of the appendix was perfectly smooth and glistening, thus disproving the statement that an uncovered stump leads to the formation of adhesions which so frequently distress the patient after operation. His final plea for the simple ligation method is that it saves time, a great surgical desideratum.

3. Innocent Laryngeal Growths.—Grant cites 14 cases of patients affected with benign laryngeal growths to show the variability of the treatment that can be instituted tending toward a removal of the tumor. He says that only very wide rules can be laid down, inasmuch as the operator must be guided by the circumstances of the individual case and by his own experience. Although Grant is very much impressed with the value of the galvanocautery, he advocates a judicious eclecticism in treatment. After operation recurrence is probable unless the removal is complete. His own experience leads Grant to the view that single pediculated growths at the anterior commissure are unlikely to recur, whereas sessile ones at the junction of the anterior and middle thirds of the vocal cord are very likely to do so, as are also multiple papillomata. Treatment is not necessarily always operative. The avoidance of exciting and predisposing causes is sometimes sufficient to produce a cure in cases of very small nodules due to overuse or misuse of the voice. Coughing must be absolutely prohibited or prevented. Avoidance of smoking and smoky or dusty atmosphere, moderation of abstinence in regard to alcohol and other causes of gastrohepatic disturbance are also valuable prophylactic and therapeutic factors. The correction of errors in voice production is of vital importance. The occasional application of astringents may contribute, but the all-important factor is complete rest for the voice.

5. Meniere's Disease.—Milligan suggests the removal of the semicircular canals in non-suppurative conditions for the relief of vertigo. The object of the treatment is to destroy the static segments so that peripheral impulses may cease to call for vertiginous phenomena. In such cases, where the morbid process has lasted for months and sometimes for years, the

terminal filaments of the auditory nerve are so disorganized and the hearing power so deranged that for practical purposes the organ as an organ of hearing may be disregarded. In accordance with this view, Milligan operated on three cases. The degree of operative shock was considerable in all three. In two of the cases healing took place and the patients recovered completely from the vertigo, although one complained of some swimming in the head and the other of tinnitus. They have been able to return to work. The hearing power has been destroyed. In the third case suppurative resulted and the patient is still under treatment. In the two cases there has been relief so far as the symptoms of vertigo and of sickness are concerned. The persistence of tinnitus in one case is suggestive either that the terminal filaments of the vestibular nerve were imperfectly destroyed, or that some lesion of the root of the auditory nerve coexisted.

7. Mastoid Abscess Following Measles.—In the case cited by Lawrence medical attention was sought because of the presence of a large swelling behind the left ear. There was also a very slight discharge from the ear itself. The patient had had an attack of measles five weeks previously and although the present trouble had existed for several weeks, no complaint was made of pain or other subjective symptoms. No previous disease of the ear had existed. On examination no granulations were present in the ear, and no pain was complained of on palpation over the mastoid. Wilde's method of treatment was adopted, and within a fortnight the case was well. Lawrence is unable to say what healing process could have produced this result.

8. Asthma and Nasal Disease.—MacDonald is of the opinion that asthma and diseases of the nose bear a clinical relationship to each other. That the removal of any obstruction whatever in the nose or nasopharynx may result in the cure of asthma, whether spasmodic or catarrhal, is well substantiated. Where there is no obstruction the treatment of an unhealthy mucous membrane will effect the same end. And finally, says MacDonald, whatever the state of the nose, free or obstructed, with a healthy or unhealthy mucous membrane, the great majority of asthmatics, be their asthma catarrhal or spasmodic or cardiac (whatever that may mean), can be cured by cauterizing the upper part of the triangular cartilage. MacDonald has put this teaching into practice and vouches for the accuracy of the statements, although again and again he has failed to benefit his patient until some one or other form of obstruction had been removed. Statistics are cited showing that he has succeeded in curing over 40 per cent. of all cases under his care.

9. Paraffin Injections for Nasal Deformities.—Downie describes in full the technic of this procedure and publishes photographs of six patients treated. The result in each case is a most decided improvement of the deformity and an entirely satisfactory outcome. In each case the paraffin has remained within the area into which it was injected. The discoloration and glazing of the skin disappeared after a few weeks. The paraffin is not affected by high body temperature nor exposure to great heat nor residence in a hot climate. Downie holds that the operation of the subcutaneous injection of paraffin to raise a sunken nose, if properly performed, is practically devoid of danger. Further, where the deformity is of the nature of a sinking in, and where the skin covering the sunken area is healthy, the shape of the nose can in all cases be improved, and in most the deformity can be wholly removed.

12. **Red Light in Smallpox.**—This paper by Finsen was written a few weeks before his death and is his comment on the report published by Ricketts and Byles in the *Lancet* of July 30, 1904, and abstracted in THE JOURNAL, August 20, '98, page 573. He says that the smallpox infection puts the skin in a state of great sensibility to light; if, now, the patient, during the period of the appearance and the growth of the exanthem, is protected against daylight—especially against the chemical rays—by means of red light, the exanthem will be less strong than otherwise and, as a rule, no suppuration will occur. It is impossible, of course, continues Finsen, to give any absolute rule, as there are many degrees of smallpox exanthemata. In many cases no suppuration occurs, although light is not shut out. But experience shows that if a patient is placed in red light or in darkness immediately after the first appearance of the exanthem, no suppuration, as a rule, will occur, even in unvaccinated cases or in cases with confluent exanthem. If the patient is put under treatment later the result will be more doubtful. Experience shows further that even a relatively short exposure to light, especially if the exanthem is fully developed, suffices for the production of suppuration. Therefore, two conditions are indispensable in order to obtain good results from the red light treatment: 1, An early treatment of the patient, and 2, an entire exclusion of hurtful rays of light. If patients come under the treatment before the fourth or fifth day of the disease suppuration will be avoided, but if the patient comes under treatment after the fifth day it is uncertain whether suppuration can be avoided.

13. **Serotherapy of Snakebite.**—This subject is thoroughly discussed by Lamb, and three cases of cobra bite are cited in which the serum treatment failed completely. In each instance the patient came under treatment within an hour after being bitten, a large quantity of serum was injected, and in one case vigorous local treatment was resorted to. He concludes his paper as follows:

1. Antivenomous sera are markedly if not absolutely specific, even between the venoms of species of the same genus. Hence in any case of snakebite the serum prepared with the venom of that species which has inflicted the bite must always be used.
2. The difficulties in collecting the poisons of the different species of snakes in sufficient quantity for purposes of immunization are apparently very great.
3. Up to the present the only sera which have been used practically are the one prepared by Calmette and the one prepared at this institute with pure cobra venom. Both these sera are practically specific for cobra venom.
4. As the neutralizing power of these two sera is not great and as a cobra can inject a large amount of venom the serum must be given in large quantity; as much as from 300 to 400 cubic centimeters, even when given intravenously, would be necessary in some cases. If given subcutaneously from ten to twenty times this amount would be required. It should therefore always be given intravenously.
5. Experiments on dogs and the records of cases of cobra bite in man bear out these calculations.
6. It is evident from the above considerations that it is a question as to whether the advantages to be gained by the serum treatment of cases of snakebite are at all commensurate with the cost entailed in the preparation of the sera.

14. **Sequel to Gastroenterostomy.**—The sequel in Barker's case was a most unusual one. The whole of the small intestine with the exception of the last seven inches or so, passed between the junction of the stomach and jejunum and the root of the mesocolon made two years before, over the first part of the jejunum and then down into the general cavity of the peritoneum. The whole small intestine thus passed also formed a huge volvulus, turning on its mesentery in a direction contrary to the movements of the clock. The intestine was placed in the normal position and the patient made an uninterrupted recovery.

16. **Treatment of Hemophilia.**—Grant reports a case in which all efforts at checking bleeding in a hemophilic proved futile until he resorted to the use of extract of ovarian substance, giving $2\frac{1}{2}$ grains thrice daily. The favorable result obtained prompts him to urge the further use of this substance.

19. **Inversion of the Uterus.**—The inversion in Croft's case occurred on the fifth day during straining while at stool. Attempts made on that day and on the next looking toward a

reduction of the organ proved unsuccessful, even with the patient under anesthesia. On the eleventh day the patient came under Croft's care and a careful examination showed the uterus to be still completely inverted. The patient was anesthetized and placed in the left lateral position. After the usual preparations Croft grasped the inverted uterus in the hollow of the left hand, the fingers of the right hand being employed for counter pressure on the rim of the inverted cervix through the abdominal wall. Reduction was effected without much difficulty. In attempting replacement of an inverted uterus at an interval of several days, Croft says the possibility of inflammatory effusion and adhesion being present on the peritoneal aspect of the uterus and cervix, has to be borne in mind. It is also preferable to anesthetize with chloroform than with ether because the uterine muscle is more easily relaxed by chloroform.

Bulletin de l'Académie de Médecine, Paris.

- 21 (LXVIII, No. 33.) *Rôle du trichocephale dans l'étiologie de la fièvre typhoïde. R. Blanchard.
22 *Rhumatisme tuberculeux ankylosant. Arthrites plastiques. Ankyloses osseuses d'origine tuberculeuse. A. Poncet.

21. **Trichocephalus in Etiology of Typhoid Fever.**—The trichocephalus which burrows into the mucosa is liable to inoculate the intestinal wall with bacteria circulating in the intestine that would be harmless under other circumstances. Guiart accepts this as a probable explanation of the reason why typhoid bacilli cause disease in certain subjects and not in others—they require the trichocephalus or other intestinal helminth to open the door for them. In a typhoid epidemic at Brest last fall he found the trichocephalus in 10 out of 12 typhoid subjects examined, and in another the worm was found at the necropsy. In the other the necropsy was not allowed. He urges that in case of a febrile enteritis of any nature, before we are positive as to its being typhoid, the first indication is to expel any worms that may be present with the bacteria, and thus prevent the constant autoinoculation of the patient. As the trichocephalus is the parasite usually involved, he advises energetic treatment with thymol without wasting time on determining the exact helminths present. In his examination of a number of healthy subjects and patients with diseases other than typhoid he found the trichocephalus in only one or two instances and very rare, while they were very numerous in 11 out of the 12 typhoid subjects.

22. **Tuberculous Ankylosing Rheumatism.**—Poncet's communications on tuberculous rheumatism have been summarized in these columns from time to time. He here draws the picture of the form of tuberculous rheumatism which appears as a plastic arthritis without effusion, entailing almost inevitably bony ankylosis of the affected joint or joints. Rhizomelic spondylitis, that is, the Strümpell-Marie, and the Bechterew types, generally belong in this group. It is distinguished by its inflammatory lesions, and the absence of the so-called tuberculous products, distinct from granulations, fungous formations, caseous infiltration, white tumors, tuberculous osteoarthritis and from chronic, deforming tuberculous rheumatism. It is evidently due to a toxemia of bacillary origin, like the other forms of tuberculous rheumatism. The prognosis is grave from the functional point of view, and it constitutes a terrible infirmity when the entire skeleton is involved and becomes rigid. In every event it is always a sign of an affection which may become more virulent and more serious as the viscera become affected. Tuberculosis should be thought of whenever one is confronted with a plastic ankylosing polyarthritis, especially in the absence of any other infection. This inflammatory tuberculosis may affect all the tissues, all the organs, all the various systems. The resulting lesions may range from transient congestion to acute or chronic lesions and final sclerosis.

Semaine Médicale, Paris.

- 23 (XXIV, No. 43.) *Report of Seventh French Congress of Internal Medicine, Paris, October 24-27. (Continued.)
24 Report of Seventeenth French Congress of Surgery. (Continued in No. 42.) See page 1493.

23. **Arterial Tension in Disease.**—Bosc and Vedel in their

address stated that the lesions in the syndromes with hypertension pass through three phases, first, a spasmodic, functional stage. It may last long and is accompanied by purely histologic, perivascular inflammatory processes. This is the pre-sclerotic or pre-fibrous stage. The second phase is that of a diffuse fibrosis affecting the small vessels and determining a progressive meioptasia of the organs. This is the stage of fibro-capillarity noted in careful clinical examination and at necropsies. The final phase is that of extension of the fibrosis to the larger vessels, that is, generalized arteriosclerosis with the development sooner or later of atheroma. Suppression of the primary cause, mechanical, reflex or toxic, may lead to complete recovery. When the cause can not be removed at once or the organism is saturated with it, organ therapy exerts an unquestionable antitoxic action. In acute and subacute infectious diseases, treatment should be continued after apparent recovery, to prevent or cure the sclerosis-generating hypertension. Medication should be even more energetic in diseases like scarlet fever, which induce high hypertension and are sclerogenic from the start. The diet is very important in treatment of hypertension. Table excesses should be avoided and all causes liable to increase or aggravate the development of sclerosis. As a rule, an exclusive milk diet—indicated in extreme hypertension with serious lesions in kidneys or heart—is well tolerated on condition that it is alternated with vegetables or unsalted meat. Constipation should be combated by repeated laxatives. Besides these measures, saline purgatives, diaphoretics and diuretics aid elimination. When sclerosis of the small vessels is superadded to the spasmodic phenomena, emotions, exertions, etc., liable to cause increased pressure in the fragile vessels, should be avoided. Drastic purgatives should also be administered prudently, the subject lying down for two or three hours after taking them, to prevent reflex action from the stomach or syncope from cerebral anemia. In permanent hypertension the above measures are only palliative. The sclerotic lesions must be directly attacked with small doses of sodium iodid, not more than .1 to .5 gm. in the twenty-four hours, with periods of rest during which alkaline, intestinal disinfectants and sodium sulphate should be given to aid in the elimination of the iodid. When the process is still farther advanced these measures are still useful to prevent the spread of the sclerotic process, but the main point is to bear in mind the fragility of the arterioles and refrain from everything that might rupture them. Hypertension is indicated when the sphygmomanometer at the radial marks above 18 cm. mercury in an adult and 20 to 21 cm. in an elderly subject. Twelve to 13 cm. indicate hypotension, 10 to 11 pronounced, 8 to 9 great, and 6 to 7 extreme hypotension. In gripe the hypotension is proportional to the severity of the infection; convalescence is longer as the period of great hypotension persists after the temperature has returned to normal. Hot and cold baths help in restoring the hypotension to normal in infectious diseases. The remedy *par excellence*, however, is profuse saline infusion. The action of adrenalin is extremely transient. Vaquez remarks that when rest and appropriate diet are unable to reduce hypertension the subject is in grave danger. The iodids act on the organic lesion, but the nitrites have a direct effect in reducing arterial pressure. Inhalation of amyl nitrite after reducing the pressure temporarily, raises it again, so that the symptoms recur, sometimes with increased intensity. It should be used only in small doses, with brief inhalations. When the hypertension is so high that it becomes menacing, lumbar puncture will sometimes relieve. He found it successful in 3 cases of uremia with brain symptoms. In a sudden crisis of hypertension, such as accompanies acute pulmonary edema, he injects .01 gm. of morphin. Teissier has observed that whenever he detected hypertension in young subjects he always found that the parents had had Bright's disease or diabetes. He calls attention to the need for discrimination, as the figure which would mean hypotension in health or in certain diseases may indicate hypertension in certain other conditions. The hypotension may be an aid in differentiating tuberculosis, etc. In typhoid fever,

increasing tension may warn of impending hemorrhage. Moutier reports 18 out of 50 cases of permanent hypertension cured by arsonization. Verstraeten has noticed that arteriosclerosis is always most marked in the arm most used, the right arm in normal subjects and the left in left-handed. Bernheim states that when the pulse is counted aloud, if the counting is done a little faster or slower than the actual pulse-beat, the pulse will become accelerated or retarded to correspond. This effect of suggestion ceases with the test in normal subjects, while it does not commence quite so quickly and lasts a few minutes longer in subjects with hypertension.

29. Ulcer of Anterior and Posterior Stomach Wall.—Riedel emphasizes the necessity for an exact diagnosis of the site of the ulcer as influencing treatment. In 2 of his cases the pains were on the left side and an ulcer was found with a tumor. In 2 other cases, where the pains were on the right, there was an ulcer but no tumor formation. He describes his technic for operating in case of ulcer of the lesser curvature.

32. Rhythmical Compression of the Thorax in Treatment of Dyspnea, Etc.—Boghean gives two illustrations of an apparatus which compresses the thorax in a manner to imitate its natural excursions, producing or deepening them as the case may be. The apparatus is adjustable and works under perfect control with an electromotor. Two pads fit tight to the surface of the chest, and rise and fall with the chest wall, but during expiration they press in deeper than the walls of the chest naturally recede. As this pressure is relieved, the lungs aspirate larger quantities of air during the next inspiration. This means of artificial respiration or correction of dyspnea is urgently indicated in every case of acute or chronic retention of CO₂. The pads exert a radial, vertebral compression, and are applied below the lower margin of the pectoral muscle to the costal arch between the parasternal and the anterior axillary line.

34. Immunization Against Tuberculosis.—Baumgarten has been experimenting for twenty years in the attempt to render rabbits immune to tuberculosis. He found them always less susceptible to human than to bovine infection, but all his attempts to immunize them with the former against the latter resulted negatively. When von Behring showed that similar procedures were successful on cattle he instituted control experiments which all have corroborated the fact. The immunity thus conferred on his cattle has persisted for two and a half years unmodified. The negative results with rabbits must be due to the greater susceptibility of rabbits to bovine infection. A single subcutaneous inoculation of the cow with human tubercle bacilli is all that is necessary to realize this immunity. Koch, von Behring and others have always supposed that repeated and intravenous injections were necessary,

but this is not the case—a single subcutaneous inoculation answers the purpose. The process induced by subcutaneous inoculation of the cattle with human tubercle bacilli extremely virulent for guinea-pigs, is not a tuberculosis, as the bacilli do not proliferate, but succumb sooner or later. The sore does not exhibit the characteristic aspect of a tuberculous process, but merely evidences of inflammation such as follow irritation from any non-specific foreign body, dead tubercle bacilli, for example. The immunization against *persucht* which follows is not due to a tuberculosis in an attenuated form, any more than the vaccine pustule is an attenuated form of smallpox. Although it may not be possible to produce an effectual curative serum against tuberculosis, yet we have strong grounds for hoping that man can be protected against the disease in the same way as cattle against bovine tuberculosis, by vaccinating human subjects with bovine tubercle bacilli. But before this can be realized in practice, the objections against the non-identity of human and bovine bacilli and their reciprocal harmless-ness must be all encountered and refuted.

35. **Triumph of an Internal Disinfectant in Phthisis and Other Severe Infectious Diseases.**—Dr. Konrad Küster is "privy councillor of the public health" (Geh. Sanitätsrath) at Berlin. In this article he does not hesitate to proclaim that a remedy has been found which promptly and energetically destroys bacilli while, even taken internally in large doses, it has no injurious action on the human organism. The remedy in question is a meta-iodo-ortho-oxym-chinolin-ana-sulphonic acid combination manufactured by the German chemists under the name of *loretin* and offered as a substitute for iodoform. Physicians were weary of new drugs and paid little attention to the announcements of Professor Claus of Freiburg in regard to the surprising bactericidal powers of the proposed substitute for iodoform. A Freiburg layman, however, saw some of these notices and tested the drug on himself, taking as much as 75 grains at a time without ill results. He gave it to advanced consumptives, and after a few months their friends were amazed at the improvement. The results in scarlet fever and diphtheria were equally striking and the layman published a pamphlet on the subject, which attracted no attention. He then presented his data to medical circles, where he finally obtained a hearing. Küster was one of those who have been testing the drug extensively, and he waxes enthusiastic over its efficacy in infectious diseases, even the severest. The drug is eliminated apparently unmodified by the intestines, kidneys, lungs and mucosa, thus following the bacilli into their favorite haunts. He is thoroughly convinced that in "griserin"—as the drug has been renamed—a remedy has been found which will place internal medicine—hitherto the Cinderella—on a par with triumphant surgery. He adds: "It will then be more of a joy than ever to be a physician, as we can be certain to cure the severest illnesses by careful individualizing use of this remedy. This will cut the ground away from under the feet of charlatans who flourish mainly on account of the limitations of our art in the past." The Birkenweder sanatorium has set aside an entire department, in charge of Küster, for patients taking the new remedy. He describes his experiences with it in detail, all bacterial affections apparently going down like card houses before it. The favorable results in cancerous affections suggest a bacterial origin. Diabetes alone, and possibly articular rheumatism, proved rebellious.

40. **Treatment of Tumors Complicating Delivery.**—Dührssen concludes his study of this subject with the following rules: In case of incarcerated ovarian or parovarian tumors no attempt at reduction should be made during pregnancy or parturition on account of the danger of tearing the pedicle with consecutive internal hemorrhage. Treatment should be restricted to vaginal ovariotomy, usually by posterior colpocelotomy. If this proves impracticable, laparotomy should be done in case all preparations have been made for this eventuality. Ventral ovariotomy should be preferred to the vaginal during parturition only when there is infection of the tumor content or of the genital tract. Tumors which can be pushed down into the anterior or posterior vaginal vault during a pregnancy should be attacked also by the vaginal route. High tumors which can not thus be pushed down should be left undisturbed during the pregnancy in case they do not increase in size and the general health remains good. This expectant treatment allows the tumors to be removed later by the vaginal route after delivery and complete retrogression of the uterus. In case of a myoma obstructing the pelvic outlet, which can not be drawn up out of the way, the growth should be removed through the vagina, with vaginal cesarean section, after which the uterus can be carefully emptied and ablated likewise through the vagina. If it is desired to retain the uterus, all the myomas can be enucleated through the incisions already made, and the points of attachment sutured.

42. **Artificial Gangrene of the Skin.**—Hollstein adds another to the long list of patients who induce artificial gangrene of the skin, probably for the purpose of posing as an interesting case. Differentiation is generally difficult. The necrosis was located more superficially than is liable to be the case with true gangrene, and it was surrounded by an area of inflammation. Examination of the scab may possibly reveal the presence of some chemical. Application of a tight bandage will sometimes reveal the deception.

44. **Experiences with Yohimbin.**—Toff relates half a dozen cases in which impotency was cured or the menses regulated by systematic use of yohimbin.

54. Roentgen Treatment of Leukemia.—Fried reports 2 cases very much improved under Roentgen treatment. The patients were men, 59 and 46 years of age, and the benefits were strikingly apparent. The leucocytes returned nearly to the normal figure, the reds increased and likewise the proportion of hemoglobin, while the spleen subsided in size.

56. Heart and Stomach Neuroses.—Schoen some time ago announced that every case of unilateral headache which he has ever encountered was accompanied by some eye defect, and was permanently cured by correction of the latter. He now reports a number of cases of chronic stomach or heart trouble which were likewise accompanied or rather preceded by an eye trouble, and were permanently cured by its correction. The eye trouble in all these cases was upward squint. These heart and stomach neuroses differ from the migraine in the respect that they occur only with upward squint, while the migraine is liable to accompany astigmatism and hypermyopia. He has had more than a hundred patients with these rebellious heart and stomach neuroses cured by correction of the upward strabismus. Such subjects are peculiarly liable to suffer from seasickness and nausea in swinging. The symptoms implicate the vagus, especially the cases with retarded pulse, hyperacidity and exaggerated salivary secretion. The subject has to make demands on a special innervation to combine the pictures seen with the two eyes and thus compensate the defect during his waking hours. This task becomes more and more laborious in time, and the fatigue experienced spreads to adjacent nerves. The overexertion of the innervation for accommodation induces headache, but the overexertion of the innervation of the elevator and its antagonist is transmitted to the vagus. The pulse returns to normal and the hyperacidity vanishes at one stroke after the correction, with the precision of a physiologic or physical experiment. The patients usually came to him after having passed from one physician to another. The diagnosis in the stomach cases had been chronic catarrh of the stomach, dilatation, hyperesthesia, nervous dyspepsia, nervous gastric troubles and even round ulcer (but without hemorrhages). One doctor diagnosed one of the above and the next, another affection, until all united in accepting a purely nervous origin for the trouble. The same is true of the heart symptoms. When asthenopic disturbances were noted they were unhesitatingly attributed to neurasthenia or the stomach trouble, when in reality the reverse was true—the entire symptom-complex was the result of the eye defect, and vanished on its correction.

66. Spinal Anesthesia During Delivery.—Martin has used the Bier-Donitz mode of spinal anesthesia in 30 cases of delivery in healthy women. The anesthesia was perfect in every case with one exception in which it was restricted to the vulva and vagina. The anesthesia generally lasted an hour or an hour and a half. If the delivery occurred during this period the absence of any pain during the entire process was most remarkable. The expulsion of the child seemed to proceed more slowly than under other conditions. The puerperal retrogression of the uterus and development of the milk secretion did not seem to be affected in any way.

77. Aplastic and Lymphadenoid Changes in Marrow.—There may be numerical decrease of the elements of the bone marrow in severe anemia without the typical megaloblastic character of pernicious anemia, and also in the so-called Barlow's disease. As the latter may be incurable in certain circumstances, it stands in the same relation to the former as helminth anemia to the pernicious form. The aplasia may be primary or secondary to bone affections, and may develop directly or by intermediation of lymphatic metaplasia. It is possible that rachitic bone affections may induce a tendency to aplasia of the bone marrow. Senator makes the above statements in connection with a case presenting the clinical picture of pernicious anemia, but the blood was entirely free from megaloblasts, megalocytes and normoblasts, while there was extreme lymphocytosis and pronounced lymphatic metaplasia of the bone marrow. Lymphatic metaplasia may be encountered in leukemia, especially in the lymphatic form, also in medullary pseudo-leukemia—the aleukemic stage preceding lymphatic leukemia—and thirdly, in the mixed forms of leukemia, in pernicious anemia and leukanemia, associated in all of these with other metaplastic changes, proliferation of myelocytes, giant cells and megaloblasts. The lymphatic metaplasia may induce proliferation or diminution of the bone tissue, and both may entail aplasia of the marrow. It may likewise follow a bone affection.

79. The Thymus and Lime Metabolism.—Sinnhuber's research has established that there is no connection between the thymus and the elimination of lime. Also that there is no direct connection between the thymus and rachitis—both are probably due to some primal cause. Energetic thyroid treatment, on the other hand, has marked influence on the output of lime, raising it much above the intake.

81. Action of Heat Stimulation on Heart and Respiration.—Winkler has been studying the effect of hot water poured on the abdomen of dogs. The stimulation from the heat induced irregularities in the heart action and sometimes affected it quite injuriously. Alternating hot and cold procedures had the same effect. He is convinced that the results observed are a warning to refrain from hot-water procedures, including the Scottish douche, in all cases in which there is a liability to stagnation in the minor circulation and increased pressure in the left auricle. This would exclude from such hydrotherapeutic procedures all valvular affections, coronary sclerosis and cardiac asthma, also a tendency to hemorrhage or hemoptysis, aneurisms and general atheromatosis. In chlorosis also hot baths have frequently an unfavorable action. The nervous heart troubles in drinkers and smokers are also liable to be augmented by the application of heat. In the treatment of scitica and emphysema the Scottish douche should not be used for subjects whose hearts are not intact.

82. Cyto-diagnosis.—This communication from the first medical clinic at Berlin is based on extensive clinical experience and experimental research, and can be summarized in the statement that lymphocytosis in the cerebrospinal fluid is an evidence of prolonged and powerful irritation. It is frequently encountered in lues, while it is far from constant in tabes, but oc-

curs somewhat more regularly in paralysis. It may possibly serve for the recognition of a dubious early stage of syphilis.

85. **Serum Treatment of Anemia.**—Engel drew 8 to 10 c.c. of blood from a young woman who presented typical chlorosis with extreme anemia. He injected a rabbit with the serum from the blood—after heating the serum to 58 C. to destroy the natural complements. This was repeated ten times, and serum from the rabbit was injected into the patient at 8 different times. A chill sometimes followed the injections, with more or less temperature, and the arm swelled more than the other arm, which was injected with serum from a normal rabbit. No iron or arsenic were given during this course of treatment, which was pursued during three months. Both objectively and subjectively the patient made fine progress. By the end of the year the hemoglobin was 90 per cent., the reds numbered 4,800,000, and the specific gravity of the blood was 1.058.

87. **Effect of Phosphorus and Arsenic on the Thyroid Gland.**—Macaggi's experimental research and clinical experiences demonstrated unmistakable structural changes in the thyroid under the influence of phosphorus and arsenic. In acute intoxication with either of these drugs there was a slight increase in the gland and passage of colloid into the lymphatics and a change in the composition of the colloid itself, but in the subacute and chronic forms of intoxication the colloid secretion was reduced and the secreting epithelium became atrophied. This latter fact justifies the therapeutic use of arsenic and phosphorus in case of hypertrophy of the gland.

88. **Typhoemia.**—Memmi reviews the findings in 30 cases of typhoid in which the blood was examined for the bacilli. As a rule, the presence of the bacilli in the blood coincided with the severity of the disease. The most favorable time for finding the bacilli in the blood is from the end of the first week to the beginning of the third, although in the severer cases they may be found much later and in the relapses. The bacilli cultivated from the blood were always feebly motile and sometimes bunched in groups. The Castellani technic of copious dilution of the blood with bouillon will sometimes enable the bacilli to be detected when they escape with other technics. Typhoid bacilli isolated from the blood have a weak agglutinating power, which becomes stronger as they adapt themselves to saprophytic existence. The Widal test with laboratory bacilli and with typhoid bacilli from the blood of the patient harmonize, although the latter do not permit generally of such dilutions as the former. The streptococcus and a diplococcus

may sometimes be cultivated from typhoid blood in association with the typhoid bacilli, especially in case of complicating pneumonia. The cases of typhoid without intestinal localization are not so rare as hitherto supposed. In one of his patients typhoid bacilli and streptococci were found in the blood and yet there was no localization of the process in the intestines. The patient died about the sixth week, having presented the roseola, diarrhea, albuminuria, enlarged spleen, delirium and heart symptoms typical of typhoid and a suppurating process in both wrists. The intestines showed no lesions, merely a slight catarrhal condition. The blood serum agglutinated the typhoid bacilli from the blood at 1/15 as also laboratory bacilli. At the second examination, the thirty-first day, nothing but streptococci were found in the blood, but at the necropsy both streptococci and typhoid bacilli were found. The article reviews the literature on the subject of the invasion of the blood by the typhoid bacillus.

89. **Aneurism of the Superior Mesenteric Artery.**—Baccelli describes the case of a man of 34 with a pulsating tumor in the abdomen. The tumor was oval and was located low down behind the stomach, about 10 cm. in its longest diameter, lying across the abdomen. Both pulsation and souffle became indistinct when the stomach was distended. The location of the aneurism did not correspond with the course of any artery except the superior mesenteric, just below the pancreas. It was evidently of syphilitic origin. There are only 20 cases of aneurism of this artery on record and only one besides the present case was diagnosed during life. The operation showed a sac aneurism of the superior mesenteric opening into the aorta in such a way that the proposed gradual ligation was impracticable and nothing was done. As the patient's general condition is good, Baccelli intends to try to control the aneurism by gradually ligating the branches back of the aneurism.

90. **Galvagni's Xiphoid Crepitation.**—Galvagni noticed in 3 patients with peritonitis a peculiar crepitation at the xiphoid process or along the costal arch, resembling that of a cutaneous emphysema. The sensation is felt as soon as the wall over the xiphoid process is palpated, but it can no longer be distinguished when the upper part of the abdominal cavity becomes filled with ascitic fluid. Campani reports 13 other cases in which this crepitation was observed, all in very sick patients. Interstitial liver affections, cancer of the rectum, ovary, liver or other organ or tuberculous processes in the peritoneum were found in the cases described. Galvagni regards the crepitation as a sign of peritoneal inflammation with consequent obstruction of the normal gaseous interchanges or gas formation from decomposition or gas exhalation substituting the altered cutaneous transpiration.

92. **Leucocyte Formula in Mushroom Poisoning.**—The treatment in the 4 cases described was with injections of atropin with an ice-bag to the region of the stomach to control the tendency to vomit, morphin and seltzer water and no food except milk. All but one patient recovered. The latter presented extreme mononucleosis and the increase in the numbers of the large mononuclears was marked in every instance. The mushrooms belonged to the family of *Agaricus virosus*. The excessive mononucleosis in the fatal case demonstrates anew the evil significance of this phenomenon in infections.

94. **Galvagni's Mouth Souffle.**—In 1896 Galvagni described what he called the divided systolic expiration or oral souffle. Auscultation of the open mouth of the subject shows an interruption of the sound of expiration with a cardiac rhythm. This interruption in the expiration was observed in subjects with pleuritic lesions, the pleural adhesions transmitting the movements of the heart to the air issuing from the lungs. Fischer has called attention to a similar finding, which he accepted as possibly an aid in diagnosing dilatation of the heart not appreciable by any other means. Galvagni accepts it as due to the expulsion of the air from the alveoles in the lungs by the rhythmic compression exerted by the heart and large vessels. He noticed the rhythmic gushes of air through the nostrils during expiration, as well as in the mouth, in one instance.

97. **Action of X-Rays on the Leucocyte-Forming Organs.**—Bozzolo has been systematically treating a number of patients with various affections by exposure to the x-rays. The list included one case of severe leukemia, one of lymphatic leukemia, 2 with Banti's disease and one of chlorosis. The condition of the blood notably improved under the Roentgen treatment. One patient was a young woman whose leukemia first manifested itself a year before with general weakness, dyspepsia, amenorrhoea and palpitation of the heart. In a few months there was high fever, the spleen had enlarged enormously and there was a hemorrhagic effusion in the left pleural cavity. The reds numbered 2,800,000 and the leucocytes 140,000, the neutrophile polymorphs in a proportion of 51 per cent., the eosinophiles 8.8 per cent., the myelocytes 14.7, and the lymphocytes 22.5 per cent. Under tuberculin treatment the leucocytes were somewhat reduced in number, but the general condition grew worse. Roentgen treatment was commenced with exposure of the spleen, knees, elbows and sternum. In a week the temperature had declined nearly to normal and in ten more days became permanently normal. The spleen also subsided nearly to normal outlines, the appetite and strength returned, the weight increased by nearly 40 pounds, menstruation became normal and the general aspect of the patient is that of health. In three months the leucocytes numbered 10,000, but then they increased again in numbers, at present being 40,000, with no myelocytes or eosinophiles and fewer lymphocytes but more polynuclears. Although the patient is so much improved, her blood still has a suggestive leukemic character which renders a relapse by no means improbable. The improvement observed in this case was paralleled by a number of other cases, showing that it was not a mere coincidence.

99. **Grocco's Triangle in Pleural Effusions.**—Ferrannini describes the mechanism of this sign, which he regards as of extreme importance for the diagnosis of a one-sided pleural effusion. Its size is a reliable indication of the extent of the effusion, and as it vanishes it shows that the effusion is being absorbed, even when no other indications of the absorption are apparent. Grocco's description, published in 1902, stated that in case of a pleural effusion on one side, the other side presented a triangular area of dullness over the back of the opposite side of the thorax. The inner line of this triangle runs along the spine, the lower line coincides with the lower margin of the thoracic resonance for 3 to 7 cm. and the outer line of the triangle follows an oblique line, uniting at an acute angle with the first line, on a level with the top of the effusion. The dullness is always more pronounced when the effusion is on the right side. Radioscopic examination always showed the exact level between the top of the area of dullness and the top of the effusion, and that the length of the base of the triangle was always proportional to the extent of the effusion. The dullness is evidently the result of the displacement and compression of the contents of the sound side of the thorax, and is thus always proportional to the extent of the effusion.

100. **Treatment of Ankylostomiasis.**—Norsa remarks that the cure of this condition is liable to be far from an easy matter. Some patients are cured readily and others require many repeated courses of treatment, with frequent examinations in the interim to finally expel the parasite. Male fern and thymol should be given the preference in treatment, but if one or the other fails, still other remedies should be tried.

102. **Treatment of Acute Coryza in Infants.**—Massei disapproves of very vigorous measures, thinking that the best treatment is by hygiene, a few air douches, glycerolate, and insufflation of orthoform to meet the indications. When the acute symptoms are past he insufflates a powder consisting of 5 parts each of boric acid and bismuth with 1 part resin, with or without 1 part menthol.

103. **Inoculability of Malignant Tumors.**—The conclusions of Sanfelice's previously published research on the pathogenic action of blastomycetes are corroborated by this latest work. He found a pedunculated sarcoma in the vagina of a bitch which contained numerous saccharomycetes which cultivated readily. Inoculation of 6 dogs with these micro-organisms and

of a number of other animals resulted in lesions in which the saccharomycetes were found in great numbers, the neoformations consisting more of these parasites than of proliferating cells and consequently not true morbid growths in any of the animals except the dogs. In the latter, however, the parasites were scanty and the lesions were true neoplasms, the proliferating cellular elements being mainly of mesodermal origin. The neoplasm amounted to an actual tumor in one out of the 6 dogs, identical in structure with the primary tumor. Inoculation of other cancerous growths in addition to these experiences has convinced him that the inoculation of malignant tumors is possible only when they contain parasites in a cultivatable form. This varies in different growths and at different times in the same growth. When the blastomycetes have become transformed under the influence of the antibodies of the serum into fuchsinophile bodies they are no longer cultivatable.

104. **Sensory and Psychic Functions in Hemiplegia.**—Marimmo's clinical experience has confirmed the fact that the paralysis is always accompanied by sensory and psychic disturbances to a greater or less degree. The changes are in the nature of involution, and they should be combated by early and progressive re-education of the sensory and psychic functions as well as of the motor.

105. **Attempt to Realize the Determination of the Sexes by Cytolysis.**—This attempt to realize the determination of the sexes by means of cytolytic injections has already been mentioned in *THE JOURNAL*, in the news columns, page 478. The present work issues from Valenti's laboratory of histology and embryology at Bologna. An iso-spermatolysin was produced in rabbits by inoculating them with an emulsion of the male genital organs from other rabbits. This iso-spermatolytic serum was then injected into 2 rabbits, each receiving in the course of two and a half months about a dozen injections, corresponding to about a dozen sets of the male organs. The serum acquired toward the last undoubted spermatolytic power, but not very intense, arresting somewhat slowly the movements of spermatozoa. The results were a little more pronounced when the rabbits were inoculated with the male genital organs from sheep. The litters of rabbits born were about equally divided between the sexes, no influence from the cytolytic treatment being perceptible. Possibly the injections induced the formation of an antibody which nullified their action. Zanotti presents several theories to explain the lack of action from the spermatolysin on the germinal cells of the male embryo.

106. **Experimental Tuberculous Infection by Way of the Vagina.**—Galbo's experiments were made at von Schrön's Anatomic Institute. They demonstrate that lesions and solutions of continuity in the female genital tract are indispensable to the development of primary tuberculosis of these parts. Inoculation of tubercle bacilli was always completely harmless so long as the mucosa was intact.

107. **Differentiation of Hemorrhagic Pleural Effusions.**—In a hemorrhagic pleuritis due to some morbid growth the pains are sharp, lancinating, progressive, radiating to the shoulder, neck and arm, with intense dyspnea, no fever, but rapid loss of strength. There is also cyanosis of the arm on the affected side, and swelling of the glands. The thorax gives on percussion a dull, woody sound, Traube's crescent is retained and Skoda's resonance and the bronchial souffle persist even after thoracentesis. The fluid is constantly reproduced and retains to the end its hemorrhagic character. On the other hand, the symptoms of a tuberculous hemorrhagic pleuritis are slight pain or, if sharp, there is no radiation; dyspnea is slight or absent; the fever is of a hectic type; the strength declines more gradually; the cough is short and dry; there is merely slight cyanosis, and no glandular enlargement. There is dullness on percussion and Traube's crescent is not to be discovered. Skoda's sign and the bronchial souffle vanish after thoracentesis. The fluid is very slowly reproduced and may become fibrinous or may be completely absorbed. The work issues from Cardarelli's clinic and is published in book form.

FEDERAL CONTROL OF DRUGS.*

H. W. WILEY, M.D.
WASHINGTON, D. C.

The Congress of the United States has authorized two kinds of investigations into the character of drugs. The term "drug," as used in the acts of Congress, may, I think, very properly be interpreted to mean any remedy intended for internal or external use. In fact, the regulations, as will be referred to later on, made under the provisions of this law, recognize this as its fundamental meaning. It may, perhaps, be surprising to many of you to know that one of the existing laws relating to the inspection of drugs was enacted by Congress on the 26th of June, 1848. This law is found in Section 2,933 et seq. of the revised statutes. The first section of the law provides that "All drugs, medicines, medicinal preparations, including medicinal essential oils and chemical preparations used wholly or in part as medicine, imported from abroad, shall, before passing the custom house, be examined and appraised, as well in reference to their quality, purity and fitness for medicinal purposes as to their value and identity specified in the invoice." The regulations made by the Secretary of the Treasury under this act, and which are now in force here, are found on pages 461 et seq. of the Customs Regulations of the United States, edition of 1899. I will not unduly increase the length of this paper by quoting to any extent from the law in question or from the regulations established. It may be, however, interesting to know that drugs imported from Scotland shall be judged as to their purity by the pharmacopoeia and dispensaries of Edinburgh, and the drugs imported from England, France and Germany are in like manner to be judged by the standards of those countries. All other drugs are to be judged by the standard established by the United States. An important feature of the law on adulterations of drugs is the extension of this examination to patent and secret medicines. There are no standards, of course, for these in any of the pharmacopoeias, and, therefore, they are judged on their own merits. Article 1,287 of the regulations prescribes: "Patent or secret medicines are subject to the same examination and disposition as other medicinal preparations, and can not be permitted to pass the custom house for consumption, but must be rejected and condemned unless the special examiner be satisfied, after due investigation, that they are fit and safe to be used for medicinal purposes."

In the case of opium it is provided that its importation by Chinese subjects is absolutely prohibited. The

execution of the law relating to the inspection of imported drugs is conducted chiefly at the port of New York; but, of course, similar investigations are made at the other ports. During the year 1903 an abstract of the work accomplished at the port of New York in the inspection of drugs was furnished the Senate by the Secretary of the Treasury in response to a request therefor from the committee on manufactures. This abstract may be found in the *Oil, Paint and Drug Reporter*, April 25, 1904, page 28C. From this abstract, among other things, it is learned that of 44 samples of opium examined, 9 fell below the standard for morphia, viz., 9 per cent. The same report shows that large numbers of imported remedies contain alcohol. The minimum and maximum quantity found ranged from 5.45 per cent. in "Ischirogeno" to 76.6 in "Eau des Jacobins." Many proprietary and other remedies were also examined, but the details of the analyses are not very full. For instance, a remedy known as antitusin is described as a "hypnotic and calmative in ointment." Again, anti-opium pills are described as containing starch, reducing sugars, extractive matter, cellulose and 3.5 per cent. of ash. There is not time nor space here to enter into the details of the valuable work which the Treasury Department is doing in the inspection of drugs. Any member of the Association interested particularly in the matter can get further information by addressing the Treasury Department.

The work of the Department of Agriculture is carried on under the provision of law embraced in the act making appropriations for the Department of Agriculture, authorizing the Secretary of Agriculture "to investigate adulteration of foods, condiments, beverages and drugs." And the further section authorizing the Secretary of Agriculture "to investigate the adulteration, false labeling or false branding of foods, drugs, beverages, condiments and ingredients of such articles." It will be seen that the authority conferred on the Department of Agriculture by the above sections relates solely to the investigation of drugs and medicines, and not to any inspection or control thereof. There is, however, a further section in the law just referred to, which authorizes the Secretary of the Treasury, at the request of the Secretary of Agriculture, to exclude from the ports of the United States foods, drugs, beverages, condiments and ingredients of such articles which "the Secretary of Agriculture reports to him have been inspected and analyzed and found to be dangerous to health, or falsely labeled or branded, either as to their contents or as to the place of their manufacture or production, or which are forbidden entry or to be sold in the countries in which they are made or from which they are exported."

In view of the fact of the rigid and effective inspection of drugs at the ports of entry by the Secretary of the Treasury, the Secretary of Agriculture has not

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Solis-Cohen and O. T. Osborne.

deemed it advisable to institute a similar inspection, which, at best, could only be a duplication of what the treasury officials are already doing. For this reason the authority above conferred has been exercised by the Secretary of Agriculture only in respect of foods, beverages, condiments and ingredients thereof. In order to better provide for the work authorized under the law above quoted, the Secretary of Agriculture has organized in the Bureau of Chemistry a drug laboratory for the investigation of the purity, adulteration, false labeling and false branding of drugs. This laboratory is working in full sympathy and collaboration with the American Pharmaceutical Association, and especially with the committee on drug adulteration of that body. It is true that the chief of that laboratory, with the two or three assistants that he has, can not be expected to go over the whole ground of drug adulteration with any degree of rapidity. The best that can be done in this matter is to take up for special investigation those subjects which seem to demand particular attention. Although this laboratory has been established only a year and a half, it has nevertheless accomplished a large quantity of work, and one bulletin embodying its investigations has already been published. This publication is known as Bulletin No. 80 of the Bureau of Chemistry, and those interested in its contents can secure copies by addressing a request to that effect to the Secretary of Agriculture. This bulletin contains three separate reports of investigations, viz.:

1. Inferior drugs and insidious methods of deception.
2. Rose geranium oil and its substitutes.
3. Phenacetin—methods of analysis and commercial status.

The introduction to this bulletin will give a general idea of the character and utility of its contents:

The first two articles of this bulletin set forth the conditions that prevail, not only in relation to individuals, but also in some of the best-regulated laboratories. There is a continual cry for cheaper drugs, and in the effort to meet this demand and at the same time make a profit adulteration has spread. The members of the pharmaceutical profession of high standing, however, are anxious to remove from the trade any odium due to adulteration which at present exists.

The third paper deals with the medicinal remedy phenacetin, which, according to reports, has been largely adulterated in this country, and many substitutes offered therefor. This subject was studied because of the great interest that exists concerning it in both the medical and the pharmaceutical world, many druggists and physicians being directly involved in the controversy. The fact that phenacetin is sold for 15 cents an ounce in Canada, while \$1 or more is charged for the same amount in the United States, creates an impression, correct or incorrect, of injustice. The conditions set forth concerning phenacetin are, moreover, typical of those affecting a large number of patented medicinal remedies. Furthermore, the attempts that have been made to secure such changes in the patent laws as would eliminate these disturbing factors have not been successful. It is hoped that the contents of this paper will place the whole situation before the public in a just and impartial manner.

Another important line in which federal inspection of drugs is conducted is in the collaboration of the Department of Agriculture with the Postoffice Department. The laws regulating the transmission of dangerous, fraudulent and deceptive matters through the postoffice are very stringent, and under these laws the Postmaster General has the right to exclude from the mails articles which, in his opinion, are contrary to the provisions of existing laws. The Congress of the United States has authorized the Bureau of Chemistry of the Department

of Agriculture to undertake investigations along chemical lines which may be asked for by the heads of other departments. This authority is found in the following provision of the law:

Authorizing the Bureau of Chemistry to continue the collaboration with other bureaus and divisions of the department desiring chemical investigations, and to collaborate with the other departments of the government whose heads request the Secretary of Agriculture for such assistance, and for other miscellaneous work.

Under this authority numerous investigations have been made at the request of the Postmaster General of secret remedies, nostrums and other bodies of this class offered for transmission through the mails, or the advertisements for which are offered for transmission through the mails. A large part of the activity of the drug laboratory during the past year has been taken up with these investigations, and as a result of them a number of fraud orders has been issued by the Postmaster General, excluding from the mails the nostrums investigated. It is seen, therefore, that the laws of the United States do afford some protection to its people in regard to alleged remedies of this class, both in providing inspection at the ports of entry for such articles and by controlling their circulation or advertisements thereof through the mails. It is evident that but little more than local business could be done by any secret nostrum of a fraudulent nature were it not for the medium afforded by the United States mails for scattering the advertisements thereof and sending the samples themselves.

I need not enter into any argument here of the benefit that would accrue to the medical profession by a proper regulation of secret alleged remedies. If remedies have real merit, or any merit of any kind, inventors of them have a right to be protected in their discovery, and this right is fully provided for by the laws relating to patents, copyrights and trade marks. On the other hand, if such alleged remedies are fraudulent in their very nature and their sale is promoted by deception in advertising, the control and abolition of such abuses is certainly to be commended.

From the above outline of what federal legislation has done and is doing, it is seen that a control and an inspection of substances used as drugs have been fully inaugurated. It is true that this control and inspection are by no means perfect or universal, but in so far as they go they are certainly useful and commendable. In the interest of the medical profession, of the pharmaceutical profession and of the public, it is hoped that federal control of drugs in general may become more universal and more efficient. In this way the interests of the two great professions mentioned, and of the public, can be best conserved.

THE FORTHCOMING PHARMACOPEIA.*

JOSEPH P. REMINGTON, *DR. M.*,
Chairman of the Committee of Revision.
PHILADELPHIA.

The interest which the members of the American Medical Association have taken in the new Pharmacopeia, numerous letters which have been received from physicians throughout the country, and a request from the Section on Pharmacology for this paper, are good and

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Sells-Cohen and O. T. Osborne.

sufficient reasons for giving information about the new book which is being printed.

Exceptional activity in providing therapeutic agents for the alleviation of disease has made the work of the Committee of Revision much greater than ever before, and it has been a task to make a judicious selection of the synthetics. Every physician must regard the present condition as confusing in the extreme, for no sooner has he commenced to learn the real value or worthlessness of a new synthetic than he is imperturbed to try another. The enormous financial returns from the exploitation of some of these products has been, of course, the moving cause for this condition. The committee has had to consider the question of copyrights, trademarks and patents, and to have accepted every one which has been strongly recommended by some physician as valuable would have not only overwhelmed the book and produced hopeless confusion, but a new revision would have been necessary within a year.

It is one of the principal functions of the Pharmacopeia to select only the substances which have proved their value by repeated clinical trials, and have gained the confidence of a large number of discriminating practitioners. Those who are interested in the financial success of the new agent, or who are employed to write up its merits, can not always be trusted to give unbiased information.

Among the important questions with which the present committee has had to deal is that of the standards for purity. In the Pharmacopeia of 1890 there are standards which have been found, by actual practice, far too rigorous and hypercritical. There is no necessity for prescribing chemical salts which are microscopically or analytically free from harmless substances (provided always that the amount of such be accurately known and a proper allowance be made), and when it is considered that in some cases the cost of manufacturing such products adds 100 per cent. or over to the price, the condition calls for immediate action. Chemical testing has reached a stage of far greater accuracy than ever was believed possible, and methods can now be employed which will determine the percentage of contamination with great precision.

The food and drug laws in the various states have been a moving power within the last few years, in calling greater attention to deviations from the standards of the Pharmacopeia, but those who have instituted prosecutions have, in many cases, chosen absurd subjects as the basis of what might be properly called "persecutions," and have permitted far weightier infractions of the law to pass unnoticed. Pharmacists have been forced to pay penalties for trifling deviations, and large manufacturers and wholesale dealers have often been severely let alone. When the food and drug laws are wisely and efficiently administered, they will prove of immense value to the country by punishing a class of druggists who regard cheapness rather than quality as of the first importance.

In view of these facts, the Committee of Revision has established the principle that it is far better to introduce standards which can be readily attained, and then look to the laws to prosecute offenders who do not comply with requirements so easily within their reach. What is known as a "purity rubric" will be attached to substances capable of being tested, and this will be framed so that the lowest limit of the standard is distinctly stated. Thus boric acid will contain the following statement immediately under the title: "This acid

should contain not less than 99.8 per cent. of pure boric acid." It will be observed that this does not prevent a manufacturer from selling a boric acid of 100 per cent. purity, if he so wishes, but it will prevent the sale of a boric acid of 90 per cent. grade for medicinal purposes.

Another great question arising out of the passage of the food and drug laws has been the strained construction placed on the laws by the judges of our courts. They have ruled that the standards required for medicines shall be rigidly applied to substances used in the arts. This may be a good law, but it is not common sense. Every one must recognize that the use to which a chemical is put must determine its standard of purity. Take, for instance, sodium phosphate. This is used largely in the arts for preventing the scale from forming on boiler tubes, and naturally those who buy it for this purpose need only know the percentage of real sodium phosphate in the product; but sodium phosphate nearly always contains arsenic, and the physician who prescribed sodium phosphate for a child would be likely to get untoward results if the boiler compound salt were used in place of the official pharmacopeial substance. In fact, the presence of minute quantities of arsenic in sodium phosphate has been the subject of special speculation. Some physicians have declared that they do not object to a trace of this contamination, but such an opinion has little weight with the committee of revision. Sodium phosphate must be practically free from appreciable quantities of arsenic if anything like exactness in therapeutic results is to be secured. Any physician who prefers sodium phosphate with arsenic can prescribe the exact quantity of the latter that he needs.

A clause will be inserted in a prominent place in the new Pharmacopeia, stating that the tests in the book are to apply solely to substances to be used as medicines. This will relieve the court judges and all from any trouble in this direction.

A small but important body of medical and pharmaceutical savants assembled in Brussels in August, 1902, constituting the *Conférence Internationale pour l'Unification de la Formula des Médicaments Héroïques*. Each country was entitled to send two delegates, the United States being represented by Dr. Horatio C. Wood and Dr. Frederick B. Power. Owing to the delegates having been appointed by the governments of the several nations, greater authority was conferred on this congress than that usually given to ordinary conventions. As the title of the congress indicates, the work was confined to the framing of an international pharmacopeia of potent remedies only. The limitation of the scope of the congress was a wise step, and, in fact, the conception of the idea of framing an international pharmacopeia of this kind arose from the recommendation of British pharmacists, the suggestion gaining impetus and assuming shape in 1893 at the Seventh International Pharmaceutical Congress, which met in Chicago in that year. The American Pharmaceutical Association aided greatly in the movement by declaring itself in favor of an international pharmacopeia for potent remedies only.

It should be stated in this connection that an international pharmacopeia, embracing all medicinal substances, has been a dream for more than half a century, and in all probability the project will continue in a nebulous condition until the millenium. The difficulties are apparently insurmountable. Each nation, through

long experience, has become accustomed to use certain drugs, and the pharmaceutical preparations made from these drugs have been in use so long that it would be an impossible task to supplant them except by the use of autocratic international power or by very gradual and slow methods. The stupendous utopian idea of having but one pharmacopoeia for the world fades in impressiveness when the actual work of framing such a book is seriously considered.

It may be of interest for the members of this Association to know that an international pharmacopoeia once progressed to the stage of a manuscript copy, and the outline was submitted to the succeeding international congress for approval. As soon as the admissions to the book were discussed in open session, a multitude of objections from the assembled delegates from the nations were heard. Naturally, the chairman, who was most influential in framing the work, had admitted a large proportion of the preparations which were used in his own country, and he, of course, thought that they were the best in the world, for with these he was most familiar. Inasmuch, however, as the great majority of the delegates knew very little about them, they preferred their own, and the result was one which could easily have been foreseen—the rejection of an international pharmacopoeia of this kind. It was then plainly seen that all that could be hoped for in the way of international unification was a very small and simple code of standards, limited exclusively to potent remedies.

The Brussels congress above referred to was the first body to practically frame standards for such a work, and the new United States Pharmacopoeia will be the first national authority to be issued which will recognize the standards of this congress. It would take too much time to detail the work of this congress, but the recognition of the standard of strength of the arsenical preparations is very important. It will not be long before every arsenical official solution throughout the world will have the strength of 1 per cent. Ten per cent. for tincture of opium, 5 per cent. of ferrous iodid in the syrup of the iodid of iron are among some of the standards fixed by this body. Ten per cent. and 20 per cent. tinctures will simplify very greatly the situation in this important class of preparations. Ten per cent. will be used for the potent drugs, and 20 per cent. for those which are weaker. This will make an important change in the strength of the tincture of aconite and tincture of veratrum viride, and information is hereby given at this early date, to physicians, that tincture of aconite will, after the new Pharmacopoeia goes into effect, have but one-third the strength of the present tincture. Due care will be taken to spread the information as much as possible in advance. It will not make the tincture less useful; the dose will simply have to be increased. In addition to this, it should be remembered that the standards of the new Pharmacopoeia will not go into effect until three months after the work is issued, and an official date will be placed on the title-page of the book announcing the fact. This action is necessary, because wholesale druggists and pharmacists must have sufficient time to adjust their preparations to conform to the new standards, and time must be given to physicians to become acquainted with the changes.

The alterations in nomenclature will not be very great. There are some, however, which will have to be made, because more accurate knowledge of the chemical composition of some of the substances will require

it. It is believed that the present is a good time to change the name of carbolic acid. It is not an acid, but a phenol, and although this fact was recognized twenty years ago, the name "carbolic acid" was so firmly established that it was not deemed wise to change it. The name will still be used as a synonym, but physicians will find a shorter and more distinctive title in "phenol."

Synonyms will still be continued in the book, but their prominence will be lessened by not printing them in the text, and they will probably be relegated to the index. Synonyms have given much trouble to revision committees at all periods. It must be recognized that as a science or art advances, the names which designate the subjects of such science or art must be accurate, definite and, so far as possible, distinctive. Pharmacopoeial revision has been traveling in this direction since the issue of the United States Pharmacopoeia of 1820. Latin titles are now almost universally used in all departments of science, and the use of vernacular popular names for medicines, on account of their variation and indefiniteness, produces confusion and sometimes dangerous results. For these reasons the use of synonyms has been properly discouraged; they certainly should never be used in prescriptions, yet it is common to find in these such names as "laudanum," "paregoric," "Dalby's carminative," "cold cream," "Goulard's cerate," etc. The importance of always using pharmacopoeial titles for prescribing official preparations should be insisted on, particularly by those who are charged with the important duty of instructing the army of young men in our colleges and universities.

The names of some of the synthetics which will be introduced may at first sound strange, but definite chemical names should be used rather than the fanciful titles given by the promoters who first introduced them. Some of these names will, of course, be longer than the trade names, but inasmuch as physicians always abbreviate titles in writing prescriptions, they will not prove burdensome.

For the first time in the history of pharmacopoeial revision in the United States, average doses will be introduced. It would be beyond the scope of this paper to enter into the arguments pro and con, first, for the introduction of doses at all into the book, and second, for the choice of the average dose over the maximum dose. In deciding these problems, the first question which confronts one is, "What is a dose?" And this is almost as difficult to decide as the question, "What is a poison?"

The physicians in the pharmacopoeial conventions in the past have almost been a unit in opposing the introduction of doses into a national authority like a pharmacopoeia. It is true that the German pharmacopoeia inserts a maximum dose, but one can imagine the annoyance and even danger which would be experienced if maximum doses were introduced in this republic, into a book which the laws of the various states recognize as an authority. The liability for prosecution for malpractice and the possibility of suits at law arising from exceeding a maximum dose, would be great, but further than this, who can say that the dose of half a grain of morphin sulphate should never be exceeded, or that every time that a physician wishes to give a dose of morphin larger than this, he must indicate on the prescription that it is a special case? For otherwise he would be sure to have the prescription returned to him by the pharmacist, with possible injury to the patient on account of the delay.

The United States Pharmacopoeial Convention decided on average doses because they will be of far greater practical service than maximum doses. It is well known that the capacity of patients to tolerate large doses of powerful agents varies greatly, and even the same person at certain periods can bear larger doses than at others. In addition to this, the idiosyncrasies of patients is a real problem that every physician must wrestle with. For these, and several other reasons, the revision committee, in accordance with the instructions of the convention, will insert average doses.

In concluding this brief paper, I trust that I have indicated, in some measure, the direction in which the improvement may be looked for in the revision of the forthcoming United States Pharmacopoeia.

THE RELATION OF THE PHYSICIAN TO PROPRIETARY REMEDIES.

HOW MAY SUBSTITUTION BE AVOIDED AND THE DESIRED PREPARATION OBTAINED WITHOUT UNDULY ADVERTISING THE MANUFACTURER?*

WILLIAM J. ROBINSON, M.D.,
NEW YORK CITY.

In their relation to proprietary preparations, physicians may be divided into three classes: A, B and C.

To class A, unfortunately a very numerous class, belong those physicians who prescribe everything and anything that is brought to their notice. The composition of the products they prescribe is a matter of utter indifference to them. The prescribed product may consist of two or three well-known substances; it may be as common a substance as sodium bicarbonate under a disguised name, or it may contain morphin, strychnin, pilocarpin or other dangerous alkaloids in a strong alcoholic menstruum—they care not. It answers, or they think it answers, the intended purpose and they are satisfied. They are supported and encouraged in this attitude by such journals as the *Medical Brief*, of which many physicians of class A are readers, if not subscribers. What our opinion is of such physicians it is hardly necessary to state. They are really not physicians. They are merely laymen with a right—a legal right, not a moral right—to practice medicine. The layman reads that Father John's medicine is good for consumption, Green's nervura for the nerves, orangeine for headache, etc., and he goes to the drug store and gets those things. He does not know what they are, but he trusts the manufacturer. The physicians of class A act in the same way toward resipiton, neurilla, and antikamnia. The difference is only in the names of the preparations, and even in the names there is sometimes no difference, for physicians of class A have been known to prescribe Radway's ready relief, Hood's sarsaparilla, Ayer's cherry pectoral, etc.

Class B is the other extreme. The members of this class are highly respectable physicians, but on the subject of proprietary remedies they are very unreasonable, or perhaps, I might better say, unreasoning; their attitude is a fanatical one, and is the result mainly of misapprehension, of ignorance of the true state of affairs. For them, the drug that is not in the Pharmacopoeia or in their old text book of medicine does not exist,—as if *materia medica*, unlike all other branches

of medicine, were incapable of further development. Calomel, digitalis, belladonna, opium and a dozen other drugs constitute their entire armamentarium. They are indignant at the mention of any proprietary or patent preparation. It is well to note, *en passant*, that many of our friends, the therapeutic nihilists, belong to this class.

Now, what is the cause of this inimical relation to all proprietary remedies? In my opinion it is due only to a misapprehension. These physicians confuse true patented preparations with the various nondescript nostrums, which are merely trade-marked and on which a patent could never be obtained. They confuse such true acquisitions to our *materia medica* as heroin, dionin, iodipin, collargol, duotal, adrenalin and orthoform, with Hood's sarsaparilla, Hostetter's bitters, Kiimer's swamp root, Warner's safe cure, peruna, phenalgin, antikamnia, manola, neurilla, etc. That some of our very best physicians make this error, I have occasion to witness almost every day. Recently I met one of our most eminent New York physicians, a man with a large practice and who is making a mark for himself by his work in physiology and pathology, and he confessed to me that up to a few weeks ago, he did not have the slightest idea that there was any difference between the two classes of preparations. Only yesterday Dr. Wm. Porter read an excellent paper at the meeting of the American Medical Editors' Association on the subject of proprietary remedies, but he made the same mistake of confusing proprietary non-patented secret nostrums with the true patented preparations. He was much surprised when the difference was explained to him. He said he did not think that one physician in a hundred knew the distinction. I therefore think that right here it will be very much *à propos* to stop for a moment and explain the real difference. It is about time that the hazy and vague ideas on the subject should give way to clear conceptions based on facts.

Now, a patented medicine is not, and can not be, a secret medicine, as I explained in another place. The very etymology of the word should show it. Patent is derived from the Latin word *patere*, which means "to be open," and a patented medicine is an open and non-secret medicine. In order to obtain a patent (on anything), the inventor or manufacturer must disclose the process of manufacture, to the minutest details. It must be described so fully and so explicitly, that any person of ordinary skill in that line of business, may be able, by following the directions, to produce an identical product; should there be any incompleteness in the description of the process, the patent becomes void; should there be any wilful deception, the inventor is liable to fine and punishment. Beside the process, he must also give the physical appearance, chemical properties, tests for identity, etc. The directions in the Pharmacopoeia for making any preparation and the tests for identity are not and could not be more explicit than those given in the application for any patent. Where is the secrecy then? But the thousand and one "sarsaparillas," "perunas," "tonics," "pain killers," "blood purifiers," "favorite prescriptions," "golden discoveries," antikamnias, phenalgins, neurillas, manolas, sengs, chionias, etc., which are the curse of the American people and of the American physicians, are not patented at all. They are only trade-marked; that is, the name of the mixture is registered, and is claimed as a trade-mark. Many of these nostrums could never be patented, even if the owners wanted to, because in or-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Sols-Cohen and O. T. Osborne.

der to obtain a patent, some novelty must be proved. Beside, the nostrum manufacturers would never think of patenting their wares. In order to do so, they would have to disclose their exact composition—which would not be at all to their interest. It is secrecy which is the chief, if not the only asset of the manufacturers of those secret but erroneously called "patent" medicines.

Another important point is that the true patents are protected for a limited time. Generally after 17 years, both the process of the patents and even the name itself become public property and every one is free to manufacture and to sell the product, while the trade-marked nostrum is a monopoly in perpetuity.

Thus, for instance, the patent on antipyrin has run out and any one can now manufacture antipyrin and sell it under that name. The name, however, of a nostrum is a monopoly forever and no one will ever be permitted to mix acetanilid, sodium bicarbonate and caffeine and call the mixture antikamnia or phenalgin. The difference is seen to be an important one. The true patented synthetic, after paying its inventor for the time, labor and money expended, becomes public property; the nostrum—never.

I think enough has been said to enlighten anybody in need of such enlightenment, as to the true difference between patented remedies and nostrums.

Our friends of class B may raise, and sometimes do raise, another objection. The objection is, that it is unethical, or even immoral, to patent and thus monopolize products which concern the life and health of the people. Measuring by the noblest and highest standard of morality, it is immoral to patent anything, and make the people pay tribute to the patentee. I believe that the time is not far distant when the state will buy every useful invention or discovery, and then give its use free to the people. And when I soar still higher and look with mental eye into the more remote future, I can perceive a state of society in which no such thing as a patent or a patent office will exist; a state of society of such a high moral and intellectual level that any inventor will be only too happy to give his invention to the community free; happy in the consciousness of having contributed something toward the comfort and welfare of humanity; that consciousness of having added a single brick to the noble structure of human comfort and happiness will be the only reward an inventor will seek or care for. But that future is far off; so far off, that neither we nor our grandchildren will see it. At present we live in an age of intense competition; the struggle for existence is so fierce, that every one must stand firmly on his feet and be constantly on the lookout—or he will be swept off by the seething current of commercial rivalry. In such a state of affairs, is an inventor to be held up to reproach, because, after having spent years of labor and considerable sums of money, he wishes to reap some pecuniary reward from his useful invention? Useful it must be; otherwise no amount of patenting will do any good; the invention will only prove a pecuniary loss to its originator. No! People who maintain large laboratories, invest large capital for problematical returns and pay large salaries to expert chemists and bacteriologists, should be entitled to protection and to pecuniary reward when they happen to discover or invent a useful product.

But, let us assume for argument's sake, that it is not right to obtain a patent on a medicinal preparation. What has that to do with our using or not using the product? Our first duty is toward our patient, and if

we consider a product useful, we should use it without bothering ourselves with the question whether somebody is getting rich by it or not. I dislike the telephone and gas monopolies exceedingly. I consider them worse than highway robbery—must I therefore do without a telephone or without gas? The morality of the chief mover in the Standard Oil Company trust would not stand a good x-ray exposure—must we therefore do without kerosene? The opposition to the use of certain remedies merely because they are proprietary, is thus seen to be ill-founded and, I might say, childish.

The physicians of class C are the broadminded and well-informed members of the medical profession; the physicians who do things and who are responsible for the progress in materia medica and therapeutics. They preserve the unbiased attitude toward any drug, any remedy. They know that many drugs, though having the official sanction of our Pharmacopeia, are either perfectly worthless or practically so, while many of the newer remedies are of the highest importance in fighting disease. The members of this class are investigators and, before they adopt a remedy into their practice, or even before they give it a trial, they try to find out several things.

First, they want to know the composition of the remedy, what it is that they are asked to use on their patients. They may not care to know just what the vehicle is, or the exact details of the process of manufacture, but they do want to know all the active ingredients, both qualitatively and quantitatively, and they want to have some idea of the process of manufacture. If this information is not forthcoming, they have nothing further to do with the remedy, absolutely nothing. The sample, if they get any, goes into the ash-barrel.

The second thing they try to learn is something about the foster parents of the remedy, the firm that launches it on the market. It is a well-known fact that perfect ignoramuses, people that have not the slightest idea of chemistry, materia medica or therapeutics, drug clerks, unable to hold a position; druggists, who fail in business; advertising agents, bank clerks, real estate agents, promoters, saloonkeepers, etc., constitute themselves "chemical companies" and try to teach the profession what to use on their patients. Now, it is not very likely that such "firms," such "chemical companies," can offer us anything really novel, really valuable. They are not likely to compare favorably with firms of long standing, firms that maintain research laboratories and scientific staffs, firms that subject new products to animal experimentation and clinical tests before offering them even tentatively to the profession. When such firms offer us something new, it is at least worthy of a trial. It does not mean that we are to accept anything that such firms offer us on faith; not at all. We must scrutinize and watch for by-effects very closely; for the commercial instinct, even at its best, is apt to exaggerate the good qualities of a product and minimize the bad ones. But I say that it is at least proper to give the drug a trial. High-class manufacturers are not very likely to put utterly worthless products on the market, for it would react injuriously on their standing, on their reputation and on their other valuable products.

This, then, is the right attitude toward proprietary remedies; unbiased, yet cautious; unprejudiced, yet skeptical. Let us hope that this—now the attitude of only a portion of the profession—may, through the efforts of this Section, become the attitude of the entire profession of the country.

So far, I have dealt with the relation of the physician to proprietary remedies. I now come to the second part of my paper: How may substitution be avoided and the desired preparation obtained without unduly advertising the manufacturer? How may substitution be avoided? The very fact that the question must be discussed is a reproach to American pharmacy, for it implies that substitution exists. Well, it does exist, and it is useless to shut our eyes to a well-known fact or to mince words. For twelve or fifteen years I have made a study of that disagreeable subject, and while I am inclined to believe that, on the whole, substitution is on the decrease, still it is yet sufficiently widespread—and in some cases in a very aggravated form—to demand attention. I believe that the abolition of substitution lies to a great extent in the physician's hands. One of the reasons why substitution has been so freely practiced by the unscrupulous is the lack of fear of detection. The patient, of course, does not know if any sophistication has been practiced, and the physician often does not know any better. It is the physician's total unfamiliarity with the appearance of the preparations that makes substitution so easy. If the unscrupulous druggist knew that the physician is familiar with the color, odor, taste and solubility of the preparation he prescribes, and that he occasionally goes to the trouble of examining his patient's medicine, substitution would be much less frequent. This is not theory, but fact. I have more than once heard drug clerks say that in their stores nobody dares to trifle with So and So's prescriptions, because he always examines his medicines and complains if anything seems wrong. Then, let the physician make it a practice to go to the drug stores in which his prescriptions are generally put up, and ask casually to see the original packages of the new preparations that he prescribes. That is a very good way of making sure that the preparations are kept in stock and are dispensed. For substitution, as a rule, is most frequently practiced when the preparation is not in stock, and the druggist is unable to get it at a moment's notice. To dispense one preparation for another, when the other is on hand, is rare indeed, though I have known it to occur. If a druggist proves an incorrigible substitutor—there are such—then it is right and proper for the physician to expose him to his medical confrères so that all physicians may cease patronizing him. Of course, great caution is necessary before such action is taken, and it should not be taken unless the physician is perfectly sure of his ground. This would be a drastic remedy, but an absolutely effective one. If the druggist, suffering with moral obliquity, knew that he might be running the risk of a universal boycott, he would be much more careful, and might gradually break himself of the habit. Finally, if the physician has a druggist in whom he has perfect confidence, it is perfectly proper for him to direct his patients to that druggist. I know that this practice is frowned on by many. I know that in Germany this practice is distinctly forbidden by law, under a heavy penalty, and nevertheless I have no hesitation in giving it my emphatic approval. The conditions here are different from Germany. There the druggists are all of about the same standing: they have to go through the same course, the same discipline; the drug stores are under strict government control, etc. Here the druggists differ very widely in their preliminary education, their attainments, in the capital invested (anywhere from \$200 to

\$50,000), in the number of prescriptions dispensed (some not putting up more than five or ten a week, others 200 to 300 a day), etc. Then, with a drug store on every corner, the competition is very fierce, and if not substitution, the employment of inferior and old drugs is inevitable. And for this reason, I say that, in this country, a physician has a perfect moral right to choose his druggist. I notice that many good men are assuming the same attitude. Dr. Rusby, though also a professor in a college of pharmacy, tells his students at the University and Bellevue Hospital Medical College that, though they may be misunderstood and their action misinterpreted, still he advises them, when they are graduated and have entered practice, to insist that their patients go to a certain druggist, in whom they have perfect confidence. A French medical society, recently discussing this very subject, came to the same conclusion: that a physician has a right to choose his druggist, and insist that his patients go there and not elsewhere. If this could be accomplished—that is, if we all had druggists in whom we had perfect confidence—the problem of the "original-package" evil would be solved at the same time. We should need no original packages. Perfectly confident that whether we prescribe a dozen tablets or capsules or 4 fluid ounces of a mixture, that the genuine article would be dispensed, we, of course, would not think of prescribing original packages. That the "original package" is an evil, none will deny. It is an open road to that greater evil, self-medication, which is so injurious to physician, patient and druggist alike.

I have spoken to a number of prominent manufacturers, in whose integrity and truthfulness I have perfect confidence, and they assured me that they were forced to adopt the original package device by sheer necessity. They were opposed to it themselves. They would rather see their products dispensed in a professional manner, but when they saw their trade slipping away from them; when they saw their products, on which they spent time, money and research, being brazenly imitated by various firms that convinced the druggist that their imitation was just as good and much cheaper (an argument which always has a powerful influence on a commercial man), then in self-defense they were compelled to urge the physicians to prescribe in original packages only. Many physicians told me the same thing, and I can corroborate it. I will take one illustration: There is a certain well-known preparation of iron and manganese; there is nothing wonderful in that preparation, but it is a good, readily assimilable, non-irritating, ferruginous tonic. I know its indications and limitations, and when I prescribe it for women and children, I want it and nothing else: nothing just as good. I used to prescribe it in 4 and 6-ounce quantities, and several times the most peculiar combinations were dispensed. Two or three times acid preparations were dispensed, so that the milk in which I ordered the preparation to be taken turned sour, and the patient's stomach was upset. Another time, tincture of iron with some essence of pepsin, which the druggist, with whom I remonstrated, told me was every bit just as good; and still another time, a turbid mixture with a precipitate at the bottom, was dispensed. Since then, whenever I find myself in a strange neighborhood, I prescribe that preparation in an original package, and I underscore original package half a dozen times, to the intense amazement of the druggist, who can not get over his

surprise at Dr. Robinson prescribing in original packages. Not at all exceptionally, I find the patient buying that preparation afterward, without my order. But what am I to do? My first and paramount duty is to my patient, and if, in my judgment, he needs a certain product, it is my duty to see that he gets that product, without considering possible future consequences.

A word here about the results of substitution may not be out of place. The possible disastrous consequences to patient and physician need not be dwelt on before a medical audience. To the druggists themselves the practice can not fail to prove disastrous. Unless the physician can be sure that his orders will be complied with strictly and faithfully, one of two things is liable to happen: either the physicians will take to dispensing their own medicines or they will form chains of drug stores for the sole purpose of dispensing prescriptions, and which would merely be expected to be self-supporting. Either one of those possibilities would mean the extinction of the pharmacist as a professional man—something that neither the true pharmacist nor his true well-wisher can look forward to with equanimity.

SUMMARY.

I would summarize my paper as follows:

1. The prescribing and using of preparations, the composition of which is unknown, is to be condemned unequivocally. It is unscientific, unethical, and is bound to react injuriously on the physician and the public alike.
2. The physician who refuses to use a thoroughly established remedy, of known composition, merely because it is proprietary, is guilty of narrow-minded fanaticism, and he is not doing the best by his patients.
3. Substitution does exist, and is a serious evil, in some localities especially.
4. The abolition of substitution lies to a great extent in the physician's own hands, and he can accomplish it by making himself familiar with the physical characteristics of the remedies that he prescribes; by patronizing pharmacists in whom he has perfect confidence, and by exposing those who, he is certain, are incorrigible substitutes.
5. The physician is guilty of encouraging substitution by ordering every new mixture that is brought to his attention by circulars, drummers and venal journals; but while this is an explanation of the prevalence of substitution, it is no justification for it.
6. Prescribing in original packages is an evil, but being a lesser evil than substitution, it is often justifiable.

119 East One Hundred and Twenty-eighth Street.

DISCUSSION

ON PAPERS OF DES. WILEY, REMINGTON AND ROBINSON.

Dr. H. C. Wood, Jr., Philadelphia, thinks that while physicians may accomplish, and have accomplished, a great deal by public education, the evil requires Federal control. Physicians can uphold the authorities, and should do so. A great influence is exerted by the rich owners and manufacturers of proprietary medicines to oppose this work. The magazines and daily papers, which derive much income from proprietary medicine advertising, also exert a great influence against Federal supervision. If those who conduct these publications could be made to see the true character of the business and its injurious results on the community, they would refuse to lend their influence and support. The members of the medical profession

are certainly to blame for taking so little interest in these important questions, so clearly related to public health. Dr. Wood reported reading an editorial in *THE JOURNAL* of the American Medical Association, urging physicians to support a pure food bill, which had passed the House of Representatives, although this was the first that he had heard of it. He spoke of it to several medical friends, and found that they knew nothing about it. One, a rather prominent man in the profession, who had not seen the matter in *THE JOURNAL*, said that he was not especially interested in the subject and did not regard it as worthy of much attention. Dr. Wood thinks that for every physician who wrote to his congressman in favor of this pure food bill, there were ten manufacturers invariably interested who wrote letters in opposition to it. Of course, we can not meet with success in passing bills unless more interest is shown by the profession. The position of the Postmaster General on this subject is known; and it behooves physicians heartily to co-operate with him and to support him in his refusal to allow the use of the mails to those who are engaged in a business which fraudulently deprives the people of their health as well as of their money.

Dr. THEODORE POTTER, Indianapolis, said that after investigating this subject, he had concluded that substitution owes its instigation among druggists to the abominable habit among physicians of prescribing proprietary medicines. Recently a leading pharmacist in Indianapolis showed Dr. Potter fourteen different varieties of proprietary iron preparations, all of about the same general character. Of course, when a prescription for a fifteenth variety comes in late at night the druggist is inclined to throw up his hands and put one of the fourteen in its place. The remedy is for physicians in each community to uphold legitimate pharmacy. Dr. Potter called attention to the fact that there has seldom appeared a paper written by a member of the Indianapolis Medical Society endorsing a proprietary remedy. There are no set rules on the subject in the society, but it is an unwritten law, a moral sentiment that is stronger than law, that no proprietary remedy shall ever be mentioned, either in papers or discussions. It is an unwritten law that no nostrum shall be mentioned in the *Indiana Medical Journal* and it does not. If a paper offered for the original department should mention a nostrum by its commercial name, this would be changed by the editor to its scientific name, or would be returned to its author, with a request for the scientific name of the agent which he employed. In the Indianapolis Medical Society there has been no resolution offered on this subject, but there is a sentiment so strong, that if any member should mention on the floor of the society the name of such a remedy, he would be laughed at. Occasionally, a young member, afflicted with the proprietary medicine disease, may use such a name, and a smile will go around the room. The physician is not likely to do so again. Another thing is that the names will never go into the records of the society. So far as law is concerned, the remedy is in the hands of the Government, as Professor Wiley has shown. The question, so far as we physicians are concerned, is one of science and good morals.

Dr. CLEMENT B. LOWE, Philadelphia, assigned as one reason for the great use of proprietary remedies, the fact that a large number of young physicians when they graduate are not well acquainted with the tools which they have to use. The medical student is taught about drugs, but does not learn how to prescribe them. In the lectures and text books they are often spoken of only in general terms. Dr. Clement spoke of an institution in which the students complained of the time they were required to spend in the pharmaceutical laboratory and they were supported in their action by a prominent physician connected with the institution, who said he did not see the necessity of their knowing about preparation of remedies to qualify them to be physicians. In other words, all the graduates were expected to settle in large cities, or if they should settle in the country, they would either not prescribe, or would use these new remedies that are coming out every

day. Every student in his third and fourth years should be required to take a course in prescription writing. Dr. Lowe said that he would bring in a case, request a diagnosis and require the students to write proper prescriptions for such a condition, make them explain their prescriptions, and discuss the reasons for giving them. He would have several such conferences each week, making the students practice prescription writing until they were familiar with it. In this way they would be prepared to use their tools, and no proprietary remedies could be pushed on them.

DR. HENRY BEATES, JR., Philadelphia, said that proprietary and patent remedies thrive because they are prescribed by the physician.

We are dealing with effects rather than with causes. No two patients present conditions which are exactly alike as to symptomatology, or which from a scientific point of view can be skillfully and successfully treated by exactly the same plan. Every remedy has its value because of its inherent properties. Every disease pursues a definite course, because of the operation of the laws underlying its cause. The healthy body has functions disturbed by morbid agencies. It also has functions restored by the influence of remedial means, and when the medical profession becomes educated to that high standard which is necessary for the comprehension of these unvarying laws and skilled in the art of applying this knowledge, there will no longer be prescribed any proprietary remedy, because each physician will know that a set formula cannot possibly be fitted to the conditions presented. Proprietary medicines will cease to exist because there will be no use for them.

DR. O. T. OSBORNE, New Haven, Conn., replying to a question, said that in the Yale medical school the teaching of pharmacy and prescription writing is commenced in the second year, and is carried on through the third and fourth years, by blackboard exercises and didactic instruction until the student is thoroughly familiar with prescription writing. Then he goes to the hospital and begins to use the formulae of the hospitals and forgets how to write prescriptions.

DR. C. B. LOWE said that some professors make the students work and others do not. When he was a student he was asked by another student if he knew how to write a prescription, and he replied that it did not trouble him any because of his previous study of pharmacy. The student said it troubled him greatly and was, for him, the hardest part of the course. A student is crammed with facts about every part of the human body and about everything required to make him a surgeon, and when he graduates he knows every point about his anatomy, and is ready to operate for appendicitis, or to amputate limbs, which he only very rarely may be called on to do; but when it comes to write a prescription—which he is called on to do every day and on which his reputation and the welfare of his patients depend—he does not know how to write prescriptions and he falls back on proprietary remedies.

DR. W. C. WESTCOTT, Atlantic City, reported having seen a recent medical graduate construct a prescription by copying the label on a bottle. Dr. Westcott called attention to a circular which the firm which markets antikamnia is sending out to druggists notifying them that their tablets are now put up in suitable packages for retail trade, convenient to be carried in the vest pocket. He also called attention to the great use among the public of sulphonal, trional, somnal, etc. Persons go into a drug store and ask for ten or fifteen grains of these coal tar products and order them by their names as if accustomed to taking them. He particularly called physicians' attention to those proprietary remedies which have their names blown in the bottles, to advertise them to the public. He thinks that the popular use of these proprietary remedies is due to the fact that physicians order them in the original packages. Where would listerine have been if it had not been first prescribed by physicians?

The remedy for substitution is in the physicians' hands. In every community there are reputable druggists who will not substitute, and these are known to the physicians. It is their duty to patronize the good drug stores and to pass the bad ones by.

DR. ADOLPH KOENIG, Pittsburg, Pa., declared that the trouble lies in defective education in medical schools. Students are graduated with a very imperfect knowledge of the medicines they are to prescribe. In this condition they are approached by suave agents with samples, they are furnished remedies for every disease, and literature to tell how they shall be used. Now, why should not an intelligent public buy these directly from the drug store? Why should it seek the advice of a physician, merely to be told to take one of these preparations? Has the physician any right to take money from patients for such advice? It is simply robbing them to do so. We should see that all advertisements of proprietary remedies are eliminated from the pages of our medical journals.

They are not necessary for a medical journal of the better kind. I have edited a medical journal for the last eighteen years—the *Pennsylvania Medical Journal*—and in it no proprietary advertisements are allowed. If a medical journal can not be sustained without this class of advertising, it deserves to fail.

DR. THOMAS L. COLEY, Philadelphia, said that he believes that any one who obtains a patent on a remedy having to do with the treatment of disease assumes a very grave moral responsibility. Such a practice puts a premium on methods of treatment and a physician who holds such a patent is on a par with the man who would take out a patent for a crutch or any apparatus indispensable to the crippled. It is the commercial element alone that induces men to patent their products and it is good business for them to get physicians to prescribe them. A market is frequently made for such preparations by methods that are not reputable. Many of these drugs are exploited without having been studied carefully and before their full effects are known. There is not a high ethical ideal, in all cases at least, actuating those who have charge of these "scientific laboratories" of which we have heard so much. At times these reports are honest, more often they are inspired and never does one see the untoward effects of the drug mentioned. Dr. Coley does not think the reason for the common use of these preparations is because prescription writing is not well taught in the best medical schools. In some, at least, it is very well taught. One strong reason is that while a physician is sitting in his office during his first years of practice no one comes in to urge him to use the remedies of the Pharmacopeia or to vaunt their excellent qualities, but there are hundreds of representatives of various firms who call repeatedly to urge him to use their proprietary medicines and who keep them before his attention. If he begins to prescribe these drugs he soon loses sight of the fact that in almost every instance there are official preparations which would serve an equally good, if not better, purpose.

MR. M. I. WILBERT, Philadelphia, said that, while it is true that some of these synthetics have been brought out by large manufacturers, who employ hundreds of chemists to discover new synthetic compounds, and in addition to this employ physiologists to discover their possible uses, these firms do not furnish us with readily applied tests by means of which we can identify their preparations, distinguish them from others or discover any probable impurities. Neither do they publish broadcast the possible deleterious effects these preparations may have. If the medical authorities in charge of hospitals would insist that the institution employ a competent pharmacist there would be no need of hospital formulas and the consequent prescribing of ready made or proprietary preparations.

DR. HARVEY W. WILEY, Washington, D. C., declared that there is no difference of opinion about the evils of these nostrums. In his examination into the composition of preparations of this class he found them to consist principally of starch, sugar, with flavoring ingredients, and often of small quantities of recognized remedies, and he supposed they might cost as much as one and a half or two cents a box at most. Experience justifies the work that is now going on to protect the sick from this class of preparations. Whether the active agent is in food, drink, or proprietary medicine, it should only be used on a physician's prescription. If persons are sick enough to take medicine they should consult a physician, and only take medicine under the direction of a physician.

DR. JOSEPH P. REMINGTON, Philadelphia, denied that the only object that physicians have, in adopting their profession, is to make money, or that the only object the pharmacist has in adopting his profession is to make money. If the large manufacturers of synthetics who employ two or three hundred chemists make money their only object, it is very good that we should learn that it is, then, solely the almighty dollar that they are after. One of these manufacturers had the audacity and greed to come from Germany to this country, to take out patents and to execute contracts which compel the sick to pay more than double price for his article. The physicians and druggists of this country can not obtain this substance, even when imported into Canada, without paying double price. If we have any object except that of getting money, if we have a spark of ethical spirit, we should inform these men that they are mistaken in their estimate of the physicians and pharmacists represented by this body, if they say we are after nothing but money.

DR. ROBINSON said that he was surprised to see men eminent in the profession assuming, through misapprehension, such a position of antagonism to true scientific progress. It has been intimated that if a druggist has fourteen articles of a class, if a prescription comes in for a fifteenth, which he has not in stock, that he has a right to substitute something else. How can he know that that something else will answer the purpose? He has no right to judge. His duty is simply to fill the prescription. For instance, if a doctor prescribes heroin, which is di-acetyl morphin, if the druggist does not have it, may he substitute morphin?

Dr. Robinson challenged any physician in the room to say that he did not use proprietary remedies, and asked Dr. Coley if he had ever used adrenalin, to which Dr. Coley answered, "Yes." Dr. Robinson said that there is a tremendous difference between these remedies as to their therapeutic value, but we must discriminate. There is a widespread habit of wholesale, indiscriminate denunciation of proprietary remedies which does much more harm than good, and this discussion has shown him the absolute timeliness of his paper. The pharmacopœial articles cannot effectually replace all these new products; to believe otherwise means to believe that all progress in therapeutics is impossible, and has ceased forever. He did not mean to defend a physician who patents anything relating to the treatment of the sick. On the contrary, he would condemn him most emphatically. But it is different with patents taken out by commercial men, who have thousands or millions of dollars in their business, and who would not carry on their investigations if they had no protection, and if the results of their work could be appropriated with impunity by other manufacturers. He considers the advertising pages of our medical journals *particeps criminis* in the extension of the use of proprietary nostrums. They should discriminate among these agents. These proprietary remedies would not obtain the vogue that they have, if some of the best journals did not bring them before the physicians. The advertising pages should have at least some supervision, the same as the reading pages. He asked, if we are to use only scientific titles in place of the names of proprietary articles, what physicians will use those titles. Who, for instance, would write for benzoyl-vinyl-diacetone alkamine hydrochlorate, in place of eucaïn? Prof. Remington believes that only scientific names should be introduced into the Pharmacopœia; what would he do with that title?

PROFESSOR REMINGTON replied that the drug was not in the Pharmacopœia on account of its name.

DR. ROBINSON said that if a drug has value it should not be excluded merely on account of its name, to which Professor Remington replied that it probably is not worth anything.

DR. ROBINSON declared that a pharmacist, be he ever so eminent, has no right to pronounce an opinion as to the therapeutic value or worthlessness of a remedial preparation. Should eucaïn be omitted merely on account of the length of its name? Is there a preparation in the Pharmacopœia which could be substituted for orthoform, which is methyl-paramido-meta-oxybenzoate?

PROFESSOR REMINGTON, replying to a question, said that there will be about fifteen or twenty synthetic remedies in the new Pharmacopœia. They will not be introduced under fanciful or trade names, for obvious reasons; the titles will be chemical names, wherever practicable. It is not necessary to give their full names. For instance, take the pyrophosphate of iron; its full name would be ferri pyrophosphas cum sodii phosphate. Of course, it is possible to use the full title, but it is not necessary. We can adopt a definite title by which it can be prescribed.

THE ETIOLOGY AND PATHOLOGY OF GOUT.

THOMAS B. FUTCHER, M.B. (TOR.).

Associate Professor of Medicine, Johns Hopkins University.
BALTIMORE.

(Concluded from page 1600.)

(B) URIC-ACID METABOLISM IN GOUT AND THE THEORIES OF GOUT PRODUCTION.

There is undoubtedly marked disturbance of nitrogenous metabolism in gout. Since the adoption of the classification of purins into the "endogenous" and "exogenous" varieties, too little time has elapsed and too few researches have been published to draw absolute conclusions as to how the metabolism of each is affected in this disease. The studies of Reach, Kaufmann, Vogt and Chalmers Watson show that in gout the exogenous nuclein is more slowly excreted than in health, and that in some cases there is a distinct retention. Vogt compared the results of rich purin-holding food on a gouty patient and a healthy individual at the same time. The gouty patient showed retention and delayed excretion of the purin bodies. It can be safely admitted, therefore, that exogenous purins lead to the excess of nuclein derivatives in the blood stream. It may be appropriately mentioned here that Vogel and Schmoll have demonstrated that the nitrogen balance is disturbed in gout and that there is a definite nitrogen retention. There is no question but that the metabolism of the endogenous purins is much disturbed in gout. This will probably be best shown by a consideration of the amount of uric acid excreted in the urine as well as that present in the circulating blood in this disease.

The Excretion of Uric Acid in the Urine.—Since Garrod's expressed opinion, based on quantitative analyses, that there was a diminished excretion of uric acid in the urine both in acute and chronic gout, the majority of observers, until a comparatively recent date, supported this view. According to Minkowski these early results can not be accepted as being correct owing to the defective methods of analysis used. Since the adoption of reliable methods of quantitative analysis in recent years Garrod's results have not *in toto* been supported. From the analyses made by Ebstein, Pfeiffer, Luff, Camerer, Weintrand, Schmoll, Kaufmann and Mohr, Magnus-Levy, His and others, all of whom used reliable methods, Minkowski's² states that the following conclusions may be drawn:

1. The daily excretion of uric acid in the intervals between acute attacks ranges within the same limits as does the excretion in healthy individuals.

2. In chronic gout, even in those cases in which there is marked deposition of biurates in the tissues, a constant variation from the normal amount of uric acid excretion in any one direction has not been definitely proved.

3. Immediately preceding an acute attack there is

2. Minkowski: H. Nothnagel, *Specielle Pathologie und Therapie*, vol. vii, No. 2, p. 193, et seq.

regularly a diminution in the amount of uric acid eliminated in the urine, whereas during and after the attack the uric acid output is increased.

My own analyses, in a number of cases in which the Folin modification of the Hopkins method of uric acid estimation was used, fully accords with the statement contained in Section 3. They, however, differ materially from those stated in Section 2. I have almost always found a marked diminution in the uric acid excretion in the intervals between acute attacks in chronic tophaceous gout.

To what are these variations in the amount of uric acid excreted in the urine due? We shall only consider the possibilities here. The diminution in the excretion of uric acid before the onset of an acute attack may be interpreted as meaning either a diminished uric acid production or a diminished power on the part of the kidneys temporarily to excrete uric acid. The sudden deposition of the uric-acid salts about the joints and in the tissues affords a third possible explanation for the diminished uric-acid elimination. The increased uric-acid output during an attack may be due to an increased uric-acid production, or to the fact that the previously retained uric acid is temporarily excreted in increased quantity. The variations in the excretion in gout may further be due to the fact that at times a smaller and other times a larger part of the uric acid in the organism is further metabolized into other waste products, as urea for instance. It may be possible to draw more definite conclusions as to the cause or causes of the variations in uric acid elimination in gout after we consider the uric acid content and alkalinity of the blood in this disease.

The Uric Acid in the Blood.—Garrod, Abeles and Magnus-Levy claim to have demonstrated uric acid in minute traces in the blood of normal individuals. Minkowski and others assert that uric acid is not demonstrable in the blood in health. In gout, however, all observers now agree that there is a marked increase of the uric acid in the circulating blood. Garrod first demonstrated this excess by quantitative analyses and also by his now famous "thread-test." Klemperer found in three cases of gout during the attack, .067, .088 and .0915 grams of uric acid in 1,000 c.c. of blood. He was unable to demonstrate uric acid in normal blood. Magnus-Levy made 34 analyses in 17 cases of gout and found the uric acid in the blood to range between .021 and .10 grams in 1,000 c.c. of blood.

Garrod's theory for the production of gout is briefly as follows: He holds that in gout the alkalinity of the blood is lessened and the amount of uric acid in the blood is increased owing to deficient power of elimination on the part of the kidneys. He attributes the deposition of sodium biurate in the tissues to the diminished alkalinity of the plasma, which is unable to hold the uric acid combination in solution. During an acute paroxysm there is an accumulation of the urates in the blood and the inflammation is caused by their sudden deposition in crystalline form about the joints.

Subsequent investigators have not been able to fully confirm all Garrod's results. As has already been stated, there is general agreement that there is a marked increase in the uric acid in the blood in gout. Garrod did not make careful quantitative analyses to ascertain whether the amount of uric acid in the blood during an acute attack was actually greater than in the intervals. Magnus-Levy, however, made a careful investigation of this question. Of ten cases of gout studied, the uric acid was the same during the acute attack as in the interval in five, greater in two and less in three. It cannot

be said, then, that there is by any means a constant increase in the amount of uric acid in the blood during an acute attack over that present in the intervals.

The methods of determining the alkalinity of the blood are notoriously unreliable. Garrod simply makes the statement that the alkalinity of the blood in gout is markedly diminished, but I find no reference in his writings of any quantitative determination, or intimation as to how he arrived at this conclusion. Recent investigations along this line by different observers and with methods believed to be reliable, are conflicting in their results. Pfeiffer, Jeffries and Drouin claimed to have found an increased alkalinity. Klemperer, in three cases of acute febrile gout in which the alkalinity was determined by estimating the carbonic acid in the blood—the most reliable method—found a very slight diminution, but not enough to account for the precipitation of the dissolved uric acid. In 16 cases in which Löwy's titration method was used, Magnus-Levy found no appreciable diminution in the alkalinity. In 11 cases he compared the degree of alkalinity during and between attacks. In 3 of these there was a diminution during the acute attack; in 2 an increase, and in 6 there was no difference. These results in general show that there is no constant diminution in the alkalinity of the blood in gout, nor is alkalinity apparently diminished to a greater extent during the acute attack than in the intervals.

Klemperer conducted a series of experiments which have a very important bearing on this question of the relative alkalinity of the blood in healthy and in gouty individuals, as well as on the effect that a possible change in the alkalinity may have on the power of the plasma to hold uric acid in solution. He found that the blood of the gouty person is not a saturated solution of uric acid and that it is still capable of dissolving more uric acid. Whereas, 100 c.c. of blood serum from three healthy persons were capable of dissolving .166, .171 and .174 grams of uric acid, the same amount of serum from three gouty patients was still capable of dissolving .126, .14 and .18 grams of the acid. The conclusion to be drawn from this is, that an over-loading of the blood in gout can not alone be regarded as the cause for the deposition of the sodium biurate in the tissues. This is substantiated by the fact that in other diseases, such as leukemia, there is a marked increase in the uric acid in the blood, yet urate depositions in the tissues do not here occur. There are only five cases reported in the literature in which definite gouty manifestations have been found in association with leukemia. This number is so small that the co-existence may well be considered accidental.

Origin of the Excess of Uric Acid in the Blood.—Three possibilities present themselves as explanations for the excess of uric acid in the blood of gouty individuals. 1. Increased formation. 2. Diminished destruction or oxidation. 3. Diminished excretion in the urine.

Although the increase in the uric acid in the blood and urine in leukemia is undoubtedly due to increased formation, resulting from increased nuclein destruction, there is no special evidence to support the view that the excess of uric acid in the blood in gout is due to the same cause.

It is also highly improbable that the excess is due to deficient powers of the organism to oxidize and destroy the uric acid. Klemperer has shown that the blood of the gouty as well as that of the healthy person possesses the power *in vitro* of destroying uric acid.

The most probable explanation for the increase is that it is due to a diminished excretion of uric acid by the kidneys with consequent retention of uric acid in the circulating blood. Minkowski, who has comparatively recently reviewed the evidence, supports this theory. Hans Vogt and Reach have shown that the output of uric acid after the ingestion of nuclein or nuclein-containing food is much less marked in the gouty than in the healthy individual. Schmoll, however, claimed to have found no such diminution. Garrod was of the opinion that the excess of uric acid in the blood was due to the nephritis present. It is a well known fact that in chronic gout serious organic disease of the kidneys occurs. It has been suggested that even before any organic disease in these organs develops there may be a "functional" disturbance of the secretory elements. Minkowski and His have advanced the view that the uric acid in gouty individuals circulates in the blood in a different organic combination than in the blood of healthy persons and that consequently the kidneys are functionally incapable of eliminating the acid in the same way they do in normal metabolism. Although there is undoubtedly an intimate relationship between the excess of uric acid in the circulating blood and the nephritis present in chronic cases of gout, the evidence is still inconclusive as to whether the former or the latter is the primary condition. Notwithstanding the fact that many competent observers failed to find any special diminution in the excretion of uric acid in the intervals excepting just preceding the acute attack, yet a diminished excretion of uric acid by the kidneys seems the most generally accepted theory for the excess of uric acid in the blood in gout.

The Excretion of the Alloauric or Purin Bases and of Phosphoric Acid in the Urine.—Too little is as yet known regarding the amount of alloauric or purin bases excreted in the urine in gout. Numerous estimations have been made by the Krüger and Wulff method which, however, was later shown to be inaccurate. Later methods, regarded as more reliable, show that normally about one-tenth of the total alloauric or purin bodies eliminated in the urine is in the form of alloauric or purin bases, the other nine-tenths being made up of uric acid. When it is remembered that the average daily excretion of uric acid is, according to Hammarsten, 0.7 gram, an approximate idea of the normal amount of alloauric or purin bases can be obtained. There is no definite evidence to show that this normal relationship is disturbed in gout. Kolisch found that the alloauric or purin bases were increased, but his results can no longer be accepted, as his determinations were made with the Krüger and Wulff method.

The excretion of phosphoric acid in the urine in gout has been found increased by some and diminished by others. Camerer found no special variation from the normal. There has been considerable discussion regarding the point as to whether the curves of the uric acid and phosphoric acid excretion run parallel in gout. When one considers that both are products of nuclein destruction, it would seem quite natural to expect that they should follow a parallel course. My own results, published elsewhere, indicate that in the intervals between attacks both fall far below the lower limits for normal, and that with the onset of the acute attack there is a parallel rise to the average or even to the upper limit for normal. Chalmers Watson and others hold that no constant relationship exists. They claim that phosphorus is taken in the food in other forms than

that contained in the purin bodies, and that this prevents any possible parallelism in the curves.

Theories as to the Causation of Gout.—Only the more important theories can be here considered, and these very briefly.

Garrod's views regarding the causation of gout have already been given and need not be repeated here. After he advanced his theory, it for a long time received general acceptance. Even to-day the portion of it which attributes the excess of uric acid in the circulating blood to deficient elimination on the part of the kidney, is in accord with the results of the investigations of recent observers.

Haig is of the opinion that there is no increased formation of uric acid in gout, but that the blood is less alkaline than normal, and consequently less able to hold uric acid or its salts in solution. As has been shown in the earlier part of this paper, recent determinations of the alkalinity of the blood in gout by more reliable methods do not bear out the opinions of Garrod and Haig that it is reduced below normal. Haig has always claimed that it is the nitrogenous content of the food ingested that does damage in gout, rather than disturbances in the metabolism of the nitrogenous products of cellular disintegration. In other words, nitrogenous food is poison to the gouty-inclined individual.

It will be recalled that Sir William Roberts believes that uric acid circulates in the blood in the form of a soluble quadriurate, which may be represented by the formula $\text{NaHC}_5\text{H}_2\text{N}_4\text{O}_8$, $\text{H}_2\text{C}_5\text{H}_2\text{N}_4\text{O}_8$, which is sodium quadriurate. The sodium atom may have its place taken by an atom of any of the univalent metals. In the gouty state, according to Roberts, either from deficient action of the kidneys or from overproduction of urates, the quadriurate accumulates in the blood. The detained quadriurate, being very unstable and circulating in a medium rich in sodium carbonate, takes up an additional atom of the base and is converted into the biurate as follows:

$$2(\text{NaHC}_5\text{H}_2\text{N}_4\text{O}_8, \text{H}_2\text{C}_5\text{H}_2\text{N}_4\text{O}_8) + \text{Na}_2\text{CO}_3 = 4 \text{NaH C}_5\text{H}_2\text{N}_4\text{O}_8 + \text{CO}_2 + \text{H}_2\text{O}.$$

The biurate is very insoluble and less easily excreted by the kidneys. It consequently accumulates in the blood, and exists first in a gelatinous and later in the almost insoluble crystalline form. It is then that precipitation is imminent or actually takes place. This is apt to occur where the circulation is poor and the temperature low, and in regions in which the lymph contains a relatively high percentage of sodium chlorid, as in the synovial sheaths.

This theory seems a very satisfactory one, but like all others has met with opposition, particularly on the part of Tunnicliffe and Rosenheim. Minkowski thinks that it is impossible for the uric acid to circulate even in the normal blood as the quadriurate, for in a medium so rich in carbonates and phosphates as the blood is, the quadriurate must necessarily be rapidly converted into the biurate. Minkowski thinks that the uric acid circulates normally in the blood in organic combination with nucleotin-phosphoric acid.

Ebstein holds that the local manifestations of gout are due to nutritive tissue disturbances which lead to necrosis. He found, after a study of many of the affected tissues in gout, that one change is common to all of them, independently of the uratic crystallization, and that is, a necrosis of the parts wherein such depositions take place. He believes that this tissue necrosis is primary, and that it is as characteristic as the biurate

deposit. Both changes must coexist in any tissue in order to constitute a truly gouty patch, and he has found such areas in the kidneys, in hyaline and fibrocartilage, and in tendons and connective tissue. He calls attention to an early stage of the necrosing process, in which as yet no deposition has occurred, and consequently maintains that nutritive tissue disturbance is the primary factor, and uratic crystallization the secondary one in the gouty process, the latter not occurring until after death of the damaged tissue. Von Noorden supports Ebstein's views, and believes that the tissue necrosis is due to the action of a special ferment.

In 1784 Cullen advanced the view that gout was primarily due to an affection of the nervous system. According to this view there is a basic, arthritic stock—a diathetic habit, of which gout and rheumatism are two distinct branches. The chief advocate of the nervous theory at the present day is Sir Dyce Duckworth, who at first thought that disease of a special tract in the cord was the cause of the tissue lesions in gout. Although he no longer insists that gout is due to a lesion of any particular column in the cord, yet he just as strongly insists that gout has a nervous origin. The influence of depressing circumstances, physical and mental, point strongly to the part played by the nervous system in the disease.

A few years ago Kolisch advanced the view that gout is due to the toxic effects of the alloxuric or xanthin bases. He found that with the Krüger and Wulff method these bases were increased in gout, because, owing to the disease of the kidneys, these organs are unable to convert the nuclein derivatives into uric acid in sufficient amounts. Owing to the subsequent demonstration that the method used was inaccurate, his views have not been accepted. Others have attempted to place the responsibility on the xanthin bases. It has been shown that the exogenous purins lead to an excess of nuclein derivatives in the blood stream, and that their presence can be demonstrated by suitable methods. There is no convincing proof up to the present date that the xanthin or purin bases are constantly increased in either the blood or urine of gouty persons. Undoubtedly some of these xanthin bases are definitely toxic. Kolisch, Croftan and others have produced arterial and renal lesions by injecting hypoxanthin into animals. I. Walker Hall³ confirmed these results and also produced parenchymatous changes in the liver by long-continued injections of hypoxanthin. We shall have to await further evidence before stating that the xanthin bases play any factor in the production of gout.

It has been suggested that gout is due to a chronic intestinal intoxication, but evidence is still lacking to prove this theory.

THE PATHOLOGY OF GOUT.

The Blood.—In the section on etiology it has been shown that practically all competent observers have confirmed Garrod's findings first published in 1848, that the blood contains a marked excess of uric acid. This has been amply shown by quantitative determinations and by Garrod's well-known thread test. The latter may be performed with the separated serum of drawn blood or with the serum obtained by the application of a blister. To two drams of the serum add five or six minims of strong acetic acid for each fluid dram and place in a watch crystal. One or two fine fibers

of linen thread are then immersed in this mixture, and the whole placed in a cool place until the serum is quite set and nearly dry. Usually from thirty-six to sixty hours are required, depending on the warmth and dryness of the atmosphere. If uric acid be present in excess it will crystallize out on the thread in a manner resembling rock-candy on a string. The actual determinations showing the excess of uric acid found in the blood of gouty patients by various observers have already been given.

There is no special tendency to the development of anemia, and the leucocytes are usually within the normal range. It is of interest that one of our cases of tophaceous gout eventually died in the hospital of pernicious anemia, the blood picture being characteristic. Neusser claimed that occasionally an eosinophilia occurs, and Chalmers Watson found in one case, particularly during the acute attacks, that there were numerous degenerated myelocytes present in the blood. Neusser's so-called "perinuclear basophilic granules" have been shown to be artefacts, and to occur in the blood of individuals other than those suffering from gout.

The Joint Changes.—The pathologic alterations of gout manifest themselves particularly in the articular structures. The metatarsophalangeal joint on one or other side is usually first involved, and repeated attacks may occur in this joint, causing considerable thickening, before any of the other joints become affected. Later the tarsal, ankle, knee and small joints of the hands may be attacked. As Norman Moore has pointed out, the joints of the lower extremities may be alone involved. The arthritic manifestations are due to the deposition of the acid urates or biurates. There is considerable difference of opinion as to the cause of these uratic deposits. Ebstein insists that there is always a primary tissue necrosis probably due to the toxic action of the excessive uric acid circulating in the blood. These necrotic areas are most liable to occur in the joint cartilages and other articular tissues in which the normal nutritional currents are slow. No matter in what part of the body the biurates are deposited, Ebstein claims that a tissue necrosis is the primary factor. In support of his view, he states that he has often found areas in which there was necrosis without biurate deposition. In these areas of coagulation necrosis the reaction is always acid, so that the conditions are favorable for the precipitation of the quadriurates in the form of the crystalline biurate.

His and Mordhorst think that the deposition of the sodium biurate is primary, and that the tissue necrosis occurs as a secondary process. According to Sir William Roberts, the biurates are deposited most abundantly in cartilaginous tissue, because here the temperature is lowest, the circulation poorest, and in the case of articular cartilage, the percentage of sodium chlorid highest. Of the structures comprising the joints, the deposits take place first in the articular surfaces. The biurate is not actually on the surface. It is interstitial and is always covered over by a thin layer of cartilage. The deposit is usually thickest at the point farthest away from the circulation. Garrod showed that it is rare for the biurate to extend beyond two-thirds of the depth of the cartilage, and often not to this extent. It looks white through the superficial layer of unaffected cartilage and has a "chalky" appearance. Thin vertical sections of the cartilage made in the direction of the bone and examined under polarized light show

³ I. Walker Hall: *The Practitioner*, July 1903, p. 74.

the crystalline character of the deposit. Its crystalline character may also be easily demonstrated by taking scrapings of the deposits, teasing out and examining in a drop of water under a cover-slip in the usual way.

With recurring attacks and as the disease becomes more chronic, the ligaments and fibrous structures about the joints ultimately become infiltrated with the biurate deposits, forming the so-called "chalk-stones" or tophi. When this stage is reached we begin to have the joint thickenings and deformities so characteristic of the disease. The tophi surrounding the joints are usually covered by skin, but in some cases, particularly in the case of the metacarpophalangeal joints, they may ulcerate through and appear externally. Not infrequently these periarticular tophi are readily seen beneath the skin. In cases of long duration the affected joints may become immobile, owing to the extent of the deposits. According to Wynne, the marginal outgrowths about the gouty joints are true exostoses. In acute attacks considerable effusion into the joints may occur. If death takes place during an acute paroxysm there are signs of inflammation, hyperemia, and swelling of the ligamentous tissues with effusion into the joints. Occasionally the joint fluid shows small whitish flakes, and these when examined microscopically are seen to be made up of acicular needles of sodium biurate.

A systematic examination of the metatarsophalangeal joints at autopsy would, I am sure, show gout to prevail much more frequently in this country than is generally supposed. They should be opened in all joint cases that come to autopsy, particularly in those cases in which the etiology is obscure.

Other Situations in Which Tophi Occur.—Wherever there is cartilage we may have the deposition of sodium biurate. Thus a common situation for tophi is on the helix of the ear. There may be one or more and usually the white biurate can be seen through the skin. Occasionally only a slightly inflamed reddish nodule is seen, and when opened the contents will very often show needle-shaped crystals of sodium biurate. If systematic examinations for tophi in the ears were made in every case of articular disease, many mistaken diagnoses would be avoided.

Tophi may also be present in the cartilages of the nose, eyelids and larynx. Occasionally they may be of enormous size on the tendo-Achillis. A point to remember is that they may occur in the subcutaneous tissue away from the joints. One of our cases had a large group of them over the sacrum. In two other cases they were scattered over the extensor surface of the forearm. They may be mistaken for the subcutaneous fibroid nodules of rheumatism, as they were in the early admissions of two of our series, and it was only on later removal and histologic examination that they were shown to contain sodium biurate.

Changes in the Kidney in Gouty Subjects.—Of the visceral lesions in gout, those in the kidneys are among the most important. A very large percentage of patients with chronic gout have evidences of chronic nephritis clinically, and may die with uremic symptoms. The kidneys may show depositions of sodium biurate in the region of the papillae. These were first described by Castelnau. They are not so frequently found as we would be at first led to infer. Norman Moore found them in only 12 out of 80 cases. On section of the kidney the apex of the pyramids often shows minute points or streaks of whitish material. On microscopic examination, these are found to consist of

crystalline sodium biurate, which is usually in the intertubular tissue, but which may also, as Virchow, Wagner and Lancereaux have observed, be in the lumen of the tubules. Ebstein holds that the primary renal changes producing these biurate depositions are a local tissue necrosis. Aschoff and Minkowski claim, on the other hand, that they have found the crystals extending from the periphery of the deposits into the surrounding renal tissue which showed no indications of death. These renal deposits must not, however, be taken to always mean the existence of gout in the individual, as they sometimes occur without the subject having had any symptoms of the disease. The type of kidney usually found at autopsy is the chronic interstitial form, the organ often showing an extreme grade of contraction. On the other hand, the arteriosclerotic type may occur. Here the kidney is rather larger than in the former, red, beefy and very hard. There does not appear to be any special difference between the kidney of lead gout and that of ordinary gout.

The Cardiovascular Lesions.—Gout is undoubtedly a very important etiologic factor in the production of arteriosclerosis. Nearly all cases of chronic gout show marked thickening of the peripheral arteries. Whether the arteriosclerosis be due to the effect of the increased uric-acid compounds circulating in the blood or to the contributory factors producing the gout, viz., alcohol, food and lead, has not been definitely settled. There is absolutely no question as to the frequency of its occurrence.

Cardiac changes are very liable to occur. Owing to the existence of the interstitial nephritis and arteriosclerosis hypertrophy of the left ventricle is likely to occur. The arch of the aorta is frequently involved in the arteriosclerotic process. The orifices of the coronaries may be narrowed and the coronary vessels themselves sclerosed. Myocardial changes occur and the hypertrophy gives way to dilatation, and death may result from failure of compensation. The coronary involvement renders the subject liable to attacks of angina pectoris. Gouty pericarditis is not an infrequent terminal event. It has been claimed that sodium biurate deposits occasionally occur in the heart valves.

Changes in the Respiratory System.—Emphysema is extremely prevalent in patients with chronic gout. Tophi may be present in the laryngeal cartilages and even in the vocal cords. Sodium biurate crystals have been found in the sputum of gouty patients.

SUMMARY.

Heredity, overindulgence in malt liquors, poor food with bad hygienic surroundings or overeating with insufficient exercise, and lead intoxication are undoubtedly important predisposing etiologic factors in the production of gout. An analysis of 54 cases treated in the medical wards of the Johns Hopkins Hospital shows that the overuse of fermented beverages seems to be the most potent factor in this country. Gout in the United States appears, therefore, in the majority of cases to be acquired or "free-hold," rather than "copy-hold" or inherited.

Studies of the metabolism in gout have as yet afforded no satisfactory explanation for the causation of the disease. There seems very little doubt but that it is due to disturbance in the metabolism of the "endogenous" and "exogenous" purins. As yet there is not sufficient experimental evidence to warrant us in abandoning the theory that the manifestations are in large part due to disturbances in uric-acid metabolism. Prac-

tically all researches agree in showing that the blood in gout contains a marked excess of uric acid, and the balance of opinion is in favor of the view that this excess is due to deficient excretion on the part of the kidneys. The alkalinity of the blood apparently is not diminished, as Garrod supposed.

The joint manifestations are essentially due to the deposition of the uric-acid combinations of the blood in the form of the crystalline sodium biurate. Whether a local tissue necrosis is primary or secondary to this deposition is a question still in dispute. Nephritis, usually of a chronic interstitial type, arteriosclerosis, myocarditis, pericarditis and emphysema are the other most frequent pathologic findings.

THE URIC-ACID DELUSION AND THE PREVENTION OF GOUT.*

WOODS HUTCHINSON, A.M., M.D.

PORTLAND, ORE.

The first requisite to an adequate discussion of the prevention of gout is a clear view of its causation.

The one thing which, it seems to me, emerges clearly from the seething caldron of the clinical and chemical researches of the past fifty years is that whatever be the cause of gout it is *not* uric acid. The first step, then, is to rid our minds of the delusion, that any means which are to cure gout, must be directed toward either increasing or diminishing the formation or promoting the elimination of uric acid or any of its precedents.

I fear that to many this position will appear radical to the verge of foolhardiness, but it is the one which appears most rational and tenable to me, and I will, therefore, proceed to sketch very briefly its basis and its bearing on this most important problem, with no further apology, save for the apparent dogmatism of statement, which the necessity of brevity forces on me.

The uric-acid delusion in gout dates from the time of Garrod, and while its pursuit has proved a most fascinating one and added much interest to the study of dry pathologic problems, it has, in my judgment, proved an *ignis fatuus*, and directed our attention from the disease itself to a mere symptom. Under gout and lithemia we have lumped together an appalling array of morbid processes of infinitely varied causation, whose sole factor in common was that they resulted in the precipitation of urates in the urine, or in the tissues.

We have been treating an effect as a cause, a mere by-product as a *materies morbi*; and while the results have been interesting and stimulating, ranging from the brilliant and attractive speculations of Roberts up to the flatulent absurdities of Haig, yet it has led us little, if any, nearer to the truth than we were in Sydenham's time. As our modern conditions of life in respect to healthfulness and variety of food, housing, clothing and training have enormously improved, gout is far less common and lithemia certainly no more prevalent than before. But we can hardly flatter ourselves that we know how to treat it better. Our situation is another illustration of that blessed truth, that our belief, therapeutic or otherwise, makes little difference, if our life be rational.

The facts which seem to me have been firmly established by the enormous mass of clinical and physiologic

researches of the past twenty-five years are briefly as follows:

1. Uric acid is not toxic.
2. It is in no sense a result of imperfect combustion of proteids of the urea series.
3. That uric acid which appears in gout is a result of the destructive metabolism of the nucleins of the body tissues, and is in no way derived from the food.
4. While some of the antecedents of uric acid, the so-called purin group, are more toxic than uric acid, it is exceedingly doubtful whether they are sufficiently so to account for the symptoms accompanying them. In short, they also are probably a symptom and not a cause of the intoxication.

Now, let us glance at the clinical basis for regarding uric acid solely as a symptom of some toxic or infective process, and consequently directing our attention toward the latter.

First of all, there is the significant fact, known from time immemorial, that all the lesions of gout, arteriosclerosis, degeneration of the kidney, neuritis, neuralgia, rhinitis, tophi, etc., may be produced by a poison, which is not only non-nitrogenous, but not even organic, and that is lead.

According to Garrod, 30 per cent. of hospital cases of gout give a clear history of chronic lead poisoning. Here there is no question of any specific influence on the part of the urates.

Second is the fact that a perfectly characteristic gouty urine is produced in the early stages of almost all febrile conditions, especially of the milder type. The urine in the early stages of a mild form of pneumonia can be hardly distinguished from characteristic gouty urine; and I am in receipt of a private letter from one of the clearest-eyed and broadest-minded of our modern pathologists, in which he informs me that experiments carried out in his laboratory have shown that inoculations with modified forms of various infective organisms have been productive of the appearance of urates in the urine and other so-called gouty symptoms, so that he is inclined to class gout as one of what he terms the "subinfections."

Third, the most frequently assigned cause for the production of the excess of urates which, in their turn, after the fashion of the "house-that-Jack-built," are supposed to produce the morbid symptoms which they accompany, is an irritant, carbohydrate poison, namely, alcohol. Waiving altogether the wrathful question as to how much of the sufferings of gouty patients are due to alcohol which they imbibe and how much to the fruit sugars and esters which accompany it; (wine and beer are your true gout producers; whisky and spirits seldom are); and admitting that the liberal use of alcohol, particularly in the form of spirits, may have no injurious effects, even on gouty individuals, yet there can be but little question that there is an overwhelming preponderance of the use, and in many cases excessive use, of either malt or vinous liquors in those who are the subjects of gout.¹

In the light of the toxic origin of the disease it would seem highly probable that we are actually dealing with a direct intoxication, either by alcohol itself, or, as seems more likely, by some of the other readily fermentable carbohydrates, either of the ether, ester or acetone group, in which the sweeter, more fruity wines, which are so indefinitely more effective in the produc-

1. The Meaning of Uric Acid and the Urates, The Lancet, Jan. 31, 1903.

tion of gout than any other form of alcohol, are particularly rich. So that we appear to have two instances in which toxic substances, formed entirely outside the body, are capable of producing the disease—not only so, but are probably responsible for something like 50 per cent. of all cases.

As we study more carefully each individual case of the disease which confronts us, I think we can hardly help being more and more inclined to the conclusion that we have to deal either with some form of more or less direct external intoxication, or with some impairment of the normal digestive and assimilative processes of the body, resulting in abnormal poisonous products being formed in the alimentary canal, or in excessive absorption of the toxic substances which are normally present in the process of digestion. I believe that in the future our study of the diet of a gouty patient will be more with reference to the detection of substances which, either in themselves or in the conditions of nutrition obtaining in the cells of his intestinal wall or possibly of his liver, are capable of producing intestinal putrefaction and consequent autointoxication than with reference to either their nitrogen or nuclein content. Nowhere is it more necessary to remember, as Roberts and Osler have with special emphasis reminded us, that in the witty paradox of Moxon, "it is quite as important to know what kind of a patient the disease has got, as to know what sort of a disease the patient has got." Time and again we have found that the question of our ability to relieve our patients from the torture of their toxemia has depended on our ability to correct some vice of bodily habit. It may be in exercise, in bathing, in sleep, in mental stress, in hurry after meals, even in errors of refraction, that the crux of the lithemic problem will be found to lie. Any agency that will improve the general nutrition and vigor and raise the resisting power of our patients may cure lithemia.

Fourth, we have the negative evidence that numerous diseases or states in which large quantities of uric acid are found both in the urine and in the tissues are unattended by any gouty or so-called lithemic symptoms, as the uric-acid showers in the urine of children, the uric-acid infarcts of the newly born, in the large quantities of urates found in the urine of leucocythemia, of acute yellow atrophy of the liver and of phosphorus poisoning.

Fifth, the behavior of the paroxysm in gout is as little reconcilable with the theory of its causation by uric acid as are the Four Gospels with one another, but it fits in perfectly with the view that it and the paroxysm are alike symptoms of some toxic influence. Preceding and in the first stages of the gouty attack there is, instead of an increased elimination of urates, marked diminution. Secondly, there is no proof whatever that at the height of the attack there is any excessive deposit of urates in any of the tissues or in the urine. Thirdly, after the symptoms begin to subside urates appear in abundance in both the urine and the tissues; in short, the whole history of the gouty attack points strongly toward the view that it is due to some active toxin which produces intense irritation in the muscles, nerves and joints, with severe pain and consequent rise of temperature, and, as a result of this toxic attack, the breaking down of an excessive number of cell-nuclei and their appearance in the urine as urates.

Sixth, as Fitcher has shown, the rise in the excretion of urates in both gout and mild febrile conditions is

accompanied by an absolutely parallel increase in the amount of phosphoric acid in the urine. Inasmuch as nuclein is made up of a purin base combined with nucleic acid, an important part of whose radical is phosphoric acid, it seems to me that the conclusion is almost irresistible that in the elimination of these two products we are dealing with simply the two results of a destructive metabolism of the body cells, uric acid representing the purin moiety, while phosphoric acid represents the nucleic acid element. In my judgment, the symptoms of gout may be just as rationally ascribed to phosphoric acid as to uric acid; both are products of an underlying intoxication. In short, I believe that under the head of gout we have grouped together an enormous variety of mild chronic intoxications, sometimes of infectious, sometimes of dietetic, other times of autotoxic origin, and that the sole unity of the group consists in the production of uric acid.

The "lord of diseases" is not an individual, but a host. Uric acid has been the same sort of convenient savior of thought to us as therapeutists that the devil was to the older theologians.

It is always a great satisfaction to be able to give a disease a name, even if you know little more about the name than you do about the disease.¹

But one great rock remains for the foundation of our uric-acid faith, massive and apparently unshaken, and that is the actual appearance of the *corpus delicti* in the joints or fibrous tissues in gout. But here, again, I believe we have utterly mistaken the meaning of appearances. Here, the enthusiastic Garrodite will say, is something which no amount of argument will explain away. The matter, however, is by no means so simple as might at first sight appear. In the first place the results of the injection of uric acid into living tissues and its occurrence in large amounts in the kidney and other tissues in leukemia and other conditions already alluded to, render it highly improbable that uric acid itself, even in the tophi of gout, is sufficiently toxic to account for the intense irritation and local inflammation. In the second place, we have large masses of these biurate crystals deposited in the tissues in gout without giving rise to any symptoms whatever, or even attracting the attention of the patient. Third, the occurrence of these deposits in the joints or other tissues does not by any means accurately coincide with the attack, but may either precede or follow it. No one would, for a moment, think of regarding the fibrous nodules of rheumatism, or the exostoses of rheumatoid arthritis as the cause of the excruciating pain, or any other of the morbid processes which they accompany; and, in my judgment, the masses of urate of soda in and about the joint are just as purely symptoms of a toxin attacking the joint tissues as are the deformities of the two other great arthritic diseases. It would seem highly probable that we have been grouping together in one heterogeneous mass, as "gout," all the chronic intoxications which happen to attack the joints and result in the production of urates in their neighborhood, just as we have probably grouped together under the title of rheumatism a number of varied acute streptococci or staphylococci infections attacking the joints (one of which has already been definitely split off as gonorrhœal "rheumatism"), and under arthritis deformans at least three different toxic or toxoneuritic processes. Moreover, we have also in rheumatism a by-product of cellular destruction, lactic acid, which has been alleged to be the toxic element, just like the uric

acid in gout. An excess of phosphoric acid is said to occur in rickets. All of which are pure symptoms.

Next arises the important question, Are the masses of urates which occur in the tissues surrounding the joints deposited there from the general circulation, or are they local products? In my judgment, chiefly the latter.

First of all comes the overwhelming testimony of modern physiologic chemists, from Horbacewski, through Burian and Schur to Chittenden and Croftan, that no excess of uric acid is to be found in the blood of the gouty. In fact, it is exceedingly doubtful whether uric acid is to be detected in the blood at all during life; so that the beautiful iridescent vision of Haig and his school, of glittering needle-shaped crystals, darting hither and thither in the blood stream, thrusting their tiny javelins into nerve, into synovia, through liver cell or kidney tuft, like a swarm of internal mosquitoes, rousing the entire organism to agonized protest, must go the way of other day-dreams.

As was long ago pointed out by Levison, the particular node of tissue which becomes the site of these urate infarcts shows distinctly signs of necrosis, which has preceded the formation of the urates. In short, granted our toxins, of widely varying origin, external or internal as the case may be, these will attack the tissues in the neighborhood of the joints as regions of least resistance, slowest circulation, and lowest vitality in the entire body. The tissues of the joints die *in situ*, and with the assistance of the leucocytes which were summoned to their aid, break down into masses of urate of soda and into phosphoric acid, which latter is usually swept away in the blood current and into the urine. Or if a sufficient amount of calcium salts be present and the other conditions are favorable, they proceed to form exostoses (calcium phosphate), which are so characteristic of chronic gout.

Next, we have the striking fact that in the gouty an injury to the affected joint may precipitate an acute attack, as anything which lowers the local resisting powers of the tissues renders them more susceptible to the power of the toxin. It is precisely those two joints in the body which are most exposed to an infinite variety of blows, contusions and strains, namely, the joints of the great toe and of the thumb, which are most susceptible to gouty attacks, and of the two, the one which bears the weight of the body and is at least twice as frequently exposed to these risks—the toe—is far the heavier sufferer of the two.

The question still remains, Why are such deposits confined to gout, and why do they attack so exclusively the joints and bones? If, however, we regard "gout" as simply a term applied to the reaction to a wide variety of poisons in patients of a certain middle grade of resisting power, the objection loses most of its force. Tophi form in the gouty in response to any intoxication because the cells have sufficient resisting power to, so to speak, die in opposing its action and form urates. They do not in the acytic because the cellular resistance is absent—the body submits without a struggle, as it were—nor in the hypercytic, because the resisting forces are sufficiently abundant to neutralize the poison, and if necessary, to dispose of their own casualties as well. Besides, this deposit is not confined to true gout, but occurs in chronic plumbism. In fact, we have agreed to term as gout all these chronic toxic processes which result in irritative lesions in or near the joints, attended by the production of urates and of calcareous con-

cretions. I see no more reason for considering all these of common origin than I do for regarding all processes which are attended with the formation of an excess of fibrous tissue, in the same regions, as due to a common cause, nor can I see that the occurrence of calcareous deposits in the neighborhood of the joints has any other significance in gout than their appearance in the scar resulting from the healing of any other chronic inflammation, such as tuberculosis of the apex.

The question of the tendency of living tissues to deposit calcareous masses or plates is an exceedingly wide one, and far from being clearly understood, but there is one singular coincidence which runs throughout the whole series from the first multicellular organisms up to man, and that is that this deposit is almost invariably either preceded by, or associated with, an accumulation of nitrogenous excretory products of the urea or uric-acid series. For instance, in the well-known coral polyp the lime is deposited on the outer surface or ectoderm, by frank precipitation of the sulphate of calcium in the sea water by means of carbonate of ammonia, into which the urea and other excretory products are decomposed; and as the researches of Irvine, Murray and Woodhead have shown the rapidity of coral building is in precise ratio to the amount of ammonium carbonate and other excretory products of the organism present in the sea water.

In the shell of the mollusc we have a similar relation; all the tissues which are engaged in the deposition of the shell are loaded with uric acid and guanin. A step higher we have the shell of the crab, in which the lime salts are deposited within the bodies of the superficial layer of cells, which latter are simply saturated with uric acid and urates; and, finally, in the formation of the mammalian bones we find a similar state of affairs. What the precise chemical process which is taking place is it would be difficult to say. In the earlier stage, lime is present in sea water in the form of a sulphate, and is deposited almost exclusively as a carbonate; in the shell of the crab it is carbonate with a moderate percentage of phosphate, while, finally, in the bones of the mammal the phosphate comes to predominate and the carbonate plays a small part. All that we can say is that the presence of excretory products of the purin or carbamid series appears to favor the deposition of lime salts, whether in the shape of coral, oyster shell, crab shell, bone or the bony nodules of gout.

One is almost tempted to suggest that what is taking place is a process of slow necrosis of the cells concerned, with the formation, as products, of the purin bodies on the one hand, and on the other of phosphoric acid. This last uniting with the lime salts brought by the blood forms phosphate of lime as the final deposit. However, the reaction is probably not so simple as this. But I am inclined to believe that in the urate deposits of gout, followed as they so frequently are by calcareous masses, bony nodules and exostoses, we have simply a misplaced process of formation of bone and shell, and that the production both of urates and of calcareous deposits is simply one of the incidents in slow, chronic, non-suppurative tissue-necrosis.

Another fact which makes this view more probable is that when we turn our attention for a moment to the formation of calculi as such, whether in the urinary passages, the salivary ducts or the intestines, we have precisely this same significant occurrence of, first, uric acid, second, lime deposits. I think the opinion is gain-

ing ground that in all these processes we have to do not with a mere chemical and mechanical precipitation of salts from the fluids of the urinary or salivary tracts, but a genuine deposition of successive layers by living cells in the attempt to cover up a morbid foreign body, such as gives rise to the pearl in the oyster.

Von Noorden's discovery that calculi, wherever found, whether in kidney or bladder, were covered by a proteid film, was remarkably suggestive, and indicates strongly that these bodies are the product of living cells, probably clusters of leucocytes, out of the bodies of which are formed at one time masses of uric acid, thus giving the well-known alternate layers of calculi, at other times calcareous plates.

There is another side to this question, but that would carry us far beyond the limits of this paper, and that is, that in these deposits of calcium we probably have an important neutralization of toxins going on. This certainly is the rôle of lime in the vegetable organism, as the fascinating researches of Oscar Loew have shown, and it is to my eye distinctly significant that three of our most serious chronic intoxications, namely, rickets, rheumatism and gout, are associated with a marked disturbance of the normal deposition of bone. Whether the abundant calcification which is going on normally all over the body has anything to do with the immunity of children from so-called gouty symptom, has long seemed to me to be a question worthy of consideration. I am afraid this will seem like somewhat of a far cry from my original subject, but the gist of it is, to my mind, that the whole series of peri-arthritis changes in gout are simply the symptoms of slow chronic intoxication, with local necrosis, at points of least vitality. The invertebrate dies and calcifies on the surface, the vertebrate at the core.

Definitions are dangerous things, but I am willing to cause my opponents to rejoice by attempting one. I would define gout as "any form of mild, chronic, intoxication occurring in an individual of a medium grade of resistance and resulting in the deposit of uric acid, or the urates in the tissues or urine." In other words, it is a symptom name, pure and simple.

When, however, we turn to the question of prevention, our attitude is by no means so hopeless nor so indefinite as might have been feared. In fact, there is almost excuse, from a therapeutic point of view, for preserving the unity of gout. It is one of the many triumphs of our good, old, hit-and-miss, survival-of-the-fittest, empiric medicine that it has managed to stumble on the right treatment for many disturbances concerning whose causation it was widely and utterly at fault. We knew that quinin cured malaria long before we ever dreamed of the hematoozon, and our treatment of gout and lithemia is infinitely more rational than our pathology. Here, as elsewhere, creed is of little consequence compared with conduct. The first thing, of course, to be done is "*chercher la femme*," and find out the particular cause of intoxication in each individual case. This is, of course, far easier to say than to do. But no class of cases will better repay the time spent in an elaborate and exhaustive search in this regard. No part of the patient's body, or I had almost said mind, should escape our scrutiny, from the roots of the teeth and the condition of the gums to the state of his refraction and the possibility of lead under his finger-nails. Every possible source of either infection, or simple disturbance of metabolism, should be passed under review.

In many cases the infection will be an autointoxica-

tion, simply due to perversion of normal metabolism, and its cause may be sought in an error of refraction, in mental worry, in grief, or overstrain. In other cases it may be a distinct external infection, such as a suppurative process about the roots of the teeth, a septic condition, with shallow ulcerations, of the septum, or turbinated bodies, or an acne, with its steady, persistent absorption of minute traces of pyogenic matter. In one case which I have under observation at present a furunculosis of nearly a year's standing has resulted in the production of enormous showers of uric acid in the urine. A large majority of the cases, however, will be found to be of autotoxic, and more or less directly intestinal, origin, and here is where our "old reliable" remedies in gout have won their laurels. First, and most important of all, we have the great group of alkaline laxatives, which, both by checking the acid processes of fermentation in the alimentary canal and sweeping the putrescent matters out of the system before they have time to give off their poisonous products to the blood, enormously relieve the situation. Next in order, the group of intestinal antiseptics which directly prevent fermentation in the alimentary canal, like the salicylates, calomel, guaiacum, phenacetin, menthol and all the aromatic group. And, thirdly, the simple alkalis which act by reducing the acidity of gastric digestion and possibly, to a certain extent, by directly neutralizing the toxins, which are usually acid in reaction, and by producing mildly laxative effects. Lastly, renal, cutaneous and other eliminants, like colchicum, the iodids, acetates and niter. In short, almost every remedy which clinical experience has proved to be of value in gout and the gouty state will be found to prevent the formation or absorption of intestinal toxins or to promote their elimination from the system.

As we well know from clinical experience, some one or combination of these remedies will usually give our patient at least temporary relief.

Heterodox as it may appear, I believe the question of diet can be dismissed almost in one sentence, and that is, direct such food as will in each individual case reduce intestinal putrefaction to the minimum, while abundantly supporting strength.

Meats as such and proteids as such have absolutely nothing to do with the production of gout. Some of the worst cases we see occur in women living almost exclusively on bread and butter, potatoes, sweets and tea.

As a matter of practical experience I have found it much more frequently necessary to limit my gouty patients in regard to potatoes, bread, pastry and preserves than in respect to meat of any sort. In a majority of cases the fault does not lie in the diet at all, except insofar as it is deficient in nutritive value, or excessive relative to the actual needs and combustion powers of the body. The value of a vegetarian diet in gout is chiefly due to its unattractiveness. Vegetarianism is merely a polite form of starvation, and where this is indicated it will be of value. In the long run, it will usually be found better to regulate the diet of our gouty patients by increasing their oxidation than by diminishing their intake.

Above all, let there be water internally, externally and eternally. First, because our digestive processes are processes of hydration, and water is a valuable aid to digestion instead of a hindrance, according to the ridiculous old nursery superstition of the last generation. Second because it is the finest eliminant, whether alimentary, renal or cutaneous, that we possess. Third,

because 99 per cent. of our body cells are still aquatic organisms and marine at that, and must be kept flooded with water in order to live. What salts are dissolved in the water aforesaid is purely a matter of taste. The one active agent in all mineral waters is H_2O .

DISCUSSION

ON PAPERS BY DRs. SOLLMANN, MENDEL, FUTCHER AND HUTCHINSON.

DR. HEINRICH STERN, New York City.—Dr. Sollmann stands entirely on the modern basis. His paper confines itself entirely to physical conditions and signals a decided advance in the conception of the intrasystemic processes. In connection with Dr. Mendel's paper, I wish to again draw attention to Weindland's experiments and the deductions which we may derive therefrom. Normal quantities of antipepsin apparently control peptic digestion and prevent lesions to the gastric walls. Antitrypsin may act similarly as a protector of the small intestines. The round gastric ulcer, which in reality is not an ulcer at all, but a circumscribed necrotic spot, probably the consequence of autodigestion, may be due to absence or insufficient amounts of antipepsin. The same may be surmised as regards the duodenal and other intestinal ulcers which may follow the deficiency of antitrypsin. However, these conceptions of autoprotection are too good to be true. We may accept them for lack of something more definite, but we have to accept them *cum grano salis*. I wanted to hear Dr. Futcher say something about the natural and normal solvent power of human blood serum. According to the more recent investigations, uric acid occurs in normal amount in the urine of the gouty. Blood uric acid is absolutely and relatively increased in leukemia; its amount is not augmented in gout. The occurrence of uric acid in the blood of gouty and nephritic conditions is due to its retention therein. In nephritis, the insufficiency of the kidneys is at fault; in gout, the presence of uric acid is the result of the deficiency or quality of the physiologic uric acid solvents. Concerning the statements of Professor Chittenden, we all appreciate the far-reaching deductions which his later experiments permit us to draw. I have done considerable work in the same field, but, naturally, I have undertaken more experiments with diseased than with normal individuals. Some of my data are published in the *Medical Record* of May 21, this year. I wished to cite some of Professor Chittenden's results, but could not obtain a copy of his paper read in Washington in April last. I find that we may well get along with a nutriment 20 per cent. less than usually employed. This is especially the case in certain of the wasting diseases where the digestive, elaborative and assimilative functions are at the bottom of the underalimentation. Here we must prepare the organism to utilize the ingested food properly and must not try to administer larger amounts of foodstuffs. In such cases, overfeeding may be truly harmful. In further corroboration of Professor Chittenden are two cases of Hirschfeld cited in my aforementioned article. A woman subsisting on a diet the nutritive value of which never exceeded 1,650 calories per day, gained thirty kilograms in six years. The other case, also a woman, was kept in metabolic balance on a diet of from 1,380 to 1,570 calories.

DR. FENTON B. TURCK, Chicago.—Our ideas to-day are very much those of Stahl in the eighteenth century. He had the idea that the "sensitive soul" protected the body from material agents; the "soul" kept the body from injury. John Hunter recognized this influence, which he thought was due to "vital power," as he named it. We have to-day the same idea of "vital resistance of the tissues," essentially the same as Stahl. In my experiments to produce gastric ulcer, I have found that bleeding or loss of hemoglobin was not sufficient to produce gastric ulcer. The ulcer will rapidly heal up even with a deficiency of hemoglobin. By repeated intravenous injections of colon bacilli I found that ulcer of the stomach could be artificially produced. The normal sera of animals do prevent the digestion of a piece of the gastric mucous membrane with pepsin and hydrochloric acid in a test tube, while the sera of animals injected with bacilli allow digestion to take

place in twenty-four hours. The products of the growth of colon bacilli produce no effect. It appears that the presence of the living bacteria alters or exhausts some substance in the serum which under normal conditions interferes with the local digestion of the mucous membrane. This has great significance when applied to the pathogenesis of many other diseases.

DR. BOARDMAN REED, Philadelphia.—Did Professor Chittenden, in his experiments, carry out the views of Horace Fletcher as to overmastication of the food so as to promote better digestion and assimilation? This theory of Fletcher's that prolonged chewing makes food go further in nourishing the body, seems to have some reason for it. Did Professor Chittenden make any experiments on persons who are dyspeptics—those who have fermentative trouble? It is one thing to cut down the diet of persons in health and quite another in the case of those who have much fermentation in the alimentary tract involving a loss of part of the nutriment by the action of bacteria. It would be interesting to know, therefore, whether any of the subjects of Professor Chittenden's experiments suffered from much fermentation in the alimentary tract involving a loss of part of the nutriment by the action of bacteria. It would be interesting to know, therefore, whether any of the subjects of Professor Chittenden's experiments suffered from either gastrointestinal inflammation or fermentative dyspepsia.

DR. H. R. CHITTENDEN, New Haven, Conn.—We had one particular experiment on a man who for two years had had considerable trouble which he called dyspepsia; it might have been gastritis. He was troubled with the usual symptoms of discomfort, flatulence, etc. In this man the food was cut down to nine grams of nitrogen a day, instead of from 16 to 18, which he had been taking. His condition improved and his digestive trouble was nearly over. We have not experimented with overmastication or insalivation. Our object has been simply to ascertain the minimal proteid requirements of the healthy man with a view to seeing if great physiologic economy in diet is not possible.

DR. S. SOLIS COHEN, Philadelphia.—Dr. Woods Hutchinson's fascinating paper controverts established traditions, but doubtless has some fundamental truth. I have seen in subjects of lead poisoning sodium urate concretions in the joints. Perhaps had we heard all the facts back of his opinions, his views might have been more convincing. There is this, however, to be said: Uric acid or the alloxuric or purin bodies, altogether, or any one of them alone, can not produce gout; and their presence is not to be considered as solving the problem of pathogenesis. Like albumin in nephritis, sugar in diabetes, these bodies are symptomatic, products of the faulty metabolism characteristic of the disease, though they may and do, in turn, cause many secondary symptoms. We must go back further for the cause. Mere words are not satisfactory—metabolism is too much like Mesopotamia—but words must answer while facts remain undiscovered. There are many persons whose condition can only be explained on the ground of a peculiar chemistry of cell-function—an abnormal normality—which they have usually inherited. Less frequently it is acquired. In treating the various disorders of these gouty patients we must recognize this fact of constitutionally abnormal cell-chemistry, and, at least for the present, our recognition of this condition and our plan of treatment must be based on the qualitative and quantitative variations of the purin bodies in the urine; this quite apart from the question of production versus elimination. Thus limitation in the dietary is often an advantage. But the mere fact that uric acid and alloxuric bodies happen to be found in the urine at one time or are absent at another, does not give a rational basis for a theory of pathogenesis or therapeutics. Our established treatment usually helps the patient, but in this, as in most other relations, art has outrun science. Dr. Edward Blake of London points out that the children of those persons commonly called lithemic, usually present deficient vasomotor control. The mutual inter-relationships of the vasomotor nerves and the body chemistry is a question deserving further study.

DR. HARVEY W. WILEY, Washington, D. C.—One object in living is to have our ideals shattered. As a boy I saw that

prominent men had the gout, and it was my ambition to attain that dignity in my old age; but I am convinced, after hearing the papers that have just been read, that I shall never be able to achieve it. A short time ago I was called on to address a society of New York farmers. They were a peculiar kind of farmer, as each one was worth not less than \$25,000,000. I looked around and saw that there was not one who did not measure more around his stomach than around his lungs. I said at once: "You measure too much around your waists; no one has a right to measure more around his stomach than around his lungs. It is a dietetic crime." Probably since the time of Adam we have been eating too much nitrogen. What the ultimate effect will be on the race we do not know, but as we have several million years more to live it will probably be seen in the course of time. What we are now is due partly to the fact that our parents have eaten so much nitrogen. Professor Chittenden has shown that for six months a man can get along with much less. What the effects would be if kept up for a million years we can not say. Some months ago I said that it was not necessary to eat meat in order to be brave, as I learned to believe in my youth, a fact which has been demonstrated in recent military operations in the far east. It has also been shown that a man who eats rice can pull a jinrickisha containing a man weighing 165 kilograms, and at the end of the day be fresher than the man he carries. Dr. Futcher said that alcohols that are distilled have not as much influence in causing gout as those that are fermented. Possibly it may be the substances associated with the alcohol in the fermentation process rather than the alcohol itself. As to the activity of lead in the etiology of gout, a great many persons are taking lead in their food without knowing it. Canned goods are kept in tins containing lead and are soldered with an alloy containing at least 50 per cent. of lead; there are pellets of this solder inside of many of the cans. Much more might be said about dietetics and metabolism not germane to this discussion, but there is one thing that is germane to therapeutics and that is food; and the physician who, in his treatment of sickness, neglects food throws out of his armament his most useful weapon.

DR. CLEMENT B. LOWE, Philadelphia—Dr. Reed spoke of overmastication. The rule is undermastication. Dr. Mendel said that food in the fundus of the stomach is not acted on by the gastric juice and that this action is confined to the pyloric portion. We have been taught that the acid secretion of the gastric juice is able to overcome the action of the ptyalin of the saliva, and that the conversion of starchy foods into maltose will stop soon after the food enters the stomach. Now it is stated that the gastric contents do not become acid as soon as we thought they did. If so, this gives a longer time for the conversion of starch into maltose in the stomach. Professor Brunton said that we ought to chew our food well; we should chew meat 32 times to give every tooth a bite; it would be better to chew it 64 times. Ordinarily, therefore, we do not chew our food sufficiently. Starchy food, especially, should be well mixed with saliva before going into the stomach. In this way it finally passes into the intestine in the form which is intended by Nature. I agree with Dr. Osborne and Dr. Chittenden that, as a rule, we eat too much. The Irish people are not the best supplied with food but they are the healthiest people on the face of the earth.

DR. FENTON B. TURCK—I have recently published some work in which it is shown by experiments on animals that excessive distension of the stomach results in fatigue of the gastric muscles with atonic dilatation of the stomach. When food, water or air is introduced into the stomach of an animal in excessive quantities, sufficient to cause marked distension and retention, fatigue with elongation of the gastric muscle occurs. Changes in the musculature are observed microscopically; cloudiness around the nuclei which do not stain well. I believe that this condition frequently occurs in children who are allowed to eat too much and too frequently, and to swallow large pieces of food unmasticated. The habit of overeating and not properly masticating the food continues through life, followed by a variety of serious ailments. Stagnation occurs,

with consequent bacterial growth. In the majority of cases of atonic dilatation of the stomach I find the history of error of diet. The muscles of the stomach can not properly triturate the food in the normal time; detention ensues and the food is only slowly expressed through the pylorus. The food mass is thus infected and the colon bacilli develop abnormally in the intestine. Micro-organisms that enter the circulation from the intestines are readily destroyed under normal conditions. When the altered cultures are developed in excessive numbers the tissues are injured by toxins obtained from the bacteria as these are disintegrated by the blood. The alloxuric bodies may thus be readily precipitated from the blood at the injured parts.

DR. T. B. FUTCHER—I gather that Dr. Hutchinson holds that gout is of toxic origin, or that toxins may give rise to the symptoms. Whether the uric acid or the alloxuric bases are at fault is still a disputed point. At one time I was of the opinion that the alloxuric bases were decidedly increased in patients suffering from gout. Kolisch had advanced this view some years before. Both his analyses and my own were made by the Krüger-Wulff method, which has since been shown to be inaccurate. The balance of opinion at the present day is still in favor of the view that disturbance in uric acid metabolism is the main etiologic factor in the production of gout, although it is quite possible that the other nuclein derivatives may play a part. I was not able, in the time at my disposal, to take up many points in connection with the etiology and pathology that I wished to. Ebstein thinks that the joint changes are primarily due to local tissue necrosis, with secondary deposition of sodium biurate. His, Mordhorst and Minkowski believe, on the other hand, that the uric acid deposition is primary and the tissue necrosis secondary. Dr. Stern inquired in regard to the solvent power of the blood serum in gout. Many have claimed that it is reduced, holding that the lowered solvent power is due to a diminished alkalinity of the blood. Determinations of the alkalinity of the blood with more modern and reliable methods seem to show that there is no particular reduction in the alkalinity of the blood in gout. I would like to say further that in gout the blood serum is not saturated with uric acid. Klemperer has shown that the blood serum of gouty individuals is still capable of dissolving a considerable amount of uric acid, although not so much as normal blood serum does. Dr. Wiley has brought up a subject which I have discussed more fully in my paper. It has been suggested that the injurious effects of the fermented liquors are due to the sugars and saline matters which they contain, as well as to the fact that many of them are decidedly acid in reaction.

DR. H. C. WOOD, JR., Philadelphia—I sympathize with Dr. Wiley. I think that most of us have derived great consolation, when we had a lithemic outburst, by picturing the deposit of uric acid. It disturbs us to have these views roughly dispelled by Dr. Hutchinson's paper.

LACERATIONS OF THE PELVIC FLOOR; THE PRINCIPLES INVOLVED IN THEIR PRIMARY AND SECONDARY REPAIR.*

JAMES HAWLEY BURTENS¹HAW, M.D.

Adjunct Professor of Gynecology in the New York Polyclinic Medical School and Hospital.

NEW YORK CITY.

Fortunately for the physical welfare of women, practical unanimity exists among obstetricians regarding the advisability of immediate repair of a laceration of the pelvic floor after labor. Unfortunately, the ultimate results of such an operation are frequently not at all satisfactory, prolapse of the vaginal wall necessitating secondary operative procedures at a later date. The lack of success attending the primary operation is to be at-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

tributed to one of three causes, or to a combination of all. First, failure on the part of the operator to appreciate the extent and direction of the subcutaneous tear; second, failure to approximate the edges of the torn muscle and fascia; third, an overstretching of the muscles of the pelvic floor, which can not be overcome or modified except by denudation and suturing of the vaginal wall, an unjustifiable procedure at this stage of the puerperium.

We know that any tyro in medicine may readily recognize a tear of the vaginal wall or perineum after the birth of the child, and may introduce sutures which will coaptate the edges of the superficial wound, but every obstetrician of experience is aware of the extreme difficulty or the impossibility at times of recognizing a subcutaneous separation of the levators and fascia, and of approximating their torn edges. An important complicating factor in the ultimate prognosis in practically every case in which the certainty of separation can be eliminated is that of overdistension or overstretching, for it is impossible to determine if the paralysis has passed the point at which it will not be amenable to natural correction as involution progresses.

T. A. Emmet was the first to draw attention to the fact that the dynamic agents attendant on the passing of the fetus through the birth canal were analogous to those brought into play by the forcing home of a piston, the point of greatest resistance being at the outlet; consequently, an abnormality in these forces or in the size of the presenting part or in the resiliency of the tissues at the introitus naturally resulted in the giving way of the structures subjected to the greatest amount of strain, the perineal body and certain of the muscles forming the floor of the pelvis. This separation, he pointed out, was to be likened to the drawing aside of curtains below which were united above.

This view of Emmet's is in strict accordance with the anatomy of the parts, and has been generally upheld. We know that, in the great majority of cases, the separation begins in the median line, extends as far as the perineal flexion, and then may radiate to one or both sides along the vaginal sulci. Under these circumstances not only are certain important fibers of the levator ani muscle ruptured, but, what is of far greater consequence, the rectovesical and rectovaginal fasciæ are also torn, and the vaginal tube is thus bereft of the greater portion of its natural support.

Theoretically at least, the primary operation should more nearly restore the pelvic floor to its original condition than an operation performed months or years subsequently, and for a very simple reason. At this time the edges of the muscle and fascia are raw, and if approximated by properly introduced sutures, will unite. It seems to me that failure in the primary operation, existing pathologic conditions being recognized, is directly due, in the largest number of cases, to the improper insertion of the sutures. I maintain that if the factor of irremediable overdistension could be eliminated proper, that is to say, deep, sweeping suturing would reduce the failures to a very small per cent. It has been estimated that fully 35 per cent. of primiparæ suffer injury to the pelvic floor at the time of confinement. It is a question in my mind if, in the case of every primipara in which the physician in attendance is in doubt as to whether separation of the levator and fascia has occurred, it would not be wise for him to introduce sutures in such a manner as to remedy the possible defect. I am not unmindful of the fact that, for

many reasons, this plan would not be practicable, but the principle of the good it may accomplish remains.

The great number of technics that have been devised to correct prolapse of the posterior vaginal wall and relaxation of the muscles at the outlet, indicates the important place such correction holds in the minds of gynecologists, yet I have long been convinced that there exists a pronounced misconception as to what is really accomplished by the several procedures. Take the well-known Emmet operation, for instance. At the meeting of the American Gynecological Society, held at Atlantic City in May, 1903, in summing up the subject of pelvic floor lacerations, one of the essayists expressed himself as follows:

"The principles underlying the repair of laceration of the pelvic floor, which Dr. Emmet gave to the profession in 1883, have been generally accepted as correct. This being so, it seems proper for this society to stand by these principles and for us to devote our energies rather to perfecting details of operative technic than to devising operations opposed to the well-established principles of Emmet."¹

I find it impossible to accept this view. No gynecologic surgeon of to-day or in time to come can fail to freely acknowledge his debt to this brilliant teacher, Emmet, and in the light of almost universal acceptance of his opinions regarding pelvic floor laceration and repair, it appears heretical to question their soundness; but it is a fact, easily proven nevertheless, that the operation devised by him for the correction of posterior wall prolapsus does not accomplish what he alleges for it. He directs that "a point in the middle of the projecting mass within the vagina be picked up with a tenaculum and drawn forward and upward toward the neck of the bladder, when two folds will be seen leading up to a point within the sulcus on each side." I have never heard his assertion disputed that these points indicate the limit of retraction and show clearly that the portion of the vagina above is still properly supported, yet these sulci may easily be demonstrated by the same means in many cases on the cadaver, and this, too, when subsequent dissection of the pelvic floor shows the levators and the fasciæ to be intact. Naturally, this demonstration is, to a certain extent, made possible by the postmortem relaxation of all tissues, but I venture the assertion, although with more diffidence, that frequently an exactly similar appearance of the posterior wall may be shown on the living subject in cases in which there exists no appreciable degree of prolapsus. I realize that the success in causing these sulci to appear in these last-named cases may be due to undemonstrable separation of the levator fascia, but I am reasonably certain that in many instances the examiner may be satisfied that this separation has not occurred.

In the Emmet operation, by means of a gutter-shaped, triangular denudation on each side of the median line of the vaginal canal, which denudation extends only through the mucous membrane, and by the introduction of three separate sets of sutures, it is claimed that "the slack of the retracted fascia is taken up throughout the pelvis, the posterior vaginal wall is lifted upward and forward in contact with the vesicovaginal septum, the everted tissues at the vaginal outlet are rolled in, and the separated levator ani muscles are brought together, so that the woman becomes apparently perfectly normal." I am candid in confessing that I am unable to accept

1. W. L. Enrage: Lacerations of the Cervix Uteri and Pelvic Floor; a Plea for Their More Careful Study, Their Diagnosis and Their Treatment. *American Gynecology*, August, 1902, p. 141.

these conclusions. The denudation is a superficial one, to begin with, and although the sutures undoubtedly are introduced in such a manner as will draw together the edges of the torn muscle and fascia, as the latter have not been freshened or individually united, they necessarily will remain in apposition just so long as the tightly drawn sutures remain in place, and no longer.

As I have said, in the primary operation the edges of the muscles and fasciæ are raw, and should unite when approximated by sutures. What is accomplished by nine out of ten of the secondary operations? Simply this: The mucous membrane covering a certain area is removed and sutures are introduced in such a way as to approximate the raw surfaces; in other words, a portion of the muscular wall of the vagina is freshened and backed up against itself, in which position the surfaces unite, the slack of the wall is taken up, the weakened perineal body is reinforced, and the gaping vaginal orifice is reduced to its normal size. Emmet's operation, in common with many others, accomplishes all this, but it accomplishes nothing more; the one factor that, in certain well-defined instances, recommends it above others, is that it more fully takes into consideration the direction of the tear. I do not for a moment doubt that, given a Y-shaped tear, beginning at the fourchette or in the perineum, extending to the perineal flexion, and radiating up the sulci, the method of denudation and suturing recommended by Emmet will properly approximate the superficial tissues; but I hold, and I think with reason, that no operation which does not provide for the isolation, freshening, and individual suturing of the levators and fasciæ will restore the woman to her former normal condition. But, as every surgeon knows, this procedure, in the great majority of cases, is impossible of accomplishment. No one appreciates more than do I the beneficial results accruing from colpoperineorrhaphy in those cases in which it is indicated; I assert only that in many of the methods of operation an exaggerated claim is made which is in no sense borne out by the pathologic conditions present.

In connection with methods of suturing, an additional factor which impresses me as being of considerable importance is this: The vaginal walls are firmly anchored to the apron-like levator below, at the orifice, and to a movable organ, the uterus, above, and are held in position by certain fibers of the levator and by its fasciæ. These muscular and fascial structures having lost their tonicity, through rupture or overstretching, and the posterior vaginal wall being deprived to a great extent of its natural support, it is reasonable to suppose that if sutures are introduced longitudinally, or in any manner except transversely, their tendency will be to draw the wall toward the fixed point, at the outlet, and so increase the traction of an already displaced womb.

It being granted that the Emmet operation does not unite the edges of the underlying muscle and fasciæ, I fail to determine its advantages over many of the more simple operative methods. I think it will be admitted that the operation is tedious, that the large number of sutures before being tied are in the operator's way, and that an inexperienced operator is very liable to denude too large an area, and thus unduly constrict the canal. It has been claimed that the pelvic floor is less liable to rupture during a subsequent labor if it has been repaired according to the Emmet method. My experience does not bear out this assertion.

To the question as to which of the operations of colpoperineorrhaphy is really the most efficient, it is natural that various operators will return various replies.

That technic which has yielded the most satisfactory corrective results in the hands of an individual operator is apt to receive the preference. No one will deny that the proper method of closing a wound is that which takes into consideration the original line or lines of cleavage. When the accident occurs the distension of the vaginal canal is lateral, the muscles and fasciæ being drawn apart by traction exerted from the sides. Therefore, as practically every colpoperineorrhaphy, as now performed, is a superficial operation, the anatomic and pathologic conditions present lead one to suppose that a triangular denudation and side-to-side suturing will most nearly meet the indications. Personally, I believe that the Hegar operation, in which the denudation is carried well beyond the crest of the rectocele and the sutures are sweepingly inserted across the vagina, will, in the great majority of cases, prove the most satisfactory. The technic is simple, and may be carried out in less than half the time required by that of Emmet; the slack of the vaginal wall is taken up from side to side, as it should be; the weakened perineal body is strongly reinforced, and the introitus is reduced to its normal size. In all cases the denudation should extend to the mucocutaneous junction. Failure to obtain the results enumerated may be attributed to improper denudation, incorrect suturing, or to low vitality of the patient.

TREATMENT OF COMPLETE UTERINE AND VAGINAL PROLAPSE.*

FREDERICK HOLME WIGGIN, M.D.
NEW YORK.

So much diversity of opinion still exists among gynecic surgeons as to the proper treatment to be employed for the cure of complete uterine and vaginal prolapse, that it seems timely to again bring this subject forward for discussion; and for this reason I desire to bring up for consideration the method of treatment which in my experience has proven the most satisfactory.

Before doing this, however, a few words in regard to the pathology of the disorder may be of interest.

The condition is best described as a reducible hernia through the pelvic floor, the sac being the inverted vagina, containing beside the uterus, tubes, ovaries, bladder and rectum, a large portion of the small intestines.

The causation of the disorder, as is well known, is primarily a separation—often submucous—of the tendons of the muscles forming the pelvic floor where they unite in the median line, and is usually due to the passage of the child's head during parturition. This separation of the tissues, which hold the rectum in its proper position, allows the lower anterior portion of the gut to bulge upward and forward into the vagina, pushing the vaginal tissues before it. This abnormal position of the bowel is increased by every act of defecation and straining at stool, and is also added to by the lifting of heavy weights. As the muscular force employed follows the line of least resistance, it tends in these cases, not to expel the bowel contents through the anus, as it should, but instead, to force the gut forward through the hernial opening into the vagina. The dif-

ficulty experienced by the sufferer in emptying her rectum causes her to exert an ever-increasing force, and gradually and steadily, day by day, the rectocele increases in size, force in a downward direction being necessarily applied to the attached uterus, and its ligaments, which, in a normal condition, serve simply as stays holding it in place, are gradually stretched and lengthened, allowing greater freedom of position to the descending organ. As the uterus descends the bladder, of course, is dragged down by it.

The descending process is hastened, after it has fairly begun, by the added weight of the small intestines, which, being contained largely in the pelvis, find their way by gravity to the lowest point. Thus after a period of a longer or shorter duration, varying usually in accordance with the natural vigor of the patient and the amount and character of the work she is called on, by reason of her environment, to perform, a complete inversion of the vagina occurs, and a hernial sac of large size appears outside of the body, and we have the condition known as complete uterine and vaginal prolapse to deal with.

This complete form of the disease does not, as a rule, appear until rather late in life, although the patient ordinarily suffers for many years from much discomfort and disability.

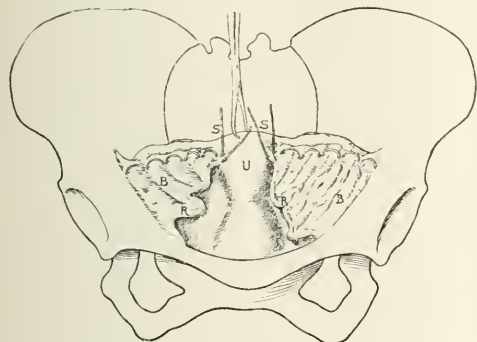

Fig. 1.—B, broad ligaments; R, round ligaments; S, sutures of kangaroo tendon; U, uterus.

In the surgical treatment of this disorder, much ingenuity has been displayed. Various operations on the anterior and posterior vaginal walls, as well as the removal of the uterus in whole or in part, have been recommended, but unfortunately, without very satisfactory permanent results.

In my opinion these disappointing results have been due to the operator's failure, in most instances, to recognize the fact that the vaginal wall in these cases is a hernial sac, with other contents than the uterus, tubes, ovaries, bladder and rectum, and that consequently the simple repair of the external perineal body, the removal of a larger or smaller portion of the vaginal walls, or even the removal of the uterus itself, will not correct the greatest cause of the difficulty, namely, the abnormal position of the small intestines.

In the elderly patients, who have come under my observation suffering from this disease, many of them having external tumors of large size, the uterus has not been found abnormally enlarged, and consequently could not be considered a factor in the causation of the trouble, and many patients have also come under observation on whom a hysterectomy for the cure of this

disorder had been previously performed by other surgeons, who stated that their tumors were larger than before operation.

TECHNIC OF OPERATION.

In view of the foregoing facts, it seems clear that the operative procedures required for the successful treatment of the class of cases under consideration, are those that will first obliterate the inverted and stretched vaginal wall—which is, in reality, a hernial sac—and then restore the damaged perineal structures and distended anterior vaginal wall as nearly as possible to their normal condition. The technic which has, in my experience, best answered these requirements, has been the following:

Preliminary Treatment.—The patient, on coming under observation, is placed in bed in the recumbent posture and the tumor is reduced, gravity being employed to help retain the parts in their normal position by raising the foot of the bed about six inches. Tampons moistened with glycozone are placed in position, and the parts treated until all ulcerated portions of the vaginal walls have healed, the general condition of the patient being meanwhile carefully looked after.

Operation.—The next step in the procedure is the performance of a laparotomy after the usual prepara-

Fig. 2.—B, broad ligaments; R, round ligaments; S, sutures of kangaroo tendon drawn taut; U, uterus.

tions have been made. The patient being placed in the Trendelenburg posture before the abdomen is opened for the purpose of obtaining the aid of gravity in drawing the parts back into their normal position, the bowels are usually in these cases found to be more or less attached to the vaginal wall by adhesions which must be broken up. The uterus which, as has been previously stated, is in elderly women, usually small, is found and pulled upward by the aid of bullet forceps, drawing the vaginal wall upward also.

When this has been accomplished, a needle armed with large size kangaroo tendon is passed through the fibers of the uterus at the point of its attachment to the round ligament and carried down the broad ligament in the form of a purse-string suture (Fig. 1) and back again, the needle being finally made to emerge about at the point of entrance, so that when traction is made on the two ends of the suture the broad ligament on that side is folded up and drawn together, thus doing away with its excessive length, and giving the uterus a new point of attachment near the insertion of this ligament at the pelvic brim.

The same process is repeated on the opposite side

(Fig. 2), the abdominal cavity is then flushed with saline solution, some of which is allowed to remain, and the wound in the abdominal wall is rapidly closed by means of buried sutures and protected by a celluloid dressing.

If the patient is then in ordinarily good condition, repair of the pelvic floor and reduction in size of the anterior vaginal wall is undertaken.

In my experience there is usually no difficulty in accomplishing this, for all the operative measures necessary to make a complete cure can easily be performed in forty minutes. In these operations time is an important factor, as most of the patients are elderly and do not bear prolonged operative procedures well, or those involving much loss of blood.

Hence the importance of not removing the uterus in whole or in part when it is not at fault in the treatment of this disorder.

I have performed many such operations, as have just been described, during the last few years on women whose ages ranged from 60 to 83 years, without mortality and with most satisfactory results.

55 West Thirty-sixth Street.

DISCUSSION

ON PAPERS BY DR. BURTENSCHAW AND WIGGIN.

DR H. O. PANTZER, Indianapolis, said that in the uteri that come for repair we have only the lateral tears to consider, because a central tear does not cause a collapse, even when it is high up. It is only the tear that goes through the levator ani muscle on either side that causes trouble, and where either one or both are involved. All the procedures recommended for the repair of these injured fibers that lie back of the rectum, simply aim to fortify the rectum. In reality, anything that will bring the lateral walls together is the proper thing to do. When the uterus comes for operation, there is more or less atrophy. The thing to do is to bring the upper ends over the rectum; therefore, it is improper, at any time, to speak of a correct or exact anatomic restoration.

DR. CHARLES P. NOBLE, Philadelphia, considers it very unfortunate that those who do secondary operations do not begin their training in an obstetric hospital, because that is the only way to learn the real nature of lacerations in the pelvic floor. Anyone who has had this experience will appreciate the basis of the Emmet operation. The primary lacerations of the perineum are lateral; the median are very rare and when they occur it means, as a rule, little or nothing. The exception is when the tear is deep enough to involve the sphincter. Any operation which considers purely the middle line of the vagina misses the chief part of the difficulty. In the beginning Dr. Noble did the Hegar operation for a number of years, then became dissatisfied because, with this operation, the rectocele is not well disposed of; he then did the Emmet operation for about ten years. This operation is far superior to the Hegar because it deals with the sulci where the lacerations are and it also takes care of the rectocele; especially in the worst cases it enables one to fasten the rectocele back in the vagina and attach the loose tissues to the levator muscle as no other operation does. He said that it is inconceivable how anyone can put sutures in the perineum that would have any effect on the uterus. If the vaginal wall is pushed into the pelvis and the suture is placed directly through the vaginal wall and into the levator ani muscle, so far from drawing the vagina out, it is fastened back within the pelvis, and when the suture runs up on the rectocele, it rolls it back and fastens it in the pelvis. The tip of the rectocele is drawn down to the caruncles in the typical Emmet operation. The defect of the operation as usually done is that we draw down between the lateral structures this central tip of mucous membrane so that there is a tendency to prevent union where it is so desirable. Some years ago Dr. Noble modified the operation by making the central denudation higher up, utilizing the principle of the

Hegar operation at the outlet. This gives a much firmer introitus than the typical Emmet. It allows one to roll the rectocele back into the pelvis, fastening the vagina to the levator ani muscle; and by denuding in center a little higher up, from one-third to one-half inch within the hymen, the lateral structures at the outlet are brought directly into contact. Dr. Noble read a paper about ten years ago, in which he referred to splitting the anterior border of the levator muscle, rolling the fascia in and suturing them together. As a result of that experience he found that he made a cicatricial band in the vagina in a considerable number of cases, which was a nuisance, especially in middle-aged and elderly married women with inelastic tissues. He agrees that it is impossible, in doing a secondary operation, to restore the parts absolutely to the original anatomic condition, but one can approximate very closely. In the normal pelvic floor, just within the hymen, there is a slip given off from each levator ani which meets its fellow in the middle line, in the tendinous center of the perineum. In doing a secondary operation it is impossible to find these slips, but they can be imitated by suturing the anterior borders of the levator muscle, covered by fascia, caught deep in the sulci, and bringing them together in front of the rectum. It is very simple and, while it is not strictly anatomic, it does reproduce, as nearly as one can, the original condition. That should be a part of each perineal operation, and is an improvement on the typical Emmet operation. Its value is best proved in proctidientia cases.

DR. H. W. LONGYEAR, Detroit, agreed with Dr. Burtenschaw that the Emmet operation, or any other operation which simply denudes, is inadequate, for the reason that only the mucous membrane is removed and the operator does not get down to the retracted tissues. When there has been a laceration, the muscular tissue constantly pulls toward its origin; thus the ruptured transversus perinei muscles are constantly pulling away from their insertion toward their origin at the rami of the ischii. If the sphincter ani has been ruptured, it retracts in the same manner and the characteristic dimples marking the sites of the retracted ends are seen. We can not take up these muscle ends of the sphincter by a simple denudation, neither can one take up the retracted transversus perinei by that method. Dr. Longyear considers that the only operation by which these can be uncovered and united is the split flap operation, because by that method one can get down beneath the overlying cicatricial deposits. By cutting into the torn muscles and fascia and bringing the split fibers together, a broad base of union is made, then by using the buried suture method the perineum is built up firmly. Examine carefully before beginning the incision, find the extent and direction of the tear and, after the initial incisions are made, dissect upward according to the necessity of the case or according to the directions of the tear or tears. Dr. Longyear uses kangaroo tendon moderately hardened, but catgut may be used. If the tissues are bunched in a mass surface, in many cases one gets imperfect approximation. After one has examined a few of these primary lacerations and put them together properly, he gets a comprehensive idea of the condition the parts assume when left to heal by themselves. In the split flap operation, after the cross-cut and cut on each side are made, the flap is dissected upward, on either side and underneath it, according to the depth of the tear, and the muscles are brought together by buried sutures. The Emmet clover-leaf operation is a failure because it is a superficial denudation. It does not bring the tissues together from side to side deep enough. Tait made his incision in a perfunctory way with scissors and did not dissect according to the tear. He made five cuts, no matter what the nature of the laceration. The last two incisions, forming the letter H of the U, are made one on each side of the anus.

DR. A. GOLDSPOIN, Chicago, said that the primary operation, restoring a recent tear, within a few hours after labor, can be one of exact restoration of severed parts; but the secondary operation, done months or years after labor, can never be of that type. Lacerations occur laterally from the

center, usually to one side or the other, and one or the other lateral half of the levator ani, lying in the deep pelvic fascia, is injured. The attempt has been made by Dr. M. L. Harris to theoretically reunite the injured levator ani on the side where the injury occurred. That, Dr. Goldspohn thinks, is a theoretical vagary, especially if it is taken with Dr. Harris' contention that it is the levator ani muscle lying between two layers of pelvic fascia that is the only important thing to deal with, and not the fascia also. The levator ani muscle is too frail a structure to be dealt with successfully by any such end-to-end union. Such restoration of this muscle certainly is not practical and can not give good results. Furthermore, the isolation of the torn parts after cicatrization has occurred is so extremely difficult and imperfect that it is not a practical procedure. Dr. Goldspohn considers that the Hegar, Martin and Emmet operations have not at all dealt with the levator ani muscle or the pelvic fascia, the two structures that are the real supports of the pelvic floor. This matter was first brought out by a German about twenty years ago, who called attention to the correct anatomy of the levator ani muscle and the pelvic floor. The subject was next overhauled by Dickinson about ten years ago, and two years later Dr. Goldspohn devised a procedure of his own, a flap-splitting operation of external structures, not like the Tait, which is purely a cosmetic procedure, but inside of the pelvic cavity—intrapelvic; lifting the posterior vaginal wall, therefore infravaginal, dissecting up the posterior vaginal wall, not simply posteriorly but also laterally, until he came to the lateral descending portions of the levator ani and pelvic fascia. The work can be guided by the left index finger on both sides, holding the rectum back and searching out the levator and fascia on opposing sides and uniting these two important structures in front of the rectum with buried sutures. All the sutures in this operation that have any holding effect are buried sutures of catgut; those that are removed serve a cosmetic purpose only. The natural bridge in front of the rectum, which is composed of a union of the median portions of the two lateral parts of the levator ani muscle that descend from the pubic rami from both sides, is thus restored. After that union has been restored the vaginal wall is allowed to come down on the newly constructed bridge in a ruffled shape and is held there by being caught submucosally by the buried continuous catgut suturing beneath, which reconstructs the bridge of levator ani. Then the outer skin wound or cosmetic portion of the operation is closed by interrupted silk-worm-gut sutures. Dr. Goldspohn says that prolapsus uteri thoroughly developed is only exceptionally curable by the best plastic operations on the vagina and pelvic floor alone. It is usually necessary to attach the fundus uteri above, either on the anterior vaginal wall or on the anterior abdominal wall, in addition to the above mentioned plastic operation below. This fixation of the fundus, however, dare not be done unless the patients are sterile, or are made so by excising the tubes at the same time. Fortunately, the marked prolapse cases are usually in elderly women, who either have no more conceptive capacity or are very willing to surrender it. The best operation for anterior colporrhaphy is one suggested recently by a German, not simply denuding the mucous membrane on the anterior vaginal wall, but making a median longitudinal incision, dissecting off the epithelium on one side superficially, and undermining the vaginal wall as a flap on the opposite side, and then drawing this flap over the denuded surface of the other side, so that for a certain distance an antero-posterior strip of nearly double vaginal wall results. It is not so important how we operate on the anterior vaginal wall for cystocele as it is important that we restore a good pelvic floor for the anterior wall to rest on. Many a cystocele of not very extensive proportions will do better with the pelvic floor thoroughly restored alone than by doing ever so good a plastic operation on the anterior vaginal wall and neglecting the pelvic floor.

DR. D. H. CRAIG, Boston, said that these plastic operations constitute the highest type of surgery; they involve the highest degree of anatomic knowledge in distinguishing the normal from the abnormal. It requires more study, skill and ability

to restore parts to their original condition than to merely remove diseased structures such as intra-abdominal neoplasms. If, because of lack of time, one is going to learn one operation, and only one, to do on all perine, it is well enough to speak of this or that operation, but if one is to pose as a gynecologist, as a specialist, one must be fitted to exercise good judgment in every individual case, and no one operation will fit all cases. So one must know the Emmet, the Hegar, the flap-splitting and every other operation, and must decide which fits the case and do it. One can not succeed in bringing muscles together except by cutting down through the vaginal wall to reach them. It is true that some one particular operation is the best for some one particular case, but there are cases in which no operation ever described is suited, and we must devise one to fit that case if we wish to restore the parts to their normal condition, no matter whether or not it has ever been described before.

DR. GEORGE TUCKER HARRISON, New York City, agreed with Dr. Noble that we must know how the original lesion was produced in order to restore the parts to the normal condition. In other words, an obstetric practice is absolutely indispensable to the gynecologist. As an assistant, Dr. Harrison followed Dr. Emmet in the gradual evolution which culminated in his last operation, and thinks the profession owes Dr. Emmet a debt. No surgeon ever recognized the true mechanical principles underlying the operation for repair of the perineum more clearly than Emmet. Dr. Harrison said that whenever a man introduces a complex and complicated method, one may be sure it means retrogression. The beauty of the operation described by Dr. Tucker lies in its simplicity. His operation has regard to the original lesion, and it endeavors to restore parts to their normal condition. There may not be any tear of the skin externally, still the levator ani muscle may be torn, and then there is a rectocele. Dr. Tucker's operation brings the separated fibers of the levator ani and the fascia into true relation with each other, and that was one of the great merits of Dr. Emmet's operation. He demonstrated that it was the injury to the fascia that was the important part in this lesion, and that you must get support from the fascia. Dr. Harrison considers that Hegar's operation has no regard for the physiologic functions or relations, although he builds up a perineum. Therefore, it was a great advance when Lawson Tait, whose operation was deficient, although not original with him but with Langenbeck, devised the flap-splitting operation, showing that it was useless to take anything at all away. Dr. Tucker takes away only superficial cicatricial tissue.

DR. JOSEPH PRICE, Philadelphia, said that Dr. Noble's remarks on the necessity of an apprenticeship in maternity ought to impress everyone. It was very exceptional for us in Philadelphia to see a patient coming from Dr. Goodell's large service at the Preston Retreat, or from the Sloan Maternity, with a deep tear, favoring a large cystocele or rectocele. Dr. Price delivered 1,500 women at the Preston Retreat and never had any of those cases come to him for a secondary operation, because he never permitted the patient to have more than a few minutes to pass before a complete primary repair. There one has an opportunity of repairing an injury after mutilation as in no other part of the body. Many of these repairs are not done properly. He makes repair of the vaginal injury by putting in only one or two perineal sutures. All others are in the vagina. The old methods of putting in three or four or five sutures are errors in surgery. Labor, if simple, never shocks the patient, and repairs can be made in a few seconds with a boiled needle and any of the suture materials. There are a number of procedures that one must resort to. The simple median tears of the first or second degree rarely, in fact never, cause protrusion of the pelvic viscera or relaxation of the vaginal outlet, more than a deep central gaping. The Hegar operation, in these central tears without a rectocele, gives a good pelvic floor, when the operation is done well. The flap-splitting operation of Tait is a simple procedure; it is an external operation and easy of execution. Men have not been willing to serve long enough as apprentices, assistants or observers to be able to do the Emmet operation well. There are only four

or five men in Philadelphia who are thoroughly familiar with this operation for the restoration of the pelvic floor or diaphragm. The operation as Tait did it was a very common one, sometimes done in his hands while the patient was trying to get away from him.

Dr. J. RIDDLE GOFFE, New York City, stated that in a fresh lesion one can restore the parts absolutely; in a long-standing lesion that, practically, is impossible, and when men talk about dissecting down and getting hold of muscle and fascia, bringing them out distinctly and separately and fastening them together, they are indulging largely in flights of the imagination. Coming in from either side are the transversus perinei muscles and the levator ani, which, as described by anatomists, is a very delicate structure and amounts to little. The transversus perinei are powerful and immediately retract, pulling the tear apart. In the course of time a rectocele develops, which is a falling down of the perineal floor. Dr. Goffe follows the line of the caruncles until he reaches the lowest. He denudes, then goes to the highest point of the rectocele, which he depresses with the finger, and with the knife draws a line from there down to the lowest caruncle, and then connects the caruncles from one side to the other, making a large flap. He strips the flap off in five minutes, pushes the rectocele back into the vagina and brings together the ends of the transversus perinei muscles, because in there are fascia and muscles all together. Commencing at the upper angle of the denuded surface (the high point of the rectocele) the sutures are entered on the mucous surface and passed obliquely downward under the denuded surface on one side and back in a reverse manner on the opposite side. Two or three sutures are passed in this way; when tightened they draw the rectocele up into the vagina and allow the fascia and musculature of the levator ani of either side to be brought in contact with each other in front of the rectocele, where they naturally belong. Then the ends of the perinei muscles are brought together with two sutures and tightened and the perineum is restored as satisfactorily as is possible.

Dr. J. H. BURTENSHAW agreed with Dr. Craig that the operation must in every case be adapted to the pathologic condition present. No single operation is applicable to every case of laceration. Dr. Burtenshaw said that the underlying principles of repair of a wounded pelvic floor, which he had attempted to emphasize, are simply these: First, in the case of primary repair, the edges of the torn muscles and fascia are raw, and will unite if properly approximated by sutures; second, when months or years are permitted to elapse before operation, unless these muscular and fascial edges are individually freshened they will not unite, but will be held in apposition only so long as the tightly-drawn sutures remain in place. It has not been denied that practically every colpoperineorrhaphy, as performed to-day, is a superficial operation, a portion of the muscular wall of the vagina being denuded and backed up against itself, in which position the surfaces unite. He does not advocate the Hegar operation in preference to all others, but asserts only that exaggerated claims are made for the Emmet method which are not borne out by the pathologic entities present. He acknowledges that, in the presence of a Y-shaped tear, if Emmet's method provided for the isolation, freshening and suturing of the separated muscles and fascia, it would approach the ideal; but it does not do these things; it is a superficial operation like the others and, therefore, does not accomplish more than the simpler Hegar. In the closure of an abdominal wound a special effort is made to accurately approximate the several layers of tissue; and the parts are restored practically to their former normal condition. In pelvic-floor lacerations these principles are completely ignored, or at least the object is frustrated by the technic adopted, yet a similar claim of normal restoration is made, and entirely without foundation in fact.

Centenary of the Author of the Wandering Jew.—It is not generally known that Eugene Sue was a navy surgeon before he acquired fame as a novelist. He was born in 1804, and his centenary will be duly celebrated at Paris, December 10.

TYPES OF CHILDREN.

W. S. CHRISTOPHER, M.D.

CHICAGO.

(Concluded from page 1623.)

There is a condition found in new-born babies, and usually confounded with sepsis neonatorum, which seems to me to be entirely autotoxic in character. This condition is often manifested on the first day of life, but may be delayed two or three days. The symptoms are vomiting, cardiac depression, poor circulation, frequently cyanosis, irregular and weak respiration, convulsions in the severer cases, and special symptoms on the part of the bowels and skin. The stools, which are generally frequent, do not become yellow, but remain green, and contain considerable mucus. A peculiar skin eruption appears about the third day, but may be delayed for a week or even more. This eruption consists of pustules, so small that their pustular character is often overlooked. These pustules are located principally on the upper portion of the chest, the neck and chin, and in the bends of the elbows. About each pustule is a slight red areola. The pustules are never close together, and in a marked case they may not number more than 50 altogether. They very quickly dry up and scale off. Sometimes there is fever present. In one case I found temperature twelve hours after birth, in another four and one-half hours, and in a third two hours after birth, and in each case the mother was free from fever, both before and after confinement. This early appearance of elevated temperature under the circumstances can hardly be attributed to anything but an autotoxic condition. At least, we know of no infection that could produce it. In no case have I found the navel other than apparently normal. In all these cases there is deficiency of urinary secretion, and the urine itself is often dark. I have records of the urine of two of these cases, one of which recovered and the other proved fatal on the twentieth day.

Of the first case I have six analyses, which were as follows:

	Age—					
	14 Days.	17 Days.	18 Days.	23 Days.	31 Days.	38 Days.
Acid	8.0	0.5	0.8	0.4	2.0	1.1
Urea	1.55	0.1	0.15	0.17	0.1	0.025
Indican	0	+	+	0	0	0
Safranin12	.5	2	.5	.5	0

The second child was found to have a temperature of 101.5 four and one-half hours after birth. The temperature never became normal. The child was seen in consultation with Dr. Sawyer of South Bend, Ind., a few days before its death. The urine obtained the day before its death showed acid, 7.5; urea, 1.6; ind., 0; saf., 3.

The urine of young infants is normally very pale and of very low specific gravity. In estimating the constituents the figures obtained are often so small that they seem unimportant, and when compared with the norms previously given they at first give the impression of being entirely without significance. When, however, the numerical relations of these constituents with each other is determined, a different situation is revealed. If the ratios of normal acidity to normal urea, and of normal safranin to normal urea be determined for each year of childhood and the results charted, very significant curves are found.

These ratios are given in Table 2, and the curves drawn from them are shown in Chart 3.

TABLE II.

Age.	Ratio Urea Per Cent., to Safranin Index.		Ratio Urea Per Cent., to Acidity Index.	
	Males.	Females.	Males.	Females.
0	1.31	1.11	2.69	2.59
1	0.98	0.88	2.12	2.13
2	1.05	0.94	2.07	1.93
3	0.97	1.03	1.87	1.93
4	1.02	0.95	1.92	1.75
5	0.89	0.82	1.83	1.75
6	0.85	0.75	1.76	1.67
7	0.86	0.85	1.74	1.86
8	0.84	0.73	1.51	2.49
9	0.92	0.81	1.82	2.45
10	0.83	0.72	1.71	2.45
11	0.84	0.95	1.79	1.61
12	0.79	0.92	1.51	1.63
13	0.70	1.01	1.38	1.66

The safranin-urea ration curve shows that the excretion of physiologic sugar is relatively high during the first year of life, lower during the next four years, and lower still during the next six or seven years. That the ratio should be kept high during the first years of life is not surprising, when we recall that during fetal life the liver is a glyeogenic rather than a urea-forming organ. The high acidity ratio is also indicative of possible acid toxemias during the first year of life, and we know from clinical experience that such is the case. But I have shown these curves principally for the purpose of show-

history, with ultimate perfect recovery and gain in weight, but the urinary history of the first few days that she was under observation are interesting and instructive. The urine was entirely negative, except as to acidity and urea, which was as follows for five consecutive days:

	Age.			
	30 Days.	31 Days.	32 Days.	33 Days.
Acidity	0.6	0.7	0.4	0.3
Urea	0.00125	0.00250	0.0025	0.005
Ratio of urea to acidity	480	280	160	80

The actual acidity is certainly not high; lower, indeed, than the normal. But the relative acidity compared to the urea is simply tremendous. We further note that the alkali produced little or no effect on the acidity, but under its influence the urea rapidly increased. Croftan has said that the organism is so jealous of its alkalinity and guards it so carefully that when fixed alkalies are wanting it uses ammonia molecules that would otherwise be built up into urea, thus cutting down the urea formation. It looks very much as though this was the process going on in this baby. We must further notice how Nature in her effort at protection

Chart 3.—Ratios of safranin and acidity to urea (urea being considered as 1.0). Solid line, boys; dotted line, girls.

ing their application in interpreting urinary findings in infants. Patty C. was first seen when one month old; had been colicky since third day of life; much flatulence requiring many enemata; stools generally dark green, with small seed-like lumps, and thin, odor often offensive, not sour. Has had no fever. An eruption said to have appeared when one week old, which lasted three days, and which was described as consisting of miliary pustules on red background, generally distributed over the whole body, but especially marked on neck and chest. On the second, third and fourth days of life urine showed brickdust deposit, but clear and free since. Weight a little less than at birth. The child was put on a mixture of cream one part, water three parts, boiled, and the coagulated lactalbumin removed. Was also given calomel gr. 1/24, q. three hours, and one-half teaspoonful soda bicarb. daily. Colic immediately became less, and in three days the child was quite comfortable and had gained 2 ounces in weight.

It is unnecessary to follow further the ups and downs of this baby, which were mere repetitions of the previous

produced a profuse diuresis. While the normal ratio of acidity to urea at her age is 2.59—say 3 for the sake of round numbers—it was here on the first day of urinalysis 480, on the next 280, next day 160, next 80, and on the last day of the series 6, and with the return to approximately normal ratio, was a return to normal comfort. These tables of ratios, since I have had them, have explained to me many otherwise inexplicable urines.

Another phase of the subject involves the relation of urea excretion to body weight. I have accepted as the normal rate of daily urea excretion 500 mg. of urea per kg. of body weight, or one two-thousandths of the body weight. Some children persistently excrete an excess of urea. This may be due to two causes—either excess of ingestion of nitrogenous food by children whose urea excretion would otherwise be normal, or to excessive disassimilation. This latter condition is, of course, found in fevers, but I here refer to children free from fever, and who would lose weight rapidly if they did not make up for the loss of nitrogen by heavy eating.

Children of this latter class are generally underweight and gain very slowly. They must be carefully distinguished from children who are under weight and size, because of hereditary tendency to smallness, and from children who from deficient appetite fail to take sufficient food. The particular class to which I refer I commonly call the greyhound type because no amount of food can make them stout.

In estimating the significance of various physical measurements, I have found very convenient the tables of norms worked out by the corps of the Child Study Department of the Chicago Public Schools under my direction as chairman of the department. These norms are based on the measurements of 6,259 pupils of the Chicago schools, selected as to neighborhoods, so as to secure data from children in fairly comfortable walks of life. When measuring each child its birthday was recorded so that its age in years, months and days could be computed. From these data norms were computed to the even years and half years of school life, with the average monthly variations. When I measure a child I put down at the head of the column its exact age, and after each measurement, the age in years and months for which the particular figure is normal; this I call his weight-age, height-age, etc. This explanation is necessary for the ready understanding of what is to be said of the case about to be reported, illustrating excessive urea output with failure to gain weight.

Robert B. first came under observation at the age of 7 years and 12 days. The following table illustrates his progress:

Age in Yrs. and Months.	Increase.	Weight-Age.	Increase.	Height-Age.	Inc.
7 and 0	2	5 and 0	..	7 and 9	..
7 and 2	2	6 and 4	16	8 and 1	4
7 and 6	4	6 and 11	7	8 and 7	6
8 and 3	9	6 and 7	8	9 and 1	6
9 and 3	12	8 and 1	6	10 and 0	11
9 and 9	6	8 and 4	3	10 and 3	3
10 and 1	4	8 and 8	4	10 and 7	4
	37		44		34

In thirty-seven months' time this boy made a weight increase of forty-four months and a stature increase of thirty-seven months, and was still seventeen months below the average weight for his age, although six months' taller than the average. The large weight increase during the first two months was partly, probably largely, due to the fact that when the first weight was taken he was just recovering from a rather severe illness. If this be thrown out, there remains only an increase of twenty-eight months' weight in thirty-five months' time, notwithstanding the efforts which were being made to increase his weight. That these efforts were of some value is shown by the fact that during a certain twelve months he made his slowest increase in weight, and during this particular time he was not under observation. During the periods he was under observation, he was seen many times, and his weight was very variable, but showed a slow general increase. During this time I made 31 analyses of twenty-four-hour collections of urine. In 3 only of these analyses was the urea output below normal, i. e., less than 500 mg. per kg. of net body weight. The lowest output found was 350. Twenty-eight times the urea output was above normal, the greatest being 1,032 mg. per kg., and the average urea excretion for all the 31 examinations was 707 mg. per kg. In each case the net body weight was determined by subtracting from the weight with ordinary indoor clothing 51½ per cent. of that weight, which gives remarkably accurate results. The other peculiari-

ties of this boy, which are also characteristic of the class he is intended to typify, are rapid pulse, quick perception, high grade of intellect generally, ready response to all kinds of stimuli, a nature extremely sensitive to rebuke, pupils often dilated. In this boy the thyroid isthmus is large, which is not always found in children who belong to the same class. Two younger sisters of this boy have clinical histories practically identical with his. As to his heredity, his mother was slender as a child, although not so now, and has very large eyes, but no prominence of the eyeballs. His father, a successful business man, is described as small, active and nervous. On both sides of the family there has been some mental trouble. The family is Jewish, and in my experience there are more such children among the Jews than among Gentiles.

I am inclined to correlate with this type of children, those infants who without gastroenteric or other local or infectious disease of any kind, persistently fail to gain weight, so that at nine or ten months of age they may weigh only nine or ten pounds. After a certain time these infants generally suddenly change and rapidly become of normal weight, and so also do older children of this type, and in adult life it is not uncommon to find obesity. This statement I base on personal knowledge of several individuals whom I knew sufficiently well in childhood to confidently put them in this class. The two well-known pictures of Napoleon Bonaparte as lieutenant and as emperor, together with what we know of his physical and mental peculiarities, would apparently put him in the same class. These are the children who are the little frail, bright pupils at school, frequently among the youngest in their classes, who constitute the great exception to the law that superiority of physique and superiority of mind go hand in hand, while inferiority of physique and inferiority of mind are likewise associated.

Since writing the foregoing, Robert R. and his sisters again came to the office. May 12, 1904, after an absence of nineteen months, eight months of which were spent in various parts of the continent of Europe.

On this date his measurements were as follows:

Age	11-7-25
Weight	29.650 kg.
Weight-age	10 and 5
Height	1,409 mm.
Height-age	12 and 3
Height, sitting	722 mm.
Height, sitting-age	11 and 0
Urea factor	638

When the Chicago school measurements were made, the cards representing the several individuals were separated into sexes and years. Then for each measurement for each year and sex, the cards were arranged in order, from the greatest to the least. They were then divided into ten equal groups, and the measurements at the beginning of each group recorded. These tables enable us to determine the percentile group into which any measurement of any child will fall. Applying these percentile tables to Robert R., taking his measurements of June 27, 1902, and May 12, 1904, for comparison, the following is found:

	June 27, 1902.	May 12, 1904.
Age	9-9-10	11-7-25
Weight (percentile group)	20—	20+
Height (percentile group)	70—	70—
Height, sitting (Do)	40—	40—

This shows that he still belongs to the same type which he did two years ago.

His sister Helen who, while she formerly presented the features of the same metabolic type as Robert, never presented those features in as marked a form, has now entirely departed from the type. Figures for her. cor-

responding to the above table relating to Robert, are as follows:

	June 27, 1902.	May 12, 1904.
Age	6-4-6	8-2-21
Weight (percentile group)....	30	60+
Height (percentile group)...	30	30+
Height, sitting (percentile group) 20		20—

Her urea output was 424 mg. per kg. These figures take her entirely out of the class to which she formerly belonged, and her general appearance fully supports this view. In the third child of the family the type persists.

What is the reason for the existence of this type? These children certainly seem to be individuals with excessive thyroid activity. So far as their peculiarities go, they are those of Graves' disease of later life. Many of their symptoms are produced by the administration of desiccated thyroid. For me such children represent the puerile form of Graves' disease, from the accepted form of which they differ only in degree.

Whether from the children in whose urine the physiologic sugar runs high, as shown by a high average safranin index, the diabetics of later life are recruited, it is as yet impossible to say.

How are the children with high acidity to be classified? As shown in Table 1, high safranin is generally associated with high acidity. Also in diabetes certain acid toxemias are among the gravest manifestations. On the other hand, high acidity is found more commonly than either of the other abnormalities here considered, and also is found to exist without either of the others and independently of indicanuria. Hence high acidity of urine, while undoubtedly of complex origin, is most commonly found in conditions which do not even remotely suggest either diabetes or hyperthyroidism. This independent cause I shall tentatively speak of as gout, because it is usually accompanied by symptoms which we are prone to associate with gout. Urines which contain excess of urates are highly acid. Some urines with excess acidity seem not to be toxic.

This deduction seems justifiable. In children three diathetic states are determinable by urinary findings and anthropometric observations which correspond to three great metabolic diseases of adult life, viz., gout, diabetes and Graves' disease. Is Addison's disease, the fourth great metabolic disease of adult life, represented in childhood? I do not know, but I have suspected it when watching those rare and fatal hemorrhages of the newly born. In one of these hemorrhagic babies I found a toxic urine, and treatment directed to this condition for a time seemed to stay the disease, but ultimately death ensued.

In considering these diathetic conditions, it must be borne in mind that they are all manifestations of peculiar metabolism and that the resulting symptoms are explicable as evidences of autotoxemias. The mechanism of autotoxemia may be considered as follows:

1. The toxins may act directly on the nervous system, producing symptoms referable to it.

2. The effort to rid the body of the offending agents leads to efforts at vicarious elimination with frequent production of pathologic states in the vicarious eliminating organs.

3. In a secondary way the toxins produce disturbance of general nutrition.

The following effort at a partial classification of the symptoms found in these autotoxemias may be found useful:

CENTRAL NERVOUS SYSTEM.

SENSORY.	
Pain	Vomiting
Various neuralgias	Aschma
Headache	Somnambulism
Paresthesia	PSYCHIC.
Disturbed sleep	Bad temper
Morfon.	
Convulsions	
Epilepsy	

VICARIOUS ELIMINATING ORGANS.

Vaginal catarrh	Eyes—
Vulvar catarrh	Conjunctival catarrh
Balanitis	Phlyctenular keratitis
MUCOSAE (CATARRHS).	
Gastroenteric tract—	SKIN.
Stomatitis	Eczema
Mucous diarrhea	Erythematia
Serous diarrhea	Furunculosis
Gastric catarrh	
Appendicitis (?)	
Respiratory tract—	
Nasal catarrh	
Bronchial catarrh	
Tonsillar involvement	
Genital tract—	

GENERAL NUTRITION.

Weight anomalies. Excessive weight. Deficient weight.

It might be well to make this distinction between diathesis and autotoxemia as here used. Autotoxemia is due to the occurrence of poisons produced in the body in sufficient quantity to cause symptoms. Diathesis is the type of metabolism which produces the autotoxemia. In other words, the autotoxemias are the principal ways in which the diatheses manifest themselves.

In considering the management of the diatheses and their autotoxemias, the autotoxemias demand first attention. The efforts are to be directed toward neutralization and elimination of the poisons. In the acid toxemias the alkalis hold the first place as therapeutic agents, and of these the potash salts have proven the most serviceable in my hands, with the soda salts next. Lithia has not been so useful. The quantities given must be large enough to reduce the urinary acidity to normal and keep it there. Mercury is extremely serviceable, and so also is colchicum. When the alkalis are given freely over a long time, and the tongue becomes coated, hydrochloric acid may be given with them; it does not increase the acidity of the urine under these circumstances. The high degree of physiologic sugar in the urine which is so commonly found with high acidity is efficaciously managed on the same lines. I do not know of any specific drug treatment for it.

The thyroid type of trouble, though less common in occurrence than either of the other two, is more constant in its manifestations. The drugs which have been most serviceable to me in its management have been arsenic, in the shape of sodium cacodylate, which is well borne in large doses, desiccated thymus (not thyroid, the use of which in such conditions has always seemed to me most illogical) and opium. In treating any of these autotoxemias, it must not be forgotten that the toxins absorbed from putrefying bowel contents often assist in producing the symptoms, and must be taken care of in ways which are well understood.

Dietetic management is directed principally to the diatheses themselves, for they certainly may be influenced to some extent by diet.

In infants, in whom the acid diathesis is very common, diet is the best means at our disposal in its management. Some of these acid babies do fairly well on the breast, but when the condition is very marked it is a proper cause for weaning. Fresh milk is badly borne by these babies, and fresh cow's milk is decidedly worse than breast milk. Cooked milk, however, is very useful. Sometimes sterilizing the milk is sufficient to fit it to these babies; in other cases the milk must be actually boiled and the coagulated lactalbumin

removed. With others it is necessary to resort to milk so thoroughly cooked as condensed milk, and even in some instances to use the dried milks. Condensed milk is generally the best, and condensed milk has a large field of usefulness with babies with acid diathesis, and that means with a large number of babies. I am, of course, perfectly familiar with the fact that condensed milk is accused of being a most powerful agent in the production of rickets and scurvy, and I have been loth to follow its use. I am not advising the indiscriminate use of condensed milk, but I am testifying to its utility for babies who have the acid diathesis. It is to some extent serviceable with thyroid babies. Any one who watches his bottle-fed babies and to those who are on condensed milk gives orange juice and cod-liver oil, need not worry about scurvy and rickets. I have fed many babies on condensed milk, but I have watched them carefully, as I do all bottle babies, and I have yet to see a case of scurvy develop in them, and no more rickets than occurs in other forms of feeding.

I have described several cases to illustrate certain points, and shall here give another to illustrate the point just made. This case is by no means unique in my experience, but it has always been a type case with me, perhaps because it occurred rather soon after my conversion to the utility of condensed milk:

Willie S. was on the breast for three weeks and one week on a milk and barley mixture, and then on Walker-Gordon modified milk, which was doubtless prepared *secundum artem*, as the formulas were prescribed by the laboratory people themselves. He was always a vomiting baby and had had colic from three months to four and one-half months. His weight at birth was 8½ pounds. He was brought to me Nov. 17, 1896, at the age of 5 months. He then weighed net 10 pounds 2 ounces. He was immediately put on condensed milk. At the end of a week the vomiting was reported as much less, sleep good, and he had gained five ounces in weight. In three weeks he had gained one and one-half pounds and the vomiting had practically ceased. At 10 months of age his weight was 20 pounds net and he had three teeth. There was some beading of the ribs, but this was noted as present when first examined, and he had had cod liver oil most of the time. At 13 months he weighed 23 pounds 3 ounces net and had seven teeth. He was kept on condensed milk until he was about 20 months old. The original rickets made no headway and there never was any scurvy. He was last seen April 24, 1901, then nearly 5 years old, while on a visit to Chicago. He was then a fine, healthy boy, weight 40 pounds 7 ounces, and stature 1,045 mm. net. What modifications were made in his food by the laboratory people I do not know; they certainly, however, did not control the vomiting, while they succeeded in producing marked deficiency in weight and great malnutrition. It is doubtful if this boy would have survived if he had been kept on his fresh milk. The trouble lay in the lactalbumin, and when this was rendered indigestible and hence unabsorbable by the process of condensing, the baby's difficulties ceased.

Fresh milk is poisonous to quite a number of babies. I remember a baby—its type I can not tell you, as it was before the days when I began to differentiate babies into types—that was very badly nourished on Nestle's food. I recommended fresh milk. The mother demurred, saying that fresh milk always made the baby sick. I was not convinced, believing then that any baby could take fresh milk, and after cleaning out the intestinal tract put the child on a fresh-milk mixture that would with a normal child have been satisfactory, but with this child, however, it produced serious vomiting and diarrhea in a few hours. After a short time on arrow root, it was again put back on the fresh milk with the same result. I then put it back on the Nestle's food to get time to think. After matters straightened out

on the Nestle's food, I tried the baby on equal parts of prepared Nestle's and the fresh-milk mixture. Again disaster. Then I put a single teaspoonful of fresh milk in the Nestle's food. This was borne, and slowly the fresh milk was increased, one teaspoonful at a time. It bore well six teaspoonfuls in each feeding, but when seven teaspoonfuls were used vomiting and diarrhea followed. The variation between six and seven teaspoonfuls was tried a number of times until both the mother and I were convinced that while the baby could stand the six teaspoonfuls it could not stand seven. I am quite sure that if prior to this experience any one had told me that any baby's stomach could make such a differentiation, I should have denied it. Some years ago a baby came under my care at the age of three months, covered with an ugly eruption, partly eczematous and partly furunculular. It was in constant pain and very badly nourished. This baby seemed to me to be of the thyroid type, and I put it on beef juice exclusively. In about a week the eruption cleared up and the pain ceased. Later arrow root was added to its diet, and some two months later it was able to take some milk with its arrow root and beef juice. Throughout the life of the thyroid child the beef proteids seem better borne than the milk proteids.

Why do children show diatheses? At birth the child is a very incomplete human being. Its anatomic deficiencies are obvious. Its physiologic or chemical deficiencies are less obvious but more important. Attention is often called to the crisis through which the child passes at birth when its heart changes from a three-chambered to a four-chambered organ. Yet this is trifling compared to the crisis which occurs when the first food enters the stomach, and that organ suddenly assumes entirely new functions; when the products of digestion reach the liver and that organ commences a series of heretofore untried chemical processes; when the products from this new organ, instead of those from the old, practiced and well-developed liver of the mother, start on their way through the circulation to do good or to do harm. It would be absurd to suppose that the physiologic processes of the new-born baby are completely developed when the anatomic elements are so markedly deficient. We know positively that these processes are not the same as those of the adult, otherwise the infant could utilize the same food as the adult. It is because of this physiologic incompleteness that autotoxemias occur, and this also explains the greater frequency of autotoxemias in childhood than in adult life, and their still greater frequency in infancy.

It may have been noticed that in describing the acid and saccharin diatheses, I described them together, not making a sharp line of distinction between them. This is in accordance with the facts as I have observed them. All these diathetic conditions constantly intermingle with each other, and at times one or another seems to exist alone, to be in its turn supplanted by another. Of them the acid or gouty toxemia is by far the commonest; next in frequency come the saccharin or diabetic manifestations, and least frequent of all is the thyroid type. As age increases and organs develop, one diathesis after another normally disappears. How fine it would be if we should hereafter find out that the great metabolic diseases of later life—gout, diabetes, Graves' and Addison's diseases—are but the exaggerated outgrowth of conditions found normally enough in early infancy. It would be the chemical analogue of Cohnheim's theory of the origin of new growths.

Clinical Report.

DISLOCATION OF THE CARTILAGE OF THE NOSE.

IRVING McNEIL, M.D.,
MESCALERO, N. M.

The following unusual case seems of sufficient interest to deserve publication:

Patient.—Mrs. W., Mexican, 30 years of age, came to me Aug. 1, 1904, complaining of a "sore nose."

History.—About a year before she accidentally struck her nose violently against a door. There was no hemorrhage, nor even broken skin, but the blow was a severe one, and her nose had troubled her ever since, hurting severely one week, and appearing to get almost well another.

Examination.—Inspection showed nothing abnormal except a little redness and swelling about the lower left ala. On palpating the nose lightly with my finger there was a most peculiar sensation of something slipping or giving way beneath. This also caused some pain.

I diagnosed dislocation of the left lower lateral cartilage of the nose. Ordinarily there was no displacement because the elasticity of the surrounding tissues held it in place. Yet it had not been allowed to remain in place long enough for complete repair to be effected; being moved about in the act of blowing the nose.

Treatment.—The indication—fixation—was clear, but how to accomplish it satisfactorily was a problem. Adhesive plaster could not be applied so as to give sufficient firmness; and an ordinary plaster mold could not be fastened on without binding up the patient's whole head. I adopted the following method, which proved successful: After protecting the surrounding parts and covering the nose with a very thin coating of vaselin, I applied over the entire projecting part of the organ a coat of flexible collodion. Quickly, before this could harden, I sprinkled in plaster of paris. Then, waiting a moment for it to "set," I applied in a similar manner another layer of collodion and another layer of plaster, and so on until there was a mold over the nose one-eighth of an inch thick. When finished, this was nearly as hard as an ordinary plaster mold, and held on securely by the adhesion of the collodion.

Result.—As the patient lived some miles away, I did not see her again, but several weeks later her husband told me that the cast had come off of itself within two weeks, that there had been no recurrence of the trouble since, and that his wife's nose seemed to be perfectly well.

New Instrument.

A RECTAL VALVE CLIP WITH APPLICATOR.

WELLS TEACHNOR, M.D.
COLUMBUS, OHIO.

Since the operation of valvotomy has been established as a means of relief from obstinate constipation or obstipation, the tendency has been to simplify the armamentarium and the operative procedure.

I have devised an instrument in the form of a clip, which painlessly divides the muscular fibers contained in the rectal valve in from three to five days without fear of hemorrhage or peritonitis. Figure 1 represents the applicator with clip in its grasp, ready for application to the hypertrophied valve. The clips are made in three sizes, short, medium and long. Each consists of two fenestrated elliptical jaws controlled by a set-screw (Fig. 2). The apposing surfaces have a slightly elevated serration in their center running from the base of one side around the tip to the opposite side. This represents the cutting surface. On the outer side of the serration is a narrow, smooth surface that makes enough gradual pressure to produce sufficient inflammatory exudation to

seal the blood vessels and lymphatics. This prevents hemorrhage and infection. At the base of the apposing surface a slight elevation is made so that when the screw is driven home the pressure will be the same at the tip as at the base. At the base of each jaw, directly opposite the center of the screw, is a slight oval depression to receive the end of the

Figure 1.

applicator. The applicator consists of two forcep handles and blades nine inches long, armed with a lock. Running parallel with and between the blades is a screwdriver which fits in the head of the screw when the base is properly grasped. It has play back and forth of about half an inch, to accommo-

Figure 2.

date the inner jaw of the clip when adjusted for application (Fig. 3). The advantages claimed for this instrument are as follows:

First, the clip presents a perfectly smooth surface and will not irritate the surrounding gut wall nor become entangled with the fecal matter.

Figure 3.

Second, the pressure can be regulated by the set-screw.

Third, the simplicity and ease with which the applicator is released when the clip is firmly adjusted on the valve.

Fourth, it places the operation in the hands of any competent physician or surgeon.

187 East State Street.

Psoriasis.—Pouffé concludes from a study of the subject that psoriasis is due to a slow chronic intoxication from defect of the internal secretion of the ovary or testicle, thus failing to neutralize cellular poisons formed in the system by failure to oxidize substances due to vitiated nutrition. The disordered cell function in arthritis, instead of a zymase, diastase or ferment needed in the general nutrition, produces a pathogenic secretion especially acting in the local manifestation of psoriasis. This indicates a serious trouble of cellular nutrition requiring a general internal medication to neutralize the toxin and favor its elimination.

ARE THERE PSEUDODIPHTHERIA BACILLI VIRULENT
FOR MAN?

For a long time it was thought that the clinical and anatomic picture of typhoid fever was always caused by one definite organism, namely, the typhoid bacillus. But when systematic bacteriologic examinations of the blood came to be made during the life of patients suffering with infections diagnosed clinically as typhoid fever, it was soon learned that a small percentage of these patients were suffering not from typhoid fever in a strict etiologic sense but from infections with bacilli closely related to, yet different from, the typhoid bacillus and thus the existence of paratyphoid fever was established. Later careful clinical and anatomic studies have shown that paratyphoid fever may differ considerably from typhoid fever in its clinical course as well as in the nature of the anatomic changes it produces. This differentiation in so thoroughly studied a disease as typhoid fever may be held up as a lesson indicative of similar possibilities in other equally well-trodden fields when submitted to careful and critical, open-eyed investigation.

The question of the relationship between the bacillus of diphtheria and the so-called pseudodiphtheria bacillus has been the subject of much and constant controversy ever since 1887, when the "pseudodiphtheria bacillus" was first described by Loeffler and by Hoffmann-Wellenhof. The general medical reader is probably not interested in the details of the various methods—cultural and morphologic—that have been emphasized as important, even essential, in the differentiation between diphtheria and pseudodiphtheria bacilli, but only to be abandoned because unreliable and inadequate for the purpose. Even the belief that the so-called pseudodiphtheria bacilli were non-virulent to animals has had to give way to the results of recent experiments. It is true that the bacilli of the pseudo group appear to have only moderate degrees of virulence, but it must be remembered that members of the diphtheria group proper may manifest the most varying degrees of virulence for animals. If we grant that bacilli, resembling each other so closely as to be with great difficulty, if at all, distinguishable by means of morphologic and cultural characteristics, are virulent, then the question arises, what is the nature of this virulence? If the pathogenic effects are promptly neutralized by means of diphtheria serum, then the problems involved would be greatly simplified, inasmuch as we would appear to be dealing with

a group of organisms which, though distinct in many respects, yet are identical in the most important feature from the standpoint of practical medicine, namely, the nature of their pathogenic action. But, unfortunately as it would seem, the recent work of Spronek, E. H. Ruediger, and Alice Hamilton shows that by the method just now suggested it has been found that there exist virulent pseudodiphtheria bacilli the pathogenic effects of which can not be neutralized with diphtheria antitoxin. Indeed, the mode of pathogenic action of the pseudobacilli appears to be radically different from that of the diphtheria bacillus which is a typical toxicogenic germ, the infection remaining local while the toxins are absorbed, whereas the pseudobacilli cause a general invasion of the blood. And Alice Hamilton,¹ in a careful study of a variety of pseudodiphtheria bacilli, isolated principally from the throats of scarlet fever, measles and diphtheria patients, shows that the loosely constituted group of pseudodiphtheria bacilli contains organisms that differ fundamentally because a serum produced by immunization with one member of the group protects against some but not against all other members of this same group. Hence the term pseudodiphtheria has in the past been applied not only to organisms that are diametrically different from the diphtheria bacillus, but also differ radically among themselves.

Naturally the next question that suggests itself will be: Does this group contain organisms virulent for man, and if so what is the character of the clinical picture? This question can not be answered dogmatically as yet. The facts and observations necessary therefore are now being gathered. Yet the following instance from Hamilton's article can not but be suggestive and instructive:

"No. 11 was isolated from the throat of a child who, without appearing very ill, had swollen tonsils covered with a delicate, veil-like exudate. Smears from the throat showed typical diphtheria bacilli, and 2,000 units of antitoxin were administered. At this time the child was playing about the room, but soon after the injection of antitoxin his temperature rose, he became markedly worse, and died in less than twenty-four hours. Pure cultures from the throat on Loeffler's serum showed short and long, straight and curved, rods with Neisser granules, which, however, were of narrower diameter than the rods. On all culture media the growth resembled that of a diphtheria bacillus. Less than 1 per cent. of the body weight of a broth culture killed guinea-pigs in twenty-four to forty-eight hours, producing a general bacteriemia and no change in the adrenals. Diphtheria antitoxin exerted no protective influence; indeed, the animal's injected with it died somewhat earlier than those without (six to eight hours). On the other hand, the Ruediger serum [a serum produced by immunization with a virulent pseudobacillus] did protect, so that we have here again a virulent pseudodiphtheria bacillus"

Cases like this teach the lesson that every instance of apparent failure of diphtheria antitoxin, whenever possible, should be subjected to rigid bacteriologic study with diversified animal experiments. Such cases should not be explained off-hand as due to mixed progenic streptococcal infection; this may explain many such cases, but in all probability it can not account for all. It is self-evident that if it should prove true that the general clinical picture of diphtheria may be caused by bacilli other than the true diphtheria bacilli, and consequently not prove amenable to diphtheria antitoxic serum, then this of course would not in any way reflect on the efficacy of this serum, which in the nature of things can not be expected to have any curative effect on infections of a radically different nature than the one we are wont to call true diphtheria. A rapid means of diagnosis would be demanded, as well as proper specific means of treatment, for the "new disease."

In view of the natural tendency of many minds to resent all disturbances in conditions long regarded as well established, let us take to heart once more the great truth contained in these words of Huxley: "Sit down before fact as a little child, be prepared to give up every preconceived notion, follow humbly wherever and to whatever abysses nature leads, or you shall learn nothing."

THE YOUNG PHYSICIAN AND MEDICAL DISCOVERY.

An old Greek philosopher said that if a man had not accomplished something worth while before he was forty, there was not much use looking for anything novel and original from him. In more modern times it has been said that unless a man has written a successful book during his first two-score of years he is not likely to do so afterward. In general, there is the feeling that if a man has not proved himself possessed of a talent for investigation before early middle age is passed, he may succeed in doing conventional things reasonably well and may make a commonplace success in life, but he will scarcely accomplish anything that will really enlarge the scope of knowledge. As a matter of fact, while old men have made many great discoveries, it is mainly to young men that the world owes those steps across the boundary of the unknown which constitute landmarks in the development of knowledge.

There is a very interesting exemplification of the truth of this principle in the history of medicine. Most of the important discoveries have been made by comparatively young men. Morgagni, for instance, began the famous set of "Adversaria," or note-books, in which he set down the details of the clinical history of the patient side by side with the autopsy findings, when he was as yet only a medical student not out of his teens. This seems a simple and ordinary thing to do now, but it was the beginning of the modern science of pathology. It is because he carried out in after-life the work

thus begun that Virchow referred to him at the International Congress at Rome some ten years ago as the father of modern pathology. Virchow himself, it may be said in passing, was only about twenty-five when he began his series of noteworthy observations in pathology, and before he was thirty-five the whole idea of his cellular pathology had taken form in his mind.

Auenbrugger, to whom we owe the beginnings of modern physical diagnosis and the demonstration of the value of percussion as a means of recognizing and differentiating conditions within the thorax, got his genial idea before he was thirty, and worked it out during the years between thirty and forty. Laennec, the discoverer of auscultation, who so amply complemented Auenbrugger's work in physical diagnosis, began the regular observations on which his method of diagnosis was founded in his early twenties. He continued his studies of the subject faithfully for twelve years before he published his famous book, which appeared before he was thirty-five. That book is probably the greatest marvel in medical literature of exact and absolutely accurate observation combined with careful determination of the etiology of symptoms observed.

About the time that Laennec was doing his work in Paris, Corrigan, at the age of twenty-five, began making observations on aortic disease in Dublin. He completed and published his observations¹ in 1832. His essay of scarcely ten pages establishes definitely for all time the knowledge of aortic insufficiency, or, as it was then called, permanent patency of the mouth of the aorta. Trousseau, the greatest of living clinicians of the time, suggested that aortic disease should henceforth be called Corrigan's disease, so completely did the young Irishman settle all the disputed points with regard to it. When he published his essay he was only twenty-nine years of age, and the hospital in which his observations were made had only six beds for medical patients. Corrigan was evidently a man who studied cases faithfully and did not merely go through wards seeing patients.

Stokes, who was Corrigan's contemporary in Dublin, published his first book on the use of the stethoscope when he was twenty-one. The instrument was almost unknown out of France at the time, and Stokes' little book did more to advance the cause of physical diagnosis in the English-speaking countries than any other contribution to medical literature. Before he was thirty, he had described the form of breathing now referred to as Cheyne-Stokes respiration. His friend, Graves, whose notable first description of exophthalmic goiter ought to prevent its being called Basedow's disease, did his best work also before he was thirty-five. Richard Bright had worked out nearly all we know, even down to the present time, of kidney disease, when he had reached the same age.

1. Edinburgh Med. and Surg. Journal, vol. xxxvii, p. 225.

The one thing that it seems worth while, then, to emphasize for the sake of progress in medicine, is that young men can not too soon begin to do something more than routine work; that they should not allow themselves to be burdened all too much with the complex technic of their generation, but should be encouraged to grasp the opportunity to see things for themselves, and not entirely nor always through the spectacles of the past, or of others.

ALBUMINURIA.

Nothing is simpler in the routine work of the clinician than the detection of albumin in the urine when it is present in considerable quantities. Every physician, however, sees cases in which only traces of albumin are present or in which the reactions obtained are atypical; it is then that he often hesitates to trust his own results, and prefers to send the specimen to an expert physiologic chemist for a definite opinion. So many different tests have from time to time been recommended for the detection of minute traces of albumin, and so many warnings regarding fallacies have been made, that it is but little wonder that the physician who lacks time to follow the advances in analytical chemistry should sometimes become confused. It would be helpful if some chemist in whom the profession has confidence would at intervals "take stock," so to speak, of the various practically important urinary tests, sift out the less essential reactions and present to practitioners, as the result of the application of his critical judgment, a few simple and reliable methods of procedure.

Out of the host of tests for albumin in the urine, a satisfactory selection for the average practitioner might, we think, be made somewhat as follows: In the first place, a very delicate test might be applied, like that of Spiegler as modified by Jolles, which, when applied as a ring test, will demonstrate the presence of as little albumin as 0.002 gram in a liter. If with this very sharp test a negative result is obtained, the urine may at once be pronounced absolutely free from albumin; if a positive result be yielded, confirmatory tests should be made with less delicate reagents—the heat and nitric-acid test, Heller's test, and the test with ferrocyanid of potassium and acetic acid. If all are positive the presence of albumin in pathologic quantity may be safely diagnosed.

Albumin being present, it is desirable to determine if it be serum-albumin or globulin, or both. For clinical purposes the presence or absence of globulin can be ascertained by simply diluting the urine, making sure that it is acid in reaction. Globulin is soluble in salt solutions of the concentration of ordinary urine, but is insoluble in very dilute salt solutions; it falls out as a flocculent precipitate if the urine be well diluted with distilled water. Thus, if 50 c.c. of filtered urine be diluted with 500 c.c. of distilled water, and one or two drops of dilute acetic acid be added, the urine will

remain clear if globulin be absent, but will show flocculi if it be present.

Whether albumin be present or absent, the urine should next be tested for the presence or absence of albumoses. In ordinary practice, as safe a method as any recommended for the purpose is to add five drops of dilute acetic acid and 2 c.c. saturated solution of common salt to 10 c.c. urine; boil and filter while hot; if the filtrate on cooling becomes turbid, albumoses are almost certainly present.

The delicate reagent of Spiegler, as modified by Jolles and recommended above, is not nearly so well known as it should be. The test fluid consists of 10 grams corrosive sublimate, 20 grams succinic acid, 20 grams sodium chlorid and 500 c.c. distilled water. To 5 c.c. filtered urine is added 1 c.c. dilute acetic acid, and this mixture is, by means of a pipette, gently and gradually passed down the side of an obliquely held test-tube containing 4 or 5 c.c. of Spiegler's reagent, so that the acidified urine forms a layer on the surface of the reagent without mixing with it; if albumin be present, a sharp white ring appears immediately, and the precipitate will not disappear on warming.

There has been much demand among physicians for a safe and practical test for albumin in the urine, applicable at the bedside, or, at any rate, at the patient's home. For this purpose there is nothing better than the sulfosalicylic-acid reaction; the physician may carry in his pocket or medical case a small phial of dry crystals of this acid. To apply the test one simply drops a few crystals of the acid into a little fresh acid urine and shakes; if albumin be present, a precipitate will be formed or the urine will become turbid; even if only a trace exists, the urine will gradually become opalescent. This reaction, though very simple, is delicate enough; if the test yield a negative result the urine may be assumed to be free from albumin; if a positive result be obtained, the urine contains albumin, and a specimen should be taken to the physician's office laboratory and examined according to the outline given above.

THE RELATIONS BETWEEN PULMONARY TUBERCULOSIS AND VALVULAR DISEASE OF THE HEART.

It was long maintained that an antagonism exists between valvular disease of the heart and pulmonary tuberculosis by reason of the increased amount of blood present in the lungs as a result of stasis, although the view did not remain undisputed. As a matter of fact, however, the coincidence of the two conditions, while it does occur, is not altogether common. It has also been contended that pulmonary tuberculosis develops especially in individuals with small hearts, cardiac enlargement when present being attributed to complicating conditions.

With the view of studying the frequency and relationship of tuberculous lesions of the lungs, pleura,

pericardium, heart and great vessels, Dr. George W. Norris¹ analyzed 7,040 postmortem records in three Philadelphia hospitals. Among this number there were 1,764 cases of tuberculosis of various kinds. Tuberculosis of the lungs was found so frequently in association with valvular disease of the heart that the conclusion could not be avoided that the latter exerts little or no influence on the former, either inhibitory or curative, even if satisfactory compensation is maintained. Mitral stenosis seemed to be not less often coincident with tuberculous disease of the lungs than other varieties of heart lesion. It appeared doubtful whether smallness of the heart predisposes to pulmonary tuberculosis in greater degree than is explainable by the general systemic underdevelopment and lack of resistance that individuals with such abnormality often exhibit. The heart was commonly found to be small in the bodies of individuals dead of tuberculosis, as the result of either wasting or hypoplasia, while the heart was not often large in uncomplicated cases. Stenosis of the pulmonary orifice seems to favor the development of tuberculosis of the lungs, death occurring from the latter disease in a large proportion of cases presenting the former condition.

Arterial and endocardial thickening is a common result of tuberculosis, but it is doubtful whether this process attains a sufficient degree to give rise to valvular incompetency. Tuberculous endocarditis and myocarditis, particularly the former, occur with considerable rarity, but pericarditis, and especially the chronic varieties, is frequently due to the tubercle bacillus. Tuberculosis of the aorta also is found but rarely. The condition, when present, may result in the formation of an aneurism. The cardiac muscle undergoes various forms of degeneration in cases of pulmonary tuberculosis, fatty and fibroid changes being exceedingly common, a fact that explains the failure of digitalis and certain other heart stimulants to bring about beneficial results in cases of this character. Uncomplicated cases of pulmonary tuberculosis often exhibit such striking differences in resistive power and frequently evince such a remarkable tendency toward recovery, even when seemingly hopeless, that only the most absolute evidence should be accepted as proof that either the coincidence of another pathologic condition or the administration of a special remedy has conferred benefit on the patient.

EXCHANGING PROGRAMS. A HINT TO SECRETARIES.

An excellent suggestion was made at the recent meeting of the Federation of Medical Societies of Belgium, held at Brussels. As given in a brief report of the gathering in our foreign news columns last week, the president, Dr. Merveille, who is also editor of the *Gazette Med. Belge*, called attention in his address to the habit of the secretary of one of the federated soci-

eties of sending to the central office of the federation a copy of each program, notice, etc., issued to the members of his society. Dr. Merveille spoke of the value of the information thus obtained in keeping the central office in touch with what is going on in the branches. Commenting on this he suggested that it would be a splendid thing if all the secretaries would not only do this, but also send to each other these evidences of what each society is doing.

Why would not this plan be a good one for the county societies of each state to adopt? The extra expense would be trifling in comparison with the good that would surely result. It would keep the different societies in touch with what the others are doing and would be a stimulation to more activity on the part of those which are inactive. The secretaries would thus exchange ideas regarding forms of programs and notices, methods of conducting meetings, etc. It would encourage exchange of essayists, for a secretary would learn that a member of another society was to read a paper on a practical subject, and would thus be encouraged to invite the essayist to read the same paper before his society—especially if it proved to be one that was well received. The programs and notices should be sent also to the councilor of the district, and of course to the secretary of the state society. This would be a stimulation and an inspiration to these officers, who in turn would become more interested in the work. Dr. McCormack, in his report of the work in Indiana (see *THE JOURNAL*, Nov. 26, page 1648), spoke of the excellent work being done by one society in a scientific way and by another from the business viewpoint, and yet neither knew what the other was doing; nor did the members of societies of adjoining counties know but that these two societies were as inactive as were their own.

If successful work is to be done it will come through co-operation, even to the exchange of ideas. Co-operation, not only among state societies but among county societies, is the fundamental principle in the new plan of organization, and we believe that the suggestion of the president of the Belgium federation, if carried out in those states which have reorganized, will prove to be most excellent and effective co-operation in scientific work.

HOTEL ACCOMMODATIONS AT THE PORTLAND SESSION.

There seems to be considerable fear that Portland will not be able to entertain the Association in a satisfactory manner, because of the Lewis and Clark Centennial Exposition, which will be open at the time of the session of the American Medical Association. To avoid overcrowding from this cause, arrangements have been made so that no other convention or attraction whatever will take place during the week of the Association session. It is advised, however, that all intending visitors make contract immediately for rooms, so that the managers

1. *Amer. Jour. of the Med. Sci.*, October, 1904, p. 649.

of the hotels will have a fair idea of what they may expect. Mr. H. C. Bowers, of the Hotel Portland, agrees to accommodate 4,000 guests comfortably. There are a large number of buildings going up, and Mr. Bowers is making contracts for every available room that is desirable for the week. The rates will be \$4 per day for each person, two to go in a room without bath, and \$6 per day for each person, for a room with bath. These rates are on the American plan.

I-RAYS AND N-RAYS.

Since the discovery of the Roentgen ray, there has been a vast stimulation of research in this branch of science, but the scientific merits of some of the claims which have been made are still in doubt, while those of others are clear over the line of probability. The N-rays of Blondlot are still *sub judice*, and their reality is doubted by some competent physicists. We are not sure by any means that the really crucial experiments which would demonstrate their existence have yet been made. Now comes the alleged discovery of a still further form of emanations, called by the describer, Di Brazza, the I-rays, closely allied to the N-rays, and given off from the brain during certain psychic processes, such as concentration of the attention. Until these can be proved to be real by physical experiments, absolutely free from suspicion of any subjective errors, it is well to reserve our opinions as to their existence. That they will ever be demonstrated by such positive tests as are the x-rays is doubtful. Now comes a British physician, claiming that the N-rays or something of their character emitted by the human body, vary according to the character and disposition of the individual. There will, perhaps, be other announcements of discoveries of the sort, as there is almost no end to the possibilities of subjective deception and credulity. The desire to correlate the psychic and physical takes on this particular development frequently, but invariably fails in the scientific demonstrations.

MR. HULL AND THE ARMY MEDICAL BILL.

Representative J. A. T. Hull of Iowa, chairman of the House Military Committee, in a recent interview published in the *Army and Navy Register*, concerning prospective Army legislation, is reported to have spoken as follows with reference to the Army Medical Bill now before his committee: "The doctors all over the United States are insisting that the Medical Corps should be increased, but to my mind they are asking too much. They all want to be officers of high rank, and think the flow of promotion too slow for them." Such a statement makes those who have had an opportunity to see the Surgeon General's statement of his case wonder if Mr. Hull can have read this strong and convincing argument. The Surgeon General makes it clear that his corps is nearly 200 officers short of the number needed to do the work of the Medical Department in time of peace, that this deficiency is made up by the obsolete, extravagant and unsatisfactory device of employing physicians under contract, that these contract surgeons, not being commissioned officers, have not the honorable and dignified status befitting members of a

learned profession. As regards the question of rank and promotion, it is shown that in the reorganization of 1901 the Medical Department suffered severe and unjust discrimination—that the proportion in the higher grades asked for by this bill is less than that enjoyed by the Medical Department before 1901, and less than that at present existing in the Medical Corps of the Navy. An examination of the Army list shows that if the Medical Corps is given everything it asks in this bill, the proportion in the higher grades (and so their prospects for promotion) will still be inferior to that existing at present in most of the other staff departments. When it is remembered, in addition, that only the medical officer has to bear the expense of a long and costly professional education, it is difficult to see on what basis of justice Mr. Hull concludes that the Medical Department "is asking for too much."

MEDICAL ERRORS IN FICTION.

It seems to be the rule, unfortunately, for writers of fiction, when dealing with medical subjects, to pay no attention to facts. This leads to the most ludicrous combinations of symptoms and to descriptions of conditions that can not exist. It is an old fault, and a repetition of this fault from an ordinary writer of fiction would hardly deserve attention here. We have to regret, however, its occurrence in the recent writings of a celebrated author who was educated as a medical man. Dr. Conan Doyle, in "The Adventure of the Golden Pince-Nez," just published, makes Sherlock Holmes say, in commenting on a pair of glasses that had been found, "You will see, Watson, that the glasses are convex and of unusual strength." In another place, speaking of the owner of these glasses, Holmes says: "Unfortunately for her, she had lost her glasses in the scuffle, and as she was extremely short-sighted she was really helpless without them." To make a short-sighted person wear convex glasses, even in fiction, is not to be commended. In dealing with medical subjects, why do not writers of fiction properly inform themselves and so avoid making such ridiculous errors? Not to do this is slovenliness. In this particular instance, the result of the neglect of attention to facts is unusually unfortunate, for it involves our friend, the famous detective, and also his friend, Dr. Watson; and this involvement shows them in a very unenviable light—they are shown to be weak where they should be strong—for Mr. Holmes appears as a poor observer and Dr. Watson as a poorly informed medical man. Holmes calls attention to the physical characteristics of the myope, and speaks of the convex glasses which had been used to counteract short-sightedness. Had this detective been a good observer of people he would have known that concave glasses go with such physical characteristics, and had Dr. Watson been a well-posted physician, he would have set his friend straight as regards the kind of glasses used for correcting myopia. We can agree with Mr. Sherlock Holmes that it would be difficult to name any article which affords a finer field for inference than a pair of glasses, but one is very apt to go wrong if he infers from a pair of convex glasses that the owner is short-sighted.

Medical News.

CALIFORNIA.

Health Officers Appointed.—Dr. Clarence L. Six, Stockton, has been appointed health officer of San Joaquin County, vice Dr. Samuel R. Arthur. Lodi, term expired, and Dr. Fred W. Colman, health officer of Lodi.

Brennan Freed.—Dr. Thomas F. Brennan, accused of embezzling \$36,000 from Rev. P. J. Grey, after a long and stubborn fight in the criminal courts, gained his freedom November 12, by the decision of the judge that the information was not filed within three years after the date of the alleged offense.

Needless Apprehension at Merced.—The health officer of Merced reported to the State Board of Health that there were two suspicious cases in Snelling's Chinatown. One case proved to be leprosy, and the other, which it was feared was one of bubonic plague, was demonstrated to be eczema rubrum universale.

Redlands Hospital.—The new hospital for Redlands has been completed at a cost of \$25,000, and the equipment is proceeding rapidly, so that the institution will soon be ready to receive patients. The hospital is governed by the following board of directors: Dr. Christopher A. Sanborn, president; Dr. Hoell Tyler, vice-president; Dr. Gayle G. Moseley, secretary, and Drs. J. E. Payton and Charles E. Ide.

COLORADO.

Women Start Free Dispensary.—At a meeting of women practitioners of Denver, held November 23, it was decided to establish and maintain a free dispensary, devoted exclusively to the treatment of women and children.

October Deaths.—The total number of deaths reported in October was 726, equivalent to an annual death rate of 14.71 per 1,000. There were 52 deaths from typhoid fever, 15 from diphtheria and one from scarlet fever during the month.

Communicable Diseases.—During October 349 cases of typhoid fever, 86 of diphtheria, 62 of scarlet fever and 15 of smallpox were reported to the State Board of Health, an increase over the preceding month of 15 cases of diphtheria and 17 cases of scarlet fever, and a decrease of 46 cases of typhoid fever and 4 cases of smallpox.

Pertinent Suggestions to Health Officers.—In order to secure accuracy and uniformity, the State Board of Health has made the following suggestions:

In case of death from cancer, require a statement of the organ or organs involved in the process, or a statement as to whether the process was general.

In case of death from septicaemia, peritonitis or hemorrhage in an adult female, require a statement as to whether it was puerperal in character.

In case of death from inanition, marasmus, malnutrition or dropsy, secure, if possible, a definite statement of cause.

In case of death from violence or poison, have the death certificate state whether it was suicide, accident or homicide.

In case of death from tonsillitis, spasmodic croup or other suspicious disease of the throat, investigate as to the question of diphtheria, and require the certificate to show the facts.

Do not accept the statement "heart failure" as a cause of death.

Do not accept senility unless deceased is 65 years of age or more.

Death certificates are required for still births and premature births, provided the fetus is twenty-eight weeks old. In all such cases be sure to see that the death certificate states whether the child lived.

DELAWARE.

Diphtheria in Laurel.—Several cases of most virulent diphtheria are present in Laurel. Two deaths were reported from the disease during the week, and the schools have been closed.

The Ridgely Will Probated.—The will of the late Dr. Henry Ridgely of Dover has been probated. The estate is estimated at from \$300,000 to \$500,000. With the exception of a few bequests the entire estate is devised to his widow.

IDAHO.

Is State Law Constitutional?—In the case of Dr. J. J. Raaf, arrested at Hailey on the charge of practicing medicine without a license from the State Board of Medical Examiners, the hearing was postponed pending the decision of the District Court on the constitutionality and other features of the medical practice act.

State Society Meeting.—The Idaho State Medical Society met at Lewiston, October 6 and 7. Dr. Robert L. Nourse, Hailey, was elected president; Dr. J. B. Morris, Lewiston, vice-president; Dr. Lucien P. McCalla, Boise, chairman of com-

mittee on legislation; Dr. John X. Alley, Lapwai, chairman of committee on nominations; Dr. Ed. E. Maxey, Boise, chairman of committee on publication, and Dr. Carol L. Sweet, Boise, chairman of committee of arrangements. Boise was selected as the next meeting place. The society agreed to contribute \$1,000 toward the expense of the meeting of the American Medical Association in Portland.

ILLINOIS.

Smallpox in Marshall.—On November 25 it was reported that there were 10 cases of smallpox in Marshall, with at least four foci of infection. An isolation hospital to accommodate 18 to 20 patients has been prepared, as an epidemic is feared.

Personal.—Dr. Chauncey H. Wilder, De Kalb, first lieutenant and assistant surgeon, Illinois National Guard, assigned Third Infantry, has resigned and will move to Oakland, Cal.—Dr. Robert C. J. Meyer, Moline, lieutenant commander and chief surgeon Naval Militia, Illinois National Guard, has resigned after nine years' service.—Dr. W. E. Taylor, Watertown, superintendent of the Illinois Western Hospital for the Insane, has been elected chairman of the committee on insane and feeble-minded adults, at the state charities convention, November 16.

Recommendations of State Charities Convention.—The convention held at Rockford, November 16, asked for appropriations of \$500,000, and adopted resolutions recommending:

The transfer of the Cook County Hospital for the Insane, Duning, from the care of the county to the state.

The transfer of all insane patients from the various county poorhouses to the state institutions.

The substitution of a "more modern system" for the present grand jury system.

The establishment of an epileptic colony and an appropriation for that purpose from the state legislature.

Investigation and correction of all faulty tenements and dwellings in Chicago.

Passage of a bill compelling the disinfection of houses in which there has been death from consumption.

More adequate appropriation for the state factory inspector's office to enable a more rigid enforcement of the laws pertaining to space and light.

Passage of a bill to regulate the surrender, placing and transfer of children.

Passage of a bill to provide for the visitation of children placed in family homes.

Custody of all feeble-minded women by the state.

CHICAGO.

Resignation.—Dr. Albert Woelfel has resigned his position in the Memorial Institute for Infectious Diseases to accept an appointment in the department of physiology of the University of Chicago.

Not Proven.—Drs. Earl J. Dennis and T. Henry Ryan, charged with having forged the signatures of 22 professors of the College of Physicians and Surgeons to a diploma issued to David Arthur Moses, have been discharged on account of insufficient evidence.

Deaths from Respiratory Diseases.—In Chicago, from October 15 to November 26, there were reported 2,611 deaths from all causes, 309 from consumption and 294 from pneumonia—ratios of 11.8 per cent. of consumption and of 11.2 per cent. of pneumonia. Since the week of November 12, however, when the Chicago pneumonia season of 1904-05 began, there have been 1,317 deaths reported from all causes, 140 from consumption and 182 from pneumonia—ratios of 11.3 per cent. for consumption and of 13.8 per cent. for pneumonia, and these proportions may be expected to continue until the close of next April.

Vital Statistics of the Week.—During the week ended November 26, 425 deaths were reported, an annual death rate of 11.49 per 1,000. The deaths were 54 fewer than the previous week and 87 fewer than in the corresponding week last year. These figures represent reductions of the annual rates, per 1,000 of population, of 11.2 per cent. and 19.3 per cent. respectively. There is also a substantial reduction from the previous week in the number of pneumonia and typhoid fever patients reported in hospital. On the other hand, there is a continuing increase of minor ailments of the nose, throat and air passages, due to the prolonged dry weather.

MARYLAND.

Hospital Soon to Open.—The Peninsula General Hospital at Salisbury will be opened during Christmas week. President William P. Jackson of the board has furnished the building at a cost of \$4,000, and Mr. Walter B. Miller donated a \$500 ambulance. The building, a gift of Congressman Jackson, will cost about \$60,000. It is heated by steam and lighted by elec-

tricity and will accommodate about 50 patients. The teachers' institute of the county will furnish and maintain one private room. The colored teachers will also furnish a room for their race.

Baltimore.

Club Election.—At the annual election at the Johns Hopkins University Club, November 19, Dr. J. Whitridge Williams was elected president and Dr. Henry J. Berkley governor, for four years.

Personal.—Dr. Claribel Cole, pathologist at the Woman's Medical College, is doing research work under Metchnikoff at the Pasteur Institute, Paris.—Dr. Roland B. Whitridge has returned from Europe.

New Building for Johns Hopkins.—Plans have been completed for a new building to be used for research work at the Johns Hopkins Medical School. It will be 30 by 80 feet, two stories in height and will accommodate the animals susceptible to the various toxins.

New Tuberculosis Building.—The new tuberculosis building at the Johns Hopkins Hospital, adjoining the general dispensary, will be formally opened about January 15. It is the gift of Mr. Henry Phipps of Pittsburg, who gave \$20,000 last winter, through Dr. Osler, for a separate dispensary for tuberculous patients. The building is two stories high. It will be equipped with a special library on tuberculosis. The walls are of brick and are painted with white enamel paint and the floors are treated with a non-absorbent preparation. The Laeance Society will have charge of the exercises at the opening. For several years special provision has been made in the general dispensary for the treatment and visiting of tuberculous patients through the generous gifts of two Baltimore ladies.

MASSACHUSETTS.

A Good Ambulance Service.—Boston City Hospital has one of the largest ambulance services in the world. The seven horse ambulances and one automobile at the main hospital and seven other at the relief stations brought in last year 6,767 patients, of whom 1,644, mostly emergency calls, went to the relief station. Besides these, 1,200 patients were taken to the relief station by police ambulances and patrol wagons.

Anniversary of Consumptives' Home.—The Cullis Consumptives' Home, Grove Hill, Boston, celebrated its fortieth anniversary November 20. During these years more than 5,000 patients have been cared for and most of these have ended their days there. The expenses have been over \$1,000,000, entirely contributed by friends of the institution. No salaries are paid except to matron and nurses. The property, valued at \$225,000, is now free from debt and 150 patients are cared for each year.

Year's Work of Floating Hospital.—At the annual meeting of the Boston Floating Hospital, November 22, Dr. Robert W. Hastings, resident physician, reported that during the season, July 6 to September 15, 290 patients were cared for in the permanent wards, an average of 13 1/3 days each. On 54 days trips were made with day patients, of whom 652 individuals made 2,484 trips, or an average of 46 on each trip. This is a considerable advance over the work done in previous years. Among the permanent patients 133 were 6 months old; 97, 6 to 12 months; 46, 1 to 2 years; 11, 2 to 3 years, and 3, 3 to 5 years; 122 were discharged well, 66 relieved, 13 unrelieved, 88 dead and one untreated. Of the 88 who died, 24 were moribund at entrance and survived less than 48 hours and 279 patients were refused, mostly for lack of room. Urgent efforts are now being made, with good prospects of success, to provide a new and larger boat for next season, which shall have beds for 100 patients instead of the present number, 57, which is inadequate.

Petition for Tuberculous Hospital.—The Boston Association for the Relief and Control of Tuberculosis has elected the following officers for the coming year: President, Dr. Edward O. Otis; vice-president, Dr. Arthur K. Stone; clerk, Alice L. Higgins; and treasurer, George S. Mainford. The good work done during the past year is shown in the report of the secretary. Eighty-two lectures have been given in schools, churches, settlements and before labor unions, to 10,500 people; 80,000 leaflets and cards have been distributed showing how to prevent the spread of the disease, and a tuberculosis exhibit at the fair held in the great Mechanics' Building in October attracted the attention of thousands. A visitor is employed to instruct and care for consumptive poor and is able to help 35 new cases each month. As a result of this contact and the

fact that Boston provides only 40 free beds for them at the institutions on Long Island, they have drawn up and are securing signatures to the following petition to the mayor and city council of Boston:

We, the undersigned, citizens of Boston represent:

1. That twelve hundred persons die annually in this city of pulmonary tuberculosis;
2. That at least three thousand persons in the city are not afflicted with this disease;
3. That a very large proportion of these patients can not be properly cared for in their homes, are not fit for the Rutland Sanatorium, and that the present hospital accommodation for such patients is utterly inadequate;
4. That many die who might with proper care be saved;
5. That being inefficiently cared for they infect other members of the family, already worn out by prolonged nursing and watching, and so rendered more susceptible to the disease;
6. That provision for the suitable care of such cases is urgently demanded, both from a philanthropic and an economic point of view.

Therefore, we petition for the immediate erection and maintenance, by the city of Boston, of a hospital for the reception and treatment of all patients in whatever state of the disease who are unable to receive proper care and treatment in their homes.

NEW JERSEY.

Anti-Mosquito Law Failed.—Dr. Henry Mitchell, secretary of the New Jersey State Board of Health, in an address before the Orange Mountain Medical Association, November 18, declared that the work of mosquito annihilation in New Jersey was far from being effective, as the health boards in the state were not willing to advance the money necessary to drain the swamps.

A Malpractice Verdict.—A citizen of North Plainfield who brought suit for \$20,000 damages against Dr. Albert Wickham, Newark, for injuries alleged to have been caused by the improper application of a plaster jacket, was given a verdict of \$780 in the Supreme Court. The defendant will appeal the case to the Court of Errors and Appeals if the Supreme Court refuses to set aside the verdict.

Sanitarium to Be Enlarged.—The Agnes Memorial Hospital in Montclair, recently erected at a cost of \$250,000, with a capacity of 80 patients, now has 100 patients and a second hundred on the waiting list. Mr. Laurence C. Phipps proposes to build a large wing, to cost \$100,000, which will have capacity for 100 additional patients. Pending the erection of the wing it is planned to put up tents to accommodate 50 or more patients.

New Sewage System for Atlantic City.—Efforts are being made to install a modern sewage system in Atlantic City. The bad condition of the present system is well known and has long been condemned. A comprehensive plan for a complete reconstruction of the sewage facilities has been adopted by the authorities and will involve an expenditure of \$300,000. The system, it is said, will be the most modern and complete in the state.

NEW YORK.

Measles Prevalent.—Fourteen cases of measles have been reported from one public school in Buffalo and closure of the school is contemplated.

Joint Hospital and Asylum Illegal.—Attorney General Cunnene has informed the State Board of Charities that the "Baptist Home of Monroe County" can not be organized under the corporation law, because it proposes to combine a hospital with an orphan asylum. The decision affects a number of similar applications before the board.

Longevity of Abstainers.—A number of actuaries and medical directors of New York insurance companies have been working on statistics running over a period of several years. From the records it is claimed that total abstainers as a class live longer by from 20 to 50 per cent, than moderate drinkers, so that this class of applicants will soon have to pay less for insurance than the moderate drinker.

Vote Against Consumptive Sanitarium.—The Sullivan County Board of Supervisors has denied New York City's application to build a sanitarium for consumptives at Mamakating because of the objections raised by keepers of summer hotels. The city has begun negotiations for 1,000 acres on the top of Mount Shawangunk. The plans for the proposed institution will entail an outlay of \$1,000,000 and the cost of maintenance will be \$100,000 annually.

Oppose Optometry Examiners.—The committee on legislation of the Medical Society of the State of New York has issued a circular letter to the medical profession of the state giving a history of the attempt of the Optical Society of the State of New York to have enacted a law creating a state

board of examiners in optometry. The state society, various county societies and the Optical League secured the defeat of the measure. The organization is now endeavoring to gain the indorsement of the medical profession, to be used before the next legislature. On account of the irregular methods practiced by the promoters of the scheme, the committee urges the profession to refuse to indorse the measure and to present the case in its true light to the members of the legislature and urge them to oppose it.

Typhoid Statistics.—The health department has made a detailed investigation concerning cases of typhoid fever reported to the department. According to the report of the inspector approximately 30 per cent. of the cases were incorrectly diagnosed typhoid fever, many cases indicating intestinal toxemia, while others had intestinal disturbances in all likelihood occasioned by temporary water disturbance. Many cases sent to the hospitals as typhoid turned out to be some other sickness than typhoid. All cases in which the Widal test was positive were typhoid. Of the 145 cases examined 97 occurred in families which were not boiling their drinking water, and 41 cases occurred in families in which the drinking water was boiled. Of the 145 cases of typhoid, 95 were mild and 50 severe; 10 lasted less than two weeks, 98 from two to seven weeks, 12 from six to ten weeks, and 7 from ten to eighteen weeks. Only 27 of the patients had been out of the city during the incubation period.

New York City.

Seaside Camp for Tuberculous Children.—This work, begun by the Association for Improving the Condition of the Poor, met with such success that it has been decided to keep the tent camp open all winter.

Brooklyn Jewish Hospital.—The annual report of this institution, which has been in existence only three years, shows that it has grounds and buildings valued at \$175,000* and \$80,000 in cash and pledges.

Eulogium to Dr. Pryor.—At the annual meeting of the New York Polyclinic Medical School and Hospital, November 10, resolutions were adopted eulogistic of the late Dr. William Rice Pryor, and expressing the sorrow of the faculty at his death.

New Brooklyn Hospital.—The application of the Brooklyn and Samaritan Hospital Association for articles of incorporation has been granted by the State Board of Charities at Albany. A building will be erected near Fifteenth street and Fourth avenue.

The Pure Milk Crusade.—Recently the fines imposed in Brooklyn for adulterating milk have been accompanied by the severer penalty of imprisonment. Even after the active work of the Health Department, during the past three months 205 dealers have been arrested and 32,000 gallons of milk destroyed.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 19, 323 cases of diphtheria, with 36 deaths; 275 cases of tuberculosis, with 147 deaths; 107 cases of typhoid fever, with 18 deaths; 174 cases of scarlet fever, with 15 deaths; 83 cases of measles, with 7 deaths; 114 cases of varicella, 4 cases of smallpox, and 13 deaths from cerebrospinal meningitis.

Disease in Schools.—Pediculus capitis has prevailed to an alarming degree in the public schools. It is said that of 283,000 children 23,000 are thus afflicted. It has been customary hitherto to send these cases to the school nurses for treatment, but the Board of Health has instituted a plan by which the nurses are sent into the homes, where they instruct the mothers as to the proper method of coping with this condition. If parents refuse to follow instructions, affected children will be excluded from school, and when they are kept out too long, the parents will be arrested on the charge of interfering with the compulsory education law.

Need Endowment.—At the one hundred and fiftieth anniversary of King's College, Columbia University, Dr. McCracken, the chancellor, called attention to the fact that in point of numbers, medical instruction in this city was declining. Twenty years ago there were in New York City and state 2,085 medical students and, at the present time, there are 2,374. In the whole country there has been an increase of 153 per cent., while in New York state the increase has been only 13 per cent. In New York City itself there has been an actual decrease of 10 per cent. This is not because the medical schools are unworthy of patronage, but because of lack of endowment and paucity of material equipment of the

schools. There is a lack of building room and a large number of well qualified students have been turned away.

PENNSYLVANIA.

Diphtheria in Coventry.—Diphtheria is widely prevalent in East Coventry and the northern section of Chester County. Numerous cases and several deaths have been reported in the last week.

A Tall Legislator.—Dr. Andrew J. Barchfield, Pittsburg, who has recently been elected representative from the Thirty-second congressional district, will be the tallest member of the House of Representatives. He is a member of the local and state societies and of the American Medical Association.

Food-Analysis Laboratory.—The state has instituted measures whereby a laboratory for the analysis of food samples secured by the pure food department will be established. A building for this purpose has been secured in Harrisburg. At present all food samples are sent to West Chester and State College for analysis.

Goiter in Rossiter.—Goiter seems to be epidemic in Rossiter, Indiana County. Investigation shows that the disease is peculiar to that neighborhood. The hamlet is situated about 1,800 feet above the level of the sea, and it has been demonstrated that every third inhabitant is a subject of the disease. Healthy persons moving into the section soon become affected. One family of nine persons contains four with goiter and four cretins. The population is made up of Americans who have lived there three generations. The cause of the disease is attributed to the water supply, which is impregnated with salts of lime and magnesium.

State Health Report.—Dr. Benjamin Lee, secretary of the State Board of Health, in his annual report emphatically recommends a law making vaccination compulsory. The recent epidemic of smallpox demonstrates the importance of this step. His report shows that 5,172 cases of smallpox, with 13 deaths, occurred in this state last year. The number of cases at present is only 42. He further urges a law for the immediate registration of deaths and births at the state capital, a law establishing local health authorities outside of the cities and boroughs, and a law providing for state control over public water supplies. He commends the activity of the Philadelphia Board of Health in enforcing vaccination. In that city during the year 1903, 142,397 vaccinations were performed, with the result that the number of cases of smallpox decreased from 396 in December last to 26 in June of the present year and none in July.

Philadelphia.

Donation to German Hospital.—At the annual donation day on Thanksgiving Day, the German Hospital received \$12,000 in cash.

Frazier Receives Appointment.—Dr. Charles Frazier, dean of the Medical Department of the University of Pennsylvania, was appointed on the major surgical staff of the Hospital of the Protestant Episcopal Church, November 25, vice Dr. Richard Harte, resigned.

Vaughan in Philadelphia.—Dr. Victor C. Vaughan of the University of Michigan will deliver an address before the Philadelphia Pathological Society at the College of Physicians, December 8, on "The Relation of Food Adulteration to the Public Health." Immediately after the meeting a reception will be tendered to Dr. Vaughan.

New Animal Hospital.—The directors of the Zoological Gardens have just completed the erection of a thoroughly equipped infirmary and pathologic laboratory, the first of its kind in this country. The purpose of this infirmary is to study the comparative pathology and also the cure of animal diseases. The laboratory work will be carried on under the direction of Dr. Charles B. Penrose, a director of the society, and Dr. Cortland Y. White, assistant director of the Pepper laboratory of the University of Pennsylvania.

Jefferson Library Report.—The report of the librarian of the Jefferson Medical College library for the year just ended showed some interesting and noteworthy facts concerning the contents and circulation of the college library. There were 3,009 volumes in the library, of which 439 were added during the year; 203 by gift and 236 by purchase and binding, the largest gift being 78 volumes from the library of the late Dr. C. W. Horner. There are fewer than 2,000 volumes of general text-books in the library and from these there was a circulation of 10,663 volumes.

Health Report.—Typhoid fever seems to be decidedly on the increase. The cases reported for the week were 29 more than those of last week. The increase is reported from wards not supplied with filtered water. Diphtheria also prevails to an alarming degree. The record-breaking figure of 119 cases reported last week was exceeded this week by 5. There were 296 cases of contagious disease reported, with 13 deaths, as compared with 249 cases and 18 deaths for the preceding week. The death rate for the week was about normal, and the total number of deaths reported was 417. This is an increase of 10 over those of last week, and a decrease of 78 over the corresponding period of last year. Diseases of the respiratory tract caused 111 deaths.

GENERAL.

Professor Hirschberg to Attend the Portland Session.—The officers of the Section on Ophthalmology announce that Professor Hirschberg of Berlin has accepted an invitation to be the guest of that section at the Portland session and to present an address. In his letter to the chairman of the section, Professor Hirschberg says: "This will be my third, and, I think, my last trip to the United States." The section officers are to be congratulated on securing Professor Hirschberg, as his reputation among ophthalmologists is worldwide.

Gross Prize.—The Samuel D. Gross prize of \$1,200 will be awarded Jan. 1, 1905. The conditions are that the prize "shall be awarded every five years to the writer of the best original essay, not exceeding 150 printed pages, octavo, in length, illustrative of some subject in surgical pathology or surgical practice, founded on original investigations, the candidates for the prize to be American citizens." The competitor who receives the prize must publish his essay in book form, and deposit one copy of the work in the Samuel D. Gross Library of the Philadelphia Academy of Surgery. The essays must be written by a single author in the English language and must be sent to the "trustees of the Samuel D. Gross prize of the Philadelphia Academy of Surgery, care of the College of Physicians, 219 South Thirteenth street, Philadelphia," on or before Jan. 1, 1905. Each essay must be distinguished by a motto, and accompanied by a sealed envelope bearing the same motto, and containing the name and address of the writer. No envelope will be opened except that which accompanies the successful essay.

American Public Health Association.—The latest information concerning rates to this meeting in Havana, Cuba, in January is given by Dr. H. L. E. Johnson, 1821 Jefferson place, Washington, D. C., as follows: Members of the Public Health Association can take advantage of an excursion from Washington, D. C., Virginia and the Carolinas to Havana, Cuba, via Tampa, round trip, meals and berth included on ship, for \$52. Leave Washington, Jan. 5, 1905; arrive Havana, January 8, a. m. Number of passengers limited to 150 out of above territory. Tickets good to leave Havana not later than January 19, reaching the starting point January 22, with stop-overs south of Jacksonville within life of ticket. Members can purchase locally to Washington or other nearer points in above territory, then purchase the special excursion ticket. If 18 passengers go via Washington, we can arrange for a special sleeper attached to train No. 29, Southern Railway, leaving Washington, D. C., 10:51 a. m., January 5. Those desiring to take this trip can communicate with Dr. Johnson. In this connection consult the published statements concerning rates to the Pan-American Medical Congress. As we go to press we receive the following information from Dr. Guiteras: "The program of the American Public Health Association will be an inviting one and of an important character. The Cuban committees are making extensive preparations for the entertainment of the congressists. From the returns now coming in it would seem that at least one-half of the members of the Public Health Association will make the round trip to both medical meetings. It is understood that the Pan-American 'congressists' who do not belong to the Public Health Association will be invited by this association to take part in their discussions as guests, and that they will also be invited by the Cuban entertainment committee to participate in the festivities."

Cuban Yellow Fever Report Denied.—Dr. Carlos Finlay, chief of Department of Health and Sanitation, Havana, is reported as saying that in three years only one case of yellow fever has occurred in Cuba, while Dr. Delgado, also of Havana, disclaims any knowledge of yellow fever cases this year, except in six persons who arrived from Mexico and who were imme-

diately isolated. Of these, two died and the others recovered. The U. S. Public Health and Marine Hospital reports state that Cienfuegos is in an insanitary condition. "There is practically no sewerage system in the city. The streets in the business section are kept fairly clean by daily sweeping. In the residence section, especially near the bay front, the streets are not kept at all clean, fruit and food refuse being allowed to remain in them all the time. The houses of the poorer people—who are three-fourths of the population—are positively filthy from accumulation of ordinary house refuse. There are very few flush water-closets, and none that connect with sewers. Nearly all are surface closets in the houses of the poorer class, and these are seldom cleaned. The better classes of houses have cesspools. These have not been cleaned for four years. The drinking water of the city is of poor quality and not in nearly sufficient quantity, the water pipes being open only from one to two hours in the day. Cienfuegos is in a very insanitary condition from every point of view."

Pan-American Medical Congress.—Physicians desiring to contribute papers on internal medicine at the next meeting of the Pan-American Medical Congress at Panama, Jan. 2-6, 1905, are asked to send titles at their earliest convenience to the secretary of the section on medicine, Dr. Judson Daland, 317 South Eighteenth street, Philadelphia. In view of the facilities offered to reach Panama via New Orleans it is expected that many will choose this route and those who intend to do so are asked to forward their names to Dr. R. Matas, secretary of section on general surgery, 2255 St. Charles avenue, New Orleans, not later than Dec. 22, 1904. Dr. H. L. E. Johnson, chairman of the transportation committee, sends the following further information about rates, etc.: The Di Giorgio line of Baltimore offers a special ship for the exclusive use of party, including meals and berth, at sea and in ports, to Panama, Havana and return, attending both meetings and visiting Kingston and Port Antonio, Jamaica, for \$130—provided 50 persons take passage. The *Athos* will leave Baltimore December 27, 11 a. m.; arrive Panama, January 2, p. m. or 3, a. m.; leave Panama, January 7, a. m.; arrive Havana, January 9, a. m.; leave Havana, January 13, p. m. or January 14, a. m. for Jamaica; arrive Baltimore, January 18. All arrangements must be made ten days before date of sailing. Passengers limited to 70. Apply to Ralph F. Nolley, 103 Park avenue, Baltimore, Panama Railroad and Ship Company; Rate from New York to Panama, one fare and a third for round trip; upper deck, \$123.33; lower deck, \$113.33. United Fruit Ship Company; Rate from New Orleans to Panama and return, \$50; one way, \$25. In connection with this, read previous announcements in THE JOURNAL. Dr. Ramon Guiteras sends the following names of secretaries of sections which were not in his letter of October 25, which was published in THE JOURNAL, Nov. 5, 1904: Dr. C. W. P. Brock, Richmond, Va., railway surgery; Dr. H. P. Newman, Chicago (present headquarters at the New St. Charles Hotel, New Orleans), gynecology and abdominal surgery; Dr. Howard Morrow, San Francisco, dermatology. Dr. Guiteras is secretary of the International Executive Commission of the congress and may be addressed at 75 West Fifty-fifth street, New York City, for further information. He remarks that the cruise of the *Athos* will probably be a memorable one like those of the old buccaners.

CANADA.

No Sanitarium for Kamloops.—The government of British Columbia has assured the Anti-Sanitarium League of Kamloops, B. C., that they have no intention of thrusting a sanitarium for consumptives on that place if the feeling of the citizens of Kamloops is against it. British Columbia will, therefore, have to look elsewhere for a location for their provincial sanitarium.

Vancouver Hospital Report.—Drs. G. D. Johnston and Glen Campbell of Vancouver have been appointed on the staff of the Vancouver General Hospital as ophthalmologists, otologists and laryngologists. The house surgeon's report for the month of October is as follows: Remaining from September, 39 males and 11 females; admitted during the month, males 54, females 15; cured, males 44, females 14; died, 2; remaining in the hospital, males 47, females 12.

Form Inebriate Reform Society.—The Inebriate Reform Society of Ontario has been organized in Toronto to promote the adoption of the probation system for the reformation of inebriates and of the home or dispensary treatment in suitable cases, and to promote the establishment of municipal sanatoria for indigent inebriates. The society will endeavor to push

through the bill which has been drafted at the next meeting of the legislature. Dr. A. M. Rosebrugh, who has taken a great deal of interest in this movement, will be the permanent secretary.

Municipal Sanatoria for Ontario.—The initial step has been taken in establishing municipal sanatoria for the indigent consumptives of Ontario. Special assistance will be provided by the legislature. Representatives from Brant, Oxford, Perth, Wellington and Waterloo counties met in convention at Galt, Ont., and each of these representatives will have the matter brought before their respective county councils. Dr. Radford of Waterloo presided, and gave the statistics for the Dominion of Canada as regards tuberculosis. According to his report there are 6,000 deaths in the dominion every year; 2,694 in the province of Ontario. The approximate number of consumptives in the dominion is 40,000 and in the province of Ontario 15,000.

Army Medical Corps.—A recent militia general order states that, for the purposes of promotion, the officers of the permanent active militia army medical corps and officers of the militia army medical corps will be considered as belonging to two distinct branches, and promotion will take place on the same principle as that in a regiment or corps. Promotions subject to the necessary qualifications will take place as follows: After one year's service as lieutenant, to be captain; after four years' service as captain, to be major. After ten years' service as major, regimental officers may be given the rank of honorary lieutenant-colonel, and their period of service extended or they may be transferred to the reserve of medical officers or the retired list, as the case may be.

Montreal General Hospital Report.—At the quarterly meeting of the board of governors of Montreal General Hospital last week, the report of the medical superintendent, Dr. Campbell, for the three months ended September 30, showed that 829 patients had been treated to a conclusion during that quarter and that there had been 57 deaths, 21 of which had occurred within three days of their admission. This makes the mortality rate for ordinary hospital cases 4.3 per cent. In the outdoor departments there were 10,235 consultations, as compared with 9,692 for the corresponding quarter of 1903. The ambulance responded to 375 calls. The committee of management reported that the receipts for the quarter were \$14,918, or \$942 less than for the same quarter last year. The expenditure amounted to \$24,888, showing a decrease of \$4,155, as compared with 1903.

FOREIGN.

Lectures on Sexual Hygiene.—Prof. Max Gruber is to deliver a course of six lectures at the College of Technology at Munich on "Hygiene of the Sexual Life."

Endowment Fund for Library of Berlin Medical Society.—Professor Lassar has started an endowment fund for the purchase of works of historical value, libraries, etc., to add to the library of the Berlin Medical Society.

The Mayor of Strasburg an Honorary M.D.—The medical faculty of Strasburg, Germany, has conferred an honorary degree on the mayor of the city, on the occasion of his seventieth birthday. The honor was in appreciation of his great services in promoting the public health.

New Psychiatric Clinic at Munich.—The new clinic was formally inaugurated by Professor Kraepelin, November 7. It is said to be the most completely equipped and convenient institution of the kind yet erected. It has 100 beds and a number of innovations designed by the late Professor Bumm.

Convalescent Home at Wiesbaden for Russian Officers.—The Russian Red Cross has opened a convalescent home at Wiesbaden for Russian army officers. The institution is also to admit German army officers when there is room. Dr. Prüssian is the resident physician, with von Noorden of Frankfurt as consultant.

Postgraduate Courses for Life-Insurance Examiners.—The medical examiners in Germany held their annual meeting at Berlin last month. One of the addresses was on the subject of the training in this specialty. The speaker urged that the new academies for practical medicine—the first one was recently inaugurated at Cologne—are pre-eminently the institutions to establish postgraduate courses in scientific medical examination for life insurance.

Spanish Physicians Heroes in Smallpox Outbreak.—The *Siglo Médico* of Madrid is circulating a petition asking for the reimbursement and reward of certain physicians in the smaller

towns who, during recent epidemics of smallpox, tended the victims, obtained food and served it to them after they had been deserted by their friends, and finally buried with their own hands those who succumbed. Eight physicians are mentioned by name, residing in as many different towns, who have done this, their unassisted efforts restricting the epidemic to the houses where the first isolated cases occurred.

Testimonial to Naunyn.—The attention of all who have at any time been pupils of Professor Naunyn at Berlin, Dorpat, Berne, Königsberg or Strasburg, is called to the following notice:

STASSBURG I. E., im November, 1904.
An die Schüler von Prof. Naunyn:
Herr Prof. Naunyn bat am Schluss des vergangenen Semesters sein Amt als Lehrer der Inneren Medizin niederzulegen.

Wir wenden uns an alle, die während seiner annähernd 40 jährigen Thätigkeit durch seine Schule gegangen sind, mit der Aufforderung, ihm in einer gemeinsamen Adresse zu danken.

Die Schüler Prof. Naunyns werden gebeten, uns ihre Namen und Adressen mitzuteilen, damit wir ihnen Blätter zum Eintragen der Unterschriften zusenden können.

PROF. NAUNYNS LETZTE SCHÜLER.
I. A. Heimendinger, cand. med.; Zschocke, cand. med.
Zuschriften zu richten an: Zschocke, Lesingstrasse 31, III, Strasburg I. E.

Educational Number of the Progres Medical.—The issue for Nov. 5, 1904, of the *Progres Médical*, Paris, rue des Carmes 14, is devoted entirely to the institutions for medical instruction and information in France and other French-speaking countries. The list of the latter includes, beside those of Montreal and Quebec, the medical schools at Brussels, Ghent, Liège, Lausanne and Geneva, and the school of medicine and pharmacy at Beyrouth, Syria. It states that the scientific information bureau established at Paris in August, 1903, has had from forty to eighty applicants a day. It is designed to supply all the information desired in regard to the lecture courses, laboratories, hospitals, clinics, museums, public and private services, etc., existing at Paris. It is open from 10 to 5, and can be reached by telephone. The attendants are versed in the current foreign languages, and all the details are classified on the card catalogue system, grouped by establishments, specialties and persons. Another system of cards comprises the details that might have special interest for applicants from given countries. The data in regard to medical institutions in this country and elsewhere are also classified for the benefit of French students. The office is in the Sorbonne, and is in charge of Dr. Blondel, who is secretary general of the International Association of the Medical Press. Berlin and London are planning similar information bureaus.

Annual Burlesque Number of the Munich Medicinische Wochenschrift.—Two numbers of our esteemed contemporary arrived in the same mail, the general make-up apparently identical, the stately list of the collaborators, however, in one being headed—in very small type—"without the slightest participation of." The ads include one for an assistant who "knows enough not to criticise his chief and not so much that the clientele will prefer him." Another advertises for a librarian capable of cataloguing the drug pamphlets and circulars that arrive in the mail daily. A health resort advertises for a resident physician, "a handsome musician preferred, no testimonials required, merely the photograph." One of the original articles describes a new mode of narcosis with ethyl chlorid. The essential principle of the ethyl chlorid was extracted, that is, its refrigerating property, and that was transferred to a vehicle which carried the refrigerating property into the digestive tract. The vehicle found most appropriate is champagne. After long spraying of the bottle with ethyl chlorid the contents were ingested and, after a stage of agitation, profound narcosis was induced. The only drawbacks are nausea and oppression in the *cavum crani* the next morning. The radiogram of a remarkable fracture is given, the picture being merely a solid black square. The "Rights and Duties of the Physician's Wife" are discussed, and the practice of one wife is commended who always added a cipher to the bills her husband made out before she had them mailed. The abstract department contains reviews of the *Grenzgebiete der Utopie und Ironie*, xiii. The first—"Laparotomies under Water" summarizes a description of an epoch-making operating chamber, filled two-thirds with warm water. The head of the patient is enclosed in a helmet like that of a diver, into which the anesthetic is conveyed in a tube. The surgeon and aids wear rubber suits. The purpose of this operating chamber is to prevent the cooling of the interior of the abdomen, and also to insure its being thoroughly rinsed, so that any bacteria introduced during the operation will be rapidly destroyed. As the heads of the operators project, they can be given refreshments from

time to time. The second abstract states that Strahler has found that the eruption in scarlet fever vanishes under intense application of red light. The effect is only temporary, however, the eruption recurring as soon as the red light is withdrawn. Another adverting an indelible ink, invented by Schmierer, to mark on the patient's body the various findings to enlighten other examiners later. Gynecologists should stamp their patients after hysterectomy with some device. The wittiest article in the burlesque is a letter purporting to be from a school girl to her chum in another city describing the progress she is making in the new course on "sexual enlightenment" which the doctors say is indispensable and which has recently been introduced into her school. She writes that the study was tedious at first, when there was nothing but the everlasting division of the cells of the protozoa, algae and sea urchins, but when they got to the mammals it became very interesting, especially when the class was taken to the medical museum to see the babies in whisky. She adds that none of the girls play with dolls any more. They find that dolls have no sex. They have all told the younger children about the "sexual enlightenment," and all play at "getting married." Class B in the fourth grade have recently written to Haeckel, "the biogenesis man," to ask him to send them some human eggs for Easter. She further informs her friend that the girls know now that when they fall in love it is merely on account of concern for the sexual products. The burlesque is well conceived and carried out, especially the skits on the medical conflicts with the sick insurance companies, the opposition to the new academies for practical medicine, etc.

Correspondence.

National Association for the Study and Prevention of Tuberculosis.

BALTIMORE, MD., Nov. 21, 1904.

To the Editor:—At a meeting of the board of directors of the National Association for the Study and Prevention of Tuberculosis in New York, Nov. 16, 1904, it was decided to hold the first annual meeting in Washington, D. C., May 16-17, 1905; having one or two general sessions with distinguished speakers on the broad topics of tuberculosis, and special meetings of the three following sections: sociologic, pathologic and bacteriologic, clinical and climatologic, and that, so far as possible, these sectional meetings should not conflict one with another, each section to be presided over by men distinguished in their respective work, and only papers of undoubted merit and interest may be presented.

The membership of the association includes a large proportion of the most eminent workers in the subject of tuberculosis throughout the country, and it hopes to make its first annual meeting an important one in the crusade in this country against tuberculosis.

HENRY BARTON JACOBS, Secretary.

11 Mt. Vernon Place, West.

Prophylaxis of Tuberculosis in Children.

SKIPPACK, PA., Nov. 16, 1904.

To the Editor:—On page 1460 of THE JOURNAL, November 12, Dr. C. F. Wahrer, in discussing Dr. Louis Fisher's paper, "gave it as his opinion that if a child born of two healthy parents was exchanged for a child born to one or two diseased parents, so that the healthy parents were to take care of the child born of diseased parents, and the diseased parents were to care for the child born of healthy parents, the child that is reared by the healthy parents will have a far better chance of life, notwithstanding its inheritance, than the child that was born of healthy parents but reared in unhealthy environment."

Possibly if some of us would not be blinded by the brilliant (?) statistics emanating from our laboratories and specialists, and would use our eyes a bit, along with just a small amount of the common sense with which we are all more or less endowed, we would not be guilty of such an assertion. Tuberculosis does not just happen because one inhales or swallows a billion or two of the bacilli. The insane, the epileptic, the

drunkard, the thief, the cancerous, the syphilitic, as well as the tuberculous, inherit as children whatever diseased or vicious tendencies they may manifest in after life. Practicing in a section where I lived as a boy, and where the past and present history of every family is known to me, I know that of a certain family, a certain percentage of the immediate or remote descendants will be degenerates and will manifest their faulty inheritance by drunkenness, insanity, epilepsy or other moral or physical weakness; of others that a certain proportion, depending on environment, will develop tuberculosis in its various forms. And I know, just as sure as night follows day, that these things will happen. Heredity is law always and ever. Let us not work ourselves into a frenzy over the presence of a few bacilli, but rather strive to make all soils barren to them, by having our children better born. This is the real work cut out for us; all the rest is simply kindergarten. We will all wake up bye and bye to a full realization of the law of heredity. But we are sleeping very soundly.

J. NEWTON HUNTSBERGER.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

SPECIFIC GRAVITY OF BLOOD—HAMMERSCHLAG'S METHOD.

LOS ANGELES, CAL., Nov. 16, 1904.

To the Editor:—In THE JOURNAL, March 19, 1904, page 801, an article on the specific gravity of the blood recommends the use of Hammerschlag's method. Will you be kind enough to give a full description of his method, one that would be suitable to give to a freshman medical class? T. H. ULLYOT.

ANSWER.—Hammerschlag's method is described in all books on examination of the blood. We reproduce here the statement in regard to it in Cabot's book: "The simplest and most available method for clinical use (in estimating specific gravity of the blood) is that of Hammerschlag, a modification of Roy's method. Chloroform is heavier than blood; benzol is lighter. Mix in a urinometer glass such quantities of the two that the specific gravity taken by an ordinary urinometer is about 1055. I. e., that of normal blood. Puncture the ear, draw a drop of normal blood into the tube of a Thoma-Zeiss pipette, a small medicine dropper, or any other capillary tube, and blow it out again into the chloroform-benzol mixture. The blood does not mix at all with these liquids, but floats like a red bead. If it sinks to the bottom, add chloroform, if it rises to the top, add benzol, until finally the drop remains stationary in the body of the liquid, showing that its specific gravity is just that of the surrounding mixture. Then take the specific gravity of the liquid, as we do of urine, and you have the specific gravity of the drop that floated in it. The following precautions are needed: 1. Have the inside of the urinometer glass perfectly dry and clean; otherwise the drop of blood may cling to it and flatten out against it. 2. It is usually well to have more than one drop of blood in the glass in case any mis-lap occurs with the first one. 3. Add the chloroform and benzol a few drops at a time, and after each addition stir the whole mixture thoroughly with a glass rod. 4. If we have reason to suppose the blood will be lighter than normal (I. e., if the hemoglobin is probably low, vide supra), it saves time to start with a lighter mixture of chloroform and benzol. 5. Avoid having any air within the blood drop. This can generally be seen either in the capillary tube or after the drop is in the mixture. It is safer to take the middle portion of the blood drawn into the capillary tube, as both the first and last portions of the column are more apt to have air in them. 6. The whole process should be done as quickly as possible, else the chloroform or benzol may work into the blood drop and affect its weight. It is better to have a urinometer with a scale running as high as 1070, but this is not essential, for the clinically important specific gravities are low, not high."

INTERNAL VACCINATION.

PHILADELPHIA, November 25, 1904.

To the Editor:—While agreeing with your editorial (p. 1,636), and the reply to a correspondent on p. 1,642, vol. XLIII, No. 22, as to the mistaken idea of the value of the ingestion of small-pox virus, I want to call attention to the fact that certain antitoxins may rightly be administered by the alimentary canal.

Maragliano, and others, have shown that tuberculous antitoxin is effectual so administered (Annali dell' Instituto Maragliano, Genova, September, 1904).

It seems reasonable that antitoxin should be effectual if so given, for any organic matter is not entirely broken up in the alimentary channels, at least to the immediate loss of identity. Maragliano shows that the milk and the proleal tissue of immunized animals exerts a decided antitoxic influence on other animals ingesting the same.

T. H. EVANS, M.D.

ANSWER.—We discovered the report referred to after we had written the answer to the query. Maragliano's announcements that tuberculous antitoxin is effectual administered by the mouth were summarized in THE JOURNAL, pages 71 and 961 of the last volume, and also mentioned on page 579 of the current volume. His latest confirmatory researches corroborate his previous statements, both in regard to the action of antitoxin in the alimentary canal and in regard to the antitoxic and agglutinating power acquired by the milk of immunized animals, which von Behring has also been proclaiming. (See page 621 of the last volume.)

RATES TO PORTLAND.

HARTFORD, Conn., November 24, 1904.

To the Editor:—Can you inform me whether it is probable that arrangements will be made for reduced rates from the East to Portland and back, which can be availed of by say June 1, so that those wishing to take the Alaska trip may do so before the session on July 1? I am told that June is the time for the trip. Will stop-overs at Yellowstone Park be allowed? I would like to attend and incidentally to give my family an outing.

S. B. ST. JOHN.

ANSWER.—The probability is that the rates will be proportionately reduced from all parts of the country, i. e., half rates to Missouri River points, from which the rate will be \$45 for the round trip. It is probable that the special rates will go into effect about the third week in May, but official announcement of the time has not been issued. Stop-overs will be allowed at Yellowstone Park. In this connection read the editorial in this issue and the one printed November 12, page 1,474.

PHYSIOLOGY OF THE BRAIN.

OCONTO, WIS., November 25, 1904.

To the Editor:—I have been reading of late Loeb's "Physiology of the Brain." I would like to read more in that line: could you advise me? I invested in the latest edition of Kirke's Physiology, but that gives me little satisfaction. I also possess Sajons', vol. 1, "The Internal Secretions," etc. I should like to have some works to show things developed along this line during the last twenty years.

C. W. STOELTING.

ANSWER.—You will find five chapters on the "Physiology of the Brain," also on the "Physiology of Internal Secretions" in the last edition of the American Text-Book of Physiology, two volumes, by Wm. H. Howell of Johns Hopkins University. Published by W. B. Saunders & Co., Philadelphia, 1900.

LAWS OF PRACTICE IN MEXICO.

TULSA, IND. TER., ———, 1904.

To the Editor:—Please give the laws governing the practice of medicine in Mexico.

J. C. B.

ANSWER.—The practice of medicine in Mexico is free, but to have any legal standing, to be able to sign death certificates, to give testimony or to hold medical positions, one will have to pass an examination, in Spanish, varying in severity in the different states. There would be some inconvenience in general practice without such a license in certain states of the republic. In others, a license may be less a requisite. A very full description of the laws and the conditions of the practice of medicine in Mexico was published in THE JOURNAL, Dec. 23, 1899, p. 1629.

Marriages.

GEORGE SEAY, M.D., to Miss Rosa Cardoza, at Blackstone, Va., November 15.

HARRY A. MEISNER, M.D., to Miss Mary L. Wernig, at Baltimore, November 16.

LEONARD K. HUSHBERG, M.D., to Miss Edna Dalsemer, at Baltimore, November 24.

CHARLES E. BENSON, M.D., to Miss Angelina J. Keenan, at Baltimore, November 14.

JOHN NEVINS, M.D., to Miss Bessie Haggarty, both of Greene, Iowa, November 15.

JOHN A. TOMPKINS, M.D., to Miss Fredericka Gore McLane, both of Baltimore, November 19.

REMY G. DUCOTÉ, M.D., to Miss Florence Bordelon, both of Bordeloville, La., November 15.

ALPHONSO J. McLAUGHLIN, M.D., to Miss Stella Potter, both of Sioux City, Iowa, November 16.

A. LEE CARMICHAEL, M.D., Little Rock, Ark., to Miss Rose Beach of Kansas City, Mo., November 16.

NICHOLAS LEEKE DASHIELL, M.D., to Miss Amelia Eleanor Marine, both of Baltimore, November 23.

ERNEST D. HAMMOND, M.D., to Miss Inez Blanche Wilson, both of Salt Lake City, Utah, November 24.

JAMES A. FARRER, M.D., Dayton, Ohio, to Miss Cora L. Kauffman of Miamisburg, Ohio, November 16.

GEORGE DEMPSTER HAWLEN, M.D., to Mrs. Estelle Louise Berckmans, both of New York City, November 21.

WILLIAM CHARLES KEETTEL, M.D., Lyons, Neb., to Miss Eunice Una Rohde of Oakland, Neb., November 9.

FREDERICK UPHAM DAVIS, M.D., St. Clair, Minn., to Miss Erna Marie Lassow of Mankato, Minn., November 28.

HOWSON W. COLE, JR., M.D., assistant surgeon U. S. N., to Miss Helen Fay Pendleton, at Annapolis, November 19.

J. B. DOUGHERTY, M.D., New Berlin, Ohio, to Miss Jeannette R. Evans of Emporia, Kan., at Granville, Ohio, November 17.

Deaths.

Nelson L. North, M.D. College of Physicians and Surgeons in the City of New York, 1854, of Brooklyn, a member of the American Medical Association, New York State Medical Association, New York Academy of Medicine; physician and consulting surgeon to the Methodist Episcopal Hospital, and the Williamsburgh Dispensary, one of the oldest and most esteemed physicians of the Eastern District of New York, died suddenly from pulmonary hemorrhage, November 23, in Brooklyn, aged 74.

Seth S. Ultrich, M.D. Jefferson Medical College, Philadelphia, 1881, associate professor of surgery in Baltimore Medical College, a member of the Medical and Chirurgical Faculty of Maryland; surgeon-major Maryland National Guard, attached to the Fourth Infantry; surgeon to the Baltimore & Ohio Railroad, died suddenly from angina pectoris at his home in Baltimore, November 20, aged 46.

D. Bird Miller, M.D. Bellevue Hospital Medical College, New York City, 1874, formerly county physician of Richland County, S. C., and assistant superintendent of the State Hospital for the Insane, Columbia, died suddenly at his home in that city November 11, from heart disease, aged 54.

Elbert Mortimer Somers, M.D. College of Physicians and Surgeons in the City of New York, 1853, surgeon of the 146th New York Volunteer Infantry in the Civil War, and postmaster of Deansboro, N. Y., from 1861 to 1869, died at his home in that city after a long illness, aged 79.

Joseph Hume Taylor, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1876, a member of Lapeer County, Michigan State and Northeastern medical societies, died at his home in Lapeer, Mich., November 24, from general tuberculosis, aged 53.

Driesbach Smith, M.D. Cooper Medical College, San Francisco, 1885, and professor of nervous diseases in that institution, formerly assistant physician at the Napa State Hospital, died at the Marine Hospital, San Francisco, November 16, from disease of the spinal cord, aged 42.

Charles V. Mottram, M.D. Indiana Medical College, Laporte, 1847, surgeon of the Sixth Michigan Volunteer Cavalry during the Civil War, for several years under treatment at the Northern Michigan Asylum, Traverse City, died in that institution November 6, aged 85.

Robert Morris, M.D. Albany (N. Y.) Medical College, 1846, surgeon of the Ninety-first New York Volunteer Infantry in the Civil War, who retired from practice a year ago on account of ill health, died at his home in Ogdensburg, N. Y., November 14, aged 94.

James A. Bond, M.D. University of Louisville Medical Department, 1881, an eye and ear specialist of Kansas City, at one time surgeon of the Third Infantry, N. G. Mo., died at his farm in Craig, Mo., November 19, from tuberculosis, aged 48.

Charles H. Cockey, M.D. University of Maryland School of Medicine, 1867, for three years instructor in microscopy in that institution, died at his home in Baltimore, November 19.

George A. Beck, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1875, of Flemington, Pa., died recently and was buried at Jacksonville, Pa., November 17.

Orison B. Damon, M.D. Harvard University Medical School, Boston, 1866, assistant surgeon in the Navy during the Civil War, for many years a resident of Chicago, died at his home in Normal, Ill., November 18, from apoplexy, aged 67.

Daniel Fordyce Randall, M.D. Vermont Medical College, Woodstock, for many years a practitioner of Chesterfield, N. H., died at the home of his daughter in North Hinsdale, November 7, from heart disease, aged 76.

Spencer J. Northrup, M.D., one of the pioneer physicians of Minnesota, was run over by a freight train, November 7, and died from his injuries at his home in Buffalo Lake, November 8, aged 62.

Richard H. Meserve, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1853, who retired from practice in Limerick, Maine, two years ago, died in Augusta, November 11, aged 85.

A. Frank Taylor, M.D. Cleveland Medical College, 1868, a member of the Broome County (N. Y.) Medical Society, died recently at his home in Castle Creek, and was buried November 13.

Lewis W. Sutherland, M.D. Albany N. Y.) Medical College, 1855, of Pittsburg, Pa., died at the South Side Hospital in that city, November 12, after an illness of nine months, aged 78.

John W. Thomas, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1858, died at his home in Charleston, S. C., and was buried November 12, aged 68.

Daniel P. Putnam, M.D. College of Physicians and Surgeons in the City of New York, 1850, died from cerebral hemorrhage at his home in Cleveland, Ohio, November 4, aged 82.

Plato M. White, M.D. Medical College of Ohio, Cincinnati, 1882, shot himself through the heart while despondent, at his home in Los Angeles, November 10, aged 45.

C. T. Taggart, M.D. Central College of Physicians and Surgeons, Indianapolis, 1886, once member of the state legislature, died recently at his home in Sullivan, Ill.

W. E. McCord, M.D. Kentucky, 1894, died at his home near Crafton, Ky., November 17, from intestinal obstruction, after an illness of one week, aged 67.

Corbin F. Hargis, M.D. University of Maryland School of Medicine, Baltimore, 1890, of Pocomoke City, Md., died at Baltimore, November 18, aged 43.

Daniel F. Burton, M.D. Rush Medical College, Chicago, 1878, died at his home in Galesburg, Ill., November 17, from peritonitis, after a short illness.

George W. Lampton, M.D. Indiana, 1897, died at his home in Jeffersonville, Ind., November 19, from consumption after a lingering illness, aged 67.

J. P. Willett, M.D. Medical College of Ohio, Cincinnati, 1883, died November 15 from an accidental gunshot wound at his home in Webb City, Mo.

George Dallas Streeter, M.D. Pennsylvania, 1872, died suddenly at his home in Waco, Texas, November 18, from heart disease, aged 60.

J. R. Porter, M.D., a prominent physician of Jones County, Mississippi, died at his home in Moselle after a short illness, November 19.

Harvey H. Stamper, M.D. Kentucky School of Medicine, Louisville, 1892, died recently at his home in Campton, Ky., aged 34.

Richard K. Paine, M.D. Illinois, 1873, died suddenly at his home in Manitowoc, Wis., November 14, from heart disease, aged 63.

John S. Boyd, M.D. Ohio, 1874, died at his home in New Brighton, Pa., November 19, from tubercular peritonitis, aged 59.

Charles H. Craddock, M.D. Kentucky School of Medicine, Louisville, 1894, died at his home in McLoud, Okla., November 16.

William W. Newburn, M.D. Memphis (Tenn.) Medical College, 1860, died at his home in Memphis, November 18, aged 65.

John S. Petrie, M.D. Louisville Medical College, 1858, died suddenly at his home in Bardwell, Ky., November 9, aged 72.

Stephen W. Moore, M.D. Illinois, 1873, died at his home in Marion, Ind., November 14, after a short illness, aged 71.

John Bunn, M.D. Starling Medical College, Columbus, Ohio, died recently at his home in Batavia, Ohio, aged 68.

Henry Moore Humphrey, M.D. Philadelphia, died at his home in Dresden, Germany, November 13, aged 83.

Samuel R. Thompson, M.D. Ohio, 1859, died at his home in Uhrichsville, Ohio, November 14, aged 75.

Jesse R. Jones, M.D. Ohio, 1856, died at his home in Jackson, Miss., November 24, aged 71.

Herr H. Woods, M.D., died at his home in Granby, Mo., November 19, aged 104.

F. E. Marsh, M.D., died at his home in Quincy, Mich., November 12, aged 71.

D. C. Scarborough, M.D. Texas, died recently at Alba, Texas.

Death Abroad.

Herbert William Allingham, F.R.C.S.

The brilliant career of one of the best known of the younger surgeons of London has been cut short under tragic circumstances by his death at Marscilles, France, November 4. Herbert William Allingham was born in 1862, the eldest son of Mr. William Allingham, who was for many years the leading authority in England on diseases of the rectum and the author of the standard work on the subject. He passed the membership examination of the Royal College of Surgeons in 1883 and the fellowship examination in 1887, and in the same year was appointed surgeon to the Great Northern Central Hospital and demonstrator of anatomy in St. George's Hospital. Soon after he was appointed surgeon to St. Mark's Hospital for Fistula, the hospital at which his father had worked and made his reputation. In 1894 he became assistant surgeon to St. George's Hospital. He made the best use of his ample opportunities and soon acquired a great reputation not only as a specialist on diseases of the rectum, but as one of the best operators in general surgery in London. From an early age he assisted his father in his work and thus was armed with an experience and skill which many surgeons could not acquire until after years of hospital work. He edited the later editions of his father's work on "Diseases of the Rectum," wrote an excellent book on "Operative Surgery," and contributed an article on the diagnosis of diseases of the rectum to "Allbutt's System of Medicine." His reputation extended to the highest circles. In 1902 he was appointed surgeon-in-ordinary to the Prince of Wales and surgeon to the king's household. He was very kind and courteous and the services which he rendered to members of his profession in difficulties are remembered with gratitude by many. The death of his wife in last January, who had long been an invalid, was a severe blow to him. To add to this he had the misfortune about eighteen months ago to contract a chronic disease while operating on a patient. To this fact his friends attribute his inability to shake off the depression which followed his wife's death and his yielding to the strain.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Nov. 26, 1904:

Sweeney, Verge E., asst.-surgeon, granted two months' leave of absence.

Borden, Wm. C., McCaw, Walter D., surgeons, and Darnall, Carl R., asst.-surgeon, appointed members of a board of officers to meet at Army Medical Museum Building, Washington, D. C., Nov. 29, 1904, for the examination of such officers of the Medical Department as may be ordered before it to determine their fitness for promotion.

Cox, Walter, and Marrow, Chas. E., asst.-surgeons, ordered to Army Medical Museum Building, Washington, D. C., for examination for promotion.

Johnson, R. W., surgeon, granted leave of absence for two months. Barron, Noel L., asst.-surgeon, died at Iloilo, P. I., Oct. 20, 1904.

Maus, Louis M., deputy surgeon general, leave further extended twenty days. Mearns, E. A., surgeon, granted thirty days' sick leave with permission to apply for thirty days' extension.

Lashford, B. K., asst.-surgeon, granted thirty days' leave of absence about Dec. 20, 1904.

Davis, Oscar F., contract surgeon, returned to duty at Fort De Soto, Fla., November 13 from leave of absence.

Van Kirk, Harry H., contract surgeon, returned to duty at Fort Sil, Okla., November 13 from leave of absence.

Lemmon, Robert, contract surgeon, ordered from Fort McKinley, Me., to Fort Du Pont, Del., for temporary duty.

Plunkston, Omar W., contract surgeon, left Madison Barracks, N. Y., November 17, on leave of absence for two months.

Cooke, Robert P., contract surgeon, granted leave of absence for twenty days.

Rietz, Hugo C., contract dental surgeon, granted leave of absence for one month.

Merriek, John N., contract surgeon, left Fort Missoula, Mont., November 16 on leave of absence for two months.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Nov. 26, 1904:

Lando, M. E., asst.-surgeon, ordered to the Naval Hospital, Mare Island, Cal.

Wright, C. K., A. A. surgeon, ordered to the Naval Hospital, Norfolk, Va.

Nelson, H. T., Jr., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant (junior grade) from Nov. 14, 1904.

Berryhill, T. A., surgeon, detached from the *Baltimore*, and ordered to the *Oregon*.

Diehl, C., surgeon, detached from the *New Orleans* and ordered to the *Baltimore*.

Crandall, R. P., surgeon, detached from the *Oregon* and ordered to the *New Orleans*.

Nelson, H. T., Jr., asst.-surgeon, ordered to the Naval Hospital, Washington, D. C.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the six days ending Nov. 22, 1904:

Carmichael, D. A., surgeon, Bureau letter of Sept. 21, 1904, granting leave of absence for one month from Oct. 18, 1904, amended so that said leave shall be for 28 days only.

White J. H., surgeon, granted leave of absence for eight days from November 20.

Greene, J. B., P. A. surgeon, granted leave of absence for four days from Nov. 11, 1904, under Paragraph 191 of the Regulations.

Lumsden, L. L., P. A. surgeon, granted leave of absence for one month and ten days from November 20.

Goldberger, Joseph, P. A. surgeon, granted leave of absence for five days from Nov. 10, 1904, under Paragraph 191 of the Regulations.

Amesse, J. W., asst.-surgeon, granted leave of absence for fourteen days from Jan. 9, 1905.

Ebersole, R. E., asst.-surgeon, granted leave of absence for fifteen days.

Duke, B. F., A. A. surgeon, granted leave of absence for twenty-five days from November 15.

Frick, John A., surgeon, granted leave of absence for thirty days from December 1.

Frissell, C. M., A. A. surgeon, granted leave of absence for fifteen days from November 9.

Goldborough, E. W., A. A. surgeon, granted leave of absence for three days from November 26.

Hume, Lea, A. A. surgeon, granted leave of absence for thirty days from November 7.

Kimmer, W. A., A. A. surgeon, granted leave of absence for fifteen days from November 16.

Sibree, H. C., A. A. surgeon, granted leave of absence for seven days from November 18.

Townsend, W., A. A. surgeon, granted leave of absence for thirty days from December 15.

Miller, Charles, pharmacist, Department letter of Nov. 7, 1904, granting leave of absence for fourteen days from Nov. 10, 1904, amended to read fourteen days from November 15.

Hanrath, F. R., pharmacist, to report to medical officer in command at Cleveland, Ohio, for temporary duty and assignment to quarters.

Southern, F. A., pharmacist, granted leave of absence for twenty-six days from November 20.

Public Health.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the period from Nov. 19 to Nov. 25, 1904:

SMALLPOX—UNITED STATES.

California: Los Angeles, Nov. 6-12, 1 case.
Illinois: Nov. 13-19, Chicago, 21 cases, 2 deaths; Danville, 1 case; Springfield, 1 case imported from East St. Louis, Ill.
Louisiana: New Orleans, Nov. 6-19, 4 cases.
Michigan: At 48 places, Nov. 13-19, present.
Missouri: St. Louis, Nov. 13-19, 10 cases.
New York: New York City, Nov. 13-19, 4 cases.
Ohio: Toledo, Nov. 13-19, 1 case.
Pennsylvania: Philadelphia, Nov. 13-19, 2 cases.
South Carolina: Georgetown, Nov. 16, 2 cases; Greenville, Nov. 13-19, 2 cases.
South Dakota: Sioux Falls, Nov. 13-19, 2 cases.
Washington: Tacoma, Nov. 6-12, 2 cases.
Wisconsin: Milwaukee, Nov. 6-19, 42 cases.

SMALLPOX—FOREIGN.

Brazil: Bahia, Oct. 15-29, 43 cases, 2 deaths; Rio de Janeiro, Oct. 9-23, 578 cases, 183 deaths.
China: Chefoo, Oct. 8-15, 1 case; Shanghai, Oct. 15, 3 deaths.
France: Paris, Oct. 30-Nov. 5, 12 cases.
Great Britain: Oct. 30-Nov. 5, Bristol, 7 cases; Manchester, 1 case; Newcastle-on-Tyne, 5 cases; Nottingham, 2 cases.
Italy: Palermo, Oct. 30-Nov. 5, 16 cases, 2 deaths.
Netherlands: Rotterdam, Oct. 30-Nov. 5, 1 case.
Philippine Islands: Manila, Sept. 19-24, 2 cases, 2 deaths.
Spain: Barcelona, Oct. 21-31, 15 deaths.

YELLOW FEVER.

Brazil: Para, Sept. 1-Oct. 20, 16 deaths; Rio de Janeiro, Oct. 9-23, 2 cases.
Ecuador: Guayaquil, Oct. 26, 1 death.
Mexico: Nov. 6-12, Merida, 1 case; Texistepec, 21 cases, 4 deaths.
Panama: Colon, Nov. 7, 1 case from Panama.

CHOLERA.

Egypt: Suez, Nov. 4, 2 cases from Br. S. S. *Coulsdon* from Java.
India: Calcutta, Oct. 8-22, 22 deaths.
Russian Empire: Baku, Oct. 11-18, 60 cases, 24 deaths; Merv, Oct. 1-7, 1 case.

PLAGUE.

Africa: Cape Colony, Port Elizabeth, Oct. 13-19, 1 case.
Brazil: Bahia, Oct. 15-Nov. 4, 18 deaths; Rio de Janeiro, Oct. 9-23, 72 cases, 25 deaths.
Chile: Iquique, Oct. 1-15, present.
India: Bombay, Oct. 19-25, 63 deaths; Calcutta, Oct. 8-22, 5 deaths; Karachi, Oct. 17-25, 9 cases, 8 deaths.
Peru: Callao, Oct. 1-15, 3 cases; Lima, Oct. 1-15, 5 cases.
Straits Settlements: Singapore, Oct. 26-Nov. 8, 1 case, 1 death.

Medical Organization.

SPECIAL WORK IN WISCONSIN.

By J. N. McCORMACK, M.D.

CHAIRMAN OF THE COMMITTEE ON ORGANIZATION.

The itinerary arranged for me in this state was even more extensive than the one heretofore reported in THE JOURNAL for Indiana. Dr. Sheldon is nearly a model of what the secretary of a state association should be, and, having ample notice of my intention to visit his state for detailed work, with the advantage of the experience gained by the Indiana Council in similar efforts, and the assistance of their circular letters and programs, he was soon able to put the entire machinery of his new organization in operation to secure a full attendance at the meeting in each council district.

Dr. Sheldon made the Indiana circulars and programs and his own suggestions into a kind of "Round Robin," and, beginning with the district in which the first meeting was to be held, had them sent from councilor to councilor until all had had the benefit of the information thus easily furnished. The success of this plan was soon made evident in both the attendance and interest.

Beginning at La Crosse, November 3, in a little less than three weeks I visited Eau Claire, Superior, Ashland, Wausau, Marinette, Oshkosh, Sheboygan, Milwaukee, Burlington and Madison, holding a meeting in each district except the one in the extreme southwestern part of the state and two in the Superior district.

Wisconsin is new in this work, having reorganized and adopted the county society plan only eighteen months ago, but the progress made in that time is remarkable. Many of the counties in the lumber regions in the central and northern sections are very sparsely settled, making it necessary for the present, at least, to organize two or more counties together, but nearly every county is embraced in some local organization and over two-thirds of the entire profession of the state have been brought into the membership.

While in none of these counties were the societies up to the standard of two or three of the best in Indiana in their practical work and in the results secured, considering their age, and especially in view of the enthusiasm aroused by these district meetings, the outlook is most promising. The younger element abounds here and dominates the profession to a degree not observed elsewhere, although this condition of affairs should have been expected in a new country. The districts were usually so large that only a representative attendance was possible from some of the counties, but these promise to begin work on the lines laid down by the Association as soon as they returned home to make each county society a vital, practical force for the scientific, social, moral and financial benefit of every physician and citizen within its jurisdiction.

In this state, as in many others I have visited, the most serious obstacle to real organization lies in the absence of any practical co-operation or even understanding between the state societies and the state licensing board, and between the county societies and the county boards of health. Even where there are sectarian boards, or sectarian representatives on one board, the difficulties of such co-operation are being constantly minimized as the work of organization progresses and will soon be entirely removed by complete frankness and fair dealing on all sides. This would all have been made easier if we had provided for a representative from all such boards in the House of Delegates in each state association, as I believe should be done.

The hospitality of the physicians of Wisconsin was only limited by time and opportunity. The only complaint which could be made was that the refreshments and social entertainments were often so elaborate as to consume time needed for the practical. Altogether the experience there was pleasant, profitable and an inspiration for even better work on my part in the future.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Southern Surgical and Gynecological Association, Birmingham, Ala., December 13-15.

Western Surgical and Gynecological Association, Milwaukee, Wis., December 28-29.

American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Nov. 2, 1904.

Dr. Harold N. Moyer in the Chair.

Stenosis of the Lower Portion of the Esophagus.

DR. B. W. SIPPY presented a man who, five or six weeks ago, began to have difficulty in swallowing. During the act of swallowing he feels great discomfort below the lower portion of the sternum, which is more pronounced in swallowing liquids than solids. The onset of the trouble was rather sudden. Some days the difficulty in swallowing is greater, and on these days food is regurgitated without any effort at vomiting. The food does not taste sour, but is regurgitated in practically the same condition as when swallowed. Dr. Sippy said that when a patient presents himself with pain in the lower portion of the sternum on eating, and when food regurgitates, or even before the symptom of regurgitation is present, esophageal stenosis should be suspected. Many things produce pain on eating, among them obstruction of the esophagus, ulcer of the cardiac end of the stomach, carcinoma of the cardiac end of the stomach, perigastric inflammation, either acute or chronic, perigastric adhesions and epigastric swelling. Dr. Sippy introduced an esophageal bougie of large size, and located the obstruction in the esophagus at about 40 centimeters from the incisor teeth, the obstruction being near the cardia. A diagnosis of esophageal stenosis at its lower portion was made. After considering at length the differential diagnosis, he said it is advisable to place the esophagus as nearly at rest as possible. Foods should be given which are mushy in character, neither too hot nor too cold, and which will pass readily without causing irritation.

He said that Mikulicz fed a patient through the gastrostomy wound for five years, and still the spasm continued. He subsequently cut down through the gastrostomy wound and forcibly stretched the cardiac orifice, producing a submucous rupture of the fibers, and the patient has had no trouble since. He has operated on three other cases since, with good results. Dr. Sippy said that cases which are recognized early may be so managed that the process does not continue. Spasmodic esophageal stricture may continue for a period of a few months, then followed by spontaneous recovery. Once dilatation occurs, it is very improbable that a patient ever recovers, and sooner or later there comes a time when there is so much spasm that the patient can no longer obtain a sufficient quantity of food for nourishment. Some patients die in two or three years, while others live many years, but it is a serious condition after dilatation is once present. Dr. Sippy passed the esophagoscope (after thorough cocaineization of the esophagus), so that the members of the society could see the point of constriction. He said that in this case a bougie would be passed day by day; the patient would be given food that was non-irritating; between 30 and 40 grains of bromid of sodium would be given every four hours, and the patient's body would be given as much rest as possible. With this line of treatment he hoped to succeed finally in overcoming the spasm, as there was no ulceration, no erosion, and no sacculation in this case.

DISCUSSION.

DR. NORMAN BRIDGE stated that Dr. E. Fletcher Ingals once found the cardiac extremity of an esophagus absolutely open. Dr. Bridge has no doubt that this was due to some pathologic state. He urged the utmost care and caution in passing esophageal bougies, as he has known of some instances where great violence was done by exerting too much

force in introducing bougies into and against the spasm of the cardiac end of the esophagus. He related the case of a woman who had a spasm of the esophagus, which was extremely unyielding at times, so that it made swallowing of food difficult, yet at other times it would relax so that she could swallow without the slightest difficulty.

DR. NORVAL H. PIERCE has used the esophagoscope in the diagnosis of tumors and in extracting foreign bodies. He thinks the instrument has a rather limited, though well-defined, sphere. In diagnosis it is extremely important, and for the purpose of removing foreign bodies it stands pre-eminently to all other measures.

DR. SIPPY said that until recently spasm of the esophagus, producing dilatation, was seldom diagnosed. Probably not more than 75 or 80 cases are reported in the literature up to the present time. The condition, however, is relatively common, but is overlooked. Within the last eight months he has seen 7 cases of idiopathic dilatation of the esophagus with cardiaspasm. He has previously reported 3 cases. Physicians must diagnose this condition of the esophagus early to prevent the serious results which will certainly follow if dilatation once takes place.

NEW YORK ACADEMY OF MEDICINE.

Regular Meeting, Nov. 3, 1904.

Dr. Andrew H. Smith in the Chair.

The Present Status in the Investigations of the Subject of Internal Secretions.

DR. WILLIAM H. THOMSON made this the subject of the Anniversary Discourse. He said that laboratory reports have shown us how ignorant we are in regard to certain pathologic and physiologic processes. The mechanism of secretion has always been more or less obscure. There is no common agreement regarding the urinary secretion nor even regarding a single element in the urine. It is still a question what the kidney has to do with urea, for when three-quarters of the kidney have been removed from healthy dogs, the remaining one-quarter has secreted more urea than a sound and whole kidney until the animal died from a general breakdown of the proteid tissues into urea. He said that uremia is not due to the suppression of the functions of the kidney, because one could have an impacted calculus, with complete suppression of urine, without developing uremia. The secretions, no matter in what amounts nor how easily procured, have but little to tell of the vital processes to which they owe their origin. He reviewed the functions of different glands in the light of recent research. The spleen must be an important organ, as it is present in all vertebrates, yet it has been proved that all animals can get along without the spleen, and its extracts show no special properties. The thymus gland seems to be in some way associated with the origin of white blood corpuscles, and, as the lymphatic tissues increase, this body becomes superfluous. The autopsies on 18 cases of marasmus that have been reported show that the only lesion found was that of atrophy of the thymus. Dr. Thomson concluded that atrophy of the thymus is always found in cases of infantile atrophy and that the condition of the thymus is an index to the general nutrition. The general increase of lymphatic tissue throughout the body, accompanied by enlargement of the thymus, is best treated by cod-liver oil. In regard to the thyroid gland, he said that myxedema has been artificially produced, and is unmistakably the result of atrophy of the gland itself. The administration of thyroid extract holds myxedema in abeyance, and the elements that this gland adds to the blood are very important. The question as to whether this gland is necessary to life has received various answers, but more recently it has been held that certain small bodies, called parathyroids, which are closely associated with the thyroid, and in some animals imbedded in the gland itself, while they can not compensate for the thyroid if this latter is removed, yet if the parathyroids are removed the animals experimented on are taken with tremors, convulsions, etc.: no such condi-

tions result if the thyroid is removed and the parathyroids left. He thought that some internal secretion may have antitoxic functions by which poisons in the body are neutralized. It is claimed that Graves' disease is accompanied by hypertrophy of the thyroid and this charges the blood with an excess of its own secretion. In all cases of Graves' disease, he has found the parathyroids smaller than normal. He has concluded that the thyroid is not primarily the seat of Graves' disease, but is only a secondary involvement, much as the spleen is involved in ague. He maintains that the treatment of this disease by diet and gastrointestinal attention gives better results than symptomatic or surgical procedures. He believes that the internal secretion of the thyroid is intimately related to the nutrition of connective tissue. Thyroid extract has been prescribed for almost every condition, but its real value is still undetermined. The fact that so small a body as the pituitary gland should interfere with nutritive changes, as in acromegaly, seems strange. One can not but concur, however, with the opinion that disease of this body is a common accompaniment of acromegaly. He believes that the normal growth of the body represents the sum of the interaction of the growth of different organs of the body. In acromegaly a general derangement of the processes of nutrition may include the functions of one or more of the ductless glands. He said that there is no doubt that the pancreas has much to do with the origin of diabetes; if the whole gland is excised, diabetes will develop in its most severe form. The extent of the influence of the islands of Langerhans on the development of diabetes is not clearly known. Diabetes is not dependent on the quantity of secretion, for if one-quarter or one-fifth of the pancreas is left in the body no diabetes occurs. Addison's disease is caused by disease of the adrenals. The chief property of adrenalin seems to be to cause arterial contraction. A not improbable surmise is that the high tension of the pulse in many forms of kidney disease is due to the action and excess of adrenalin in the blood. The inference is that a high tension pulse goes with a contracted kidney; if this action is exerted by some agent in the blood, the administration of some vasodilator should be followed by increased urinary secretion. He considers it very important that the adrenals should be carefully examined in every case of kidney disease.

Travel Notes.

XVIII.

BENGAL MEDICAL COLLEGE AND CALCUTTA GOVERNMENT GENERAL HOSPITAL.

NICHOLAS SENN, M.D.
CHICAGO.

PORT SAID, EGYPT, Sept. 26, 1904.

The medical interests of Calcutta, a city of great commercial importance, with nearly a million of inhabitants, center in the Bengal Medical College and the Government General Hospital; its clinical department, college and hospital are located on the same spacious grounds, artistically laid out, intersected by well-made and well-kept walks and ornamented with trees, shrubbery and flowers. (Fig. 1.) Both institutions are managed by officers of the Indian Medical Service, who constitute the faculty of the college and attending staff of the hospital, thus cementing together the didactic and clinical teaching and uniting them practically under one administration, and securing uniformity in the methods of teaching and a systematic progression of the courses from term to term and year to year.

BENGAL MEDICAL COLLEGE.

The Bengal Medical College was founded in 1830, and from a small beginning has gradually developed into a great medical school with an attendance at the present time of about 600 students. The original structure is an imposing, massive stone building with graceful fluted columns and broad stone steps on the side of entrance. The college, as well as the hospital

which in reality forms an integral part of it, had to be enlarged from time to time in order to accommodate the rapidly increasing number of students. The requirements for admission and graduation correspond with those of the other medical colleges of India. Separate laboratory buildings have been erected, well adapted for the purposes for which they are intended and fairly well equipped. The medical classes are very much mixed, not only in nationality and color, but also in the different aims pursued by the students. Thus there are "regular" and "casual" students; the former continue their studies for five years with a view of passing the final examinations for the L.M.S. or M.B. degree; the latter are permitted to take a partial course of lectures or any department of hospital

Fig. 1.—Bengal Medical College, Calcutta.

practice, with the permission of the principal of the school and the professor, on payment of the fees in advance at the fixed rates.

Then there are special provisions made for female medical students and military pupils. Admission to the female certificate course is granted by the principal, provided the student has passed the preliminary arts examination. Admission to the military pupil course is regulated by the director-general of the Indian Medical Service. I am particularly anxious to define in connection with the Bengal Medical College the status of female medical students in the medical colleges of India. Female students may enter: a, As regular students for the

Fig. 2.—Quarters for military pupils.

university course; b, as female certificate students; c, as casual students. The preliminary arts examination required before entering is: a, The F.A., Calcutta, or its equivalent; b, the entrance, or its equivalent; c, the entrance, or its equivalent. A student who has entered for the university course may be permitted by the principal to change her plans of studies at any stage, and to join the certificate class instead. Female students entering as regular or female certificate students are eligible for a government scholarship, 20 rupees per month, and are not charged any fees.

FEMALE CERTIFICATE CLASS.

Admission to this class is granted by the principal. The

Fig. 3.—Eden Hospital, Calcutta.

Fig. 4.—Elephantiasis of legs. By courtesy of Capt. Rogers, I. M. S.

number of admissions is determined by him. Students of this class must be over 17 years of age before commencing their studies. They must have passed a preliminary arts examination before admission to the college, viz., 1, entrance examination of the Calcutta university or an equivalent; 2, a preliminary arts examination recognized by the British general medical council.

THE SURNOMOVE HOSTEL.

All female students are expected to reside in the hostel, located in the college grounds, and only under exceptional circumstances will they be allowed to live with friends or guardians outside the college. Applications may, therefore, have to be refused on the ground that there is no accommodation in the hostel. Under the rules of the hostel preference is given to native students. While in the hostel students are under the supervision of the lady superintendent and must conform to

Fig. 5.—An undiagnosed case. By courtesy of Capt. Rogers, I. M. S.

the rules laid down for their guidance. While within the college precincts students are under the disciplinary control of the principal.

MILITARY PUPIL CLASS.

The present attendance of Bengal Medical College includes 96 military pupils who, at government expense, are being edu-

cated for the subordinate Indian Medical Service. These students are in uniform and reside in a separate building across the street from the college (Fig. 2), and besides pursuing their routine studies are drilled daily by a retired captain of the Indian army, who at the same time exercises supervision over them and is responsible for their conduct outside of the college precincts. The following are the regulations for this class:

1. The administrative control of this class, as a portion of the Indian subordinate medical department, rests with the director-general of the Indian Medical Service.
2. Students are admitted to this class under the orders of the government of India, military department.
3. Students must be of European or Eurasian parentage, physically fit, of good character, and between 16 and 18 years of age on admission.
4. While at the college they will be styled military pupils.
5. Their education at the college is intended to fit them for employment in hospitals of British troops and in military and civil appointments.
6. The course of study is four years.
7. Military pupils must obtain permission from the principal before attending lectures on subjects outside their curriculum.
8. The periodical and final examinations of the curriculum will be conducted by the faculty, and students who fail to pass them will be dealt with in accordance with the rules laid down in the prospectus issued by the director-general of the Indian Medical Service.
9. At the end of the course military pupils, if reported qualified, will be attested and admitted into the Indian subordinate medical department.
10. At the same time they will receive a certificate qualifying them to practice physic in India and designate themselves diplomates of the Medical College of Bengal.
11. A military pupil who, at the end of his first year at the college, does not, in the opinion of the principal, give promise of proving a successful or desirable student, will be liable to removal.
12. A military pupil, in the event of failing to pass the periodical and final examinations of the curriculum, or misconducting himself, may be summarily removed by the director-general of the Indian Medical Service, and all certificates to which he may otherwise be entitled withheld.
13. A military pupil desirous of relinquishing his studies can only do so with the sanction of the director-general, and on refunding the whole amount of pay received by him.
14. A military pupil who, after completing the course, declines to be attested, will similarly refund the whole amount of pay received by him, and will not receive any certificates.
15. The order and discipline of the military pupils is maintained by the superintendent of military pupils and the resident staff, under orders of the principal.
16. While under instruction in the college or hospitals military pupils are subject to the rules for the maintenance of discipline applicable to other students.
17. Leave of absence to military pupils is granted by the principal.
18. No certificate of attendance on any course of lectures, or practical work, will be granted to a military pupil unless he has passed the entrance examinations of the Calcutta university, or its equivalent, before commencing the course, and has also paid the fees laid down for casual students.

Female medical students who enter the certificate class continue their studies for four years and are required to pass a satisfactory examination in the following branches:

First Year.—Descriptive and surgical anatomy, general anatomy and physiology, materia medica, elementary chemistry, dissection, practical pharmacy, followed by a test examination in anatomy, physiology, materia medica and chemistry.

Second Year.—Descriptive and surgical anatomy, general anatomy and physiology, materia medica, chemistry (full course), dissections (six postmortems), nine months' hospital practice, three months' out-patient practice, to be followed by a final examination in anatomy, physiology, materia medica, and chemistry.

Third Year.—Medicine and clinical medicine, surgery and clinical surgery, midwifery, medical jurisprudence, pathology, practical midwifery (three labors), ophthalmic medicine and surgery, six postmortems, nine months' hospital practice, three months' ophthalmic hospital practice, to be followed by final examination in pathology and medical jurisprudence.

Fourth Year.—Medicine and clinical medicine, surgery and clinical surgery, midwifery, practical midwifery (six cases of labor), three months' hospital practice, midwifery wards (six months), dental out-patient practice (three months), dental surgery (optional), to be followed by final examinations in medicine and surgery and midwifery.

It will be seen from the above that in the whole curriculum there is only one optional branch—dental surgery. The English teachers of medicine and surgery believe in the wisdom of making the attendance on all lectures and clinics obligatory, as it should be. Some of our best American medical colleges are making a serious mistake in giving the students too much liberty in the choice of their studies, the results of which must necessarily be a fragmentary and imperfect knowledge in some of the most important branches they are expected to master. Optional liberties in a medical college are as harmful as they would be if they were introduced into our primary schools. Students thus privileged will only learn enough of the branches that are distasteful to them to squeeze through the final examinations and no more. Optional studies are in place in post-graduate education, but should not be countenanced in a medical college whose function it is to instruct the students systematically and thoroughly in all branches pertaining to medicine and surgery.

The Bengal Medical College has undertaken the education of midwives, a very commendable extension of its wide field of usefulness.

MIDWIVES AND DAIS.

The regulations for this department are formulated under this heading.

Women who have a fair knowledge of English, but who have not passed the entrance examination or its equivalents, will be admitted into the Eden Hospital to learn midwifery. The government grants 20 rupees (\$6.40) a month toward the board, washing, etc., of each pupil and gives them free quarters. After a year's tuition and bedside practice, if found proficient, they will obtain a certificate qualifying them to practice midwifery. The fee for each certificate is 5 rupees (\$1.60). They are expected to do general nursing in the wards as well as midwifery. Women who have not passed the entrance examination or its equivalents, but who can read and write Bengali, can be admitted into the Eden Hospital as pupil dais. The government grants 6 rupees (\$1.92) each month to eight pupils toward their board, washing, etc., and gives them free quarters. After twelve months' tuition and bedside practice, if found proficient, they will obtain a certificate qualifying them to practice midwifery. They are expected to do nursing in the wards as well as midwifery. The education of these two classes of midwives for country and village practice must meet a pressing need, as in many remote parts of India medical aid is too remote to be available in obstetrical cases. These women can be made also very useful to physicians and patients as nurses in grave cases of illness or accident.

Major F. J. Drury, I.M.S., is principal of the college, and Professor Bird occupies the chair of surgery.

CALCUTTA GOVERNMENT GENERAL HOSPITAL.

The Calcutta Government General Hospital is virtually the clinical part of the Bengal Medical College. The different pavilions and laboratories form a group of buildings of which any city and country might well be proud. The Eden Hospital (Fig. 3), a separate, new modern building, is the maternity in which about 600 women are delivered every year. The strictest cleanliness prevails throughout this building and sepsis in in-patients is almost unknown. The woman in labor is prepared with the same care as for a major operation, and everything brought in contact with her during the delivery and lying-in period is carefully disinfected (hands) and sterilized (dressings). The delivery room has all the aspects of an operating room. Three tables are always kept in readiness. Mother and child remain in the hospital from ten to fourteen days after delivery. The Ezra ward, with forty beds, the gift of a rich Jew, is for the exclusive use of Jews. The original hospital building is an old-fashioned two-story solid stone

building which in the light of modern improvements would appear somewhat antiquated if it were not for the electric lighting and electric punkah motor. The latter is kept in motion night and day during the hot season and is a source of immense comfort to the patients. The hospital can accommodate 450 patients and has a few private rooms for which a charge of 2 rupees (64 cents) a day is made. The operating room has a small amphitheater which affords standing room for the students, but lacks many of the conveniences and appliances considered at the present time so essential for aseptic surgical work. As in all hospitals in India, chloroform is the favorite anesthetic and the bichlorid of mercury takes the first place as an antiseptic. Buried sutures have been abandoned almost entirely and the removable silk and silkworm-gut sutures are in general use. The nursing is in charge of two Anglican sisters, who are also at the head of a recently organized training school for female nurses, which has now an attendance of forty pupils. Male and female ward attendants assist the nurses in their work. The pupil nurses are Europeans or Eurasians and remain for only one year in training.

Among the more interesting cases Professor Bird showed me five patients recently operated on for abscess of the liver. All were doing well, although greatly emaciated from the effects of the disease. Abscess of the liver appears to be extremely common in this part of India, as Professor Bird not long ago operated on twenty cases in two months. Carcinoma in all its forms is met with here with about the same frequency as in Europe. Acute osteomyelitis and surgical tuberculosis, on the other hand, are comparatively rare. Syphilis and gonorrhea are very common, but in the native both of these diseases pursue a benign course. Enlargement of the prostate gland in the aged natives is very rare. This statement is confirmed by all surgeons I met in India. They can offer no explanation for this, but there must be something in their habits or manner of living that protects them against this curse of advanced life so common among Europeans and Americans. Stone in the bladder is very common, but comparatively few of these cases enter the hospital, as they are operated on by physicians who practice in the country districts, the operation being regarded by them as a safe and easy one.

A chronic parenchymatous inflammation of the mammary gland in young men is of frequent occurrence here and is usually treated by excision. Cystitis is very rare as compared with our hospital experience. Two reasons might be advanced to explain this: the rarity of prostatic hypertrophy in India and the very mild course gonorrhoea pursues in the natives.

Professor Quicke of Bombay made the statement to me that he never knew of a rajah to enter on a catheter life. Tuberculosis of the kidney and bladder is also infinitely more rare in India than in our country. As is the case with all colored races, the natives of India are very subject to benign tumors, especially fibroma, keloid, lipoma, papilloma and cystoma. On the other hand, affections of the veins, hemorrhoids, varicocele and varicose veins of the lower extremities, are not nearly as frequent as with us. Among the thousands of bare-legged men I saw in India I did not observe a single instance of well-marked varicosity and, considering the enormous clinical material that passes through the large hospitals, the number of operations for hemorrhoids and varicocele is astonishingly small. Laxative vegetable diet, active exercise, absence of tendency to obesity and looseness or absence of dress will go far to explain the comparative freedom from ectatic disease of the hemorrhoidal, spermatic and saphenous veins, a suggestion which might be of some service to our numerous sufferers from plethora, obesity and stagnant venous circulation.

In the medical wards I found here, as in all hospitals in India, the greatest variety of malaria and its multitude of complications. A large part of the hospital space is occupied by malarial patients and the physicians here have an excellent opportunity throughout the entire year to study malaria in all its endless clinical and pathologic aspects.

What an excellent place Bombay or Calcutta would be for a great school for the study of tropical diseases! (Fig. 4.) The material is here, and not in London nor Liverpool, and if

utilized to greatest advantage it must be studied here and not thousands of miles away from where the diseases had their origin.

Typhoid fever is not so common as we would suspect after an inspection of the water supply and insanitary environments of the masses of the natives. The native prefers to draw his water from the well that has served his ancestors for centuries rather than from the tap of the modern water-works. If it is at all within reach, water from the sacred Ganges is his favorite drink. Most of the cases of typhoid fever I examined in the different hospitals of India were of a mild type, and the mortality from this disease as published in the hospital reports is not great.

India has its share of pulmonary tuberculosis, but for reasons that can not be explained tuberculosis of bones and joints is very rare as compared with the frequency with which this disease attacks our childhood population. In any of our large hospitals we see ten cases of joint and bone tuberculosis to one in the hospitals of India, and on the streets of Chicago ten cripples from this disease to one in India. The same remarks apply to tuberculosis of the lymphatic glands and genito-urinary organs. Diarrhea, dysentery and malaria are the prevailing diseases of India and it is these affections that tax most heavily the therapeutic resources of the physicians, both in hospital and private practice. In this as well as in all clinical hospitals of India, much stress is placed on the practical training of the students, more especially by bedside instruction. The out-patient department is utilized to the greatest advantage and it is here that the students are given the very best opportunities to come in touch with the patients. Under the supervision and guidance of the professors or competent instructors, they are required to make thorough clinical examinations, apply dressings and assist in the operative work, and the last year students are privileged to perform some of the minor operations.

The average medical student in India has a keener taste for practical work than for scientific research, and consequently makes good use of his clinical opportunities. The female medical students are no exception to this rule, although it is generally admitted that at the end of the curriculum, in consequence of a more diligent attendance on the didactic lectures and a more liberal use of midnight oil in reading their text-books, they are ahead of their male colleagues in the theoretical knowledge of medicine. The male medical students are very fond of all kinds of athletic sports, and the time spent by them in developing their physical strength is made use of by the women in committing to memory the contents of their text-books. Then, too, the young men spend more time in amusements when away from the playgrounds and out of the hospital and lecture-rooms than the young women, who have less desire in this direction and are kept under stricter supervision.

If I had any criticism to offer in the methods of teaching clinical surgery in India I would say that the clinical material and specimens obtained by operations and postmortems are not made use of to the greatest advantage for the benefit of the students. Pathology should be made the most important feature in the teaching of surgery as well as of medicine. In defense of this apparent neglect it must be said that the clinical teachers in some of the colleges are without the necessary appliances and equipments to give surgical pathology the prominence it so well deserves (Fig. 5).

It was in the pathologic laboratory of the Bengal Medical College that I was given an opportunity to examine a new parasite, the *Piroplasma donovani*, through the courtesy of the director of the laboratory, Capt. Seward Rogers, I.M.S. He was also kind enough to furnish me with several mounted slides containing this parasite so recently discovered by Leishman and Donovan. In another place I will give a more detailed account of this parasite, history of its discovery and etiologic relationship to splenic anemia. Medical science is much indebted to the researches of the members of this corps, many of whom are indefatigable workers in a climate well calculated to undermine physical strength and paralyze mental activity.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Tinea Tonsurans.

The following outline of treatment is recommended by Gaucher in *Med. Press* in treatment of tinea tonsurans occurring in children: The hair should be cut as closely as possible once a week; massage to the scalp twice daily is recommended, giving special attention to the diseased spots. After the massage the following should be applied by means of a tooth brush, with friction:

R. Olei ricini	℥i	4
Tinct. cantharidis	℥i	4
Spiritus camphoræ	℥iv	120

M. Sig.: To be applied locally once a day.

In adults it is not necessary to cut the hair. The scalp should be washed once a week with tar soap and frequent massage applied by the patient. As a local application the following is recommended:

R. Spiritus odoratus (Eau de cologne)	℥ss	45
Spiritus lavendulæ	℥ss	45
Tinct. capsici	℥i	4

M. Sig.: To be well applied locally once a day.

The following ointment may be substituted for the foregoing liquid preparation:

R. Balsami Peruviani	℥ss	15
Acidi salicylicii	gr. xx	130
Resorcini	gr. xx	130
Liq. petrolati	℥iii	90

M. Fiat linimentum. Sig.: To be applied locally at night.

At the same time the patient may be instructed to rub the scalp every morning with the following stimulating mixture:

R. Essentia terebinthinæ	℥ss	15
Spiritus camphoræ	℥iii	90
Liq. ammoniæ	℥i	4

M. Sig.: Apply locally in the morning.

In the case of a woman the following combination is recommended by the author:

R. Hydrarg. chloridi corros.	gr. iv	25
Acidi aceticii glacialis	gtt. xx	130
Resorcini	℥ss	2
Chloralis hydratis	℥i	4
Tinct. cantharidis	℥i	4
Tinct. jaborandj	℥i	4
Spiritus rect.	℥vii	210
Olei ricini	℥i	30

M. Sig.: To be applied locally once daily.

Lumbago.

The following combinations are recommended by *Med. Press* in the treatment of lumbago:

R. Antipyrini	℥i	4
Sodii salicylicis	℥i	4
Aquæ	℥iii	60

M. Sig.: One teaspoonful four times daily.

The local treatment is important. As a liniment the following is recommended:

R. Methyl salicylicis	℥iii	8
Tinct. belladonnæ	℥ii	8
Tinct. opii	℥ii	8
Spiritus camphoræ	℥iv	120

M. Fiat linimentum. Sig.: Apply locally twice daily with light massage.

Yeo recommends the following local application:

R. Spiritus chloroformi	℥i	4
Olei olivæ, Æ.	℥ii	60

M. Sig.: To be rubbed thoroughly over the affected areas.

Or:

R. Liqnoris ammoniæ	℥ss	15
Olei terebinthinæ, Æ.	℥i	30
Olei olivæ	℥ss	2
Olei limonis	℥ss	2

M. Fiat linimentum. Sig.: Apply locally.

Or:

R. Olei cajuputi	℥i	8
Tinct. opii, Æ.	℥iii	8
Olei terebinthinæ	℥ss	15

M. Fiat linimentum. Sig.: To be applied locally with thorough friction.

Aconite in combination with opium is of value in relieving the pains of muscular or joint rheumatism. The following combination is recommended:

R. Tinct. aconiti	℥iii	8
Olei terebinthinæ	℥i-℥ii	30-60
Tinct. opii	℥i	30
Linimenti saponis q. s. ad.	℥vi	180

M. Fiat linimentum. Sig.: To be used locally three times a day.

Internally the following combination is recommended by Yeo in the treatment of chronic muscular rheumatism:

R. Pulv. resinæ guaiaci	℥i	4
Potassij iodidi	℥i	4
Tinct. colchici sem.	℥iii	12
Syrupi simplicis	℥ii	60
Aquæ cinnamomi q. s. ad.	℥vi	180

M. Fiat mistura. Sig.: A dessertspoonful to a tablespoonful twice daily.

Pruritus Ani.

Pruritus, according to Mr. Malcolm Morris in *British Med. Journal*, is more often a symptom than a disease. As an etiologic factor, gout ranks first as a cause of pruritus ani. Certain articles of diet, such as shell fish and strawberries, are apt to cause it. Other general causes are tobacco, rheumatism, albuminuria and diabetes. Locally, hemorrhoids, constipation, fissure, fistula, foreign bodies, worms, parasites, especially pedicula, growths, irritating discharges and diseases of the sweat glands, all are etiologic factors. It may be a reflex symptom, pointing to disease of the urethra, uterus, bladder, tumors, etc.

In the treatment of pruritus ani, therefore, the cause should be ascertained if possible, and removed. Any disorder of the liver, stomach, intestines and genitourinary tract should be properly treated.

A bland, nutritious diet should be recommended and constipation corrected. Condiments, rich sauces, highly seasoned foods and game should be forbidden. Abstinence from alcohol should be insisted on or it should be used very moderately. Coffee should also be prescribed in very limited quantities.

Autointoxication must be prevented by antisepsis. Small doses of calomel are particularly useful, given at night and followed by a saline the following morning. Ichthyol, five grains (.30) taken on an empty stomach in the morning and late at night is of value. Salol should also be given as an antiseptic. As a laxative aloes is contraindicated because of its irritating action on the rectum. If the appetite is poor and nutrition failing, tonics are indicated. Quinin, arsenic and nux vomica may be given under proper circumstances. Opium should not be given, as it has a tendency to produce itching.

If the pruritus is so severe as to disturb the sleep, succus conii, one dram (4.00), given three times a day, is of value. The bromids with sulphonal or chloral may be cautiously allowed. Thorough flushing of the system with large quantities of weak alkaline waters is often a potent aid in treatment. For this purpose the author recommends a course at certain mineral springs. Scrupulous cleanliness must be observed. The use of paper in the ordinary way is quite insufficient to clear the small portions of fecal matter. And, according to Adler, the use of harsh paper, especially when printed on, is a cause of pruritus. Pledgets of cotton serve the purpose better, moistened in warm water. The application of water as hot as can be borne is recommended by the author as one of the most efficacious measures. Oatmeal, bran, borax or sodium bicarbonate may be added to the water with advantage. In persons who sweat profusely carbolic acid lotion (1 to 60), a

saturated solution of boric acid or permanganate of potassium lotion should be used. After bathing, a soothing or cooling remedy should be applied.

Local remedies for pruritus ani may be classified as anodyne, antiseptic and caustic.

Cocain ranks first as an anodyne. It should be applied in the form of a suppository containing one-half a grain (.03) of the substance, or an ointment (4 per cent.) with boric acid ointment as a base. The patient should not be allowed to use it long at one time. Menthol may be used combined with cocain or alone in a solution as follows:

R. Mentholigr. x | 65
Alcoholisʒi | 30

M. Sig.: To be applied locally.

Sodium bisulphate frequently applied in the form of a poultice in most instances gives relief. Carbolic acid is especially good in many cases, applied in solutions one grain to six (.06 to .40) to the ounce (.30) of water, or in the form of a liniment (1 to 19) of olive oil. Or it may be combined with cocain or mercury in the form of an ointment. The following formulae are recommended by the author:

R. Acidi carbolicim. xx | 30
Cocainæ hydrochlor.gr. x | 65
Liq. petrolatiʒi | 30

M. Fiat unguentum. Sig.: Apply locally after cleansing the parts well.

Or:

R. Acidi carboliciʒss | 2 |
Cocainæʒss | 2 |
Aq. laurocerasiʒi | 30 |
Aq. rosæʒi | 90 |

M. Fiat unguentum. Sig.: Apply locally.

Or:

R. Acidi carboliciʒss | 2 |
Hydrarg. perchlor.gr. ii | 12 |
Olei olivæʒi | 8 |
Ung. zinci oxidii benzoatis q. s. ad.ʒi | 30 |

M. Fiat unguentum. Sig.: Apply locally.

The author also recommends the tar preparations in the treatment of pruritus ani as follows:

R. Lotio picis carbonisʒi | 8 |
Lotio calamineʒviii | 240 |

M. Sig.: Fiat lotio. Sig.: Locally as a wash.

Tar combined with bismuth may also be applied in the form of an ointment as follows:

R. Ung. picis liquidæʒi | 4 |
Bismuthi subnit.gr. xx | 130 |
Adipis q. s. ad.ʒi | 30 |

M. Fiat unguentum. Sig.: To be applied locally.

Compresses soaked in oil of cade or Peruvian balsam in liquid petroleum are of value.

Silver nitrate is also recommended where other combinations fail, applied as follows:

R. Argenti nitratisgr. iiii | 20 |
Spiritus etheris nitrosiʒi | 30 |

M. Sig.: To be locally applied.

Tincture of iodine is also recommended by the author, and when piles are the cause the unguentum gallicæ will relieve the itching. Zinc oxid is best applied as follows:

R. Zincii oxidiiʒi | 8 |
Liq. petrolatiʒi | 8 |
Olei olivæʒss | 15 |
Aque calcisʒss | 15 |

M. Fiat unguentum. Sig.: Apply locally.

As an antiseptic mercury is the best, applied in the form of the oleate and combined with morphin. The mild chlorid of mercury is advised combined as follows:

R. Hydrarg. chloridi mitisʒss | 2 |
Liq. petrolatiʒi | 30 |

M. Fiat unguentum. Sig.: To be applied locally.

Lotio nigra is frequently used to relieve the itching and to effect a cure combined as follows:

R. Lotio nigraʒi | 120 |
Liq. calcis, aa.ʒiv | 120 |
Mucil. tragacanthæʒi | 4 |

M. Sig.: Apply locally.

Another combination recommended by the author is as follows:

R. Hydrarg. perchlor.gr. ii | 12 |
Glyceriniʒss | 15 |
Aque chloroformi q. s. ad.ʒviii | 240 |

M. Sig.: Apply locally.

Or:

R. Hydrarg. ammoniatigr. xx | 130 |
Adipis benzoatisʒi | 30 |

M. Sig.: Apply locally.

As a caustic, silver nitrate is recommended in the following strength:

R. Argent. nitratisʒss | 2 |
Spiritus etheris nitrosiʒi | 30 |

M. Sig.: To be applied locally on an applicator as a caustic.

The actual cautery is recommended, in some cases, first anesthetizing the patient, and running it lightly over the areas at a white heat. If there is spasmodic tightness of the sphincter the muscle ring may be forcibly dilated. In purely neurotic forms the less local treatment the better it will be for the patient. "Straight talking," as he expresses it, is far better than drugs in this class of patients. Tonics such as quinin or strychnia are also indicated in these neurotic cases.

Medicolegal.

Who "Able" to Pay for Care by Board of Health.—Section 51 of chapter 18 of the Revised Statutes of Maine provides, in substance, that when any person is infected with any disease or sickness dangerous to the public health the local board of health may remove him to a separate house, and there care for him at his charge, "if able." The Supreme Judicial Court of Maine holds, *Inhabitants of Greenville vs. Beauto*, that such a person is not chargeable with any part of the expense incurred, if he is not able to pay the full amount. Such a person is not chargeable with the expense incurred, if he is not financially able at the time of his discharge, although he was able to labor, and did labor, and afterwards accumulated sufficient money to pay the expense. The phrase "if able" relates to the pecuniary ability of the party at the time the expenses were incurred.

Pretending to Cure Sickness by Removing Evil Spirits.—The Court of General Sessions of Delaware says, in the case of *State vs. Durham*, that it was claimed on the part of the state that the defendant pretended that a certain Rachel A. Fitzgerald was possessed of an evil spirit, that her sickness was caused by the presence of this evil spirit, and that he alone possessed the power to remove the same, and to heal her disease or cure her of her sickness. The indictment was founded on a statute of that state against pretending to exercise the art of witchcraft, conjuration, fortune-telling, or dealing with spirits, which statute, the court says, is founded in wisdom. The purpose of that statute manifestly is to protect people in certain grades of life from being imposed on by persons pretending to possess a power that they do not have. It is a matter of common experience that persons afflicted with disease rely oftentimes on, or give credit to, persons who claim to be possessed of supernatural powers. Those who are oftentimes subject to that imposition are particularly people who are weak, and who are in great straits of sickness; and this law was designed to protect just such people from impostors, if any such there be, who may go around and make pretense of healing or curing through the exercise of supernatural power, which the intelligence and enlightenment of this day utterly denounce and discredit. If the jury believed from the testimony in this case that the defendant did make pretense that he alone had the power to remove these evil spirits and cure Rachel A. Fitzgerald of her sickness by reason of his influence over these spirits, its verdict should be "Guilty." If the defendant was guilty, he ought not to be turned loose. The verdict returned was "Guilty."

Foundations Required for Opinions as to Sanity.—The Supreme Court of Iowa says, in the case of *Stutsman vs. Sharpless*, that attention has been directed in previous decisions to the difference between the foundations to be laid for a non-expert's opinion of the sanity and of the insanity of a person under investigation. See *Alvord vs. Alvord*, 109 Iowa, 113; *In re Illull's Will* (Iowa) 89 N. W. Rep. 981. The facts on which an opinion that deceased's mind was unsound should appear in their natures somewhat inconsistent with mental soundness, as that the acts or talks of deceased were unnatural or unusual, or such as would not ordinarily be anticipated from a person of his character. In other words, the facts and circumstances must have been such as tended to support the witnesses' conclusion. But the court says that it was only necessary in this case, as already stated, that the circumstances related tended to indicate an unsound mind. Undoubtedly the witness must have enjoyed adequate opportunity of observing the deceased's capacity, but habits of observation, as well as conditions of the subjects of investigation, differ so radically that no general rule as to what character or number of circumstances shall be related before the witness may speak his opinion can be laid down. See *Wigmore's Evidence*, section 659. Having indicated some facts which tend to support the opinion to be given, the witness should be allowed to express it, and its value, as well as the effect thereon of any explanatory circumstances, as that the condition was produced by a stroke of apoplexy, is for the determination of the jury, rather than the court. It will not do to allow juries to say what facts were material in securing the opinion of a medical expert, and to what extent a variance in the facts would have changed his opinion. The only safe rule is to reject the opinion unless the facts hypothetically stated are established by the evidence. If a portion of the facts are to be eliminated, the witness, and not the jury, should be permitted to estimate the difference this change would effect in the opinion he has expressed.

Failure to Register Prevents Recovery for Services.—The Supreme Court of Georgia says that the only question presented by the record in the case of *Murray vs. Williams* for adjudication was whether a physician who has registered, as required by the statute, in the county of his former residence in the state of Georgia can, after his removal into another county in the state to reside and practice his profession, recover for professional services rendered by him in the latter county before he has registered therein. The Code provides that: "Every person lawfully engaged in the practice of medicine within this state, before commencing to practice, shall register in the office of the clerk of the Superior Court of the county wherein he resides and is practicing, or intends to commence the practice of medicine, in a book to be kept for the purpose by said clerk, his name, residence and place of birth, together with his authority for practicing medicine, as prescribed in [Chapter 4 of the Political Code of 1895]. The person so registering shall subscribe or verify, by oath or affirmation, before a person duly qualified to administer oaths under the laws of this state, an affidavit containing such facts, and whether such authority is by diploma or license, and the date of the same, and by whom granted, which shall be exhibited to the county clerk before the applicant shall be allowed to register. The county clerk shall receive a fee of 50 cents for each registration, to be paid by the person so registering."—Political Code of 1895, Sec. 1479. "Any such registered physician in this state, who may change his residence from one county into another county in this state, shall register within the clerk's office of the county to which he removes and wherein he intends to reside and to practice medicine, as provided in the preceding section."—Pol. Code 1895, Sec. 1480. "Any person who shall fail to register or who shall practice medicine or surgery in violation of the provisions of the Civil Code, shall be guilty of a misdemeanor."—Penal Code of 1895, Sec. 455. These sections of the Code, the Supreme Court says, are intended to protect the public against incompetent and unqualified practitioners of medicine, and not for raising revenue, and are, therefore, prohibitory. One who practices medicine without having registered as the Code requires can not

recover for his services. Clark on Contracts (2d Ed.), Sec. 153. "Even where there is no express provision that the contract for remuneration for services rendered by an unlicensed physician shall be void, still, if the statute imposes a penalty for practicing without having obtained a license, or without having complied with other statutory provisions, the courts will apply the prohibition, and a recovery can not be had for professional services rendered."—22 Am. and Eng. Enc. of Law (2d Ed.), 795. See also in this connection Conley vs. Sims, 71 Ga., 161 and citations. Wherefore, the court holds that a physician who has failed to register in compliance with the provisions of sections 1479 and 1480 of the Political Code of 1895 can not recover for professional services rendered by him, and that the judgment of the trial judge, who decided contrary to the views herein expressed, must be reversed.

- 6 *The Treatment of Epithelioma by Means of the Roentgen Ray. George C. Johnston.

2. **Postdischarge Mortality.**—Brown and Pope emphasize that the real test of the sanatorium treatment is not the immediate but the ultimate result. The mortality among patients discharged in various conditions affords the best method of studying the permanent results of sanatorium treatment. Of those discharged apparently cured, 93 per cent. of the expected living are alive; of the disease arrested, 65 per cent.; of the cases discharged with active symptoms, 23 per cent. The authors found that the death rate among the apparently cured patients is, during the first ten years, about three times the ordinary death rate. The death rate among the patients discharged with the disease arrested increases during the first few years to many times (10 to 15) the normal death rate, but afterward decreases. Nearly half the patients discharged with an active disease from the Adirondack Cottage Sanitarium died in the first two years. Patients between 30 and 40 when discharged apparently cured, seemed to relapse less than younger patients. This tendency is little, if at all, marked among the patients discharged with the disease arrested. Incipient cases seemed to relapse less than the advanced, when both were discharged in the same condition. These data are based on a study of 1,157 patients.

5. **Treatment of Basedow's Disease.**—In the case reported Lademann made use of the Lanz method of treating this affection—feeding with the milk of thyroidectomized goats. The patient drank three pints daily and in two and a half months her weight increased 15½ lbs.: the pulse rate diminished from 160 to 118; the circumference of the neck diminished 3 cm., and the blood findings improved markedly. The case was an unusually severe one, and surgical interference was beyond question. Therefore, Lademann believes that the result obtained is all the more remarkable. He is convinced that the more severe the disease, the more milk is required to neutralize the poison circulating in the economy as a result of the thyroid cachexia. He suggests the use of desiccated thyroidectomized milk in the form of tablets, as preferable to that in its natural state. He does not, however, regard this treatment as in any way a specific one.

6. **Roentgen Ray in Epithelioma.**—Johnston divides his cases into two classes: 1. Those in which, owing to location, ex-

tent, metastasis, poor physical condition of the patient, and various other factors, no clinical cure may be expected, and the treatment instituted is solely for the relief of pain, cessation of irritating and offensive discharge, and possible prolongation of the patient's life. 2. Those cases in which the location and extent of the disease are such as to enable a favorable prognosis to be given, and a cure may be reasonably expected to follow proper treatment. The treatment of epithelioma possesses one advantage over the treatment of the various internal malignant growths. The disease being superficial, the effect of treatment can be readily seen and the dosage accurately adjusted to the needs of the case in hand. There is also less danger of auto-intoxication in the treatment of such growths. Disadvantages are that the majority of these growths are recurrent and that the majority of patients suffering from epithelioma are old, their vitality is low, the reparative power of the tissue is slow, deficient, in some cases absent, their nutrition is below par, their kidneys weak and inadequate, the skin inactive. The average duration in the 44 cases reported by Johnston was 4 years and 8 months. In 4 patients it was 15 years, and 10 years in 2. Of the 44 cases, 10, or 33 per cent., were recurrent; 34, or 77 per cent., were primary. The average number of treatments necessary in each case was 22. In but 3 cases did metastasis occur. Eight patients, or 18 per cent., were benefited; in 3 cases, or 7 per cent., there was recurrence; 30 patients, or 81 per cent., were cured; 3 cases, or 7 per cent., terminated fatally. In the latter cases a cure could not have been expected by any method of treatment. Johnston says that the mistake most commonly made in the treatment of epithelioma is the use of a tube of high penetration and the employment of protective screens. Success in treatment also depends on the ability of the operator to limit metastasis, and the degree of the success achieved will be in direct proportion to the operator's experience, the correctness of his technic, his familiarity with the apparatus, and his ability to distinguish an active from a worthless tube.

- 11 Rheumatoid Disease in Children. John L. Morse.
- 12 Types of Rheumatoid Disease. C. F. Painter.
7. The So-Called Rheumatoid Diseases.—In this paper Goldthwait classifies these conditions as follows: (1) Chronic villous arthritis or "dry-joint"; (2) atrophic arthritis; (3) hypertrophic arthritis; (4) infectious arthritis, and (5) chronic gout. The article is illustrated by a number of excellent photographs of casts, bones, x-ray pictures, and affected members.
9. Chronic Joint Disease.—In connection with the treatment Jackson mentions the great help given by properly applied fixation which relieves pain and is instrumental in preventing serious deformity. He urges that inasmuch as the disease is a chronic, depressing, debilitating process similar to tuberculosis, the most nourishing food that can be assimilated must be given in large quantities.

- 18 *Uncinariasis as Seen in North Carolina; Its Frequency, Etiology, Pathologic Significance, Symptoms and Treatment. J. L. Nicholson and Watson S. Rankin.
- 19 A Case of Pneumococcal Infection. Frank I. Given.
17. Complications of Diphtheria.—Fischer's paper deals rather with treatment and not with symptomatology. Speaking of antitoxin, he urges the use of large doses, as much as 10,000

units in 24 hours and even more if necessary. Feeding, he says, has an important bearing on the prognosis in malignant diphtheria. As there is a decrease in the quantity of hydrochloric acid secreted, the patient should be given one to five drops of diluted hydrochloric acid after feeding, and if digestion is not improved thereby, peptonized milk should be resorted to. When the usual method of feeding is unsuccessful or when children refuse food, gavage should be remembered. If vomiting is provoked by gavage, the pharynx may be sprayed for several minutes before feeding with a 3 per cent. cocain solution, or rectal feeding can be substituted. He has had some excellent results in the feeding of intubated cases by rectal alimentation when the same was carried out by one who was competent. The rectum and colon are first washed clean by means of soap water. After the feces are washed away, he waits half an hour and then injects two or three ounces of the following:

R. Yolk of egg..... 1 yolk.
Starch water..... 2 ounces.
Fatschlid's peptonizing powder..... 1 tube.
Salt..... A pinch.

Mix thoroughly and inject slowly into the colon through a funnel to which a soft rubber catheter is attached. These injections may be repeated every four hours.

Attention to the nose is more important in diphtheria than in any other disease. Fischer's rule has been to wash the nose with a weak permanganate of potash solution or normal saline solution even in intubated cases. He advocates nasal washing in every case of diphtheria as a routine measure. Septic infection will persist until the nose is thoroughly cleaned. Elimination of the poison through the bowels is next in importance, and for this purpose Fischer favors calomel, first giving a large dose, this to be followed by repeated small doses. The feeble condition of the heart's action requires active stimulation with whisky, champagne and strychnin. Tincture of musk, in 2 to 5 minims doses every hour, is also valuable. Fischer says the temperature alone is not a sure guide as to the outcome of a case of diphtheria. The heart is the guide, hence a study of the pulse is more important in estimating the prognosis in any given case.

18. Uncinariasis.—Nicholson and Rankin have given this study considerable attention and conclude that the mass of evidence obtained favors ground-itch as the most important factor in the transmission of hookworm disease, and that while drinking water and dirt eating are predisposing factors they are not as important as ground-itch. They have noted that in localities where ground-itch is frequent there hookworm disease is also frequent. Where there is no ground-itch there is little or no hookworm disease. Over 99.5 per cent. of 150 cases studied by them gave a history of ground-itch, and in 69 out of 90 cases the history was that ground-itch preceded the development of the other symptoms. In the majority of cases the severity and number of attacks of ground-itch bear a definite relation to the severity of uncinariasis. The disease is definitely associated with the period of life when the child goes barefooted. From this age (3) there is a definite steady increase until the fifteenth year, when there is a decline. Cases are comparatively uncommon beyond the twenty-fifth year, rare beyond 30 and when they do occur are light and nearly always on the decline. When the patient ceases to be troubled with ground-itch it is the rule for improvement to begin. For these reasons the authors feel justified in drawing the conclusion mentioned in the beginning of this abstract.

- 26 Passage of a Tooth Plate through the Alimentary Tract. M. K. Elmer.
- 27 *An Improvised Method of Operating for Varicocele. Lucien Lottet.

21. **Impacted Ureteral Calculus.**—Meyer's case offered unusual difficulties in the diagnosis, but the stone was finally located positively by means of the x-ray and removed through an abdominal ureteral lithotomy. Meyer considers it advisable in all cases where profound septic symptoms, especially a chill and rapid pulse, accompany the always present renal colic, promptly to resort to operative treatment. In the presence of subsiding symptoms he strongly urges removal of the stone or stones during the interval.

24. **Ideal Tent Life for Consumptives.**—Masten calls attention to a stretch of territory extending across northern New Mexico and southern Colorado which he believes particularly suitable for the establishment of a tent colony for the treatment of consumption. Aside from the climatic conditions prevailing in that particular region, a strong point in its favor is the fact that cattle are seldom affected with tuberculosis. The construction of a model colony is given in detail.

25. **Treatment of Diffuse Peritonitis.**—The essential factors responsible for the success obtained in the treatment of diffuse peritonitis, Blake believes to be an early operation; a rapid operation, but not necessarily a large incision; the least possible handling of the intestines (if they escape from the wound and cannot be returned they should be emptied through a small enterotomy incision); thorough lavage of the peritoneal cavity; the omission of drainage, when possible, and an after-treatment in which the main features are absolute rest for the alimentary canal and the exhibition of large quantities of fluid. Reference is made by Blake to 51 cases of diffuse peritonitis, comprising 29 cases caused by appendicitis with a mortality of 28.5 per cent.; 5 by typhoid perforation with a mortality of 40 per cent.; 6 cases by perforating ulcers of the stomach or duodenum, with a mortality of 50 per cent.; 1 by perforating ulcer of the ileum with fatal result; 1 by rupture of the jejunum, with recovery; 1 by acute pancreatitis, with recovery, and 8 cases by infection through the fallopian tubes, partly gonorrhoeal and partly pneumococcus and streptococcus infections, with a mortality of 62 per cent. Deep drainage was employed in 26 cases, with 14 deaths; superficial drainage was employed in 25 cases, with 5 deaths. In a number of cases in which deep drainage was employed the conditions which demanded drainage were the ultimate cause of death.

27. **Inprovised Varicocele Operation.**—Lofton offers the following modifications of the usual varicocele operation: The patient is permitted to assume a semi-recumbent position. The scrotum is grasped with the left hand, the index finger and thumb separating the vas deferens and spermatic artery, that is, placing them on the anterior border of the testicle, while the pampiniform plexus is brought well up against the anterior and upper walls of the scrotum and held there firmly. With a surgeon's ordinary curved needle, three inches in length, armed with a double strand of No. 2 fiddle string, the pouch is pierced at the seat of election and the mass transfixed. The needle penetrates the opposite inner wall of the scrotum, but does not perforate it. With the point of the left index finger the needle is guided so as to slip along the inner wall of the bag, making a half-circuit of the interior lining and over and above the transfixed veins, and is brought out at the original puncture and securely tied to the dangling ends of the external ligature. Caution must be observed in drawing the mass of veins well up against the inside anterior wall of the scrotum. This procedure may, at the same sitting, be repeated from one to three times, at whatever points the surgeon's judgment may dictate. Thus only one opening is made in the scrotum, and when secondary inflammation sets in the mass will be securely welded to the interior wall of the scrotum, bringing about a shortening, which is always to be desired, as 95 per cent. of these cases are accompanied with elongated scrotal tissue. Furthermore, the veins are securely anchored and the patient can continue his business without a day's interruption. Recovery follows in from 25 to 30 days. Complete atrophy generally follows in about six months. Lofton reports only excellent results in 17 cases operated on according to this method.

28. **Bacteria of the Stomach.**—Paller examined the gastric juice of 13 cases, 3 of cancer, 5 of hypochlorhydria and 5 of hyperchlorhydria. He found that carcinoma ventricula is characterized bacteriologically by (1) the presence of a bacillus which he calls the "*Vibrio geniculatus ventriculi*;" (2) numerous staphylococci, and (3) the absence of fungi. In simple hypochlorhydria the "*Vibrio geniculatus ventriculi*" may be found, but any other micro-organism may also be met with, either alone or in combination with it. In hyperchlorhydria, yeasts and fungi are met with and also occasionally sarcine and a small bacillus which is Gram negative, and in cultures discharges an ammoniacal odor. In subacidity of the stomach, with alimentary stasis, he found yeasts, mycelie, and the *Vibrio geniculatus*. He urges that the bacteriologic examination of the stomach contents should become as much a routine work in clinical medicine as is that of the sputum. The gastric juice is obtained by means of the stomach tube, which should previously be sterilized in boiling water. It is preferable to get the sample for examination after some of the stomach contents have already escaped, as one is thus not so liable to get the first part, which may come from the esophagus. The receptacle containing the sample should be immediately closed, and the examination should be conducted under sterile precautions.

29. **Carriers of Malaria.**—Powell reports ten cases of tertian, intermittent fever, among the enlisted men at Ft. Hamilton, N. Y. All but three of these cases occurred in the same company, the barracks of which are located on the highest elevation in the post, overlooking a more or less salt marsh and situated but a short distance from the post dumping grounds. They are also near the battery stables. With the exception of a single anopheles, killed by Powell in his own quarters, careful examination of the stagnant water in the vicinity, as well as search throughout the entire post, failed to reveal any mosquitoes that differed from the *Culex sollicitans* or *Culex pungens*. Powell concludes, therefore, that some other unknown factor must be concerned in the transmission of malaria, and that the etiology of the disease is as yet far from being definitely and conclusively settled.

30. **Treatment of Maxillary Fractures.**—Lederer favors the double interdental splint for the fixation of fractures of the lower jaw. The results obtained by him from the use of this device have been uniformly good. He describes the technic for applying the splint and cites one case of compound multiple maxillary fracture of unusual difficulty to illustrate his method.

31. **Massage Treatment of Sprains.**—Norstrom sums up his treatment as follows: At the initial stage, in the presence of classical phenomena, including a great deal of pain—effleurage. When the pain has decreased a great deal—friction and passive movements; later, active movements. Walking at the beginning ought not to be permitted. In all sprains of the lower extremities, after every seance, applications of a gauze bandage, a precaution all the more indicated when the patients are allowed to use their legs and to walk. In order to prevent real relapses, as well as to prevent the inflammation becoming chronic, the treatment ought to be continued until complete restitution has taken place.

32. **Oxygen in Anesthesia.**—Gwathmey has carried out a series of experiments on cats with the different anesthetics in order to determine their relative value when used with air and oxygen, respectively. He found that chloroform and oxygen is more than twice as safe as chloroform and air and is also safer than any of the other general anesthetics with

air. In fact, oxygen increases the value of all anesthetics as regards life, without decreasing their anesthetic effect.

39. Antistreptococcus Serum in Puerperal Septicemia and Scarletina.—Hamilton reports a few selected cases which serve to illustrate the unmistakably beneficent action of antistreptococcus serum in conditions produced solely, or in large part, by the streptococcus. To obtain good results from the serum, Hamilton urges that the following points must be observed: The disease must be due to the streptococcus alone or this micro-organism must be decidedly predominant, depending solely on the microscope as evidence. The serum must be administered early, or as soon as the origin of the disease is known. The quantity administered must be sufficient to produce a perceptible change in 12 hours and must be repeated as often as indications demand. About 30 c.c. should be given for the first dose, and repeated in 12 hours at the furthest, and kept up until benefit is derived, the dose being gradually diminished. Hamilton says that this interferes in no way with other treatment, such as stimulation, and the treatment of any particular symptom. The serum used should be known to be of standard strength. No bad effects were noted from the use of the serum in the treatment of puerperal septicemia and scarlet fever. In mixed infections it may be used as an adjunct to other methods, but its success is not so striking.

54. Ulcer of the Stomach.—A case of single ulcer located in the lesser curvature, 4 cm. from the pylorus, was reported by Bloodgood because of the short duration of the symptoms, three weeks, and the difficulty in making a positive diagnosis at the exploratory operation. Although the gross appearance and the findings on palpation were in favor of ulcer, Bloodgood considered that there was sufficient doubt to justify a complete operation. A resection was done in the ordinary manner. In closing the stomach and in performing the end-to-end anastomosis between the stomach and duodenum, two rows of sutures were employed, continuous catgut passing through all the walls, reinforced by interrupted mattress sutures of fine black silk. The patient made an uneventful and rapid recovery. Bloodgood says that if the indurated tumor is either freely movable or only slightly adherent, complete resection should be performed. This operation gives the only hope for cancer, and as these patients are usually in good condition the mortality for gastrectomy, if it is an ulcer, should be but little, if any, greater than for gastroenterostomy. If the indurated tumor is adherent to surrounding structures and it is a carcinoma, it is past the hope of complete removal. For this reason gastroenterostomy should be performed. If the lesion is an ulcer there will be permanent relief. He urges that physicians should secure a more positive differential diagnosis between ulcer and cancer in its earlier stages by the chemical study of gastric secretion. The problem of the surgeon is the differential diagnosis between the ulcer and cancer at the exploratory operation.

56. Clinical Effects of Anesthesia on Anemia.—Hutchins studied this question in the case of 60 women, each showing a hemoglobin percentage of 50 or less, who received a general anesthetic for operative purposes, the duration of the anesthesia varying from twenty minutes to three and a half hours. Fifty-six of the 60 cases had uneventful recoveries. There were 4 fatalities. Severe heart lesions complicated two of these: in the third the patient had already bled until her hemoglobin registered 15 per cent., and in the fourth case the anesthetic had been given for two and a half hours before the patient showed any signs of immediate collapse. Only 2 cases died on the table under the anesthetic. The worst shocked patient was one with a hemoglobin percentage of 50, on whom an ordinary suspension of the uterus and repair of relaxed vaginal outlet were performed, the operation consuming an hour and seven minutes. The patients, as a rule, took the anesthetic well. No respiratory distress was noted, and in neither of the cases dying on the table was respiratory failure primarily the cause of death. In no case, says Hutchins, was it thought that the persistence of the anemia after operation was in any way prolonged by the giving of the anesthetic. Preliminary tonic treatment proved of value in raising the hemoglobin percentage in the 6 cases in which it was tried.

60. Ergot in Cerebrospinal Fever.—Chase reports several cases of epidemic cerebrospinal meningitis in which he made use of ergot in the form of ergotin (Bonjean). He gave it internally in all cases except where hypodermic medication was necessary because of vomiting. In these cases Squibb's solid extract, dissolved in water, was used. In an adult the dose was on the average 3 gr. of ergotin (equivalent to about 30 grains of ergot) every hour, although double that amount was given on occasions. The extract was given in about similar

doses hypodermically, although not so often. Children received proportionate doses. Although carefully watched for, no evidence of poisoning was noticed. The drug was never given for long periods without intermission. The effect was usually seen in from twenty-four to forty-eight hours, and consisted in a gradual remission of all the symptoms, especially those directly due to intracranial and spinal congestion. The intense pain became more bearable. The retraction of the head less marked, hyperesthesia not so noticeable, the fever, still irregular, did not average as high, and in general, the patient became more comfortable. Two markedly noticeable features of Chase's cases were absence of the usual complications (pneumonia in particular), and absence of troublesome sequelae. The recovery in each case was complete—no deafness, no impairment of vision, and none of the persistent severe headache that is so apt to make the lives of those who recover unbearable.

67. *Pneumonia in Infants.*—As important symptoms to aid in making a diagnosis of pneumonia in infants, Northrup mentions: 1, Sudden onset, with fever and torpor; 2, disturbed respiration—pulse ratio; 3, rales. Speaking of the treatment, he advises careful regulation of the functions of the gastrointestinal tract in order to avoid flatulence, fermentation and to correct indigestion; plenty of water, in small quantities, cool and fresh, both inside and outside; quiet and rest. One of the most refreshing and helpful external applications is cold to the head. The application of cold cloths, wrung dry and frequently replaced on the forehead, with sponging of the face and lips with cold water, soothe and comfort the patient, thus promoting sleep. It is more effective than an ice cap, as this may not reach the scalp at all if the hair is thick. However, says Northrup, cold is applicable only to sthenic cases. Finally, he continues, the patient should have plenty of fresh, cool, flowing, outdoor air, as nothing stimulates the heart better than a current of fresh cool air on the face. For a limping respiration, a narrowed lung capacity, a sore breathing apparatus, nothing is so efficient as air. It also quiets restlessness, favors sleep, improves secretions and digestion, in short, meets most of the indications for the treatment of pneumonia in infants. No matter how cold the air may be no fear need be entertained that the patient will "catch cold," especially from air striking on the oval of the face alone.

75. *Treatment of Diseases of Hepatic and Pancreatic Ducts.*—Eastman emphasizes the importance of the intimate relation between the ducts of the liver, of the pancreas, and of the second portion of the duodenum, and to consider their etiologic influence on certain digestive disorders commonly referred to as dyspepsia, intestinal indigestion and the like. Eastman says that the pancreas is more frequently involved in disease than is generally credited; it is rarely the seat of primary diseases and it is nearly always infected through its anatomic relations with the gall ducts, and the treatment, without question, consists in drainage of the gall bladder and the removal of gallstones, if they be found.

77. *Functions of the Tonsils.*—Wood presents the results of his research into the functions of the tonsil, and they may be summarized as follows: 1. That the epithelium of the crypts by a myotic division of its cells exhibits a marked tendency toward constant growth. This is shown by the penetration of the epithelial cells into the parenchyma of the tonsil and the formation of teratoid masses in the lumen of the crypt. 2. That the theory of the migration of lymphoid cells from the secondary follicles into the crypts does not satisfactorily explain the presence and character of the cells in the interepithelial spaces. 3. That there exist transitional cells by which all stages may be traced between the epithelial cell and the lymphocyte. 4. That the variation in types of the lymphocyte is most marked in the region of the cryptal epithelium. 5. That the degree of infiltration of the epithelium holds no relation to the cryptal contents. On the other hand, the ingrowing sprouts of epithelium possessing no lumen show as much, if not more, infiltration than the true crypts. 6. That the complete destruction of the cryptal epithelium is a very rare occurrence, almost always a sufficient number of epithelial cells being left to provide an intact barrier along the surface toward the cryptal lumen. The thought that the epithelial lining of the tonsillar crypts may be converted into cells that are generally supposed to be of connective tissue origin is not one to be accepted lightly. It suggests the possibility of the interchange of cell types; that no distinct line can be drawn between the epithelial cells, connective tissue cells and endothelial cells. Wood believes himself justified in saying that the tonsil is a primogenetic source of leucocytes, and that it is possible that all adenoid tissue which has developed in intimate relation with epithelium is playing a rôle very similar to that which he accords the tonsils.

84. *Blood in Measles.*—Tillston made repeated examinations of the blood in 23 cases of measles and found that during the incubation period of the disease a leucocytosis is present, which begins soon after infection, reaches its maximum six days before the appearance of the eruption, and lasts into the first part of the stage of invasion. During the latter part of the stage of invasion and during the stage of eruption the white count is normal, or more usually diminished, reaching its lowest point at the height of the rash. The presence of leucocytosis points to the existence of a complication; its absence during the eruptive stage does not exclude one. The onset of leucocytosis with a complication may be preceded by a rise in the percentage of neutrophils or a failure on their part to decrease at the proper time. The differential count in measles Tillston found to take the following definite course: The polymuclearneutrophils are increased during the stage of incubation, invasion and eruption, fall below normal at convalescence and reach normal in convalescence. Myelocytes are often present in small numbers during the period of eruption, especially in young children. The lymphocytes follow the opposite course—at first decreased, and increased after the crisis. The large mononuclear and transitional cells (including large

lymphocytes) are normal at first and increase later. The eosinophiles are decreased or absent during the eruption, and later increased. The mast cells show no changes; the blood plates are usually decreased during the eruption. The blood becomes normal in all respects at about the twelfth day. In doubtful cases the absence of leucocytosis with decreased eosinophiles is in favor of the diagnosis of measles as against scarlatina and vice versa. The blood of measles in children shows the same changes as in adults, if the differences between the normal blood of children and that of adults be taken into consideration.

87. Longevity of Typhoid Bacillus.—The writers of this paper state that they were requested by the sanitary district of Chicago in the fall of 1903 to conduct some experiments on the life of the typhoid bacillus from the waters of Lake Michigan, the Chicago Drainage Canal and the Illinois River. From the experiments recorded in the paper it appears that under conditions that probably closely simulate those in nature, the vast majority of typhoid bacilli introduced into the several waters studied perish within three to four days. The authors state that it is theoretically possible that specially resistant cells may occur which are able to withstand for a longer period the hostile influences evidently present in water. Their experiments, however, show that if such resistant individuals exist they must be very few in number and constitute only a small fraction of the bacilli originally entering the water. But they do not claim that the behavior of typhoid bacilli under the conditions described by them is representative of all conditions obtaining in all natural bodies of water.

89. Experimental Streptococcus Arthritis.—While making a series of cultures of cases of acute rheumatic fever and endocarditis Cole succeeded in cultivating a streptococcus from the blood of a patient, the autopsy on whom disclosed an acute and subacute vegetative mitral and aortic endocarditis, cardiac hypertrophy and dilatation, chronic passive congestion of the internal viscera, multiple infarction of spleen and kidneys, thrombosis of left middle cerebral artery, with extensive softening of the internal capsule. The results obtained by inoculation of this streptococcus agreed quite closely with those obtained by other observers with inoculation of the so-called "*Micrococcus rheumaticus*." Cole then undertook experiments with six races of streptococci aside from those obtained from the case mentioned. The sources of these various races were: Peritonitis following carcinoma of the stomach; puerperal fever autopsy; blood during life in terminal septicemia following myocarditis; empyema; blood during life in septicemia following appendicitis; scarlet fever adenitis. There was no essential difference in the results obtained between the several races studied, except in the virulence. With all seven races studied, intravenous inoculation of amounts insufficient to cause death of the animals within six or seven days lead to the production of mild grades of arthritis. In many cases the joint affection is so mild that unless one is especially interested in looking for it, it might be overlooked. It seems that when streptococci from whatever source are inoculated intravenously into a rabbit, they tend early to localize in the joints even before any definite lesions can be detected. Cole concludes that arthritis and endocarditis may be produced by the intravenous inoculation of rabbits with streptococci from various sources, and the results obtained are quite similar to those described as resulting from the inoculation of the so-called "micrococcus" or "*Diplococcus rheumaticus*." Therefore, the description of a distinct variety or species of streptococci based on this property of causing endocarditis and arthritis is unwarranted. Whether the evidence is sufficient to show that acute rheumatic fever is simply a form of streptococcus septicemia, Cole does not say.

I. Artificial Maturation of Immature Cataract.—McHardy states that complete ripening of immature senile cataracts may be safely and almost certainly secured in from three days to eight weeks by preliminary iridectomy, with trituration of the lens through the cornea and pupil, if it is done with judgment, experience and care. The ultimate results, surgical and visual, of extraction operations in such cases are quite equal to the results of similar operations for senile cataracts which have been allowed to fully mature spontaneously. Further, the removal of such artificially matured cataracts is entirely free from those risks, drawbacks, and often impaired ultimate results which follow from the removal of immature senile cataracts. The procedure was originated by Förster. McHardy has practiced it for about twenty years with the most satisfactory results. The method is as follows: The pupil is widely dilated with a four grains to the ounce solution of sulphate of atropin, applied twice in the preceding twelve hours. Cocain is used for anesthesia. McHardy usually does a preliminary iridectomy on both eyes, tritürating only one. Having done a preliminary iridectomy, he lets the

aqueous humor escape from the wound by depressing its posterior lip with the edge of a spoon, and then, wetting the back of the shell or silver spoon with the patient's tears, applies its convex surface to the center of the cornea, stroking the cornea in a radiating direction, at first very carefully, observing that the iris always slips away in front of each stroke of the spoon. That is to say, as the cornea goes down against the lens, the iris recedes from the center towards the periphery, before the pressure of the spoon. A nipping of the iris between the lens and the cornea often is followed by iritis. It is to be remembered that one may do an enormous amount of rubbing on the front of the cornea, but without ripening the cataract—if there be a fair quantity of aqueous humor in the chamber. The amount of trituration to be done depends (1) on the amount of cortex that requires to be rendered opaque; (2) on the character of the cornea. If the cornea is one of those nice-looking, stand-up cornea a good deal of trituration is required; if not, exceedingly little trituration is sufficient. After the trituration atropin is to be used, within thirty-six hours, to keep the pupil widely dilated. This method renders it important that the patient should be very accessible. McHardy makes use of it in all cases of immature senile cataract with greatly hampered vision and with uniformly successful results.

15. Carcinoma of the Appendix.—Cullingworth's patient, a woman, aged 31, suffered for some time from uterine trouble, for which she was cured. Six months before her admission to the hospital she was operated on for hemorrhoids. Two months later she had a second attack of pain in the right side which lasted two hours and caused her to faint. After a fortnight's interval she had a similar but less severe attack. The pain was over the right iliac fossa, low down. On deep palpation in the right iliac region the patient complained of a little tenderness at a point midway between the umbilicus and the anterior superior spine of the ilium. The right kidney was found to be movable. Per vaginam there was a hard mass to the right of the uterus depressing the vaginal fornix. This mass was about the size of a pigeon's egg, and was thought to be either a solid tumor of the ovary or a subperitoneal fibroid burrowing into the broad ligament. On opening the abdomen the tumor was found to be a small fibromyoma of the right broad ligament, close to but not directly connected with the uterus. After its enucleation the appendix was examined. It was found to have only a few omental adhesions and to be apparently healthy, except that at the extreme tip it was thickened and bulbous. It was on this account removed. On opening it the mucous membrane was seen to be somewhat thickened at its end, and the lumen of the tube was obliterated at the tip by a little nodule which had the appearance of caseous material, though somewhat harder. Sections showed that this little nodule was a spheroidal-celled carcinoma. Three years after the operation the patient was still free from a recurrence.

18. Exophthalmos in Newborn.—Borland reports a case of bilateral exophthalmos in a child, the vault of whose cranium showed evidence of protracted pressure and presented a perfectly flattened-out, squashed appearance; the frontal and parietal bones, while not overlapping, were practically at right angles. The child's face was pallid, and both eyes protruded to such a degree that the sclera was seen above and below the cornea and the eyelids were unable to meet. There was no ptosis. The pupils were equal and fully dilated. The child is still alive, strong and healthy in every way and is now 3 years of age.

- 19 *The Use of the X-rays as an Aid to the Early Diagnosis of Pulmonary Tuberculosis. A. Stanley Green.
- 20 The Attitude of Our Profession Toward the Educational Questions in These Countries. R. B. McVittie.
19. X-Rays in the Diagnosis of Pulmonary Tuberculosis.—Green points out that if physicians will remember that a diagnosis of any condition can not be made by one single method of examination, but that advantage must be taken of all other aids, particularly history, symptoms, and physical signs, the x-rays will be found as valuable in the diagnosis of early tubercular deposit in the lungs as the ophthalmoscope is in the diagnosis of many diseases. Apart from ethical reasons, he says that it is very important that this work should remain in the hands of medical men, and not be given over to chemists and photographers. The screen examination, to which he attaches considerable importance, is carried out with the patient lying on a table with a vellum top and with a tube placed in a box beneath, which is movable in both directions, or else standing up about eighteen inches from the tube, with the surface of the anode parallel to the greatest transverse diameter of the chest. It is absolutely necessary for the patient to be stripped to the waist and the room kept at a suitable temperature. The light in the tube must be under perfect control, so that the penetration of the tissues may be buried at will. The first point to notice is the position and movements of the diaphragm on the two sides. The patient should then be asked to take a deep inspiration followed by a full expiratory movement. The excursion of the diaphragm is again measured. The patient must then be examined with the screen on the chest and the tube at the back, to ascertain the height and movements of the diaphragm as seen from the front. Other conditions which can be noted in the screen examination are the slope of the ribs and the width of the intercostal spaces; the position and shape of the heart, shadows and opacities in the lung, and the effect of deep inspiratory movements on these—a very important point. In a few cases small opacities can be seen in the mediastinum suggestive of enlarged and perhaps calcareous glands. Unilateral limitation of movement of the diaphragm is the earliest sign of pulmonary tuberculosis, and in no case which Green examined where this sign was noted (in the absence of a history of pleurisy), has he failed to find deposits in the lungs, either then or later. Furthermore, if the history and symptoms are taken into consideration the movements of the diaphragm may be taken as a measure of the activity of the disease. Fluid in the pleural cavities can also be detected easily by a screen examination. The shadow cast by a purulent effusion is much more dense than that of a serous effusion, obscuring the shadow of the ribs, which can be seen through a serous effusion. It is also possible to say whether air is present in addition to fluid or not. In the former case the upper level of the shadow in the erect position is horizontal, while in the latter, under the same conditions, the shadow has the form of a concavity, the sides of which are prolonged upward for a considerable distance. Green uses a 10-inch coil so arranged that when necessary to go to the patient's house it can be worked by one 6-volt accumulator and the Charpentier-Gaiffe interrupter, which will admit a variation of current of from 2 to 10 amperes, and at the same time permit of the use of a 230-volt current through a Wodal jet interrupter in the consulting room. In the former case the exposure necessary to give a good skiagram of an adult thorax varies from two to three minutes, whereas in the latter thirty to sixty seconds is ample to give a good definition, the tube being placed from twenty to twenty-four inches from the plate, the anode being on the level with the third or fourth rib. In some cases he uses a separate plate for each lung; in others, only one plate for both lungs. The back to plate method is used in every case. Sometimes he exposes the plate while the patient holds his breath after a deep inspiration, cutting off the light as soon as the second inspiration is necessary. This means three or four periods of exposure to bring up the requisite time. Rapid plates, which will stand long development without fogging, are essential. Where cavities are suspected it is important to take one skiagram

and then, after the patient has coughed and expectorated, to expose another plate. In this way the cavities, being emptied, will be seen as light areas in an opacity; in the first skiagram the opacity would be more homogeneous.

22. Rational Treatment of Burns.—Nageotte is so impressed with the necessity for surgical cleansing of the burned surface that she is credited with scrubbing it. She restricts the scrubbing to the sound skin around, but cleanses the burned surface with soap, applying it on a non-absorbent compress, under chloroform. Anesthesia is necessary, especially for children and burns of the face. The subjects rouse from the chloroform free from all pain and thus continue to complete healing, whatever the dressing applied. Families should learn to treat a burn like a wound of any kind, cover immediately with a clean cloth or first-aid dressing. The gauze can be saturated then with a 1 per cent. solution of picric acid. This emergency dressing should not be disturbed until the physician is ready to cleanse the burned area, preferably in a hospital or operating room. She describes a case of a severe vitriol burn over the entire face, neck and part of the arms. The burned surface was covered at once with compresses dipped in ammoniated water. The entire burned surface was cleansed by a surgeon an hour later, with soap, rinsed with bichlorid and dressed with dry iodoform gauze. The dressing was not disturbed until the ninth day, when the eschars were found as dry scabs adherent to the gauze and only the magnifying glass revealed that the apparently normal skin was less smooth than before. There was no suppuration except at a few points where the skin had been scratched in the struggle.

23. Hematuria in Nephritis.—Albarran accepts the idea that the inflammation in the kidney in Bright's disease is merely one manifestation of a primal, a more general, affection. This affection involves other organs and other systems, but the kidney is invariably affected and secondarily causes other disturbances. These phenomena secondary to the kidney disturbances superposed on the general affection, explain why an apparently insignificant alteration in the kidney may give rise to copious and persisting hematuria. The same is observed at times in cases of tuberculosis and cancer of the kidney. Some trifling lesion in the kidney may cause a disturbance in the blood vessels and thus secondarily induce hematuria with or without an angioneurotic reflex action. This mechanism explains why any surgical intervention on the kidney is liable to arrest the hemorrhage by breaking the angioneurotic chain. Simple exploration of the kidney, nephrotomy, decapsulation, any of these is liable to cure the hematuria, but not the underlying general and kidney affection. The operation produces a series of vascular and nervous modifications in the parts which puts an end to the hematuria.

24. Spinal Stovainization.—THE JOURNAL has mentioned recently the advantages of a new anesthetic put forward in France, stovain. Kendirdjy reports a series of 64 operations undertaken with spinal anesthesia induced by injection of a 1 per cent. solution of stovain in physiologic salt solution. In the entire series there was not a trace of any by-effects. There was no nausea or vomiting, no mishaps of any kind, and microscopic examination of the cerebrospinal fluid afterward showed it anatomically the same as before the stovainization. The anesthesia was as perfect as with cocaineization, to say the least, and it lasted forty minutes on an average. The injections were made in the second lumbar space, and the operations included a number of radical cures of hernia, resection of the scrotum, excision of hemorrhoids with dilatation of the sphincter, epididymectomies and amputation of the penis. There was slight headache in one case, but the headache had been observed before the operation. In the only other

case in which headache was noted afterward the patient was a syphilitic with roseolae. The intermittent character of the headache and the absence of any other symptoms that could be ascribed to the anesthetic render its syphilitic nature almost certain.

 32 (No. 4.) *De l'emploi du sérum de cheval chauffé contre les infections en chirurgie abdominale (hot horse serum). R. Petit.
 33 *Hystérectomie et infection puerpérale algue. C. Cristeanu.

27. **Uterine Cancer and Remote Results.**—Duret and Besson remark that 104 out of 173 cases of cancer at the Lille hospitals, 1891 to 1903, proved to be inoperable. About 38 per cent. of the 69 operated on survived more than two years. The mortality after laparotomy was 88 per cent. during the first year, while it was only 38 per cent. after vaginal removal of the cancer. In advanced cases, with much general debility, any radical operation is contraindicated, as the general health never recuperates and the subject does not survive the year. Palliative measures are best in such circumstances.

32. **Hot Horse Serum and Surgical Infections.**—Petit relates the details of 15 laparotomies in which he used hot horse serum to combat infection. There was only a single death due to the infection for which the operation was undertaken. The cases were all extremely grave, and the benefit from the serum was marked. The patients all felt better, the pulse was good, respiration normal, expression tranquil and tongue moist. No ill effects were observed, and he is convinced that the measure may prove very useful in the clinic to enhance the natural resistance to infection and reduce the number of deaths from peritonitis. After the toilet of the peritoneum he drains the vaginal and abdominal wounds and pours about 30 gm. of hot horse serum into the pelvis. He gives the details of all his cases thus treated. The thermometer sometimes shows a slight rise in temperature, but it is transient.

33. **Hysterectomy for Acute Puerperal Infection.**—The balance sheet of this intervention is made out by Cristeanu in a comprehensive monograph. The mortality is much higher than that of other modes of treatment. Only a single instance is known of a favorable termination to uncomplicated, acute, puerperal infection without localization treated by hysterectomy. In the 80 cases on record the cures reported were all of some more or less manifest complication.

34. **Fevers of Unknown Origin.**—Bozzolo classifies in nine groups the various types of a prolonged febrile state for which none of the ordinary causes can be discovered. One group includes ulcerative endocarditis, another the affections whose localizations do not appear until late and then in the glands. Group 4 includes the febrile state that precedes the discovery of a cancer. In a case recently observed a tumor in the kidney was first revealed by fever; hematuria did not appear for three months later. Group 5 includes the febrile state noted in old syphilitics. It is rebellions to quinin but yields to iodid. Group 6, the nervous and hysterical febrile states, very rare in men. Group 7 is the large class of bacteriemias and septiciemias without localization or only at a tardy stage. The fever has no invariable specific type, but the streptococcus usually induces a fever with exacerbations, while the pneumococ-

cus and the typhoid and tubercle bacilli cause a more continuous, remittent febrile condition. Intravenous injections of quinin or other drugs are of only transient benefit. The prospects are promising for treatment of these septiciemias by vaccination with attenuated cultures or intravenous administration of specific serums. The other groups are those of "tuberculous typhoid" and Malta fever. The tuberculous septiciemia may be absolutely primary, the entire lesion being restricted to the vascular system. Maragliano advises intravenous injections of sublimate in dubious cases of prolonged fever. De Renzi has derived great benefit in Malta fever from change of air and 4 to 8 capsules of i-thyol a day. The latter acts so effectually that he tries it as a diagnostic measure in many cases. Lucibelli of Naples described the case of a woman of 39 who for eleven years has suffered from weakness, constipation, swelling of the left knee and fever. No treatment has had any effect on the condition. No parasites can be found in the blood; the proportion of leucocytes is as 1 to 60; lymphocytes, 15 per cent.; mononuclears, 5 per cent.; polymuclears, 50 per cent., and no mast cells. The source of the fever is still a mystery.

35. **Physico-Chemistry in Relation to Clinical Medicine.**—Ceconi terminated his address with the remark that the latest researches and discoveries, far from detracting from the value of the "vitalist theory," supply more solid foundations for it, as they show that physics and chemistry are totally unable to explain the vital processes. When the freezing point of the blood is normal, it is a sign that the kidney is functionally capable, but only on condition that the composition of the blood is normal. He regards cryoscopy as of little if any value for the diagnosis of unilateral kidney affections. It varies for the cerebrospinal fluid to such an extent that a low freezing point can not be regarded as necessarily pathologic.

36. **Nephrototoxic and Hemolytic Action of the Kidney.**—De Renzi ligated the pedicle of one kidney in 15 dogs. The results observed indicate that kidney tissue is able to cause hemoglobinuria.

37. **Radiotherapy of Leukemia.**—Colombo treated 3 cases of leukemia with the Röntgen rays. At first the symptoms were aggravated, but then marked improvement followed. The course comprised 120 to 150 exposures of forty minutes each, ten given to the sternum, ten for the spleen, ten for the elbows and ten for the knees.

38. **Serum Diagnosis of Tuberculosis.**—Marzagalli announces that 2 drops of blood serum added to 8 drops of a filtered emulsion of tubercle bacilli will give the precipitation reaction in case of tuberculosis. He prepares the emulsion by triturating in the presence of distilled water the tubercle bacilli previously rinsed with cold water.

39. **Mercurial Injections.**—In the discussion that followed the address on this subject, Fournier observed that the method of mercurial injections has established its usefulness, but should not be stretched to apply to tabes and general paralysis. He has never witnessed a cure of the latter, although he has injected calomel to an amount of .1 gm. once or twice a week. Injection of large doses of calomel once a week has sometimes displayed almost miraenous efficacy in his experience, but only in cases of phagedena, tuberculous syphilitis, gummatous laryngitis, inveterate plantar or palmar psoriasis and syphilitic affections of the tongue.

40. **Obesity.**—Murel's address emphasized the fact that most of the symptoms attributed to the obesity are in reality due to the same primal cause. Treatment should aim to reduce the weight to the standard proportion for the height. The number of calories required by the organism varies according to the season, the age and the sex, and this point must be borne in mind in reducing the intake of food. The nitrogenous ingredients should be taken according to the normal dietary and the reduction should be exclusively in the fat-producing foods, the "ternary nutrients." The patient must be supervised to watch that the urine is never less than 15 gm. per kilogram of weight, that is, about a quarter of an ounce to the

found. The treatment should be kept up for six months at least, with frequent intermissions, the latter to favor the recession of the skin. Leven of Paris believes that dyspepsia is the rule in excessive corpulence, and that the latter will right itself when the dyspepsia is conquered by appropriate treatment.

41. **Psychic Localizations.**—Grasset, in his address, suggested the classification of the psychic functions into three groups, the sensory-motor psychic functions, the inferior—involuntary and automatic—and the superior—voluntary and conscient. He thinks that this classification will promote the study of psychic localizations much better than grouping by faculties.

42. **Senile Gangrene.**—Verhooen of Brussels treats incipient gangrene with the iodids to widen the arteries, giving about .2 gm. of the active substance a day for months without interruption. Hypodermic injections of the alkaline nitrites, in the dose of .05 gm., are also efficient. They can be kept up for several months without ill effects. As a tonic for the heart he gives the preference to theobromin, 1 or 2 gm. a day, also continued for several months. It can be associated with .5 to 1 gm. of caffeine a day. When gangrene is once established he disinfects with a 1 per 1,000 solution of potassium permanganate, followed by the permanent application of fresh hydrogen dioxide. Brissaud stated that when the arterial lesion is located high up, as for instance at the bifurcation of the aorta or in the iliac, surgical intervention is the only resource and should be prompt and thorough. The cause is not inevitably atheroma. In one case he found at the necropsy a clot entirely obstructing the lumen, due solely to intense angioplasm. Neurasthenia are extremely subject to the latter. The state of the liver and kidney is an important factor in the pathogenesis of gangrene. When these organs are intact atheroma is not followed by gangrene.

43. **Buttermilk in Gastroenteritis.**—Decherf of Tourcoing reported that infants with severe gastrointestinal troubles improved to a remarkable extent when put on buttermilk. In 22 cases of acute gastroenteritis, including 8 very severe ones, all the children recovered rapidly, as also 3 adults with mucoc-membranous enterocolitis and a large number of children with chronic gastrointestinal troubles. The toxic-infectious symptoms vanished in the acute cases in less than twenty-four hours.

44. **Orthostatic Albuminuria.**—Teissier distinguishes between the residual post-infectious albuminuria, the associated forms and the true variety. Linossier believes that standing has a great influence on the functioning of the kidney at nearly all times.

45. **Treatment of Writer's Cramp.**—Ballet emphasized the fact that this condition is of cortical origin and requires psychic re-education.

46. **Fatal Anasarca After Saline Infusion.**—Sorel reported the case of an infant suffering from severe enterocolitis. The intestinal symptoms were improved by irrigation of the intestines, with saline solution, but, simultaneously, diffuse edema developed, rapidly fatal.

47. **Diazoreaction in Prognosis of Tuberculosis.**—Holmgren's experience has been that when the reaction was intense the subject succumbed within two months. When it was less marked or dubious, the subject lived six to eighteen months, and a negative reaction was always followed by long survival.

48. **Adrenalin in Eczema.**—Weill of Paris was able to cure a rebellious, recurring patch of eczema on his hand with adrenalin. He applied 5 or 6 drops of the 1 per 1,000 solution, and after it had dried a little starch glycerolate was applied and dusted with equal parts of starch and zinc oxid. This was repeated six to eight times a day at first and then only morning and evening. By the end of the second week the patch had healed and recurrences have been promptly aborted by the same.

49. **Epidural Iodized Injections in Meningitis.**—Mauclair has treated Pott's disease successfully with epidural injections of iodoforned oil, and Rossini now reports excellent results in

a case of tuberculous cerebrospinal meningitis. The patient was a lad of 16 and the disease was subacute and not influenced by any of the usual measures. He then withdrew 1 to 5 c.c. of cerebrospinal fluid and injected into the subarachnoid space the same quantity of 1 per cent. iodoforned oil. He repeated the procedure every six hours, inserting the needle at different points. As an adjuvant he injected into a vein every second day 1 c.c. of a solution of 1 gm. iodine and 4 gm. potassium iodide in 100 gm. water. The temperature declined the day after this treatment was instituted; diuresis was re-established and improvement progressively continued. After the fifth day the cerebrospinal fluid was always sterile as demonstrated by inoculations which had been positive before.

50. **Lumbar Puncture.**—Gerhardt regards lumbar puncture as a valuable diagnostic aid in meningitis. Bacteriologic and cytologic examination and determination of the albumin content of the cerebrospinal fluid not only reveal the meningitis but disclose its nature in most cases. In acute febrile diseases, especially typhoid, grippe and pneumonia, it differentiates the cerebral symptoms from suppurative meningitis, and also excludes suppuration in serous meningitis. Normal behavior of the cerebrospinal fluid in otogenic brain processes testifies to the integrity of the meninges. The most important information derived from lumbar puncture is when headache or vague cerebral symptoms are the only clinical indications of trouble, but anatomic changes in the cerebrospinal fluid confirm the probability of a syphilitic origin. Cytology and determination of the albumin will aid in the differentiation of paralysis from other forms of dementia and the liquor psychoses. Lumbar puncture has contributed to explain the bacterial etiology of acute myelitis, and possibly also of spinal paralysis. Another point learned from it is that the fluid is not always under excessive pressure in uremia. From the therapeutic point of view, lumbar puncture has proved useful in serous meningitis, in the headaches of chiorosis, in acute and chronic hydrocephalus and in meningeal apoplexy. In tuberculous meningitis and with brain tumors, very little relief has been obtained, although in exceptional cases some of the symptoms subsided. Some physicians have reported great improvement in epidemic and in otitic meningitis after lumbar puncture; Mya in 3 cases of suppurative meningitis with influenza bacilli, and Bertelsmann an otogenic suppurative meningitis cured by lumbar puncture. Little benefit is derived in chronic affections, with the exception of the severe headaches in secondary and tertiary lues. These have yielded to lumbar puncture in many instances after having long been refractory to all other measures. Brain tumors contraindicate lumbar puncture except with the greatest precautions. With this exception, lumbar puncture is not followed by evil results in any case. The article is based on both personal experience and study of the literature.

51. **Primary Tuberculosis of Spleen.**—Bayer adds another to the 6 cases on record in which primary tuberculosis of the spleen was diagnosed and completely cured by removal of the spleen. In 2 others on record the operation proved infef-
