factual to arrest the tuberculous process. In 19 other cases the tuberculosis was not found until after death. The tuberculin test or exploratory laparotomy is indicated when primary tuberculosis of the spleen is suspected in the presence of tumefaction, hyperglobulia and cyanosis. Prompt removal of the affected organ is the only treatment.

52. **New Views of Ether Narcosis.**—Engelhardt relates the results of considerable experimental research and clinical experience in regard to the influence of ether on the blood. The melting point of the red corpuscles and the point at which the albumin in the red corpuscles coagulates afford reliable data for determining injurious action of a narcotic on the blood. Further study of this subject is needed.

53. **Idiopathic Persistent Priapism.**—The condition in the case described lasted for eight weeks, when relief was obtained by an operation. The trouble was evidently due to thrombosis in the corpora cavernosa, and complete *restitutio ad integrum* followed an incision and evacuation of the clots. Goebel reviews 2 cases of leukemic priapism. In one, white thrombosis of the corpora cavernosa of penis and urethra was discovered at the necropsy. In the other case there were repeated attacks of priapism, and an operation revealed a deposit of putrefied blood containing the colon bacillus. In certain other cases on record the trouble was due to pyemic thrombosis of the corpora cavernosa, but in 9 others no cause could be discovered for the priapism. It is probable that in every protracted case there is some distension of the corpora cavernosa by an accumulation of blood, with consecutive thrombosis. The blood can easily be evacuated by a small, absolutely harmless incision, although there is a possibility that the clots may be absorbed in time.

54. **Suppuration in Pneumonia.**—Bloch describes a case of multiple suppurative metastasis, by the way of the lymphatics, in pneumonia. He also reviews 29 articles that have been published on the subject. His conclusions are to the effect that metastasis by way of the lymphatics has a favorable prognosis if prompt radical operative treatment is practicable, and if no vital organs are involved and there is no true pneumococcus pyemia. Metastasis by the blood route requires a general predisposition, such as is afforded by debility from some recent infectious disease, the rapid growth of the young or a congenital tendency. A local predisposition, induced by trauma, articular rheumatism or gout, is also necessary. The prognosis is doubtful on account of the danger of secondary pyemia.

56. **Total Exclusion of Large Intestine in Colitis Ulcerosa.**—Implantation of the ileum in the anus offers the best prospects for operative treatment of the severer cases of ulcerative colitis. Moszkowicz describes the technic he has worked out on animals with successful results in regard to tolerance, continence, etc. The operation is as simple as ordinary colostomy.

57. **Tuberculides.**—The chief importance of the benign exanthemata, known as tuberculides, lies in their affording a clue to a tuberculous internal process. They are always secondary, and can be classified in 2 groups, those belonging to the category of lichen or acne scrofulosorum, and those with necrosis, including the folliclic, nodular tuberculides and erythema indurativa with flat infiltrates. They are probably due to the action of the tuberculous toxin alone. Five pages of bibliographic references accompany the article which is based on this literature and the material at Neisser's clinic at Breslau.

58. **To Enhance Resisting Power to Infection.**—Miyake's experiments to increase resistance to infectious processes were numerous and varied. His final conclusion has already been announced in these columns, page 1267. It is to the effect that subcutaneous injection of nucleic acid has a remarkable effect in summoning the leucocytes to the spot, and reducing the danger from operative intervention. The dose for an adult is 50 c.c. of a 2 per cent. neutralized solution of yeast nucleic acid. The .5 per cent. solution is preferable, but as this requires 200 c.c. of fluid, the more concentrated solution is

generally used. No by-effects were ever noticed in the 38 cases in which Mikulicz had used it at date of writing.

60. **Hemorrhage from the Kidneys.**—Stich relates 4 cases of severe and prolonged hemorrhage from the kidneys, in one of which the necropsy revealed diffuse chronic parenchymatous and interstitial nephritis in one kidney while the other was normal. In another case the kidney was incised for assumed nephrolithiasis. No stone was found, but the hemorrhages were arrested. They recurred again four years later, but were conquered by repeated subcutaneous injections of gelatin. Suggestion and hydrotherapy have arrested the hemorrhage in some cases on record. An ice bag may be useful to supplement gelatin injections. If the symptoms persist a week or so, uninfluenced by these measures, an exploratory incision is indicated.

61. **Puncture of the Brain.**—In Neisser and Pollack's experience with 138 punctures through the intact skull there was no arterial hemorrhage in a single instance. They ascribe their success to their technic which they minutely describe. They also review the anatomy of the parts and summarize their clinical results. They found the measure extremely valuable from a diagnostic point of view, and also for evacuation of pathologic fluids.

62. **Peptic Ulcers in Jejunum.**—Tiegel reports 6 cases observed at Mikulicz' clinic, and summarizes 16 already published. The peptic ulcer in the jejunum may run a latent course to perforation or it may cause severe trouble from the start. It has a great tendency to recur. It has been noted hitherto only after gastroenterostomy on account of some non-malignant gastric affection. The subjects are almost invariably males. Prolonged internal treatment, as for gastric ulcer, offers better prospects for a cure than surgery, except in case of perforation. It seems better to prefer posterior to anterior gastroenterostomy, with transverse fixation of the loop, or better still, to substitute a pyloroplasty operation or gastroduodenostomy. In prophylaxis, alkalies and careful dieting should be the rule after a gastroenterostomy for a benign stomach affection. The ulcer is generally referable to the peptic action of the gastric juice superadded to disturbances in the circulation (arteriosclerosis), lesions of the mucosa or an individual predisposition.

64. **Simulation of Insanity.**—Schott emphasizes the necessity for caution in certifying to feigned insanity as the simulation may co-exist with true mental disturbance. It is frequently one manifestation of the latter. All subjects suspected of simulation should be placed for observation in some psychiatric clinic or asylum. The assumption of pure simulation is justified only when evidence of the mental soundness of the individual is forthcoming.

65. **Narcosis Paralysis.**—Commenting on a serious case in his own experience, Glitsch remarks that it is advisable to change the position of the arms from time to time during protracted operations, to avoid post-operative paralysis. If the victim should appeal to the courts, the judge might easily assume some carelessness on the part of the operator in case of severe paralysis of this kind. Glitsch thinks that probably more cases occur than are published.

66. **Lung Sequester.**—Bildinger relates that a man of 40 exhibited symptoms suggesting typhoid fever, but the temperature persisted high, and by the fifth week he began to cough and suddenly indications of a large abscess in the lung developed. An operation disclosed a foreign-body suppurative in the lung which had resulted in the casting off of a sequester of the lung as large as a man's fist. It floated on water, and presented histologic evidence of pneumonic infiltration. The most striking features of the case were the sudden development of physical findings suggesting a large cavity in the lungs and the small amount of expectoration under the circumstances.

69. **Nursing Bottle Holder.**—A small standard is screwed to the edge of the bed or baby wagon. It terminates above in a spiral spring on which is mounted a broad half ring in which the bottle fits tight. The bottle is thus held horizontally at the proper height, and the flexible spring allows it to follow every movement of the child's head. The child can also drop the nipple, taking it again at will, the same as the natural nipple. The bottle is kept from contact with the bedding, etc. The contrivance is shown in an illustration.

73. **Foreign Embryonal Cells as a Cause of Cancer.**—Kelling's previous announcements in regard to the cause of cancer in the digestive tract were summarized in an editorial on page 269. He here relates further experiences which have apparently corroborated his former assertions and suggest both an effectual mode of diagnosis and prophylaxis of malignant growths. He has found that it is possible to induce cancer in dogs at will by inoculating them with embryonal cells from pigs' uteri or from hen's eggs. Old dogs are the best adapted for the purpose, and the liver and the testicles are the organs most predisposed to malignant growth. The inoculation is best made between the sheets of the mesentery, which enables the substance to find its way better into the glands and retroperitoneal tissue. The cancerous nodules which developed in the liver or testicles after such inoculation of hen or pig embryos in dogs showed the microscopic findings characteristic of cancerous growths, and the most careful search failed to reveal any other malignant growth in the dogs when killed fifty to a hundred days afterward. The biologic precipitin test was always positive for the specific albumin used, and was negative for albumin from other sources. This biologic test was also positive for hen's albumin in 9 cases of cancer from the human digestive tract. He accepts this as evidence that these cancers resulted from ingestion of raw eggs. In 13 others the results were negative for hen or pig embryonal elements but, of course, the possible sources for embryonal inoculation in the digestive tract are legion. It is also possible that the specific reaction might have been obtained at some previous stage of the cancer. He was able to group certain kinds of cancers by the serum biologic test, finding that certain groups gave certain specific reactions. In one group, for instance, a sarcoma of the human ovary, a teratoma of the testicle, a mammary cancer and one on a dog, all induced intense precipitation of the albumin in a prepared serum obtained by injecting rabbits with human mammary cancer substance. They also all induced intense precipitation in a prepared serum obtained by injecting rabbits with embryonal albumin from the pig. In 2 other cases of inoperable gastric and rectal carcinoma, the serum of the patients gave a positive response to the biologic test with embryonal pig cells, with which also the history of the cases harmonized. In 15 further cases of cancer of the digestive tract precipitins for hen albumin were found in 8 and for pig albumin in 2. This specific reaction was so intense and unmis-

takable that in a dubious case of apparent gastric catarrh he advised an operation for cancer merely on the basis of this reaction, and advised against it for the same reason in other cases. The operation or the course of the affection confirmed his diagnosis in every instance. The reaction is more intense the younger the subject, and it is most instructive in cases of beginning scirrhus. In some cancer subjects there is no formation of precipitins, and he has sought to influence inoperable growths by inducing the precipitin formation by injection of the prepared animal serum. In the prophylaxis of cancer, the ingestion of live embryonal cells should be avoided, especially by subjects with catarrhal or other changes in the mucous lining of the digestive tract. The uteri of animals slaughtered for food should be destroyed, and no raw meat or raw eggs should be eaten. Kelling has sought to destroy the germinal area in eggs by some means which would not injure the looks or taste of the egg. If a fresh egg is laid horizontal the germinal vesicle usually rises to the top and a current of electricity sent perpendicularly through the egg will destroy all life in the germinal area. Such prophylactic measures offer prospects for successful extermination of cancer. Many of our younger physicians may live to see the day when cancer has become a pathologic rarity among civilized peoples.

76. **Graphic Fixation of Physical Findings.**—Kranhals writes to express his satisfaction with the Curschmann method of graphic notation of the physical findings in examining patients. The findings are marked on the skin of the patient and certain of the landmarks are also marked. A sheet of transparent paper is then laid over the skin and the marks below are traced on the paper.

78. **Jute Dressings for Local Application of Heat.**—Application of superheated air is necessarily a more or less transient process. The results are better when the heat is applied more permanently, and especially when the parts are exercised at the same time. Langemak says that a thick dressing of jute under oiled silk fulfills all these conditions. He has been applying it in his practice with the greatest satisfaction. The jute can be obtained for a trifle at any saddlery or upholsterer's shop, and holds the heat better than anything else. He has found it particularly useful to apply after removal of the hot air oven. The only drawback is the size of the dressing, as the layer of jute must be several inches thick. He sometimes applies it at night only; in severe cases he leaves the dressing undisturbed for several days. The indications are the same as for superheated air. The thermometer shows that the parts under the jute are kept at a constant temperature of about 104 F.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

MENTAL DEFECTIVES: THEIR HISTORY, TREATMENT AND TRAINING. By Martin W. Barr, M.D., Chief Physician Pennsylvania Training School for Feeble-minded Children, Elwyn, Pa. Illustrated by 53 Full-page Plates. Cloth. Pp. 368. Price, \$4.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

OUTLINES OF PHYSIOLOGICAL CHEMISTRY. By S. P. Beebe, Ph.D., Physiological Chemist to the Huntington Fund for Cancer Research, and B. H. Pixton, M.D., Professor of Experimental Pathology, Cornell Medical College, Ithaca. Cloth. Pp. 153. Price, \$1.50. New York: The Macmillan Co. 1904.

Addresses.

THE CHOICE AND USE OF MEDICAL LITERATURE.*

HUGH T. PATRICK, M.D.
CHICAGO.

The choice and the use of medical literature depend first on what the physician tries to be; not on what he would like to be, not on what his ideal may be, but on what he thoughtfully, consistently, persistently strives to be.

KINDS OF PHYSICIANS.

Our day-dreams of attainment are much the same, but the daily walk of physicians varies greatly. Most of us have met a physician who may be called the family factotum. He hobnobs with fussy mothers and puttering fathers. He is greatly interested in grandma's cough, knows just how to wash the baby, has his special poultice, and can take off warts. Dropping in to ask about Aunt Em's backache, he stays an hour visiting with the folks. He is a gentle and kindly soul, but his mind is occupied with the trivialities of medicine and domestic chit-chat.

Then, there is our old friend who in winter airs his surgical deeds and medical acumen about the drug-store stove and in summer holds a like symposium on the shady side of the street. He knows a good cigar, is a pleasant gentleman and harmless in all things save only the practice of his profession.

We have heard of the affable society physician who dresses well, talks well, knows the best families, attends receptions and makes social calls. We know and respect the God-fearing church physician who teaches the Bible class, sings in the choir, gets together the pastor's salary and finances the church debt. The lodge physician, the sporting physician and the physician deep in politics are familiar figures. We know them all. They are of us, members of our honorable guild. With loyalty and affection we take them by the hand. They are good friends and good citizens; but really fine physicians—not one of them. And not one of them has any real use for good medical literature.

But there is another man—the man we would like to be; the capable man who knows his work and does it; the man up with the van, who can talk face to face with the great in our noble profession. He has enthusiastically striven or doggedly persisted until he is the wise, skillful physician who practices with no uncertain hand, but knows when he is right and knows where he is ignorant. To be what he is and do what he does means familiarity with what others have done and are

doing. To this there is no exception. He reads. He selects his literature well and uses it wisely.

WISE SELECTION OF BOOKS.

The selection of our books is a task as delicate, a duty as significant as is the choice of remedies for our patients. Every book is a prescription for our mental self. And yet, who can deny that the clever book-agent puts thousands of volumes on our shelves? In this day and generation it is the physician's obligation not only to be able to recognize the good in medical literature, but to know the great and the safe among medical writers. A conscientious physician calls in consultation no unknown man, but, strange to relate, he will blindly follow an author of whom he knows nothing except that he has produced a book.

THE RÔLE OF THE TEXT-BOOK.

Another somewhat frequent professional indiscretion, to call it by no harsher name, is the good old student plan of sticking to a text-book. Progress means expansion. The more a man progresses the less prominent is the rôle of the text-book. It is necessary for babes, but not meat for strong men. No text-book physician is an A No. 1 man. The latter needs the treatise, the "system," the cyclopedia, and particularly the monograph.

THE MONOGRAPH.

Of all medical books the monograph is the best—and the worst. As a rule, it is the product of special interest and the wise employment of opportunity. In it we often find the rich harvest of many years of loving labor by a great mind. In all probability, the author has not only consulted the writings of others, but has acquired a sure judgment in weighing their merits. Unfortunately, sometimes he is an enthusiast without balance, a faddist, a man with a theory, a prejudiced observer, a dealer in sophistry. Then, if in addition he be a positive and clever writer he may do untold harm. I have now in mind an interesting, attractive book which in the last twelve years has led astray thousands of physicians, and I am sure that the next quarter of a century will not see rooted out the fallacies planted by its brilliant author. Why is this? Because thousands of well-meaning physicians bought the book without knowledge, read it without care, absorbed its tenets without proving, and promulgated its dicta without prudence.

DISCRIMINATION IN READING.

If he is to really profit by the precious time spent in reading, the physician must be able to read with discrimination. In medicine there is no such thing as an authority. The critical sense must be keen and ever alert. The reader must learn to be a judge, for the plea of every paragraph is to be adjudicated. And if he feels himself at fault, assistance is on every side.

* President's address, delivered before the thirtieth annual meeting of the Mississippi Valley Medical Association, at Cincinnati, Oct. 11, 1904.

I think there is no case in which those who know are more happy to lend a hand than in the selection and interpretation of medical writings.

MEDICAL JOURNALS.

And next, what of the journals? This is a big question and a hard one; one I approach with considerable feeling, but with no confidence. Nevertheless, I shall not attempt to dodge it; and since to advise is more human than to confess, to find fault more spontaneous than to praise, to say "don't" easier than to say "do," I venture first to advance a few of the "don'ts" in my mind. Be it understood, however, that these are suggestions purely tentative, as the expression of only one of a vast company, and that no remark is meant as criticism of editor, censure of publisher or condemnation of publication *per se*. All is addressed to the reader. I am not talking of foods, but of diet.

Don't admit to your presence a journal that is not perfectly straight and clean. As the first requisites of the good physician are conscientiousness and strictest integrity, so no journal is safe if it be not honest on every page. Humiliating as is the admission, we must confess that there are mercenary medical men writing subsidized articles for the benefit of tradesmen. We may not be able to stop the practice, but for the love of decency, let us drop the articles into the waste basket as soon as received and bar the journals from our table.

Just to illustrate how vigilant we must be, I may state that one medical screech has appeared in different journals as a straight advertisement, an editorial, an "original," a therapeutic hint, a news item and a clinical note. Again, of seven so-called original papers in one journal, four were obviously for ulterior purposes.

A thinly veiled deception is that of putting amidst scientific matter blatant advertising quoted from *Der Deutsche Medizinische Schurkenstreich* or *La Nation Médicale Trompeuse*. It is simply knavery with German or French sugar coating.

Another sort of debasing journal is the one that pretends, perhaps honestly, to help the physician to success by means other than pure professional excellence. A type of this kind of thing I recently found in an address to the graduating class of a medical school. I have no doubt the orator thought he was advising fact and inculcating practical methods for the management of patrons, the confusion of competitors and the increase of income. As a matter of fact, he was teaching those young men deception, subterfuge and meretricious connivance, to take the place of scientific knowledge and manly worth. Concerning the editor who spreads such pestilence, I have nothing to say. The physician who admits it to his library and his mind not only injures himself, but is recreant to his trust.

Don't indulge in yellow journals—for such there are—of deeper or fainter dye. The more harmless kinds merely present a sort of pseudoscientific vaudeville of striking oddities, rare curiosities, marvelous happenings and other side-show monstrosities of the medical world. All of this serves only to excite a passing interest, and makes no reader one whit better as scholar or practitioner. The worse kinds, under the cloak of medicine, pander to our appetite for the startling, the scandalous, even the salacious, and appeal to passion and prejudice. They lean strongly to sexual perversion and suggestive gossip. Behind the mask of independent thought they delight in strictures on those high in the profession and even indulge in dirty innuendo. They start hot discussions on ethics and

foment controversies over personal rights, privileges and immunities. And this, God save the mark, is circulated as medical literature, because it is read by medical men.

Don't take a journal which is run as an advertising medium, and do not look at it if it is sent to you. Such publications are of two sorts. One kind is issued by some commercial gentleman to assist in selling his wares. In the guise of a scientific periodical, it is to all intents and purposes a sort of medical almanac, about as wholesome and edifying as the pamphlet for Bone-setter's bitters or the bulletin of Mother Udder's uterine uplifter. The other kind is conducted by a medical man with the dollar mark stamped on his aspirations. The good of the reader is no concern of his. He is after the money of advertisers, all of them. Original communications, editorials, excerpts, correspondence, everything, is arranged purely as a bait to induce the gullible to swallow the ads.

Don't read a journal that accepts abortive papers by undertone doctors. There are journals which systematically encourage that sort of thing. Unquestionably, to report cases and write down his opinions is good for any physician. But how about the reader? When the cases are incompletely studied, the writer ignorant or narrow, his conclusions lacking foundation and his judgment immature, the contribution is not only valueless—it is injurious. Smooth is the descent that leads to Avernus, and easy the downward road of this damning third-rate literature. It is light and easy reading, but begets self-satisfaction, blunts the critical sense, lulls ambition, dulls observation, stunts mental growth, and before he knows it the reader is found on a low plane of thought and practice—no higher than the twaddle he reads.

Don't waste time on journals abounding in short cuts. They are an abomination unto the mind, a snare for the unwary, and their name is legion. A hint or two will indicate the sort I mean.

Purporting to be practical and immediately helpful, some journals make a specialty of what may be called recipes for disease. And they are very alluring. Instead of learning all about pneumonia, its nature, course, variations and complications, what methods of treatment have been tried and abandoned and what has been the experience of those seeing hundreds of cases, it is so much easier to take some fellow's or some journal's statement that a peculiar poultice or ambitious alkaloid cures the disease. Stamped deep on my feelings is a paper on dyspepsia in a journal of great vogue. With no statement as to what dyspepsia may be, with no word as to diagnosis, with no allusion to pathology, no mention of gastroptosis, dilatation, hyperacidity or motor power, and no hint of test meal or examination of stomach contents, the author proceeded to advise the administration of seven different drugs. In spite of the multifarious remedies, such advice simplifies practice to a degree. It is no task simply to remember to give this tonic for appetite, that capsule for digestion, this granule for pain, those drops for nausea, one pill for constipation, the other for diarrhea, and the powder for flatulence. It is a short cut, but it leads to disaster.

In this same category belong the medical magazines that make a leader of questions and answers; a department modeled on the *Ladies' Fireside Guide*, where anxious inquirers go off at half-cock and the answers pop back as prompt and empty as echoes. A very little reflection will show not only the utter futility of

this kind of reading, but how it prevents development by curtailing wholesome mental effort.

Then there is the petty journal corresponding to the family factotum above mentioned. Its short cut is simply the avoidance of the great and profound in medicine. Ignoring such fundamental things as anatomy, physiology and pathology, oblivious alike to basic principles and the best of accumulated experience, it propagates a sort of family confab on the various specialities of practice. How to bring out the eruption of measles; what is good for hiccough; the best liniment for sprains; these are cheerfully aired in numerous columns. What do you say to the parturient woman when she grows impatient? What is your favorite catarrh snuff? In the treatment of "threatened" appendicitis should acetone be given the first day and veratrum the second, or vice versa? On questions such as these, the editor and his writing readers expend great energy, priceless time and endless ink. With great zest the contributors, as Charles Lamb says, encourage each other in mediocrity. I carefully went through 115 pages of such a penny-wise, pound-foolish publication, and found just six pages of good stuff. And yet that journal has an enormous circulation—to the great renown of the publishers and the great discredit of the medical profession.

Don't pay much attention to columns of formulæ, notes on treatment, therapeutic hints, brief paragraphs on recent discoveries and items on new drugs. Pass over abstracts in which the process of condensation has squeezed the life out of the matter, and skip society reports so meager as to amount to mere personal mention. Most of such matter is garbled at the best, has no educational value, and even when a bit of it has virtue, is pretty sure to just slip through the otic tunnel—in one ear and out the other.

From the foregoing negatives a few positives may readily be inferred. As we are to buy only the best books, so let us take only high-class medical periodicals. And then let us read them well. If there are many poor journals, there is much poor reading done; reading that is casual, unsystematic, careless, superficial, cursory, profitless. We have three sources of information and inspiration: personal experience, personal contact with colleagues, and reading. The first may be limited, the second unsatisfactory, but the last offers to all the highest inspiration, and knowledge without end. Then let us read up and not down.

There is a certain comfortable ease in reading what we already understand. We may gratify our natural craving for approval by reveling in nice little papers which repeat what we have been saying for years. To tickle our vanity by reading papers so poor that they show the author to be more ignorant than ourselves is a pleasing process. Sometimes we feel luxuriously virtuous when reading a medical journal purely for entertainment and mental relaxation. None of these things should be. One and all they create a slovenly habit of mind. They are destructive of good method, and in the end incapacitate us for good work.

Here I must notice an objection or complaint that we have all heard and most of us have made: "I have no time to read." It is not true. The apportionment of time is not a matter of necessity, but of choice. What do I consider of the greater importance? What do I like and dislike? What do I choose to do? These are the determining questions. And in the modern physician's life there is precious little paramount to study.

It pays to read. Beside the pleasure of knowledge and the power that knowledge gives, beside the gratifying sense of achievement and the satisfaction of progress toward a goal, it pays in dollars. In conversation with the busiest, the greatest and the most successful of our colleagues, I have often been astonished at the amount of reading they do and how they rely on it. Very, very often good reading makes the difference between \$5 and \$25 for an examination, between \$50 and \$500 for an operation.

And now, if I may be allowed four little hints as to the manner of reading, I shall have finished.

One excellent way to use medical literature is systematically to get up one subject well; to investigate it thoroughly; to trace its history and follow its development; to scrutinize diverse observations, review conflicting opinions and weigh different conclusions. Having once mastered the thing, it will be surprisingly easy to follow it through the succeeding years, for the annual increment to any given subject in medicine is astonishingly small. After one topic is exhausted another may be attacked, and so onward.

This method easily falls in with a second good one, namely, to read up fully on cases in hand. Note that I say "fully." Hastily to look up an ointment for eczema or to consult a text-book or two on the diagnosis of iritis may be one of the exigencies of practice; it is not reading. Likewise hunting up a remedy for an obscure case may possibly be a necessary makeshift, but generally it does the patient little good and the physician less. We should read for a perfect understanding of the case, which means a complete comprehension of the subject. No case can properly be considered alone. It is always in relation to variant cases under diverse circumstances. For no patient can there be a paragraph explanation and no recipe treatment.

Now, these two plans of reading naturally lead up to a third—reading to write. Of course, this plan is good only when the writer compels himself to produce really good stuff. This proviso fulfilled, I know of nothing more wholesome than the writing of papers and the reading of them where others may pass judgment. If the first two plans have been well carried out, it is reasonably certain that this one will not miscarry. The man who has excellently well worked up any subject or any case of any abnormal condition, is not only well prepared for the next one of the kind, but he is in a position to tell others something they do not know.

Pursuance of these three plans of reading will almost inevitably produce a most desirable habit, viz., the keeping of case records. The virtues of this practice are many. Two of them are that it stimulates reading and enhances its value. Accurate comparison of our experience with that of others not only serves to impress the facts, but ripens knowledge into wisdom.

The fourth and last suggestion for medical reading is really but a summary of the other three. It is that we acquire the mental attitude, or aptitude or habit of reading for reproduction. To be a student is not enough. We must be effective students; student soldiers, if you please, preparing for action. There is a vast difference between the acquisition of knowledge as a mere accomplishment and as a means of accomplishment. It is well for us to regard our store of knowledge not as simply an interesting museum of Nature's wonders marvelous to contemplate, but rather as an armamentarium; an orderly array of goodly weapons ready for instant use.

THOUGHTS SUGGESTED BY A STUDY OF THE EYE INJURIES OF INDEPENDENCE DAY.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OPHTHALMOLOGY, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

ROBERT L. RANDOLPH, M.D.,

Associate Professor of Ophthalmology and Otolaryngology, Johns Hopkins University, BALTIMORE.

In these days of progressive municipal hygiene, when laws are being constantly enacted to protect us from the results of ignorance which is so often criminal, I have thought it a suitable moment to call the attention of ophthalmologists to a condition which savors strongly of defective legislation, a condition which is peculiar to our country.¹

It is not the first time by any means that the subject has been brought to public notice, for the medical journals throughout the land, and especially THE JOURNAL of this Association, to say nothing of the newspapers generally, have long since presented facts and figures which should convince us that the Fourth of July is a day of mourning to a large number of those who participate in its celebration and an unmitigated nuisance to thousands of others who come more or less indirectly within the zone of its activities.

Generally speaking, those who are faithful in observing this occasion will sooner or later be made to appreciate with some degree of force the truth of this statement, for while the unfortunates are drawn in large measure from the ranks of childhood, some of the most destructive injuries which I have seen were in individuals who had passed unscathed through the turmoil and heat of more than twenty Fourth of July celebrations. For example, there are to be seen in these records 15 cases where the ages ranged from 30 to 45 years, and each of these individuals was left to finish life with one eye. There were 52 others who had gone quite a distance into mature life, two of them being men of 60 years old, and eight women, two of whom were nearly 60, the other six being over 40, and each of this last group was badly injured.

This thing of getting wisdom is usually attended with some tribulation, and before we get it most of us have lost "the wild freshness of morning." Such an

experience as that of the eight foolish virgins just mentioned certainly worketh wisdom.

The frequency of railroad accidents in this country has given rise to the opinion expressed in some quarters that we Americans are a violent people and that we have a disregard for human life, although it should be said in this connection that the statistics of Mr. Thompson² show that for the year ending June, 1902, railway travel in America, mile for mile at least, is safer than that of Great Britain, France and Germany. Be that as it may, our attitude toward the absolutely unnecessary mortality from fireworks on Independence Day is open to the severest criticism. Railroadng or even traveling on railroads is essentially a somewhat hazardous business, but equally essential is it for the good of society, while the use of fireworks is at best only a so-called amusement, and one toward which all legislation has been hostile and for obvious reasons. The remarkable thing is why there should be a day on which this form of lawlessness is condoned.

How singular, not to say preposterous, is the spectacle of this country celebrating the anniversary of its independence at the expense of 466 lives, 10 persons totally blind, 95 eyes lost, and 500 other individuals maimed and disfigured. This is the record of July 4, 1903,³ a record which eclipses in its death list the losses in killed on the American side in the battle of Bunker Hill.⁴

In comparing these numbers with the mortality from tuberculosis, it is interesting and suggestive to note that nearly five times as many persons were killed last Fourth of July by fireworks as have died from tuberculosis in Baltimore for any month during the past ten years, and more than twenty times as many as the average daily mortality from the same disease in the city of Greater New York with its population of over 3,000,000.

It should be remembered, too, that there must have been hundreds of other and minor casualties which were never reported, so that the complete record of last Independence Day will hold its own with that of any of the tragedies of this or other lands for 1903, with the additional sting of the folly and ingloriousness of it and of the fact that it is a story which we have heard with some complacency and regularity for many years. Such a thing is a reproach to any people.

I need hardly say that if the celebration of Independence Day had been attended in one community with a loss of 466 lives, that community would have risen up and wiped the holiday from its calendar. We see this power of public opinion illustrated in Norfolk, Va. Two years ago that community, exasperated beyond endurance by the mortality from the toy-cartridge pistol during the Christmas holidays, took active measures at once, and the toy-cartridge pistol was voted an intolerable nuisance and a severe penalty imposed for its sale. Fortunately, no such wholesale destruction has befallen any one section, for this record represents the tax levied on the nation for the license to use fireworks for one day of the year, and it is doubtful in the highest degree whether the significance of that day was understood by half of those whose names are to be found on the list of dead and injured. This sort of patriotism sounds like barbarism.

Thanks to the press, the wedge of reform has been

1. A large portion of my original address appeared in the *Baltimore Sun*, June 27, in connection with a crusade started at that time against the "Fourth of July Nuisance." That part has been abbreviated in this version. It is interesting to note the success of the movement in Baltimore as compared with reports from other cities:

NEW YORK CITY.	
New York Eye and Ear Infirmary.....	20 cases.
Manhattan Eye and Ear Hospital (N. Y.).....	42 cases.
New York Ophthalmic and Aural Institute.....	5 cases.
Total	69 cases.
BOSTON.	
Massachusetts Charitable Eye and Ear Infirmary.....	16 cases.
PHILADELPHIA.	
Wills Eye Hospital.....	15 cases.
BALTIMORE.	
Johns Hopkins Hospital.....	1 case.
Presbyterian Eye and Ear Hospital.....	0 cases.
Baltimore Eye and Ear Hospital.....	1 case.

The Presbyterian Eye and Ear Hospital, which has the largest clinic south of Philadelphia, shows a clean sheet for the first time in twenty years.

I thank the following gentlemen for help in getting together these statistics: Drs. John E. Weeks, Edgar S. Thomson and Arnold Knapp, of New York City; Drs. S. D. Risley and C. A. Oliver, of Philadelphia; Drs. Myles Standish and F. H. Verhoef, of Boston, and finally, Drs. Davis and B. B. Browne, Jr., of Baltimore.

2. *Railway World*, Feb. 12, 1904.
 3. *THE JOURNAL A. M. A.*, Aug. 29, 1903.
 4. The Americans lost 449 killed, *The American Revolution*, by John Fliske, vol. 1, p. 139.

driven in a short way, and things now are in better shape in some respects than they were a few years ago. For example, on July 5 and 6, 1888, there were 16 cases of eye injury treated at the Presbyterian Eye and Ear Hospital, Baltimore. On the same days of 1897 there were 14 cases treated, and in the intervening years there was an average of 6 cases for each Independence Day. Now and again there has been an outbreak of what might almost be called an epidemic of this class of injuries. For instance, on July 4, 1898, we had a record at the Johns Hopkins Hospital of 14 cases. In 1899 there were 16 cases treated at the Presbyterian Hospital and in 1901 13 cases. It should be remembered, too, that every year a certain number of eyes are treated in other hospitals than in the ones mentioned, and, again, a certain number are treated by the various physicians throughout the city, in their private offices. The number, no doubt, would be multiplied many times if the record of every case could be reached.

I note that 84 cases of eye injury were treated at the New York Eye and Ear Infirmary on July 4, 5 and 6, 1902, and on the same days of last year 42 were treated. Comparisons are unnecessary to show the condition of affairs prior to 1902, for the records of this one year are sufficient to prove that this kind of lawlessness is still deeply rooted in the metropolis, and that it blossoms out with surprising freshness and vigor with each returning Independence Day.

I have collected 493 cases of eye injury caused by the explosion of fireworks July 4; 249 of these occurred in Baltimore, while the others have been obtained from the records of the New York Eye and Ear Infirmary, the Manhattan Eye and Ear Hospital, New York City, and the Massachusetts Charitable Eye and Ear Infirmary. Practically all of these accidents occurred within the last few years, that is to say, only recent records were consulted. The numbers would mount up into the thousands had earlier records been utilized.

I have already called attention to the fact that the majority of such injuries are to be found among the young, a fact which these records help to establish. Of the 493 cases, 357 were children, and 136 were 21 years and over. There were 3 cases where the child was 3 years old; 5 cases where the age was 4; 7 cases where the age was 5; 1 case where the child was 2½ years old, and an infant of 3 months. It is to be regretted that the records of these hospitals gave so little information as to the variety of fireworks which proved to be the most dangerous, but so far as this point was considered, I gathered enough to feel satisfied that one of the varieties of firecracker was generally responsible for the injury, particularly for the very serious ones. Sky-rockets and Roman candles, however, were not found to be blameless by any means. In 110 cases the injury was to the right eye, and in 55 cases both eyes were injured. In the lists furnished by two of the hospitals, there was no mention made as to which eye was injured. The chief injury was one in which at the same time the lids, conjunctiva and cornea were peppered with grains of powder which was usually imbedded in these parts, and which injury we all know entails considerable suffering and frequently leaves permanent scars. Of these there were 269. Presumably most of these cases were discharged cured after being treated for a certain length of time, but it would have been interesting had it been possible to have followed up these

cases months later to see if the eyes had regained their integrity. In 40 cases, however, the injury was so serious as to make it necessary to take out the eye in seven instances for fear of sympathetic trouble, while in the remaining 33 the vision was permanently impaired, either by traumatic cataract or by inflammatory changes in the deeper structures.

A study of these statistics shows that we have pretty much the same train of events as is seen in other matters which pertain to public safety. A long period of freedom from sickness and sudden death makes the memory hazy and begets the carelessness which sooner or later brings disaster. The apathy which had settled over Baltimore in the few years previous to 1899 and 1901 could only be shaken off by some such violent provocation as the outbreak in these two years, since which time we have had some falling off in the number of injuries, so far as the eye is concerned. Not only in Baltimore, but in all of our cities the law is distinctly hostile to the "harmful and pernicious practice of setting off fireworks in the streets." The law, though, to be a real boon must become aggressive and the axe must be laid to the root of the evil.

An amusement which is essentially associated with such danger to life and property becomes too serious a matter to be regarded as legitimate amusement, and should be classed at once with crime and disease; in other words, with the things with which every civilized community is waging a war of extermination.

Take this incident as illustrating what I mean by defective legislation: A number of young men were celebrating the day in the usual manner. A small boy espied a fuse sticking out of the pocket of one of the men. The temptation was irresistible, and unseen he lit the end of the fuse. The man's side was blown open and he died in two hours. This is not an exaggerated nor an isolated case, for 465 others were killed in practically the same way and on the same day throughout our land. A man of 34 was having a good time with his children on the night of the "Fourth." A large firecracker had failed to explode and he went up to investigate. The next morning he came to me with a rupture of the eyeball extending clear across the cornea at its upper part and with the iris protruding. The eyeball subsequently underwent atrophy. This, too, is not an exceptional case, for ten individuals were made blind in both eyes and ninety-five lost one eye each in practically the same way and on the same day in the United States. One can never say what a cannon cracker is going to do, and it stands high as a vain thing for safety.

The root of the evil lies principally in the sale of fireworks, and on the basis of these statistics an ordinance was recently introduced which makes the penalty for selling fireworks \$50 instead of \$2 (as the old law stands), and for setting them off in the streets not less than \$10 nor more than \$25. I am convinced from the opposition which has sprung up from those who sell that the law will be a substantial blow to their business. It would seem that these people are willing to run the risk of being caught and fined when the penalty is only \$2, but fear to take the risk with a more severe penalty.

I have brought this matter before the Section because ophthalmologists probably see more of this class of injuries than other physicians; not that injuries to the eyes from exploding fireworks, although very frequent, are more frequent than burns and wounds of other parts of the body, but that this latter class of in-

juries are treated by or divided up among the great body of medical men, while eye injuries are usually seen by a limited few in the cities and towns. We are better able, then, to give effective testimony in a matter of this kind.

Usually when an ordinance is introduced, it is a simple matter to get permission to appear before the committee of the council and present one's arguments. This I shall do, and I will also have a representative from each of the eye hospitals to strengthen my hands. I think it advisable to have two or three surgeons who are well known in the community to present the question in its general surgical aspect. Most of our surgeons have been confronted with serious wounds resulting from the explosion of fireworks. The support or testimony of several general practitioners and hospital superintendents who can relate the very injurious effect of the noise on their patients, especially on those who have just undergone severe surgical operations, will be found most valuable.

I would suggest, too, that you incorporate in your statistics some of the facts in connection with fires. For the year ending December, 1903, we had about two fires a day; that is to say, we had a few over 750 alarms. Normally, then, this is about what might be expected annually in a city of the size of Baltimore. According to a statement of Fire Chief Horton,⁵ there are usually between twenty and thirty fires on July 4. All of our cities pass through this kind of experience on Independence Day.

There is such a thing as the legitimate use of fireworks, but, to my mind, that means setting them off in a big park under the supervision of men who are trained for the purpose and are experienced in handling fireworks, the entire exhibition being given under a special permit from the city authorities, and I think it would pay our cities to make an annual appropriation for this purpose. I feel sure that there is a large element in all of our cities which would be glad to contribute every year to a fund of this character.

Evidence arrayed in this manner will be convincing to the public, and may probably bring forth fruit. I say probably, for no matter how urgent the need may be for new legislation in this matter, the banding together of the dealers in fireworks and the use of money may be expected to have considerable weight with the ordinary run of city councils, which are largely composed of men who set private gain above the public good and party above principle. But no matter what the outcome before the council, in any event present your evidence in the same manner before the police commissioners, for without the co-operation of the police the whole thing will prove a failure. The heads of the police department, if their sympathy be secured, can and will issue such orders as will give us a reasonable and peaceful Independence Day.

I offer these suggestions, hoping that they will at least serve to stimulate in the Section an interest in this question. There is scarcely a large city in this land which has not one or more representatives in this Section, and I am convinced that as ophthalmologists we can accomplish much toward lessening the fatalities of Independence Day.

Our communities look to us as physicians for knowledge in the things which pertain to public hygiene, and nearly every year witnesses some victory over ignorance at the hands of our great profession, our high calling

which, I see, from these annual sessions (to paraphrase a quotation), "renews its strength, is mounting up with wings as an eagle runs and is not weary, walks and faints not."

Original Articles.

SOME FURTHER OBSERVATION ON THE USE OF THE STEM PESSARY FOR SCANTY MENSTRUATION DYSMENORRHEA, INFANTILE UTERUS AND STERILITY.*

J. H. CARSTENS, M.D.

Professor of Surgical Gynecology, etc., Detroit College of Medicine;
Chief of Staff, Harper Hospital.

DETROIT.

In a paper on the above subject last year, I called attention to the great value of the stem pessary for some of these intractable cases. While a general practitioner I think I had more trouble with cases of scanty and painful menstruation than any other cases of pelvic troubles. The inefficiency of medication and general hygienic rules we have all observed. These patients go from one physician to another. We have gradually been enabled to unravel the different questions involved, and are now able to relieve many cases by understanding the pathology and the causative factors. The complex symptoms produced by the many various pathologic conditions naturally require that a correct diagnosis must first be made. After eliminating all those cases caused by diseases of the tubes and ovaries, adhesions and displacements, there still remains a goodly number of cases of painful menstruation which are not relieved by ordinary local or constitutional treatment.

With advancing civilization and the work thrown on the brain at puberty by the intellectual requirements of to-day, we have found that many young girls at the age of puberty, on account of the studies they have, remain physically defective. It is too much work for nature. The body may even develop, but the nutrition is all used up in supplying the brain with the necessary nourishment and the pelvic organs are neglected, and the result is an infantile uterus, while menstruation is painful and often scanty. All the emmenagogue remedies usually recommended are absolutely of no avail. By stopping all studies, putting the young girl in the fresh air, and letting her live a normal life, with plenty of exercise, development of the uterus may still take place, if this is done in time. If this is neglected, however, until she is through with her school and college life, that is, until she is 18 or 20, the poorly developed uterus will generally remain.

Now, what are we to do in such a case? If we have a poorly developed muscle of the arm or the leg or the back, do we use aloes, myrrh, tansy, or pennyroyal, or, in fact, any other remedy? You would all laugh if anyone suggested such a line of treatment. No, you develop the muscle by exercise. A thorough system of gymnastics will restore and strengthen almost any muscle of the body. I started out with this idea. You must exercise the uterine muscles if you want to develop the uterus. It is well known that the uterus containing a foreign body will try to expel it. A constant contraction goes on, the muscles contract and

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

relax, they exercise, so I have used the stem pessary, leaving it there for months and years, with wonderful results.

Now, we have another class of cases: The young girl with a bright mind, quick perception; learns easily and goes through school without the least trouble. Nature has no particular work at puberty. There are no long hours of study burning the midnight oil, but the girl learns her lessons, gets out in the fresh air, takes plenty of exercise, and Nature has no trouble at all in developing the pelvic organs. They become normal. The girl menstruates regularly and painlessly. She goes on that way for years. She becomes an intelligent worker, teacher, or something of that kind. Gradually, in the course of time, dysmenorrhea is noticed, perhaps only for an hour or two, but it gradually increases in severity. She is laid up for a day or two every month, and has trouble in following her vocation. If you will examine a girl like that you will find that the uterus is small. It is undergoing atrophy; the uterus not so much as the cervix. The cervix has become very much smaller, the canal is contracted, there is painful obstruction and pain from the lack of muscle, which has been superseded by connective tissue. The uterus will simply become small from the lack of exercise, just as any muscle of the body will from lack of exercise. That woman ought to be married, she ought to have children; then she would not have dysmenorrhea, but she has it now. What are you going to do here? Give her various remedies from gauliac to aloes? They will do no good. The uterus needs exercise. If she is examined by the ordinary physician, he finds the small cervix, and says it is stenosis and needs dilatation. He proceeds to do it. The next menstrual period she will feel better. The second time she begins to have trouble again, and in a little while she is as bad as she was before. Perhaps she has this repeated, but with the same result. What she needs is constant exercise of the uterine muscles. The stem pessary will fill the indication, and she must wear it for a long time—a year or two.

For this kind of cases the ovaries were removed formerly, and are to-day by inexperienced surgeons. The slightest little pain during menstruation is an excuse to remove the ovaries.

This method of treatment, I hope, will save many. In ordinary stenosis, where there is a tendency to re-contrast, the use of the stem pessary for a few months will bring about a permanent cure. In cases of single flexion and version, the stem pessary or any other kind of pessary will generally relieve the condition. Cases of sterility will be relieved if there are no tubal or ovarian diseases.

Some of the most intractable cases are those of scanty menstruation in fleshy women. It seems to have a peculiar mental effect. They seem to worry a great deal about it. The stem in such cases generally brings on the normal flow. The stem increases the flow in some cases rather profusely, but, as a rule, that is desirable. The various nervous symptoms and disturbances we often find seem to quickly vanish after they have worn the pessary for a short time. There certainly are many reflex conditions, which we do not quite understand, that are caused by flexion, stenosis and dysmenorrhea, which will all disappear as soon as the uterine or pelvic trouble is relieved.

Just a few cases that may make clearer the point I am trying to make. I will not give you an elaborate history, but just a few salient points:

CASE 1.—Infantile uterus—Mrs. B., aged 27; dysmenorrhea

since the beginning of menstruation; married six years; sterile. Stem pessary introduced Aug. 17, 1903. Menstruation regular and painless; working hard, and the stem still in place.

CASE 2.—Mrs. B., aged 31; amenorrhea and retroversion; had not menstruated for seven months; sterile. Stem pessary was introduced Sept. 10, 1903; menstruation regular since; still in place.

CASE 3.—Mrs. M., age 33; amenorrhea and sterile. Very fleshy; had not menstruated for nine months. Stem pessary introduced Oct. 31, 1903; still in place; menses regular since.

CASE 4.—Miss G., aged 20; menstruation painful; uterus small. Stem pessary introduced Oct. 27, 1903. Removed May 7, 1904. Menstruation became regular and painless as soon as stem was introduced.

CASE 5.—Mrs. H., aged 24; sterile five years. Stem pessary introduced Oct. 15, 1903. Removed Dec. 17, 1903. Menstruated last, Jan. 14, 1904; pregnant at present time.

CASE 6.—Mrs. O., aged 30; scanty, painful menstruation; uterus small; hysterical. In bed for two weeks; taken to the hospital and stem pessary introduced Feb. 6, 1903. In one week she left the hospital, able to do her work, and has been an entirely different person since. All the nervous symptoms disappeared; menstruation became regular. Pessary was removed May 22, 1904.

CONCLUSIONS.

In conclusion, I would say that:

Dysmenorrhea in young girls is often produced by infantile uteri, when it occurs after 30 in virgins, by premature atrophy of the uterus.

The uterus can only be developed by exercise. This is accomplished by the stem pessary, as the uterus contracts and tries to expel it.

Recurring stenosis or flexions are often cured by the stem pessary if kept in for six months or a year.

Scanty menstruation in fleshy women is wonderfully improved by the use of the stem pessary.

Amenorrhea caused by any of the above conditions, or sometimes without our ability to recognize the cause, is promptly relieved in the same manner.

As all the above conditions cause sterility, the latter is often cured by the introduction of a properly fitting stem. Any kind of stem pessary will do, but the hard rubber Chapman is the one used.

All pelvic diseases, ovarian or tubal, must be absolutely excluded. The stem is only used in disturbances caused by the uterus alone.

MEMBRANOUS ENDOMETRITIS.*

FLORENCE F. LAWRENCE, M.D., D.Sc., LL.D.

Clinical Lecturer, Diseases of Women and Abdominal Surgery,
Starling Medical College; Chief Staff and Surgeon
to Lawrence Hospital.
COLUMBUS, OHIO.

The unsatisfactory results of all forms of treatment for membranous endometritis directed to the uterus, have been so commonly noted that it seems strange its pathology is still in doubt. So far as I know the idea that this condition may be a secondary trophic one has not been suggested. Within the past few months a number of cases coming under my care in close succession in which membranous casts, either partial or nearly complete, were among the symptoms noted, caused me to look carefully over my records for several years back. The first surprising thing I found was that in 42 cases on which I had operated for the removal of tubal and ovarian diseases, membranous casts

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

accompanying painful menstruation were noted as a prominent symptom. The second thing found was that in 19 of the 42 cases the tubal or ovarian disease was unilateral. The third thing found was that in 37 of the 42 cases pelvic adhesions were noted.

I have, since that time, either seen or communicated with 17 of the 19 patients who were the subjects of unilateral trouble. Two of the patients I have not been able to find, although one of these in a letter a little over a year ago made the statement that she was entirely well (five years after operation). Of the 17 but one still has the membranous casts, and an examination a few weeks ago disclosed a hard and immovable mass at the side of the uterus; probably a pus tube, inasmuch as the operation performed was for the removal of a left-sided pus tube; the right tube, seemingly normal, was not removed.

The conditions found in these 42 cases were as follows: In 19 cases unilateral diseases of tubes and ovaries; in 23 cases bilateral; in 37 there were pelvic adhesions.

Of the 19 unilateral cases, 14 followed or appeared to have started with some one of the exanthemata.

Of the 23 bilateral, 19 appeared from the history to have started with scarlatina, measles, mumps, rheumatism or smallpox.

Of 5 unilateral cases, no definite history of childhood could be elicited, and in 4 of these pain and membranous casts were noted at first, and all subsequent menstruations; 3 had chorea at puberty.

Of 4 bilateral cases, no definite history could be elicited, but one had smallpox at 14, and one had chorea at pubescence.

Of the bilateral cases, 8 were tubercular, 3 having tubercular deposits in peritoneum. Of these 8 cases noted as tubercular, only 2 developed general tuberculosis subsequently.

Inasmuch as the bilateral cases can not be considered in a positive way, we have, then, but 19 cases which would seem to furnish positive clinical data, although the other 23 support the theory.

Of these 19 cases the conditions noted were prolapsed and adherent tube and ovary with sclerosis of ovary, 7; prolapsed tube and cystic ovary, with adhesions and obliterated tube with hydrosalpinx, 3; hydrosalpinx and dermoid ovary, 2; hydrosalpinx hematoma, 1; retroverted adherent uterus with adherent chronic salpingitis and chronic ovaritis, 4; ovarian cystoma and salpingitis, 2.

Miss M. L., aged 22. Menstruated first at 13.

History.—Menstruation free, not painful and regular. Health remained good until the age of 19, when she had smallpox. Did not menstruate again for four months, when menstruation was accompanied by severe pain and the passage of almost a complete cast of the uterus. From that time to the present menstruation has been irregular, painful and always accompanied by the passage of more or less complete casts of the uterus.

Examination.—Examination revealed a tender slightly movable mass on the left side, pressure on which caused pain, which she said is like that she suffers during menstruation.

Operation.—April 27, 1894. The hydrosalpinx and cystic ovary on the left side removed. The right tube and ovary were normal with the exception of a small sclerotic area at the outer portion of the ovary which was excised and the wound stitched over with fine silk.

Results.—Her recovery was perfect; menstruation became regular, free from pain and without any membrane. She has since married and now has two children. She tells me she has

never suffered any menstrual pain or discomfort since her operation.

Mrs. H. B., aged 34. Menstruated first at 14. Regular, free from pain; health good.

History.—Married at 25. One child fifteen months later. Puerperium normal; health good again until three years ago, although no further pregnancy. Had severe attack of measles, followed by muscular rheumatism. Was sick ten weeks, during which time she did not menstruate. When menses reappeared suffered severely and flowed profusely. A few shreds of membrane were noticed. Since that menstruation has grown more painful, irregular and always accompanied by passage of membrane.

Examination.—Examination revealed a hard, sensitive, adherent mass to the right of the uterus.

Operation.—April 28, 1894. A thickened adherent fallopian tube and sclerotic ovary were removed from the right side, the tube being nearly an inch in diameter and very hard. The left tube and ovary were not adherent and apparently not sufficiently involved to justify their removal.

Results.—She recovered, but did not menstruate regularly for nearly seven months, although menstruation was accompanied by less pain than formerly and each time with less membrane. After this her menstruation became more regular, she became pregnant and was delivered of a child at term. When I last saw her she was well. About a year ago I had a letter from her in which she states she has no pain and considers herself well. Since that time I have lost trace of her.

Miss M. P. A., aged 28. First seen April 22, 1895. Menstruated first at 15.

History.—Had chorea for about three months previous to this and continued ten months after. First menstruation free from pain, lasting about four days and normal in quantity. (Statement by her mother). Second menstruation did not occur for seven months, when there was some premenstrual pain, which passed away in a few hours after flow started. Menstruation then became regular every twenty-eight days, flow lasting four days, no clots or shreds. When about 16½ years old had a severe attack of scarlatina. Had some kidney trouble with it, menstruated while desquamating, suffered very severely and passed a few small shreds of membrane. Since that time has always suffered severely. Premenstrual pain chiefly on left side. The past year menstruation has been irregular, the pain more severe and the shreds of membrane larger, the last time almost a complete cast of the uterus was discharged.

Examination.—Examination revealed an adherent cystic mass behind uterus and low down.

Operation.—May 5, 1895. An adherent cystic ovary and small hydrosalpinx with the fimbriated end of the tube adherent to the ovary were removed from the left side low down in the cul-de-sac. The right tube and ovary were apparently normal.

Results.—During the first menstruation following the operation there were a few small shreds and clots, but comparatively little pain. The next and all subsequent menstrual periods have been free from pain and shreds. (This patient married in August, 1899, and is the mother now of two children, both girls.)

M. L., aged 23. Menstruated first at 13, free from pain and normal.

History.—Flow four and a half days, perfectly normal and free from pain for about a year, then had severe attack of parotiditis and what the doctor said was inflammation of the right ovary; was very sick for four weeks; did not menstruate while sick, nor for three weeks after. She then suffered very severely and had to go to bed and have hot applications: flow lasted eight or nine days. The next menstruation came on five weeks later after two days of very severe suffering. This time she passed several large pieces of membrane the first day and some smaller ones the second day of the flow. From that time until the present suffering has become more severe and flow is always accompanied by pieces of membrane.

Examination.—Examination showed a prolapsed, enlarged and tender right ovary in the cul-de-sac.

Operation.—Jan. 11, 1896. The right ovary and tube were prolapsed and adhered. The ovary was about as large as a hen's egg and of unusually firm consistence. The tube was much thickened and very hard. The left tube and ovary were apparently normal.

Results.—There was comparatively little relief from pain during the first menstruation, but each subsequent menstruation became less painful and with fewer shreds, until the fifth month following the operation, when there was no pain and no shreds. Since that time until her marriage, eighteen months ago, she has been absolutely free from all her old trouble. She became pregnant a short time after marriage and gave birth at term to a boy baby.

Mrs. E. G., aged 26. First seen Aug. 2, 1895. Childhood healthy.

History.—No sickness until 12 years old; had measles, and three months later scarlatina; very sick for six weeks; had peritonitis (?) mostly on left side, following scarlatina. Had three attacks, one in October, one in November and one in December. Menstruated first in December, 1881. "Was very sick, suffered severely for two days, when doctor injected something into my arm which eased the pain and caused the flow to start. The flow was very profuse and there were pieces of something which looked like pieces of thin skin." She has always suffered severely before flow starts and always had these pieces of membrane. "Last month there was a large piece almost as big as two fingers and several small pieces." Married at 23; never pregnant.

Examination.—Examination showed a hard, sensitive mass, firmly fixed on left side.

Operation.—Aug. 25, 1895. The left tube and ovary were firmly adherent. The uterus latero-flexed and the ovary cystic. Adhesions separated and left tube and ovary removed. The right tube and ovary were not much involved, a few adhesions were separated, a fine probe was passed into the tube to insure its patency. The ovary was fastened to broad ligament by fine silk suture and the wound closed.

Result.—Her recovery was without incident. The pain at menstruation was relieved. The membrane disappeared, but she still remained sterile.

Miss L. E., aged 24. First seen Sept. 6, 1896.

History.—Always perfectly healthy until at 17 had scarlatina followed by rheumatism; sick three months; had menstruation regularly from the thirteenth year until this sickness; did not menstruate while sick nor for a month after, then suffered with severe pain on right side and passed some shreds. Has always suffered since and always passed pieces of membrane.

Examination.—Examination showed a tender, movable cystic mass on right of uterus, very low down.

Operation.—Sept. 1, 1896. Right hydrosalpinx and sclerotic ovary removed.

Recovery.—Complete.

Miss A. L., aged 19. First seen March 9, 1897. Childhood healthy.

History.—Menstruated first at 17; suffered severely for two days prior to flow; flowed seven days; did not menstruate again for four months; suffered very severely again and passed large pieces of membrane, after which pain was relieved; has never menstruated more than six or seven times and has always had the same experience.

Examination.—Examination showed a mass on left side of irregular consistence, movable and not particularly sensitive. The diagnosis of ovarian dermoid was made.

Operation.—April 12, 1897. A non-adherent dermoid of left ovary about two and a half inches in diameter was removed.

Result.—Patient made an uninterrupted recovery and has since menstruated regularly, is free from pain and passes no shreds or casts.

Miss E. B., aged 19. First seen May 2, 1898. Childhood healthy.

History.—Menstruated first at 13. No pain; flowed four days; for five months menstruated regularly every twenty-eight days and flowed four days without pain. In December,

1891, went skating and fell through broken ice; had pneumonia; sick four weeks; did not menstruate during this time nor for three weeks after; then suffered only slight pain and flowed five days. In January, 1892, had scarlatina and peritonitis; did not menstruate until the first week in March, when suffering was severe, particularly on left side. First two days' flow scant, then large pieces of membrane were passed and flow became very free for five days. Has since that time been irregular, suffered severely and always passes pieces of membrane. For past four months has had tenderness in left groin; leucorrhoea.

Examination.—Examination shows left ovary very hard and small; left tube can be felt as a hard ridge.

Operation.—May 17, 1898. Left ovary sclerotic and about the size of a lima bean; left tube hard, enlarged and constricted by three bands. The tube firmly adherent to broad ligament. Right ovary and tube healthy.

Result.—Three months after operation, no pain, no shreds and menstruation regular. Is now well.

Mrs. A. J., aged 31. First seen Sept. 11, 1898.

History.—Childhood history negative; when 15 years old she had scarlatina, measles and mumps in rapid succession. Did not menstruate until nearly 16; then suffered severely, passed pieces of membrane and flowed only one and a half days. Has never been regular, always suffered and always passed membrane. Has had peritonitis three times. Never pregnant, although married nine years, and never used any means to prevent conception.

Examination.—Cervix small; an ill-defined, hard and immovable mass to the left of the uterus, ovary and tube can not be made out; right side of pelvis apparently free from disease.

Operation.—Nov. 3, 1898. The left tube and ovary were densely adherent, several inches of small intestine adherent to left side of pelvis. Uterus retroverted and adherent. All adhesions separated, the left tube and ovary removed, pelvis flushed with salt solution, drainage inserted and wound closed.

Results.—For six months patient did not menstruate regularly, but had no pain, and passed no shreds after second month. Is now well and mother of one child.

Mrs. E. B., aged 28. First seen Dec. 2, 1898. Childhood healthy until 13; then she had scarlatina, followed by chorea.

History.—Menstruated first at 15; suffered very severely. Physician said she had inflammation of the left ovary; did not become regular; always suffered severely; flowed three days and always "passed pieces which looked like red skin." Was told marriage would cure her. Married at 19; never pregnant; has never yet been regular and suffered very severely; last two periods had to go to bed and physician gave her hypodermic.

Examination.—Cervix and uterus normal; a small cystic and very sensitive mass to left of uterus.

Operation.—Dec. 9, 1898. A small dermoid of left ovary with hydrosalpinx, moderately adherent, removed.

Result.—Patient recovered and has since been free from pain, shreds or casts.

Mrs. J. E. W., aged 24. First seen June 14, 1899. Childhood sickly. Had all children's diseases except scarlet fever before puberty.

History.—Menstruated first at 14, regular and normal. At 17 had scarlet fever; was very sick for seven weeks; had abscess on left side of neck. Menstruated while sick and suffered terribly. Has always suffered since. For a few months after, passed a few small pieces of membrane, then pieces became larger until lately they have been almost complete casts. Was married at 22. Pain worse and flow lasts ten days.

Examination.—Uterus retroverted and adherent; a hard, firmly adherent mass to left of uterus and low down behind the retroverted uterus which occupied Douglas' pouch.

Operation.—July 9, 1899. Uterus firmly adherent and retroverted. Left tube and ovary firmly adherent low down in pelvis behind the uterus. Adhesions separated, left tube and ovary removed.

Result.—Patient very poor and surroundings not conducive

to rapid recovery; for some months she continued to suffer some pain and pass a few shreds of membrane. In January, 1900, she became pregnant and gave birth to a child at term. Since that time menstruation is regular and normal in every particular. No pain; no membrane.

Miss A. K., aged 18. First seen Aug. 25, 1899. Was healthy until 13, when she had typhoid fever.

History.—Menstruated first at 14; regular, free from pain; flowed four days; had scarlet fever, followed by rheumatism, at 15; was sick over three months. Did not menstruate for five months, then was very sick and flowed a great deal for nearly two weeks. Did not menstruate again for six weeks. Suffered severely and passed pieces of something which physician told her mother was part of a growth which was interfering with menstruation. She was curetted and treated by electricity, but still passes those pieces. Pain mostly on right side.

Examination.—A hard, immovable mass was felt behind and to the right of the uterus.

Operation.—Sept. 2, 1899. Right ovary and tube with an adherent appendix bound down firmly low in the pelvis. Uterus retroverted and held down by adhesions. Tube and ovary removed. Left tube normal; left ovary partly cystic. The cysts split open and a portion of the ovary resected, a probe passed into the tube to insure patency and the wound closed.

Results.—She recovered without complications and has been free from pain and membrane ever since. She married two and a half years ago, but is apparently sterile.

Miss B. L., aged 21. Did not menstruate until 17.

History.—Had mumps at 12 and scarlet fever at 14. Was quite sick at 14 for over a year, then health improved. Probably, from her description, chlorosis. First menstruation very painful, but she had been injured in a runaway just a few days before and physician said that she had torn something inside. Was bloated very badly; passed large clots and pieces of something. Has never been regular, always suffered and has been curetted twice with no benefit.

Examination.—Uterus retroverted and adherent; a mass which is indistinctly cystic on left of uterus.

Operation was not performed until Oct. 15, 1900. A hematoma of ovary and adherent left hydrosalpinx were removed; adherent uterus freed. Abdomen and pelvis flushed and salt solution left in cavity.

Result.—Recovery complete. Pain relieved and membrane disappeared from menstrual discharge.

Mrs. H. W., aged 30. First seen June 29, 1901. Childhood healthy until 15, when she had chorea; was sick several months.

History.—Had scarlatina at 17, just after first menstruation; was quite sick for two months; had inflammation of the left ovary; did not menstruate for nearly a year then suffered severely and passed pieces of skin. Has always suffered and yet has been regular for past seven or eight years. Was married at 23. Took local treatment for over a year without relief; has been curetted three times; the last time was a little better at first menstruation but since that worse than before; never pregnant.

Examination.—A hard adherent mass to left of uterus; very sensitive.

Operation.—Feb. 5, 1901. An adherent sclerotic left ovary and thickened tube removed. Right ovary had a cyst in upper outer part, which was resected.

Result.—She recovered completely, has no pain and no membrane, but is still sterile.

Miss N. A., aged 23. Childhood healthy until 14.

History.—Menstruated first at 13. At 14 had typhoid fever. Health good until 19, when she had measles, and two months later had scarlet fever. Did not menstruate for two months, then suffered severely. Passed a few pieces of membrane. Has always been irregular and passed membrane. Past year growing worse every time.

Examination.—Right ovary and tube prolapsed and adherent.

Operation.—April 13, 1901. Right ovary cystic, tube adherent to side of uterus and coiled on itself. Enlarged and indurated.

Result.—Recovery was prompt and for two years she was free from pain and membrane. Since that she has married and moved to another state, but two years' freedom from the condition is sufficient to warrant the supposition that the cure is complete.

Miss G. H., aged 22. First seen Sept. 1, 1901. German; can not get good history. Says she has pain in right side all the time and passes "pieces of fleisch" every time she menstruates.

Examination.—Hard mass to right of uterus; very sensitive; uterus retroverted.

Operation.—Sept. 16, 1901. An adherent tube and sclerotic ovary on right side, with the appendix adherent to the ovary, were removed.

Result.—She has since married and has a baby three or four months old.

Miss O. B., aged 29. First seen May 4, 1902.

History.—Suffering severely (was menstruating at this time). A complete cast of uterus was discharged. Said she had suffered and passed membrane ever since she had smallpox, four years ago. Had never suffered before and had never been sick until she had smallpox. In this case I advised curetting and curetted the uterus on May 12. In June she did not suffer, but in July was worse than before. The left ovary was small.

Operation.—She consented to oöphorectomy and was operated on August 9. A small indurated hard tube and sclerotic ovary were removed from left side. The right tube and ovary seemed to be normal and were left.

Result.—I was agreeably surprised in this case to get almost immediate and perfect relief both from the suffering and the membrane.

V. A., aged 26. Never strong; had all the diseases of childhood except mumps before puberty.

History.—Menstruated first at 12; normal. Regular until at 20 she had mumps. Suffered severely with pain low down on left side for several weeks and menstruated profusely two or three times. Suffering became worse each time and she always passed pieces of thin membrane, sometimes very large pieces.

Examination.—Left tube and ovary prolapsed slightly, adherent and very sensitive.

Operation.—July 14, 1902. Left ovary and tube adherent to side of uterus and to broad ligament; tube hard and enlarged. Ovary sclerotic. Adhesions all separated and tube and ovary removed.

Result.—Complete relief from pain and absence of membrane characterize her menses since.

Mrs. S. H., aged 31.

History.—Always healthy until two years ago; then had measles; since that has suffered severely. Has profuse leucorhea. Menstruated two and a half days every three weeks. Suffers severely and passes pieces of membrane every time.

Examination.—A doughy mass on left of uterus, very sensitive; uterus retroverted.

Operation.—Sept. 20, 1902. A left pus tube and sclerotic ovary removed. Adhesions firm and vascular. Right ovary and tube apparently perfectly normal.

Result.—She was relieved of menstrual pain and also from the membrane for a few months, but both are now as severe as before operation. Examination a short time since shows what is in all probability a right pus tube. This is another instance in which an effort at conservatism has not proved to be conservative.

Mrs. W., aged 27.

History.—Had splendid health until after she had scarlet fever at age of 21. Had always been perfectly regular and free from pain since first menstruation at 12. Was married at 19 and had a child fourteen months later. No trouble. In November, 1898, had scarlet fever. Menstruated while desquamating, suffered severely and casts were passed. Physician said the scarlet fever had been in the womb and that it was

sealing just like the skin. Has suffered ever since. Always has some membrane, but lately passes large pieces.

Examination.—A hard, sensitive tube on left side with ovary very small and hard, low down in cul-de-sac.

Operation.—Jan. 17, 1903. A sclerotic ovary and indurated tube; firm adhesions were removed from left side.

Result.—Complete relief from all symptoms has resulted.

Since July, 1903, I have had 5 more cases in which membranous endometritis has been a prominent symptom, on which I have operated for the removal of unilateral disease, but sufficient time has not yet elapsed to make them of value in the present discussion.

In presenting these cases I have selected only those in which the symptoms of membranous casts was noted as a prominent feature, and which may, therefore, be taken as typical of the class of cases.

The number of cases of bilateral disease is larger than of unilateral, and in all of them the pain has been more aggravated and the membrane cast off in larger quantities. This, it seems to me, would, in a measure, support the theory of trophic change.

The argument may be offered that in these cases there was a primary infection of the uterine mucosa, and by extension the tubes and ovaries became involved.

This is not a sound argument for two reasons, viz.: First, several of these cases presented pathologic conditions of the tubes and ovaries in no way the result of infection, as in dermoids, hematoma and sclerosis of the ovary, and yet they were cured by extirpation of the diseased structures without any uterine treatment.

Second, in those cases which might be considered as an extension of infection from uterine mucosa to the tubes and ovaries, no form of treatment directed to the uterus is or has ever been of any benefit, probably because it can not relieve the tubal or ovarian condition, at the same time the fact that these cases were nearly all sequelæ of the exanthemata, would indicate that the primary trouble was probably glandular, hence the ovary was probably the first, the tube second, and the uterus last involved. There is a further corroborating fact to be added to this theory, viz.: In the cases in which the membranous casts were noted for the shortest time the tubes were less involved in proportion to ovarian involvement than in those of long standing, and the pelvic adhesions were less dense and fewer. This would seem to indicate that the disturbance of circulation and innervation by intrapelvic adhesions and diseases of tubes and ovaries play a very important part in the pathology of this condition.

I can not arbitrarily state that the pathology of this condition is proved to be a trophic change wrought in the uterine mucosa by tubal and ovarian disease and by inflammatory products in the pelvis, but that it is always an indication of disease beyond the uterus as a primary factor, I believe. It may be asked if pelvic adhesions, tubal disease or ovarian disease are the cause of membranous endometritis, why we do not always find it in these conditions? Again, I wish to emphasize that in practically all of these cases the pelvic trouble seems in some way to be connected with the exanthemata, although not in all can the indications to this effect be said to be positive, notably, the dermoid cases. And yet each of these had scarlatina with some abdominal symptoms at adolescence or soon after. This renders the part played by the dermoids doubtful, and suggests a possible scarlatinal infection of the ovary and tube as the real primary factor.

Nineteen cases are not enough, I know, to determine positively the pathology of any condition, but 19 cases

of unilateral diseases, supported by 23 cases of bilateral diseases, in which this symptom has been a prominent feature, would seem to me to warrant bringing this subject before you for discussion.

CONCLUSIONS.

When in the cases of unilateral disease of the tubes and ovaries, ablation of the diseased structures has been followed by complete relief in all cases from a symptom which curetting, local treatment, electricity and constitutional treatment have failed to relieve, it would seemingly warrant the following deductions:

1. Membranous endometritis is probably a condition due to trophic changes in the endometrium secondary to some intrapelvic disease.

2. This intrapelvic disease often is unilateral.

3. It is probably always unilateral in the beginning, although this remains to be proved.

4. The fact that all local methods of treatment of the uterus have failed to relieve the condition, together with the foregoing facts, would seem to warrant removal of the tubes and ovaries on one or both sides when shreds or casts are a part of painful menstruation.

5. The fact that nearly half of these cases were unilateral, although all of them had suffered for years, would warrant the hope of saving the possibility of maternity in all cases given early operation.

6. That many, if not all, the cases of membranous endometritis are due to ovarian and tubal disease developing as a complication or a sequela to the exanthemata.

7. This being true, the strictest attention should be given those structures during the exanthemata, and the slightest indication of trouble should be promptly dealt with.

8. Early attention may often save one tube and ovary where neglect will sacrifice both.

9. That in all cases, no matter what age, in which membrane is cast off during menstruation, a thorough pelvic examination should be made.

10. The importance of a thorough case history in all cases of menstrual pain should be emphasized.

11. That conditions of tubes and ovaries not inflammatory and not due to any form of infection may possibly cause this symptom.

DISCUSSION.

DR. L. H. DUNNING, Indianapolis, has had membrane brought to him which dissolved in an alkaline solution, showing that it was blood and not membrane. He considers Dr. Lawrence's idea of the etiology of this condition entirely new.

DR. F. F. LAWRENCE, in reply to questions, stated that he had seen the membranes in all these cases and that most specimens were examined microscopically.

DR. CHARLES L. BONFIELD, Cincinnati, Ohio, said that he has seen not more than three cases in eighteen years of practice. Dr. Ramey some years ago reported two cases; they were mother and daughter. The mother developed membranous dysmenorrhea after she had given birth to her children. Dr. Ramey succeeded in curing her by one or two curettages, followed by the application of acetic acid to the endometrium. Her daughter developed the disease soon after she began to menstruate and was cured by the same treatment. There are cases in which no disease of the appendages will account for the trouble.

DR. JOHN M. FISHER, Philadelphia, has seen only two cases of membranous dysmenorrhea. He said that Dr. Lawrence's experience has been an extraordinary one, so far as the number of cases is concerned. We may be lax in our examinations, however. In the two cases Dr. Fisher saw the symptoms were so pronounced that on investigation a complete cast of the

uterus was found at each menstruation. The mere discharge of shreds from the uterus during menstruation with pain in a given case can not be looked on as membranous dysmenorrhea.

Dr. L. H. DUNNING said that one of the most severe cases he ever saw occurred in a woman from whom he had removed bilateral pus tubes and both ovaries. She menstruated for two years afterward and had membranous dysmenorrhea.

Dr. F. F. LAWRENCE said that in the last few years he has made it a rule in every case where shreds or casts were passed, whether partial or complete, to turn them over to the pathologist for examination. So far nothing has been shown by these examinations on which we can hang anything of practical value in the therapeutics of the condition. In nearly all the cases there was a low form of degeneration of the epithelial cells, with an increase in the connective tissue stroma, dipping down into the deeper layers of the mucous membrane, as in chronic atrophic endometritis. The term membranous dysmenorrhea means nothing. It should be called membranous endometritis. As soon as a woman begins to cast off shreds of membrane and suffers painful menstruation he believes it is a case of membranous endometritis. It has occurred to him that this condition has an intrapelvic origin. It is possible that by following out this matter in detail we may find a satisfactory pathologic basis and possibly we may be able to tell our patients positively that we can cure them.

ADHERENT UTERUS AS A COMPLICATION OF LABOR, CITING TWO CASES.*

JOHN C. APPELDATE, M.D.

Professor of Obstetrics at Medical Department, Temple College; Obstetrician and Obstetric Surgeon to the Samaritan Hospital.

PHILADELPHIA.

The causes of adherent uterus are multiple, and as a complication of pregnancy and labor give rise to various results, which can not be detailed in a paper of this character with a subject of such wide application.

We do not presume, therefore, to do more than to present a few facts as they appear to the obstetrician, reporting the two cases typical of adherent uteri complicating pregnancy and labor under entirely different circumstances.

Viewing the situation from an obstetric standpoint, the advancement in the science of surgery, while marvelous, has not yet reached that degree of perfection whereby the discomforts of woman, by reason of her sex, are satisfactorily alleviated to the best advantage during her period of propagation.

While correction of the abnormal deviations of the uterus belongs especially to the gynecologist, the results of reposition and fixation by the various methods of operative procedure, as well as by inflammatory adhesions when pregnancy follows, are met face to face by the obstetrician.

It is in the conduct of pregnancy and labor, thus complicated, that the relative results of the various methods of correcting uterine displacements during the child-bearing period can be proven, and one can only arrive at definite conclusions as to the best and most appropriate course to pursue in correcting such displacements by a knowledge of the test of pregnancy and labor with fixed or adherent uterus, remembering that of those requiring operative interference, the child-bearing women are largely in the majority.

The various operations for retrodisplacements and proclivata have their good points and their strong

advocates, but to operate for the purpose of restoring comfort and health, without due regard for her future ability to propagate safely, is one thing, while to satisfactorily and permanently fix the uterus, with the positive assurance that a future pregnancy will not jeopardize the life of the individual, is quite another thing. In other words, the most positive methods of restoring and permanently supporting the uterus are often the most dangerous in the event of a future pregnancy.

From my own personal observation and from information obtained from other clinicians, I have become convinced:

First.—That the round ligament operations have little, if any, effect on future pregnancies or labor, but that subsequent pregnancies very frequently defeat the object of the previous operation by reason of the relaxation and elongation of the ligaments. The Alexander method, for instance, while safe under all circumstances, and most admirable for selective cases, as unmarried women with no prospects of matrimony, but failing or yielding under the test of pregnancy, the subject in a large percentage of cases must be subjected to a second operation or continue in life with a recurrence of the original malady. The results of the Montgomery subperitoneal operation, whereby he attacks the strongest portion of the round ligament, buttonholing the peritoneum, are awaited with a great deal of interest. This, we believe, can have but little or no effect on future pregnancies, nor will pregnancy be so liable to defeat the object of the operation.

Second.—That the results of the simple peritoneal suspension of the uterus are often futile and dangerous because the peritoneum is too thin, weak and yielding to support a gravid uterus, and is liable to rupture during retching and vomiting following etherization. Post-operative accidents of this character are on record, and I doubt not that there are many not recorded. I have purposely refrained from depending on statistics from medical literature, since the profession is deprived of full and accurate knowledge on this line, failures, accidents and deaths not being reported in proportion to the successes. Further, I question whether the inexperienced, or operator of medium experience, is not oftentimes lured into the methods of operating by unfair reports that appear in literature uncondemned, which are almost or quite irrational.

Third.—That the ventral fixation, after the usual technic, while one of the best, so far as supporting the uterus is concerned, is unjustifiable before the menopause, except under certain very rare circumstances. I can not conceive of a more embarrassing position for the obstetrician, nor a more critical condition for the pregnant woman who has proceeded to term with the fundus of her uterus firmly adherent to the anterior abdominal wall, the cervix drawn high in the pelvis posteriorly, perhaps near the brim, the posterior wall as thin as paper, in danger of rupturing at any moment under uterine contractions or artificial manipulation; or a firmly adherent uterus that has not been permitted to rise out of the pelvis, giving rise to a variety of symptoms jeopardizing the life of the individual.

If the operator could have the positive assurance that abdominal suppuration would not follow his fixation operation and that the bands of adhesions would form on the suture lines, allowing freedom and mobility of the uterus, ability to rise and expand symmetrically during the enlargement of pregnancy, under which circumstances labor would not be seriously complicated,

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

ventrofixation might be regarded as one of the most satisfactory operations for retrodisplacements of the uterus at any period of life. On the other hand, if the bands of adhesions do form, and are sufficiently long to allow the necessary freedom and mobility in pregnancy, they are too long to be of any value in supporting the uterus after it has been emptied at term. Since we have not this assurance, I do not regard the operation justifiable during the child-bearing age, except under certain favorable circumstances.

The justo-minor pelvis, with a short conjugate diameter of the inlet, is certainly a contraindication for fixation or suspension after the usual method. Again, the retrodisplaced uterus or the simple procidentia are invariably accompanied by hypertrophied and elongated cervixes, especially of the anterior lip, which do not retract nor become utilized in the enlargement of pregnancy; if the uterus is markedly anteфлекed and adherent; so that I regard as an essential counterpart of the ventral fixation or ventral suspension, the amputation of the hypertrophied cervix, and a goodly portion of the anterior lip, thereby overcoming reasonably well the greatest resistance in a labor of this character.

The following clinical history of a case recently admitted to the Samaritan Hospital illustrates the favorable circumstances under which we think the ventrofixation may be the selective operation.

This patient had, it will be noted, a justo-major pelvis and a previously amputated cervix:

Age 34 years. Married twelve years. Her first child still-born ten years ago. Her second eight years ago after a normal labor. A year later her left ovary was removed; pathologic condition not known. About a year later still, she miscarried at six months, for which her uterus was curetted. Three years ago her third child was born after a normal labor. Thirteen months before the labor here referred to, the following operations were performed on her: curettement, perineorrhaphy, amputation of the cervix and ventral suspension. The abdominal wound suppurated, so that the fundus became firmly bound to the anterior abdominal wall, resulting in ventral fixation. For two weeks before being admitted to the hospital she suffered great pain in the lower part of her chest and somewhat in the abdomen. She was under the impression that she had pleurisy and was treated for it. Just prior to admittance she had a moderately severe convulsion with loss of consciousness. Examination showed the uterus to be firmly adherent to the anterior abdominal wall, and instead of a regular cervix a narrow ring, very high in the pelvis, brought within reach of the examining finger with the greatest difficulty; a vagina a little smaller than normal, compared with the size of her pelvis and a firm pelvic floor. External pelvic measurements: interspinous, 26 cm.; intercrestal, 30 cm.; bitrochanteric, 34 cm.; external conjugate, 26 cm. Urinalysis showed a large amount of albumin, many pus cells and a few granular casts. Position L. O. A. Fetal heart sounds heard.

She continued to have great pains referred mainly to her chest, constant in character but not in any respect resembling labor pains. Thirty-six hours later, after a second examination, at which time slight dilatation was produced, her pains became regular in character but still referred to her chest. In three hours the membranes ruptured and the child was born in half an hour by the natural forces. The child was well formed, weighing nine and one-half pounds, and apparently healthy. The patient made a rapid and uncomplicated recovery.

This patient came to us with the statement that her physician could not find her womb, and it was with the greatest difficulty that her miniature os could be brought within reach and slightly dilated. The rapid spontaneous dilatation thereafter, the speedy expulsion and absence of the characteristic pains could only be accounted for by the large pelvis and

previous amputation of the cervix. The rigid close perineum only prevented a precipitate labor.

Calculations taken from the external conjugate (26 cm.) gave her a true conjugate of at least 16 cm. and in every respect the pelvis was roomy.

Equal contraction of the uterus in labor on all sides is absolutely essential to produce equal relaxation and dilatation of the cervix. This we do not ordinarily get in labor with an adherent uterus. The anterior wall does not contract regularly, because it has not been permitted to properly expand and become regularly utilized in the enlargement of pregnancy, has not the opposing force, and is held by the adhesions, while the posterior wall is thin, weak, overdistended and can not contract.

This inequality can be reasonably well compensated for, by the previous amputation of the cervix, particularly the anterior lip, which does not seem to increase the tendency to laceration. If the subject quoted had not had a large pelvis and the cervix amputated previously, I doubt if anything short of cesarean section would have given her a living child weighing 9½ pounds.

Fourth.—That in vaginofixation, which I believe is never intentionally done until after the menopause, our resources are limited, and it is hazardous and a waste of time not to terminate pregnancy by the induction of premature labor, or even immature labor if necessary, sacrificing the life of the child, as soon as it is clearly demonstrated that the uterus is incarcerated within the pelvis, or at the first evidence of pernicious vomiting, as the following brief clinical history will illustrate:

Mrs. C., white, aged 26 years; married three years; no children; miscarried two years previously, followed by pelvic inflammation, presumably parametritis, which was undoubtedly the cause of the fixation. Patient came to us after having been ill ten days. Weak, emaciated, unable to retain nourishment, vomiting incessantly and with intestinal obstruction, pulse small and rapid, vomit consisted of greenish fluid, including mucus, bile and finally some blood and fecal matter. Pains in lower abdomen were constant. The intestinal obstruction was relieved with high rectal enema, but had no effect on the vomiting or pains.

Examination found the uterus firmly fixed in the pelvis, adherent along the median line anterior to the bladder and above the bladder. The fixation was such that the mechanical intestinal obstruction and pernicious vomiting could readily be accounted for. The bladder protruded in the shape of a cystocele; the urine contained pus. Head in utero was pressing firmly on the perineal floor in the L. O. A. position. Membranes could be palpated within the os with one finger, but notwithstanding the constant pains the cervix did not further dilate. When admitted positive evidence of a living child existed at about the seventh month of gestation.

Having tried for three days to improve her condition with high nutrient enemas and rectal medication, at the expiration of which time the fetal heart sounds and quickening ceased. I dilated manually and delivered instrumentally under partial anesthesia, receiving no assistance from uterine contractions, terminating labor in one hour.

The external measurements were below normal: Interspinous, 23.75 cm.; intercrestal, 24.74 cm.; bitrochanteric, 30 cm.; external conjugate, 18.25 cm.

Following the completion of labor, postpartum hemorrhage resulted from uterine inertia, patient becoming pulseless. Strychnia and ergot were administered hypodermically, uterus firmly grasped and an intrauterine douche of normal saline solution, temperature 115 degrees F., given; uterus packed with sterile gauze wrung out of sterile acetic acid, which was removed at the expiration of four hours. Patient speedily recovered. The uterus at no time following delivery was more than a finger's breadth above the pubes.

Subsequent examination on the tenth day found the uterus in anteflexion, of normal size for that period, firmly fixed anteriorly with no cystocele nor any vesical irritation. No surgeon could have done a more perfect vaginal fixation than here existed, nor given better results so far as her comfort was concerned, barring the risk and danger of pregnancy.

In conducting a labor thus complicated, whether the uterus is adherent anteriorly or posteriorly, careful speedy manual dilatation is the most satisfactory method in our hands, since the uterus is very low and the dilatation can be readily accomplished under the eye.

The conduct of the complicated pregnancy and labor which concerns us most, however, is that with the adherent uterus following ventral fixation. We can not lose sight of the fact that the suspension after the usual technic is liable to become fixation and, although many well-known operators have abandoned this operation, there are still many women with ventral fixation yet to become pregnant. Shall she be allowed to proceed to term? This is still a mooted question, and depends wholly on the following factors: The degree of mobility, size of the pelvis, thickness and rigidity of the lower segment of the anterior wall of the uterus and cervix. Each individual should be a law unto herself. If the cervix, by repeated examinations at regular intervals, is found to be markedly rising posteriorly, the uterus immobile and the lower segment of the anterior wall, including the cervix, not becoming utilized in the enlargement, I regard it as unwise to allow her to proceed, unless when an offspring is especially desired and she prefers to accept the risk, with full knowledge of the gravity of labor under such circumstances, including cesarean section.

Of the two methods of dealing with this complication when the condition is not recognized until after the ascent of the cervix, with a thick rigid os, it is my impression that the modern cesarean section by an experienced operator is equally as safe as podalic version, or when too great traction force is necessary to cause the descent of the presenting part into the pelvis, which is liable to rupture the uterus on the posterior surface.

CONCLUSIONS.

My conclusions in reference to the whole matter, from a varied experience, are as follows (which, by the way, coincide with a report from Dr. Oui of Lille, very recently, after careful investigation), viz.: That in hysteropexy, with slightly different technic from that originally practiced, this complication may be obviated; not the suspension to the peritoneum, but to the anterior abdominal wall with two sutures in the anterior surface of the uterus opposite or a little below the insertion of the tubes, instead of in the fundus on the median line or posterior to it, as in the ordinary ventral fixation.

The advantages of a high suspension in this way are: anteflexion; support; ability of the uterus to expand more symmetrically during pregnancy and contract regularly during labor; short bands of adhesion are just as liable to form; does not seriously complicate pregnancy, and, if the bands do not form, the pendulous yielding abdomen and enlargement of the uterus to that point are fairly well proportioned, and when the uterus is emptied it symmetrically contracts and retracts. Inertia is not a factor, and the organ is still supported.

Contrasted with this the disadvantages of the ventral fixation are: Extreme anteflexion, particularly if

the bands of adhesions are short or do not form; frequently vesical irritation; in pregnancy, inability of the uterus to expand symmetrically or contract regularly in labor; torsion of the uterus; malposition of the ovum; uterine inertia and the danger of rupture in labor.

DISCUSSION.

DR. D. H. CRAIG, Boston, referred to a case on which he had operated at the Free Hospital for Women, performing a double suspension, practically at the bases of the round ligaments, making two points of suspension from the anterior abdominal wall. Eighteen months later the same patient returned to the hospital and was operated on by Dr. Baker, who found the uterus again in retroversion of the third degree and supposed that the suspensory ligaments had given way. They had, however, only stretched, one being about four and the other about five inches in length. The conclusion drawn from this case was that this method was neither better nor worse than other methods of suspension, and that a recurrence of the retroversion after any ventral suspension should always be considered an indication for immediate operation because the bands resulting from the stretching of the suspensory ligaments may cause intestinal obstruction.

DR. GEORGE ERETY SHOEMAKER, Philadelphia, stated that for several years he has been suspending the uterus in front of the tubes, and has yet to see a complication in pregnancy resulting. The hand is liable to stretch, but it will not get in the way of an expanding uterus.

DR. L. H. DUNNING, Indianapolis, has employed a method of suspending the uterus for four years with good results. Eight of his patients, so far as he knows, have been delivered at full term without any complications. The suspension is made just opposite to the insertion of the fallopian tube. He uses three sutures, the first two being of chromicized catgut. These sutures are passed into the uterus for about one-third of an inch, and are buried for from one-half to three-quarters of an inch, and are about one-third of an inch apart. Another suture of silk-worm gut is introduced between the two and is not carried deeply into the uterus and the ends are carried through all the layers of the abdomen. The catgut sutures are carried through the peritoneal and deep fascia, muscle and superficial fascia, where they are tied. Before the sutures are tied a small rectangular space is scarified. The result is that there is only one ligament, not two, and it stretches readily so that there is finally a movable uterus. Dr. Dunning operated on one of these cases three months later and found a ligament about half the size of a piece of chalk. He has employed that method in 165 cases, and at last accounts there were eight pregnancies without any complication. It would require an unusually severe case to convince him that any danger can result from that method of suspension. The Alexander method, in his experience, has failed in more than one-half of the cases, when delivery took place afterward. The internal shortening of round ligaments results in failures in more than one-half of the cases, and, furthermore, there are unpleasantnesses attending that operation that are distressing, such as very severe pulling and pain on one side. He has seen two cases in which the distress was so great as to impair the nutrition of the patient, so that, at one time, a premature delivery was contemplated. In reply to a question, Dr. Dunning said that these sutures are placed on the anterior portion of the uterus just opposite the insertion of the fallopian tubes.

DR. F. B. DORSEY, Keokuk, Iowa, said that for more than ten years he has been employing a method similar to Dr. Dunning's, except that he uses two sutures through the anterior part of the uterus, introducing a through-and-through silk-worm gut into the uterus and including only the serous coat, not allowing the needle to enter the muscular coat, and bringing it out from one-half to three-quarters of an inch away, and then out through the abdominal wall. These sutures are allowed to remain for from twelve to fourteen days. Seventeen pregnancies followed, and only two were delivered by instruments, not because of any malattachment, but because of a disproportion existing between the maternal pelvis and the

child's head. There have occurred three abortions, and, so far as he can learn, they were not due to the suspension. The anterior attachment of the uterus is not followed by the usual discomfort or annoyance that is experienced when the attachment is made to the fundus, and particularly when the attachment is on the posterior surface of the uterus. He agreed with Dr. Dunning that the Alexander operation, and any of the operations thus far devised, do not give the results obtained from anterior suspension of the uterus.

Dr. H. D. Fry, Washington, D. C., said that he has done ventral suspension in about 150 cases, and has attended labor in 15 cases after the operation had been done. In not one of these cases was there any trouble during the pregnancy nor difficulty in labor requiring any artificial means to terminate it. He operated on six of these cases afterward and found a suspensory ligament two and a half inches in length, fan-shaped, or simply holding the uterus loosely in position. He has not had a case of recurrence or displacement after suspension. He did a suspension operation in one case during pregnancy. The uterus was retroverted and incarcerated at about the third month. He broke up the adhesions, put the uterus into place and suspended it. The woman went on to full term, was delivered, and the uterus went back into its proper position. His experience with ventral suspension is very satisfactory. One of the worst cases of suffering he ever saw occurred after an Alexander operation. In some respects it was a great success. Dr. Kellogg of Battle Creek, Mich., operated on a woman, married for twenty years, sterile and a chronic invalid. Dr. Kellogg cured the displacement and in a few months the woman became pregnant, but for seven months she was confined to bed, suffering constantly from a dragging on the shortened ligament on the left side. However, the labor was normal and the position of the uterus was satisfactory at the time Dr. Fry saw her. He saw a case where the intention was to perform suspension, but the uterus became fixed to the abdominal wall and the woman had a ventral fixation. She came to the hospital, having been in labor twenty-four hours. The pains had not been very strong, and his attention was not directed to her until that time. Examination showed a dragging of the abdominal scar; the uterus was bound tightly to the abdominal wall. The anterior part of the uterus was held closely, and its neck was flexed at a right angle; the posterior part had descended, the os pointing directly forward and in right angle flexure. The case was delivered by cesarean section, which was successful.

Dr. F. F. LAWRENCE, Columbus, Ohio, said that on several occasions he had brought before this section an operation that has been uniformly successful. It is simple, effective, and supports the pelvic organs and does not interfere with pregnancy. A suture of kangaroo tendon is passed through the fundus of the uterus slightly posterior to the median line and then passed through the posterior layer of the broad ligament on one side; the suture is brought over and tied at the point of beginning, then passed through the opposite broad ligament, brought back and tied again. Two or three stitches through both these folds, passing also through the peritoneal coat of the fundus, completes the operation. It shortens and raises the broad ligament and absolutely supports the uterus without there being any possibility of interference with pregnancy.

Dr. JOHN C. APPLEGATE has not seen any bad results follow suspension, provided the sutures are placed on the anterior surface of the uterus. He has not had the experience of the physician who reports a case where elongation of the suspensory bands allowed a recurrence of the original symptoms.

Physicians' Business Methods.—The *Medical Times* says that if a patient gets the impression that his physician may be paid at any time or not at all, that bills are carelessly made out and as carelessly attended to, the patient will become equally careless. There is no loss of dignity in informing the patient that bills must be promptly paid. When a physician has allowed accounts to run for months, or perhaps years, without a murmur and then employs a collector, he generally loses both accounts and patients.

A STUDY OF EIGHTEEN CONSECUTIVE CASES OF WHOOPING COUGH TREATED BY THE ELASTIC ABDOMINAL BELT.*

THERON WENDELL KILMER, M.D.

Assistant Attending Physician to the Out-Patient Department of the Babies' Hospital.

NEW YORK CITY.

In June, 1903, I published an article entitled "Whooping Cough: A New Method of Treatment." This method consisted in the application of a slightly constricted silk elastic abdominal belt to all children having pertussis. The results attained at that time from a very few cases were of so startling a nature, that I determined to study a number of consecutive cases in detail and the results in this series of cases are now presented.

These cases, it is to be remembered, are all consecutive. When a drug or a method of treating a disease is first brought forth, it is easy for the originator, if he select his cases, to prove that his new method is positively without flaw. Let him, however, report a chain of consecutive cases, and the weak links will be seen immediately. I therefore especially invite criticism of this new pertussal chain which it has been my pleasure to forge during the past few months.

METHOD OF APPLICATION OF BELT.

The method of applying the belt is as follows: A stockinette band is placed on a baby with whooping cough, in the same manner as is done by orthopedists before applying the plaster-of-paris jacket. This band extends from the axilla to the pubes and fits the baby snugly. Two muslin shoulder straps are used to prevent the band from slipping down (Fig. 1). On this stockinette band a single width of silk elastic bandage is sewn, extending entirely around the body and covering the abdomen (Fig. 2). This silk elastic bandage is of the same quality as that used for elastic stockings. If the child is under a year old, it will be found necessary to use but one width (5 inches) of this elastic bandage; in an older child, two widths will often be found necessary to entirely cover the abdomen. This silk elastic bandage is pinned in place when very slightly on the stretch. After it is pinned in place, it should be sewn to the stockinette band underlying it, all around its entire edge; this procedure keeps the silk elastic belt flat and prevents its rolling up or becoming creased. The lower projecting portion of the stockinette band should be pinned down to the outside of the diaper or other clothing, thus keeping the elastic belt smooth over the abdomen.

I have used this belt with great success to control the obstinate vomiting of pertussis where an infant in some cases would die without its use, on account of the inanition caused by the incessant vomiting. The old sea-sickness belt is well known, but its application to a child for the vomiting of whooping cough is, I think, entirely a new feature, and one which I have failed to find mentioned in my perusal of the literature of pertussis. In some of the most aggravated cases, the vomiting has been seen to stop on the application of the elastic abdominal belt. Should the vomiting continue after the belt has been applied, tighten the belt slightly, and in most cases the vomiting will cease.

Although the graphic charts show some diminution

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

EXPLANATION OF CHARTS.

Vomiting is indicated by the solid lines, coughing by the broken lines. B indicates the application of the belt. T indicates the tightening of the belt.

Chart 1.—Age 4 years. Paroxysms ceased immediately on application of belt.

Chart 2.—Age 2 years. Gradual diminution of cough and vomiting.

Chart 3.—Age 13 months. On application of belt both cough and vomiting decreased. On the fourteenth day the mother removed the belt, and the number of paroxysms immediately increased, the belt was consequently reapplied and the paroxysms immediately decreased. The seventeenth day the belt was permanently removed and the paroxysms still remained low.

Chart 4.—Age 2 years. After application of belt the number of coughing paroxysms remained about the same. The vomiting was diminished from 20 a day to 3 a day. This case was a dispensary case and was not seen after the ninth day.

Chart 5.—Age 6 months. On first application of belt, slight diminution in paroxysms. When the mother removed the belt the following day paroxysms slightly increased. Subsequent use of

belt proved a failure. In the entire series this is the only failure to reduce the number of vomiting spells by the belt.

Chart 6.—Age 18 months. Paroxysms immediately fell on application of belt. They gradually increased for 4 days until the belt was tightened, and then marked decrease.

Chart 7.—Age 3 years. Paroxysms immediately decreased.

Chart 8.—Age 5 years. Gradual diminution of paroxysms.

Chart 9.—Age 4 months. Although the cough was apparently not influenced by the belt, the vomiting was greatly diminished.

Chart 10.—Age 22 months. Immediate diminution of both cough and vomiting.

Chart 11.—Age 7 months. Vomiting entirely ceased, although the number of coughing paroxysms slightly increased.

Chart 12.—Age 6 months. Diminution of both cough and vomiting on application of belt; also diminution of paroxysms after belt was tightened.

Chart 13.—Age 4 years. Cough and vomiting entirely ceased. Three weeks afterward the paroxysms had not returned.

Chart 14.—Age 9 years. Although the paroxysms increased after belt was applied vomiting decreased to an absolute cessation of vomiting. The mother removed belt on the sixth day and vomiting began again and increased. Belt was applied again on the seventh day and the vomiting decreased to 0.

Chart 15.—Age 6 years. Gradual cessation of vomiting.

Chart 16.—Age 7 months. Immediate cessation of vomiting and gradual cessation of cough.

Chart 17.—Age 5 years. Vomiting absolutely ceased on application of belt. Cough gradually diminished.

Chart 18.—Age 4 years. Vomiting stopped immediately on application of belt. Belt was removed on the twenty-first day, and vomiting immediately recommenced. Belt was reapplied the next day and vomiting immediately stopped.

Chart 19.—Age 2 years. A case of whooping cough in which no belt was used. This chart may be compared with those of cases where the belt was used.

in the number of paroxysms of coughing, the character of these paroxysms seems to be modified to a great degree. The benefit of the belt is best seen in the cutting short of the vomiting spells. The child will cough, but he will not vomit. In many of these charts the vomiting will be seen to have immediately fallen from twenty paroxysms a day to an absolute cessation of

vomiting. The following series of charts was made by giving a whooping-cough chart to each mother of a child with pertussis. The name, address, age and stage of the disease were plainly written on the chart; the mother was in each case instructed how to use it; she was told that each time the baby coughed she was to place a cross (X) in the paroxysm column, noting the

graphic charts represents the careful record made by each mother, and is based on the study of the charts that she kept; the number of paroxysms of coughing and vomiting are graphically depicted in a similar manner to a temperature chart. The solid black line

TABLE 1. SAMPLE OF CHART KEPT BY MOTHER.

Name, X Y; age, 2 years; address, —; stage of disease, spa-medic (3 days).

Date	Time	Paroxysms	Vomiting	Remarks

Jan. 5	5.30	X	X	
Jan. 5	6.10	X	X	
Jan. 5	7	X	X	

represents the vomiting, and the dotted black line represents the coughing. In several instances it will be seen that the mother for some reason removed the belt, with the result that the vomiting was immediately and markedly increased; the belt was then placed in

time of day; if the baby vomited when he had the paroxysm, the mother was told to place another cross (X) in the vomiting column. Through the kindness of our chairman, Dr. C. G. Kerley, I was enabled to make many of my observations on cases seen at his clinic at the Babies' Hospital; other cases in this series were seen at my own clinic at the West Side German Dispensary, and a few cases were observed for me by personal medical friends. In all cases observed the intelligence of the mothers keeping the charts was a prominent feature. When it was possible to do so, we had the mothers keep the charts for a week before applying a belt. We gave each case some plain placebo to keep control of the patient. After the case had been watched for one week, we then put the elastic abdominal belt on the child, kept up the same placebo, and continued to have the mothers keep the charts. The results, especially as to the vomiting, were surprising and in some cases spectacular. Each of the following

position once more, and the vomiting immediately ceased.

The charts of the eighteen consecutive cases explain themselves. The aspect of a case of whooping cough when wearing the belt is entirely different from an ordinary everyday case when the child is not wearing the belt. This difference is very strikingly shown by comparing Chart 1, in which both the vomiting and cough ceased immediately on the application of a belt, with Chart 19, which is of a case in which no belt was used.

Does the belt cut short certain cases of whooping cough? I do not know, but, from the study of several of my charts, such would seem to have been the case. If some skeptical person is asking, "Were all your cases positive cases of whooping cough?" I can answer by saying that when a child has had a short, dry cough for a week or two, becoming harder, then more paroxysmal in character, the patient becoming red in

the face, holding his breath, whooping and vomiting, and having a chest that is entirely negative, I claim that such a case is positively whooping cough. Again, nearly all of my cases were also seen by men whose reputation in the pediatric world is unassailable. The question of a faulty diagnosis, therefore, I think, can be safely ruled out.

I was first induced to try this belt method of controlling the paroxysms by a patient, a little boy five years old, who would run to his mother each time he felt a paroxysm coming on and beg his mother to "hold my stomach tight!" The belt simply puts the stomach and abdomen in a splint; it supports the abdominal walls and prevents that discomfort and relaxation which we have all observed when suffering from any disease which produces a distressing cough. By way of digression, this belt has been used of late to control the vomiting of phthisis and pregnancy; it has been of marked service in cases of pleurisy and also makes an ideal dressing for a fractured rib.

The expressions from children themselves when wearing the belt are very instructive; one of my cases, a boy nine years old, actually cried for his belt, his mother having removed it. To use his own words, he cried, "Mamma, my stomach will burst without my belt on." Another child said that she was afraid to cough unless she had on her belt.

I thought that I was the originator of this form of treatment for whooping cough, until I came to my fourteenth case; when I proposed putting on the belt in this case, the mother, an old German woman, informed me that ten years ago in Germany she had brought her eldest son through an attack of whooping cough and that she had taken a bandage and tied it "as tight as anything" around her child's abdomen with the result that he vomited very little after the application of the belt.

The study of this series of cases has evolved some interesting and I think unique information; for instance, the ratio between vomiting and coughing has been found to be as 2 to 3, that is to say, if a child vomits 8 times a day, he must have had 12 paroxysms of coughing to have produced the 8 vomiting spells. The converse of this is also true—therefore, a child empties his stomach two-thirds as many times as there are paroxysms of coughing. For example, if a child has 21 paroxysms a day and we wish to know how many times he vomited, we take two-thirds of 21, which gives 14 vomiting spells a day. Or, if a child has vomited 8 times a day, to find how many paroxysms of coughing he had to produce these 8 vomiting spells, we employ the equation: 8 is 2/3 of what? and find the answer to be: 12 paroxysms a day, to produce the 8 vomiting spells. The above information, although of practically little value medically, is nevertheless interesting.

This otherwise fairly constant relation of 2 to 3 between vomiting and coughing has been disturbed in Chart 9 and the disturbing factor is the belt. In Chart 18 the relation of vomiting to cough (2 to 3) is very well exemplified during the first week without the belt, then, as the belt is applied, this normal relation of 2 to 3 is disturbed. What has disturbed it? It is the belt. This disturbed relation goes on for two weeks, the belt is now removed, and immediately the normal relation of 2 to 3 is once more established, but again to be disturbed the next day by the re-application of the belt. What is more conclusive of the beneficial action of

the elastic abdominal belt than the study of this one chart alone?

In Table 2, which is a summary of all cases treated, I wish to simply bring out a few well-established facts. It is true that the suggestion may be made that a series of but eighteen cases is not sufficient to establish conclusive proof of the efficacy of any new method of treatment, but, as I said in the beginning of my paper, these cases are consecutive and, if certain marked factors are present in practically all of the series, truly the most skeptical mind must admit that something other than mere coincidence has been at work to cause such results. The final results are as follows:

1. Out of 18 cases there have been but 6 failures to benefit cough.

TABLE 2.

No.	Name	Age	Stage When Belt Was Applied.	PAROXYSMS a day	VOMITING			COUGH			EFFECT ON VOMITING ONLY

SUMMARY OF CASES.

Males, 9. Females, 9. Ages, from 4 months to 9 years. Vomiting ceased immediately and permanently in 9 cases; was markedly lessened in 8; was not lessened in 1. There were beneficial results in 17 cases and 1 failure, or 94 per cent. benefited. Cough ceased immediately and permanently in 3 cases; was markedly lessened in 9; was not lessened in 6. There were beneficial results in 12 cases and 6 failures, or 66 per cent. benefited.

2. Out of 18 cases there has been but one failure to benefit vomiting. Positive good effect on coughing is seen in 66 per cent. of cases in series. Positive good effect on vomiting is seen in 94 per cent. of cases in series.

CONCLUSION.

In conclusion I wish to say that a method for the treatment of whooping cough which will reduce the total number of vomiting spells (as was done in the above series of cases) from 3,951 a week to 463 a week, thus showing a reduction of 89 per cent. in the vomiting, certainly should be given a fair and impartial trial.

DISCUSSION.

DR. CHARLES G. KERLEY, New York City, reported having seen the treatment of some of these cases, and declared that relief was afforded. He thinks that it is particularly valuable in very young children under 18 months of age, in whom medication is rather difficult because of the effect on the stomach.

DR. LOUIS FISCHER, New York City, reported having tried the method in three cases, with considerable benefit. In one case particularly, where bromoform, belladonna and morphin in considerable doses did not give any relief, some benefit was obtained by the use of a stout binder fastened about the chest.

DR. R. B. GILBERT, Louisville, Ky., suggested an objection, the danger of a hernia resulting from the tight constriction of the chest and abdomen. It is well known that in young in-

fants such a constriction, if too tight, may result in hernia during the effort of crying, and perhaps in older children it might also give rise to a hernia when the child coughs.

Dr. J. P. BIGONY, Hinton, W. Va., asked Dr. Kilmer if he had ever tried a constriction about the head and underneath the jaw in the treatment of whooping cough. Dr. Bigony has seen this method relieve the paroxysms very markedly.

Dr. JOHN L. MORSE, Boston, asked if Dr. Kilmer was not mistaken in regard to the proportion between the number of paroxysms and the number of attacks of vomiting; he thought that there could not be such a definite relation between the two. All physicians have seen undoubted cases of whooping cough in which there was no vomiting whatever.

Dr. L. C. AGER, Brooklyn, N. Y., asked Dr. Kilmer at what stage of the disease the cases came under his observation. We all see cases of whooping cough where the disease has existed for some time, and in which there is very sudden and rapid improvement.

Dr. L. BERNHEIM, Butte, Mont., said that pressure on the thorax relieves the pain in pleurisy, because it limits the movements of the chest. The same explanation probably applies to this method of treating whooping cough. With a stout binder around the chest and abdomen, it is impossible to take a deep inspiration, and this may prevent the onset of a fit of coughing or vomiting.

Dr. THERON W. KILMER said that this method can be used with good effect to control the pain of pleurisy. It possesses some advantage over the use of adhesive plaster in that it can be easily removed. He agreed with Dr. Gilbert that this method is purely mechanical. Hernia does occur in whooping cough, but Dr. Kilmer said he had never seen it. About four years ago he saw a case in which hernia developed subsequent to whooping cough. No bandage had been used, and he did not know the cause. In his cases, no treatment was used outside of the belt, excepting some harmless placebo. He has never seen any benefit follow the method of constricting the movements of the jaw.

In regard to the proportion between the vomiting and coughing spells, the ratio is as two is to three in this series of cases. Some patients with whooping cough do not vomit at all, but they are exceptional. We see cases of diphtheria without any temperature, but they are also exceptional. In many cases the belt was applied very early in the disease. Dr. Kilmer said he had no scientific explanation to offer for the relief afforded by the belt. It is well known that persons suffering from seasickness get some relief from wearing a belt, but what the scientific explanation of it is, he does not know other than that it puts the stomach, as it were, in a splint.

THE NERVOUS SYMPTOMS PRODUCED IN CHILDREN BY UNCORRECTED REFRACTIVE AND MUSCULAR ERRORS.*

J. HERBERT CLAIBORNE, M.D.
NEW YORK CITY.

To present the subject in a logical manner, permit me to review in a general way the refractive quality of the normally and abnormally constructed eye, and the adjustment of its external muscular system.

The eye may be emmetropic, hypermetropic, myopic, or astigmatic.

Emmetropia is, of course, the ideal condition, and it may be defined as that refractive condition in which distant or parallel rays of light are focused on the retina without any effort on the part of the accommodative muscle. Such an eye, in regarding distant objects, i. e., objects at or beyond 20 feet, is merely a camera obscura, in which the focus is formed on the retina. Such an

act, under such conditions should be, in the natural order of things, achieved without discomfort. (Fig. 1.)

The hypermetropic eye is an eye that is shorter in its anteroposterior diameter than the emmetropic eye, and hence, given the same refractive media as the emmetropic eye, it can not bend parallel rays to a focus on its retina by virtue of its refractive power in a state of quiescence.

If such an eye be in a state of rest, parallel rays would fall on its retina while in the act of coming to a focus, i. e., before the focus is achieved. The cone of light would thus be obtruncated, and the retina, instead of receiving a point for each pencil of rays, would receive a cone, the size of which would be greater the farther from the focus the retina cuts the cone. In other words, the shorter the eye, the more hypermetropic it is, and the larger the cone or circle of diffusion on the retina will be.

Figure 1.

Now, if the hypermetropic eye has to depend on its length alone to bend rays to a focus on its retina, it would never see distant objects well for obvious reasons, and its English synonym, far-sighted eye, would be a misnomer. (Fig. 2.)

But there is within the eye the accommodative apparatus, consisting of the accommodative muscle, the lens and the ligament of Zinn, by means of which refractive power can be added to the eye, and the rays be brought to a focus on the retina.

This accommodative apparatus is well named; it is surely an accommodation in some conditions. But Nature never intended that it should be used to further the interests of the hyperope. It was primarily given in order that the emmetrope might see objects well within

Figure 2.

20 feet. For it must be clear from the foregoing that since the emmetropic eye can only focus parallel rays, the divergent rays coming from objects nearer than 20 feet, would fall on the retina of the emmetrope in the act of convergence, and circles of diffusion instead of points would be formed. (Fig. 2.) This apparatus has its natural function in bending the divergent rays of light coming from objects nearer than 20 feet, to a focus on the retina of the emmetrope, or the man with the properly shaped eye. This is its primal function and this alone. Our brain apparently abhors an imperfect image on the retina, for the only occasion in which this can possibly happen to the ideal emmetropic eye, the occasion of looking at near objects, is quickly met by the apparatus of accommodation and the imperfect image is immediately transformed into a perfect one.

When, then, the hyperope opens his eyes on the world

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

and perceives an imperfect image on his retina. he turns to his native instinct for relief, the instinct or desire for perfect vision. A call is made on his accommodation, the mechanism of this apparatus is set in motion, and a perfect image obtained. But this is distinctly a vicarious and a vicious act, contrary to right, vicious in its conception, and subversive of physiologic law. Law broken demands its inexorable penalty and the uttermost farthing is paid. Imagine a child with 2 D. of hypermetropia, and look for a moment at the effort that that child supports even to see for distance—an act that ought, in the natural order of things, to be achieved without discomfort, if not with pleasure.

Two D. of hypermetropia measured in the inch system, means that the possessor, in order to see clearly in the distance, has to strain as much as an ordinary emmetrope does to read a fair-sized type at 20 inches from his eyes. To put it in other terms, it would require as much work as would be required for an emmetrope to wear a pair of concave lenses of 20 inches focal distance in going about. When near work is attempted by such a child, of course this labor is added to the natural accommodative act.

These illustrations give a fair idea of the condition of the hypermetrope, and the cost at which he purchases clear distant vision. The condition of the myope is no less unfortunate, but in a different way.

Myopia is the condition in which the eyeball is longer in its anteroposterior diameter than in emmetropia. Given the same refractive media then as the latter, the parallel rays of light from distant objects will come to a focus before they reach the retina, in fact, in the vi-

Figure 3.

treous humor, and having formed a focus, will cross each other, and will fall on the retina in the act of diverging. An obtruncated cone of light thus falls on the retina, and points are seen as circles. Such a person has an enlarged, badly defined image on the retina. Now, there is a great similarity between the state of the myope and the hypermetrope, and if one can imagine the accommodation eliminated, this similarity becomes evident. It will be remembered that the rays from distant objects fall on the retina of the hypermetrope in the act of converging, so that circles are formed instead of points, hence the image is badly defined and enlarged. (Fig. 3.)

The rays from distant objects come to a focus in the vitreous humor of the myope, cross and proceed to their destination on the retina in the act of diverging; hence, on the retina circles are formed instead of points, and the image is enlarged and badly defined. In the one case, the hyperope, it was the converging rays, before the focus was reached, in the other, the diverging rays, after the focus was reached.

Now given, let us say, 2 D. of error, hypermetropia and myopia, in two cases, and suppose the accommodation eliminated: the size of the images in the two cases will be the same, and the definition of the image equally bad. But the actual result is different. As a matter of fact, the child with 2 D. of hypermetropia overcomes its error and achieves a perfect image by an appeal to

its accommodation. But suppose the myope should do the same thing. The act of accommodation in his case will simply add refractive power to his eye and the focus, so far from being thrust toward to the retina, will be brought still further forward in the vitreous, the circles on his retina will be enlarged, rather than decreased, and his sight made worse rather than bettered.

It is quite probable that every myope, as the condition commences to develop, attempts to remedy his evil by appeals to his accommodation, in accordance with the apparently natal instinct for perfect vision and abhorrence of an imperfect image. As a rule, time teaches the myope the futility of the effort, and his hope lies in the art of man. The hyperope sees well, but has to pay the price in the coin of broken law; the myope can not see distinctly and is doomed, unless artificially relieved, to imperfect images and the mental confusion that naturally results therefrom.

The eyes that have just been described are called "spherical eyes," and are so named for good reasons. The radius of curvature of the cornea in spherical eyes is the same in the two principal meridians, and this fact constitutes the spherical quality. Now it is possible for eyes not to be spherical, and when they are not, they are astigmatic.

An astigmatic eye, in short, is an eye the radius of

Figure 4.

curvatures of whose two principal meridians is not the same: the two meridians differ in curve; broadly speaking, the cornea is not the segment of a perfect sphere. Given a difference in radius in the two principal meridians, it is obvious that the image formed on the retina of the astigmatic eye is an indistinct one, and it is one which can not be correct in shape.

If a perfectly circular object, say the moon at full, is viewed by an astigmatic eye, the image of it can not be round—it must be more or less oblong. This is the essential character of the image in astigmatic eyes. Two foci must exist in such eyes, the one caused by the junction of the rays passing through one meridian, the other caused by the junction of the rays passing through the other. Mental confusion must necessarily result to the possessor of such an eye. (Fig. 4.)

CORNEAL ASTIGMATISM.

In astigmatism, the three conditions, emmetropia, hypermetropia and myopia are found severally in the principal meridians. There are five kinds of corneal astigmatism; simple hyperopic, simple myopic, compound hyperopic, compound myopic and mixed astigmatism. There are other kinds of astigmatism, but the corneal is the kind to which I would call your attention.

Simple Hyperopic Astigmatism.—Of the various kinds of astigmatism, there is little doubt that the hyperopic varieties cause the most important and the most

varied nervous symptoms. The reason for this is obvious. In simple hyperopic astigmatism, one focus is on the retina and the other behind it. Following the natural impulse to accommodate in the presence of an imperfect image, the brain sets the accommodation in motion, the swelling of the lens brings the hyperopic focus to the retina, but immediately the focus of the cymetropic meridian which was before on the retina, is now advanced into the vitreous, and the error is changed into a simple myopic astigmatism, because the muscle of accommodation is a ring-shaped muscle and acts spherically, and the lens increases its curve in the two principal meridians equally. The individual relaxes again and then accommodates again until a vicious habit is acquired, called an "accommodative spasm."

Compound Hyperopic Astigmatism.—If this is true of simple hyperopic astigmatism, how much more so is it true of compound hyperopic error. There is a double impulse to accommodate, to overcome the spherical error common to the two meridians and the astigmatic error of one meridian. These cases present the most varied and protean forms of reflex symptoms.

Myopic Astigmatism.—In the case of myopic astigmatic errors, the impulse to accommodate is less marked; the possessors of these errors usually do not develop spasm of the accommodation; but the images on the retinae are blurred and misshapen, and thus reflex symptoms are the result of mental confusion rather than accommodative strain.

Mixed Astigmatism.—In mixed astigmatism, the image is possibly most misshapen of all, and the resultant confusion on that account, most marked. But there is apt to be also in this condition an element of spasm by virtue of the instinctive attempt to correct the hyperopic meridian.

ACCOMMODATION IN ASTIGMATISM.

It will be seen from this that it is entirely impossible for the astigmatic person to profit himself by the accommodative act. Like the myope, these unfortunates look to man's art for relief. It is important and necessary to remark here that the smaller errors of refraction, both spherical and astigmatic, are more frequently responsible for reflex symptoms than the greater ones. When the error is slight, as in hyperopia, for example, it seems quite impossible for the owner of the eye to avoid using his accommodation. In slight myopic errors, the brain seems to be unable to realize that it is quite as impossible to remedy an error of .50 D. as it is an error of 3 D. or 4 D. The analogue of this phenomenon is found in life. For example, one would not think of attempting to carry one or two hundred pounds, but would laugh at 25 or 30. The latter, if borne on a long and tedious march, will soon make itself felt.

Our European confrères can not be induced to share our views on this point. They maintain that slight refractive errors cause no discomfort, and correct only the great ones. Their views may be supported by their experience in Europe, but are contradicted by daily experience in the United States. Even our working classes are more highly strung than theirs, and the children in our schools are surely built of more nervous and sensitive tissues. The terrific pressure under which we live is largely at the bottom of this fact.

MUSCULAR DEFECTS.

We come on now to consider the external muscular system of the eye, consisting of the recti and the oblique muscles, by means of which the eye is turned in the various possible directions. To each eye there are four

recti and two oblique muscles, making twelve for the two eyes. Now if in the natural order of things we had been made cyclopeans, with one eye in the middle of the forehead, this chapter in ophthalmology would not have been written, the task imposed on mankind simplified, and the nervous system would have been saved many disorders. As a matter of fact, however, we have two eyes, and we have an irresistible, instinctive desire to fuse the images of the two eyes and see an object single instead of double. If this act is achieved with comfort, it is not appreciated, but if it is achieved and continued with difficulty, it will nevertheless be continued whatever may be the price until paresis of one or more of the muscles sets in. When once single binocular vision is no longer possible (as a rule the nervous symptoms subside) and the possessor of the eyes sees double, or the brain denies one image, and single vision with one eye exists. While double vision may produce varied and diverse nervous symptoms, they are not of the character of those symptoms which are produced by the single binocular vision with muscular imbalance. When once the image of one eye is denied, all symptoms referable to the muscular system disappear. Children who have squinted from early life, generally see with one eye alone; in such cases it is exceptional to observe nervous symptoms referable to the eyes.

Each eye, then, has six muscles, and each muscle has its co-worker and antagonist, and each is entitled to a certain amount of pulling power for its own use and a certain amount of check power to limit the actions of its opponent.

When we consider the phenomenon of single binocular vision, the necessity of a clear and perfect image on both retinae, the fusion of the two images into one, and the associated and antagonistic actions of the twelve external or extrinsic muscles, we can not but be impressed with the complicated and intricate nature of seeing one with two eyes and of continuing to perform the act. If by any chance the image on one or both retinae is blurred, if by any chance it is necessary to strain to obtain clear vision, if further, even one of these complicated muscles possesses too much or too little power, the entire mechanism is disturbed, the balance is destroyed and disorder results.

Now, there are few if any eyes which are in all these particulars perfectly adjusted, and the wonder of it all is that men are able to perform their duties and achieve good results under such conditions.

Those who live out of doors, or whose occupations do not demand constant use of the eyes near by, do not so frequently exhibit the effects of eye-strain as those whose duty requires constant use of the eyes for near work.

CAUSES OF EYE-STRAIN IN CHILDREN.

The causes of eye-strain in children are found in refractive and muscular irregularities, in the unhygienic and badly illuminated school and study rooms, and in the silly and unreasonable demands made on the brain and nervous systems of the children of this generation by parents and educators. At the very age when the tissues are most yielding and soft, and the whole nervous system is tingling with new and unanalyzed sensation, before experience has had opportunity to teach the value of economy of time and effort, mental and nervous loads are put on our children that could not be borne under the most ideal conditions.

NERVOUS SYMPTOMS IN CHILDREN.

Headache is, by far, the most common nervous symp-

tom in children, caused by ocular irregularities; it is usually frontal, over both eyes, and is at times accentuated over the supraorbital notch. It may, however, be in the occiput, in the back of the neck, and there are areas of tenderness just behind and below the mastoid process. The headache may be constant, after the duties of the day are begun, or may come on only when near work is commenced, and disappear when it is laid aside. As a rule, however, the headache persists during school hours. Along with headache may be associated nervousness, inability to fix the attention, the lack of power of concentration, cold hands and feet, restlessness, irritability, peevishness, sleeplessness, lassitude and scotoma scintillans.

The severer forms of headache met with by eye surgeons, in my experience, do not occur amongst children, and I have rarely seen a school child who came to me with a story of periodic sick headache in which there was vomiting, photophobia, nervous exhaustion, and the necessity of taking to the bed. The headache which I have found in children that is due to ocular disturbances is, as a rule, headache of the subacute and chronic variety, or that form which comes on directly the eyes are set to do near work. Such patients generally possess a facial expression which ought to lead the acute observer to the suspicion of ocular strain. The brow is usually corrugated, either by straight vertical furrows between the eyes, or by nervous lifting of the brows, which throws the forehead into longitudinal wrinkles; sometimes one eyebrow alone is lifted, and is kept in that position or drops and lifts alternately in nervous spasm. I have two such cases of the latter in mind at this moment. At the same time, the general expression of the countenance is one of weariness and anxiety. Sometimes it hegets a furtive look, at others, the aggressiveness of the frown.

When the error is hyperopic, the expression is generally one of painful alertness, but when the refractive error is sufficiently great and of a character to produce bad distant vision the expression is one of uncertainty, hesitation and indecision. In high spherical myopia, the expression of the face is placid, inane and vacuous; in young girls it has sometimes been esteemed a mark of dreamy beauty; in boys, it has been considered a mark of stupidity. In these particular cases the utter impossibility of achieving a sharp image on the retina has already been recognized, and the vacuous look is an expression of hopelessness. At times, such patients, particularly when they desire to scrutinize anything at a distance, squeeze their eyelids together in order to lessen the size of the circles of diffusion on the retina. This act, while it strongly suggests myopia, and is indeed the basis of the word describing the condition, is nevertheless not peculiar to the myope, but may be used for the same purpose by one whose pupils are artificially dilated or by those with very high degrees of spherical hyperopia which they can not overcome; and still again by those with a high grade of astigmatism. One should not be misled by this act. It suggests myopia, and should arouse the suspicion of refractive errors, but it should not necessarily be interpreted to mean the presence of myopia.

The expression of the human face is usually an index of the visual acuteness; those who see sharply, quickly and accurately generally present the facial expression indicating alertness and intellectual or intelligent perception of surroundings. The face naturally mirrors the impressions received from the outside world, and chiefly those received through the eye.

When the impressions of the outside world received through the eye are acquired at the expense of pain and labor they are accordingly mirrored in the countenance. When the impressions are indistinct and confused, they are again consistently reflected. The value of facial expression as an aid in diagnosis has not, in my opinion, been sufficiently appreciated. In ocular disturbances, it is particularly significant.

Migraine.—Referring to the condition known as migraine or hemicrania, I observed that it has rarely been my fortune to find in children the typical attacks of periodic migraine or hemicrania. I have generally found these headaches among young adults, or adults who are literary, or whose occupation demands the constant near use of the eyes; yet, I have at times found it among children. It is held by some that cases of true periodic sick headache or migraine can not be cured by correcting ocular faults, and by others that they can. The truth, in my opinion, lies as usual, between the two. I can cite several cases in young adults, in whom the recurrence of the periodic attack and all the accompanying symptoms have been absolutely prevented by the correction of an ocular defect.

In this connection I would refer to the so-called cyclical vomiting in children, recently described by Holt. The refractive errors in such cases should always be corrected, and I herewith suggest that careful histories be kept of all such cases after the refractive correction has been made. It is not improbable that some of these cases, at least, may be relieved, and I believe that all of them may be modified by ocular correction. From the standpoint of the eye surgeon, I do not believe these cases have been properly studied.

I regret the scope of my paper will not permit me to go more thoroughly into the philosophy of migraine. But I can not let the subject pass without reiterating the statement that I have had a number of cases in my practice in which the recurrence of sick headache has been absolutely prevented by the correction of refractive errors. Such cases may be said to be cured, but under all circumstances I consider that the first rational method of treatment should be the accurate and careful adjustment of ocular errors, particularly the refractive ones.

Epilepsy.—Within the last fifteen or twenty years certain claims have been set forth to cure epilepsy and insanity by correcting ocular errors. Just after these claims were made, a number of test cases were given by a committee in the city of New York to the author of them, and a report was made by said author of the results of treatment at the end of a length of time sufficient to warrant conclusions. The results were practically *nil*, and the author and his claims were set aside by the great body of eye surgeons and neurologists as not worthy of scientific consideration. More recently abundant experiments have been made in the Craig Settlement for Epileptics. No case has been found to be cured or materially benefited by treatment of the eye.

Neither time nor the scope of my subject permit me to review more thoroughly the experiments referred to, the method of treatment, or the results of it. But the above simple assertion will be found to be amply corroborated by minute investigation. In my opinion there is not one single scintilla of scientific evidence to prove that either insanity or epilepsy has ever been in the slightest degree modified in their essential symptoms, by the correction of refractive errors, or the adjustment of the muscular imbalance.

While epilepsy and insanity do occur in children, they are rare, particularly the latter; and while they

are not, in my judgment, caused by ocular errors, yet so many absurd and vapid claims have been made by a few eye surgeons that the subject has been considered to be entitled to mention. Be it said, to the credit of neurologists, there are none among that ilk who held such views.

Paralysis and paresis have been mentioned as the result of ocular errors. I am not able to cite in my experience any single case in which a refractive error could be said reasonably to lie at the bottom of a true paresis or paralysis, be it in eye muscles or other structures. There are certainly mild cases of squint which may be interpreted as squint or phoria, which are relieved by refractive correction, but they are not cases of paralysis or paresis. Temporary paralysis or paresis of ocular muscles, ptosis and double vision have been cited, but I do not believe the observations on these cases have been correct. I believe they can all be placed in the category just mentioned, or are the result of hysterical mental imbalance.

I have frequently known people with refractive errors to complain of numbness in the hands or feet and in other portions of the body, and I have known these symptoms to disappear after the correction of the ocular errors. I believe all these cases are the result of hysteria, and the refractive or muscular error is simply the direct cause of the nervous storm. Such cases generally occur in neurotic subjects who are neurotic by nature, and who have been rendered exceedingly nervous by circumstances coupled with peripheral irritation.

Such symptoms do not very frequently occur in children unless the subject is the type just described, and possesses extraordinary intelligence and development. Hysteria and all the protean sensations characteristic of it are the result of experience, knowledge and introspection, coupled with the neurotic temperament. The combination just outlined is rarely possessed by children. Psychic sensations do, however, occur in children as the result of ocular strain, and one should not shut one's eyes to the fact. But they are much modified by lack of intelligence and experience, and the faculty of introspection, the latter being, in my opinion, a basal element.

Chorea.—It has also been claimed that true chorea is cured by ocular correction, but I have never known of a case of the chorea of Sydenham being caused by refractive or muscular error, or cured by its correction. This disease is prevalent among neurotic children, even among those who are not, and I have no doubt it is often confounded with an allied but different affection, namely, *tic convulsif*. This affection may often be relieved by correction of refractive errors or the adjustment of muscular imbalance.

Blepharospasm.—Blepharospasm or convulsive snapping of the lids, is a frequent concomitant of refractive errors, particularly hyperopic ones, and is almost invariably relieved by correction. In addition, however, it is a common custom to exhibit arsenic at the same time. These two particular nervous symptoms are by far more frequently associated with refractive errors than muscular ones. Nevertheless, convulsive movements and grimaces of the entire face may be caused by muscular errors, and the following case, briefly related, illustrates this fact:

A boy of 13, highly nervous and of headstrong character, had exhibited for several years irregular and almost continuous facial spasms and grimaces. His hyperopic error had been partly corrected by some one, but without materially benefiting him. I corrected his error under atropin, giving

him an almost complete correction. He was so willful that it was quite impossible to make him wear his glasses all the time, and the symptoms so far from getting better, grew much worse in the course of several months. It was observed by me at the time of the first examination, that he had marked exophoria, particularly in the right eye; finally the exophoria became so troublesome and the nervous symptoms became so much more marked, that his entire face was contorted into wrinkles and grimaces. He said that these grimaces were necessary in order to keep him from seeing double; at will he could let his eyes "go" and see double, or bring the images together. His parents permitted an operation, and his right external muscle was accordingly completely divided. On the next morning he could retain single binocular vision with ease, and all his facial contractions had gone; he threw away his glasses and has never used them since. His parents informed me later that he was cured. I saw him two years afterward, and he appeared to be normal, albeit a trifle annoyed by his hyperopic error while reading.

REFLEX DISTURBANCES.

Some writers have laid much stress on gastric disturbance caused by uncorrected refractive errors. There can be no doubt that eye-strain, by reflex action, will affect the stomach; it frequently causes nausea; sometimes the nausea goes to the extent of vomiting; generally, however, it is simply a constant sickening distress, and can not possibly be appreciated by any but those who have experienced it. It simply fills one with unqualified disgust for the world.

It would be bootless for me here to review the cases in children and adults, whose gastric symptoms I have known to be relieved by correction of refractive errors. At the same time I would be understood as recognizing the fact that acute or chronic indigestion may be a causative factor in the production of eye-strain and ocular headaches, but I have always observed that in such cases there are at the same time present refractive or muscular errors, or both.

I have a case in mind in which flatulence frequently produces diplopia and dizziness, which symptoms immediately disappear the moment the flatulence is relieved. I do not doubt that this has been remarked by others. It is my firm conviction, however, that refractive and muscular errors more often affect the digestion than that bad digestion affects the eyes. The two things often react on each other, and so create a vicious circle, the beginning and end of which it is impossible to define.

I find the above symptoms as frequently among children as adults.

MENTAL AND MORAL RESULTS OF EYE-STRAIN.

I can not let this subject pass without making some observations on the effect produced by uncorrected ocular errors on the mental and moral characters of children. When we think of the highly sensitive quality and plasticity of the juvenile tissues, particularly the brain, we can not scientifically omit to give every influence its full value. As an eye surgeon, it has been my fortune to be able to keep track of a number of boys whom I knew at school, whose qualities and characters I even then thoroughly appreciated, and whose ocular conditions I have subsequently come to examine and to know.

If I may be permitted to cite my own case, it will represent one of a type. I now know I have always carried about 1.50 D. of hypermetropia; in my very early days, possibly more. Books and school were to me a nightmare, a source of unutterable disgust. I drove myself to my tasks with the scourge of duty; I never took one moment's joy or pleasure in the acquisition of knowledge, unless it was a satisfaction of a

task accomplished or conquest gained. I have no memory of a sense of pleasure connected with my studies at school or college. The only pleasant memories I have of these periods of my life are those connected with outdoor sports or facts gained through observation, or in the lecture room through my ears; and from my boyhood I could never understand why we were forced to read from books all that we learned.

Early in life I pondered over the easiness of the task of those who never sat at the feet, but who followed in the tracks of the peripatetic philosophers. Verily, my school and college days would have been a joy to me had my ears and my distant vision been my means of acquiring knowledge. And yet, I never had a headache in my life at school nor in after years until the commencement of presbyopia. I was nervous to the point of madness at times, and the more nervous I was the more diligent I became, and the nearer I put my nose to my book. I have frequently observed that my right eye was crossed after prolonged study, or after a long written examination; this was also at times observed in my case by a fellow student. The difficulty lay in my hypermetropia. I have no manner of doubt. I had inherited a love of learning. I felt sure, and I had a right to the assurance, and my hatred of close application was a mystery to me. I created a frown by my accommodative strain, which has ever been a part of me. Prolonged application to books would be followed often by sleeplessness or violence in the field at play. I learned for these reasons the art of complete concentration, but at what an expense of nervous energy!

I can also remember a boy with remarkable mental ability who seemed to achieve his tasks very quickly and easily, but who was shy, retiring and apparently did not like study any more than I. He showed in after life 3 D. of hypermetropia, and was practically, at the age of 31, debarred from the practice of the law for a long while on account of his eyes; and then I remember a fool, as we thought him, blear-eyed as Crispinus, with red lids, and eyes within ten inches of his book, who knew nothing, who never learned anything, who never played in the field, and who early became the victim of vicious habits. Examination of his eyes later in life showed a high grade of astigmatism and distant vision, amounting to two-fifths of normal. And then I remember the myope, with head bent down, peering about, living in his books, and the world which revolved within his far-point; and the stupid myope, with no love of learning, the early victim, likewise, of vicious habits.

These things are not imagination. These boys live to me again, and I can judge them by a different standard to that I then used. If the hyperope is relieved of his strain, near eye work becomes easy and natural, and if he is intellectual by nature, he has unending avenues of pleasure and profit before him, without paying the price of learning in the coin of pain and exhaustion, and for the myope, a new and enlarged world is opened. Impressions are received at an early age that may go to the formation of his character along profitable lines. He may easily improve his physique by exercise and play, since he can see without danger and with comprehension. He will grow up straight, perhaps, without stooping shoulders, bent head and facial characteristics of his error, for he will no longer try to reach things by sticking his nose into them; they will come to him instead.

We do not observe our children enough, particularly in these respects. Many a career and many a character might have been altered by correction of refractive er-

rors at an early age. That child that hates its books, that resents the incarceration of school, that is nervous, restless and irritable, is entitled to have its eyes examined. That child that avoids its fellows, that is always pouring over its books, that stoops and looks stupid, is entitled to have its eyes examined.

In the beginning of this paper, I cited the irregularities of the external muscular system as a factor in the results of eye-strain. I desire to make myself unqualifiedly clear when I affirm that I do not believe the irregularities of the muscular system of the eye are so frequently the cause of nervous symptoms as refractive errors. Indeed, unless the muscular insufficiency is very marked, and borders on absolute squint, I believe it has no bearing on the great majority of cases of nervous disorder. It is well known that absolute squint when it has persisted from early life causes no symptoms of itself.

Squinting children hardly ever complain of asthenopia after the double vision has been eliminated by the mental abnegation of the image of one eye. Such people are in an ideal condition of "cyclopia," if I may be permitted to coin a word. It may safely be said that in the majority of cases muscular insufficiency or imbalance adjusts itself after the proper correction of refractive errors. When it is not adjusted by this measure, operative interference is usually demanded.

Good effects from the use of prisms, in such cases, have rarely been found by me; nor do I belong to that class of eye surgeons who believe that prismatic exercise is of value; I have found this procedure of no value whatever. By constant practicing with muscles it becomes possible for one to induce a weak muscle to overcome a very high grade of prism. In this manner, the minds of the surgeon and the patient are often led to a false conclusion. If any benefit has been found to follow this method of treatment of muscular insufficiency, it has been due, I believe, to the refractive correction, and the other treatment which has been employed at the same time.

I would like to put myself on record as stating the opinion that it is the small refractive errors, rather than the large ones, which produce nervous symptoms. And this applies as well to those cases in which it is possible for the eye to overcome the error, as to those in which it is not. I have rarely seen nervous symptoms follow 3 or 4 diopters of hypermetropia. It is the errors ranging from one-half to two diopters which produce the symptoms in hypermetropia. Of course, in astigmatism and myopia, the eye can not correct its own error. The small errors of refraction, I think, may be likened to the straw that breaks the camel's back, or, more properly still, the farthing-weight which the camel invariably resents. I believe that these small errors more frequently precipitate nervous symptoms in those of exceedingly nervous organization and neurotic temperament, but I distinctly, likewise, can affirm from my own experience, that I have known refractive errors to throw into imbalance the nervous system of strong and well-regulated men.

As a source of peripheral irritation, eye-strain has been overestimated by some, but has been underestimated by more.

There are, then, in my opinion, three factors in eye-strain which are the result of refractive errors:

1. The accommodative effort which at times degenerates into spasm.
2. The spasm which is the frequent result of the

fruitless attempt on the part of the eye to overcome astigmatism or myopia.

3. The mental confusion and psychic perturbation which ensues when an imperfect image persists on the retina.

CONCLUSIONS.

1. Nervous symptoms of a variety of kinds occur as the result of eye-strain.

2. Eye-strain is due to refractive errors, to imbalance of the external ocular muscular system, or, more frequently, to a combination of the two.

3. Of these two, the refractive errors are by far the more frequent cause.

4. Muscular imbalance alone may cause it.

5. Headache is by far the most common nervous symptom in children, caused by eye-strain.

6. The headache is chronic or induced directly by near work and is generally in the forehead or temples.

7. Migraine or hemicrania, due to eye-strain, is comparatively rare in children.

8. Any nervous symptom in children should arouse the suspicion of ocular defects, either as the direct or a contributory cause.

9. The refractive correction should be made under atropin.

10. Muscular defects are secondary to the refractive, and should be corrected only in certain cases.

CONGENITAL OCCLUSION OF THE LACHRYMAL CANAL

AND ACUTE CONTAGIOUS INFLAMMATIONS OF THE CONJUNCTIVA IN CHILDREN.*

JOHN E. WEEKS, M.D.
NEW YORK CITY.

I have endeavored to write in a more or less general manner of the acute contagious inflammations of the conjunctiva that occur in children, prefacing my remarks on the subject by a brief allusion to a perplexing condition that sometimes confronts the pediatricist. I refer to congenital occlusion of the lachrymal canal.

Shortly after the secretion of the lachrymal fluid begins (from three to eight weeks after birth), one or both eyes become suffused with tears and some flakes of mucus appear in the conjunctival sac. Pressure over the lachrymal sac may cause the escape of a minute quantity of pus from the sac. Accompanying this appearance of mucus, there is little redness of the conjunctiva, but no marked swelling, nor is there any marked swelling of the lids. The presence of the secretion excites the concern of the parents, and the physician is called.

This condition is often mistaken for acute contagious conjunctivitis, and it requires careful observation to avoid confounding the two. Treatment, if at all irritating, rather tends to increase the difficulty than to cause it to subside, and the persistence of the affection becomes somewhat alarming. The disturbance to the child is very slight. If during the continuance of this condition the cornea should become abraded, infection of the latter may result.

TREATMENT.

The treatment should be extremely mild and should

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Keller, H. M. McClanahan and John C. Cook.

consist simply of cleansing the conjunctival sac with a solution of boric acid two or three times daily, and in protecting the skin of the lids by the use of some bland ointment. No attempt should be made to open the lachrymal canal by the passage of probes or in any other way until Nature has been given a fair opportunity to establish the passage. The patency of the passage will become established in from two to six weeks in a large percentage of the cases. If after the lapse of two months the passage is not free, a canaliculus may be slit up sufficiently to permit the passage of a small lachrymal probe (Bowman's No. 4 or 5) and a probe passed through the obstruction. A single passage of the probe is usually sufficient. A solution of boric acid should now be syringed into the canal by means of a lachrymal syringe to determine the patency of the canal.

It is very evident from the nature of a case of this character that measures for the protection of other members of the family or of the other eye, if one eye only is affected, are unnecessary.

ACUTE CONTAGIOUS OPHTHALMIAS.

The acute contagious ophthalmias to which children are subject are those which are developed as a consequence of infection from the pneumococcus, the Koch-Weeks bacillus, the gonococcus, and the Klebs-Loeffler bacillus.

DIFFERENTIAL DIAGNOSIS.

The clinical picture as a result of infection from the first two micro-organisms mentioned is that of mucopurulent conjunctivitis; a purulent conjunctivitis is the characteristic clinical picture of infection by the gonococcus, and a membranous conjunctivitis is the characteristic clinical picture of the infection produced by the Klebs-Loeffler bacillus. All of these forms of conjunctivitis are contagious, some to a much greater degree than others, and since this is the case, a safe rule to follow in treating cases of acute conjunctivitis is to isolate, or to virtually isolate, the patient as soon as secretion occurs as a result of acute inflammation of the conjunctiva. This rule may be carried further to the length of continuing the isolation until the discharge has entirely disappeared.

A pneumococcus conjunctivitis is indistinguishable clinically from a Koch-Weeks bacillus conjunctivitis. On the whole, a conjunctivitis produced by the latter cause is considerably more severe than that produced by the former. A differential diagnosis is possible only on examination of the secretion with the microscope, but the necessity for differentiating between the two is really not great, as the treatment is very nearly the same and the results are almost always benign.

It is well known that the pneumococcus requires a soil especially favorable for its development, and that individuals who do not present a favorable soil may have the pneumococcus in the conjunctival sac without a conjunctivitis; but when the small bacillus of acute contagious conjunctivitis (Koch-Weeks) is in question, the conjunctiva on which the bacillus falls, whatever its condition, is sure to become affected. These remarks also hold true in regard to the gonococcus. The Klebs-Loeffler bacillus holds the same relation to the mucous membranes of the body as does the pneumococcus, the frequency with which it may produce its pathologic manifestation being perhaps less than with the pneumococcus.

Acute conjunctivitis as a result of the pneumococcus

may be epidemic in small localities, but it never, so far as my observations and investigations have been able to determine, produces widespread epidemics. Occurring in families, one or two individuals may be affected; frequently one only. Occurring in residential schools, a few of the inmates may be affected. This relatively slight tendency to spread is due in all probability to the necessity for a favorable soil, as before mentioned.

Conjunctivitis due to the small bacillus is very apt to affect all the members of a family and, occurring in residential schools, is apt to affect the greater number of inmates; perhaps all of the inmates, unless isolation measures are instituted. This form of conjunctivitis may become widely epidemic, affecting the inhabitants of large sections of the country.

Gonorrhoea of the conjunctiva can become epidemic in localities, as in institutions where numbers are massed together in residential schools, barracks, etc., but it can not become epidemic in communities. When gonorrhoea of the conjunctiva occurs in children, whether in a family or in asylums or residential schools, it is desirable to ascertain, if possible, the source of infection, and it is incumbent on the physician to examine any urethral or vaginal discharge occurring in boys or girls. I once observed an epidemic of gonorrhoeal conjunctivitis affecting twenty-two of the inmates of a residential school for girls. Examination disclosed the fact that a number of the girls were suffering from a gonorrhoeal vaginitis.

Diphtheria of the conjunctiva, while contagious, is probably never epidemic.

All of these affections vary greatly in degree of severity. It is possible that an acute conjunctivitis due to the pneumococcus or the Kochs-Weeks bacillus may be so severe as to be confounded with a conjunctivitis of gonorrhoeal origin. It is possible that a gonorrhoeal conjunctivitis may be so mild that it may be mistaken for an ordinary mucopurulent conjunctivitis, but the secretion for this mild case will possess the power of producing in another eye a gonorrhoeal conjunctivitis of the most severe type. It is possible that gonorrhoea of the conjunctiva may reach a degree of severity which would cause it to be confounded with diphtheria of the conjunctiva.

Acute mucopurulent conjunctivitis due to the pneumococcus or to the small bacillus is devoid of danger to vision except in an extremely small percentage of cases, while gonorrhoea and diphtheria may cause great damage to vision in a large percentage of cases. The making of a true diagnosis not only gives one an idea of the contagiousness of the affection, but it also gives one knowledge of the proper measures to be employed in the treatment and makes it possible to form a correct prognosis. For these reasons, if any uncertainty exists regarding the kind of conjunctivitis, a microscopic examination of the secretion should be made.

Different forms of treatment are necessary for all of the different varieties.

In the mucopurulent conjunctivitis due to the pneumococcus, the milder cases recover within a few days if ordinary cleanliness is observed. It is well to have the eyes cleansed with a 3 per cent. solution of boracic acid every one or two hours, or sufficiently frequently to remove the secretion as it forms. The application of cold to the lids in the acute stage is sometimes gratifying to the patient.

RATIONALE OF MOIST COLD APPLICATIONS.

In considering this matter, it is well to bear in mind

the thermal conditions under which the pneumococcus, Koch-Weeks bacillus, gonococcus, and Klebs-Loeffler bacillus develop. The thermal range of development of the pneumococcus is between about 55 F. to 110 F.; of the Koch-Weeks bacillus and the gonococcus, 88 F. to 110 F.; of the Klebs-Loeffler bacillus about the same as the pneumococcus. The object of cold applications is really to inhibit the growth of the specific micro-organism. This can be accomplished in the cases of conjunctivitis caused by micro-organisms that do not develop below 88 F., as by cold applications the temperature of the conjunctiva may be reduced, approximately, to 92 F. In cases due to micro-organisms that develop readily below 92 F., cold does little good.

APPLICATION OF MOIST HEAT.

Moist heat applied to the lids can not be employed to raise the temperature of the conjunctiva above 110 F., seldom above 102 F., consequently it is of no value as an agent to inhibit the growth of the micro-organisms concerned. It is only of value to assist in disposing of effete material, plastic or otherwise, which may be present in the tissues by rendering the flow of blood and lymph more free.

GENERAL TREATMENT.

In pneumococcus conjunctivitis, cold applications, when applied, should be made for from one to two hours at a time with intervals of from one to three hours, as desired. In these cases, if severe, a solution of a salt of silver in water (protargol 10 per cent., or argyrol 20 per cent.) should be dropped into the eye two to four times daily. When the subacute stage is reached, the protargol and argyrol should be discontinued, and, in addition to the cleansing of the eyes with boracic acid solution, an application of nitrate of silver (0.5 per cent.) may be made to the conjunctiva once daily if required. Experience has proven that protargol, and to some extent argyrol, leave the conjunctiva in a slightly thickened condition if their use is persisted in long after the acute stage has subsided, and that some other astringent, particularly the nitrate of silver, will cause the conjunctiva to return to a normal condition very much more rapidly.

The conjunctivitis due to the small bacillus requires similar, but more energetic treatment. Cold applications are positively indicated in the acute stage. They should be made for from two to three hours at a time, the interval between periods being from one to two hours. The cleansing of the eyes must be performed more frequently and the solution of silver salts also used more frequently.

In the conjunctivitis due to the gonococcus, similar measures may be employed in a somewhat more vigorous manner. The solution of protargol should be 15 to 20 per cent., and the solution of argyrol 30 to 40 per cent. The solution used should be freely dropped into the eye every two hours in severe cases during the acute stage, somewhat less frequently in the milder cases. Cold applications should be made for a longer period of time and the intervals should be shorter. The tendency of the lids to become glued together may be combated by the introduction of borated vaselin (5 per cent.) or bichlorid vaselin (1-3000 to 1-5000) into the conjunctival sac three or four times daily. The conjunctival sacs should be cleansed with a solution of boric acid sufficiently frequently to keep them free from secretion. In addition to this, the urethritis or vaginitis that may exist must also be treated.

The results after treatment of this kind in gonorrhoeal ophthalmia occurring in children is almost always satisfactory. Corneal ulceration may be obviated in perhaps 95 per cent. of the cases.

In diphtheria of the conjunctiva the treatment is altogether different and consists in the early administration of diphtheria antitoxin in sufficiently large dose and sufficiently often repeated to cause the membrane to disappear and to bring about rapid amelioration of the symptoms. In addition to the use of the antitoxin, cold applications may be made for two hours at a time with intervals of one hour during the acute stage, should they prove agreeable to the patient; they will have little influence on the course of the disease. The eyes should be cleansed frequently by means of boric acid solution. Accompanying nasal or faucial diphtheria should, of course, receive attention.

In diphtheria of the conjunctiva, the results depend entirely on the stage of the disease at the time of the commencement of treatment. While diphtheria of the eye before antitoxin was known caused destruction of the cornea in perhaps 95 per cent. of the cases, it is now possible to prevent any affection of the cornea in almost, if not quite all, of the cases by the proper use of antitoxin, provided the patient comes under observation before the cornea is involved. If ulcer of the cornea is already present, its progress may be arrested within twelve or twenty-four hours, and the damage done can be materially limited.

DISCUSSION

ON PAPERS OF DRs. CLAIBORNE AND WEEKS.

DR. ARTHUR G. BENNETT, Buffalo, N. Y., indorsed Dr. Claiborne's remarks about the apparent stupidity of school children who are suffering from errors of refraction. In connection with Dr. Burrows, he examined all the pupils of the truant school in Buffalo. There were 66 pupils, and the great majority had marked defects of vision. Three had strabismus. He told the principal of the school that it was the absolute duty of these children to play hookey. The nervous strain was greater than they could carry. The result of treatment in these cases was very satisfactory, excepting in those who were mentally deficient. The majority were much benefited by proper correction of the defective vision. Dr. Bennett has recently seen three very pronounced cases of cyclic vomiting. In one he discovered a very grave error of muscular balance, the correction of which by glasses gave marked relief. In this case the child was nervous and undersized. In another similar case an absolute cure followed the correction of a small degree of compound hypermetropic astigmatism. In this case the vomiting had recurred every two months for two years, at least. In the third case, which was lost sight of, he discovered by objective measures 2 D. of hypermetropia. At the Craig Colony for Epileptics, although only one case was apparently cured by correcting the errors of vision, the number of attacks in the aggregate was materially diminished. Dr. Gould and Dr. Bennett examined 100 patients in five days, and the work could not be satisfactorily done in so short a period of time. Dr. Bennett believes the statistics showed a reduction of 35 per cent. in the number of attacks for one year. Certainly the patients in whom the attacks did not stop were made much more comfortable. He doubts whether true epilepsy is ever cured by eye treatment, but believes that many of these patients are made more comfortable by correcting the errors of vision, and a certain number, in which there is an epileptiform condition, which is many times regarded as true epilepsy, are absolutely cured.

DR. ISAAC A. ABE, Chicago, asked Dr. Claiborne at what age he would correct refractive errors. Parents are often conscious of these errors of vision in their children, but they usually prefer to postpone treatment until the child is old enough to go to school.

DR. SAMUEL J. WALKER, Chicago, has seen numerous cases which would probably be described as cyclic vomiting, but he has never seen a case of what he could call by that name. The cases he had in mind were always associated with other features, such as loss of appetite, disinclination to play, marked depression, and in some cases even a stuporous condition; these symptoms practically always preceding the vomiting by from six to twenty-four hours. Several years ago in a paper on migraine he gave it as his opinion that cyclic vomiting, so-called, is in reality an atypical form of migraine; and in the discussion following the paper, several men agreed with his view of the question. His experience with such cases since then has tended to confirm that view. We all agree that all abnormal conditions should be corrected, and that errors of refraction and any other abnormal state will precipitate attacks of epilepsy or migraine, or serve to make the attacks more severe in character, but that refractive errors can be a fundamental cause of epilepsy or insanity, is in his opinion not tenable.

DR. HERMAN JARECKY, New York City, said that at the Manhattan Eye and Ear Hospital and in his clinic at the Sydenham Dispensary, so far as he could see, in no case was the chorea cured by correcting the eye errors. In these cases there is apparently a lack of general muscular balance; the whole system seems to participate in the condition. The child should be taken away from school, given proper tonics, etc. He should insist on refraction in every case where the error is at all marked. In those cases where the error is slight, it may be allowed to go uncorrected, and the majority do not require glasses. It is a serious question to put glasses on very young children, and while he does not hesitate to put them on, yet in those cases of astigmatism where the error is slight, he believes it should be corrected until the child's general condition improves under the combined influence of systemic treatment and the use of proper glasses. Then the glasses should be discontinued in a number of cases, and if there is further weakness shown, the errors can again be corrected. He has never seen epilepsy or insanity improve after the correction of eyestrain. He has seen certain cases of chorea helped by attention to the eyes, but the general care of the choreic will depend on the pediatrician and not on the ophthalmologist. While in a certain number of cases glasses must be worn all the year round, he never insists on their use during the summer months, when the children are romping in the country.

DR. CHARLES G. KERLEY, New York City, asked Dr. Claiborne how many cases of cyclic vomiting he has relieved by correcting refractive errors.

DR. J. H. CLAIBORNE, in replying to a question, said that he has not seen a great many cases of cyclic vomiting, but has come to regard it as an exceedingly difficult condition to cure. He also looks on it as an atypical form of migraine. The only suggestion he makes in regard to these cases is that the possible coexistence of refractive errors should be borne in mind, that they be completely corrected under atropin when found, and that careful records of those cases be kept, and a subsequent report made regarding them. Dr. Claiborne has never seen epilepsy cured by the correction of refractive errors. He believes that the effect in such cases is a distinctly moral one. Couple personal magnetism with a bloody eye and a distinct impression is made on the nervous system. He usually takes glasses off children during the summer. Eyes have much to do with the nervous system, but not everything. When the children return to their lessons in the fall glasses should again be worn, and in cases of myopia or astigmatism they should not even be removed during the summer. He has never seen a child injured by breaking its glasses.

War Prices on Drugs.—Alcohol, carbolic acid, picric acid, anise seed, cinnamon bark, ergot, camphor, menthol and lycopodium are mentioned by *Meyer Bros.' Druggist* as affected in price because of the war. It is stated that a barrel of alcohol is consumed every time a thirteen-inch gun is discharged. Carbolic acid and picric acid are necessary ingredients in the manufacture of modern high explosives.

PROPHYLAXIS.

ITS VARIOUS PHASES IN RELATION TO CONSERVATION OF

THE TEETH.*

CHARLES F. ALLAN, M.D.

NEWBURGH, N. Y.

I want to make a broad distinction between reparative and restorative operations, and to weigh relatively the importance, from a tooth-saving point of view, of some prophylactic measures.

Broadly speaking, prophylaxis, the prevention of disease, should be the highest aim of the physician. In our specialty of medicine we are nearer, perhaps, concrete facts than the general practitioner; the organs that furnish us our principal work are in sight and lesions are generally visible and within reach, and possibly it is not asking too much of the average patient to expect more of us in the way of prevention than in the warding off of disease by the family physician. Certainly if we do not accomplish quite as much, we are very culpable.

Prophylaxis is prevention—prevention of what? Not simply the loss of teeth by caries, nor added to it the loss of few or many teeth by pyorrhea, but it means the prevention of the loss of the full comfortable use of thirty-two teeth through the whole or main part of possibly a long life. I do not think this at all a too high ideal to have before us. At present, in a large majority of cases, we certainly will not reach to this standard.

The great controlling factor in relation to immunity or non-immunity from caries has reference to the condition of the secretions of the mouth. We are now in the early stages of our examinations in the histo-chemistry of the saliva, and though we have a limited knowledge of the conditions making for decay, we are as yet unprepared and unable to change those conditions to one of immunity. Often we will not have the complete support of the patient in the matter of hygienic cleanliness, without which we are powerless to accomplish the best results; and it will also generally be impossible for any one person to have the consecutive management of many mouths extending over a series of years dating from childhood, without which the best services can not be rendered.

Still, prophylaxis is steadily gaining; hygienic cleanliness is being more and more insisted on by the dentist and more and more practiced by our patients, and this greatly offsets environment. With better modes of treatment and a more careful living up to the high ideals of Nature, we have every reason for encouragement.

The high standard of success here outlined in the salvation of the teeth involves of necessity a knowledge of the perfection of the normal conditions of the tissues and organs of the mouth; this in the environment of the teeth, in the teeth themselves and in their arrangement, and in the relation of the teeth of one jaw to the teeth of the opposing jaw.

I have placed at the head of these phases of necessary normal conditions that of environment; and yet if I am asked to describe what I consider a normal environment, mainly, of course, with reference to the juices of the mouth, I can only say I can not tell. So far the chemical constitution of what may be called normal

saliva has, to my knowledge, never been described and I think can not be; that is, in its exhaustive and ultimate analysis within the varying limits of what still may be termed normal.

We occasionally hear of the rare case of an aged person who has never been to a dentist and who never has lost a tooth, and very, very much more rarely we meet such a person, but in what respect the saliva of this *rara avis* has differed from the mouth secretions of the ordinary individual we do not absolutely know.

We do know that Dr. Michaels (to whose investigations in the histo-chemistry of the saliva I will shortly refer) found that a hypo-acid condition of the saliva was generally associated with rapid destruction of tooth tissue, and the hyper-acid condition was associated with comparative immunity from decay. The researches of Drs. Kirk, Kyle and others confirm those of Dr. Michaels. We know also that the immunity from caries in the rare cases I have referred to has not been as the result of extraordinary cleanliness. The deduction seems obvious.

The researches of Black, Williams and others have proved to us that, in the main, the physical conditions of the teeth of different individuals of adult age are substantially the same, and the facts that are before us every day, showing the wide difference of conditions of tooth preservation, all point to a cause for tooth destruction outside of the teeth themselves; this means, of course, in their environment, and this is now universally recognized.

In August, 1900, before the Third International Dental Congress, Dr. Michaels of Paris read a paper on "Sialo-Semciology," which was a record with deductions therefrom, of a long series of examinations and analyses in connection with the histo-chemistry of the oral secretions. The limits of my paper preclude even a résumé of this paper, but he clearly proved the intimate relation of immunity from caries with certain conditions found in the saliva, and he found radically different conditions of the saliva where caries in a mouth were rampant.

Though by no means exhaustive, Dr. Michaels' investigations were most carefully made, and his results and deductions have been amply confirmed by other investigators.

To quote a truism of medicine put in simple words: "It is a well-known clinical and laboratory fact that a study of the products of the secreting organs, which in their excreting functions throw off waste material, gives us by deduction a fair idea of what process is going on within the body." This being true, why, as an index of systemic condition, would not the study of the saliva give as good an idea as the study of the urine, especially as the latter is solely a waste product, while in the saliva, swallowed as soon as excreted, we have products of metabolism which return into the system as a part of a physiologic process?

The bearing of all this on tooth destruction is, of course, even more intimate than I have suggested above in connection with general systemic conditions, for the teeth are bathed in the secretions of the mouth and are exposed continuously to the fermentative and bacterial results of their environment.

The present relation of prophylaxis in this connection is as follows: We know the distinctive condition of the saliva, as found by Dr. Michaels and others, when related to rapid decay of the teeth; we know another distinctive condition of saliva seemingly always associated with immunity from decay; but I am afraid to

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

say that as yet we know how to influence nutrition to that point that we can change the one undesirable condition to the one that means tooth preservation.

The study of the histo-chemistry of the saliva is one involving organic chemistry of the most intimate nature, and requiring an immense amount of laboratory detail and the study of formulae and analyses requiring any amount of time. The advance already made is very great, and the introduction of the micropolariscope, according to Dr. Kirk, is a most valuable aid. To know the actual condition from which we require relief is a great point gained.

Drs. Kyle, Milligan and others, in connection with hay fever, ozena and diathetic and nervous diseases of various kinds, have gathered diagnostic indications from the saliva that have secured successful treatment and have proved to them of the greatest professional value. We are pointed in the right direction, with a solid substratum of facts to work up from. Laborers in this field are very necessary, and the reward, how to help secure immunity from caries, is the greatest that can be put before the dentist.

We can not conceive of any period when absolute hygienic cleanliness in the mouth will not be necessary, but up to that time in the future when we shall be able to change by treatment the destructive character of the mouth secretions, this same hygienic cleanliness, as advocated and practiced by its well-known exponent in Philadelphia, is, and will be, our best sheet anchor for the preservation of the teeth. So much has been written by him, and his principles and practice are so well approved by the profession in the main, though not in all details, that it would be supererogatory for me to add any words.

Normal occlusion, that is, occlusion as opposed to mal-occlusion, as described so well by Dr. Angle in his record work on "Orthodontia," is a very necessary factor in prophylaxis. The knuckling up of the several teeth against one another, thereby securing for each tooth under stress the support of all the teeth of the arch, is most necessary and most helpful, and is provocative of comfort and tooth preservation. Now, when we add to this the perfect normal relation of the teeth of the mandible to the teeth of the upper jaw, that perfect relation of the planes and cusps of the teeth of the two jaws to one another, we have an ideal arrangement, a perfection of mechanical adaptation and artistic lines better than which we can not conceive of; so, when we have before us a case of mal-occlusion to correct, it is this perfect ideal we must try to work up to, and we must always remember that the Almighty found thirty-two teeth none too many for the purposes of his perfect work, and it is not at all likely that we can do as well with less.

Now, the practical application of this matter of normal occlusion to prophylaxis lies in the interdependence of one tooth on another, as mentioned above. It lies in the fact that each tooth in a normal arch is necessary to the best welfare of every other tooth, and that you can not remove one tooth without injuring all. The natural tendency of the back teeth, in the absence of mesial support, is to move forward, and unfortunately that tendency is not to move *en masse*, but to follow the line of least resistance and seemingly pivot on the ends of the roots, the crowns tilting, with the effect of not only destroying to a great extent the mutual support of adjoining teeth, but also destroying more or

less that perfect relation of the teeth of the two jaws to one another.

All irregularities of the teeth, and especially all losses of teeth, are provocative of further trouble. The proper interdigitation of the cusps of the teeth of one jaw in the sulci of the teeth of the opposing jaw is interfered with, the area of masticating surface is reduced, and what remains is usually not in as good condition for service. Some of the teeth no longer have the stress of use along the line of the axis of the roots, and the tilting continuously increases. The mal-occlusion affects also certain teeth that otherwise would be in normal health by putting on them unusual strain, and that strain in a direction the teeth are not expected to bear, with the result of loosened teeth in diseased sockets. The tendency of all such mal-occluded teeth is to get lame and loose and to be early subjects for pyorrhea, and in the end the forceps. Teeth irregularly placed in the jaws are difficult to keep clean, and are much more prone to caries, and in more ways than I have time to speak of mal-occlusion tends to tooth loss. Proper occlusion, especially when attended to early in life, is an eminently important factor in prophylaxis.

Tooth loss is mainly occasioned by departure from the high ideals established for us by Nature. The teeth, generally erupting with normal shapes and with normal structure and physical conditions, are, by reason of perverted environment, subjected to caries. Caries generally means repair and, in the fullest sense of the word, should mean restoration; and it is this in many cases incomplete repair and hardly at all restoration that is a great cause of tooth destruction. To give a broad generalization in one short clause, we should live up to Nature.

All of these many years, in which we have made so many and great advances as a profession, we have been handicapped by the fact that we have had no filling material that was at all ideal. Amalgam, tin, gutta-percha, cements, have all done us great and good service, and above all gold. The latter is a royal metal, and has done our patients a royal amount of good, but restoration has been a restoration of contour only; not a restoration of color and appearance; not a restoration of thermal non-conductivity; not a restoration of the vitreous polished enamel surface which is of such immense importance; and this lack of restoration has generally been at the expense of serious distress to our patients; often of serious physical and nervous strain to the operator. Drs. Varney and Webb, and others as well, practically gave their lives to establishing their high ideals of tooth restoration, and then their ideals failed in the above-mentioned serious respects. All glory to them, however: they were in advance of their fellows, and we are greatly better dentists by having had their ideals to work up to.

Now the relation of all this to prophylaxis lies in the fact that in just these important matters in which tooth restoration fails with gold, it is a success with porcelain. The vitreous polished surface, practically continuous with the enamel surface, the non-conductivity of the material, its comparative ease of insertion at an immense saving of time, pain, and nervous strain, are all important respects in which the prophylactic value of porcelain transcends that of other materials.

Again, I can not go into details, but it is entirely practical in the great majority of cases to fill the occluso-proximal cavities of the bicuspid and molar teeth with porcelain, at a great saving of strain and pain to the patient, with a perfect restoration of contour made in

the furnace and not in the patient's mouth. Some of you, I fear, will dissent from this statement, but I want to go on record as saying that it is practical, and that such restorations, if properly made, will be permanent.

For the sake of brevity, I have instanced only occluso-proximal cavities because they are, possibly, the most difficult and the necessities of such cases are greater, but the principles involved are the same with all proximal fillings, and the essential saving conditions are just as evident.

The last few years have developed an immense amount of literature on prophylaxis, but it has been of the narrow kind that has seen but one phase of the subject, and for that has claimed the earth. All of you know that prophylaxis is many sided—has, indeed, many more sides than I have had time to indicate—and that though hygienic cleanliness is one phase, and that a very important one, it is still not all there is that stands for the prevention of the loss of the teeth.

The investigations of Michaels, which include an immense amount of painstaking laboratory work, have opened up a field of activity whose promise is very great.

In the language of the very reserved and modest claim made by the eminent editor of the *Dental Cosmos*, "Dr. Michaels has thrown a ray of scientific light on the problem of dental prophylaxis and has clearly indicated the direction from which greater light on the problem may be expected to come."

Dr. Angle in his great work on mal-occlusion has treated his subject in a scientific manner quite beyond anything hitherto attempted, and in the simplicity of his classification and in the clear idea he has given us of the ideal we are always to work up to, with methods and apparatus most simple of use, has given the profession great aid in treatment, which in so many cases makes for prophylaxis.

To this should be added a word of tribute to the enthusiastic and earnest labors of Dr. Jenkins, stretching over many years and all to the end that tooth structure might be imitated and that tooth repair might mean tooth restoration in the fullest and best sense of the word.

Other names could be added to this brief list, but these I have mentioned seem to me typical of the best, in that they have obtained their important results only because of great labor, backed up by most earnest enthusiasm.

It is such enthusiasm that in the end will conquer for tooth salvation. It is such enthusiasm that always conquers.

43 Montgomery Street.

CHANGES IN THE SALIVARY SECRETION, AFFECTED BY SYSTEMIC DISEASE.*

HEINRICH STERN, M.D.

AND

WILLIAM J. LEDERER, D.D.S.

NEW YORK CITY.

Compared to other subjects of interest to the stomatologist, only a few papers of practical value have appeared on this subject as yet. Various experiments, and conclusions drawn therefrom, are scattered throughout medical literature, but these are of no great practical value, as the investigations were carried on at dif-

ferent times, under varying conditions and on different subjects.

The task which the writers have undertaken is to study the saliva in a number of systemic diseases under as analogous conditions as possible, which is rendered more difficult by the fact that the literature existing on the subject is so little congruous and the results so far obtained are at a great variance.

For example, if we study the investigations of the saliva in febrile conditions, what a chaos confronts us. If investigators do not agree on the modifications of the salivary secretion in so ordinary a condition as a febrile disturbance, how much more lacking in unity must be the results of investigations of the oral fluid in chronic affections which present so many different phases and aspects.

The conclusions of this paper are the results of investigations which were carried on under as uniform and congruous conditions as possible concerning the saliva in: *a*, diabetes mellitus; *b*, uricacidemia; *c*, gastric disease.

It is not our intention to enter into the details of this vast subject, as time is limited, but we simply present the results of certain examinations, which will be fully described and published in various journals at a later period.

Before studying the salivary secretion as it becomes modified by systemic disease, it is, perhaps, not out of place to define normal saliva.

Saliva, in the strictly physiologic sense of the word, implies the secretions of the parotid, the submaxillary and sublingual glands. Ordinarily, however, the term denotes the aggregate secretions of all the glands pouring their contents into the buccal cavity; the sum total of all these secreta shall be spoken of as saliva in this paper, as it is impossible to obtain saliva in that condition in which it is secreted by the salivary glands proper, and before it becomes admixed with the other fluids and factors introduced into the mouth.

In order to collect any amount of saliva for measuring or examination, it becomes necessary either to introduce a sponge into the mouth to collect the fluid, or to instruct the subject, from whom the sample is to be taken, to keep the mouth open for some time, without swallowing, so as to permit the secretion to accumulate. Anything or any method that may be employed to collect the saliva directly, will act as a stimulant to the gland, by contact or reflexly, and when nothing is employed and the mouth is simply kept open, the muscular exertion of keeping the jaws apart, the air striking the oral mucous membrane, as also the psychical influence, will act as stimulants, and the saliva obtained is not true physiologic saliva, but saliva obtained by stimulation; hence the output of the gland is augmented and more fluid is obtained than would be secreted without the stimulant. However, as the fluid medium is but water, and the chemical factors and active principles are held in solution or suspension therein, it will facilitate matters, by only considering these organic and inorganic constituents of the secretion, irrespective of the solvent medium, and to define physiologic normal saliva as:

"The total amount of organic and inorganic material, elaborated and secreted by the salivary glands under normal conditions, i. e., without undue stimulation by either drugs or other factors, irrespective of their fluid medium and without the admixture of excessive amounts of histologic elements."

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rheln.

Under normal conditions but varying diet, the glandular cells may be taxed to perform varying amounts of work, for the ingestion of large amounts of soluble, assimilable elements which enter the blood current may be followed by an increased output of salivary solids. As long as the system retains perfect metabolic equilibrium, and as long as no local disease obtains in the salivary glands, it does not matter how large the excretion of solid matter may be. The greater the amount of the solvent medium, up to a certain limit, the more perfect may be the excretion. However, it will always remain an open question whether the salivary solids should be completely excreted, or if a residue in the gland, of the same composition and concentration, is normal or not.

The variations that the saliva may be subject to in health may either be a change in the quantity secreted or an alteration in the composition. In order to ascertain any deviation from the normal, it becomes necessary to establish a standard as normal.

The actual amount of saliva secreted during twenty-four hours has been expressed in varying figures by different authors. However, as the activity of the glands is modified by many conditions, all of which must be considered normal, as diet, amount and nature of ingesta, the manner of eating and masticating and also the psychic condition of the subject, and as all these factors do exert a positive influence on the organism and actually modify the secretion, and as it is impossible to have all these conditions congruous in any two cases, and as the results under unlike conditions must vary, figures are but relatively correct and can not be accepted as the absolutely physiologically correct standard of the amount of fluid secreted. As figures will not express the normal amount of saliva secreted, for stated reasons, it will, perhaps, be physiologically correct to define the normal output of saliva as follows:

"The normal amount of saliva secreted is that which is put out without artificial stimulation (by drugs or any factor that will act as an irritant to the gland directly or reflexly) without the subject being aware of its secretion, irrespective of figures."

Having determined what can be called the normal output of saliva, what will be abnormal and what will be pathologic, and which can be classed as either?

Any condition beyond those productive of normal secretion will, of course produce an abnormal or pathologic action of the gland, but how to distinguish between these two, what is abnormal, what is pathologic?

"An abnormal secretion is one produced by artificial stimulation, as by drugs or any other factor producing an altered secretion."

"A pathologic secretion is one produced or altered by local or systemic disease."

Another property of the saliva that is expressed in greatly varying figures is the specific gravity of the fluid. Inasmuch as this property depends on the amount of solids contained in the secretion it (specific gravity) also is subject to many modifications, and the absolute physiologically correct standard can only be obtained by determining the amount of solids in a given amount of normal saliva.

Experiments in this direction will also appear at a later period.

To study the question of modified saliva from all points of view would necessitate an accurate quantitative and qualitative analysis of the secretion in a normal state and the same examination of the fluid as se-

creted in disease. To do this at the present is impossible, as the glandular activity and the secretion itself are subject to many and rapid changes, so that no two examinations would show like results. Therefore, we confine ourselves to the study of such eventual alterations of the oral fluid which are not accidental and thus may become of practical value to the medical and dental diagnostician.

ALTERATIONS OF THE SALIVARY SECRETION IN DIABETES MELLITUS.

The saliva of 158 cases of diabetes mellitus was examined; altogether 384 tests were made, from which the following data were obtained:

Alterations of the Quantity Secreted.—The amount of saliva was found to be decidedly increased in 6 cases, decidedly diminished in 89 cases, normal in 63 cases.

The subnormal secretion was very likely due to the same causes as is the diminution of the secreta of other glands in this disorder, namely, the increase of the urinary water.

In making these quantitative examinations, the samples were always obtained about two hours after breakfast (except where otherwise stated). In order to avoid any secretory changes due to psychical influences, the patient was requested to expectorate into a watch glass, while being engaged in conversation. This was measured by a standard obtained by taking many hundred samples in the same fashion from healthy individuals. If the patient could not bring forth but a few drops of saliva after repeated efforts, the secretion was called decidedly diminished; if, on the other hand, the amount expectorated would fill or flow over the watch glass, it was termed decidedly increased.

The Reaction.—Acid in 47 cases (215 examinations); alkaline in 92 cases (116 examinations); neutral, 8 cases (14 examinations); not examined, 11 cases.

The tests for the reaction were litmus paper and phenolphthalein.

ALTERATIONS IN COMPOSITION.

Glucose was found in the saliva in 85 cases (181 examinations), and no glucose was found in 73 cases (203 examinations).

The examinations for glucose were made with Nylander's solution, and with phenylhydrazin.

The diastatic quality was found unchanged in about 90 per cent. of the cases examined. A quantitative test for the conversion of amylum into maltose, glucose and dextrin was not made on account of the small amount of secretion obtained at a time.

Trommer's test was employed in these examinations; the tests were made at 40 C.

One gram of amylum was boiled with 10 c.c. of water and 10 parts of the starch solution were mixed with 1 part of saliva and kept at 40 C. To this Trommer's solution was added. If the diastatic quality of the saliva is normal, a yellow precipitate, which later turns red, is formed in from fifteen to forty-five minutes. If the changes take place in from five to fifteen minutes, the diastatic property is increased, and if it takes longer than forty-five minutes for the reaction to take place, the diastatic property is subnormal.

All the cases in which glucose was demonstrated in the saliva were of undoubted genuine diabetic character, and in those cases where glucose could not be found in the oral secretion, although it was excreted in considerable amount in the urine, the glycosuria of some was apparently of non-diabetic origin. The cases of true diabetic glycosuria, after a rigid antidiabetic diet, had been

pursued for some time, so that the urine became free from sugar, exhibited the same changes in the salivary secretion, so that no salivary glucose could be demonstrated after the urinary sugar had disappeared. This fact would evidence the common hyperglycemic origin of the glucose in both fluids. Again, the appearance of salivary glucose is by no means indicative of the severity of the diabetic condition, for the degree of the diabetic condition does not depend on the degree of hyperglycemia. The milder cases of diabetes, at least those cases of well-established diabetes not influenced by dietary regulations, are often characterized by the excretion of very large amounts of urinary and salivary glucose. The reduction of the carbohydrates often causes a secession of the sugar in both fluids. In some of the graver cases of diabetes no glucose was found whatsoever in the saliva on any occasion. In one instance more than twelve examinations were made, and salivary glucose could not be demonstrated. These are the cases where, very likely, secondary glandular changes, sclerotic in character, had taken place and where no secretion whatsoever was going on.

ALTERATIONS OF THE SALIVARY SECRETION IN URICACIDEMIA.

Twenty-eight cases were observed; 59 examinations were made. These cases examined partly manifested symptoms of arthritis urtica, partly of chronic affections of the upper air passages, and partly of contracted kidney and its consequences.

The saliva was found to be increased in not one case; was diminished in only one case.

The reaction was obtained by the same tests employed in diabetics, was found to be alkaline in 52 examinations, acid in 5 examinations, neutral in 2 examinations.

The diastatic quality in but 18 examinations made was found normal 13 times, somewhat subnormal 3 times, and decidedly subnormal twice.

Biliary pigments were looked for at 14 examinations, and demonstrated but once by Gmelin's test.

Uric acid was looked for 59 times, and demonstrated in the saliva but 21 times, the murexid test having been employed.

ALTERATIONS OF THE SALIVARY SECRETIONS IN SOME GASTRIC DISEASES.

All the examinations of the saliva in gastric disease were undertaken after the diagnosis had been made and before treatment had been begun, as medication would influence the saliva both systemically and locally.

Acute Gastritis.—Twenty cases were examined.

The quantity of saliva secreted was found to be increased in 9 cases; in the others, about normal.

The reaction was found to be acid in 8 cases, alkaline in 12 cases; acidity was found to be due to lactic acid in 2 cases. Uffelmann's test was employed (modified, as it has been used in Dr. Stern's laboratory for some years; that is, salicylic acid is substituted for carbolic acid). Twice the acidity was found to be due to acetic acid (ferrie chlorid test), and in 4 cases the character of the acidity was not determined.

Hyperchlorhydria.—One hundred and eighty-two cases examined gave the following results: An increased secretion was found in 27 cases; the others showed a fairly normal secretion.

The reaction was found acid in 71 cases, alkaline in 41 cases, neutral in 5 cases; amphoteric in all others, or in 65 cases—that is, the secretion was both alkaline and acid; in other words, red litmus paper turned blue and blue paper turned red.

These facts are of interest to the stomatologist, as it shows that a hyperchlorhydric stomach does not always produce an acid saliva; also is it important to always use both red and blue litmus paper in testing the reaction of a secretion, as one or the other, used alone, is liable to mislead the examiner.

The acidity was found to be due to lactic acid in 12 cases, acetic acid in 12 cases, lactic-acetic acid in 9 cases, inorganic acid (HCl) in 6 cases (Guinberg's test); in the others it was not demonstrated.

Hyperchlorhydria.—Twenty-three cases were examined.

The quantity of saliva secreted was found to be decidedly increased in but 1 case; the other cases showed a fairly normal quantitative secretion.

The reaction was found to be acid in 2 cases, alkaline in 15 cases, amphoteric in 6 cases; acidity was found to be due to lactic acid in 1 case, formic acid in 1 case.

Pyloric Stenosis.—Fifteen cases examined.

The secretion was found to be increased in 3 cases; balance fairly normal.

The reaction was found to be acid in 5 cases, alkaline in 8 cases; in 2 cases the reaction was not determined. Acidity was found to be due to lactic acid in 2 cases, acetic acid in 2 cases, lactic-acetic-formic acid in 1 case.

REMARKS.

In presenting these data, obtained from over 1,300 individual examinations, we do not claim to have brought forth anything new or startling, but have applied old principles in a new direction, and the results obtained may not be of direct value presently, but they open new avenues for investigation which in course of time may become instrumental to shed light into pathways that at present are somewhat dark, namely, the coherence or non-coherence of systemic and oral disease, what rôle the salivary secretion plays in these derangements, how it is affected by either, and the disclosure of this will entail new, better and perhaps more successful treatment.

DISCUSSION

ON PAPERS BY DRs. ALLAN AND STERN AND LEDERER.

DR. EUGENE S. TALBOT, Chicago—So far as malposition is concerned, the extraction of a tooth or teeth has great influence on the alveolar process and the dental arch. The irregularity of the arch (other than the local causes) is due to an unbalanced nervous system. The teeth that decay the most in this country and Europe are in those persons who suffer with nervous difficulties. They are found in the insane hospitals, schools of idiocy and all institutions for degenerates. In a study of the teeth of nationalities it is found that the English lose their teeth sooner and irregularities are more common among them because evolution has gone on to a greater extent. Decay of the teeth next in frequency is in New England, and in the older parts of the country. Irregularities are also greater there than in the newer parts of this country. In pregnancy teeth decay faster; in neurasthenia the teeth begin to decay rapidly, and the same condition obtains in grief. How far the environment and the saliva have to do with this matter is a question. I believe these factors have something to do with it, but the experiments shown do not indicate the saliva has very much to do with the conditions. If the saliva be at fault, why does the decay not occur except at the approximal surfaces and the crowns? Why does it not occur at certain periods rather than others? These things must be taken into consideration in regard to the general condition of the system. I have been experimenting along certain lines to show from my standpoint why decay occurs in certain mouths more than it does in others. I believe that in disease, pregnancy and in conditions of neurasthenia there is a want of resistance in the pulp which has as much to do with decay as any other cause. It is not often that acidity of the salivary

glands takes place to a marked degree. It is unlike the urine which carries off the waste products. The saliva is a physiologic secretion for the purpose of digestion, and therefore diseased conditions are not expected to be found in the saliva of mouths where changes have taken place in the system, as in the urine.

DR. EDWARD A. BOGUE, New York City—I hope that Dr. Talbot will not regard as unfriendly anything I may say. He has been for years gathering facts. These facts we accept, but not his conclusions. In the past twenty years not a child who has ever come into my hands and stayed there has ever had the toothache or ever lost a tooth. Not only that, but during that twenty years only five adults who have been in my hands have lost a good, firm tooth. Three of these were impacted molars; one was an upper wisdom tooth and one was a right lateral incisor from a lady having an irregular row of teeth from which a number of teeth had been lost already. Dr. Talbot's remarks are so mingled with splendid truth and possible error in his statement that evolution shows loss of teeth that I can not accept his conclusions. Whether the removal of the last molar which has been so extensively practiced is going to result in Nature excluding that tooth is a question. He also says that teeth are not necessary. Perhaps that is true, and perhaps not. For the present time we may look on teeth as necessary for our healthful existence, and the better we can keep them the better it will be for the individual's health. He also said that perfect occlusion was not necessary and that what it had to do with decay of the tooth he could not see. Dr. Talbot says that the English people lose their teeth most frequently and next in frequency the New England people; and he had just said that loss of teeth was especially noticeable in degenerates, ergo, the English people and the New England people are degenerates. That being the case, and these being the head nations of the earth, with them the whole world is degenerating. Dr. Talbot said that the loss of pulps and the destruction of the resisting power of the pulps tended toward decay. With this I heartily concur. He did not seem to know that that is in opposition to the statement of one of our profession who says that teeth do not need pulps after adult life. I also agree that prophylaxis begins as far back as Dr. Rhein has suggested, and as far back as Dr. Talbot suggests in his book, long before birth. And this brings us to Dr. Allan's paper. If the child is born in good health and has a constitution which is adequate to the eruption of good temporary teeth which perform their function in life and are shed at the proper moment and replaced by the permanent teeth in their proper position, there is no reason why those teeth should not last during the threescore years and ten almost without care. I have before spoken of a man 52 years of age who told me he had never had a toothbrush in his mouth. Yet that man's teeth were clean and in good condition. The dental apparatus was so admirably arranged for the purpose of mastication that it not only did that part of the work thoroughly, but in the very act of mastication the teeth were cleansed by the flow of the saliva and by the friction of the food taken in. When civilization came and gave us soft food instead of hard, cooked food instead of fibrous and raw food, it did us a damage so far as the teeth are concerned. I find that where the occlusion and the arches are perfect there is very little decay; and acting on that principle during these last twenty years my results have been attained.

DR. M. H. CRYER, Philadelphia—Dr. Angle and others have used a picture made from a photograph of a negro skull which indicates considerable prognathism to illustrate the typical and normal occlusion of the teeth. In my paper on "Retarded Eruption of the Teeth: Their Liberation and Extraction," will be shown a fairly good illustration of the teeth of a Caucasian, which, in my opinion, gives a better standard than this photograph of the negro. Dr. Allan spoke of the teeth moving forward in the jaws. He said the crowns move forward, while the roots do not, thus causing the tipping of the teeth. In the normal jaw where there has been but little interference with its physiologic functions, the roots will advance in the same proportion as the crowns. The cancellated tissue of the

alveolar process, in which the teeth are developed and retained, moves forward in mass, but when the physiologic functions or any portion of this cancellated tissue has been interfered with by either pathologic means or mechanical appliances, then the crowns may tip forward or twist because the cancellated tissue, holding the roots, is more or less withheld.

DR. N. S. HOFF, Ann Arbor—I think the value of a perfect occlusion of the teeth is one of the most important facts that Dr. Angle has brought into prominence by his work. It has its bearing not only as a prophylactic measure but on operative procedures in filling teeth. Much injury has come to the teeth by the use of amalgams, cements, and other plastic filling materials, because it is impossible to restore the contour of the teeth with them. We all know that amalgam is liable to change form, and that cements are transitory in character. The teeth tip out of their normal positions because an incline plane is made as an occlusal surface where a cusp is the natural condition. There is but one material that can be successfully employed to restore the cusps of the teeth as they ought to be, and that is gold. Many operators prevent recurrence of decay with gold fillings which securely stop the cavity, but the occlusal surface of the tooth is put into such form that it changes its place or position in occlusion. It does not occlude in a proper manner to perform its function. Many a filling, for lack of contour, provides a condition between the teeth which favors destruction of the gum, by irritation, or perhaps ulceration, which may result in so-called pyorrhea, which is often nothing more than an inflammatory condition caused by the impact of food in the interdental spaces. The attention of the profession has not been properly called to the value of restoring the cusps of the grinding teeth to their original form for the purpose of preserving the surrounding gum tissue and also for preserving these teeth in their proper articular relations. Dr. Allan said it could be done with porcelain. I have no doubt it can in a measure be done with higher fusing porcelain, but tendency of porcelain is to flatten in fusing and thus lose the valuable cusps. The crown surfaces are too often made without regard to their articular relations; inlays are made to conform to cavity margins only. The restoration of natural cusps is one of the most important features in operative dentistry, and I would emphasize the necessity for it because I think it is being overlooked in the present agitation for cavity extension, and in the increasing use of the plastics and inlays which are made only to accurately fit cavity margins.

DR. G. V. I. BROWN, Milwaukee—It seems to me that Dr. Lederer is in a way to reach the pith of the question. What we want to know first of all is the relation between urine, an excretory product, and saliva, that which is simply a secretion for a specific physiologic purpose. I believe that the work which Dr. Kirk has done is going to give our branch of this great profession a standing which it has never had, and I believe examination of saliva will ultimately be accepted as one of the standards of physical diagnosis. I speak of it to illustrate the broadness of this subject and to warn against using terms, such as perfect occlusion and various other expressions, that may be construed in a narrow way and misunderstood when they get into cold print. It seems to me that "typical occlusion" and "perfect occlusion" are vastly different. I have an illustration of a condition due to malocclusion pure and simple. Dr. Talbot will tell you the condition is due to degeneracy. Dr. Cryer will tell you that he can prove conclusively the influence of the want of development and the want of symmetry, and both would be right, yet we, in our treatment of the case, depended simply on correction of the occlusion. Another illustration is along similar lines and represents a case of nervous spasm, *tic douloureux*, cured by grinding down the teeth and removal of the pulp. Another is apparently the same condition associated with disturbance of the salivary secretion, which was markedly different from other saliva. Another condition represented is due, as we believe, to miliary tubercle, from which the patient finally died. Another is due to malopposed teeth. We ought to be particular about cataloguing such things all under one head.

DR. M. L. RHEIN, New York City—I sympathize with Dr.

Brown's desire that we should be very particular about our statements. I agree with him about the question of a perfect occlusion. I think that a perfect occlusion is too radical a remark. I have made a chemical analysis of oral secretions in a number of cases of diabetes mellitus and simple glycosuria, but I have never published the result. Dr. Lederer speaks of "salivary secretions." He has no right to make use of that term. It is saliva mixed with oral secretions and to a large extent is the secretion from the mucous follicles. I may be at fault in my criticism.

DR. BROWN—When we speak of a condition due to pathologic change of some organ or organs of the body, and undertake to show that coincident with such disease there may, by examination of the salivary secretion, be determined certain distinct pathognomonic changes in its character under chemical or microscopic study which can be recognized by reaction or the form of crystals, or in any other way as sufficiently indicative to warrant dependence in basing a diagnostic opinion, then it goes without saying there must first be accurate methods of excluding from the tests all results of mixtures with other fluids and agents in the mouth, since saliva, as we recognize it, is a mixed product, and since it is equally true that dependence in leading to diagnosis of more or less remote disease must be placed on results apparent from the true physiologic secretion of the salivary glands, and until this can be done the results must be largely influenced by oral conditions and necessarily variable.

DR. RHEIN—In order to speak of saliva, it is necessary for us to draw that saliva from the ducts or the glands as the catheter would draw the urine from the bladder before it passes through the urethra and is not allowed to come into contact with the urethral glands. The catheter-drawn urine and the ordinary urine are different. In the mouth the difference is still more marked. Dr. Lederer speaks of examining the saliva by having the patients spit. It is impossible for that to be saliva. I have devoted a vast amount of attention to the clinical observation of the fluids of the mouth, and have examined over 5,000 cases of guinea-pigs infected with tuberculosis, and the clinical observation in every one of them was identical, and it has been of such value to me that I can tell a case of tuberculosis of the lungs at once by inspection of the mouth. This is not necessarily saliva. The saliva, so far as we can judge from our clinical experience with the salivary glands, is one that is less apt to be infected by general pathologic conditions than the mucous follicles of the mouth and the other secretory organs which do not excrete materials especially for physiologic functions. Until a method can be evolved by which the secretion from the salivary gland can be examined without mixture with the other fluids of the mouth, all the statistics that Dr. Lederer has presented to us are absolutely valueless. They do not at all correspond with facts according to my observations. The very things he tells us in regard to the acidity and alkalinity in the same line of cases illustrate that there is something substantially wrong. The error lies in the fact that a great many of these cases are of acid reaction from the mucous follicles where there is likely nothing of this kind from the saliva itself. The prophylactic care of the mouth—and I prefer that term to prophylaxis, because I do not think the noun is well adapted to the purpose—has been very well presented to us by Dr. Allan. To preserve the occlusion as nearly akin to perfection as possible, it must naturally be started almost, as Dr. Bogue said, before birth. Dr. Talbot misunderstands my views in regard to the value of the pulp. I have never said that the teeth of adults would be better off without the pulp. No one appreciates the value of the pulp in the tooth more than I do. What I have said is that in a large number of diseases, especially of the arthritic and sclerotic types, when we see pulp disease inviting constant trouble, removal of those pulps is of the utmost value to the patients. I agree with Dr. Hoff relative to the filling up of the cusps so that the occlusion will be perfect. I have replaced the rubber dam many times on an operation to add to the cusps of my molars or bicuspids where I failed to get the occlusion that should be normal under such circumstances. I do, however, dis-

agree with him when he says that only the high fusing porcelains can be used. I have too many cases of the Jenkins body that had been used in bicuspids and molars where I have absolute restoration of occlusion. There is an objection to the use of porcelain in these cases. The number of favorable cases, as Dr. Allan has outlined, is rare, because of the difficulty of obtaining the filling as near perfection as possible. I claim that when a porcelain inlay is inserted it should be so closely adapted to the margin of the enamel that the line is almost imperceptible. If that is not obtainable, a gold restoration is by far the more serviceable.

DR. VIDA A. LATHAM, Chicago—I would like to draw the attention of the section to work done by Dr. Joseph M. Flint in the *American Journal of Anatomy*, Vol. I, No. 3, on the structure of the submaxillary gland. It is one of the most profound histologic researches ever made in this connection. There are new theories, new facts, and new methods of investigation which will certainly make a great difference in our future work. He is now, I believe, at work on the second part of the contribution. I should like to ask, how much do the deposits that occur on the teeth bear on the question of salivary or oral secretions? There are cases where a set of teeth may be typical of that type of person. There has been no disturbance, when suddenly the teeth become sensitive and there is a discharge of secretion from the glands of the gingival surfaces. The condition may be due to the saliva which produces irritation. I have a case now in which a V-shaped piece is dissolved or eroded at the cervical border, and if teeth are extracted the patient is relieved from neuralgia. I simply bring this question up, because there is something in the relation of the deposits of the teeth with prophylaxis.

DR. BROWN—I have been criticised and I want to make myself clear. It seems to me that the remarks are unnecessary, because the author very clearly distinguishes between saliva of the mouth and of the glands. Until we can distinguish these differences which are due to mixture and to other conditions of the mouth, from the saliva pure and simple, we are not warranted in ascribing the condition of the saliva to constitutional diseases.

DR. RHEIN—I think it is wrong to speak of the oral secretions and claim that they are saliva.

DR. ALLAN—It is such investigations as those of Dr. Lederer, involving great labor and serious inroads on one's time, that dignify our profession and lead to practical results. In relation to the use of the word "saliva," which has been so much criticised by one of the speakers, I wish to say that there is the best of authority for such use. Gould ascribes saliva as "the mixed secretion of the parotid, submaxillary and sublingual glands and the small mucous glands of the mouth," and Gould is supported by general usage. Dr. Hoff said that porcelain restoration, such as I have referred to, would have to be made by the use solely of high heat porcelain; but, as Dr. Rhein has so well observed, it can be as well or better done by low heat porcelain and with equally good results.

DR. LEDERER—In answer to Dr. Rhein, I would say that he came in late, and did not hear the first part of the paper, therefore he can not accuse me of using a misnomer. No one has as yet made an accurate quantitative or qualitative analysis of any oral secretion, and as we can only work with what can actually be obtained in a normal condition, we must be satisfied with the mixed secretion of all the oral glands. I think Dr. Rhein is doing a great injustice to humanity at large by not telling how he is able to diagnose tuberculosis and diabetes by simple oral inspection; he is withholding a good thing, of inestimable value, from the general medical profession.

Whooping cough, a disease little dreaded by the laity and considered lightly by the profession, is as much to be dreaded because of its fatality as scarlet fever. It may cause less after-effects than scarlet fever does, but it causes enough serious after-effects to make it a disease to be avoided.—Root, in *Pediatrics*.

PNEUMONIA.

THE VALUE OF INTERNAL MEDICATION AND LOCAL EXTERNAL APPLICATIONS.*

GEORGE DOCK, M.D.

ANN ARBOR, MICH.

In carrying out the part assigned to me on this program I shall try to consider some of the more important aspects as briefly as possible. If in my efforts at brevity I lapse into dogmatism or incompleteness, I must ask your indulgence.

So long as the best method of treating pneumonia is unsettled discussion is proper and experimentation legitimate. I think we can safely assert that the best treatment is not yet established, despite the many articles claiming specific value for various methods. Of these methods it can be said that they give no greater assurance than dozens of others which were looked on in the past as perfect and abandoned as the result of further trial.

In many of the reports we can see the reasons for ultimate failure. Among them can be mentioned: 1. A belief that all cases of pneumonia are very severe and that without the treatment carried out each would run a long and dangerous course. In regard to this it is important to note that mild or abortive cases of pneumonia occur, not often, it is true, but often enough to weaken many small statistics. 2. The fact that many claims are based on small collections of cases, in which the possible errors are necessarily large, and when, as often happens, these small groups are added together the weak points are multiplied. 3. The failure to report unfavorable cases, depending on many things, especially the desire to avoid the accusation of unskillfulness of the use of an inferior preparation. 4. The use of impressions instead of objective descriptions.

There is need of further experimentation in the treatment of pneumonia along various lines, but for those who have not facilities nor inclination for this I would urge, as a fairly satisfactory plan, the treatment of the patient in the light of the natural history of the disease. As I shall outline this, there is nothing novel nor original in either principles or details.

Among the advantages of this method I place first the obligation it imposes of careful examinations in the beginning and at all times in the course of the disease; next, the familiarity it teaches with the action of various details of treatment, so that the physician can carry out promptly and with confidence such procedures as may be necessary, and from past experience recognize when the results desired are being obtained.

I shall speak only of the most important details.

THE NECESSITY FOR REST.

First I place rest, physical and mental. The possibility of a long course, or of serious complications or sequels, makes it wise to conserve all the energy possible. For mental and nervous rest, quiet, the absence of all mental effort, and sufficient sleep, are essential. Regarding the mind, I find it useful to follow the principle that every pneumonia patient is delirious, even when, as we so often see in the case of physicians, the patient is able to carry on complicated trains of thought. Even in these, temporary lack of attention by the nurse may result in overexertion, serious accident, or even death.

DIET.

Proper feeding is important for the same reasons that indicate rest, and as a full meal or an indigestion may cause serious inconvenience to the heart or lungs, the food must be nutritious, easily digestible and given at short intervals. Water is useful, not only on account of the high temperature, but also to assist in washing out the poisons formed in the disease, and in keeping up the volume of the blood. Like the food, it must be given with regard to time and amount, and it may be medicated or flavored, or carbonated, provided the latter does not cause distension of the stomach. Both for comfort and to lessen the danger of infection of self and others, scrupulous care of the mouth is necessary.

MEDICINAL AND OTHER TREATMENT.

In pneumonia, as in most other acute diseases, a cathartic in the beginning often conduces to comfort and saves trouble in the later stage. Calomel is a convenient remedy, but castor oil or other preparations may be used if preferred.

In some cases of pneumonia nothing more is needed than the treatment mentioned, except a faithful and cool-headed nurse and a physician to examine the patient and chart at intervals, noting at each visit the general condition, state of pulse, color, breathing, cough, expectoration, lungs, heart and pleura, stools and urine, mouth and abdomen, and frequently the ears. The examination of the blood for the number of leucocytes is often interesting, but not essential during treatment. The diagnostic value of blood examinations in pneumonia needs no argument, and the cultivations of the bacteria in the blood is of great value in explaining many irregularities and complications.

Often there are symptoms that need attention.

Pain is often severe, either in the chest or abdomen, and suggests the use of morphin. In most cases I find the ice bag will relieve pain just as well, and its use avoids the untoward effects of morphin on the stomach and mental condition. I admit that it requires some courage, and often involves much difficulty to change from the use of the hypodermic needle or Dover's powder to the ice bag, but those who have used the latter will agree with me when I say that one can often see patients crying with pain in spite of liberal doses of morphin, who quickly become calm with the ice bag.

Heat sometimes seems to relieve pain as well as cold, but the latter has other advantages. Among these is the relief of the cough, and the improvement of the breathing.

It is necessary to speak of expectorants, because there are many who believe these are necessary for the removal of the exudate, notwithstanding positive knowledge to the contrary. In some cases there is a complicating bronchitis that can be treated with advantage by expectorants, but in many cases the expectoration and cough are kept up by unnecessary drugs.

Fever rarely requires active treatment in pneumonia. Coal tar antipyretics are with reason reprobated in print, but still used too much in practice. If the nervous or cardiac symptoms are severe, not from the fever, generally, but from intoxication, ice bags or cold coils to the head and heart region, or bathing, are useful. If the symptoms are only moderately severe local ice bags, or coils, with tepid sponging of the body will suffice. If toxic symptoms are marked the full bath, as in the Brand treatment, either beginning at 65 F. or reducing.

from 85 F.-90 F., according to the case, with friction, often gives striking relief to all the symptoms. In some cases insomnia more than delirium requires treatment. Here morphin is useful, a single dose often being sufficient, though a full dose of bromid is sometimes successful.

Tympanites usually yields to simple enemas if treated early as it should be. It may require calomel, turpentine enema or the rectal tube. An ice bag to the abdomen often does good.

Other internal medication is not a regular part of this treatment. Alcohol can be left out without loss. Strychnia is sometimes given, never necessary as a routine remedy, never indicated at a particular day, in all cases, and I can not yet admit its uselessness in circulatory weakness. I consider the heart and vascular conditions as the most important single ones in pneumonia. So-called cardiac stimulants, however, are not always needed, and when they are, the ice bag externally, hot milk, beef tea or coffee internally, come into use before medicines. Hypodermoclysis, often used for circulatory weakness, I shall also not consider, though I recognize the value of the method in introducing water into the body.

As regards external applications, the only routine ones I use are the ice bag and coil. In some cases, old people or babies especially, cotton jackets are used instead, but even in young children a light ice bag, not kept on all the time in all cases, or a cold coil, often seems better than any other treatment I have seen.

The cold bath is invaluable in some cases, but not necessary in all. Blisters are still recommended by some. I used them very thoroughly under one of the most accomplished masters of that heroic school, putting on fly plasters from 9x15 to 12x18 inches, sometimes on both sides, and drawing literally quarts of serum. I have put them on soon after the initial chill. I have never been able to see any shortening of the course or lessening of the symptoms, and pleurisy and pericarditis were as frequent as under other methods. I have occasionally seen less radical counter-irritation, but with the same negative results.

Two or three years ago it would have been unnecessary to speak of poultices in the treatment of pneumonia. They often relieve symptoms, but can usually be substituted without loss by the cotton jacket. Within a short time the poultice has been revived in a new form under the stimulating influence of printer's ink and an amount of physiologic and therapeutic misinformation that would make Rabelais laugh, but must make all judicious therapeutists grieve.

Oxygen is one of the most important needs for the pneumonia patient, but the compressed variety could often be replaced with advantage by fresh air. Nothing can be more paradoxical than the practice of putting oxygen tanks in the sick room, and turning on a few gallons every half hour or so, while all the windows are closed, often battened down with cotton, sometimes an oil lamp burning in the room and not rarely as many people as can find place in it. Open windows, avoiding actual draughts, give much more distinct relief to dyspnea and cyanosis, are indicated on obvious grounds, and should be used. If it seems desirable, the atmospheric kind can be reinforced by pure oxygen, given in an efficient manner, but it is well to ascertain whether the cyanosis, the usual indication for oxygen, can not be relieved by treating a tympanitic abdomen or a dilated heart.

THE PREVENTION AND TREATMENT OF HEART FAILURE IN PNEUMONIA.*

SOLOMON SOLIS-COHEN, M.D.

Professor of Clinical Medicine in Jefferson Medical College; Physician to the Philadelphia General Hospital.

PHILADELPHIA.

"The time to treat heart failure is before it happens." These words, used by Abraham Jacobi in a discussion on the treatment of diphtheria nearly twenty years ago, impressed me forcibly. The maxim applies equally to pneumonia.

From what sources does the danger of heart failure in pneumonia threaten? Its causes are many and their interaction may be complex. There are three principal causes and many secondary ones. The principal causes are, first, the toxemia; second, the mechanical obstruction to the circulation in the lung, causing overburdening and dilatation, especially of the right heart; third, the alteration in the physical and chemical constitution of the blood which, apart from the toxic effect on nervous and muscular action, central and cardiac, predisposes to the formation of antemortem clot. Among the most important of rare causes are hyperpyrexia and a sudden paralysis of inexplicable origin.

THE TOXEMIA.

The old name "lung fever" is, perhaps, better than the modern one of croupous pneumonia, inasmuch as it emphasizes the fact that we are dealing with a general infection of which the local lesion is merely one expression; while the modern term, concentrating attention unduly on the morbid anatomy of the disease, has certainly misled an earlier generation, if not our own, into neglect of the toxic condition which is the source of greatest danger to the patient. The pneumotoxin unquestionably disturbs cardiac and respiratory action much more than does the interference with pulmonary and cardiac function caused by the local morbid process. No further proof of this is wanting to him who, having observed the respiratory distress and the laboring pulse just before crisis, has seen the return within a few hours to tranquil breathing and quiet cardiac action, while the physical signs over the consolidated lung remain practically unchanged. Whether the toxin acts centrally or peripherally, or both, is a question unsettled and of minor importance at present, but that it acts is evident; and from clinical observation I am inclined to believe that its action on nervous tissues, both central and peripheral, is supplemented by a directly depressant effect on the cardiac muscle itself. Thus we have to guard against failure of the central organ of circulation, as well as against widespread vasomotor paresis.

Against the toxin and its action in bringing about cardiovascular failure, effort must be directed from the moment we are summoned to the case. Our chief means of combating it at present is elimination. Hence the value of early blood letting, followed or accompanied by subcutaneous or venous infusion of saline solution, in cases in which this measure can on other grounds be considered justifiable, and of free sweating if a case is seen sufficiently early. Hence also the importance of maintaining free diuresis and excretion generally. Chemical neutralization of the toxin by antitoxin is a measure strongly indicated theoretically, and we may

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Solis-Cohen and O. T. Osborne.

some day be supplied with an efficient preparation for this purpose. The antipneumococcic and antipneumotoxic serums thus far introduced do not seem to meet the requirements.

Other chemical antagonists—natural drugs, synthetics, serums or animal extracts—may be found that, if unable to neutralize the toxin completely, may yet in some measure interfere with its reception by the cells, or its destructive action on them, and it is possible that this will be found to be the explanation of the good effects attributed from time to time to a number of drugs, some of which are still used and some of which have fallen into disuse. We must, however, wait further development of the studies now being made on the action of the specific toxins and the actions and reactions of the animal tissues and juices, before opinions or therapeutic experiments of this kind can be more than vague guesses. A few recent experiences with veratrum viride, so highly lauded on empiric grounds by many experienced practitioners, but whose usefulness, if real, most surely does not depend on its supposed substitution for the lancet, have led me to inquire whether there might not be some principle in veratrum that in part or in whole antagonizes the pneumotoxin or prevents its action on cells, or stimulates the formation of an immunizing body or complement. For whatever reason, veratrum given early and freely and stopped soon, is of proved usefulness. Concerning quinin, from time to time advocated as a jugulant of the disease, the same queries may be raised.¹ These questions, however, I can not answer, nor am I prepared to advocate the routine use of veratrum or of quinin as a means of bringing about an early crisis on the strength of three surprising observations in the course of twenty-one years of practice; more especially as the apparent abortion of the disease in these instances precludes diagnostic certainty. I am, however, willing to mention these observations and to state that I consider them seriously. I am both willing and prepared to advocate strongly the use of a hot bath or any other means available for inducing copious diaphoresis, in any case of either croupous or catarrhal pneumonia, and especially of influenza pneumonia, when seen at a comparatively early stage.

In the late stages, in the dangerous period of the disease, that is to say, about the height of the stage of consolidation, and later toward crisis and after crisis, while the toxic action and its results are still to be feared, forced elimination no longer offers the same prospect of success either as a measure of prevention or as a means of treatment. In the absence of a known chemical antidote we are compelled to depend empirically on drugs that meet the symptomatic indications. To these I shall refer later. At this point, however, mention may be made of a combination of sodium salicylate (10 grains) and sodium benzoate (20 grains) which, given in a pepsinated vehicle every hour or two until the full physiologic effect of the salicylate is manifest, as by *tinnitus aurium*, seems to supplement admirably the effect of the sweat-bath.

THE MECHANICAL OBSTRUCTION TO CIRCULATION IN THE LUNG.

In the early stage, interference with the pulmonary circulation has but slight influence on the heart, but,

as the lesions progress, and especially if large areas be involved, blood begins to accumulate in the right heart, which is not only weakened by the effect of the toxin, but also over-distended by an accumulation with which it can not deal. The left heart, weakened by the toxin, attempts to carry on the circulation against this double obstacle, but labors, and frequently fails. Vasomotor tone being diminished generally, the weakness of peripheral circulation embarrasses the cardiovascular system still further. Here the indication is direct to relieve the circulatory channels of the volume of liquid with which they are unable to deal; and venesection is strongly indicated or, perhaps, even an emergency puncture of the right heart might be justified. It is possible, however, in some degree to prevent this excessive accumulation of blood on the venous side of the body by measures which delay the general circulation and which increase the capacity and regulate the tone of the peripheral arteries, arterioles, capillaries and veins—as counter-irritation, vigorous friction with or without cold water, the use of a precordial ice coil, the use of digitalis, perhaps the use of veratrum, and certainly the use of nitroglycerin and amyl nitrite when vascular dilatation seems most desirable, or of barium chlorid, strychnin, adrenal preparations, atropin, digitalin, perhaps ergot, when it seems most necessary to heighten vascular tone.

THE EXCESSIVE TENDENCY TO COAGULATION OF THE BLOOD.

That the pneumotoxin so alters the chemical relations of the blood as to favor coagulative processes needs no demonstration at this time. I am aware that modern pathologists discard the old theories of death from antemortem clot, but admitting the alteration in the constitution of the blood and realizing the fact that the circulation in the pulmonary artery and its tributaries is obstructed, delayed, and in some places brought to a standstill, the mechano-biologic conditions are present for the formation of thrombi and the suddenness with which death sometimes occurs in patients whose other symptoms have given no intimation of the imminence of cardiac, vascular or respiratory failure, or of general exhaustion, seems to point to the actuality of such occurrences.

In rare cases, pulmonary thrombus, as verified by postmortem examination, has even occurred during apparent convalescence. Measures to maintain the fluidity of the blood are therefore wise. The disturbance in chlorid excretion seems to point to the wisdom of increasing the sodium chlorid content of the blood. Ammonium, too, is known to oppose the deposit of fibrin. In the absence of an efficient antitoxin the old empiric use of ammonium chlorid and ammonium carbonate and the modern use of saline infusion after the method of F. P. Henry, of Philadelphia, to whom credit for its introduction should always be given, seem to have their philosophic justification. Of their practical advantage I shall speak later.

SECONDARY CAUSES OF CARDIAC FAILURE.

The secondary causes of cardiac failure are so numerous that an attempt at systematic study of them and of their indications would be both prolonged and incomplete. It will suffice therefore to indicate briefly a few of the more prominent. When febrile heat rises to an excessive degree (106 F. or more) undoubtedly it aids in depressing the heart. Antipyretic measures, chiefly the application of external cold, are then indicated. I have already referred to the value of cold friction rubs

1. Since this paper was read I have seen a similar suggestion concerning digitalis, whose antipneumotoxic power is said to have been verified by test-tube experiments. The field is a promising one for investigation.

in stimulating peripheral circulation, but this use of cold water is independent of temperature. When the temperature is persistently low, on the other hand, it usually evidences deficient reactive power on the part of the individual, or what amounts to the same thing, from the other side of the shield, a profound and overwhelming toxemia. Eliminative and supporting measures are thus indicated, and among these may even be the external application of heat.

The effect of heat in relaxing the external circulation, and reflexly the pulmonary circulation, may even assist to diminish the effect of mechanical obstruction.

Distention of the abdomen, pressing on the diaphragm, often adds a straw, perhaps a determining one, to the load the heart has to carry. Loss of appetite, deficient digestion, absorption and assimilation—in other words, general want of nourishment—deprives the heart of potential energy. Deficient oxygenation of the blood acts in a similar manner and also perhaps impedes the destruction and elimination of toxins.

Such contributing causes are best met either by general measures or by symptomatic means directed to the removal of the special symptom or condition. Thus turpentine internally, in relieving tympanites, helps the heart. Inhalation of oxygen in maintaining the store of oxyhemoglobin and in relieving respiratory distress and in diminishing the toxemia, helps the heart. Strychnin, in calling forth a greater liberation of the stored energy of the system, compensates temporarily for the deprivation of the potential energy of food. Alcohol, readily oxidizable, may be an efficient substitute for food and thus help the heart, apart altogether from its disputed stimulant and antitoxic effects.

MEDICINAL TREATMENT.

Drugs may be employed with care and discretion to antagonize the results of the toxemia on the cardiovascular apparatus. We recognize two classes of remedies—those used to support the heart and vessels during the progress of the case, and those used in emergencies. Of the former, I have already mentioned digitalis, barium chlorid, strychnin and atropin. Digitalis, of which an efficient preparation must be obtained, may be given as soon as there are signs of hepatization; before this, it is counterindicated, as aconite or veratrum should be used. The dose, the frequency and the persistence of its use, will depend on the conditions present in the individual case. It has the advantage of raising peripheral vascular tone as well as of increasing the force and diminishing the rate of the heart. Often very large doses have to be given to obtain physiologic effect, a circumstance for which a chemical explanation may some time be forthcoming. The infusion, if it can be tolerated by the stomach, is usually the best form, for the sake of the diuretic effect. It can be strengthened by adding the tincture, if necessary. Four-hour intervals are usually appropriate. Barium chlorid (in doses of about $\frac{1}{2}$ grain every 4 or 6 hours) and atropin (1/200 grain every 2, 4 or 6 hours) are useful, more especially for effect on peripheral vessels. In the bronchopneumonia of children, the alternate use of atropin and digitalin hypodermically is often of signal service. Sometimes a combination of atropin and camphor in very small doses—1/2,000 grain of atropin and 1/8 grain camphor—may be given at short intervals (every half hour) with better effect than larger doses further apart. Strychnin is an extremely useful drug to maintain general neurocardiovascular strength, but is also extremely apt to be abused. It should be given alone when there is no special indica-

tion for any of the cardiac and vascular tonics mentioned, and usually should be continued in conjunction when the other drugs are indicated. Small, comparatively frequent doses are needed, the exact intervals depending on special conditions. For this reason the drug should never be put into a mixture, but is to be kept separate, and best in the form of tablet triturates or minute pellets. Sugar-coated and gelatin-coated stock-pills are to be avoided; their solution is too uncertain. The usual dose of strychnin arseniate is $\frac{1}{2}$ milligram (1/128 grain) every hour for ten hours daily. This produces a mild and continuous discharge of nervous energy and avoids violent and exhaustive discharges. For prompt emergency effect, hypodermatic injection is needed, and the dose may be from 1/40 to 1/10 grain (1.5 to 6 milligrams).

Usually, however, strychnin is not the best drug for use in an urgent case of collapse. When we desire to cause, as it were, a prompt artificial contraction in a heart no longer sustained by its natural functional stimulants, there are at our service three more potent agents—suprarenalin, camphor and musk.

Suprarenalin may be given on the tongue or injected in any convenient solution under the skin. Its effect is quick and transient. I have had made by my druggist suprarenalin triturates containing 1/20 grain active principle in a very small quantity of sugar of milk. These are preferable to solution for lingual administration. They dissolve quickly and do not fill the mouth with liquid. Such a tablet may be given every ten minutes, if needed; as a rule, one every one-half hour to two hours suffices. The drug likewise raises vascular tone—a great advantage. Camphor may be injected hypodermatically in a 10 per cent. solution in sterilized olive oil or in 10 per cent. solution in ether. Exact dosage is unnecessary, about a syringeful, say from 20 to 30 minims, can be used. The effect is prompt and usually lasts for some hours. The injection is to be repeated as needed.

Five or ten drops of tincture of musk given hypodermatically exert a powerful influence in overcoming the tendency to cardiac collapse, and the action of musk is even more sustained than that of camphor. Unfortunately much of what is sold in the shops for musk consists of the outer covering of the musk mixed with a great deal of dirt and is therapeutically inert. Real musk is expensive, but is therapeutically potent. One must see that his druggist has the real musk in stock and is prepared to dispense it on prescription, and one must provide himself with a small quantity of the tincture to be prepared for emergencies when the druggist cannot be reached.

In cases in which a cardiac collapse is suspected to be impending it is useful to administer five or ten drops of musk by the mouth two or three times a day in anticipation, and often in successful prevention of such an accident.

The camphor solution and the adrenalin should be at hand for use hypodermatically in any sudden emergency. Compound spirit of ether, in doses of 10 drops every ten minutes, and aromatic spirit of ammonia, in similar dosage, may be used, if at hand, in the absence of the more active agents previously mentioned. Ammonium carbonate is of little use in an emergency, but given with alcohol and liquor ammonii acetatis, after the emergency has passed, may help to avert its recurrence.

Such drugs should be used promptly. An intelligent

nurse being provided, she should be given liberty to employ them at once without waiting to call the physician and without delaying for his arrival. I sometimes think that perhaps cases of pneumonia have been saved by the fact that a resident physician in the hospital or an attending physician in a private house has inspected the patient frequently during the night and has been at call within a few yards of the bedside. The timely use of strychnin, atropin, camphor, amyl nitrite, sup-renalin, or musk, whichever may have been indicated by the conditions present, has enabled the machinery of the patient to continue working under artificial stimulation long enough for crisis to occur and to pass safely.

PRECORDIAL ICE COIL.

The precordial ice water coil is one of the most efficient agents that we have for direct and continued invigoration of the heart in all infectious fevers, and especially in pneumonia. Its efficiency, however, depends very much on the manner in which it is applied. In the first place, the application of a cold coil should always be preceded by a brief application of heat to the precordium. This may be done by applying a hot compress over the precordium and running a current of hot water through the overlying coil for two minutes, after which a cold compress is to be substituted and cold water run through the coil. The cold application is to be continued for from ten minutes to half an hour, according to the effect on the heart as shown by the pulse.

The action, as Winternitz observes, is practically that of digitalis without any of the unpleasant effects of the drug. I am not in the habit of applying cold to the chest as a routine measure in pneumonia, preferring, as already stated, the relaxing and pain-relieving effects of heat, but the application of the precordial ice coil twice daily for from 20 minutes to 30 minutes, does seem to have a steadying and strengthening influence on the heart that is well worth the trouble it causes.

When the precordial coil is not available, hot-water and ice-water compresses or hot-water and ice bags may be used instead.

I have frequently seen the pulse rate reduced by ten beats and strengthened proportionately from twenty minutes' application of cold to the precordium in this manner. The advantage of the coil over the ice bag is that it is less weighty and that it maintains a constant temperature.

Prolonged cold applications should not be used, however, in the late stages when the right heart begins to be overdistended. In such cases brief applications of heat followed by very brief applications of cold, say a hot compress for two minutes, followed by a cold compress for two minutes, are more useful.

Whenever and however used, the temperature and time of the cold application must be carefully regulated and changed according to necessity. No fixed temperature and no fixed time can be laid down. One accustomed to hyriatric applications can judge from the general condition of the patient about what prescription to give on these matters. But even he must work tentatively and observe carefully. More necessary is it for one who is beginning to make his experience to go cautiously. A tentative prescription may be somewhat as follows: Compress at 108 F., coil at 104 F. for two minutes; then, compress wrung out of ice water (32 F. to 40 F.) and coil of 60 F. for five minutes. If this is well borne, the temperature of the water running through the coil may then be reduced to 50 F. for five

minutes more, and if the effect as observed by the pulse is still good, the application may be continued for ten minutes longer. The second application may be made some six hours later and if the preceding application has had a good effect the temperature of this one may be 50 F. to begin with, or may be higher or lower according to what seem to be the necessities of the case. As a rule it is not wise to make a very cold application, that is to say 40 F. or less, for longer than fifteen minutes. An application of 50 F. may be continued for half an hour, or even for an hour in exceptional cases.

NITROGLYCERIN AND AMYL NITRITE.

These are drugs of the first importance in the prevention of heart failure in pneumonia. It is true that unless they are given in very large doses these drugs do not have any relaxing influence on the pulmonary circulation, but their influence on the peripheral circulation does unquestionably diminish the load on the heart, improve the contraction of the ventricle and lessen the tendency to pulmonary congestion. They raise pulmonary blood pressure favorably, therefore assisting both pulmonary and systemic circulation. Especially is their combination with digitalis of use. The attempt should be made to reduce radial tension as appreciated by the finger a little below normal, while at the same time bringing the rate of the pulse distinctly under the influence of the digitalis. In this way the best effect of each drug can be obtained, the work of the heart being lightened and the organ helped. An additional guide to the use of these agents is the effect on respiration and on the circulation in the skin. Reduction in the rate, increase in the ease of breathing and the change from cyanosis toward a normal color of the lips and cheeks are indications of the good effects of the remedies. It is, however, quite possible to abuse these drugs, first, by using them when there is no necessity for their use; second, by giving them in insufficient doses; third, by giving them in too great doses; fourth, by continuing their use beyond the point at which they are helpful. No exact rule can be laid down for this use and abuse. It is a matter of careful observation in the individual case; a question of art, not of science. When the pulse tension is already too low the nitrites are contraindicated. When the pulse tension remains too high, notwithstanding the free use of the nitrites, digitalis is contraindicated. So, too, dependence on digitalis or on the nitrites early or late when venesection is called for, is unwise and prejudicial to the patient. The effect therefore in the individual case and the changing circumstances of the case are to be our guides in administering, withholding or intermitting the use of these agents rather than maxims or theoretic considerations.

HEAT.

The external application of heat is a matter concerning which there has been considerable diversity of opinion. The vogue of the old-fashioned flaxseed poultice and its present desuetude are well known and I shall not discuss the subject in full. From the standpoint of the prevention of cardiac failure, however, I wish to urge strongly the use from the beginning of the case of the external application of heat, and I find a well-made poultice the best means of applying heat evenly and comfortably in such a manner that the application can be kept up with a minimum of disturbance to the patient.

If a cuirass of rubber tubing could be made which would fit snugly to the chest, which would not be heavy

or uncomfortable, and which could be fed with hot water at a definite temperature in such a manner as not to be disturbed by the movements of the patient, it would be preferable to the poultice. But the mechanical difficulties in the way of this measure are quite great. A well made and properly applied poultice will retain its heat for at least four hours and should not be uncleanly. My practice is to apply poultices during the day and to wrap the patient up in a lamb's wool jacket at night so that his sleep need not be broken by the expiration of the fourth hour period nor, on the other hand, a poultice that has lost its heat be suffered to remain in place.

When possible, hot-water bags are placed outside of the lamb's wool jacket in such a way as not to incommodate the patient. I believe that the use of heat in this way tends to equalize the circulation within the bony thorax as well as to relax the external vessels. Also there can be little question that pleuritic pain is relieved by heat more quickly and more certainly than by any other means.

IMPORTANCE OF REST.

In the effort to combat toxemia by elimination or by neutralization or to give relief to pulmonary circulation by any of the methods mentioned, we must not lose sight of the fact that rest is imperatively demanded and that unwise interference by the physician and unnecessary disturbance of the patient by the nurse will do harm by depriving the heart, and the organism in general, of the rest needed. In certain instances, indeed, the necessity will be presented to make choice between undisturbed rest and the problematic good that some measure of treatment may seem to offer. Unless there is a clear indication for the treatment, unless its effect is reasonably certain or unless the patient is in such danger that it is worth while to risk a clearly indicated, but uncertain measure, rather than to let certain death come unopposed, it is wise in all such instances to refrain from interference. One reason why the old-fashioned poultice fell into undeserved disrepute was the fact that poorly made poultices necessitated such frequent change that the evil wrought by the disturbance outweighed the good done by the poultice. Well-made poultices, retaining their heat from four to six hours, however, give so much relief from pain—thus acting as sedatives to the nervous system—that they may be classed among agents promoting rest. Sleep is necessary, and there is a tendency among some practitioners to give opium to relieve pain and to promote sleep. Opium, however, has always seemed to me a dangerous drug in pneumonia, being depressant to the respiratory centers and the heart and possessed of a deleterious influence on excretion, especially through the kidneys. Hence other means of inducing sleep must be sought. Among these the external application of heat by poultice or otherwise is again to be mentioned.

DANGERS OF ANTIPYRETIC AND HYPNOTIC DRUGS.

Ice caps to the head, ice to the nape of the neck, hot applications to the feet, cool and cold sponges, even cold sprinkling and tubbing; in extreme cases, nitrous oxid and oxygen by inhalation; in other words, agents that tend to relieve pain, equalize circulation, soothe the higher nervous centers, ease respiration and diminish toxemia, tend to promote sleep. In the presence of a sufficiently urgent indication, however, when all of these measures have failed and the loss of sleep is among the depressing and irritating influences that tend to exhaust the strength

of the patient and consequently to make heart failure more probable, full doses of bromids, preferably strontium bromid, may be given.

DANGERS OF ANTIPYRETIC AND HYPNOTIC DRUGS.

Such drugs as chloral, chloralamid, trional, sulphonal and *a fortiori* acetanilid, antipyrin and the proprietary abominations such as thermol, antikamnia and the like, are too depressing to the heart to be considered for a moment. Thermol is among the worst of these preparations, and in several cases which I have seen in consultation, and in which this poisonous agent had been used prior to consultation, I have observed a degree of cardiac irregularity and weakness which could not be attributed to the advanced stage of the disease and the profundity of the toxemia or to the mechanical interference with circulation. In some of these cases recovery has ensued on cessation of the thermol, others have died. Death is not unknown in cases of pneumonia in which thermol has not been given, and consequently I cannot say positively that in these instances it was caused by that compound, but I have every reason to believe that the patient's chances for recovery were greatly diminished by its use, and on account of the unwarrantable claims made for this proprietary agent and its rather extensive use in cases of pneumonia (in the neighborhood of Philadelphia at least). I have been impelled to utter this special warning against it. It certainly does no good, and as certainly does much harm—to the heart especially. I have little doubt that in a case wavering between life and death the use of some depressing coal tar product, needless as an analgesic or as an antipyretic, may directly determine the fatal issue. It is also to be remarked that in many cases of pneumonia in which the heart is found to give trouble from the outset, or in which irregularity and feebleness of its action supervene unexpectedly without apparently sufficient cause, inquiry will elicit the fact that the patient has been in the habit of taking trional, sulphonal, acetanilid and other hypnotic and analgesic synthetics for the production of sleep or for the relief of headache. I have little doubt that many of the cases of death from heart failure in pneumonia within recent years, and thus a large part of the increased mortality of this disease, are to be attributed to the self-drugging habit, or, in other words, to the abuse of hypnotics and headache powders.

I wish I could feel sure that the skirts of physicians are entirely clear of blame in this matter. I have frequently had occasion to warn patients who have acquired this habit before coming under my care of the danger involved, and in some instances I have found that patients had begun taking these sleeping and pain-relieving powders either through the original recommendation of a physician or by the advice of a friend or of a friend's friend for whom they had been prescribed. We cannot, of course, be held responsible directly for this indiscriminate prescribing, but we certainly should warn all persons for whom we have occasion to order such drugs that they are dangerous agents, to be used only under medical advice. It is necessary on our own part to be careful not to prescribe them needlessly and not to permit them to be continued for any length of time.

DANGERS OF CHANGE OF POSTURE.

Rest is necessary not only during the period of active disease, but also, and especially, during the earlier period of convalescence. It not infrequently happens that the patient who has safely passed the crisis of pneumonia

and seems on the way toward full recovery, has suddenly collapsed, dying immediately or after some hours of struggle as the apparent result of the mere effort of sitting up in bed. Patients should not be allowed to lift or turn themselves for examination, feeding, evacuations, sponging or any purpose whatsoever. They should be told and trained to remain passive while all necessary changes of posture are gently made by the attendants; even then there should be no unnecessary changes nor any lifting out of the horizontal for any purpose at any time until recovery is thoroughly established. In very many cases this extreme degree of caution is unnecessary. In a few cases it may be the means of saving life. As we have no means of discriminating between the cases in which it is unnecessary and the cases in which it is imperative, until the accident occurs, it would seem the wiser plan to avoid such accidents by considering the caution absolutely necessary in every case.

NURSING SCHEDULE.

In order to prevent even the best of nurses from disturbing the patient too frequently for food, medicine, external application or other purpose, it is often necessary for the physician to write out a detailed schedule with explicit directions as to the time of giving water, medicine, food and oxygen, and of performing the other nursing duties. The more complicated the treatment the more difficult will it be to arrange such a schedule and still give the patient sufficient time for rest. The wisdom, therefore, of simple treatment is evident from this standpoint at least. On the other hand, there should be no hesitation in doing whatever is necessary at any time, the important point being to be sure that the thing done is necessary and then to be prompt with it. This applies especially to the inhalation of oxygen and the use of saline infusion and to the administration of the emergency cardiants. Concerning these, it is to be said that "readiness is all." They may never be needed in the course of the case, but they should always be at hand to avoid the least delay in their administration when necessary.

FOOD.

The diet is an important element in maintaining the nutrition and in keeping up the strength of the heart. In this paper it is not necessary to go into that subject in detail; it is sufficient to say that the food should be such as may be absorbed readily with the least possible demand on the energy of the system for digestion, while producing the least possible amount of toxin necessary to be guarded against by the liver. It should be given in small amounts, at not too frequent intervals. As the patient's sleep should never be disturbed for medicine so it should never be disturbed for food.

Milk, pancreatized, and given to the adult in intervals of about four ounces every three hours while awake, is all-sufficient when the patient can be induced to take it in that way. Alcohol may be added to it in the beginning of the disease and should be added about the fourth day if it has not been used earlier. Koumyss (kefir), junket, buttermilk and other milk preparations, when more agreeable or better borne than pancreatized milk, may be substituted for it. If the patient can be induced to take the milk hot it may suffice to mix equal parts of milk and hot water with or without the addition of lime water. Sometimes a little essence of pepsin given after the milk has been swallowed is useful. But it is unnecessary to elaborate

the subject further. The diet, while sufficient, must not be burdensome.

GENERAL OBSERVATIONS.

The evacuations must be carefully watched and maintained at a little beyond the normal rate. To avoid straining at stool as well as to avoid all danger of constipation, with attendant intoxication or liberation of putrefactive gases and intestinal distention, it is well to begin the treatment of every case with the administration of calomel and to wash out the bowel daily with hot saline solution when this can be done without disturbing the patient, as is usually the case when the nurse is skillful. Sometimes the administration of calomel or a mild saline laxative, or of some vegetable laxative, such as cascara, throughout the case or on occasion, is useful. When tympanites occurs notwithstanding due care of the intestinal evacuations, consequent pressure on the diaphragm increases the load thrown on the heart and thus adds to the factors which are tending toward heart failure. In such circumstances the administration of intestinal disinfectants such as guaiacol, spirit of chloroform, ichthoform, ammonium formaldehyd, acetozone, etc., may be useful. I have seen the greatest benefit, however, from the use of turpentine, or when turpentine fails, the injection into the rectum of milk of asafetida. Hot compresses or a hot coil over the abdomen, or turpentine stupes over the abdomen are sometimes useful.

Elimination of urine must be promoted by the administration of a sufficient quantity of water, given at such periods and in such quantities as will not unduly disturb the patient. Saline injection into the colon may be used when from any reason it is impossible to administer a sufficient quantity of water by the mouth, and it is not considered wise to resort to hypodermoclysis. Indeed, I have often thought that it might be wise to do this as a routine measure, watching the effect on the elimination of chlorids by the urine and endeavoring to restore the normal quantity. The effect of calcium chlorid in stimulating the cardiac muscle suggests the employment of this drug, but, on the other hand, its tendency to increase fibrinogenesis is a contraindication, and for that reason there at least can be no objection to its omission from saline mixtures given under the skin or in the colon.

I have not made a sufficient study of the chlorid elimination and of the attendant toxicity of the urine to dogmatize on this point, but it seems to me deserving of serious study both pathologically and therapeutically. In this connection it may be well to recur once more to the great value of cutaneous stimulation by systematic friction, which may be pleasantly done with alcohol and cold water. This measure has been urged, not as a means of antipyresis, although it does tend to prevent dangerous hyperpyrexia, but as a means of equalizing circulation. A further usefulness remains to be pointed out—nerve stimulation and increase of elimination of toxins both by the skin and by the kidneys. It, therefore, has a deservedly high place among the means of prevention and treatment of heart failure.

The Physician's Greatest Problem.—Patients will take medicine when they will not take advice, and too often it is advice they need and not medicine. The physician whose force and character make his advice sought after and followed is the one who accomplishes the most. He can not ignore drugs, but his success depends on the extent to which he can dominate his patients and correct the omissions, errors and excesses of their lives.—*Vermont Medical Monthly.*

SERUM TREATMENT OF PNEUMONIA.*

J. M. ANDERS, M.D., LL.D.,

Professor of Medicine and Clinical Medicine in the Medico-Chirurgical College; Physician to the Medico-Chirurgical Hospital; Consulting Physician to the Jewish Hospital.

PHILADELPHIA.

The most rational treatment of pneumonia is that which aims to neutralize the pneumotoxins in the circulation. By the side of this object of treatment, efforts to influence the local inflammatory process are subordinate in point of practical importance. It is now universally recognized that the continuous high death rate in this disease is dependent on the toxemia, and that the cardiac exhaustion is to a greater extent due to the same cause than mechanical embarrassment. Recognizing the fact that the principal danger arises from the general pneumococcal infection, the great desirability of finding successful means of combating this source of danger must be obvious.

The effect of antipneumococcal sera, according to the reports of those who have had experience of their use, seems to manifest considerable variety both as to character and extent. A somewhat extended series of observations by a large number of careful clinical observers are now on record, as may be seen by an analysis of the subjoined table.

One point is clear at the outset, namely, that the serum treatment has not, as a rule, been employed alone, but in conjunction with other expectant and symptomatic treatment and the usual supportive measures. Indeed, some observers have used the serum in cases of pneumonia without the slightest success, while others have obtained encouraging results. Unfortunately, too much stress has been laid on individual instances in which the serum treatment appeared to be influential in bringing about recovery. It is reasonably certain that we have no conclusive evidence to the effect that the serum exercises a specific influence in this disease, as will be shown hereafter.

METHOD OF PREPARATION AND STANDARDIZATION.

We are sadly in need of further laboratory experiments with a view to furnishing a more effective product than has been available until the present. The accurate standardization of the anti-pneumococcal serum is a question that awaits final solution. The method of preparing the serum is of great practical importance in order to obtain its best action in this disease. Both Washburn¹ and McFarland² state that practically the same process applies to the manufacture of the antipneumococcal serum as that of diphtheria antitoxin, although, according to the last-named author, it is necessary to cultivate the pneumococcus by a special method.

All investigators have thus far failed to produce a serum that produces antitoxic properties, although it is claimed by some (Lambert, Washburn, Pane et al) that antipneumococcus sera have anti-infectious qualities and may prevent death from pneumococcus septicemia. Thus Lambert's serum (prepared from horses) would invariably protect any rabbit when 1 c.c. was mixed with .001 c.c. of culture and injected subcutaneously. "But, if the pneumococci were already in the blood in sufficiently large numbers to be proven by cultures, even large doses of the serum given for several consecutive days would

not save the animal. It would prolong life, but not save it." W. H. Welch³ affirms that the present stage of progress does not hold out any hope of a protective antitoxin owing to the low vitality of the pneumococcus in artificial inoculation, and, further, that there is absolutely nothing that can be termed specific in the disease. Tyler⁴ has given a detailed statement respecting the leading methods of preparation, to which the reader may be referred for further information.

CONTRADICTIONARY RESULTS OF THE SERUM TREATMENT AND THEIR CAUSES.

Croupous pneumonia is not an uncomplicated affection, in many instances at least. The disease is often to be classed as a mixed infection with the streptococcus. Obviously, in cases of mixed infection with the streptococcus or other micro-organisms, less favorable results are obtained than in simple pneumococcus infection. McFarland and Lincoln⁵ state that in about 15 per cent. of cases of pneumonia the pneumococcus is present in combination with the influenza bacillus, streptococcus, staphylococcus, colon bacillus, etc., and in an additional 10 per cent. of the cases various bacteria other than the pneumococcus. Moreover, still other specific organisms than the pneumococcus may give rise to clinical lobar pneumonia, hence it is necessary to prove the specificity of any given case by bacteriologic studies before accurate results from any form of serum treatment can be obtained.

As a prime preliminary requisite, then, a rigid bacteriologic classification and differentiation of the cases it is proposed to treat, must be attempted, so that the clinicians may eliminate from consideration cases that are clinically identical with the disease, but show some infecting microbe other than the pneumococcus, and this diagnostic precaution would also render the reports on the antipneumococcus serum treatment more trustworthy. One thing is certain, it would be found that the serum is not indicated in all cases in which a clinical diagnosis of pneumonia is possible.

EFFECTS OF THE SERUM ON THE SYMPTOMS AND COURSE OF PNEUMONIA.

An analysis of the effects of the antipneumococcus serum on the symptoms and course of the disease brings to light certain contrasting results and points worthy of record. Most authors who have reported personal experience of the use of serum in the treatment of this disease, invite attention to a slight fall of temperature following the administration as the most constant, although oftentimes slight, effect. In the minority of instances a slight rise of temperature occurred. Individual observers, however, report variable, and even diametrically opposed results. Thus Cooke,⁶ who treated two cases of acute lobar pneumonia with antipneumococcus serum, states that the serum injections were generally followed by some degree of subjective improvement, though no marked effect, either on the temperature or physical condition of the lung, was observed.

Park,⁷ speaking from personal observations, together with a review of the literature, remarks that, as a rule, the cases did better than was expected, "but certainly no striking curative effects were apparent. The cases did

develop pneumococcus blood infection, and it seems probable that the serum may be a preventive of general infection, even though it may fail to influence the local process." Snively⁸ says: "Our own experience with the serum has impressed us favorably. It certainly lowers temperature, relieves pain, ameliorates symptoms, shortens the attack by hastening crisis, brightens the patient, and starts him earlier and more surely on the road to recovery."

A careful review of the reports of those authors who first employed the serum reveals the fact that the doses administered were too small, in view of later experience, to prove of practical utility, and I shall therefore pass over the earlier writers. In recent years, as before stated, a manifest tendency to massive doses at frequent intervals has been observed. Furthermore, the only promising results furnished by the literature have been obtained from the latter mode of administration.

J. C. Wilson and H. F. Page,⁹ as a result of its use in a series of 18 cases, state that the effect on the temperature and respiration was not marked. Defervescence occurred by crisis or by rapid lysis, the average day of normal temperature being the tenth. They conclude that these clinical studies have not been satisfactory, and "it has been determined to abandon for the present the treatment of pneumonia by the antistreptococcal serum in the wards of the German Hospital." Writes Lambert:¹⁰ "The pneumonia serum at present does not seem to shorten the duration of the disease, nor cut short the pneumonic processes in the lungs, nor bring about the desired 'crisis.' But it does seem, in certain cases, to prevent a general pneumococcus septicemia, and thus in these cases it may save life." This observer continues: "I have not persisted in the use of the serum because I could not see that it shortened the duration of the disease nor held in check the pneumonic processes within the lungs. In one or two patients I honestly believe it did marked good; in others it was useless."

The last-named authority refers to favorable results reported by Italian physicians, who found that Pane's turkey serum produced a lowering of the temperature, improvement in the pulse and a diminished death rate, as compared with the results of any other known method of treatment. Per contra, the disease, as a rule, ran the usual course of six to ten days. Those Italian clinicians who expressed contrary opinions seem to have done so on theoretical grounds or have employed it in minute doses. Goldsborough¹¹ confidently affirms that the serum possesses a curative effect if administered early and in large doses. He adds: "I should feel culpable to a great degree had I a case of pneumonia and failed to use the serum."

My own experience of the use of antipneumococcus serum is limited to six cases. In not a single instance did the results justify its employment. The principal effect consisted of a slight primary reduction of temperature, although invariably a rise to the former degree of elevation occurred. A premature crisis was not observed in any case, but, as stated above, a notable delay occurred in two instances. The essence of my personal experience is to the effect that, judged by its merits, the serum treatment, as at present conducted, is undeserving of popular favor.

EFFECT OF THE SERUM ON THE CRISIS.

It may be stated that favorable terminations with

crisis often occur, but there is no evidence of any specific effect in hastening a true crisis. Certain writers have adduced the claim that when the serum is employed early the pneumonic process may be aborted; in other words, that a premature crisis may be brought about at the end of twelve or twenty-four hours instead of the usual period in the course of the disease. In two of my own cases in which the antipneumococcal serum was administered, the crisis was greatly delayed; it occurred on the fourteenth and sixteenth days respectively. Lara¹² has used both rabbit and dog serum in ten cases of pneumonia and affirms that the crisis occurred on the third to the fifth day in all. Lambert employed his own serum in twelve cases of pneumonia; it did not cause a crisis in any case nor seem to cut short the pneumonic process.

If the serum possessed a truly specific action it would tend to bring about a crisis by successfully combating the toxemia and pneumonic septicemia. It is to be recalled, however, that pneumonia is not uniformly due to the same organism, hence no form of antipneumococcal serum could be expected to produce a specific, therapeutic effect (i. e., induce an artificial crisis) in all cases.

It may be reasonably claimed that an efficient antitoxin would induce a rapid fall of temperature or premature crisis. In this way the course of the disease would be greatly abridged and convalescence less protracted owing to the short duration of the illness. Unfortunately, as previously stated, the sum total of human experience with this agent contradicts any noticeable influence on the crisis.

NECESSITY FOR A MORE UNIFORM MODE OF ADMINISTRATION OF THE SERUM.

It is to be regretted that the profession has not adopted a standard mode of administration with a view to obtaining uniformity of results. Since the antipneumococcus serum is employed to neutralize the pneumotoxin, the question of dosage must be one of first importance. The great majority of authors emphasize the fact that massive doses should be administered at the earliest possible moment and repeated at intervals of about eight hours. Says Washburn:¹³ "I would suggest that the injections be made twice a day until the patient is convalescent, and it is important to commence the treatment as early in the disease as possible." Snively found that the action of the serum is favorable, especially in early cases, and markedly so where there is not mixed infection and where a freshly-drawn serum is available, and where it is used in sufficiently large doses. McFarland¹⁴ confirms the same view. He states: "We found that small doses of the serum did but comparatively little good; it should be administered ad libitum until a large total amount of serum is given."

Tyler administered the serum in 20 c.c. doses every six hours in six cases. It was given to pneumonia patients regardless of the general condition of the patient or the stage of the disease. The administration of antipneumococcal serum to pneumonia patients that might be considered hopelessly ill, or at an advanced stage, is not to be encouraged and advised. We may expect *a priori* the serum to yield the best results when administered early or before a pneumococcal septicemia is developed. The best results have also followed the exhibition of large quantities of newly-made serum. Rosen-

Summary (including 61 cases treated with the antiphtheria serum):
 Total recoveries 377
 Total deaths 70

Total cases 447
 Percentage of deaths 15.7

From a review of the literature and personal experience, I have added to the above list of Goldsborough, the following 88 cases:

Cases treated by	No. cases treated.	No. of recoveries.	No. of deaths.	Per cent. of deaths.
Wilson and Rosenthal.	1	1
Wilson and Page.	18	12	6	33.3
Snively	6	5	1	16.6
Little	1	1
Rosenthal	0	0	?	?
Jones	14	13	1	7.1
Bosley	1	1

TOTAL RECOVERIES 73
 TOTAL DEATHS 15

TOTAL CASES 88
 PERCENTAGE OF DEATHS 17.0

In summarizing the cases tabulated by Goldsborough and the figures given in my own table, the following results are obtained:
 Total recoveries 450
 Total deaths 85

TOTAL CASES 535
 PERCENTAGE OF DEATHS 15.9

SUMMARY.

thal¹² has pertinently pointed out that none of the foreign antipneumococcal serums or antistreptococcal serums are reliable, since they must lose their efficacy before reaching practitioners in this country. Fortunately, the antipneumococcal serum is perfectly harmless and does not prevent the simultaneous use of other methods of treatment. Injections should be made into the subcutaneous tissue and strict aseptic precautions should be observed.

CONCLUSIONS.

1. A sufficiently extensive trial of the antipneumococcal sera has been made to determine with a reasonable degree of accuracy their efficiency, and the results, as a whole, fail to carry conviction.

2. An efficient serum, or one that will cut short the pneumonic process, is yet to be produced, although according to some clinicians, the sera available at present have a restricted field of usefulness.

3. Recent observers have employed the serum in massive doses from the commencement of the disease without gratifying results.

4. The practical results of the use of antipneumococcal serum, as shown by the very slight reduction in the mortality percentage, does not warrant its general introduction.

5. The sera thus far found possess no antitoxic qualities, and their supposed anti-infectious properties have not been proven.

6. Further investigations into the subject with a view to discovering an efficacious serum are to be strongly advised and encouraged.

DISCUSSION

ON PAPERS BY DRs. DOCK, SOLIS-COHEN AND ANDERS.

DR. F. R. WEBER, Milwaukee, Wis.—In considering the subject of pneumonia we are apt to conceive of it as a toxemia. It has been referred to as a complex disease, a proteinemia and toxemia. In order to study this disease we must approach it from the point of view of experimental physiology. Observers, especially French, have taught us that the pneumococcus has among its products some which have an especial effect on the arterial circulation. These products, which the French call ectosins, produce a paralysis of the vasomotor nerves. This paralysis is the first thing which we notice in going into the sick-room. There is a peculiar pallor and loss of turgescence of the face; the abdominal viscera appear to be turgid, and we have all the symptoms of vasomotor dilatation. This has nothing whatever to do with the condition of the heart muscle. When the heart muscle is affected we have disturbance of rhythm of the pulse, dyspnea, and the symptoms of beginning myocarditis. In our treatment we should observe particularly this effect of the products of the pneumococcus on the arterial circulation. One can also study the effect of the application of the ice-bag. If the experiment be made with the moist chamber, under proper conditions of heat, the heart of a dog can be kept heating for an hour or more. Defibrinated blood can be passed through the heart, and various medicaments may be added to it and their effects studied. We see that when the ice-bag is used the amount of blood passed into the veins is increased from 30 to 40 per cent. The application of the ice-bag, therefore, increases the work of the heart. The effects of strophanthus, digitalis, barium chlorid and other agents can also be studied. Thus it has been found that digitalis has some effect on the heart muscle, but more on the vasomotors. It also contracts the coronary artery and thus reduces the amount of blood going to the heart itself. We should not, therefore, apply the ice-bag to act on the heart muscle when digitalis is given. Barium chlorid is always reliable; according to German investigators, if three or four

doses a day are used dilatation of the heart muscle and vessels is prevented; it does not interfere with digitalis, and one can keep up the action of digitalis by combining it with barium chlorid.

DR. T. POTTER, Indianapolis—We gain our clue to the study of pneumonia by the study of the crisis, that most remarkable event in its clinical history. The more we study the crisis of pneumonia the more we become impressed with the significance of the toxemia. Aside from any complication that may appear there are three things that stand in the foreground, the embarrassment of the respiration, the mechanical strain on the heart and the evidences of toxemia. The more we study the crisis the less we are impressed with the importance of the mechanical strain on the heart. When a patient has one or two lobes filled with exudation, so long as he keeps quiet he is in no special danger from embarrassment of respiration; but how about the mechanical strain of the heart? Do we not see in cases with large pleural effusion the lung contracted, and yet the heart does not suffer greatly from strain? Even where the effusion accumulates rapidly, if these people keep quiet there is little danger; it is very rare for such people to die of heart failure. Then again we have the treatment of tuberculosis by injecting nitrogen into the pleural cavity, where one lung is quickly made useless for the time, and yet these patients do not die of heart failure. There must be some other cause of heart failure than the mechanical disturbance. At night we leave the patient suffering with dyspnea, with laboring heart, in a condition of great danger hovering between life and death. In the morning we find him apparently convalescent, all the symptoms relieved, but the condition of the lung is about the same. Something has happened in the night that has relieved the strain on the heart, but it is not a change in the mechanical condition. The more we study the crisis of this disease the more we are convinced that we have to deal with a toxemia, and in our therapeutics we want an agent to counteract it. While I realize that the fight we have is a fight for the heart and approve of means for sustaining the circulation, yet what is wanted is an antitoxin for pneumonia that will do what diphtheria antitoxin has done for that disease; and the phenomena of the crisis show what may be expected from such an immunizing agent.

DR. H. C. WOOD, JR., Philadelphia—We might as well confess the truth even though it is unpleasant. The death rate from pneumonia is the same to-day that it was fifty years ago. While the death rate from typhoid fever and other acute diseases is falling off that of pneumonia is the same. I know that Dr. Cohen will say that we are not dealing with statistics but with individuals, but statistics deal with individual cases, and our statistics would be better if our results were. The truth of this is shown by the very bedlam of therapeutics: Veratrum viride, acouite, digitalis, quinin, creosote; in fact, nearly every drug in the Pharmacopoeia has been used in pneumonia. Dr. Anders has just told us that the serum treatment is of very little use in pneumonia. Symptomatic treatment is all we have to fall back on, keeping in mind the toxemia and the strain on the heart. Now, the drug that will carry the patient through the trouble is something which will keep up the power of the right side of the heart. Unfortunately, we know very little of the action of drugs on the right side of the heart. We do know, however, that the great cardiac stimulant, digitalis, does not affect the right side of the heart as it does affect the left side of the heart. I am pleased to know that Dr. Cohen's clinical experience confirms the truth of my laboratory experience. The drug that I have found to have the greatest effect on the right side of the heart is nitroglycerin.

DR. DAVID S. FENK, Harrisburg, Pa.—Dr. Wood spoke of the search for drugs to sustain the right heart in pneumonia. As we all know, there are cases in which the onslaught of the disease is so sudden and terrific that the right heart seems to be overwhelmed because of the resulting obstruction to the pulmonary circulation. This is evidenced by a full bounding pulse, and cold extremities with cyanosis of the lips and face. My experience inclines me to believe that the physician, when

confronted with this condition, is not doing his whole duty unless he practices venesection. I am sure I have seen lives saved by having had recourse to this measure—taking about sixteen ounces of blood from the arm.

DR. W. R. WHITE, Providence, R. I.—I would feel exceedingly gratified if some of the teachers present would refer to that terrible form of acute pneumonia in which the most marked symptom is a type of delirium which is active, violent and apparently beyond control. In almost all the cases that I have seen of this type the end was fatal. It was practically acute mania. The underlying symptoms do not seem to be severe; the pulse is good, the pulmonary signs are not very marked, but the chief symptom is this mania. The patient seems to be overwhelmed by the nervous struggle. What is to be done for these cases?

DR. J. O. STRANAHAN, Rome, N. Y.—We have just heard that the primary effect of the toxins in pneumonia is a paralysis of the vasomotor nerves. One drug that has been useful in my hands in overcoming this effect is ergot, which I use freely in this disease. It should be used in full doses, enough to overcome this vasomotor paralysis. I give two drams of aqueous solution hypodermically every two hours. It keeps up the tension of the pulse. There is always a low tension pulse in pneumonia. My experience is that if you keep this up you do not have dilatation of the right heart. Ergot is the best means of overcoming the delirium which Dr. White has mentioned. I recall a case that had a temperature of 106.3, and the whole lower lobe was consolidated and part of the upper lobe. I gave him two drams of ergot in watery solution. This was given every two hours for forty-eight hours. He showed improvement from the first dose and became more quiet, although he had been highly delirious. His crisis came a little early, on the seventh day, and he recovered. I have had several experiences of this kind illustrating the value of ergot in acute pneumonia. It has proved very efficacious in my hands, and I wish to recommend it.

DR. O. T. OSBORNE, New Haven, Conn.—In New Haven, as in Chicago, we have studied the distribution of the disease in all parts of the city, and have found that pneumonia follows congestion of population. As regards climate, it is more prevalent when there is dust in the air; we found that there is no pneumonia so long as there is snow on the ground. When we take a map of the city showing the distribution of pneumonia and compare it with a similar map of tuberculosis, we observe that they both observe the same law of following the points of congestion of the population.

DR. GEORGE DOCK—I was very glad that Dr. Weber brought out so clearly the vasomotor conditions of the disease, for, although we all speak of it as a condition of heart failure, it is generally admitted that it is not so much heart failure as vasomotor failure that we have to deal with. From that point of view ergot is useful. And from that point of view strychnia also receives support. In regard to the delirium, of course I realize that these cases are extremely serious. Some of these cases have meningeal symptoms, and the pneumonia may be secondary. Many are relieved by the ice-bag to the thorax. They are very good subjects for cold bathing; they may be put in the bath at a temperature of 70 or 65. In older persons the bath can begin at 85 or 90 and be reduced by five degrees each subsequent bath. If one only watches these patients and sees how they are improved, he will have more confidence in the treatment and courage to carry it out.

DR. S. SOLIS-COHEN—The questions of therapeutics in pneumonia can not be settled by any statistics now at our command, because these statistics do not make the distinctions that have to be made. Young persons and old persons, the robust and the weak, drunkards and abstainers, cases of terminal infection in various diseases, pneumococcus and other kinds of general and local infection are lumped together as pneumonia in statistics, and results in cases so varied, thus aggregated, can not be made the basis of any rational therapy. Moreover, the stages of the morbid processes at which treatment of any given order is instituted are not set forth in the

tables. I would welcome a trustworthy antitoxin, but we have none such as yet. We are reduced at present to symptomatic treatment, and because individual cases vary so, we can not observe fixed rules. One patient needs alcohol, another aconite, another digitalis, another venesection, another external heat, another cold bathing, another cold sprinkling. Cold sprinkling will often overcome the delirium in the class of cases inquired about by Dr. White. We get much less objection from the patient and his friends to sprinkling with ice water than to the bath. It should be a very brief application, from three to five minutes, accompanied with brisk friction, and used for effect on nervous symptoms without regard to febrile temperature. In other cases of the kind venesection and saline infusion may bring about marked relief.

DR. O. T. OSBORNE, New Haven, Conn.—It is possible that many reported deaths from pneumonia are not really caused by pneumonia. Since insurance companies are so strict, it may be that a great many deaths from tuberculosis are reported as from pneumonia.

LATENT AND AMBULATORY PLAGUE.

MAXIMILIAN HERZOG, M.D.

Pathologist in the Bureau of Government Laboratories.

Assisted by

CHARLES B. HARE,

Bacteriologist in the Biological Laboratory.

MANILA, P. I.

From the Government Biological Laboratory, Manila, P. I.

On Aug. 21, 1903, Mr. Henry A. Blake,¹ Governor of Hongkong, addressed a communication to the Secretary of State for the Colonies, entitled "Bubonic Plague in Hongkong; Memorandum by His Excellency the Governor, on the Result of the Treatment of Patients in Their Own Houses and in Local Hospitals During the Epidemic of 1903." The writer of the memorandum makes some very startling assertions as to the danger of the spread of plague by animals of the most varied kinds and also comes to the amazing conclusion that there existed in Hongkong during the period of time intervening between June 23 and July 10, 1903, between 8,000 and 9,000 or more cases among the native population, in which plague bacilli existed in the circulating blood in spite of the absence of all clinical symptoms of the disease. The Governor calls this condition "latent plague" and considers it a potent factor in the spread of the disease and a factor which can not, of course, be reached by the ordinary methods employed to limit the spread of and possibly to suppress plague.

Fully to understand the assertions of the Governor of Hongkong it will be well to quote a few paragraphs from his memorandum, which read as follows:

We have from Professor Simpson's report evidence that pigs, calves, sheep, monkeys, geese, ducks, turkeys, hens, pigeons and rats are susceptible to plague, which may be contracted by food or by inoculation direct, or by means of suctorial insects. To this list the examination mentioned above adds bugs, spiders, flies and cockroaches. I may add that quails kept in the market for sale were also found to be infected. In paragraph 22, page 100, Professor Simpson points out that domestic animals suffer from chronic plague and surmises that this is probably one of the bridges by which the interval of the attacks in man is connected. I have for a considerable time been of the opinion that man himself is subject to chronic plague, which may either pass away after a considerable time, or continue dormant over the winter months, regaining activity with the annual movement of spring, when the curve of the epi-

1. Henry A. Blake: Bubonic Plague in Hongkong. Memorandum by His Excellency the Governor on the result of the treatment of patients in their own houses and in local hospitals during the epidemic of 1903. Hongkong. Printed by Noronha & Co., government printers. 1903.

demic is almost constant. This opinion was strengthened by the fact that in August, 1899, the body of a Chinese lift-man at Queen's buildings, who was accidentally killed when attempting to enter the lift while in motion, was found to contain plague bacilli. A similar result followed the examination of a man who, on March 4, 1901, was killed at Tal Koo sugar works by a bag of sugar falling on his head from a height of 20 feet; while on April 2, 1903, in the body of a chief steward of a ship lying in dock, found floating with a large wound on the head, were also found plague bacilli. Early in June several men from H. M. S. *Ocean* were sent to the Naval Hospital, suffering from pneumonia; on examination of their blood seven were found to be suffering from mild cases of plague. In like manner two officers of the Sherwood Foresters who developed feverish symptoms were, on having their blood examined, found to be similarly affected. In the *Boletín Oficial* of Macao, containing the report of the plague epidemic, 1895, Dr. Gomes de Silva, the medical officer who published the report in 1895, stated that during the height of the epidemic he had discovered plague bacilli in his own excreta.

Sec. 21. In June 1 directed Inspector Gidley to obtain as many specimens of blood as possible, on slides secured from the government bacteriologist. He obtained 110 specimens from men, women and children taken at random. These slides were sent to Dr. Hunter for examination, who reported that in five slides he found plague bacilli, and in seven "bacilli were present in considerable numbers, some of which showed bipolar staining. They were not sufficiently distinctive, however, to be regarded as *Bacillus pestis*." These slides were obtained between June 23 and July 10. Since they were obtained there were but three cases of plague in the district, from none of which a specimen of blood was taken.

Sec. 22. I am not unmindful of the fact that these reports were the result of microscopic examination only. But the examination was the same as that on which a great many of the cases treated in the Kennedy Town Hospital were sent to that institution, where their cases ran the usual course of plague invasion.

Sec. 23. Now, putting aside the seven doubtful slides, it will be seen that of those people examined at random 4.54 per cent. were found to be infected with plague, though to all appearances perfectly healthy. If we exclude all the well-to-do, and take the working coolie population alone, they probably number 180,000, and, assuming the same average amount of infection, there are among that class alone 8,172 persons at present infected in Hongkong. If even a quarter of that average be accepted for the 105,000 inhabitants of the superior class, the number of infected will be increased to 9,634. In appendix G will be found the number of rats examined in each month of the present year, with the proportion of infected rats. I am afraid that the incidents mentioned in paragraph 5 weaken deductions as regards Hongkong. But from whatever source the rats were procured the proportion of infection in June was 9 per cent., or 4.46 per cent. more than the percentage of the slides examined; or, if doubtful cases mentioned by Dr. Hunt be included, 1 per cent. less, while in January the proportion falls to .8 per cent. This being so, with the complete circle of vermin, insects, food, rats, domestic animals and man all infected in possibly similar, possibly different, proportion, it appears to me unsound to concentrate attention on the rat as the principal means of bridging over the dormant season.

It appears that Governor Blake, after writing the above, felt the great danger of coming forward with so sweeping an assertion, and in the introduction to his memorandum he himself makes an appeal for a more thorough scientific investigation of the hypothesis of the existence of latent or dormant plague among the natives of countries where this disease is endemic. He says:

My hypothesis in paragraph 23 may not bear the light of scientific investigation, as the hypothesis of a layman may not carry much weight, but I venture to submit that it is worthy of scientific inquiry, for, while a timely glass of water may prevent a great conflagration, and plague at its first intro-

duction may be stamped out by immediate segregation and thorough disinfection, its endemicity once established this is no longer practicable, and if the hypothesis of dormant or chronic plague in man be ultimately proved to be correct it is difficult to see how quarantine for even ten days can prevent its annual recurrence, or how any practicable examination of departing passengers can prevent its export from the plague center and possible dissemination elsewhere, if suitable conditions for its propagation be present. What the remedy, or what the necessary precaution, I leave it for scientific men to determine, but if my hypothesis results in a wider radius of investigation the experiment will not have been useless.

THE RESULT OF BLOOD EXAMINATIONS IN CASES OF PLAGUE.

It is, of course, obvious to anyone versed in this kind of examinations that a diagnosis of plague can not be made by a microscopic examination of the blood. Such an examination may possibly be resorted to in urgent situations, when a rapid clinical diagnosis is desired, but to base on such a microscopic examination far-reaching deductions is certainly not permissible. What is necessary in order to determine beyond doubt the presence of plague bacilli in the circulating blood is the examination of the latter by cultural methods. We have undertaken a series of such examinations in order to determine whether or not there exists such a thing as latent or dormant plague, as suggested by the Governor of Hongkong. Before giving the details of these experiments it will be well to take a survey of the work that has been done with reference to the presence of plague bacilli in the blood in undoubted cases of this disease.

The German Plague Commission,² in its report, says that it made blood examinations in the case of 141 plague patients, including 17 convalescents, who were in the period of convalescence varying between the seventh and the twenty-fifth day after the disease. These examinations were made in the following manner: A drop of blood was obtained from the finger, with the usual aseptic precautions, and inoculated into agar tubes, while at the same time a cover-glass preparation was made. It was found that in a number of cases where the cultural method furnished positive results, the mere microscopic examination failed to demonstrate the presence of the plague bacilli. In 10 cases the bacilli were encountered only once, while in the case of 33 other patients sick with the plague they were repeatedly found in the blood. Of 81 patients, the examinations of whose blood were always negative, 52 recovered and 29 died. Of 10 cases in which there was a positive result only once, the other examinations being negative, eight died and two recovered. It is interesting to note that in one case the bacilli could be detected two and three days before death, while twelve hours before the crisis and at the postmortem examination it was impossible to find them. Seventeen cases of convalescent patients invariably failed to show any bacilli in the circulating blood.

Zobolotny,³ in his researches on plague, says that the bacilli are found in large numbers in the blood of animals sick with the disease, but that in the case of human beings the bacteria are much less abundant and sometimes can not be found at all.

Musehold,⁴ quoting the work of Albrecht and Gohn, reports that the latter examined 122 cases of undoubted plague. In 55 the bacilli were found by the culture

3. Zobolotny: Recherches sur la peste. Archives des Sciences Biologiques, St. Petersburg, 1901, vol. viii, p. 81.

4. Musehold: Die Pest, Berlin, 1901, pp. 150-178.

method in the circulating blood during life. Four of these 55 cases recovered, in two of them the bacilli being present in large numbers in the circulating blood. In the case of 51 patients who died the bacilli were found in considerable numbers in the blood on the day of death as well as on the previous day.

Cairns⁵ studied the blood of patients during an epidemic of plague occurring in Glasgow in 1900. He gives the results of the examinations made *inter vitam* on cases which subsequently terminated fatally. Four of these cases may be cited in connection with our investigation. In three of them juice drawn from the buboes developed pure cultures of *Bacillus pestis*. Only in one of the four fatal cases was it possible during life to obtain cultures of the bacilli from the blood. The other three cases gave negative results. In one of these seven daily consecutive examinations were made, as well as one shortly before death, all of them proving negative.

Calvert⁶ studied two epidemics of plague in Manila in 1900 and 1901. He found that the clinical examination of the blood for *Bacillus pestis* gave unreliable results, it being impossible to place any weight on the negative findings. He made his examinations by taking the blood at intervals of four hours from the ears of the patients, examining it in smears as well as by the cultural method. This plan was followed until the death or recovery of the patient. Thirty-six cases, four of which recovered, were examined in this manner. Most of the cases were followed to autopsy, when the plague organism was demonstrated by culture and even by animal inoculation.

This author gives the following table of positive findings of the bacilli in the blood:

	Per Cent.
24 hours before death in 51 cases.....	100
48 hours before death in 7 cases.....	82
72 hours before death in 5 cases.....	16.12
96 hours before death in 2 cases.....	6.45
120 hours before death in 1 case.....	3.22

On looking over the table it appears that the plague bacilli could be found in all fatal cases twenty-four hours before death, but that forty-eight hours before death the percentage of positive findings was much smaller. In searching for the bacillus in the blood of plague patients who finally succumb to the disease the chances of finding the microbe five days before the fatal termination are only one out of thirty. All of this shows that even in fatal cases the plague bacilli are not found at an early date in the peripheral blood.

Jennings⁷ says that it is extremely rare to find the plague bacillus in the blood in large numbers except immediately before death. Their absence, therefore, in the early stages of an attack is frequent, and must not be regarded as a negative diagnosis of the plague.

Terni,⁸ who studied the plague in Rio de Janeiro, in an excellent article on the disease, makes the following statement:

"The examination of the blood is by no means reliable. It is astonishing that Galeotti places any value in blood examinations in the diagnosis of early plague."

Terni found that in many cases diagnosed as plague septicemia, examinations of the blood, both microscopic and by culture method, were negative. This was true even at the postmortem examination, because the bacilli were exclusively localized in the lymph channels. Even in the most profound cases, in individuals particularly

predisposed to the disease, the bacilli were found in the blood in only moderate numbers. Their presence could never be compared with what we find to be true in connection with other septicemic microbes, such as anthrax or diplococci. Only in exceptional cases do we find a multiplication of the plague bacilli in the circulating blood during the agonal stage.

One of us has been studying for some time the morbid anatomy and histo-pathology of a number of cases of plague. These studies appear fully to confirm the statement of Terni to the effect that plague, as a rule, is not to be looked on as a true septicemia, but, on the contrary, as an infection, particularly confined to the lymphatic system. Even in cases where sections from the lymph glands contain innumerable bacilli, the lumina of the blood vessels are generally free from such microbes. In fact, in the study of sections from all of the internal organs, when plague bacilli are seen, they are always found in the lymph channels or lymph spaces and not in the blood vessels.

Powell⁹ has recently reported the result of 3,400 blood examinations of febrile diseases in Bombay. Most of these cases were malaria, but 117 were plague. In only 15 of the latter were the bacilli easily seen in blood smears. With reference to the finding of the bacilli in the blood in cases of plague, the author says: "As regards the recognition of the plague bacilli in the finger blood, for some years I was very skeptical about the reports of certain medical men, and until within the past 18 months had been unable to detect the bacilli except on cultures. At the beginning of this year there was a particular type of septicemic plague, in which the bacilli were found in every case. Such patients, in my experience, always died. One seemed to be convalescent and had a normal temperature for three days, but suddenly died. Plague bacilli were found 11 days before death.

In looking over these statements (all that we can find in the literature at our disposal), one is certainly impressed with the fact that the finding of plague bacilli in confirmed cases of the disease, except very shortly before death, or in the rarer cases of plague septicemia, is the exception and not the rule. Indeed, we should be mindful of the fact that plague, as a rule, is not a true septicemic, but a bacterial infection localized in the lymphatic system. It is, therefore, from a purely theoretical standpoint, highly improbable that there should exist a dormant, latent clinical form of the disease, in which patients harbor the bacilli in the circulating blood.

Our investigations to determine whether such is the case or not were made on a number of native Filipinos and Chinese of this city. We attempted to get material which, if latent plague exists at all, would give us some evidence to this effect. We selected natives from houses in which plague cases had occurred, and examined a number of inmates of Bilibid prison, particularly such as were under the most unfavorable hygienic conditions, namely, insane prisoners, and prisoners of the third class, who were most crowded in their quarters. Since we could not always get natives of this description, we selected also a number who were not under particularly unfavorable hygienic conditions, such as native police officers and native members of the constabulary.

While plague has never at any time been as widespread here as it has been in Hongkong, we have had a sufficient number of cases to make it clear that the disease is endemic, though fortunately not markedly so.

SUMMARY.

Cases of plague reported in 1900.....271, of which 199 were fatal
 Cases of plague reported in 1901.....485, of which 427 were fatal
 Cases of plague reported in 1902.....10, of which 10 were fatal
 Cases of plague reported in 1903.....198, of which 174 were fatal
 Cases of plague reported in 1904.....64, of which 58 were fatal
 *January 1 to May 31.

It appears from these statistics that plague has been endemic in Manila during the last few years, though never attaining dangerous epidemic proportions. In 1902 the disease had almost completely died out, and during four of the months of this year not a single case came under observation. Since August, 1902, however, until the time of writing the present report, there has not been a month entirely free from plague, though the

figures have generally been low, the maximum during this period being reached in April, 1903, when 52 cases of the disease were reported.

The object in giving these figures in connection with our report is to show that plague has been sufficiently prevalent here for several years so that blood examinations should furnish evidence of latent plague, provided that such a form of the disease exists at all.

The figures of plague morbidity for Hongkong^o during the same years are as follows:

In 1900.....	1,086 cases
In 1901.....	1,637 cases
In 1902.....	540 cases
In 1903.....	1,135 cases

BLOOD EXAMINATIONS OF 245 APPARENTLY HEALTHY NATIVE FILIPINOS AND CHINESE.

The method employed to ascertain whether apparently healthy Filipinos or Chinese of Manila have any plague bacilli in their blood was as follows:

The bend of the elbow, generally of the left arm, was very thoroughly cleansed, first with strong alcohol and then with a strong solution of mercury bichlorid, and finally with alcohol or sterile distilled water. A rubber bandage was then placed around the arm above the elbow, and 1 c.c. of blood was drawn from one of the veins by the aid of a sterile hypodermic syringe. The blood so obtained was added to 50 c.c. of bouillon in a flask. The bouillon used was prepared as usual, and when neutral to litmus, .5 g. of bicarbonate of soda was added to each 1,000 c.c. of the bouillon, making it slightly but decidedly alkaline. The bouillon thus prepared forms a very excellent culture medium for plague bacilli. As a control experiment, in some of the cases twice the amount of blood was drawn from the vein, and the 2 or 3 c.c. so obtained was distributed in two flasks. One of the flasks was then immediately inoculated with a very small amount of material from a young plague culture. This was, of course, done to see whether plague bacilli, if present, would develop in the bouillon in the presence of a small amount of freshly drawn blood. It may be said that the control flasks always developed a typical plague growth. So there was evidently nothing in the arrangement of the experiment to prevent development of the plague bacilli, if present. The culture flasks to which blood had been added were kept either in a dark chest at room temperature or in a brood oven which was fairly constant at 25 C. The media were inspected daily and when a growth had developed it was examined in stained preparations and by culture on agar.

The native Filipinos whose blood was examined included 32 laborers from the Serum Institute and the morgue. The native servants of the latter, where all the plague postmortem examinations are made, are, of course, particularly exposed to infection, and would be especially prone to show latent plague, provided that such a condition exists. These 32 cases were kindly examined for us by Dr. E. H. Ruediger, bacteriologist in the Serum Institute, whose technic differed from the method generally used, only in that he employed a 5 per cent. carbolic acid solution to sterilize the elbow. Dr. Ruediger also examined all his 32 flasks by staining and by cultural methods, whether they showed any change in appearance or not.

The blood examinations in all of the 245 cases were made between March 4 and May 20, 1904, i. e., during a period in which from 35 to 40 cases of plague were reported in Manila.

The following is a summary of the blood examinations made:

On March 4 there were examined five native Filipinos from a house in Santa Cruz, in which an ambulatory case of plague terminating in embolism of the pulmonary artery had occurred. Ten native Filipino police officers were examined on April 6 and 7. Nine of these men lived in infected districts, i. e., districts in which cases of plague had recently occurred; one lived in a non-infected district. Ninety native Filipinos, members of the Philippine constabulary, were examined on April 13 to 30. These men live in barracks, but are often free to visit their families and friends. Thirty-two native Filipinos, laborers at the Serum Institute and the morgue, were examined during the first week of May. In the former place the various vaccines and sera, including plague vaccine and serum, are prepared, and in the latter are performed all the necropsies on plague cases. Fifty-eight native Filipinos, prisoners in Bilibid prison, were examined on May 12 and 13. There are confined in this place about 4,500 men. Last year a number of the inmates died from pneumonic plague. This year no case of plague has occurred there, although one of the prisoners died of pulmonary plague four days after his discharge. Of these 58 men, 16 were insane prisoners, all in advanced stages of mental disease, and the remainder were the so-called third class prisoners, who lived under the most unfavorable conditions to be found in the prison.

On May 16 to 20 there were examined 50 Chinese, small shop-keepers, clerks and coolies, either from houses in which plague cases (in one instance, two such cases) had occurred or from houses adjoining them.

RESULTS OF THE EXAMINATION.

Most of the flasks to which 1 c.c. of blood had been added remained sterile, although a few developed a growth, which, however, was clearly a contamination from the air, such as common molds or similar forms of life. One of the cases examined by Dr. Ruediger developed *Staphylococcus pyogenes aureus*; and those of two other natives examined developed a bacillus which, when examined in a stained cover-glass preparation, might possibly be mistaken for *Bacillus pestis*. One of these organisms, however, in culture looked very different from the bacillus of plague, and also kept Gram's stain. This bacillus developed in a flask to which had been added blood from one of the insane prisoners. The other growth occurred in a flask containing blood from a member of the constabulary. This organism greatly resembled the plague bacillus; but it kept Gram's stain, and when rubbed in large amounts on the shaved abdomen of a guinea-pig failed to produce any disease. In short, not in a single instance out of 245 examinations made on persons of whom a large percentage had certainly been greatly exposed to plague infection did we find a trace of evidence of the existence of plague bacilli in the blood.

From these investigations it may be safely concluded that a condition of latent or dormant plague does not exist in Manila, and there is scarcely any reasonable doubt that it does not exist in Hongkong. There certainly has not been furnished the slightest proof, of such a character as to stand the searchlight of exact methods of bacterial investigation, to indicate that there is such a thing as latent human plague, with the presence of plague bacilli in the circulating blood in the absence of clinical symptoms of the disease.

Why the Governor of Hongkong should have recourse to the untenable hypothesis of the existence of dormant

or latent plague, in order thereby to explain the failure to stamp out the pest in that city, is not at all obvious. Mr. Blake himself, in his memorandum, clearly sets forth some of the circumstances which unite to make it practically impossible completely to eradicate the disease in Victoria City.

In Hongkong it is the custom of the Chinese—if they can possibly do so—to throw human corpses, dead from plague, into the street, in order that they may not be found in the houses and thereby subject the inmates to quarantine, disinfection, etc. In spite of measures to prevent this procedure, the number of corpses dead from plague and so disposed of, has during the ten years preceding 1898 increased from 25.1 per cent. to 32.7 per cent.

The Chinese in Hongkong, according to the Governor's memorandum, offer passive resistance to the catching of rats in their house, being afraid that plague bacilli might be found in the rodents, as this would lead to measures of disinfection or to the requirement of repairs in the houses. The Chinese rat-catchers are said to be dishonest; they fail properly to label the rats, so that infected houses escape detection, and they import rats from the outside of Hongkong and label them at random. In general, they are very unreliable in their work and are actuated solely by the desire to secure from anywhere the largest number of rats in order to obtain the premium for them.

"To those who know how Chinese houses are constructed," says the Memorandum in paragraph 6, "it will be apparent that effective fumigation is practically unattainable; while even if the spraying process, scrubbing and disinfection of clothing reached externally everything in the room, it would not kill the vermin lying deep in the joints and cracks of the tables, chairs and settees or beds. Nor would it reach the vermin with which the heads of the poorer classes of coolies are infected. But apart from this, what took place in many cases when a case of plague was detected was that before the constable could arrive to take charge of the house goods liable to injury by disinfection were removed by the door, or if too late for this were taken on to the roof, always easily accessible, and deposited in some neighboring house."

In W. J. Simpson's report¹¹ "On the Causes and Continuance of the Plague in Hongkong, Etc.," which is quoted in the memorandum of the Governor, we find the following statements as to the sanitary condition in Chinese quarters in the city of Victoria:

When a case of plague has once occurred in a house there is a great tendency in subsequent years for the same house, or that adjoining, or that on the opposite side, or that close by, to be attacked with plague. When plotted out on a map, the distribution of plague appears to be closely connected with previous infection of the house or of a defined locality, the infection having been retained in an unrecognized form in the interval. The houses which suffer principally are, speaking generally, the most insanitary and the oldest. It has already been mentioned how closely packed the buildings are in the older portions of the town, narrow streets and high houses being the leading features, by which the admission of sunlight and fresh air is considerably obstructed. Narrow streets and high houses, however, are not peculiar to Hongkong; they are to be found in other towns, with their injurious effects on health; but in Hongkong there is, moreover, in the Chinese quarters a defect in the construction of houses which intensifies the obstruction of light. The rooms are long and narrow, with a window at

11. Simpson: Reports on the causes and continuance of plague in Hongkong and suggestions as to remedial measures. London: Waterlow & Sons, Limited, 1903.

each end, the front window looking into a wide and covered veranda, and the back window into a small open space at the back, which forms a sort of wall between the two houses. The lower floors of many of the houses are remarkable for their darkness, and this in a region not far from the tropics; they are also frequently damp.

Since the epidemic of 1894 many of the lower floors of the worst kind have been changed into store rooms to contain the goods and merchandise for which Hongkong is an *entrepôt*. These store rooms as a rule are infested with rats, which at times find their way up to the rooms on the higher floors. The basements are generally rat-infested, both floors and walls, and as the walls are often hollow it is easy for rats to reach the upper floors. The admission of sunlight into the dwelling rooms of Chinese tenement houses is still further obstructed by the subdivision into several cubicles or compartments, sometimes numbering up to six, which every room is subjected to. Each cabin is let out to a separate tenant, and not infrequently accommodates a separate family. These compartments or cubicles are windowless and are often so dark that it is impossible for anyone, coming directly from the light outside and opening the door of the cubicle, to see at once whether it is occupied or not. Some attempts have been made to improve this state of things by limiting the height of the subdividing walls to six feet. The condition which obtained before this improvement was made is somewhat difficult to realize, for what I am describing is that which now exists. Fresh air and sunlight never get into the cubicle, except, perhaps, the compartment at each end of the room opposite the window. The subdivision of a single room into a number of rooms called cubicles is an ingenious device for crowding together a large number of people into a small space and securing a correspondingly large rental, but it is an arrangement which engenders disease and favors its spread. There is no doubt whatever that every such windowless cubicle is unfit for human habitation and should not be permitted.

Probably another cause for the continuance of the plague, besides the insanitary condition of the houses referred to, is the very inadequate number of latrines and urinals with which Hongkong is provided. The number of public latrines appears to be 29, belonging to the government, and 17 to private owners. The total number of seats is 1,202. Most of them have urinals attached, and in addition there are three small public urinals in the town. Seeing that all the men and boys go to the public latrines, and there are no sanitary appliances in the houses except earthen pots, which are used exclusively by women and children, the total inadequacy of the latrine accommodation provided is obvious. It is not one seat to 100 of the male population. On the Kowloon side of the colony the latrine and urinal accommodation is still more deficient. Large blocks of houses have been built, and not a single latrine or urinal provided by the builder of the block. It is impossible under these conditions that the ground should escape being sewage polluted. . . . The existing latrines are far from being models of what they should be. They are, in fact, insanitary in structure and deficient in light and ventilation.

Quite recently Surgeon-General Evatt, P. M. Q. H. M.'s Troops, Hongkong, has been quoted by the daily papers in an interview in which he speaks in the strongest terms of the insanitary conditions, which he holds responsible for the continued prevalence of plague in Hongkong. He calls Victoria City the plague-distributing center of the world, a standing menace to the human race. So we have the most convincing evidence, both official and unofficial, as to the vicious sanitary conditions in Hongkong. They furnish the soil in which plague thrives, from which it can not be completely eradicated, and from which it breaks forth again and again in menacing epidemic form. There is not the least necessity for assuming the existence of dormant or latent plague, as the Governor of Hongkong has done on evidence most incompetent and irrelevant.

A CASE OF AMBULATORY PLAGUE TERMINATING IN EMBOLISM OF THE PULMONARY ARTERY.

While the investigation reported above shows clearly and beyond question that latent or dormant plague in the sense in which the Governor of Hongkong used the term does not exist, it has been known for many years that occasionally cases of ambulatory plague occur. Such cases, which may be free from any marked elevation of temperature and which may be compared to ambulatory typhus, had already been reported before the plague bacillus was found, as, for instance, by Griesinger, Liebermeister, Montague, Lubbock and others.⁴ Manson,¹² Scheube¹³ and others have called attention to the fact that these cases of ambulatory plague are liable to collapse, and that fatal termination may occur very suddenly. However, it must not be supposed that examples of this type are latent in the strict sense of the word, because postmortem examination shows changes which existed *inter vitam*, but escaped detection in the absence of urgent subjective symptoms.

A case illustrating these points came to postmortem examination on Feb. 27, 1904. The history and findings, which are somewhat complicated by a simultaneous, evi-

Fig. 1.—Cover-glass preparation from a two days' agar culture of plague inoculated from the liver and showing typical plague bacilli with polar staining and rounded ends, as well as early involution forms. Zeiss apochr. obj. 1/12; comp. occ. No. 6; length of bel-lows, 40 cm.

dently very recent, tuberculous infection, were as follows:

CASE.—The death of a Filipino lad, 17 years old, was reported to the Santa Cruz Board of Health Station, Manila, P. I., on Feb. 27, 1904, at 11 o'clock a. m. The body was found in a dimly lighted loft in the corner of a lower unparved room adjoining a soda water factory. On examination nothing worthy of note was found, except enlargement of the glands in the inguinal region and Scarpa's triangle on both sides, as well as a chronic skin infection of both legs. The position of the body had been changed since death.

History.—The boy had been employed about the place for general purposes for from four to five months and during that time had appeared to be in good health, except that for some weeks previous to his death his face was rather pale and he did not sleep well. He spent the evening of February 26 playing in the street with other boys until 11 o'clock, when he went to bed. About 12 o'clock he awoke, complaining of pain in the chest and difficulty in breathing. His condition soon became alarming, and a physician was sent for, who, however, was unable to do anything for him. At 2 o'clock he died.

12. Manson: Tropical Diseases, London, 1903, p. 249.

13. Scheube: Die Krankheiten der warmen Laender, Jena, 1903, p. 28.

The postmortem examination was made at the San Lazaro morgue on Saturday, Feb. 27, 1904, at 3 o'clock p. m., with the following results:

Autopsy.—The body of a Filipino boy, about 17 to 18 years of age and well developed. Postmortem rigidity was well marked. Postmortem lividity was prominent on dependent parts and extended over the sides of the trunk and neck, as well as over the anterior surface of the latter. A greenish-brown, foamy, ill-smelling fluid oozed from the anterior nares. The anterior surface of the lower extremities, from the ankles upward to about midway between the knees and Poupart's ligaments, were covered with a vesiculo-pustular eruption. The lowermost portion of this eruption consisted of shallow ulcerations covered with brownish, bloody scabs. The skin lesions higher up on the thigh were still purely vesicular, and the collapsed vesicles were covered with dry epidermal scales. The chain of lymph nodes below Poupart's ligaments on both sides was swollen, the most marked swelling being found in the lower glands on each side. The swollen region felt soft and doughy. No fluctuation, however, was noticeable. On incision of the skin the superficial veins discharged a rather small amount of dark fluid blood.

The pericardium was found to be smooth and normal. The visceral layer of this organ showed dilated and congested veins. On the posterior surface over the left auriculoventricular zone

lowish fluid. The upper lobes were dark grayish-pink in color and contained a considerable amount of air. The lower lobes, particularly the posterior surface of the right, were dark purplish-blue in color and contained very little air. On section the lower lobes were found to be quite edematous and filled with a very dark, purplish fluid blood, which oozed out freely from the larger and smaller vessels. The bronchi contained a small amount of foamy, grayish-white fluid. Their mucous membranes were injected and rather bright red in color. The trachea and the larynx likewise showed a swollen, injected mucosa.

The spleen was large and bluish-pink in color. Its capsule was smooth and shining. The cut surface was dark purplish-brown. The trabeculae and the Malpighian corpuscles were distinct. The pulp was fairly firm in consistency.

The kidneys were rather small, and their surface smooth and of a dark grayish-pink color. The capsules peeled off easily, and the denuded surface then showed the small vessels to be very much injected. They stood out plainly on a grayish-yellow background. On section the vasa recta and the glomeruli appeared quite strongly injected and intensely scarlet. The tubules were quite markedly yellowish-gray, the surface on the

Fig. 2.—Section showing tubercle in the lung, with a giant cell in the center of the field. Zeiss obj. D. D., occ. No. 4.

Fig. 3.—Section showing congested vessels in the inguinal lymph node. Zeiss obj. A. A., comp. occ. No. 6.

there were seen from two to three dozen hemorrhagic areas, varying in size from a pinhead to a millet-seed. Otherwise the visceral pericardium appeared normal. The myocardium was fairly firm and somewhat pale. The left ventricle was contracted and the right dilated. The latter contained a rather firm, though somewhat gelatinous, reddish-gray coagulum, which did not completely fill the ventricular cavity. The coagulum was continued into the pulmonary artery, which it filled completely. It was here firmer in consistency and decidedly more grayish in color. These changes from the consistency and color of the clot in the heart became greater the farther the distance from the entrance of the pulmonary artery to the interior of the ventricle. The thrombus extended into the main branches of the pulmonary artery; from there it could be followed into the lower, secondary branch of the right side, and was then lost in the highly congested lower lobe of the right lung. A distinctly hardened, infarcted area could not be found. The blood in the left ventricle and auricle was fluid and of a dark purple color.

The lungs were found to be quite firmly adherent to the parietal pleura. The lower lobe of the right lung was particularly firmly adherent to the diaphragm. The partly obliterated pleural sacs contained a small amount of slightly turbid, yellowish

whole being rather dull. The pyramids were purplish. The mucous membrane of the pelvis was smooth and somewhat congested.

Liver: The capsule was smooth, shining, transparent and pinkish-gray in color. Some areas were decidedly mottled. The cut surface showed the center of the lobules to be grayish-white. The lobules were rather distinct in outline. The surface as a whole was dull. The veins contained much dark fluid blood. The gall bladder contained some turbid, greenish-yellow bile. The mucous membrane was smooth. There were no stones. The ducts were normal.

The stomach and intestines appeared fairly normal. The suprarenals and the pancreas were normal.

The inguinal glands on both sides were enlarged, swollen, soft and rather dark bluish-pink in color. On section they showed injected vessels which stood out prominently on a grayish-yellow background. The substance of the glands was soft. No abscess formation had occurred. An abundant turbid, grayish-white fluid could be scraped from the cut surface. The lower glands of the chains on each side were the largest, showing quite markedly a central softening. There was, however, no abscess formation. These glands were about equal in size and measured 4.8x3.7x1.7 cm.

The mesenteric, the cervical and the other glands examined were all moderately enlarged and more or less congested. Marked congestion existed in the bronchial glands.

Smears were made during the postmortem examination from the liver, spleen and the glands. In the smears from the spleen and the glands only a very small number of bacilli were found. They were more numerous in the smears from the liver. Some of the bacilli found in the latter were quite typical in appearance, showing polar staining and rounded ends. Other bacilli were swollen and somewhat irregular, and approached in type the involution forms seen on artificial media. Still others were small and looked decidedly like diplococci. Others formed small chains, the individual members of which appeared to be in a state of partial dissolution. The culture tubes inoculated from the organs developed typical plague bacilli.

Histologic Findings.—Pieces of tissue were fixed in Zenker's solution and subsequently sectioned and stained with various dyes, including Weigert's stain for elastic fibers, Weigert's fibrin stain, Ziehl's carbol fuchsin, etc.

The microscopic examination showed the following tissue changes:

Liver: The liver showed extensive interlobular inflammatory foci, formed by a cellular exudate. The infiltrating cells were found around the interlobular arteries, veins and small bile ducts. The small interlobular vessels showed a marked thickening of the adventitia, and most of the lumina were found to be surrounded by a number of concentric rings, composed of delicate connective tissue fibers. Occasionally there was found a small vessel entirely occluded by an obliterating proliferation of the lining endothelium. The cellular exudate of the inflammatory foci consisted of lymphoid cells and a high percentage of eosinophilic polymorphs. In some places the latter cells formed one-fourth or one-fifth of the total number of infiltrating cells. Plasma cells were very sparingly represented. While this description conformed in general to most of the inflammatory foci in the liver, other areas presented a decidedly varied appearance. In these the more or less nearly oval or circular foci clearly showed a center consisting of epithelioid cells, with a vesicular nucleus and a large protoplasmic body. In some nodules among these cells multinuclear giant cells were found. The histology of these round or oval nodules was clearly that of the bacillar tubercle. The nodules also showed a fine, concentrically arranged fibrillar network of connective tissue fibers. Regressive changes were not seen. There was no caseation, nor did Weigert's stain show any fibrin.

The histology of the small tubercles in the liver, and it may here be added that of the similar structures found in the lungs, was identical with what has recently been again described by Baumgarten¹⁴ as the structure of the experimentally produced tubercle, about two to three weeks old, which has not yet undergone any regressive changes, but in which the appearance of the first giant-cells indicates that the proliferation of the tubercle bacillus, as well as that of the inflammatory cells, has come to a standstill. Baumgarten also describes the occlusion of small vessels by endothelial proliferation as a part of the general cellular proliferation brought about by the presence of the tubercle bacillus. The nodules in the liver as well as those in the lungs contained an element which is foreign to the typical uncomplicated tubercle, namely, numerous eosinophilic polymorphs. It was impossible to prove the presence of tubercle bacilli, but the tubercles were found to be infected with plague bacilli. The latter were seen here and there in both types of the inflammatory foci, in those which showed simply the structure of an ordinary inflammatory area and in those possessing the features of a bacillar tubercle. The parenchyma cells of the liver exhibited a moderate degree of fatty degeneration. The capillaries were well filled with blood.

Lungs: Pieces of tissue from the right lower lobe showed a great engorgement of the interalveolar capillaries; in fact, all the blood vessels were highly congested. The alveoli presented a varying picture. Some were open, having contained air only; others were filled with extravasated blood, which did not show

any degenerative changes. Desquamated alveolar epithelia, containing hematoïdin granules, were seen but occasionally. The unchanged character of the blood, the small amount of pigment containing alveolar epithelia, and the absence of areas of coagulation necrosis showed that the blood extravasation must be of a comparatively recent date. Quite a few of the air spaces were filled with a homogeneous coagulated material, staining deeply with eosin. Other alveoli contained a lighter staining granular material. Neither the homogeneous nor the granular material stained with Weigert's fibrin stain, nor did the capillaries contain any hyaline (fibrin) thrombi.

Here and there was found a small solid nodule, hardly larger than the larger alveoli themselves. These nodules were composed of epithelioid and lymphoid cells and a considerable number of eosinophilic polymorphs. Multinuclear giant cells were likewise found in or near the center of some of the nodules. In fact, the latter were absolutely identical in their make-up with the tubercles which may be seen in sections of the hepatic tissue. Both in the pulmonary and in the hepatic tissue were found neighboring nodules, the peripheries of which were in contact with one another. However, the individual nodules had not become confluent and their outlines were well preserved. It was impossible to demonstrate tubercle bacilli in these nodules; but they showed a small number of plague bacilli found scattered between the cells. In properly stained sections it was seen that some of the alveoli contained enormous numbers of plague bacilli. Such air spaces appeared almost filled with them. Small groups of scattered bacilli could be found all over the sections.

Inguinal lymph nodes: The inguinal lymph nodes showed numerous enlarged, dilated vessels, replete with blood corpuscles. Around the larger vessels, particularly the hilus vessels, there was a marked, even, powerful development of the connective tissue. The general fibrillar connective tissue reticulum was likewise everywhere much increased. The peripheral follicles generally showed a well differentiated proliferation center. The peripheral lymph sinus and its branches were dilated. Eosinophilic polymorphs were found throughout the tissues, though nowhere in so large numbers as in the lungs and liver. Bacilli were seen sparingly in the sections. The necrotic changes described by Albrecht and Gohn as occurring in the vessels of the lymph nodes in bubonic plague were not seen.¹⁵

Kidneys: Sections of renal tissue showed practically normal glomeruli, moderate parenchymatous changes in the tubular epithelium and highly congested vessels.

The interesting features of the case above described are its ambulatory nature, its sudden termination by embolism of the pulmonary artery, and its complication with what undoubtedly appears to be a very recent tuberculosis. It is useless to speculate on the question why no tubercle bacilli were found.

Clinical Reports.

A CASE OF DIPLEGIA BRACHIALIS TRAUMATICA DUE TO PRIMARY HEMATOMYELIA.

JAMES B. CUTTER, M.D.

Surgeon in Charge A. T. & S. F. Ry. Coast Lines Hospital.

ALBUQUERQUE, NEW MEXICO.

Introduction.—Dr. Pearce Bailey, in his "Diseases Caused by Accident," says: "Traumatic hematomyelia is one of the most interesting of traumatic disorders of the nervous system. In severe general injuries when it occurs as a complicating factor, its individuality is usually lost in the general mutilation. But when it constitutes the chief lesion it very often has distinctive and recognizable symptoms. In its most characteristic

14. Baumgarten: Ueber die pathologisch histologische Wirkung dea Tuberkelbacillus. Berlin klin. Wochen., 1901, No. 44, p. 1101.

15. Quoted from a short notice in Muschold's "Die Pest." The original report of Albrecht and Gohn on this subject is not at present accessible.

form it occurs without any bone injury, being demonstrable during life, and many autopsies have proved that such a lesion in the spinal cord is possible without the integrity of the spinal column being interfered with. This variety, which I have called primary hematomyelia (the word primary indicating that the bleeding results directly from the violence without the intervention of crushing or pressure by bone), is found almost exclusively in the lower cervical and upper thoracic regions, and results from sudden forced flexion or extension of the neck, e. g., diving in shallow water; the symptoms come on immediately."

History of the Case.—A lad, aged 16, was caught in a drill machine at the A., T. & S. F. shops at Gallup, N. M., Dec. 24, 1903, and sustained severe wrenching of the neck and shoulders, as was indicated by numerous abrasions about the face, neck and chest. He was rendered unconscious, but quickly revived and described his sensations during the receipt of the injury to the effect that his head was forced forward on his chest and was somewhat twisted. On recovering consciousness within a few minutes he found himself unable to raise either arm from the shoulder, though the function of forearms and wrists was unimpaired. He experienced no pain further than that due to the superficial violence about his head and neck, which disappeared within a few days, there being also absent muscular tenderness about the neck. The young man was kept quiet in bed and under close observation. Sensation for heat and cold was normal; in fact, no sensory disturbance seemed present except the existence of numbness over the occipital region, diminishing downward toward the insertion of the ligamentum nuchae. About ten days later the temperature suddenly rose to 104, accompanied by a rapid and feeble pulse, nausea and general malaise. Bromids were administered in this attack, which passed without further symptoms.

Considerable atrophy of the suprascapular muscles and a general diminution in the size of the arms were apparent at the end of six weeks, though the patient had learned to use his upper extremities with much dexterity, finding a way to throw them up to his head and shoulders by the use of the pectoral muscles and the *litissimus dorsi*.

The general condition improved with increase of weight, and the patient was finally dismissed from the hospital and allowed to return to his home at a town a hundred miles distant, whence come reports of constant improvement in the tone and in the use of the members.

Comments.—The point of lesion in the cord in this case would seem to be easily defined by the clear limitation of the muscles involved; those supplied by the anterior thoracic, posterior thoracic, circumflex in part, suprascapular, and principally the musculo-cutaneous, that portion of the brachial plexus arising from the fifth, sixth and seventh cervical nerves (the outer and posterior cords), which undoubtedly represents within definite limits the portion of the cord which was the seat of hemorrhage, which would appear to have been confined to the gray matter. Examination of the case eleven months after the injury shows complete recovery with perfectly restored function.

A CASE OF HEMORRHAGIC TYPHOID.

J. R. DURHAM, M.D., F.T.M.C.

WARREN, PA.

History.—J. O., aged 28, single, occupation woodsman, was admitted to the hospital on the evening of Sept. 3, 1903, with a history of having been ill one week, and of coming from a camp where typhoid fever was present. Temperature, 104.6; pulse, 94; respiration, 34; urinary analysis negative.

Course of the Disease.—The next morning the temperature was 105; pulse, 100; respiration, 42; considerable bronchial cough, severe headache and delirium. The pulse becoming weaker, he was placed on strychnia, gr. 1/60 every four hours, while the nervous symptoms and pyrexia were treated by the icebag to the head and ice-water sponges every two hours.

September 5. Temperature ranged from 102 to 105; pulse from 90 to 100; respiration varied between 40 at 8 a. m., 22 at 2 p. m., and back to 40 at 6 p. m.; abdominal symptoms were now more pronounced, there being considerable tympanitis and diarrhea; for these turpentine stupes and turpentine injections were used, with salol and bismuth betanaphtholate internally and later turpentine emulsion; large quantities of gas were expelled. The next night showed no change in his condition except that there was circulatory depression during the sponges, for which he was given a half ounce of whisky before the treatment.

September 6. The temperature remained through the day at 105, pulse from 95 to 104 and weaker, respirations 28 to 36. Ice-water enemas were given every three hours, while strychnia was given hypodermically every four hours in dose of 1/40 grain; the rectal tube was also used with good results.

Between this date and September 10 the patient continued to be desperately ill; the heart showed some intermittence so nitroglycerin, gr. 1 200, was added to his strychnia; the other symptoms were the same.

September 11. Temperature from 102.2 to 104, pulse from 88 to 94, better quality; respirations from 22 to 32; cold packs were used at this point, being better borne by the patient. There was considerable cough and some congestion of the bases of the lungs.

September 13. Temperature falling very slightly, the pulse lower and of fair quality; respirations still from 28 to 36.

September 14. Temperature from 101.8 to 103.6, pulse from 92 to 94, respirations from 28 to 44. This was the eighteenth day of the disease. Hemorrhages from the gums and mucous membrane of the mouth now made their appearance, and also under the skin wherever the hypodermic needle was used.

September 15. There was a continuous hemorrhage from the rectum, the urine also being quite red; a slight oozing of the blood was next noticed from the skin of the nose; ergotol in 10 minim doses was given hypodermically every four hours and 15-grain doses of calcium chlorid by the mouth every five hours. Besides this, a mouth wash of adrenalin chlorid 1 to 4,000 was used and with good effect.

September 17. The temperature ranged from 100 to 101.6, respirations from 22 to 30, pulse from 98 to 106; after an enema at 2 p. m., he expelled a great deal of gas and dark blood, while the urine was almost black. Protein, gr. 15 every three hours, was added to the treatment at this point.

September 18. Temperature, 100 to 103.6; respirations from 22 to 28. The bleeding from the mouth was much better, but a severe hemorrhage from the bowels occurred at 5 a. m., there being three pints of fresh blood expelled; bladder hemorrhage same. Morphine, gr. 1/4, was given at once, as well as ergot, m. x, and the administration subcutaneously of 700 c.c. of normal salt solution. After the use of the morphia the respiration dropped as low as from 14 to 18 a minute and no fresh hemorrhages appeared.

September 20. Urine began to clear up; pulse became as low as 78; temperature, 99.8; respirations from 15 to 18. About this time two superficial abscesses appeared on the nates, but with antiseptic dressings they soon healed.

Between September 21 and October 4 the patient made steady progress, his bedside record being discontinued on the latter date. He was discharged from the institution October 21, after having been under treatment for 55 days. His convalescence was marked by a bradycardia, the pulse running as low as 45 beats per minute. The diet throughout consisted of broths, peptonized preparations and malted milk.

Remarks.—The symptoms which required the closest scrutiny were the diarrhea and tympanitis, the heart's action and the hemorrhages; the character of the latter making it an unusual clinical feature.

This patient lost in all about six pints of blood, which illustrates the point to which attention has been called by other clinicians, that a surprising amount of blood may be lost and yet recovery follow.

PROGRESS IN CHILD LABOR LAWS.

One hundred and twenty years ago Dr. Percival, of Manchester, England, was asked by the justices of the peace of that city, to inquire into the causes of a serious epidemic among the factory employes. After personal investigation of the conditions, Dr. Percival reported in favor of placing the mills under legislative control, especially as regarded hours of work, which, in his opinion, were so long as to be a contributory cause of disease through confinement and exhaustion. In consequence of his representations the magistrates passed a resolution that they would not allow parish apprentices to be bound to owners of mills in which children were obliged to work in the night or more than ten hours in the day. This resolution is said to be the earliest recorded attempt of any public body to limit the hours of children's labor. The earliest child labor legislation, therefore, owed its origin to the spirit of scientific inquiry into questions of public health, and it seems proper that this same spirit should still take the initiative whenever public health is menaced through lack of proper legislation.

The condition of the factory population of northern England during the early part of the last century was pitiable. We are told of children of six and seven years working fourteen or fifteen hours a day; of pauper children from London workhouses, sent in hordes to mill owners, who were allowed to work them without inspection or control. We are also told of the condition of these children in later life: "Feeble in frame, their intellect shrunk up and dry like a tree. Their children are feebler still." England reaped a bitter harvest from the unrestricted greed of the early years of her industrial development, but she has learned her lesson and a century of factory legislation has changed the world for the English working child.

Our own country is far in advance of England, so far as our public school system is concerned, but there are few of our states which can boast of child labor laws as good as hers. Child labor means two evils, physical underdevelopment and illiteracy. There are 66,000 illiterate children between the ages of ten and fourteen years in Alabama, 63,000 in Georgia, 55,000 in Louisiana. Even in our northern states the showing is bad. Pennsylvania has 6,300, Missouri 11,600. In all of these states the laws regarding child labor are utterly inadequate.

In places where child labor is allowed, the wages of adults are lowered and parents are sometimes compelled to send their children to work. We must reckon, also, with the greed and ignorance of the foreign immigrant, whose one thought in coming to this country is to make money and to whom education seems a needless luxury. Some employers are benevolent and some are not, and the stern laws of competition force the benevolent to adopt the methods of the non-benevolent, if these methods are unrestricted by state control.

In an interesting reference hand-book¹ on "Child Labor Legislation" in the United States, recently issued, the statistics as to illiteracy in the different states are given, and the laws concerning the age below which children may not work, concerning compulsory school attendance, the educational test for children seeking employment and the restriction of night work for children. The widest differences are found to exist between the different states. In some instances the differences can be explained by the absence of certain industries, but in others one is forced to believe that in some states a few powerful industries have been able to influence legislation in their own favor. Thus the glass industry in New Jersey has been able to obtain special privileges whereby children under sixteen may work all night in its factories, an exemption which the glass-workers of Illinois fought hard to obtain, but could not. The canneries of Maryland and New Jersey enjoy special privileges in the employment of children which are denied in other states. Children of fourteen years in the latter and children of any age in the former may work in canneries night or day for a number of hours, determined only by the will of the employer and their own physical endurance. The textile mills of Pennsylvania may work girls of thirteen all night, those of Massachusetts may not. It is well to note that these three states stand far down in the list of states placed in the order of the literacy of their children. The textile industry of the southern states is the most notorious offender in the matter of immature labor. Of twelve southern states only two make the age limit for employment in factories fourteen years, five make it twelve years, one eleven years, and the remaining have no restrictions, or only such as are easily evaded, "consent of guardian," "poverty necessitating employment." In Missouri, Kentucky, Tennessee and Georgia, children of any age may be employed at night, and in three other states the age limit for night work is only 12, 13 and 14 years.

Certain of the newer western states have surprisingly defective legislation in this respect. Thus in Washington a girl of 12 years "necessarily employed" may not only work ten hours at night, but may do so seven nights in the week, and a boy of the same age is not even restricted to ten hours. Nebraska, Idaho, Colorado, Nevada, Wyoming and New Mexico have no restrictions at all for night work, and only one, Colorado, makes up

1. The National Consumers' League, 105 E. 22d St., New York City.

for this in part by a really excellent compulsory education law. It is urged in excuse that in these new states the evil of child labor has not yet attained such proportions as to require legislative control, but surely it is easier to strangle the monster in his cradle than to wait until he is full-grown.

Delaware enjoys the distinction of being at the very bottom of the list, for she has no age limit for employment, no compulsory education and no restriction of night work.

In Massachusetts, Illinois and New York, in spite of the continual influx of foreign illiteracy, the number of illiterates is kept amazingly low through the working of excellent compulsory education laws. New York state has less than 300 more illiterate children than has New Mexico. Illinois has 300 fewer than the latter, yet New York City and Chicago are the two principal Meccas of our foreign immigrants. The usual arguments in favor of child labor can not appeal to a physician.

The plea that children are better off in the factory than in the street, "that they learn habits of industry," etc., is readily met by the retort that nothing in street life is so detrimental to health as is the confinement and strain of factory life, and that the monotony and long hours stunt a child's intelligence instead of developing it. Even less does the sentimental plea appeal to the physician. That children should be sacrificed for the support of adults, no matter how indigent, is a reversal of the law of nature. The higher the species the longer is the period of immaturity and to cut short that period and force a premature activity is to invite physical and mental degeneracy. Child labor is the truest form of race suicide.

The National Consumers' League has framed a standard child labor law which embodies the best features of the Massachusetts, the Illinois and the New York laws. Briefly stated, it would prohibit the employment for wages of any child under fourteen years during school hours or after 7 p. m., and also the employment of any child under sixteen years for more than eight hours a day or after 7 p. m. An educational test would be required for children under sixteen years. It should be a matter of personal interest to every public-spirited physician to work for the passage of such a law in the states which are as yet without adequate legislation.

THE MEANING OF THE QUALITATIVE SUGAR-REACTIONS IN URINE.

In a preceding issue we discussed briefly and in an elementary manner the use of various tests for albumin in the urine as they concern the general practitioner; a similar summary critic of the qualitative reactions for sugar will, it is believed, be welcomed by some of our readers.

Certain precautions should always be taken before examining the urine of a patient for sugar. The physician should, for example, know what drugs, if any, have recently been administered, since rhubarb, cascara sa-

grada, salicylic acid preparations, morphin, various coal-tar products and other medicaments may give rise to substances in the urine which lead to confusion in the application of the various sugar tests. Again, if albumin or sulphuretted hydrogen be present in the urine they must be removed before testing for sugar. Finally, fresh urine, rather than that kept from decomposition by preservatives, should be employed, for formalin and chloroform, sometimes added to urine to keep it, will yield some of the so-called sugar reactions; if any preservative has to be used, the addition of a little copper sulphate (1 per cent.) is least objectionable.

The reducing property of sugar is that most commonly utilized in the detection of the substance in the urine. Glucose, or grape sugar, the form most often present, reduces, by virtue of its aldehyd group, alkaline solutions of cupric salts to red cuprous oxid (Cu_2O): Fehling's or Haines' solutions are the best to use. The exact chemistry of the process is rather complicated, since the copper of cupric salts, in the presence of tartaric acid or glycerin, enters into the formation of complex ions, the composition of which need not be discussed here. In the case of both fluids the complex organic copper ion, which has a dark blue color, is changed by various reducing agents, of which grape-sugar is one, in such a manner that it deposits a red precipitate of cuprous oxid. Unfortunately urine may contain substances other than grape-sugar which reduce these copper solutions; thus milk-sugar (lactose) and less often fruit-sugar (fructose or levulose) may be present in urine and reduce the copper salt, or uric acid or kreatinin if present in excess will cause reduction, as will also glycuronic acid compounds and certain other reducing agents, especially after the ingestion of drugs like turpentine, chloral hydrate, salicylic acid, copaiba and cubeba.

The bismuth tests, like the copper tests, depend on the reducing property of sugar and if employed in the form of Nylander's reagent afford a convenient and sharp method for the detection of sugar by the practitioner. The reduction of the alkaline bismuth solutions can, however, be effected also by glycuronic acid, by excess of indican, and especially by reducing substances present in the urine after the ingestion of various drugs, particularly rhubarb, senna, and antipyrin. A positive reaction does not, therefore, any more than with Fehling's or Haines' solutions, indicate necessarily the presence of sugar; control tests which exclude other substances must accordingly be made.

The safest test for the presence of sugar in the urine, the one, which when applied as directed below, we unhesitatingly recommend to practicing physicians as the most reliable of all, is the fermentation test. To apply it, one needs three fermentation tubes and some good compressed yeast. A lump of yeast the size of a hazelnut (0.5 to 1 gram) is rubbed up in a small mortar with one or two cubic centimeters of water, and this suspension is mixed with about 25 c.c. of urine (acidified

with a few drops of a solution of tartaric acid). An Einhorn fermentation tube or some similar apparatus is carefully filled with the mixture and the whole set aside in a warm place for from 12 to 24 hours; if sugar is present it will be converted into alcohol and carbonic acid gas and the latter will accumulate in the upper part of the fermentation tube. To make sure that the yeast itself does not contain starch or sugar, a second fermentation tube is filled with water (acidified with tartaric acid) and yeast and, to prove further that the yeast is active, a third tube is filled with an acidified 1 per cent. solution of grape-sugar and yeast. No gas (or only a minimal amount) should appear in the second tube at the end of 12 hours, while the third tube should contain an abundance of CO₂. By means of this simple test all the members of the group of reducing substances other than sugar are excluded, for they do not ferment with yeast. Levulose and maltose do ferment with yeast, it is true, but they are only very rarely present in urine, while glucose is very often present. Glucose is, moreover, strongly dextrorotatory to polarized light, while levulose is strongly levorotary; and, again, if levulose is present the urine should yield Seliwanoff's reaction for ketoses (test with resorcin and hydrochloric acid). If the fermentation test, carried out as above recommended, be positive, then the practitioner may be reasonably sure that he is dealing with glycosuria, and, if he wish to make assurance doubly sure, he may exclude the presence of levulose by the methods mentioned.

An excellent confirmatory test for the presence of sugar, delicate enough to detect quantities as small as 0.03 gram in 100 c.c., is the phenylhydrazin reaction of E. Fischer as applied to urine by v. Jaksch and Jolles. The reaction may be positive with glucose, lactose, levulose, maltose or pentoses; even unpaired glyconic acid may yield a crystalline osazone. Solutions of the various osazones behave somewhat differently to polarized light (P. Mayer) and the purified crystals have different melting points: these differential methods are, however, altogether too complex to be used by the average busy practitioner; moreover, they are rendered superfluous for ordinary purposes, as we have shown above, by the simple fermentation test.

The quantitative estimation of sugar is another matter, which we may discuss later. We dismiss it at present with the simple statement that, for practical clinical purposes, we advise the use of any one of three methods: (a) titration with Haines' solution; (b) polarization with the half-shadow apparatus; and (c) fermentation in Lohnstein's saccharometer.

THE OCCURRENCE OF PEPTIC ULCERS IN THE JEJUNUM AFTER GASTROENTEROSTOMY.

In 1891 the *Wiener medicinische Wochenschrift* published an anniversary number, in which a number of prominent physicians contributed a series of aphorisms. Among these was one from Anton von Frisch, which

read as follows: "Antisepsis is the triumph of modern surgery, but perhaps also the ruin of the old surgical skill, for to-day, under its protecting wing, children and fools operate unpunished." Like most aphorisms, this presents rather a one-sided view of the truth, but that it contains truth can not be denied. Perhaps it would be fairer to say that on account of the relative safety to life conferred by asepsis, operations are performed, often with the best motives, which would not have been performed if more thought had been given to the case. Within the last few years the surgery of the stomach has held a prominent place, and the beneficial results of stomach operations have been widely published in the literature; that very unpleasant results may follow in certain cases, and those the ones with non-malignant affections, has not been prominently discussed.

Tiegel¹ has drawn attention recently to the frequency with which gastroenterostomy for non-malignant diseases of the stomach is followed by peptic ulcers in the jejunum. The jejunal ulcers have mostly developed in male subjects past the age of 30, and have in all instances occurred in cases in which the original operation was performed for a non-malignant affection, generally a stenosed pylorus resulting from gastric ulcer. The particular form of operation which was performed seems to have no influence on the development of the ulcers. The ulcers developed at varying intervals after the primary operation, some appearing as early as ten days after, and some not until eight years after.

So far as clinical symptoms are concerned, two great groups of cases are to be recognized. In one group the patient presents absolutely no premonitory symptoms, the illness coming like a thunderclap out of a clear sky. There is very sudden onset with severe abdominal pain, vomiting, and the rapid development of the signs of acute peritonitis. Operation or autopsy in these cases shows an acute perforation of the ulcer into the peritoneal cavity. In the second group of cases the onset is gradual, and the symptoms are similar to those of round ulcer of the stomach. There is pain sometimes constant, sometimes intermittent, which may be increased by taking food or may be most marked an hour or two after taking food. The pain may be in the epigastric or umbilical region, or may occur either to the right or left of the median line. Usually as the case progresses, there develops an infiltration of the abdominal wall, or at any rate an area of localized resistance. In some cases there is an actual inflammatory tumor; in some there are signs of gastric stasis, and in a few there may be the passage of blood by the stomach or rectum. These differ from the preceding cases in that they almost never perforate into the general peritoneal cavity.

The condition of the gastric secretion before and after the original operation in these cases is of impor-

¹ Mitteilungen aus den Grenzgebieten der Med. und Chir., vol. xlii, Nos. 5 and 6, 1904. THE JOURNAL, page 1732.

tance; it has been determined in relatively few of the cases, and, as far as one can judge from these, is inconstant. In some a definite hyperacidity of the gastric juice is present, but in others this is not the case, either before the original operation or before the development of the jejunal ulceration. Pathologically, the jejunal ulcers are just like the gastric peptic ulcer. They are usually single, and are generally situated in the wall of the jejunum opposite or near to the gastrointestinal opening; rarely where an enteroenteric anastomosis has also been made they are situated near this.

The diagnosis of jejunal ulcer following gastroenterostomy is not always easy. The acute cases have been taken for appendicitis and other acute abdominal inflammations, but the absolute lack of premonitory symptoms in the jejunal ulcer is very suggestive. The chronic cases are very easily confused with recurring gastric ulcer, and operation may be necessary to decide the point. The presence of tenderness or infiltration lower down and further to the left than is usual with gastric ulcer would be in favor of the jejunal form.

The treatment of these cases, and particularly of the chronic form, is mainly medical and along the lines of the usual treatment of gastric ulcer. Surgical intervention is, of course, demanded in the cases with acute perforation, but the chronic cases do badly under surgical intervention. The results of Tiegel's investigation suggest to him that in certain forms of gastric disease too much surgery has been done, and strangely enough, it is in the non-malignant cases that intervention has been practiced too much. In view of this work, it would seem best to avoid surgical interference in benign gastric affections unless it is absolutely necessary, and in those cases where a gastroenterostomy must be done, a postoperative treatment in the form of alkalies and a strict diet should be adhered to for a long time.

A SUCCESSFUL COUNTY MEDICAL SOCIETY.

One of the most successful local organizations in the United States is the Chicago Medical Society, the medical society for Cook County, and its working methods and accomplishments may be cited as examples that should be followed in other large cities. Among its good features is the weekly *Bulletin* which it publishes. This contains the programs of the weekly meetings of the central body and of the monthly meetings of its branches and affiliated societies, as well as much other matter of interest. It is issued as second class matter, and so can be published at less expense per member than could a simple postal card. The last issue is a special number, most of which has been prepared by the organization committee to call attention to those who are not members to the work the society is doing and to the advantages of membership. Two years after the reorganization of the state society, the Chicago Medical Society also reorganized, so that its constitution and by-laws conform to that of the general plan. In doing

so, however, the needs of those living in the suburbs were considered, and the county, which practically means the city, was divided into eleven districts. In each of these has been organized a local branch, composed of all the members of the society who reside in the district, on the plan long prevailing in Massachusetts.

Each of these local branches meets monthly, and some of them combine science and good fellowship at each meeting by having a smoker or lunch. An annual banquet to which the members' wives are invited is also held by all the branches. In fact, one of the main ideas of each district branch is to bring together physicians living in its territory, making it as much a social body as a scientific one. It is recognized that to bring together men who live in the same community, thus making them acquainted, will do away with most of the petty jealousies which are found in a community where physicians do not really know each other. These branches are supported by the central society, and are forbidden by the constitution to levy any tax on their members. The members are elected by the central body, and, of course, are members of the central body as well as of the branches. Membership carries with it membership in the Illinois State Medical Society, and each member receives the benefits of that membership, as well as a copy of the excellent journal that is published monthly by that organization. Beside these branches, there are the scientific sections—called "affiliated societies"—and including the surgical, laryngological, pathological, ophthalmological and otological, orthopedic, gynecological, and pediatric societies. Each of these is more or less independent of the main body, but its membership is limited to those who belong to the Chicago Medical Society. The members are supplied also with a medical directory of Cook County, and—to some the most important point of all—have a medical defense organization of their own, managed by a medical defense committee. For all this each member pays an annual due of \$5, \$1 of which goes to the medical defense and \$1.50 for state society dues.

The society is also doing good work in carrying on a series of free public lectures. The membership has reached nearly 1,600, and is steadily growing, the bulletin before us indicating that there are fifty applicants awaiting action. Only seven state societies now have a larger membership. The central body meets weekly, and it is not unusual to have an attendance of 300 or 400.

It thus seems to us worth emphasizing that the Chicago Medical Society is an example for other large cities to follow. Philadelphia is doing something in the way of branch societies, but it has not taken up the work systematically as has Chicago. Pittsburg, if we may judge from a recent letter from the secretary of the Alleghany Medical Society, has also considered the advisability of adopting some such plan. What a magnificent thing it would be for New York, for instance, if the members there would come together and organize as have the physicians of Chicago.

THE ACTION OF RADIUM ON CANCER.

Whatever the clinical results from the use of radium rays in the treatment of cancer may be, there is no question that they are able to produce a greater or less amount of retrogressive change in living tissues, both cancerous and non-cancerous. As is the case with the Roentgen rays, however, the means by which these changes are brought about is quite unknown. Experimental work with Roentgen rays has failed to show conclusively in what manner the "x-ray burns" are produced. Vascular changes, although sometimes conspicuous, can not explain all the changes of this white gangrene, and hence the unsatisfactory conclusion generally reached has been that the loss of vitality of the cells is due to some mysterious alteration in their metabolic properties. Cell life being the outcome of cell chemistry, an explanation may be found by a study of chemical changes that occur within the cell, so far as such study is possible by the means at present available. In this line of investigation is the work of Schwarz,¹ who considers that the radium rays decompose the lecithin of the cells, and as lecithin is an important if not essential constituent of all cells, particularly those that are rapidly growing, he looks on this as an explanation of the death of cells exposed to the action of radium rays. Unfortunately, the destructive effect of radium on lecithin has failed of confirmation, and this theory is not accepted by other investigators.

More promising are the results obtained by Neuberger,² who studied the effects of radium rays on the self-digestion of cancer cells. We have frequently referred to the importance of this self-digestion of cells, autolysis, by the trypsin-like ferments which every cell contains. It would seem that in every cell there are continually occurring processes of synthesis and of autolysis, and as soon as the cell is separated from its sources of nourishment the autolytic processes alone occur, and hence the cell is rapidly broken down and absorbed, as in the case of infarcts, for example. Cancer cells, like all other actively growing cells, possess this autolytic property to a high degree; hence the rapid softening of necrotic areas in tumors. Neuberger found that if two specimens of tissue from the same cancer were allowed to undergo autolysis, one exposed to radium rays and the other not, the exposed specimen at the end of four days would show nearly twice as much autolysis as the other, and at the end of eight days four times as much. In other words, cancer cells exposed to radium rays undergo self-digestion at a much more rapid rate than do similar cells without the influence of these rays. French and Scandinavian experimenters have shown, on the other hand, that most enzymes, e. g., trypsin, pepsin, and coagulating ferments, are very susceptible to the action of radium rays, being soon rendered inactive. The autolytic ferment is, therefore, an exception, and in this Neuberger believes the explanation of the biological effects

of radium to lie. If the radium kills the enzymes that have to do with cell life, such as oxidizing ferments, reducing ferments, and ferments that have to do with cell synthesis, but leaves unimpaired the autolytic ferment, the cell will be killed and its destruction and absorption will be exceptionally rapid, because the autolytic process will not be opposed by synthetic processes. This explanation agrees well with the facts observed in practical application of radium, and has the advantage of being capable of further investigation since it places the action definitely in the cell enzymes, about which we are just beginning to get a working knowledge.

From time to time reports have appeared indicating that x-rays have a considerable influence on growths of lymphoid tissue, particularly leukemia and Hodgkin's disease. According to the experimental results obtained by Heineke,³ it may be found that radium rays are also very active in such conditions, for he found that radium rays seemed to have a particularly marked influence on lymphoid tissue. Extensive retrogressive changes occur after exposure, followed by absorption, and so susceptible are lymphoid tissues to these rays that extensive alterations may occur in subcutaneous lymph glands, when the skin overlying them is unaffected by the rays that pass through it before reaching the glands. As lymphoid tissue has considerable autolytic activity, much more than the skin, this susceptibility may be considered as in corroboration of Neuberger's theory.

DEMENTIA PRECOX.

While the term dementia precox was first used by Pick in 1891, to designate a group of cases of the juvenile insanities characterized by progressive mental deterioration, Kraepelin's name is chiefly associated with the modern clinical acceptance of the term. Dementia precox stands in some danger of losing its philologic significance through frequent reports of cases in adult life, and even in extreme old age. There are few physicians in or outside of asylum practice to-day who do not see frequent illustrations of the more or less classic types of Kraepelin's description. Indeed, about a fifth of all the insane admitted to asylum care are of dementia precox, hence the importance of knowing the nature and cause of this deteriorating mental disorder. Nor is science unaware of the pressing importance of the solution of this problem. Nearly every psychiatric journal contains researches into the etiopathology of dementia precox. Notwithstanding that the clinical foundation of dementia precox appears firmly established, there are a few who deny that Kraepelin's clinical description of this psychosis signifies any real advance in our knowledge of psychiatry. The great value of Kraepelin's work along this line, however, is shown by the rapid adoption of dementia precox as a clinical entity in asylum practice here and abroad. It stands

1. Pfäfer's Archiv, vol. c, 1903, p. 533.

2. Zeitschr. für Krebsforschung, 1904, vol. 11, p. 171.

3. Münch. med. Woch., 1904, No. 31 THE JOURNAL, page 847.

the proof of clinical needs. Sachs¹ very properly raises the question whether all the insanities of the juvenile period are to be classed with dementia precox. He presents cases which he believes are non-dementing psychoses occurring in this period. In rare instances, simple melancholias may begin at this period, and, of course, in such dementia does not appreciably enter. It is true Kraepelin maintains that the great majority of the juvenile insane deteriorate, but he expressly states that a small per cent. do not; they may not require asylum care, but may remain at home and finally be able to take up their life work in their chosen narrow field.

To detect the presence or absence of slight grades of mental deterioration in any given case is often difficult under ideal conditions; thus in asylum records, which are based on the severer grades of dementia precox and in which a certain uniformity of deterioration ought to be recorded, the degree of deterioration varies somewhat with the personal equation of the different staff physicians who make the notes. One needs to live in more or less constant contact with the insane to properly appreciate many of the difficulties of the problem. Certainly the routine office consultation of private practice is often a very inaccurate method in deciding these delicate points. The statistics of asylums Sachs believes to be insufficient to determine the dementing or non-dementing character of these psychoses, as only the worst mental cases go there; consequently, the invariable mental deterioration noted in cases sent there is vitiated. Unfortunately the inclusion of outside data often must be misleading and inaccurate. If some mental deterioration is invariably present in dementia precox, then Sachs believes his cases are exceptional and form a new type in the adolescent insanities. The subdivision of dementia precox as made by Kraepelin is only tentative; many atypical cases are certain of occurrence the more intently the types are studied. Kraepelin was the first to recognize this himself. A desire for simplicity in classification of the juvenile insanities, however, will demand much proof of those who attempt to establish new types of the adolescent period.

One of the strongest arguments for the dementing character of this psychosis must be based on the fact that it almost invariably develops in a soil of family and personal degeneracy. We would expect that the deterioration would be accompanied by a degenerative lesion either in the cortical neuron or its association processes. Researches are slowly accumulating which seem to support this view. There are but few who still believe in an auto-intoxication pathology for dementia precox, the origin of which must have been largely fanciful.

There are reasons to believe that the early death of imperfectly developed association tracts in the cerebral cortex may explain much in the pathology of this condition. We would urge a reapplication of Gower's abio-

trophy hypothesis for the early deterioration of certain brain tracts in dementia precox. It is at present the best explanation at hand for the early death of nerve systems in juvenile cord diseases, as shown in hereditary ataxy for example.

THE RIGHT TO GIVE AND TO TAKE DISEASE.

The latest development of anti-vaccination is the plea raised by Massachusetts anti-vaccinationists that the compulsory vaccination regulations conflict with the fourteenth amendment of the Constitution of the United States. To have smallpox is evidently in their opinion one of the privileges of citizens of the United States. We had supposed that compulsory vaccination laws were for the protection of the citizen, but these people wish the public to be denied such protection. A case of smallpox is a peril to everyone who comes in contact with it unless protected by vaccination or previous attack, and the fourteenth amendment might as well be pleaded against the non-enforcement of laws requiring vaccination. There is evidently here a good chance for lawyers to quibble, but the outcome of the suit ought not to be doubtful.

THE INSANE AS PUZZLE SOLVERS AND SHORT-STORY WRITERS.

Occasionally the Associated Press serves us up an excellent breakfast jest, while endeavoring to be serious. On November 29 our morning papers soberly informed us that a female inmate of a Minnesota insane asylum had won first prize in a magazine puzzle and "short-essay" contest! The humor of the occurrence seems to have passed unnoticed. The alienist will find in this incident some light on the psychologic status of the designers of magazine puzzles. The publicist will grasp at a new and promising method for agreeably occupying the time of the inmates of asylums and penitentiaries. Asylum superintendents will rejoice at the advent of a new amusement for their charges. Magazine publishers (those who promote circulation by guess) will immediately experience a forward jump in subscriptions. The physician may be perturbed over the probable fate of some of his, at present, sane patients. The possibilities of the situation are inexhaustible. It will be interesting to know the subsequent effect of the experience on the mental state of the successful solver.

INTERNATIONAL UNIFICATION OF MEDICAL STATISTICS.

There is published this year from the office of the Surgeon-General of the Army, for the first time in separate form, the complete series of the tables of "International Military Medical Statistics." These are the tables agreed on at the meeting of the International Commission for the Unification of the Medical Statistics of Armies, held at Budapest in 1894, and modified by the last meeting held at Madrid in 1903. Of the twelve countries which were a party to the agreement only one other than the United States has published all of the ten tables, and in no other "Supplement" are they so complete and detailed. These tables show the

1. Proceedings Amer. Neurolog. Assn., September, 1904; Proceedings N. Y. Neurolog. Soc., October, 1904.

total movement of sickness and mortality in absolute and proportional numbers by departments, by the larger garrisons, by months, and by arms of service; the same data for thirty-five of the most important diseases or disease groups; also the influence of rank, length of service and age on deaths and discharges for disability. Thus for the first time the most important medical statistics of the United States Army become available for comparison with those of foreign services, and much interesting and valuable information will no doubt be obtained.

THE PHYSIOLOGIC EFFECTS OF DIGITALIS.

The view has been put forward that under normal conditions digitalis strengthens the left heart by causing maximum dilatation of the left coronary artery and at the same time enfeebles the activity of the right heart by causing contraction of the right coronary artery. Accordingly, it is suggested that a deviation from such conditions may be considered as indicative of the existence of some disorder causing increased activity on the part of the right ventricle as a result of diminished contractility of the right coronary artery. This, it is pointed out, may be brought about by the administration of digitalis in the presence of disease of the right coronary artery, of which therefore the phenomena described may be considered as diagnostic. A case illustrative of this relation was recently reported by Prof. T. von Openchowsky¹ to the Society for Internal Medicine at Berlin. The patient was a man with a previous history of articular rheumatism and disease of the heart, who presented symptoms of failing compensation, in association with mitral stenosis and insufficiency and aortic insufficiency, together with diffuse arterial sclerosis. One grain each of calomel and powdered digitalis was prescribed, but on account of the development of alarming general symptoms the digitalis was withdrawn. Some improvement followed, but the symptoms became once more aggravated when digitalis was subsequently again administered. After each administration of digitalis increased activity of the right heart was observed, as indicated in cardiograms and tracings of the venous pulse, while at the same time diminution in the activity of the left ventricle was noted. Death resulted and on postmortem examination the diameter of the right coronary artery was found to be larger than that of the left, namely, 14 mm. as compared with 8 mm. The anterior branch of the right coronary artery was the seat of sclerosis in slight degree and the trunk of the vessel in lesser degree. The explanation offered for the phenomena observed is that as a result of the abnormal dilatation of the right coronary artery and its failure to contract under the influence of digitalis the work of the right ventricle was needlessly increased, while the left ventricle was unable to propel the larger amount of blood sent to it. The case illustrates among other things the pharmacologic and dynamic dissociation in the activity of the two ventricles and also the danger that may attend the indiscriminate administration of digitalis, especially in the presence of disease of the right coronary artery, and particularly arteriosclerosis.

Medical News.

ARKANSAS.

Smallpox in Pulaski County.—On November 29 and 30, 13 new cases of smallpox were reported to the county health officer. All the patients were negroes and live near Argenta. In all 24 cases have been discovered.

Accredited List for Hot Springs.—Nearly 150 physicians have applied to the federal medical board to have their names placed on the accredited list, which is intended to do away with the "drumming" nuisance at Hot Springs.

New Railway Hospital.—The new hospital for the Cotton Belt System at Texarkana is now in operation. The surgeons, nurses, servants and 35 patients arrived by a special hospital train, November 22, and were at once installed in their new quarters.

ILLINOIS.

Diphtheria is said to be epidemic in Pike County, where five cases and one death have been reported.

New Hospital Opened.—The new hospital for contagious diseases connected with Cook County Hospital, which has been erected at a cost of \$122,000 and will accommodate 175 patients, was inspected by the advisory committee of the county board, November 30, and is ready to receive patients. The committee also inspected the new hospital for children, which will be completed early in next year.

Personal.—Dr. Joseph E. Lowery, Homer, was run over by a train in Peoria, November 22, and his left foot was so crushed that amputation may be necessary.—Dr. Henry G. W. Reinhardt, Chicago, has been appointed assistant coroner's physician of Cook County; Dr. Haim I. Davis, Chicago, county physician, and Dr. Vaclav H. Podstata has been reappointed superintendent of the county institutions at Dunning.

Chicago.

Homeopathic Colleges Consolidate.—It is announced that Hahnemann and the Chicago Homeopathic colleges have consolidated under the name of the former, and that this consolidation is preliminary to a merger with the University of Illinois.

New Michael Reese Hospital.—The competition of architects for plans for the new Michael Reese Hospital has resulted in the acceptance of the design of Richard E. Schmidt. The new building will be a six-story fireproof structure and will cost about \$400,000.

Personal.—Dr. Henry Gradle has resumed practice after recovery from a severe illness.—Dr. Henry William Howard has been appointed secretary to the surgeon general, with rank of first lieutenant and assistant surgeon.—Dr. Alfred De Roulet suffered the loss of \$100 worth of jewelry as the result of a burglar's visit, November 28.

Deaths of the Week.—The total deaths for the week ended December 3 were 450, 25 more than for the preceding week and 28 less than for the corresponding week of last year. The respective annual death rates per 1,000 were 12.44, 11.49 and 13.30. Pneumonia caused 64 deaths; consumption, 54; heart diseases, 49; violence, 41; Bright's disease, 35, and cancer, 30.

Pneumonia Less Virulent and Less Prevalent.—Pneumonia is much less prevalent and less fatal this year than usual. During the first eleven months of 1903 there were 4,133 deaths from the disease. During the similar period this year only 3,690 pneumonia deaths occurred. In November, 1903, there were 333 deaths and last month only 260 from pneumonia. The present Chicago proportion of pneumonia deaths to deaths from all causes is 13.6 per cent.; from consumption it is 11.3 per cent.

IOWA.

District Society to Meet.—The Central District Medical Association of Iowa will meet at Ames, December 20.

Did Not Report.—Dr. George G. Bickley, Waterloo, was fined \$10 for failure to report contagious diseases to the health department.

A Warning.—Dr. R. J. Ludlow, Mechanicsville, asks us to warn physicians of Iowa and the west regarding a traveling man who is selling surgical instruments and appliances, claiming to represent a Chicago firm, and carrying various side lines. He succeeded in getting \$8 from Dr. Ludlow by offering to send him a special attachment to some instrument, which was con-

sidered a very excellent offer. It is the old story, the traveling man made a good appearance, what he said was very plausible and the doctor was "worked."

Upholds State Board.—The Supreme Court, on November 17, greatly strengthened the State Board of Medical Examiners by deciding two important cases in its favor. In Wright County, J. W. Edmunds had been unsuccessfully prosecuted because he as an itinerant oculist had professed to heal everything. The court held that he should have paid a license fee as an itinerant doctor. In Boone County a magnetic healer, G. H. Heath, had escaped because no proof could be given that he had actually tried to heal anybody and he claimed also that as he administered no drugs he was not under the law. The court held to the contrary and that he was amenable to the law.

LOUISIANA.

Student Dies.—Mr. P. Lestang Sarpy, a member of the class of 1906 at Tulane University Medical Department, died November 22 from tuberculosis at his home in New Orleans, aged 22.

Aged Physician Beaten and Robbed.—Dr. Waldemar Bille, an aged practitioner of New Orleans, was assaulted in his office by an unknown miscreant, November 14, who, after beating Dr. Bille into unconsciousness, robbed him of \$10 in cash and a number of checks, and escaped.

Sues Picayune.—Dr. J. Denegre Martin, New Orleans, has sued the Nicholson Publishing Company of that city, claiming damages of \$10,000 alleged to be due for injuries sustained by the publication in the *Picayune* of the report of an operation performed by Dr. Martin, said publication being unauthorized and not desired by him.

Indictment Quashed.—The indictments against Dr. George A. B. Hays, superintendent of the Insane Asylum of the State of Louisiana, Jackson, for alleged violation of the law relative to postal rights of inmates of the institution, was ordered quashed, on account of the unconstitutionality of the act under which the indictments were returned.

MARYLAND.

Baltimore Deaths.—The deaths for the week ended December 3 numbered 167, a general annual rate per 1,000 of 15.12; colored, 29.14, and white, 12.19.

Will Build Isolation Hospital.—The Baltimore Municipal Hospital Commission has decided to locate the infectious diseases hospital on 20 acres of land in the eastern suburbs, recently purchased by the city.

Personal.—Dr. Jane E. Robbins of New York, head resident of Normal College Alumnae House, is to be head resident at the Locust Point Social Settlement. —Dr. James S. Woodward, Sparrow's Point, has gone on a trip to Pensacola, Fla. —Dr. Samuel G. Fisher, Chestertown, has had a stroke of paralysis.

New Society.—A society to be known as "The Library and Historical Society," and designed to promote literary and historical research, will be founded December 20 at the University of Maryland, Baltimore. At the opening meeting papers will be read by Dr. William Osler, Prof. Henry E. Shepherd and Dr. Eugene F. Cordell.

One Nurse's Work.—Last March Mrs. Osler started a fund to support a visiting nurse for tuberculous cases under the supervision of the Visiting Nurses' Association of Baltimore. She has cared for 132 cases, has paid 778 visits, in all instances with assistance and instructive advice, and has distributed 364 tickets for milk and eggs. Care-takers were provided in urgent cases and many were referred to dispensaries and hospitals.

Cocain Habit Alarming.—The cocain habit has grown to an alarming extent, chiefly among the negroes and the inmates of houses of ill repute. At the last session of the legislature a law was passed forbidding its sale except on a physician's prescription, on penalty of a fine, doubled for each conviction and accompanied by six months' imprisonment on the third offense. A number of druggists have been arrested for violating this law.

MASSACHUSETTS.

Physician Gains Verdict.—In the damage suit of Mrs. Horace Chouinard against Dr. Pierre Brunelle, Lowell, in which she claimed malpractice to have caused the death of her husband, the jury, after short deliberation, found for the defendant.

Changes in Medical Examiners.—The governor has appointed Dr. Clifford S. Chapin, Great Barrington, associate medical ex-

aminer in the fourth Berkshire district, vice Dr. John B. Beebe, Great Barrington, promoted to be medical examiner.

Osteopath Not a Doctor.—H. Wilmot Johnson, an osteopath of Worcester, was arraigned before Judge Utley, November 21, on the charge of violating the registry of medicine laws, and was fined \$100. He appealed. His contention was that he had the right to call himself "Dr." provided he did not prescribe medicine.

School Inspection.—There was appropriated this year by Boston for the medical inspection of its schools \$47,000; 50 physicians are employed and they visit daily schools where there are 2,000 pupils. Their purpose is to advise the teacher what to do when a child is ill. If an infectious disease is detected, they have the authority to remove patients to the hospital or to institute strict quarantine in the home. Whether first seen by the inspector or not, quarantine is not removed from any child in his district without his written approval.

New Anti-Spitting Ordinance.—The new anti-spitting ordinance adopted by the Springfield Board of Health, November 18, is more comprehensive than the previous ordinances. It provides:

Spitting is prohibited either on the sidewalk, crosswalk or footway of any public street, way, park or square, or on the floor of any hall or office in any hotel, apartment house, tenement or lodging house which is used in common by the guests or tenants thereof, or on the floor, platform, steps or stairs of any public building, hall, church, theater, railway station, store or factory, street car or other public conveyance.

September Health.—The Boston Board of Health reports for September shows 888 deaths, or an annual rate of 17.34 per 1,000. Chief among death causes were: Typhoid fever, 17; diphtheria, 14; tuberculosis, 103; cancer, 51; meningitis, 20; apoplexy, 32; heart disease, 65; pneumonia, 60; diarrhea, 111; intestinal obstruction, 12; acute nephritis, 38; chronic Bright's disease, 17, and congenital debility, 84. Unusual causes noted were: Cholera nostras, 2; whooping cough, 6; saturnism, 1; tetanus, 1; epilepsy, 1; thyroid disease, 1; appendicitis, 4, and puerperal septicemia, 2.

MISSOURI.

Diphtheria Closes Schools.—On account of the prevalence of diphtheria at Ludlow, schools and churches have been closed and public meetings prohibited.

Hospital Saturday.—The collections made December 3 in St. Louis to the Hospital Saturday and Sunday Association amounted to \$15,546.46, or \$4,141.54 more than in 1903.

Personal.—Dr. George B. Thompson, Kansas City, the new coroner of Jackson County, entered on his duties December 1. —Dr. Walter M. Cross began his work as city chemist of Kansas City November 15.

Requests to Hospitals.—By the will of Mrs. Agnes Kennett, St. Louis, \$5,000 is bequeathed to St. Luke's Hospital and \$2,500 to the Mullanphy Hospital Association in memory of her son, the late Dr. William C. Kennett.

To Organize a Medicolegal Society.—About fifty physicians and lawyers of Kansas City took the initial steps, November 15, toward organizing a medicolegal society to study medical jurisprudence. Dr. John Puntin presided. A committee was appointed with instructions to form definite plans.

Imprisoned and Fined.—Dr. Caleb E. Mathis, Kansas City, who pleaded guilty November 18 to the charge of sending through the mails matter prohibited by law, was fined \$500 and sentenced to imprisonment for one year. This sentence was afterward modified to six months' imprisonment and a fine of \$750, and he commenced his term at Clinton prison November 29.

NEW YORK.

Crusade Against Tuberculosis.—The Charity Organization Society of Buffalo, through its committee on tenements and tuberculosis, has undertaken a crusade against tuberculosis. An effort is being made to tell the poor how they can resist this disease, and cards and leaflets of instruction have been issued to be distributed widely through physicians for the education of those suffering from this disease and their friends.

Swindler in the Toils.—F. W. Kingland, who is wanted by the Rochester police, was arrested at Niagara Falls on a charge of swindling a number of physicians in that city. He represented himself as an agent of the United States Health and Accident Company of Saginaw, Mich., and victimized physicians by offering them positions as medical examiner in the place they were located, provided they took out policies with the company. In most cases he would demand a deposit on

the policy. He was arrested and confessed, saying his downfall was caused by drink. He was sentenced to four months in the Niagara County jail. He is known to have operated in Waterloo, Albion and Rochester.

New York City.

Verdict in Favor of Doctor's Widow.—The jury has awarded the widow \$40,000 in her suit against Richmond Light and Power Company on account of the death of Dr. Francis Morhard, who was killed in his home by a heavy electric current which entered the house because of the failure of the transformer to perform its work.

Rockefeller Laboratory Begun.—The corner-stone of the first building of the Rockefeller Institute was laid December 3 by Dr. Simon Flexner, chairman of the governing board of the institution. This building will have a frontage of 100 feet and will be five stories high. The estimated cost is \$325,000. A small hospital will be built near it within the next two years.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended November 26, 376 cases of diphtheria, with 40 deaths; 324 cases of tuberculosis, with 166 deaths; 184 cases of scarlet fever, with 9 deaths; 136 cases of varicella; 98 cases of measles, with 9 deaths; 89 cases of typhoid fever, with 12 deaths; 3 cases of smallpox, and 14 deaths from cerebrospinal meningitis.

To Inspect Dairies.—The health department in continuing its crusade for pure milk has appointed several special inspectors, who have started on a round of inspection to include all the dairies that supply New York City with milk. The health department is gratified with the improvement in the milk supply and the assistant corporation counsel has expressed the determination to send future offenders to jail whenever possible.

Hospitals Still Need Money.—The annual report of the Society of the Lying-in Hospital shows that the scope and extent of its work have greatly increased during the past year. The excess of expenditures over receipts for the year ended September 30 was \$87,357.—The annual report of the Presbyterian Hospital shows that it has wards vacant because of lack of public support. The deficit for this institution for the past year was \$72,936.—The Society of St. Vincent de Paul is in need of \$12,000 in order to complete its fresh-air home for convalescent women in the Ramapo Hills. This institution will be opened to all regardless of creed.—At the annual meeting of the directors of the New York Skin and Cancer Hospital it was reported that about 5,000 patients had been treated in the different departments during the past year and that its resources had been greatly taxed.

OHIO.

Personal.—Dr. R. C. Longfellow has been made associate editor of the *Toledo Medical and Surgical Reporter*.

Ricketts Recovered.—Dr. Edwin Ricketts, Cincinnati, who was successfully operated on a short time ago at the Good Samaritan Amex by Dr. Charles A. L. Reed for umbilical hernia, has again resumed his professional work.

Regret Buechner's Death.—The medical and surgical staff of the Youngstown Hospital, at a meeting held November 10, adopted resolutions setting forth the work done for that institution by the late Dr. William H. Buechner and expressing their sorrow at his death.

Academy of Medicine Meets.—Dr. G. W. Crile, Cleveland, was the guest of the Academy of Medicine of Toledo and Lucas County November 25, and presented a paper on "The Prevention of Shock and Hemorrhage in Surgery." Dr. Crile was elected an honorary member of the academy. After the meeting a five-course supper was served, at which the academy and visiting practitioners met to honor their guest.

District Society to Meet.—There will be a meeting of the physicians of the Sixth Councilor district at Canton, December 19. The sixth district is composed of the counties of Mahoning, Portage, Summit, Stark, Wayne, Holmes, Ashland and Richland. A large representation of the physicians of each of these counties is expected at the meeting. The committee on arrangements and program is composed of Drs. Jacob F. Marchand, Odo E. Portmann, James Frankefelter, Austin C. Brant, all of Canton, and Dr. T. Clark Miller, Massillon, the councilor for the sixth district. Dr. J. N. McCormack, the organizer of the American Medical Association, will attend the meeting in the interest of more perfect organization of the physicians of the state.

PENNSYLVANIA.

Personal.—Drs. John and James H. Montgomery, Chambersburg, are spending the winter at Buena Vista, Fla.—Dr. Shoemaker of Oklahoma has been appointed physician at the Indian Training School, Carlisle.

Nurses' Home.—The new Nurses' Home of the Good Samaritan Hospital, Lebanon, was dedicated December 1. The home was the gift of Mr. and Mrs. Horace Brock and was erected and furnished at a cost of \$7,500.

Smallpox at League Island.—One case of smallpox was discovered among the marines on the United States ship *Prairie*, which recently arrived at the navy yard. The presence of contagious disease on the ship was reported in the lay press as diphtheria.

Philadelphia.

Bequests.—By the will of Charles Scott, the Methodist Hospital receives \$5,000 for a free bed, and the Methodist Home for the Aged \$1,000.

Carlsbad Physicians in Philadelphia.—Drs. Isadore Muller, Gustave Toepfer and Tyrnauer of Carlsbad, visited Philadelphia and its hospitals, December 2. They were the guests of Dr. Lewis W. Steinbach.

More Food Indictments.—The grand jury has indicted 47 persons on charges of violating the pure food law. All but one of the accused were dealers in fruit syrups or extracts, or proprietors of cheap soda water fountains.

Personal.—Dr. C. Edwin Verdier and Dr. Walter E. Fine have resigned from the resident staff of St. Luke's Hospital.—Dr. Charles Crosby has been appointed pathologist to the State Hospital for Insane, to succeed Dr. Edith Barker, deceased.

Dinner to Dr. Chapin.—A dinner was given in honor of Dr. John B. Chapin, superintendent and chief physician of the Pennsylvania Hospital for the Insane, in this city, December 1. The dinner was given in commemoration of the completion of Dr. Chapin's fiftieth year in serving the insane. He was presented by the members of the staff and the board of trustees with an oil portrait of himself. He has been superintendent of the hospital for more than 21 years.

Health Report.—Diphtheria is still prevalent throughout the city, 125 cases being reported for the week, an increase of one over the previous week. In all there were 255 cases of contagious disease reported, with 18 deaths, as compared with 296 cases and 20 deaths for the preceding week. Deaths from all causes numbered 426. This is an increase over last week, and a decrease of 25 from those of the corresponding period of last year. Of the deaths 51 resulted from pulmonary tuberculosis, 13 from cancer, 18 from apoplexy, 39 from cardiac disease, 33 from pneumonia, 36 from Bright's disease, and 8 from typhoid fever.

White Haven Exhibit.—A free exhibition of the work and results of the White Haven Sanitarium for Poor Consumptives was recently held in Philadelphia. The methods of outdoor treatment were demonstrated and the general plan of treatment employed in the institution was shown. Free lectures were delivered by members of the staff of the Henry Phipps Institute and men interested in the affairs of the sanitarium each night during the week. The lectures delivered were as follows: Monday, Dr. H. R. M. Landis, "History of Sanitarium Treatment in America"; Tuesday, Dr. Joseph Walsh, "Fresh Air"; Wednesday, Dr. W. H. Stanton, "Rest and Exercise"; Thursday, Dr. O. J. McCarthy, "Discipline and Personal Control of Patient"; Friday, Dr. H. M. Neal, "Nourishment"; Saturday, "Methods of Prevention."

GENERAL.

Northern Tri-State Medical Association.—This body of physicians of northwestern Ohio, southern Michigan and Indiana will meet in Toledo, Ohio, Jan. 10, 1905. Dr. G. W. Spohn, Elkhart, Ind., is president.

Increased Consumption of Hair Dyes.—The prejudice against elderly men in business is said to have resulted in a large number of men with gray hair resorting to hair dyes to make them look younger. The increased demand for hair dyes is almost simultaneous in this country, in England and on the continent. Inquiry at Liverpool showed that the recent enactment of more stringent regulations in regard to age in connection with industrial insurance was followed by a great demand for hair dyes.

Mosquitoes Increasing Near Laredo.—Since the withdrawal of the United States Public Health and Marine-Hospital sanitary forces on the Tean border, to which reference was made in THE JOURNAL, Oct. 29, 1904, page 1318, an increase has been noticed in the number of mosquitoes. The adult mosquito of the stegomyia variety is found everywhere and, while not in large numbers, shows that many breeding places must still exist.

Health Report of the Philippine Islands.—The report of the Board of Health for the Philippine Islands for July, 1904, shows that in the city of Manila there were, during the month, 563 births reported and 866 deaths of residents of the city and 57 deaths of transients, making a total of 922 deaths for July, as compared with 847 in June. Forty-eight per cent. of all deaths in the city of Manila, including transients but excluding stillbirths, occurred among children under one year of age. There were 11 cases of plague, with 10 deaths. Three cases of smallpox occurred in Manila; two of the patients were natives, the other was a European. One of the Filipinos died and the other two patients recovered.

Pan-American Congress and Public-Health Meeting.—The special sleeper, referred to December 3, page 1710, in the announcement of the Havana meeting, January 9-13, of the American Public Health Association, will leave Washington, January 4, instead of 5 as stated. The final announcement has been issued by the secretary, Dr. C. O. Probst, Columbus, Ohio, and may be had by those interested. The excursion route out of Virginia, District of Columbia and the Carolinas to Havana and return, as published in THE JOURNAL, December 3, page 1710, has been reduced from \$52 to \$48 for the round trip. Other conditions remain the same. Rates to Panama: in the South-eastern Passenger territory a rate of one fare plus \$1 will be granted to New Orleans, plus the ship rate, \$50, for the round trip to Panama. Date of sale of tickets, December 26 and 27. Connecting with United Fruit ship sailing December 28, 10 a. m., with final limit of thirty days from date of sale.

Bill to Increase the Medical Department of the Army.—The Secretary of War in his annual report, just issued, speaks in terms of approval and advocacy of this bill. He says:

It is evident that a staff department which has a personnel insufficient to perform the duties required of it in time of peace can not be successfully expanded to meet the increased responsibilities of war. The commissioned personnel of the medical department is nearly 200 short of the number required to perform its work at present, and the deficiency has to be made good by the employment of civilian physicians under contract. This is an expensive and unsatisfactory expedient in time of peace, while in time of war it heavily handicaps the efficiency of the department.

A bill to increase the efficiency of the medical department was sent to Congress at its last session with my approval, it having also received the favorable indorsement of my predecessor, Mr. Root. It provides for an increase in the medical department from 320 to 450, so as to do away with most of these contract surgeons. It also provides, approximately, the same proportion in each grade as is now given to the medical department of the Navy, and which the medical department of the Army enjoyed prior to the reorganization of Feb. 2, 1901. While this bill will only slightly increase the cost of the medical department, it will very greatly increase its efficiency.

FOREIGN.

First International Congress for Education and Protection of the Child in the Family.—The organizers of this congress announce that it will be held at Liege in September, 1905, and that the committees of propaganda in each country are composed of philanthropists, physicians, educators and philosophers of all kinds, as the subjects to be treated interest every one. Circulars will be sent on demand by addressing the Bureau du Congrès, rue Rubens 44, Brussels, Belgium.

Prizes for Pharmacy Students.—A scholarship of \$250 and four consolation prizes of \$25 each are offered by the firm of Fairchild Bros. & Foster, New York, for annual award to students of pharmacy in the United Kingdom. Examinations will be held in July and the winner of the scholarship may select any well-known school or college of pharmacy in Great Britain at which to study. Further particulars may be had of Mr. A. E. Holden, Bath House, 57, Holborn Viaduct, London, E. C.

A Medical Sketch Book.—A group of 13 well-known artists in Paris has founded a so-called medical journal to contain nothing but sketches, no reading matter except the titles underneath and the advertisements. A portrait sketch of Professor Hayem fills the first page of the second number of the new periodical, which bears the name of *Medica*. It is announced as an illustrated and humorous medical journal destined to fill a long-felt want and rest eyes weary of so much reading matter.

Medical Care on the Easy Payment Plan.—The *Gazette Méd. Belge* reproduces an advertisement now appearing in certain European journals. It announces the incorporation of a society which assumes the charges of medical attendance, medicines, operations, deformity apparatus, etc., the expenses to be repaid by the patient on the easy payment plan. "The patient can thus obtain the care and aid hitherto available only for the rich, and can complete the course of treatment now too often interrupted from reasons of economy. The charges are the same as when cash is paid, there being no expense or interest."

The Langenbeck Army Surgery Fund.—The family of the Berlin surgeon, von Langenbeck, founded in 1897 an endowment of about \$12,500, the income of which was to be devoted to sending some medical man to the seat of any war in progress in which the German Empire is not participating. The stipend was awarded this year for the first time, Dr. Schäfer of Berlin being given funds for a trip to Manchuria, and he has just left for the seat of war. The trustees of the fund are the surgeon general of the German army, the president of the German Surgical Association, and the successor of von Langenbeck in the chair of surgery at Berlin. The income can be devoted to any phase of military surgery in case no war is in progress.

Prophylaxis of Cancer.—The efforts of Winter to teach the public the danger of delay when cancer is suspected have been chronicled recently in these columns. The great increase in the proportion of operable cases testifies to the great benefit realized from this crusade. The obstetric and gynecologic societies of Leipsic and Dresden are sending duplicates of Winter's circulars to all the physicians in Saxony. The *Berliner klin. Wochenschrift* remarks, however, that the chief obstacle to the proper prophylaxis of inoperable cancer is the activity of the irregular practitioners and "herb women," who promise a cure by internal or local measures until the opportunity for an operation is lost. Unless such practices are regulated by law the efforts of medical men toward prophylaxis of inoperable cancer will be more or less futile in certain regions.

Electro-Vigor Before the Courts of Germany.—The dealer handling the apparatus called electro-vigor was sued recently at Hamburg and Breslau for advertising extravagant statements in regard to its therapeutic efficiency. The medical authorities asserted that it was a very defective apparatus and contained nothing to justify the high price charged for it, nor the assertions as to its curative powers in certain diseases. The majority of the cases reported as cures were fraudulent. The Hamburg court imposed a fine of \$37.50, and the Breslau court a fine of \$7.50. The defendants in the suit at Hamburg were the dealer, a merchant and the advertising department of seven journals. The suit against all but the first was dismissed. At Breslau he was the sole defendant. The details of all these suits brought against irregular practitioners and methods are given weekly in the *Allg. med. Ct.-Ztg.* of Berlin, from which the above is quoted.

Organization of the Profession in Germany.—The enormous growth of the *Leipziger Verband*, the German society founded a few years ago to protect the economic interests of physicians in Germany, especially in the matter of contract practice, has necessitated its reorganization on a somewhat different basis. This was accomplished at the representative meeting, held at Leipsic, November 6. It was learned that with a few exceptions the matter of contract practice had been satisfactorily adjusted, the sickness insurance societies—the *Krankenkassen*—no longer trying to grind down their medical officers to the extent that had prevailed previously. In many instances they had forestalled the demands, learning from the experiences in other places that the demands of a solidly organized profession could not be treated lightly. Those interested in this organization will find the details in THE JOURNAL of May 28, 1904, page 1435.

French Congress of Surgery in 1905.—The congress will convene at Paris the first Monday in October. The questions appointed for discussion are "Surgery of the Pancreas," "Restorative Surgery of the Face," and "Conservative Surgery in Trauma of the Limbs." It was decreed that suggestions for a subject to be inscribed on the order of the day at these congresses must be signed by at least twenty members to receive consideration. Before the recent congress adjourned it passed a resolution in regard to the Doyen cancer serum to the effect that the Pasteur Institute should be asked to repeat and control Doyen's researches, and that the Society of Surgery should admit Doyen—at his request—to present cancer sub-

jects before treatment and at every third month thereafter to note the progress of treatment. The appointment of a permanent committee had been suggested, but was outside the powers of the congress. The matter was thus left to the Pasteur Institute and the Société de Chirurgie to confer with Doyen and agree on the mode of investigation. The conference has been held and the Doyen serum is now being studied by eminent authorities.

Multiple Arsenic Poisonings by a Hysteric.—A woman at Bordeaux, belonging to the upper classes, has been convicted of theft, arson and of the poisoning of several members of her family. In the expert testimony, Anglade stated that she presented all the symptoms of the hysteric neurosis. She should be placed under restraint, he said, but not in an insane asylum. She belongs in the institution which all the congresses on mental disease have been clamoring for, a place where the dangerous incomplete, imperfect and semiresponsible should be kept under restraint. Pitres of Bordeaux compared the serenity of the prisoner, her lack of fear and of remorse, to the anesthesia of her integument and organs. He considered her responsible for her acts. They showed a logical sequence and love of crime. She voluntarily plans deeds, but she would never carry them into execution if she were not a victim of hysteria.

Isolation of the Tuberculous.—The Paris Société des Hôpitaux was requested by the authorities to suggest the best means for prompt, practicable isolation of the tuberculous in the hospitals. The committee in charge recommended that certain quarters in the hospitals should be set apart for tuberculous subjects. They should be in a separate pavilion, if possible, or, at least, it should have a separate entrance. The dishes, etc., should be numbered for individual use of the patients, and sterilizing apparatus should be provided for the linen and spittoons. Subjects with recognized tuberculosis should not have access to the other wards. Each ward should have several beds isolated from the rest of the room for provisional isolation of the dubious cases. There should be some establishment to serve as a home for the surplus tuberculous, and the number in the hospitals should always be kept down by evacuating the surplus, without further formality than a line from the physician in charge certifying to the diagnosis and demanding the admission of the patient on account of the crowded condition of the hospital quarters.

The Statue to Ollier.—On November 13 the colossal bronze statue of Prof. L. Ollier was unveiled at Lyons with appropriate ceremonies. Contributions for the statue had been received from physicians and surgeons the world around; some of the surgical societies made a special corporate contribution and sent a delegate to the ceremonies. Oscar Lassar of Berlin thus represented the German Surgical Association, and Lambotte of Brussels, van Stockum of Rotterdam and many other prominent surgeons were there in a similar capacity. The statue is the work of A. Boucher, one of the foremost sculptors of France, and represents Ollier standing, scalpel in hand. It is not far from the statue of Claude Bernard, another of Lyons' famous sons. In the addresses, Ollier's great work in promoting conservative surgery based on physiologic laws was duly emphasized. It was recalled that at the surgical congress held at Lyons in 1894 he exhibited 58 patients operated on according to these principles from ten to twenty-five years before, showing the fine functional results obtained in the new articulations resulting from his surgical intervention. On a table before him lay the bones resected from these patients, and those present could see for themselves the physiologic repair of the missing parts, and compare the bones with their regenerated substitutes.

Physician as Mayor.—Lyons is the second city in France, and for several years it has had a physician for mayor, Dr. V. Augagneur, who has recently been elected deputy to the national legislature, receiving 4,237 votes out of a possible 4,668. Dr. Augagneur is 49 years of age and is professor of pathology. He founded and edited for 15 years the *Province Médicale*, but relinquished this task when he became mayor. His stringent regulations in regard to posters, etc., have already been mentioned in THE JOURNAL, as also his nickname of "the emperor." His specialty is syphilography, and his address at the Brussels Preventive Congress led to the organization of the French extra-parliamentary preventive commission, of which he is one of the most active members, as also of the supreme board of the *Assistance Publique*—the administration of the hospitals, etc. He was a member of the city council for years before he succeeded Dr. Gaillon as mayor, and writes frequently for the local *Republican* on subjects of social

economics and hygiene, popularizing the latter in a series of papers entitled "Chats with the Doctor," signed with a nom de plume. The *Gazette Médicale de Paris* gives the platform on which he was elected deputy. We notice that it includes the assumption by the national government of all railroads, mines, insurance, banks, monopoly of alcohol and sugar refining. Further planks in this medical platform are child labor, the eight-hour day and the entire responsibility of the proprietors in industrial accidents, surveillance of factories by inspectors and limitation of inheritance of property to the direct line, outside of the direct line fortunes to be taxed by a progressive assessment.

From the Seat of War.—The *St. Petersburg med. Wochenschrift* has been publishing extracts from the letters home of physicians at the seat of war. The issue for November 12 contains a long letter from Dr. O. Hohlbeck, dated September 24. He describes the first weeks in August as passed in tents watching the pouring rain, with very little to do in the hospital in his charge just outside of Liaoyang. Then the Japanese advanced on the town and the great battle was fought, the Russians firing 104,000 grape shells and the Japanese many more. The hospital, with accommodations for 400, was soon overcrowded, and every day detachments of the wounded were forwarded by train to hospitals farther inland, to make room for the new hundreds and thousands constantly arriving. The wounded seemed to do well at first; if they could have been tended further without removal all would have been well, but the necessary evacuation and railroad trip brought on complications in many cases. The station was close to the hospital quarters and the reserve troops helped to carry the wounded to the cars. The system and order displayed seem to have been remarkable under the circumstances. The hospital force worked night and day and gradually grew so accustomed to the infernal din that they almost ceased to notice it. The thought of personal danger amid the shrapnel shells bursting around them does not seem to have occurred to them. The evening of the second day the commanding officer came that way and was amazed to find the hospital still there. He ordered them to clear out at once and move to a safer place up the railroad. So the tents were taken down and all the hospital paraphernalia put on the train and the hospital established again at a point farther north. Hohlbeck remarks that he did not have much linen to pack, as he had given away all of his to the wounded. Just before the hospital was evacuated several hundreds of the wounded were taken to the train, and as the soldiers were all engaged in the battle, the hospital force had to manage as best they could alone. He draws a graphic picture of the waiting for the trains, after nightfall, hundreds of wounded lying in tents or on the ground, in an agony of dread lest they be left behind, no lights allowed, and the cannonading and firing keeping up incessantly. The day had been the mikado's birthday and the Japanese were making superhuman efforts to complete their work on that anniversary. These letters are all in German, and are most interesting from every point of view. As they were not written for publication, the simple, homely style is all the more forcible. The surgeons found it necessary to operate at once in cases of injury of the blood vessels or of the bladder and in wounds of the skull, especially those with splinters and those in which the bullet took a tangential course. All other injuries were merely dressed and further surgical intervention postponed. The *Russkii Vrach* of November 6, No. 45, contains an article in Russian on the "Evacuation of the Wounded," read before the Charbin "Temporary" Medical Society in September. The physicians at the front are anxious to know if any means are known for restoring to consciousness persons overcome by the fumes of lyddite.

LONDON LETTER.

Presentation to the University of Cambridge of Dr. Ole Bull's Drawings.

The University of Cambridge has recently been placed under considerable obligation to Dr. Ole Bull, the eminent ophthalmic surgeon of Christiania, by his gift of 372 highly finished drawings in water color, illustrating diseases of the eye and ear. These drawings were exhibited at the museum of the recent meeting of the British Medical Association. They are portraits taken from typical and rare cases met with in hospital and private practice during the last thirty-six years, and show a minute accuracy and realism which have seldom been equaled. An important feature is that the collection is purely clinical, without any attempt at diagrammatic representation, and without exclusion of cases

which slightly differ from the usual type. Thus each disease is illustrated by drawings (with brief clinical notes) of a series of cases which should convey to the student a clear idea of its most common forms and variations. In his work, Dr. Ole Bull displays a high degree of technical excellence and the advantages of the surgeon being his own draughtsman; for only the trained observer can delineate the finer points of morbid changes with a correct appreciation of their meaning and importance. The thanks of the university have been given to Dr. Bull by a special act of the senate, which is accorded only to donors of gifts of recognized value.

The Conveyance of Smallpox by Vagrants.

The conference of sanitary authorities of England and Wales, to decide on a remedy for the tramp nuisance, referred to in THE JOURNAL, November 5, was held in London November 10, under the auspices of the London County Council. Many motions were adopted, and a committee was appointed to bring the views of the conference to the notice of the local government board and also to obtain parliamentary support. The members of the conference seemed to be of the opinion that the rights of the vagrant to personal liberty should be set aside where questions of public health are concerned. They considered that powers should be conferred on local sanitary officials to detain him if he is suspected of liability to convey infectious diseases, and to vaccinate or to revaccinate him and to disinfect his clothing. The conference also requested an investigation of the causes of vagrancy in Great Britain, and of the best methods for its repression.

The Infants' Health Society.

This society, formed last spring to spread the knowledge of the best way to combat the factors prejudicial to the health of infants, desires to maintain an infants' hospital; to encourage the formation of dispensaries and milk depots to supply with or without payment food adequate for the infant; and generally to further the work by means of pamphlets, leaflets, lectures, etc. A special committee, including Mr. Mayo Robson and Sir A. D. Frripp, will carry on a special hospital at Hampstead under the name of the Infants' Hospital. Sir Lauder Brunton, Dr. T. M. Rotch and Dr. Henry Ashby have been appointed consulting physicians and Dr. R. R. Vincent, physician. The society takes as its postulate that the public are lamentably deficient of the knowledge of the right manner to succor their children and that the medical profession does not realize that fact. The society has just published a pamphlet stating that one-fourth of the deaths in the United Kingdom occur in children under the age of one year and that a large proportion of those which survive develop rickets. Attention is called to the almost complete failure of the present method of rearing infants of the working class. The remedy proposed is the encouragement of maternal nursing under proper conditions and the insuring of adequate substitute food when this is impracticable. It is proposed to establish the following organization: 1. A milk depot or out-patient department where babies can be seen at regular intervals by a physician, who will prescribe suitable food; 2. a trained nurse resident in the district, with special experience in regard to infants, and 3, the co-operation of coroners so that inquests may be held on all infants whose deaths are *prima facie* due to improper feeding.

Arsenic in the Urine.

Mr. William Thomson, F.I.C., of Manchester has proved by an interesting investigation that arsenic may occur in the urine as a result of the environment of the individual. He found arsenic in the urine of some people living in that city and the question arose as to its source. In the urine of inhabitants of Manchester convalescing at the seaside, arsenic was only exceptionally found. The urine of persons engaged in glass manufacture in which arsenic was used was found to contain the drug in considerable quantities. Similar results were obtained with the urine of persons engaged at Swansea in metallurgical work in which the presence of arsenic may reasonably be presumed. It was also found in the urine of those not engaged in the operations, but living near the works. Laborers in nickel and cobalt works, copper smelters, colliers, pearl grinders and spelter furnace-men all excreted arsenic in the urine. On the other hand, the urine of people living in districts where only peat is burned was free from arsenic. Milk taken from cows in the neighborhood of Manchester contained minute quantities of arsenic, while samples taken from cows in the Hebrides showed no trace. Mr. Thomson also examined grilled meat for arsenic, as it was considered probable

that arsenic from the coal or coke used in grilling might contaminate it. This was found not to be the case, probably owing to the rapid current of air between the fire and the meat, which carries away any arsenic that may exist in the fuel. In cigarette papers only an inappreciable amount of arsenic was found. In the thyroid gland Mr. Thomson found a very minute quantity of arsenic, so minute that he thought it could hardly be regarded as a normal constituent, as Gautier had stated. The heart, spleen, liver, kidney and rib bones were found free from arsenic, but the lung contained considerably more arsenic than the thyroid gland and the hair a great deal more than either. In the brain a minute quantity was found.

The Royal College of Surgeons of England.

The annual meeting of the fellows and members of the Royal College of Surgeons of England was held with the president, Mr. Tweedy, in the chair. He placed before the meeting a report dealing with a large number of matters affecting the profession. Amongst these was the question of instituting a diploma in tropical medicine and hygiene. The attention of the council of the college was first called to the subject by the colonial secretary, who wrote referring to the decision of the University of Cambridge to establish such a diploma (as previously announced in THE JOURNAL) and suggesting the desirability of similar encouragement being given by the college to the study of tropical medicine. The Royal College of Physicians received a similar communication and the question was referred to the joint committees of management of the two colleges who, while expressing an opinion in many respects adverse to the proposal, nevertheless recommended that after a sufficient period of observation of such tropical diseases candidates should be admitted to an examination held by the royal colleges and, on passing, receive a diploma. After further opposition from the College of Physicians, who would not adopt the recommendation, holding (with their usual conservatism) that as tropical medicine is only a part of general medicine, such a diploma is unnecessary, a conference was held between representatives of the two colleges, and the following recommendations were adopted: 1. That visitors be appointed to attend the examinations of the School of Tropical Medicine and to report on the scope and study and on the examination, and that a request be addressed to the naval, military and colonial authorities to allow visitors to attend their examinations in tropical medicine for a similar purpose. 2. That at the end of a year a report be made by these visitors on the whole subject of tropical medicine. 3. That in the event of the colleges adopting these recommendations a communication be sent to the colonial secretary.

Another subject of the report was the communication received by the council from the Spectacle Makers' Company asking for the views of the college on a proposal to include sight testing in the examination held by the company and to extend their diploma by certification of efficiency therein (a proposal previously condemned by the British Medical Association at the last annual meeting, and by the Ophthalmological Society, as previously reported in THE JOURNAL). In replying, the council said that "considering the hidden dangers and the untoward possibilities that may attend almost any morbid state of the body, it is against public safety and welfare that any one should be deemed competent to prescribe any remedy or appliance who has not had an efficient medical and surgical training. In the interest of the public no countenance should be given to any proposal likely to foster the belief that tradesmen, whatever be their technical skill, are safe guides in the treatment of diseased conditions." The usual resolution, which has been passed for the last 20 years, condemning the refusal of the council to accede to the demand of the members for representation on that body was passed.

The New Buildings of the Liverpool University.

The foundation and development of universities in the provinces on the basis of the local medical schools is a phenomenon of quite recent years. New buildings of the medical school and a new physics laboratory have been opened at Liverpool by the chancellor (the earl of Derby) and Lord Kelvin respectively. A new anatomic museum 60x40 feet, lighted on both sides and surrounded by a gallery, and a dissecting room 70x40 feet, lighted on both sides as well as from the roof, have been built. Between the medical school and the physics laboratory are the laboratories of physiology and pathology named after the late Rev. Thompson Yates, who munificently provided the cost, and the Johnston laboratories of biochemistry, tropical medicine and comparative pathology. The physics laboratory covers 9,600 square feet and has an average height

of 55 feet. The foundation is on solid rock and every precaution has been taken to provide the solidity and rigidity required for the department. The buildings are heated by low-pressure hot water, ventilated by an exhaust fan in the roof and supplied with electricity for lighting and other purposes. In fact, they are replete with every modern apparatus and improvement. The cost is \$500,000.

Correspondence.

The Crusade Against Tuberculosis in St. Louis.

ST. LOUIS, Dec. 1, 1904.

To the Editor:—St. Louis is keeping pace with other cities in this work. Following the presentation of the subject of the limitation of tuberculosis in the conference of charities last spring, a committee on organization was appointed resulting in the formation of the St. Louis Society for the Prevention of Tuberculosis. The plan adopted was to make each branch as representative as possible and yet to some extent interdependent. The chairmen of the different special committees constitute the executive committee, which in turn is made the special committee on tuberculosis of the Civic League, which has over 3,000 members. In this way the society has the indorsement and sanction of the league without being limited in its work. The advisory committee consists of the president or manager of each large charity association, viz., the Provident Association, the Jewish Charities, the St. Vincent de Paul, the Salvation Army, and a member of the St. Louis Board of Health. The publicity committee includes the editor of each of the large dailies and the editors of medical journals. Beside these there are the committees on legislation, inspection, ways and means and the medical committee.

The plan of work has been somewhat delayed by the exposition, it being thought unwise to attempt public action until after December 1, but the measures proposed are as follows:

1. A statement to the public of the prevalence and danger of tubercular infection and an appeal for active, personal co-operation.
2. The distribution of leaflets in different languages with instructions for the hygienic care of the sick, the disposal of the sputum etc.
3. The inspection of the tenement parts of the city and the classifying of reported cases and the preparation of statistics as to places of greatest house infection.
4. Public lectures and school instruction.
5. Appointing of physicians in each ward who will give an hour in their office two or three times a week to the consumptive poor who come with an inspector's card.
6. The enforcement of the antispitting law in public places.

The question of a central dispensary and city sanatorium will come up later. Meanwhile a bill is pending in the city council giving the health commissioner specific power in dealing with tuberculosis in the crowded parts of the city. The new city hospital almost completed, will have a special pavilion for the consumptives, and it will not be long till we will have a city sanatorium outside the city limits for the convalescent and those in early stages.

The work at Mt. St. Rose, under the care of the Sisters of St. Mary, has been most gratifying. While the percentage of cures has not been great, possibly because cases in all stages are admitted, there certainly is a great opportunity for study in the care of these cases and of the methods for prevention and limitation. Plans for additional buildings are now completed which will double the present capacity.

Active effort in the work of the Society for the Prevention of Tuberculosis has been delayed because of the fact that the attention of all St. Louisans has been more or less given to the World's Fair, but with the happy termination of that enterprise we propose a more aggressive campaign. With an excellent organization and thorough indorsement by our great charities and health department, we hope to at least keep pace with other cities.

There is no doubt but that the limitation of tuberculosis is the question of greatest interest just now not only to the medical profession, but also to the public. It is largely a matter of education, for, while we do not know all about it by any means, if we only intelligently apply what we do know the disease will be largely controlled.

WILLIAM PORTER.

Travel Notes on Ceylon and the Singhalese.

CHICAGO, Nov. 23, 1904.

To the Editor:—I have read with much interest the "Travel Notes" on Ceylon by your able correspondent, Dr. Nicholas Senn. The statements of Dr. Senn apparently seek to give the impression that the Singhalese are the aborigines of Ceylon and are savages. The doctor says that "Ceylon was called Singhala by the natives of the island." It is not so. Originally Ceylon was known as Lanka or Lanka Dwipe (meaning the resplendent island). The word Singhalese was not derived from the name of the island, and the Singhalese are not the aborigines of Ceylon. Singhala (Sanskrit) means, literally, lion-killer—Singha, lion; hala, to fell. And the story is this: Wangu Desa, northeastern part of India, was the original abode of the ancestors of the present Singhalese race. A lion that devastated a part of that country, defying the prowess of many warriors, was killed by Prince Singhabahu, who was from that time known as the lion-killer. The band of warriors of the Rajput caste who came over to Ceylon under the leadership of Prince Wijaya, the son of Prince Singhabahu, called themselves Singhalese or lion-killers.

The Singhalese are the descendants of the Aryans of Central Asia and are members of the Indo-European or Caucasian race (see reports of John Bartholomew, F.R.G.S. Edinburgh).

"The rapid increase of the population of Ceylon," says Dr. Senn, "is not in accord with the fate of our Indians and Polynesians, whose rapid decimation and eventual extermination followed so promptly the footsteps of civilization." Allow me to say that the Singhalese have been a highly civilized and enlightened people for many centuries. Surely, however, the students of history are aware that the civilization of the world originated in north India, the original abode of the Singhalese race. Permit me to say that when I speak of world civilization I mean it in its spiritual as well as in its material sense. When the ancient Britons were in the wildest confusion on the banks of the Thames, having only leaves to cover their backs, we lived in substantial palaces built of stone, in the midst of luxurious surroundings. The ruins of palaces, temples, etc., which can be seen in the different parts of the island, eloquently testify to the fact of my statements. . . . The Singhalese should not be judged by the street beggars. The better classes of Singhalese have never been satisfied with the loin cloth alone. We have always robed ourselves in costly garments made of the finest textures of cotton and silk. . . .

I can not help but say that some of the results of the intercourse with Europeans are the introduction of abominable intoxicants, licensed prostitution and sensualistic habits, etc., and it is no wonder that the weaker races that were willing to ape the Europeans disappeared altogether. I am not blind to the many excellent qualities the Europeans possess, but I am forced to make the statement that those bad qualities counterbalance the others.

Discussion on Proprietary Remedies.

PHILADELPHIA, Dec. 5, 1904.

To the Editor:—On page 1680 of THE JOURNAL of the American Medical Association I am quoted as stating that eucain "is probably not worth anything." I trust that you will publish the statement that I had no intention whatever of singling out in the discussion eucain, and of stating that "it is probably not worth anything," for I have never believed this.

JOSEPH P. REMINGTON.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

INTERNAL VACCINATION.

EAST ORANGE, N. J., Nov. 28, 1904.

To the Editor:—In THE JOURNAL, November 26, you state that, so far as known, antitoxin, when administered by the mouth instead of by hypodermic injection, is powerless, because the digestive juices destroy the antitoxin before it can be absorbed by the system. You refer him also to an editorial in the same number, condemning the practice of certain homeopaths in Indiana [Iowa is evidently meant.—EDITOR] who are giving vaccine internally as a prophylactic against smallpox, and you say: "When taken internally, antitoxin and vaccine are easily [Our editorial said "usually," not "easily."—EDITOR] digested, and thus destroyed." It is with diffidence one questions editorial pronouncements, but there is much to be said against the view here expressed. During the last few years several communications from physicians have appeared in the columns of the *London Lancet*, and very probably elsewhere, concerning the administration of antitoxin by the mouth, and all speak very favorably of it, as it is a much less troublesome method with children, and the remedy loses nothing of its efficacy. The diagnosis had been confirmed in many cases by bacteriologic examination. My own experience in undoubted cases of diphtheria is similar. Further, in a doubtful case recently, where antitoxin was given by the mouth before the report from the board of health had been received, a few days later after the subsidence of all symptoms, there suddenly appeared on the body of the patient, an extensive erythematous rash, not resembling the characteristic eruptions of the infective fevers, and unaccompanied by any of their symptoms, that was evidently due to the action of the antitoxin. Why should antitoxin be destroyed or rendered inert in the stomach more so than other toxic substances? As to the particular prophylactic method mentioned against smallpox. I am not a homeopath, and am not greatly concerned to defend the practice. Indeed, I frankly confess that I never heard of it before. But during a residence abroad, I have known patients—children and others—to have been deliberately inoculated with smallpox by inserting in the nostril the crust of a pustule from a patient suffering with the disease, this being the primitive custom of the country. But why should this homeopathic practice be thought unreasonable? The specific action of vaccine is due to certain micro-organisms. Do not the germs of many diseases survive contact with the gastric juices, or has Koch's dictum as to the difficulty or impossibility of conveying tuberculosis by means of contaminated food and drink been so stretched as to cover all communicable diseases? The germs of typhoid fever certainly survive such contact, and as if to place the matter beyond all doubt, a nurse in a French hospital who wished to commit suicide, swallowed the contents of two tubes of a pure culture of typhoid germs. She did not die, but she had a very severe attack of typhoid fever, which seems to show that the germs did not die either, at least not for many days, and not until they had done their work. So with protozoan germs of malaria, Ronald Ross, who has done so much original investigation in this field, speaks of having seen cases of malaria arise in persons who had drunk water containing mosquitoes and their larvae. These germs, therefore, escaped digestion, first in the stomach of the mosquito, and later in that of the human being. Will you not favor us with a little further light on this whole subject, as, if we are sure of the efficacy of the method, it is certainly a great advantage to be able to give a crying, struggling child the serum by the mouth, instead of by hypodermic injection.

E. M. M.

ANSWER.—We do not find the clinical evidence cited by our correspondent sufficient to show that diphtheria antitoxin has any effect when given by mouth. His observations are too few, and which is more important, they lack altogether adequate control observations. The results of observations of such character do not at all satisfy scientific requirements. The fact that an erythematous rash appeared on the body of a patient who had received diphtheria serum by mouth proves absolutely nothing as to absorption of antitoxin, even though we may grant that the serum caused the eruption, because we know that it is not the antitoxin and other substances that give rise to the eruptions that sometimes follow injections of antitoxic serums. The following extract from Oppenheimer's "Toxin and Antitoxin" will give a good idea of what we really know concerning the possible fate of diphtheria antitoxin in the digestive tract: "In the digestive canal it (antitoxin) appears to be destroyed. Dzierzgowski found that immunization could not be accomplished by ingestion of antitoxin by mouth. Only in rabbits is it possible to demonstrate a slight

resorption after pouring antitoxin into the empty stomach. Hydrochloric acid is especially injurious, but neutral pepsin, pancreas and bile are fairly harmless. Nevertheless, it is not absorbed from the intestines." Carrière (*Ann. d'Inst. Pasteur*, 1899, xiii, 435) found that digestive ferments and intestinal organisms destroy antitoxins. Hence we see that experimental studies afford no support for the internal administration of diphtheria antitoxin. As to our correspondent's statements anent "internal vaccination," we would refer to our comments on Dr. Conner's letter. Nasal inoculation with the crusts of smallpox is a far different thing from "internal vaccination." In the further interest of greater discrimination in the use of the results of observations, we would ask whether other sources of malarial infection were wholly excluded in the case of the persons alleged to have acquired malaria after drinking water containing mosquitoes and their larvae. Finally, granting that such water may convey malaria, it nevertheless must be insisted that as yet we are not in position to draw many analogies between malaria, smallpox and "internal vaccination."

PASA, ILL., Nov. 30, 1904.

To the Editor:—I note your editorial on "Internal Vaccination," page 1636, and the answer to the question asked about the internal administration of antitoxin, page 1647, in which you say: "We do not know how universal in that school (homeopathic) is the faith in this method, but we can hardly believe that an educated homeopath would advocate it. . . . When taken internally, antitoxin and vaccine are usually digested and thus destroyed." Formerly I thought there could not be any other sensible way of looking at the question, and Feb. 4, 1902, I wrote an article for publication in the public press, at the request of a member of the State Board of Health, on "The Proper vs. Internal Vaccination," in which I denounced as silly and worse than useless the so-called "internal method" of vaccination. Since that date I have hunted up the authorities on the subject, and find in an accepted work on veterinary medicine, viz., "The Pathology and Therapeutics of the Domestic Animals," by Dr. Friedberger, professor of veterinary medicine in the Royal Veterinary School at Munich, and Dr. Fröhner, professor of veterinary medicine in the Royal Veterinary School at Berlin, translated by Prof. W. L. Zullif, M.D., D.V.S., late professor of surgery and obstetrics in the veterinary department of the University of Pennsylvania, the following words on the subject: "Very rarely is variola in the horse generalized. Chauveau has produced this form by inoculating the virus into the veins under the skin, and by causing it to enter the organism by inhalation or by insection. Warlomont and Pfeiffer have obtained similar results." Volume 2, page 629. I am not arguing for the method; I merely point to the curious statement, and shall let it go for what it is worth.

J. J. CONNER, M.D.

ANSWER.—Before long we may find it advisable to discuss more fully in our editorial columns some of the questions raised by the proposition to introduce "internal vaccination." At this time it may be well to point out for emphasis the general fact that vaccination and antitoxic treatment of diseases, such as diphtheria and tetanus, are fundamentally different and wholly distinct procedures. Antitoxin and vaccine are radically different substances. For the sake of clearness in discussion, these facts must be definitely recognized. The quotation cited by Dr. Conner certainly can have little or no value in deciding the real merits of the proposed internal vaccination in man. In the first place, the passage quoted is translated somewhat differently in Hayes' rendition of the same work into English: "Horse-pox rarely becomes general, a fact which Chauveau observed when he made his inoculation experiments with vaccine, intravenously and subcutaneously, by inhalation and by feeding. Warlomont and Pfeiffer obtained similar results." There is nothing in this statement to show that the virus of horse-pox is absorbed from the equine stomach. Unfortunately, we are not in position to consult the original to form some idea as to which translation is the more correct. The practical disadvantages of "internal vaccination," even if it were possible in this way to immunize susceptible individuals, are so obvious that the method will not receive serious consideration from the practical point of view. How would we know whether the vaccination had taken or not? And would there fore vaccine vesicles on the mucous membrane of the stomach or some other part of the digestive tract? To seriously propose "internal vaccination" in the present state of our knowledge bespeaks a condition of mind which we are loathe to believe exists in any "school."

INTERNAL DISINFECTANT IN INFECTIOUS CONDITIONS.

ATLANTA, GA., Dec. 5, 1904.

To the Editor:—Please tell me where I can obtain lortin, the drug mentioned in the abstract of Dr. Konrad Küster's article on page 1667 of THE JOURNAL. Do you know anything of its merits? J. E. A.

ANSWER.—The preparation in question may be obtained from Victor Koechl & Co., 122 Hudson St., New York City. We know nothing about its merits.

APPOINTMENT OF PANAMA HEALTH OFFICERS.

To the Editor:—Will you be so kind as to tell me how the medical corps of the health department of the Panama Canal is appointed? A. B. C.

ANSWER.—Through the Civil Service Commission, which should be addressed at Washington, D. C., for further particulars.

Marriages.

WALTER MILES, M.D., to Miss Zina Collins, both of Viola, Ill., November 9.

LINCOLN M. BOWMAN, M.D., to Mrs. Tillie Herzog, both of Alton, Ill., November 24.

JAMES E. BODEN, M.D., Milwaukee, Wis., to Miss Blanche L. Griffith of Chicago, November 1.

EDWIN WARREN RYERSON, M.D., to Miss Adelaide K. Hamilton, both of Chicago, December 6.

CLIFFORD BAILEY FARR, M.D., to Miss Katharine Elliott, both of Philadelphia, November 22.

EDWARD GUSTAVE BURGMAN, M.D., to Miss Winifred La Velle, both of Chicago, November 16.

CHARLES SAUR, M.D., Cincinnati, Ohio, to Miss Georgia E. Hayes of Cleves, Ohio, November 17.

WILLIAM J. HOSFORD, M.D., to Miss Nellie Elizabeth Benson, both of Alameda, Cal., November 23.

SUMNER M. MILLER, M.D., Peoria, Ill., to Miss Sarah C. French of Evansville, Ind., November 16.

W. TURNER WOOTTON, M.D., to Miss Emma Wilson Whittington, both of Hot Springs, Ark., October 5.

JAMES H. MONTGOMERY, M.D., Chambersburg, Pa., to Miss Nell Singleton Jackson at Miami, Fla., November 24.

EDWARD L. H. BARRY, M.D., Jerseyville, Ill., to Mrs. Anna R. Hayes of Wilksburg, Pa., at Alton, Ill., November 22.

REN A. SCHLAG, M.D., Monroe, Iowa, to Miss Emma A. Swanson of Cambridge, Neb., at Des Moines, Iowa, November 16.

Deaths.

William Robert Hutchinson, M.D. Castleton (Vt.) Medical College, 1849, delegate from Vermont to the American Medical Association in 1877 and 1892, member of the Vermont State Medical Society, thrice president of the Franklin County Medical Society, state senator in 1869 and 1870, died at his home in Enosburg Falls Vt., November 26, from cancer, aged 79.

William L. Newell, M.D. Jefferson Medical College, Philadelphia, 1859, a member of the American Medical Association, one of the ablest practitioners of southern New Jersey; a surgeon during the Civil War, and for many years local surgeon of the Pennsylvania system, died at his home in Millville, N. J., after a prolonged illness, November 27, aged 73.

William McGillivray, M.D. Toronto (Ont.) University Medical Faculty, 1890, a member of the College of Physicians and Surgeons of Ontario, the Minnesota State Medical Society and the Southwestern Minnesota Medical Society, died at his home in Pipestone from septicemia following an operation wound, after a short illness, November 28, aged 36.

James Newton McCandless, M.D. Jefferson Medical College, Philadelphia, 1863, of Prescott, Ariz., surgeon during the Civil War, for 35 years a resident of Arizona, died at Mercy Hospital, Prescott, November 25, aged 67. At a meeting of the Ypapai County Medical Society resolutions laudatory of its late member were unanimously adopted.

William Brooks Gray, M.D. Jefferson Medical College, Philadelphia, 1852, some time vice-president of the Medical Society of Virginia, of the Richmond Medical and Surgical Society and of the Richmond Microscopical Society, died at his home in Richmond, Va., November 24, aged 71.

John P. Ralls, M.D. Medical College of Georgia, Augusta, 1845, a member of the Alabama State Constitutional Convention of 1861, and a year later a member of the Confederate Congress, died at his home in Gadsden, Ala., November 23, after a long invalidism, aged 85.

William L. Coleman, M.D. Medical College of Georgia, Augusta, 1857, an authority on yellow fever and sent by the

United States government to Cuba in 1898 as an expert to study fever conditions there, died at his home in Houston, Texas, November 27, aged 70.

Alexander Rudolph Becker, M.D. New York Medical College, New York City, 1862, of Seattle, Wash., surgeon in the Civil War, who established a pathologic laboratory in Seattle in 1900, died in Victoria, B. C., from peritonitis following dysentery, September 2, aged 62.

James E. Gildersleeve, M.D. New York University, New York City, 1853, for many years health officer of Brookhaven, N. Y., died at his home in Port Jefferson, Long Island, November 25, nine days after an accident in which he had been thrown from his carriage, aged 78.

William E. Palmer, M.D. University of Buffalo (N. Y.) Medical Department, 1897, of Spokane, Wash., died at Sacred Heart Hospital, in that city, November 21, from acute nephritis, two days after an operation for appendicitis, aged 32.

James M. Brown, M.D. University of Louisville, 1882, chief medical examiner of the Pennsylvania Railroad Relief Association, died at his home in Spruce Creek, Pa., November 28, from paralysis, after an illness of sixteen days, aged 56.

James E. Booth, M.D. Medical College of Virginia, Richmond, 1894, of Petersburg, Va., died at the Memorial Hospital, Richmond, November 17, five days after an operation for appendicitis, which was followed by peritonitis.

William R. Newsome, M.D. University of Nashville Medical Department, 1860, the oldest practitioner in Carroll County, Tennessee, died at his home in McLemoresville November 17, after a short illness, aged 73.

William Osborn Taylor, M.D. Bellevue Hospital Medical College, New York City, 1866, of San Francisco, Cal., died in Alameda Hospital, November 11, from chronic leptomeningitis, after a long illness, aged 64.

William F. Cushman, M.D. College of Physicians and Surgeons in the City of New York, 1862, a retired physician of Chelsea Village, Manhattan, died at his home in Ridgefield, Conn., December 1, aged 66.

Leonard F. Pitkin, M.D. New York University, New York City, 1879, surgeon for the Interborough Company, died at his home in New York City, December 2, from kidney disease after a long illness, aged 46.

Phoebe A. Sprague, M.D. Northwestern University Woman's Medical School, Chicago, 1873, formerly of Springfield, Mass., died suddenly at her home in Albion, N. Y., November 28, aged 56.

Eli Griffin, M.D. Atlanta (Ga.) Medical College, 1856, one of the oldest physicians of Fulton County, Georgia, died at his home on the Brown Mill road near Atlanta, November 30, aged 75.

Edward F. Stevens, M.D. University of Maryland School of Medicine, Baltimore, 1853, some time coroner of Baltimore, died at his home in that city, November 19, from apoplexy, aged 77.

Abraham H. Shiveley, M.D. University of Louisville Medical Department, 1852, of Pleasant Hill, Mo., died at the home of his daughter in Kansas City, Kan., November 11, from dropsy, aged 76.

Thomas M. Edwards, M.D. Bellevue Hospital Medical College, New York City, 1874, of Dunlap, Iowa, died at the Woman's Christian Association Hospital, Council Bluffs, Iowa, November 18.

C. T. Taggart, M.D. Central College of Physicians of Indianapolis, 1856, a member of the Twenty-sixth General Assembly, died at his rooms in Sullivan, Ill., October 28, from pneumonia, after a brief illness, aged 57.

William H. Hill, M.D. Tulane University of Louisiana, New Orleans, 1869, health officer of Smith County, Mississippi, and once state senator, died at his home in Sylvanena, November 27.

Henry Cornelius Comegys, M.D. University of Maryland School of Medicine, Baltimore, 1854, died November 29 at his home in Scranton, Pa., after an illness of five days, aged 71.

Robert G. Wiley, M.D. Dartmouth Medical School, Hanover, N. H., 1836, died at his home in Bethel, Maine, where he had practiced for more than 67 years, November 22, aged 97.

Lorenzo M. Johnson, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, died at his home in Charleston, Ohio, November 13, from paralysis, aged 86.

Robert E. Dennis, M.D. Medical College of the State of South Carolina, Charleston, 1858, died suddenly from acute gastritis at his home in Bishopville, S. C., November 28.

Charles A. Foster, M.D. Ohio, 1848, died at the Thompson Memorial Hospital, Canandaigua, N. Y., November 25, from apoplexy, after a prolonged illness, aged 89.

David G. Hartzell, M.D. Jefferson Medical College, Philadelphia, 1858, surgeon during the Civil War, died at his home in West Philadelphia, October 25, aged 68.

William A. Lindsay, M.D. Medical Department University of Cincinnati, 1866, formerly of Louisville, died recently from pneumonia, at his home in English, Ky.

William J. Tripp, M.D. New York, 1881, died at his home in New York City, November 22, from cancer of the liver, after an illness of several months, aged 60.

J. N. Iliff, M.D. College of Physicians and Surgeons of Kansas City, Kan., 1895, died at his home in Welch, Cherokee Nation, I. T., August 23, from typhoid fever.

Austin S. Moak, M.D. Pennsylvania, 1872, of Helmer, Ind., died at St. Joseph's Hospital, Fort Wayne, after an operation for cancer, November 19, aged 55.

Charles Manville Downs, M.D. Yale University Medical Department, New Haven, Conn., 1883, died suddenly at his home in Chicago, November 24, aged 44.

Josephine Briggs, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, died at her home in Pasadena, Cal., September 8, aged 56.

Robert W. Eddleman, M.D., one of the first settlers of Pilot Point, Texas, died at the home of his son in that city, November 13, from pneumonia, aged 81.

Charles S. Durand, M.D. Medical College of Ohio, Cincinnati, 1889, of Chattanooga, Tenn., died at San Antonio, Texas, after a long illness, November 23.

William S. Hunt, M.D. Cincinnati College of Medicine and Surgery, 1870, died at his home in Springfield, Ohio, November 21, from apoplexy, aged 58.

Eugene Edward Martin, M.D. Niagara University Medical Department, Buffalo, N. Y., 1883, died at his home in Buffalo, November 23, aged 37.

A. G. L. Van Lear, M.D. Portland (Maine) School for Medical Instruction, 1867, died at his home in Long Glade, Va., September 8, aged 71.

Larkin L. Clark, M.D., formerly representative from Elbert County in the Georgia legislature, died recently at his home in Elberton, aged 85.

Alexis I. Dupont, M.D., but never a practitioner, died at his home near Greenville, Del., November 26, after an illness of one year, aged 61.

Pleasant T. Mask, M.D. University of Louisville, Ky., 1857, died at his home in Fourche Dam, Ark., November 27, after a lingering illness.

David E. Strain, M.D. Jefferson Medical College, Philadelphia, 1854, died at his home near Brownsburg, Va., November 26, aged 75.

John J. Diehl, M.D. University of Giessen, Germany, 1865, a pioneer physician of Centralia, Ill., died recently at his home in that city.

J. H. Alexander, M.D., for more than 50 years a practitioner of Hermon, N. Y., died at his home in that village, November 12, aged 80.

Jacob A. Bixler, M.D. Jefferson Medical College, Philadelphia, 1866, died at his home in Carlisle, Pa., of apoplexy, December 3, aged 65.

Sherburne L. Wiswell, M.D. Vermont Medical College, Woodstock, 1853, died at his home in Cabot, Vt., November 26, aged 79.

John H. Ruppert, M.D. Medico-Chirurgical College of Philadelphia, Pa., 1896, died at his home in Paterson, N. J., November 28.

Wilford L. Dunkeson, M.D. Kansas City (Mo.) Medical College, 1888, died recently at his home in Sprague, Mo., aged 41.

Marvin G. Hart, M.D. Illinois, 1883, of Chicago, died from apoplexy at St. Luke's Hospital, Chicago, November 26.

David W. Birge, M.D. Cleveland Medical College, 1848, died at his home in Hector, N. Y., November 24, aged 82.

Ascher S. Parker, M.D. Ohio, died at his home in Kendallville, Ind., November 16.

Book Notices.

THE ART OF CROSS-EXAMINATION. By Francis L. Wellman, of the New York Bar. With the Cross-examinations of Important Witnesses in Some Celebrated Cases. New and Enlarged Edition. Cloth. Pp. 404. Price, \$2.50 net. New York: The Macmillan Co., 1904.

This book, while primarily written for the lawyer, will be found both interesting and instructive by physicians. It is well in battle to know how the enemy looks on things and how he has entrenched himself, for then it will be more easy to meet his attacks. Physicians go on the witness stand more than any other class, and those who have had experience know to their sorrow what it is to go through the ordeal of a rigid cross-examination. Mr. Wellman has presented the matter in a very interesting way, and has mixed his suggestions with illustrative examples of cross-examinations, and not a few of these are examinations in which the witnesses were medical men.

A MANUAL OF EXPERIMENTAL PHYSIOLOGY for Students of Medicine. By Winfield S. Hall, Ph.D., M.D. (Leipzig), Professor of Physiology, Northwestern University Medical School. With 39 illustrations and a Colored Plate. Cloth. Pp. 245. Price, \$2.75. Philadelphia and New York: Lea Brothers & Co., 1904.

This manual appears to meet its purpose very satisfactorily. The experiments designed to illustrate special physiology seem to be wisely selected, well arranged and clearly described. It may be permitted to suggest that one or two simple experiments might be introduced with advantage to illustrate the bactericidal and hemolytic qualities of normal blood. Phagocytosis by leucocytes also merits an experimental demonstration in the course of physiology. In general physiology muscle-nerve experiments are described with great detail from the electrical point of view. Unfortunately, there is not a single experiment to illustrate the rôle of ions in physiologic processes. In future editions it is hoped that this serious defect will be fully remedied.

A TEXT-BOOK OF PHYSIOLOGICAL CHEMISTRY. For Students and Practitioners of Medicine. By Clowes M. E. Simon, M.D., the Resident Physician Johns Hopkins Hospital. New (2d) Edition. Revised and Enlarged. Cloth. Pp. 500. Price, \$3.25 net. Philadelphia and New York: Lea Brothers & Co.

The exhaustion of the first edition of this text-book in the comparatively short time of three years speaks well for its popularity and usefulness. The present edition has received many important additions, including an appendix of laboratory exercises which increases the usefulness of the book very much for the student and his instructor. Some chapters have been wholly rewritten, to-wit, those on digestion and the albumins. Simon's Physiological Chemistry may be recommended as a reliable and up-to-date text-book. Its arrangement is logical and the subject matter presented in a clear way.

THE OPTICAL DICTIONARY. An Optical and Ophthalmological Glossary of English Terms, Symbols and Abbreviations, Together with the English Equivalents of some French and German Terms Relating to Physical, Physiological and Pathological Optics, Optical and Other Instruments of Precision, and Terms Descriptive of Color and Photo-chemistry, to Which Are Added a Number of General and Mathematical Expressions. Edited by Charles Hyatt-Wood, F.R.P.S. Cloth. Pp. 196. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co., 1904.

This book gives a little more fully than the average dictionary the meaning of words and phrases used in ophthalmology. The list of symbols and abbreviations with their meanings, as employed by various authors, is also given. For the benefit of those who do not know Greek the author has added the Greek alphabet, which is frequently used in expressing optical and other mathematical data. The pronunciation of the letters is also given. This work should be of especial value to medical men who have not had ophthalmologic training as well as to specialists in ophthalmology.

THE URINE and Clinical Chemistry of the Gastric Contents, the Common Poisons and Milk. By J. W. Holland, M.D., Professor of Medical Chemistry and Toxicology, Jefferson Medical College of Philadelphia. Forty-one Illustrations. Seventh Edition. Revised and Enlarged. Cloth. Pp. 172. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co., 1904.

When a handbook of this character has reached its seventh edition little need be said in its praise. Suffice it to say that the subjects of normal and morbid urine, gastric contents, poisons and milk are succinctly treated and the methods of analysis and examination well described.

State Boards of Registration.

COMING EXAMINATIONS.

Ohio State Board of Medical Registration and Examination, Columbus, December 13-15. Secretary, Frank Winders, M.D., Columbus.

State Medical Examining Boards of Delaware, Wilmington and Dover, December 13-15. Secretary, P. W. Tomlinson, M.D., Wilmington.

The Medical Examining Board of Virginia, Richmond, December 13-16. Secretary, R. S. Martin, M.D., Stuart.

Board of Medical Examiners of Maryland, Baltimore, December 14-17. Secretary, J. M. Scott, M.D., Hagerstown.

Missouri State Board of Health, St. Louis University, St. Louis, December 19-21. Secretary, W. T. Morrow, M.D., Kansas City.

Iowa State Board of Medical Examiners, Capitol Building, Des Moines, December 21-22. Secretary, J. F. Kennedy, M.D., Des Moines.

Oklahoma Medical Examining Board, Guthrie, December 28. Secretary, E. E. Cowdric, M.D., Euld.

New Hampshire State Board of Medical Examiners, State House, Concord, December 28 and 29. Regent, Henry C. Morrison, Concord.

Utah State Board of Medical Examiners, Salt Lake City, January 2. Secretary, R. W. Flesher, M.D., Salt Lake City.

Board of Medical Examiners of Arizona, Phoenix, January 2-3. Secretary, Ancil Martin, M.D., Phoenix.

Board of Medical Examiners of the State of Oregon, Portland, January 3. Secretary, Byron E. Miller, M.D., The Dekum, Portland.

Minnesota State Board of Examiners, State Capitol Building, St. Paul, January 3. Secretary, C. J. Ringell, M.D., Minneapolis.

North Dakota State Examining Board, Grand Forks, January 3. Secretary, H. M. Wheeler, M.D., Grand Forks.

Rhode Island State Board of Health, Providence, January 5-6. Secretary, Gardner T. Swarts, M.D., State House, Providence.

Wisconsin Board of Medical Examiners, Hotel Pfister, Milwaukee, January 9-11. Secretary, Philip A. Forsbeck, M.D., Milwaukee.

State Medical Board of the Arkansas Medical Society, Little Rock, January 10. Secretary, J. R. Runyan, M.D., Little Rock.

Indiana State Board of Medical Registration and Examination, State House, Indianapolis, January 10-12. Secretary, W. T. Gott, M.D., Crawfordsville.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Burlington, January 11-12. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, January 12. Secretary, Wm. C. Woodward, M.D., Washington, D. C.

Illinois State Board of Health, The Great Northern Hotel, Chicago, January 19-21. Secretary, J. A. Egan, M.D., Springfield.

New York—Three Medical Boards, New York, Albany, Syracuse and Buffalo, January 24-27. H. J. Hamilton, Education Department, Albany.

British Columbia Medical Board.—The examining board of the British Columbia Medical Council recently examined thirteen candidates for admission to practice in that province, nine of whom received licenses. The board for the current year consists of Dr. J. C. Fagan, Victoria; Dr. W. J. McGuigan, Vancouver; Dr. R. E. Walker, New Westminster; Dr. A. P. Proctor, Kamloops; Dr. J. M. Lefevre, Vancouver; Dr. J. C. Davie and Dr. O. M. Jones, Victoria.

Florida Report.—Dr. Louis de M. Blocker, secretary of the Medical Board of Examiners of the First Judicial District of Florida, reports the written examinations held at Pensacola during 1904. At each examination the number of subjects examined in was 7; number of questions asked, 70; percentage required to pass, 75. Five persons were examined, all of whom passed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Maryland Medical College.	(1904)	78, 80
Med. Dept. Univ. of Tennessee.	(1883)	76
Coll. of P. and S., Baltimore.	(1897)	84
Meharry Medical College, Tennessee.	(1904)	80

Georgia April Report.—Dr. W. V. Robertson, president of the Georgia State Board of Medical Examiners (Eclectic), reports the written examination held at Atlanta, April 1, 1904. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 80. Fifteen persons were examined, all of whom passed. All the candidates were graduates of the Georgia College of Eclectic Medicine and Surgery. The grade of 80 was reached by two, 82 by one, 84 by two, 85, 86 and 87 by one each, 89 by two, 90 by two, 93, 96 and 99 by one each. The general average attained was 87.6.

Georgia Homeopathic Report for 1904.—Dr. R. E. Hinman, secretary of the Homeopathic Board of Medical Examiners of the state of Georgia, reports the written examinations held at Atlanta during 1904. The number of subjects examined in was 10; total questions asked, 100; percentage required to

pass, 75. Only two persons were examined and both passed. Both were graduates of the University of Michigan Homeopathic Medical College. One (1903) reached the grade of 77.1; the other (1886) reached the grade of 75.

Kentucky Regulations.—Dr. J. N. McCormack, secretary of the Kentucky State Board of Health, has notified medical students that the new rule requiring applicants for admission to medical colleges to pass an examination will be enforced. Dr. McCormack emphasizes the importance to the students of attending a college which complies with the requirements of the Kentucky State Board of Health.

Michigan October Report.—Dr. W. D. Harrison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination held at Lansing, Oct. 11-14, 1904. The number of subjects examined in was 19; total number of questions asked, 94; percentage required to pass, 75. The total number examined was 8, of whom 7 passed and one failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Michigan	(1904)	84.52
Coll. of P. and S., Chicago	(1896)	80.21
Univ. of Helsinki, Finland	(1903)	83.57
Western University, London, Ont.	(1891)	80.68
McGill Univ., Montreal, Quebec	(1903)	90.53
Med. Coll. of Indiana, Indianapolis	(1904)	89.21

FAILED.

Mich. Coll. of Med. and Surg. (1899) 66.52

New Hampshire April Report.—Dr. James T. Greeley, secretary of the New Hampshire State Board of Medical Examiners, reports written examination held at Concord, Sept. 8-9, 1904. The number of subjects examined in was 7, and total number of questions asked, 70. The total number examined was 24, of whom 20 passed and 4 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Roston Univ. School of Medicine	(1899) 88,	(1896) 88
Baltimore Medical College	(1904)	77, 78, 75
Harvard Univ. Med. School	(1900) 77,	(1903) 75,
Univ. of Vermont Med. School	(1904)	85, 85, 75,
Puffs College Med. School	(1901)	82, 80, 75,
Dartmouth College Med. School	(1903)	79, 80
Medical School of Maine	(1904)	76
McGill University	(1904)	78

College.	PASSED.	Year Grad.	Per Cent.
Laval University	(1902)	45,
Coll. of P. and S., N. Y.	(1902)	71
Univ. of Bishop's College	(1904)	69

New Jersey October Report.—Dr. E. L. B. Godfrey, secretary of the State Board of Medical Examiners of New Jersey, reports the written examination held at Trenton, Oct. 18-19, 1904. The number of subjects examined in was 9; total number of questions asked, 90; percentage required to pass, 75. The total number examined was 44, of whom 33 passed and 11, 25 per cent., failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
University of Maryland	(1904)	84.1,
Columbia University, N. Y.	(1904)	80.8,
(1903) 85.1,	86.2,	94.9;	(1890) 87,
College of F. and S., Boston	(1904)	79.1
Harvard University, Texas	(1904)	75.3
Baltimore Med. Coll.	(1904)	87.5,
Baltimore Univ. School of Med.	(1904)	77.7,
College of P. and S., Baltimore	(1903)	80.1,
Georgetown Univ., Washington, D. C.	(1903)	81.9
Jefferson Med. Coll., (1902) 85,	83.5*;	(1903) 77.7,	(1904) 79.6*
81.7,			
Woman's Med. Coll., Penn.	(1901)	79.7,
Hahnemann Med. Coll. and Hosp., Penn.	(1904)	80.6,
Medico-Chirurgical Coll., Penn.	(1904)	75.8,
Johns Hopkins University	(1902)	90.7
Chicago Med. Coll.	(1879)	77.1

College.	PASSED.	Year Grad.	Per Cent.
Baltimore Univ. School of Med.	(1904)	62.5*,
Albany Med. Coll.	(1902)	62.7
Illinois Med. Coll.	(1902)	70.5
University of Naples, Italy,	(1888) 65.6,	(1898) 71.7*,
(1900) 71.2*,			
College of P. and S., Boston	(1904)	70.1
Medico-Chirurgical Coll., Penn.	(1903)	71.1
Columbia University, N. Y.	(1904)	73.6

*Second examination. †Third examination.

Oregon April and July Reports.—Dr. Byron E. Miller, secretary of the Oregon State Board of Medical Examiners, reports the examinations held at Portland, April 22 and July 14, 1904. The number of subjects examined in at each examination was 15; total questions asked, 100; percentage required to pass, 75.

At the April examination the total number examined was 32, all of whom passed. The following colleges were represented:

	PASSED.	Year Grad.	Per Cent.
Imperial Alexander Univ.	(1896)	80, (1901)	80
Willamette University, (1904)	the grade of 80 was reached by five and the grades of 81, 82 and 83 by one each.		
University of Oregon, (1904)	the grade of 79 and 80 were reached by one each, 81 was reached by five, 82 by four, 83 by four, and 84 by one.		
American Medical College	(1897)		79
Ohio Medical College	(1881)		80
Rush Medical College	(1903)		80
University of Michigan	(1901)		79
College of P. and S., Chicago	(1895)		80
College of P. and S., San Francisco	(1902)		83

The general average for all representatives of Willamette University at this examination was 80.7; for all representatives of the University of Oregon, 76.75.

At the July examination the total number examined was 27, of whom 21 passed and 6 failed. The following colleges were represented:

	PASSED.	Year Grad.	Per Cent.
Dunham Med. Coll., Chicago	(1901)		78
Crelighton Med. Coll., Omaha	(1902)		87
Hahnemann Med. Coll., Chicago	(1904)		79
College P. and S., Keokuk	(1895)		75
University of Michigan	(1904)		86
University of Minnesota	(1892)		82
Jefferson Med. Coll., Philadelphia	(1904)		84
Western Univ. Med. Dept., London, Ont.	(1904)		82
Northwestern University, Chicago	(1890)	84, (1904)	75
University of Iowa	(1901)	78, (1904)	76
Medical College of Ohio	(1893)		83
Harvey Med. Coll., Chicago	(1904)		83
Detroit Medical College	(1897)	87, (1903)	83
Miligan College of Medicine	(1895)		78
Kansas Medical College	(1900)		79
Rush Medical College	(1902)		90
Univ. and Bellevue Hosp. Med. Coll.	(1899)		86
Cooper Medical College, California	(1904)		86

	FAILED.	Year Grad.	Per Cent.
Starling Medical College, Ohio	(1895)		74
Ohio Medical University	(1895)		71
Western Reserve Med. Coll.	(1878)		59
St. Louis Coll. of P. and S.	(1904)		61
Two non-graduates.			

Pennsylvania June Report.—We quote here a further analysis which has been made of the June examination which we summarized in THE JOURNAL, August 27, page 623. Thirty-eight colleges were represented, among them colleges in Canada and Italy, the total number of candidates being 378, of which 2 failed to appear, 1 candidate withdrew and 1 was expelled. The number of failures was 72, making a percentage of 19 per cent. Among the Pennsylvania schools the Women's College of Pennsylvania leads with a percentage of 100, there being 13 candidates and no failures. The University of Pennsylvania presented 71 candidates, of whom 5 failed, being 7 per cent. failures. Jefferson Medical College is third, 12 out of 93 applicants failing, making a percentage of 13. Medico-Chirurgical College had 57 candidates, of which number 15 failed, giving 26.33 percentage of failures. The West Penn Medical College was represented by 51 candidates, with 8 failures, showing a percentage of 15.7. The Temple Medical College had 1 candidate and no failures. The highest individual average was obtained by Martha Tracy, Women's Medical College, 91.07. The relative grand averages obtained by the candidates of each institution show the following results:

Women's Medical College of Pennsylvania	83.57
University of Pennsylvania	73.39
Temple College (one candidate)	79.50
Jefferson Medical College	77.54
Medico-Chirurgical College	77.46

Association News.

The American Medical Association and the 1905 Fair.

The American Medical Association is going to find itself in excellent company at Portland next year, remarks the *Medical Sentinel*. Stimulated by the brilliant success achieved by the International Congress of Arts and Science at St. Louis, the directors of the Lewis and Clark Fair have made the broad and statesmanlike decision to arrange for a series of literary, scientific and sociologic conferences or institutes, of which the great national meetings shall form a harmonious part. For instance, the meeting of the National Association of Charities and Corrections, which is to be held here in June, 1905, will be made the center for an institute or conference on sociologic and penologic subjects. Similarly, the Association of American Libraries, whose annual meeting has just been secured for Portland, will be utilized for a series of conferences on lit-

erary topics, attended by the distinguished men of letters and literary experience who will be drawn by the national association. It is also proposed to utilize the American Medical Association in the same manner, by following or preceding it with conferences on scientific subjects whose chief attractions will be furnished by the eminent physicians and scientists who will be in attendance at the sessions. The attempt, of course, will necessarily be on a far more modest scale than that of the Congress of Arts and Science at St. Louis, but it will form an admirable feature of the fair, and will show that Portland is fully capable of appreciating and utilizing in a marked degree not merely the commercial and economic advantages of her fair, and of the great national sessions which will meet at that time, but also the literary and scientific. The plan adopted will be somewhat similar to that carried out so successfully at St. Louis, only probably limiting itself to American leaders, instead of including those of the world. Prominent workers and thinkers in the lines of literature, sociology, education and science will be selected and formally invited by the president and directors of the fair to attend and address the conferences held on their respective subjects. . . . Coming as it does during vacation time of the greater part of them, there is little doubt that many of them will consider the invitation favorably. If this admirable move meets with the success which it deserves, and can be followed by the erection of a fireproof art building, so that the loan of valuable pictures can be secured and the building retained as a permanent art gallery for Oregon, it will give a stamp to the fair which, together with its beautiful and picturesque natural surroundings, will render it unique and peculiarly attractive, in spite of its comparatively modest size. The profession of Oregon, together with the board of the Portland City Library Association and the State Association of Charities and Corrections, can rightfully be proud of their share in making a start toward this feature of the fair and toward rendering its further development possible.

NEW MEMBERS.

New members for the month of November, 1904:

ARKANSAS.	COLORADO.
Autrey, J. R., Columbus.	Allen, E. D., Telluride.
Atkinson, H. H., Furdoyce.	Anderson, Andrew, Boulder.
Bennett, Alfred, Limestone.	Cattermole, G. H., Boulder.
Carichael, A. L., Little Rock.	Cunningham, A. A., Denver.
Dorr, J. P., Do.	Martin, E. E., Denver.
Floyd, J. H., Western Grove.	McFadden, J., Del Norte.
Huddleston, G. D., Lamar.	South, John, Ouray.
Lindsay, Jas. H., Bentonville.	
Morgan, R. S., Do.	
Mackey, E. W., McMurrain.	
Poynor, Geo. V., Green Forest.	
Rhea, B. S., Hope.	
Thompson, J. S., Stephens.	
Westerfield, J. S., Conway.	
Webster, H. R., Texarkana.	
Younfner, F. W., Lewisville.	
CALIFORNIA.	CONNECTICUT.
Armstrong, Robt., Ramona.	Bassett, C. W., Sharon.

Medical Organization.

Delaware.

KENT COUNTY MEDICAL SOCIETY.—Drs. George W. Marshall, Milford; Ezekiel W. Cooper, Camden, and other physicians met at Dover, November 17, and organized this society on the standard plan. Dr. James Wilson was elected president and Dr. L. August H. Bishop, secretary and treasurer, both of Dover.

Indiana.

FAYETTE COUNTY MEDICAL SOCIETY.—With the aid of Dr. David W. Stevenson, Richmond, counselor for the Sixth District, this society was organized at Connersville, October 13, on the standard plan, the following officers being elected: Dr. George F. Van Pelt, president; Dr. Frank J. Spilman, vice-president, and Dr. E. Everett Hamilton, secretary, all of Connersville.

THIRTEENTH DISTRICT MEDICAL SOCIETY.—Physicians of this councilor district met at South Bend, October 20. Dr. Charles A. Daugherty, counselor for the district, presided. Dr. J. N. McCormack, national organizer, made an address, and the society organized with the following officers: Dr. G. W. Thompson, Winamac, president; Dr. Irvin J. Beeknell, Goshen, vice-president, and Dr. John B. Berteling, South Bend, secretary.

Iowa.

SEVENTH DISTRICT MEDICAL SOCIETY.—At the first annual meeting of this society held in Des Moines, October 27, organization was perfected and the following officers were elected: Dr. Edward E. Dorr, Des Moines, president; the presidents of the component county societies, vice-president, and Dr. C. A. Ayres, Des Moines, secretary and treasurer.

Kansas.

ANDERSON COUNTY MEDICAL SOCIETY.—The physicians of the county met at Garnett November 30, to discuss the advisability of reorganizing their county society, which has had only a nominal existence. After the plan of work had been explained by Dr. J. N. McCormack and thoroughly discussed, the standard constitution and by-laws were adopted and the present officers continued until the annual meeting to be held in December. These officers are: Dr. George Schoonover, Garnett, president; Dr. David O. Taylor, Greeley, vice-president; Dr. John R. Scott, Garnett, secretary, and Dr. J. B. Jones, Garnett, treasurer.

BOURBON COUNTY MEDICAL SOCIETY.—The physicians of the county met at Fort Scott December 1, with a representative attendance from several adjoining counties. After an explanation of the plan and purposes of organization by Dr. J. N. McCormack and a free discussion, the standard constitution and by-laws were adopted and the following officers were elected: President, Dr. Millard F. Jarrett; vice-president, Dr. Robert Aikman; secretary and treasurer, Dr. Joseph B. Carver; censors, Drs. Charles A. Van Velzer, E. P. Payne and William S. McDonald, all of Fort Scott. There are over sixty physicians in this county. Weekly meetings will be held and the prospects for an excellent society are promising.

SEDGWICK COUNTY MEDICAL SOCIETY.—The physicians of the county met at Wichita November 29, and after a full discussion of the matter, adopted the standard constitution and by-laws, decided to hold weekly meetings and elected the fol-

lowing officers: President, Dr. J. Franklin Gaell; vice-president, Dr. James W. Cave; secretary, Dr. H. S. Hickok; treasurer, Dr. John C. Brown; censors, Drs. John D. Clark, George C. Purdue and James W. Kirkwood, all of Wichita. The physicians of Wichita have been organized for some years as the Academy of Medicine, and this body has met weekly and done much valuable work. The question of merging the two bodies was discussed and left open for future consideration.

FORD COUNTY MEDICAL SOCIETY.—The physicians of Ford county met at Dodge City November 26, and after addresses by Drs. Horace G. Welch of Hutchison and J. N. McCormack of Bowling Green organized a county society, adopting the standard constitution and by-laws. Dr. W. H. Graves was elected president; Dr. Herbert Whitworth, vice-president; Dr. Claude E. McCarty, secretary; Dr. Harvey W. Garrett, treasurer, and Drs. Charles A. Milton, James Hawkins and Thomas L. McCarty, censors, all of Dodge City.

RENO COUNTY MEDICAL SOCIETY.—The physicians of Reno County met at Hutchison, November 25, and after explanations by Drs. Oliver J. Furst, Peabody, counselor for the district, and J. N. McCormack, chairman of the Committee on Organization, formed a new county society on the standard plan. Dr. Hunter J. Duval, Hutchison, was elected president; Dr. William H. Bauer, Sylvia, vice-president; Dr. George R. Gage, Hutchison, secretary; Dr. Cornelius A. Mann, Hutchison, treasurer, and Drs. Horace G. Welch, Clemens Klippel and Cornelius A. Mann, all of Hutchison, censors.

Maryland.

ALLEGANY COUNTY MEDICAL SOCIETY.—This society was organized at Cumberland October 6, on the standard plan, with the following officers: Dr. J. Jones Wilson, Cumberland, president; Drs. Arthur H. Hawkins, Cumberland, and A. G. Smith, Midland, vice-presidents; Dr. Edgar T. Duke, Cumberland, secretary, and Dr. John A. Doerner, Cumberland, treasurer.

WASHINGTON COUNTY MEDICAL SOCIETY.—At a recent meeting of this society the following officers were elected: Dr. S. Seibert Davis, Boonsboro, president; Dr. William P. Miller, Hagerstown, vice-president; Dr. Victor D. Miller, Jr., Hagerstown, secretary; Dr. Hamilton K. Derr, Hagerstown, treasurer; Drs. J. McPherson Scott, Hagerstown; V. Milton Reichard, Fairplay, and C. D. R. Miller, State Line, censors, and Dr. James W. Humrhouse, Hagerstown, delegate to the Medical and Chirurgical Faculty of Maryland. The society approved the adoption of the constitution as suggested by the American Medical Association.

New Hampshire.

COOS COUNTY MEDICAL SOCIETY.—This society was organized at Whitefield in October, with the following officers: Dr. Ezra Mitchell, Lancaster, president; Dr. John D. Holt, Berlin, vice-president; Dr. Frank W. Evans, Coos, secretary and treasurer; Drs. Edwin E. Jones, Colebrook, Louis B. Marcou, Berlin, and Richard E. Wilder, Whitefield, censors, and Drs. Charles C. O'Brien, Groveton, and William H. Leith, Lancaster, delegates to the state society.

Ohio.

ROSS COUNTY MEDICAL SOCIETY.—Physicians of the county met Drs. Theodore W. Rankin, Columbus, and Horace Bonner, Dayton, at Chillicothe, October 5, and organized a county society on the standard plan, with the following officers: President, Dr. Jefferson E. Seacare; vice-president, Dr. F. T. Marr; treasurer, Dr. Raymond E. Bower; secretary, Dr. Mary Peatter, and censors, Drs. Josephine Riley, Joseph M. Hanley and Harry R. Brown.

SECOND DISTRICT MEDICAL SOCIETY.—The first annual meeting of the society was held in Dayton, November 17. Dr. Horace Bonner, Dayton, counselor for the district, presided. The temporary organization was made permanent, and Dr. David R. Silver, Sidney was elected chairman, and Dr. Frank P. Anzinger, Springfield, secretary. The society adopted the following resolution:

Resolved, That the society uphold the character of Dr. Ohlmacher, the superintendent of the Gallopis state hospital, and condemn the political machine tending to put him out of office.

South Carolina.

AIKEN COUNTY MEDICAL SOCIETY.—At a meeting held in Aiken, two weeks ago, a county society was organized, with the following officers: Dr. Benjamin F. Wyman, president; Dr. Theodore G. Croft, vice-president, and Dr. W. C. R. Turnbull, secretary and treasurer, all of Aiken.

Wisconsin.

FIRST DISTRICT MEDICAL SOCIETY.—This society was organized at Burlington, November 17, with the following officers: Dr. James C. Reynolds, Lake Geneva, president; Drs. Walter S. Haven, Racine, Benjamin J. Bill, Genoa Junction, and J. L. Cleary, Kenosha, vice-presidents, and Dr. Joseph P. McMahon, Union Grove, secretary.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.
Southern Surgical and Gynecological Association, Birmingham, Ala., December 13-15.

Western Surgical and Gynecological Association, Milwaukee, Wis., December 28-29.

American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

Pan-American Medical Congress, Panama, Jan. 2-6, 1905.

CLEVELAND ACADEMY OF MEDICINE.

Meeting of the Section of Experimental Medicine, held Oct. 14, 1904.

Dr. Spenser in the Chair.

Total Nitrogen, Ammonia and Urea in the Urine.

Dr. H. D. Haskins read a paper on the value of various methods of estimating total nitrogen, ammonia and urea in the urine. He stated that the accuracy of the Kjeldahl method of nitrogen estimation was corroborated by experimental evidence. He mentioned the Schlosing, Wurster and modified Wurster methods, but did not consider them as of the same value. He recommended Folin's method in preference to these, on account of its greater simplicity, combined with equal accuracy. He considered in detail all the important methods of urea estimation. He especially emphasized the inaccuracy of the hypobromite method, and pointed out that the only time when the finding is of any clinical value is when the quantity present is small in amount. The method estimates an uncertain amount of the total nitrogen rather than the nitrogen of the urea alone. He described the Pflüger-Schöndorff, Möerner-Sjogvist and the Folin methods and the amount of accuracy obtainable from each. None of these four accurate methods can be well carried out by the clinician, but the Möerner-Sjogvist he considered as the least difficult, and the most convenient of any of them.

Meeting of the Clinical and Pathological Section, held Nov. 4, 1904.

Dr. Hamann in the Chair.

Presentation of Clinical Cases.

ACQUIRED SYPHILIS IN A BOY.

DR. WILLIAM OSBORN presented a case of primary and secondary syphilis in a boy of 8. The lesions consisted of a primary sore on the prepuce, with swollen inguinal glands, unilateral condylomata of the anus, mucous patches in the mouth, and a fine macular eruption. The source of infection was genital abuse of various types. The usual antisyphilitic treatment was being carried on.

SACULAR ANEURISM.

DR. BACON related the history of a case of very early aneurism of the sacular type, associated with another small aneurism of the mycotic or infectious type. The patient went to the hospital with symptoms of pneumonia and died soon after. At autopsy there were found, besides the pneumonia, an acute septic endocarditis, grafted on a chronic process, with acute pericarditis and some patches of meningitis probably secondary, besides the usual changes in the organs denoting an acute infectious process. Just above one of the cusps of the aortic valve was a small depression, about the size of a lima bean, in which the aorta was markedly sclerotic, and which was apparently the beginning of a sacular aneurism seen at an unusually early stage. One of the other cusps was entirely perforated, in

spite of which there had been no physical signs of valvular lesion, and at its base was another small sacculation, due to weakening of the aortic wall by the direct extension of the inflammatory process, the so-called mycotic form of aneurism. The chief point of interest was the small size of the aneurism, only seen when as in this case the patient dies of some other trouble.

RECURRENT HEMOPTYSIS.

DR. THOMAS WOOD CLARK read a paper on recurrent hemoptysis in a case of aortic aneurism, with extensive involvement of the right lung and with rupture into the pleura. In the case mentioned there were 16 hemorrhages, varying from 2 to 36 ounces, and extending over a period of nine weeks, a total of 225 ounces in all. Early diagnosis of aneurism was made, but the patient would not submit to the Tuffnell treatment and refused to keep quiet. The hemorrhage always followed some sudden exertion and consisted of almost pure blood, with very little mucus. Hemoglobin estimations showed a progressive secondary anemia. On the sixty-fourth day after admission, after a sudden effort, the patient became very white, declared he was dying and only lived a few minutes. At the autopsy a very unusual condition was found. There was marked general arteriosclerosis, but the organs showed no particular changes other than passive congestion. The heart was moderately hypertrophied, and just above the aortic valve was a slit 4 cm. long, opening into a large sacculated aneurism. This aneurism involved the entire upper lobe of the right lung, the line of demarcation between the sac and the lung tissue being macroscopically indistinguishable. The main sac was filled with a dense laminated clot. Probes could be passed directly from the bronchi into the clot without having to penetrate any sac wall. On the outside of the lung, about in the axillary line, was a fresh rupture 6 cm. long, opening into the pleura, which was found completely filled with fresh blood and clots, the lower lobe of the lung being markedly compressed. The earlier hemorrhages had evidently taken place through the clot into the bronchi, and death occurred from bleeding into the pleura. Dr. Clark then gave a résumé of the few similar cases of repeated hemoptysis in aneurism, in none of which was there such a number of hemorrhages at such short intervals.

Operations in Impassable Strictures and in Hypospadias.

DR. N. STONE SCOTT reported several cases. The first case reported was that of a man of 29, with hypospadias extending to the scrotum, which was itself not cleft. The man had submitted to several operations and was willing to try again, as he wished to marry. A series of operations was performed in this case, in two main groups, the first tending to straightening the penis, the others to closing in a new urethra. On account of the tearing out of the stitches, for various reasons, five separate operations were necessary before a new urethra was formed, and two more before the urethral fistula could be finally closed and put into service. The results were, however, quite satisfactory, and the patient's marriage was followed in due course of time by the birth of a child.

The other cases reported were of impassable strictures, some of them infectious in origin, and others traumatic. It was necessary to dissect out the scar tissue and to form a new urethra. Diagrams were shown indicating the impossibility, in many cases, of passing a sound, as the channel does not necessarily follow a straight line, sometimes even forming a right angle, making the passage of even a filiform bougie impracticable.

DISCUSSION.

DR. W. E. LOWER noted the necessity in these last cases of absolute hemostasis, which he obtains by means of a stream of water flowing constantly over the field of operation. He also noted the advisability of beginning high up, as it is easier to find the urethra in this way.

DR. BENTZ spoke of the extreme antiquity of the operation for hypospadias, recalling that Charles XI of France was operated on with apparently good results. He also referred to Mayo's operation, in which a flap is taken from the dorsum, made into a tube and passed through an artificial opening in the penis to form the new urethra.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held in San Francisco, Oct. 25, 1904.

The President, Dr. T. W. Huntington, in the Chair.

Posture in the Treatment of Disease.

DR. C. M. COOPER stated that patients frequently assume attitudes which are more or less beneficial to themselves; as, for example, when an inflamed joint is immobilized by reflex muscular contraction, or when by a more volitional process, the chin-in-hand attitude is assumed in diseases of the cervical vertebra. In other cases an ignorance as to the nature of his disease does not permit the patient to reason out what would be the most advantageous posture to assume, and in these cases the physician should prescribe the attitude.

The value of a low position of the head in the treatment of the syncope caused by cerebral anemia is universally recognized. It also seems logical and has apparently been beneficial, to employ a similar inverted posture in treating more chronic conditions of cerebral anemia; e. g., the anemic insomnia of aortic regurgitation. Conversely, a relatively erect position is advantageous in the treatment of congestive headaches such as may occur in the early stages of cerebral inflammations, and in the treatment of the sleeplessness due to cerebral hyperemia. Possibly the nocturnal headaches of many syphilitics and the nocturnal attacks of epilepsy are in some measure due to the relative congestion of the brain occasioned by the reclining posture. Possibly, also, we may be able to influence the spread of inflammatory processes in the spinal meninges and in the spinal cord by elevating the foot or the head of the patient and so in this manner we may be able to protect important structures from involvement in the disease.

The erect sitting posture assumed by patients with severe cardiac affections is probably of direct advantage to them and it should be tried more often in the earlier stages of the disease. Frequently it can be shown that the heart rate becomes slower in this position. The tracheal symptoms of aortic aneurism may be relieved by having the patient lie face downward with a pillow under his chest below the seat of the aneurism. In pleurisy and pneumonia, it is possible that the erect posture would tend to prevent the spread of the disease upward. The nocturnal frequency of gallstone colics may be due to the fact that when the patient is lying on his back the mouth of the gall bladder is at a lower level than is the fundus. Attacks of gallstone colic have been aborted by having the patient assume the knee-chest position, thus favoring the falling back of stones from the neck to the fundus of the gall bladder. Possibly also renal colic could be thus aborted if the foot of the bed were elevated and the patient lay on the affected side. A right lateral position in appendicitis would tend to localize the inflammatory process to a comparatively favorable locality. A right lateral inverted posture should be tried in the treatment of dilatation of the stomach, for this posture would aid in emptying the organ.

DISCUSSION.

DR. EMMETT RIXFORD referred to a case described by Macewen where the patient said that he could not lie down. On being induced to do so by the physician, he died suddenly, and at autopsy a clot was found in the brain, which had slipped down in the recumbent posture and caused death. The relief afforded by the sitting posture in cardiac disease is probably due to the fact that when the patient lies down the abdominal contents press on the overworked heart. In the Trendelenburg position it is of advantage to place a pillow under the shoulders in order to render the abdominal wall less tense. When the patient with a dilated stomach is told to lie on his right side for the purposes of better drainage, we should remember that unless the contents of the stomach are heavier than are other abdominal structures they will not sink to the pylorus, but will be pressed up by these other structures.

DR. HARRY M. SHERMAN questioned the advantage of Dr. Rixford's modification of the Trendelenburg position, because it would tend to interfere with respiration. The hand-in-chin position assumed by patients with cervical caries can hardly be called a voluntary position, for the patients can not reason

out its mechanical advantages. He would be inclined to regard it as a reflex.

DR. CARPENTER stated that he had seen patients with hydro-nephrosis who suffered considerable pain in the back when lying down, but in whom this pain could be relieved by elevating the head of the bed, so as to favor drainage of the sac.

DR. C. M. COOPER said that the Trendelenburg position was not without danger and had caused death. The characteristic position assumed by patients with cervical caries is not a reflex, but is voluntary. The patient himself has learned that this position relieves his pain, even though he does not understand why it should do so. When the individual with a dilated stomach lies on his right side the fluid in the stomach comes in contact with the pyloric region and so causes reflex peristaltic movements which tend to empty the stomach.

Diagnosis and Treatment of Fractures of the Neck of the Femur.

DR. H. M. SHERMAN reported several cases of injuries about the hip which illustrate the importance of a special symptom, viz., the inability of the patient to lift his foot off the table when lying on his back. In two of these cases this was almost the only important symptom pointing to a fracture of the neck of the femur. On account of the absence of other symptoms, however, comparatively little attention was paid to it and subsequent events showed that both patients had had impacted fractures of the neck of the femur. In a third case of hip injury the patient could lift his foot from the table and the x-ray showed no fracture. Great care should be taken in all cases not to do violence to a femur which is the seat of a supposed fracture, for an impacted fracture may easily be converted into an unimpacted one by manipulation. For this reason an examination under an anesthetic should never be made. In the operative treatment of ununited fractures of the neck of the femur it is extremely difficult to drive a nail into the head and to obtain a good alignment. Furthermore, as a rule, only fibrous union is obtained. In two children who had been operated on it was found that the shortening of the leg gradually increased and a coxa vara developed, probably on account of a fibrous union of the fragments.

DISCUSSION.

DR. EMMETT RIXFORD stated that, on account of the great leverage involved, the effort to lift the foot off the table puts considerable strain on the fragments. For this reason he would hesitate to use the test described by Dr. Sherman. A symptom of considerable importance in fractures of the neck of the femur is the relaxation of the fascia lata above the great trochanter. He has operated on one case of ununited fracture of the neck and obtained a good result.

DR. SAMUEL HUNKIN, in reply to Dr. Rixford, stated that if the patient had a fracture of the neck, he would not attempt to lift the heel off the table, so that there is no danger in the test. He believes that the test is a good one. Other important diagnostic points are the local tenderness and the pain on slight rocking movement of the joint. The shortening of the extremity which occurred in the cases of the children operated on was perhaps caused by an injury to the epiphyseal line.

DR. H. M. SHERMAN stated that early operation in cases of fracture of the neck of the femur is not justified. The fracture is not usually at the epiphyseal line so that it should not interfere with the growth of the bone.

Travel Notes.

NIX.

THE CITY OF JAIPUR, INDIA, AND MAYO HOSPITAL.

NICHOLAS SENN, M.D.
CHICAGO.

BRINDISI, ITALY, Sept. 30, 1904.

Jaipur is one of the largest, most important and interesting inland cities of India. It is the local seat of government

of the state of Jaipur and the residence of the maharajah, whose palace, exhaustive gardens, crocodile tanks, state and private carriages and elephant stables are objects of growing interest to every visitor.

The city proper is enclosed by towering walls and the two gates are closed and locked regularly at 10 o'clock every evening, in the same manner as was done 300 years ago, when they were first opened during the feudal times, to serve as a safeguard against nightly invasions. This old custom continues with great punctuality, although the protection for safety of life and property has become superfluous since the strong arm of the English government has done away with internal strife and has made India secure against invasion from without.

Jaipur has taken the place of the ancient capital city Amer, a mountain stronghold seven miles distant, once a great and prosperous city, now deserted and its great palace and former mansions and ramparts crumbling into dust. A great fort on the highest mountain ridge overlooking the ancient palace and depopulated city is kept in good repair and is occupied by a regiment of native troops. Looking at this great city, now in ruins, centuries ago the power and pride of this part of India, the safe refuge of a large and prosperous population, the seat

ducted in the same manner now as they were a thousand and more years ago. The elephant, camel, donkey and buffalo are the beasts of burden now as then, and are trained and used in the same manner as under the masters of centuries ago. The little open shops and corners, where the artisans do their work with the crudest kind of tools, are the same now as they were when first opened for business, hundreds of generations ago.

This is the place to see Hindu feasts and processions in their original form (Fig. 2). The Hindu, above any other people, is proud of his race, his ancestry and ancient civilization, and is deeply, almost hopelessly, rooted in the teachings and faith of his Brahmin religion. Hindu life, habits and customs as seen in Jaipur illustrate the meaning of:

Fig. 1.—Native of Jaipur.

Fig. 2.—Hindu dancing girl.

of a gay and powerful nobility, we are strongly reminded of the significance of:

"The fashions of human affairs are short and changeable and fortune never remains long indulgent to men."—Quintus Curtius Rufus.

A few coolies and numbers of monkeys make up the scanty population of the abandoned capital city which centuries ago was the seat of political power, fashion, wealth and general prosperity.

In the meantime its rival, Jaipur, has become old. The present population of Jaipur is about 85,000; the principal streets are wide, lined by houses three and four stories high, with walls covered with plaster, painted a light uniform roseate hue, ornamented with rude artistic designs in white, representing plants and flowers. This is the place to see the real types of natives (Fig. 1), their habits and customs unaffected by time and European influence.

Agriculture, gardening and the different industries are con-

"So difficult is it to bring people to approve of any alteration of ancient customs; they are always naturally disposed to adhere to old practices unless experience evidently proves their inexpediency."—Livius.

The greatest trouble with the Hindu is to convince him of the inexpediency of anything inaugurated by his ancestors, as he is a firm believer in their infallibility concerning happiness in life and an ascending scale of blessedness in the hereafter.

Jaipur represents the center of one of the most fertile and prosperous agricultural states in India. Indications of considerable local wealth in the city are not lacking. The reigning maharajah is very popular and is well and favorably known for his many unostentatious works of charity. It was this prince who, during the last long famine, kept hundreds of his poor subjects from starving by his liberal contributions of food and money. He is the friend of the poor and takes a paternal interest in the Mayo Hospital.

Medical affairs in the city and state of Jaipur are managed

by P. Durrel Pank, Lieutenant Colonel, I.M.S. His last official report¹ contains many interesting facts, and from it I have gleaned much valuable information.

In speaking of the temperature and rainfall he says: "The mean temperature was 77.7 F., or 0.9 F. above the average; the maximum temperature was 115.20 F., on June 3 and 12, and the minimum 35 F., on December 27; the amplitude of yearly fluctuation was 80.2 F., and the greatest on any day was 41.4 F., on February 9. The rainfall registered at the Jaipur Observatory was 23.39 inches, or 1.07 below the yearly average."

The vital statistics show that during the year 1903 the number of births recorded was 4,436, against 6,641 deaths, the death rate being much larger than the birth rate. Infantile mortality is responsible for the large death rate, as the number of deaths among children under one and five years, during the same time reached the astonishing figure of 3,863. The three months most fatal to child life were: June, 531; October, 461, and September, 459. During the year there were 58 deaths from smallpox, 244 from measles, 7 from cholera and 7 from imported plague in Jaipur city.

In reference to the steps taken to check the cholera epidemic the report states: "The usual necessary precautions were taken in every village and city where the outbreak of cholera took place—wells were disinfected with permanganate of potassium; insanitary conditions in the villages and towns removed, so far as possible, and hospital assistants with proper medicines were dispatched to treat all cases."

Malarial fevers were prevalent in many districts in the autumn and 236 packets, containing 100 doses of quinin in each, were supplied to officials of the government for free distribution to the people; there was also a free distribution of quinin and other cinchona alkaloids from each of the district dispensaries.

The mortality from malaria was low, owing undoubtedly to the liberal distribution of quinin free of cost through the different branches of the government service. Free vaccination is performed on a very large scale, 84,019 cases during the year covered by the report. A very interesting account is given of the experience of the medical officers in carrying out the prophylactic serum treatment (Haffkine) during the epidemic of bubonic plague, and the prejudice of the people against this measure was only overcome by the noble example of one of their chiefs.

"In regard to inoculation, the adoption of this in the early days of the epidemic was most difficult and at one time apparently hopeless; but patience, tact and moral suasion at last overcame the dense ignorance and stupid prejudices of the villagers. The last argument, and that which really compelled them to give way in the end, was the fact that their nazim stripped and bared his body before their eyes in order to be inoculated as an object lesson. This they would not allow, and rather than that he should be a scapegoat in their behalf, a few consented. The plunge was made and all followed suit; before many had been inoculated others clamored to be inoculated at once as they could not afford to run the risk of delay in waiting to be done in their proper order and turn, and protested against others being inoculated before themselves. When once they saw and believed that no harm and little inconvenience followed the inoculation, they implicitly believed in it and attributed to it many virtues which it does not possess nor lay claim to." What a striking illustration of

"Men are but children of a larger growth."
Dryden.

MAYO HOSPITAL.

The Mayo Hospital, so called in memory of a former governor of this part of India, is the government general hospital of Jaipur and is the largest of the twenty-six hospitals and dispensaries in the state of Jaipur. It has a superb location, the buildings and grounds facing the beautiful botanical garden and the fine statue of the governor whose name it commemorates. The main building is a solid two-story stone

building, and there are a number of one-story pavilions of the same material, connected by roofed cement walks with the central building. The hospital has accommodations for 160 patients, all natives, cared for at government expense. The wards are capacious, well lighted and ventilated, but the furniture is scanty and of the simplest kind. The operating room is small and the appliances for asepsis of a somewhat primitive character. Lieut.-Col. Pank is at the head of the medical staff, assisted by several assistant surgeons of the subordinate Indian Medical Service.

The worst feature of this hospital is a lack of an adequate number of trained female nurses. Most of the nursing is done by male and female ward attendants, who receive at best only the most elementary training and, consequently, can not be relied on in the operating room or in the care of grave surgical and medical cases. A training school for female nurses is a desideratum that should be met without any further loss of time, as it would be the means of greatly facilitating the work of the medical officers and would secure more efficient care for the patients afflicted with grave disease and for those who are subjected to operative treatment. The records of the hospital speak well for the surgical skill of Lieut.-Col. Pank, who does most of the operative work, which includes general surgery, gynecology and ophthalmology. Considering the difficulties he has to contend with, his results compare well with those of other surgeons in India who have better assistance at their disposal and whose patients are under the care of competent trained female nurses.

During the year 1903, 24,648 out-patients and 2,124 in-patients, total 26,772, were treated at the Mayo Hospital. During the same year 696 major and 664 minor, total 1,360, operations were performed; of these 21 per cent. were on women. Five ovarian cysts were removed by ovariectomy without a death—two of these cysts were very large and in three cases the adhesions were extensive. Ten successful operations for tuberculosis of the lymphatic glands in the neck, axilla or groin were performed and were in many cases very extensive, entailing long and careful dissections. Thirty-seven operations on bones were made without mortality. Among these were two cases in which the whole lower jaw was removed on account of an enormous epulis; and in three cases partial excision of this bone, in one case for sarcoma and in two for necrosis. The right upper maxilla with malar and nasal bones, was removed for sarcoma. No death in ten amputations of all kinds. Operations on the eye constitute the bulk of the operative cases. Lieut.-Col. Pank has had an enormous experience in operations for cataract.

During the year mentioned above 239 cataract operations by von Graefe's method were performed, 219 by Lieut.-Col. Pank and 20 by Assistant-Surgeon Daljaag Singh. These operations were performed on 199 persons; 224 were recorded as able to see well, 4 discharged otherwise and 11 were under treatment at the end of the year. Artificial pupils for corneal opacity were made in 5 cases, in 3 persons, and all were useful in increasing vision. Iridectomy for glaucoma was performed in 14 cases and the disorganized eyeball was extirpated in 14 cases. Eight operations for the radical cure of inguinal hernia by Bassini's method were successful. In four of these cases the hernia was congenital.

The rectum and anus were operated on 31 times with one death (anal fistula); 14 times for hemorrhoids by ligature and 8 times for anal fistula. Vesical calculi were removed in 43 cases by litholapaxy with no death; in 3 cases by lateral lithotomy with one death, and in 4 cases by perineal lithotomy with no death. All cases treated by litholapaxy made excellent and speedy recoveries. The largest stone removed by this operation weighed 935 grains and the average hospital life for each case was 4.18 days. The 3 cases operated on by lithotomy were unfit for any other operation, and the patient who died after operation was a man worn out by the disease complicated by cystitis and renal trouble; his stone weighed 1,072 grains. Perineal lithotomy was reserved for cases in which a lithotrite large enough to crush the stone could not be passed by the urethra. The operation was performed by making, on a

¹ Annual Report on the Jaipur Medical and Meteorological Institute for 1903.

small staff, a median incision just large enough to permit a sufficiently large lithotrite to enter the bladder, one direct stabbing incision going straight into the bladder on a grooved staff was sufficient. The largest stone weighed 1,501.5 grains and the average stay in the hospital was 12.5 days.

SPLENIC ANEMIA.

In the medical wards of this hospital I had an opportunity to examine four cases of so-called splenic anemia, that is, a disease characterized by great enlargement of the spleen with progressive anemia. All the patients were young men, natives, from 18 to 35 years of age. In all the abdomen was very much enlarged and pendulous, and through the thin abdominal walls the outlines of the enormously enlarged spleen could be very plainly traced. In some of these cases the spleen extended beyond the median line and its lower border almost reached the level of Poupart's ligament. In two of the cases the liver was also markedly enlarged. Emaciation and a profound anemia in all of them were the most prominent clinical features. I was informed that this disease generally yields in the course of time to a sulphate mixture which is used in this hospital, of which the most active ingredients are sulphate of quinin and sulphate of iron.

During my visit to the Bengal Medical College, Calcutta, Capt. Seward Rogers, I.M.S., professor of pathology, was kind enough to show me under the microscope the parasite which has been shown to be the cause of this strange disease. It was discovered by Leishman and Donovan, and has been classified by Laveran and Mesnil under the name of *Piroplasma donovani*.

This newly discovered parasite has attracted a great deal of attention, and among the numerous articles descriptive of it I will only refer to the article on Piroplasmiasis by Captain Donovan, published in the "Annual Report and Statistics of the Government General Hospital, Madras, for the Year 1903." And a very important monograph, "A Preliminary Report on a Parasite Found in Persons Suffering from Enlargement of the Spleen in India," by Lieut. S. R. Christophers, M.B., I.S.M., a government publication.

Captain Donovan, in the article referred to, gives a short history of his discovery, from which I will give here some extracts. In speaking of piroplasmiasis he says: "Under this head I have classified a new disease prevalent in Madras; the symptoms are those of so-called chronic malaria. . . . I had noticed many cases of chronic irregular pyrexia, with enlargement of the spleen, and occasionally of the liver, bronchitis, edema of the feet, subcutaneous hemorrhages, chiefly of the petechial type, diarrhœa of a dysenteric nature and cancrum oris. The treatment was most unsatisfactory, no drug having the least beneficial effect."

Captain Donovan doubted the malarial character of the disease and at once made a thorough examination of postmortem specimens. "With a view to remove this doubt I attended the postmortems and took smears of blood from the spleens of patients said to have died of chronic malaria. On the first day, April 9, 1903, I found, in a slide containing such a smear, numerous peculiar round and oval ring-like little bodies, with two masses of chromatin situated in opposite poles. Convinced as I was of their parasitic nature, I could not, however, refer them to any group of protozoa. I thought I had discovered the long-sought-for resting stage form of the malarial parasite in man, but on perceiving the same bodies in two other cases on April 23 and 24, 1903, I changed my view and considered that they might be postmortem degenerations of the nuclei of the splenic pulp cells. On June 15, 1903, I received the *British Medical Journal* of May 30, of the same year, and in it, on page 1252, was an account by Major Leishman, R.A.M.C., of organisms identical with mine. I at once recognized the similarity of what Leishman called degenerations of the trypanosomata, to the bodies found by me in the spleen blood of the three cadavers above mentioned."

On June 17, 1903, Captain Donovan punctured the spleen of a boy suffering from this type of fever and found in it bodies identical with those found postmortem. The results of this

examination were published in the *British Medical Journal*, July 12, the same year. On September 23 he sent a slide containing these bodies to the Pasteur Institute, where they were carefully examined by Laveran and Mesnil and named in honor of their discoverer *Piroplasma donovani*.

A large clinical experience has demonstrated the direct etiologic relationship of this parasite with the splenic affections in question. The parasite is not found in the peripheral blood and, for diagnostic purposes, blood has to be obtained from the spleen by puncturing it. It is in this organ that the micro-organism is found in greatest abundance. Puncture of the spleen for diagnostic purposes is not entirely devoid of danger; there is, at least, one case on record in which the puncture gave rise to fatal internal hemorrhage (Donovan, Case 24). The presence of this parasite in the splenic blood furnishes absolute proof of the nature of the splenic enlargement and settles the differential diagnosis between this disease and malarial and leukemic enlargement of the spleen. In the paper quoted above Captain Donovan gives a detailed account of 31 cases that came under his personal observation during one year with many postmortem findings.

Captain Donovan describes the clinical features of this disease as follows: "The symptoms are, in typical cases, an irregular pyrexia of two or three months' duration, accompanied with shivering with apyrexial intervals. About this time the spleen becomes enlarged and painful, and edema of the feet begins; there is usually diarrhœa of a dysenteric nature, which comes and goes for a week or so at a time. Later the lungs are affected; there is cough and expectoration; enlargement of the liver, ascites (unusual); subcutaneous hemorrhages of a petechial nature; soreness of the mouth, gums or hard palate and cancrum oris. Marked emaciation and anemia supervene, the skin becomes dry and furfuraceous and, if the patient is not washed, the skin takes on a dark discoloration. . . . The blood examination, in cases of piroplasma infection, always shows a marked decrease of the red globules; these vary from two to three millions to the cubic millimeter. There is no actual increase of the leucocytes, but a relative one of the mononuclears, as in malaria. The urine usually contains albumin and invariably pigment, urobilin. The feces in some cases contain balantidia, ankylostoma and rhabdonemata. Quinin has been given by mouth, hypodermically and intramuscularly *ad nauseam*, with no appreciable result. The same may be said of other less suitable drugs, i. e., arsenic, salicylate of sodium, carbohc acid, etc.

I will give here as an illustration the findings of only one postmortem examination: "Case 30. Raghavan, aged 30 years, lived at Periyamett. Fever irregularly for a month and a half; spleen enlargement noticed a month ago; during this period he had occasional attacks of diarrhœa and soreness of the mouth. Admitted for diarrhœa and distension of the abdomen; his spleen and liver were enlarged and he had edema of the feet. He died on the fourth day after admission. The postmortem was made by Captain Symons, I.M.S., and the following notes were recorded: Considerable amount of clear fluid with floating lymph in abdomen; colon at splenic flexure gangrenous; transverse colon much thickened—almost half an inch in places and ulcerated, containing raised papillæ on the mucous surface of a bright red color; descending colon a dark gray color; spleen much enlarged with pigment in patches; liver enlarged 2½ pounds in weight."

The *Piroplasma donovani* is found free in the splenic blood and as a cell inclusion in the red corpuscles and macrophages, but more frequently in the leucocytes; in some of the cells it is multiple.

Lieut. S. R. Christophers, in his exhaustive monograph on this parasite, gives a very minute description of its morphology and multiplication by fission. "In films stained by Romanowsky's method the bodies are seen with great clearness. They exhibit a remarkable uniformity in size and appearance. The majority are about 2.5 micromillimeters in diameter, but forms may be found which are a little larger, 3 to 3.5 micromillimeters, or a little smaller. Very occasionally still smaller bodies, 1.5 micromillimeters in diameter, may be encountered. Most of

the bodies are approximately circular in outline, but very many, and especially the larger forms, are irregularly oval and very much resemble a cockle-shell in shape. This, indeed, appears to be the most typical shape, and even in the apparently round forms an approach to this shape can be made out. Occasionally specimens are found more elongated and distinctly pear-shaped. . . . Except in very rare small forms which show only a single chromatin mass, the bodies invariably possess two chromatin masses—a large one staining lightly and a small one staining intensely, with the red coloring matter of Romanowsky's stain.

"The two chromatin masses are usually situated opposite to each other in the shorter axis of the parasite. . . . The large chromatin mass is situated near what would be the hinge in the cockle-shell-shaped forms and in the thicker end of the pear-shaped forms. The body substance usually stains pink by the method employed (fixation in alcohol and staining by watery solutions of eosin and Romanowsky's blue).

. . . . Forms may be seen which appear to show division of the bodies into two. Appearances showing both longitudinal and transverse fission are seen. In the former two pear-shaped bodies are found lying side by side. The larger chromatin masses are situated in the thick end of the pear and the small red bodies at the thinner end, and the small chromatin mass may often be seen undivided when the larger masses are widely separated."

The discovery of the real parasitic cause of splenic enlargement and anemia, such a common and very fatal disease in India, will, it is to be hoped, soon lead the way to a more successful treatment.

The work done in this, one of the newest fields in pathology and bacteriology, by the officers of the Indian Medical Service reflects great credit on that branch of the British colonial service and will undoubtedly serve as a stimulant to others to blaze new pathways in the as yet but imperfectly explored wilderness of tropic diseases, tropic medicine and tropic surgery.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Furuncle.

As the non-operative procedure of treating furuncles, Hunter, in *Med. Age*, states that the objects to be borne in mind are:

1. Soothing and protecting the inflamed area.
2. The exclusion of the air.
3. Antisepsis.

To carry out these suggestions it is recommended that the following ointment be applied, spread on a piece of absorbent cotton considerably larger than the inflamed area. This should be applied and held in place by strips of adherent plaster across the ends, but not passing over the boil:

R. Acidi carbolicgr. v-x	[30-.65
Ext. ergotæ fld.3i-ii	4-8]
Pulv. amyli3ii	8]
Zinci oxid3ii	8]
Ung. aq. rosæ3i	30]

M. Fiat unguentum. Sig.: Apply locally.

This dressing may be allowed to remain in place for from twelve to twenty-four hours, when a new application should be made. If pus is present and discharging, the surface should be cleansed, but the boil should not be squeezed. According

to the author, it is never found necessary to incise a boil when this treatment is employed. This ointment can be used in all stages, keeping the ointment on until the lesion is quite healed. Another non-operative plan of treatment may be carried out by thoroughly cleansing the area with soap and water, followed by a sponge with alcohol. If suppuration has begun, a strong germicide should be applied in the center by means of some absorbent cotton on a toothpick. For this purpose carbolic acid is the best antiseptic and germicide. Aristol should afterward be dusted over the affected area and covered with antiseptic cotton. The flaxseed poultice is condemned by the author as a splendid field for the growth of micro-organisms. He does recommend, in the early stages of the disease, where the tension and swelling are so great as to produce constant, severe pain, that a bichlorid or carbolized gauze be wrung out of boiling water and applied in a thick pad over the diseased area and covered with oiled silk or with oil paper. If the simple procedure of painting the area early with tincture of iodine, tincture of camphor or other antiseptics be carried out the boil may be aborted. In all cases where suppuration has begun it is better to incise. In earlier cases the foregoing treatment is certainly of value. As to internal medication, any constitutional disease should be treated.

Yeast has been recommended internally, two or three teaspoonfuls mixed with beer.

Colchicum, one-half grain (.03), daily is also highly recommended, especially in gouty subjects.

Treatment of Epilepsy.

Dana, in an abstract in *Ther. Gazette*, recommends the following outline of treatment of epilepsy in patients who can not arrange to be treated in an institution:

THE REGULATION OF THE DAILY LIFE.

Some study or some systematic work. The patient may be permitted to attend school for a part of the day or to take special lessons. If possible he should be encouraged to acquire some musical accomplishment or to learn some handicraft.

EXERCISE AND BATHING.

Three times a week or even six times a week, if the patient is strong, he must take some very active exercise for from 20 to 30 minutes, sufficient to make the perspiration pour out profusely. In the country he may chop or saw wood or ride a wheel. In the city he may learn to fence or box. If this can not be arranged, have the patient get a "hot box" and thrice weekly take a sweat followed by a cool ablutio. This should be done about 5 p. m. in order that the patient may rest until the evening meal. Three times a week the patient should take a short (one minute) hot bath (98 to 108 degrees F.), followed by a lukewarm bath. In the morning a cool sponge may be taken. The foregoing are indicated in order to secure a free action of the skin, muscles and liver.

DIET.

The author gives no specific diet. These patients should have a simple mixed diet, with meat once or twice a day in moderation. The digestive tract must be carefully guarded. According to the author the non-saline diet is of no advantage.

OPERATIONS.

The author does not believe in the reflex causes for epilepsy, but regards it as a progressive degenerative disease, congenital in character. The history of alcoholism, syphilis or trauma should be inquired into, the eyes should be examined as well as the sexual and pelvic organs. While the fits may cease for a time, after operation for phimosis or removal of ovaries, the case is never permanently benefited. Operation is, of course, indicated in Jacksonian epilepsy, but in no other cases except in certain imbeciles.

MEDICINES.

The basal medication is bromids. The average daily dose, for patients over 14 years of age, is 60 grains (4.00). The author regards the glycerophosphate of sodium as the best adjuvant given in doses of 30 grains (2.00) daily, combined as follows:

- R. Aq. sol. sodii glycerophos. 50 per cent. ʒii 60
 Sodii bromidi ʒiii 90
 Aque q. s. ad. ʒvi 180
 M. Sig.: One teaspoonful twice a day in water, six days in the week.

The author emphasizes the importance of giving the medicine twice a day only, and omitting one day in the week in order to allow the patient time to cleanse the alimentary tract. Once a month the author prescribes a mercurial and one day in the week a glass of hot water containing 30 grains (2.00) of sodium bicarbonate three times a day before meals.

- After each meal an acid tonic is given as follows:
 R. Tinct. ferri chloridi (1 year old) ʒi 30
 Acidi sulphurici dil. ʒiv 15
 Aque ʒxxx 40
 Olei menth. pip. m. v 30
 M. Sig.: From 15 to 25 drops well diluted or dropped in capsule after each meal.

INCREASE OF MEDICATION.

As the patient improves the medication should be increased. The less frequent the attacks and the more secure the patient feels, the more stringent should be the watch and the larger the dose. What has been gained must be secured or the work all done over again. After a year's remission it is especially important to increase the medication, and the general care of the patient and for two months he must be closely observed, then the treatment may be decreased for six months. Some relief may be felt after fourteen months, some security after two years and strong confidence after three years.

Malaria.

The following combinations are recommended by *Critic and Guide* in the treatment of malaria:

- R. Quin. sulph. |
 Salol, aa gr. xl-ʒi 2.66-4 |
 Codeina sulph. gr. iii 20 |
 Acetanilidi gr. xx 130 |
 M. Fiat cap. No. xii. Sig.: One capsule every three hours.

Ten drops of dilute hydrochloric acid is recommended after the capsule to insure its solution in the stomach. If it is desirable to administer the medicine in solution the following is recommended:

- R. Quin. sulph. gr. l-xxxx 3.30-5|30
 Acidi hydrochlor. dil. ʒi-ss-ʒi-ss 6-10|
 Tinct. zingiberis ʒi-ss-iv 10-16|
 Tinct. opii camph. ʒi-iv 8-16|
 Syr. limonis ʒii 60|
 Aque q. s. ad. ʒviii 250|
 M. Sig.: One tablespoonful ever four hours in water.

For malarial cachexia following either the remittent or intermittent forms of malaria the following is recommended:

- R. Quin. sulph. ʒi-ss 6|
 Ferri redteti ʒi 30|
 Ext. nucis vom. gr. viii 50|
 Acidi arsenosi gr. i 06|
 Ext. colocynth. comp. gr. x 65|
 Podophyllini gr. i-iii 06-20|
 Mellis q. s. |
 M. Fiat pil. No. lx. Sig.: One after each meal.

For latent and masked forms of malaria the following is recommended by Krauss:

- R. Quin. hydrochlor. ʒss 2|
 Hydrarg. chloridi mitis gr. v 30|
 Pulv. capsici gr. iss 09|
 Pulv. opii et ipecacuanhe gr. v 30|
 Aloini gr. i 6|
 M. Fiat cap. No. vi. Sig.: One every four hours.

Substitute for Milk in Intestinal Diseases of Children.

Helprin, according to an abstract in *Med. Record*, recommends the following as a substitute for milk in the treatment of intestinal diseases of children:

Two tablespoonfuls of ordinary flour, browned in the oven, then dissolved in a little cold water. This amount should then

be added to and stirred in two pints of boiling water. This may be given in quantities of three ounces at a feeding. One-half a dram of condensed milk, gradually increased to one and a half drams, may be added at each feeding. The following prescription is of service in checking the diarrhea:

- R. Bismuthi subnit. ʒv 20|
 Bismuthi salicylatis gr. xii 75|
 Syr. rhei aromatici ʒiii 12|
 Aque dest. q. s. ad. ʒiv 120|
 M. Sig.: One teaspoonful every two to four hours.

Venercal Warts.

The prophylaxis and initial treatment, according to Röhrer, in *Amer. Jour. Med. Sciences*, are practically the same. In either case the cause should be removed. If gonorrhoea is present, treat it. If balanitis exists, repeated cleansing and drying of the parts are imperative. The treatment proper of venercal warts may be either medical or surgical. The former, according to the author, includes dusting powder, ointments, lotions, pastes and caustics. The latter may be carried out by means of the knife, scissors or curette and caustic agents.

MEDICAL TREATMENT.

Dusting with calomel alone is one of the simplest methods, or the following combination is more efficacious:

- R. Hydrarg. chloridi mitis ʒi 4|
 Bismuthi subnit. ʒi-ss 8|

M. Fiat pulvis. Sig.: Apply locally as a dusting powder. Dusting the growths with boric acid is very frequently sufficient to cause their disappearance. Or the following is recommended:

- R. Zinci oxidi |
 Bismuthi subnit. aa ʒii 8 |

M. Sig.: To be applied locally.

A 10 per cent. salicylic acid ointment may be more serviceable in some cases. Resorcin is also recommended by the author as superseding all other local applications:

- R. Resorcini gr. xv 1|
 Liq. petrolati ʒi 30|

M. Fiat unguentum. Sig.: To be applied locally after thoroughly cleansing the parts.

The following combination, it is said by Martin, will remove warts in from twelve to twenty-four hours:

- R. Acidi salicylici ʒi 4|
 Acidi acetici ʒi 30|

M. Sig.: Apply locally with a brush once daily.

A sufficient amount of the foregoing should be deposited on the warts to cover their entire surface and then allowed to dry. One or two applications usually causes them to disappear without a recurrence.

It is also recommended that ferric chlorid be applied to the growths three times daily, the shrunken portion removed with a curette and the drug reapplied until the base is reached. If bleeding takes place it may be stopped with a 5 per cent. solution of antipyrin.

SURGICAL TREATMENT.

The author states that neither curettement nor excision is so effectual as removal by curved scissors unless the growths are very small and few in number; an anesthetic, either general or local, is necessary. Of the local anesthetics, ethyl chlorid and cocain are the best, and ether as a general anesthetic. After the growth is cut off the base should be cauterized with nitric acid or carbolic acid. The wound should then be dusted with iodoform or a powder composed of zinc oxid and calomel, followed by a gauze dressing. Where hemorrhage is severe from excision of large papillomata the actual cautery may have to be brought into service.

CAUSTICS.

The principal caustics are nitric acid, chromic acid, caustic potash, silver nitrate, carbolic acid and glacial acetic acid. When nitric acid is employed the surrounding parts should be protected by some bland ointment. The caustic should be applied on alternate days until the warts are removed. Chromic acid is liable to produce toxic symptoms. With proper care it may be applied locally once daily, either pure or in 10 per cent.

solution. The following combination is quoted by the author as being a very valuable caustic:

R. Plumbi oxidii	gr. ii	12
Potassii hydratis	gr. x	30
Aquæ q. s. ad	ʒi	4

M. Sig.: Shake well and apply, by means of a brush, to the lesion. One or two applications are sufficient.

Intraurethral growths may be removed by means of the urethral forceps, the wire snare, the urethral curette or the galvanocautery through the urethroscopic tube. The treatment of venereal warts in women is analogous to that in the male.

Aspirin in Symptomatic Treatment in Inoperable Cancer.

Ruemann, in *Deut. Med. Wochenschrift*, recommends the administration of aspirin as the substitute for morphin in relieving the excessive pain in cancer. He usually gives it in doses of $7\frac{1}{2}$ grains (.50) every half hour, if necessary, until 30 grains (2.00) have been given. For the production of sleep he gives a dose of 15 grains (1.00) at bedtime. No bad results were produced from the administration of the drug in this manner and its effects were not lessened by time.

Medicolegal.

Non-expert Opinions Based on Insufficient Knowledge.—The Supreme Court of Illinois holds, Chicago Union Traction Co. vs. Lawrence, that if a non-expert witness gives an opinion without sufficient knowledge of facts to support it, opposing counsel may, on cross-examination, show that it is of little value and should have little weight. It may be attacked on argument, and the jury may be instructed that the weight to be given to such opinion depends on the intelligence of the witness, on his acquaintance with the person if mental condition is the subject of investigation, on his means of observation, and on his veracity.

State of Mind of Declarant May be Shown.—It must be remembered, the Supreme Court of Illinois says, in Nordgren vs. People, that dying declarations are in their nature merely secondary evidence, and the party against whom they are produced in evidence has no opportunity to cross-examine the party making such declarations. It has been held that, when dying declarations are offered in evidence, it is competent for the accused to show, on cross-examination of the state's witnesses, or by other witnesses, that the deceased in making the statements was in a reckless, irreverent state of mind, and entertained feelings of malice and hostility toward the accused.

Regarding Schools of Medicine, Chemistry, Pharmacy.—The Court of Appeals of Kentucky says, in the case of the Louisville College of Pharmacy vs. City of Louisville, that if the teaching of law, medicine, chemistry and pharmacy in universities does not deprive them of the character of "institutions of education," it seems to the court that an institution which confines its instructions to one of them is no less an institution of education. The question in this case before the court was whether the college of pharmacy mentioned was an "institution of education" exempted from taxation under the state constitution. The court says that it can conceive of no more useful and important branch of knowledge than that of pharmacy. That knowledge is necessary to protect the lives and health of the citizens of the commonwealth. So important is this branch that the General Assembly has taken the matter in hand and has prohibited any one from compounding medicines unless he has been graduated from some institution of education where pharmacy is taught. In this case public-spirited persons had associated themselves together and organized an institution not for gain or profit but that persons might be educated in pharmacy so that the drug business might be conducted according to law, and the public protected from the uneducated and ignorant pharmacists. It is a home institution, infantile in the matter of age, and merits the protection given by the constitution. Consequently the court is of the opinion that it is exempt from taxation.

Liability for Care of Persons with Contagious Diseases.—Section 7059 of the General Statutes of Minnesota of 1894 authorizes the board of health of any town, village, borough or city to provide for any resident thereof or person coming from abroad who may be afflicted with smallpox or other contagious disease. It in part reads: "And shall provide for such person or persons, nurses, medical attendance and other necessities which shall be a charge in favor of such town, village, borough or city on the person so provided for, his parents, guardian or master, if able; otherwise on the county in which he has a legal settlement, or on the state, if said person be a non-resident of the state and has no property within the state." Under the provisions of this section the Supreme Court of Minnesota holds, Board of Commissioners of Marshall County vs. Board of Commissioners of Roseau County, that a county is not liable to the various towns, villages or cities throughout the state for expenses necessarily incurred in caring or providing for a person having a legal settlement in said county, who is afflicted with a contagious disease in such municipalities, where the person so provided for is solvent. It says that this section, being section 15 of chapter 132 of the General Laws of 1883, has been greatly confused with section 29 of said act, being section 7073 of the General Statutes of 1894, as amended by chapter 238 of the Laws of 1901, and since reamended by chapter 29 of the Laws of 1902. The act of 1901 has reference solely to expenses incurred by towns, villages or cities in the control of contagious or infectious diseases. It has no reference to expenses incurred in caring for individuals. The line between expenses incurred for the purpose of preventing the spread of such diseases and in caring for individuals may be a delicate one to draw, but it is clear the legislature in the two provisions referred to has fastened a liability on the various counties of the state for necessary expenses incurred by the public authorities of the various towns, villages or cities situated therein in preventing the spread of an infectious or contagious disease; while, on the other hand, by section 7059 it is clearly provided that the various counties of the state shall reimburse towns, villages or cities either situated within or without their respective borders for necessary expenses incurred in providing nurses, medical attendance and other necessities for persons having a legal settlement in such counties, who are afflicted with an infectious or contagious disease, but only on condition that they or their parents or guardians are financially unable to discharge such obligation. As this court construes section 7073, as amended, it deals solely with expenses incurred in controlling contagious diseases.

2. Intubations for Laryngeal Diphtheria.—Engelmann adds 23 cases of intubation for laryngeal diphtheria to 47 published previously, making a total of 70 patients operated on in 10 years. All the operations were done under adverse circumstances and in the worst possible environment. The majority (47) of these operations were done in the earliest antitoxin period; consequently, there is a 38.4 per cent. mortality for this first series of cases, as compared with a 36.6 per cent. mortality for the second series of 23 cases; or, deducting 3 preventable, unjustifiable deaths from this latter series (23 cases with 5 deaths) to a 21.7 per cent. mortality, and for the total of 70 cases to a 37.2 per cent. mortality. One prevent-

able death was due to a choked tube, which the parents refused to have removed; another to a choked tube removed three hours too late; the third was due to the removal for cleansing of a tracheotomy tube by an un instructed interne, who probably could not quickly enough replace the tube, the parts being very edematous. Engelmann believes that laryngeal diphtheria, recognized as such in its early stage, and treated properly by a sufficient antitoxin dosage, need never advance to the obstructive stage that necessitates even intubation, much less tracheotomy. In support of this belief, she refers to the fact that her cases numbered 23 in the second five years, as compared with 47 in the first five years. The greatest number of times intubation was done on a patient was 19 times. The number of autoextubations, or expulsion of the tube, was 18 times in one case, 16 times in four cases, 3 times in 15 cases, and 4 times in 4 cases, making 24 cases. The tube was placed and finally removed in 46 cases. In the patients who recovered, the minimum number of hours the tube was worn was 7, and the maximum, 692, or 28 days and 20 hours. In another prolonged case that ended fatally the patient wore the tube 548 hours, or 22 days. The average time of wearing the tube in the 70 cases was 108½ hours, or 4 days and 12½ hours. In the death list, the minimum, maximum and average time of wearing the tube was 2¾, 548, 86¾ hours. The culture was negative and unknown in 2 cases; showed Klebs-Loeffler bacillus in 50 cases; staphylococcus and streptococcus in 3 cases; Klebs-Loeffler associated in 9 cases; staphylococcus in 3 cases; streptococcus in 1 case; pneumococcus in 1 case. All the cases were fed by the inverted Casselberry method, either on the bed, with the head hanging over the edge of it, or in the same position on the mother's lap. There was spasm of the larynx in 11 cases, and the tube was found choked in 14 cases. Pneumonia complicated 13 cases; rashes, 15; arthritis, 1; measles, 1, and decubitus of the larynx, 1 case; sepsis, 8 cases; cardiac paralysis, 1; nephritis, 1 known case. Engelmann says that the type of disease seen during the past year is more malignant than that observed in previous years. She has also seen comparatively more of the so-called primary laryngeal type during the past year than in the previous 9 years, and also did the largest number of the 23 cases in this short period.

4. **Inversion of the Uterus.**—In the case cited, Anspach adopted the simple plan of amputating the inverted mass, because of the lessened danger of infection, and the undesirability of removing the adnexa, which were normal. The pedicle of the mass was compressed by a large hysterectomy forceps. After cutting away the necrotic mass beneath the forceps, the latter were left in place, their points being pushed back into the uterus and this packed with gauze. Forceps seemed safer than sutures because there was less liability to infection of the peritoneum. The forceps sloughed off on the fifth day, and the patient made an uneventful recovery.

6. **Skin Diseases and Metabolism.**—Bulkley reviews the underlying principles of metabolism and the means by which abnormal variations in the process may be recognized. He considers a proper study of the urine an invaluable aid in the practical management of this class, and that without such study much of the treatment would be experimental and empirical. Metabolism represents the changes occurring in the system, whereby nutritive materials and oxygen are transformed into living tissue, and retransformed into waste products, while during these processes, their potential energy

is being given off in living force and heat. A healthy cell action and transformation is produced and maintained by perfect metabolism, so, when there is perverted metabolism, the structures in various parts of the body must suffer, and that is called disease. Furthermore, inasmuch as every cell in the body constantly takes up and gives off material, so the results of metabolism can be affected by the normal or abnormal action of every living cell in the organism. Metabolism, however, is principally affected by the kind of nutriment taken: the action of the digestive organs and ductless glands, and the action of the nervous system. Among the skin lesions or eruptions which are believed to be associated with or dependent on metabolic conditions are gout, rheumatoid arthritis, diabetes, obesity, and scrofula. As yet, no absolute statements can be made, says Bulkley, as to the necessary connection between the two, for the same eruptions occur in several of the metabolic affections. The idiosyncrasy of the patient, and many causative elements, external or internal, nervous, etc., often determine which form of skin disturbance or alteration shall take place. Errors of diet, disorders of digestion, faulty excretion and nervous derangement, which have all been recognized as etiologic factors in many diseases of the skin, often find their ultimate expression or mode of action through the faulty metabolism induced thereby. Metabolic errors are exhibited in the excreta from the lungs, skin, intestines and kidneys, and, of these, as mentioned, the urine best affords a satisfactory indication, as it represents nearly one-half of the total excreta, and practically all of the nitrogenous and soluble mineral substances, together with about one-half of the water expelled from the system.

7. **Tubercle of the Choroid.**—Pooley reports a case of conglomerate tubercle of the choroid, with extension into the sclera and retina, and secondary glaucoma occurring in a man aged 26. The eye presented the usual symptoms of absolute glaucoma and there was no ophthalmoscopic reflex. The other eye was normal. The affected eye was enucleated and microscopic examination of the tissues showed that the process was well advanced, and tubercle bacilli were demonstrated in stained sections. The patient made an uneventful recovery, and one year after the operation there is no evidence of any pulmonary involvement.

8. **Treatment of Pneumonia.**—Reese cites 21 successive cases of lobar pneumonia, which were treated with few drugs and without alcohol. There were two deaths in the series, one, a man 28 years of age, who died from uremia produced by retention of urine because of an impassable urethral stricture. The other was a traumatic case, that of an old lady, of 83 years, who fell and broke two or three ribs, and developed pneumonia; she lived only a few days. Eliminating this case from the series, there was a mortality of only 5 per cent., and that was not because of the treatment employed. Reese urges that the treatment of pneumonia should always be eliminative, and that we should refrain from putting anything into the system in such large doses as taxes the vital powers to eliminate it. He inaugurates his treatment by giving a foot bath according to Dr. Rochester's method, thus equalizing the circulation and quieting the nervous system. Then he gives 5 grains of calomel, followed by a saline, to empty and disinfect the alimentary canal and stimulate the action of the kidneys. He also gives salicylate of sodium in small doses every hour, until the diagnosis is fully established. Then the patient is put on acetate of potassium, 10 grains every four hours with half a glassful of water. He believes that if we can stimulate the kidneys by making the blood more alkaline, the system will be relieved of the ever-accumulating toxins, which depress the nervous system and poison the heart muscle. His experience inclines him to the belief that the potassium salts have some specific action in the treatment of pneumonia, and that they should be administered in some form to every case. Associated with the acetate of potassium, there is given one dessert-spoonful of liquor ammoniac acetatis, with fluid extract of licorice, diluted with

water, every two hours. Reese expects with this to relieve the hurried right heart by bleeding the patient into his capillary vessels and eliminating the toxins by diaphoresis. With this also, pyrexia and cough are controlled to a great extent. Cold sponging is resorted to, or the cold pack to the chest, changed every two hours, if the temperature rises to 105. The patient should not be fed too often nor too much, and the food should consist of the most digestible substances, such as milk, beef tea, broths, and beaten egg. Abdominal distention is relieved by the use of a rectal tube or by a daily enema, and turpentine stupes to the abdomen. The pulse should be closely watched. A hard pulse is softened with Dover's powder and nitroglycerin, and a soft pulse is strengthened with strychnin, digitalis, ergot, and especially rest, on which great emphasis is laid. His experience has taught him that the mortality is less when alcohol is not given, because alcohol really does just what we try to undo with our treatment. There is no indication in the treatment of pneumonia that can not be met by other remedies than alcohol.

14.—See abstract in THE JOURNAL of November 26, page 1651.

15. **Surgical Cure of Chronic Dyspepsia.**—Reed cites some illustrative cases and discusses in detail the confusing symptomatology, the pathology and natural history and other clinical data, the principles of treatment, and the after-course. He says that the majority of cases of so-called "chronic dyspepsia," "gastralgia," "nervous gastralgia," "neuralgia of the stomach," "cardialgia," and "hyperchlorhydria" are, in fact, cases of ulcer or the organic consequences of ulcer of the stomach or duodenum, or both. Cases amenable to medical treatment should be cured in from five to six weeks, after which time they should be placed in the surgical category, while hemorrhagic cases should be operated on without the delay prescribed by medical writers. Surgical ulcer of the stomach, says Reed, if neglected, may develop adhesions, perforations, hemorrhages, or cancer, or, in the absence of these, may provoke sepsis and anemia, which, if the underlying conditions are not corrected by operation, may, and frequently do, prove fatal. Therefore, it is important that the cases should be promptly brought to operation, which should establish rest and maintain drainage for the diseased organ. Reed believes that the comfortable after-course of these cases, the low primary mortality, and the permanent curative results following the operation comprise its complete justification.

16. **Fibroma of Auditory Apparatus.**—In the case cited by Pooley, there was found a large elastic growth, situated behind the ear, close to the attachment of, and extending for some distance on the posterior surface of the auricle, about the size of a pigeon's egg; also another filling the meatus, and extending for some distance into the auditory canal, about the size of an olive. The tumors were removed by operation, but, owing to the unsatisfactory course of the healing, treatment by the x-ray was resorted to. This was followed by immediate improvement in the patient's general condition, and an early healing of the entire wound. The pathologic diagnosis of the tumor masses was fibroma. The clinical diagnosis was sarcoma, and Pooley inclines to the belief that the course of the disease, with its frequent relapses and the length of time required to secure a healing, show the malignant character of the disease.

 18 **Metatarsal Valgus or Humped Foot and Its Relation to Boots.* E. H. Bradford.
 19 **The Pain of Osteo-arthritis of the Spine; Its Bearing on the Diagnosis of Urinary Disease.* Arthur L. Chute.

18. **Humped Foot and Boots as a Cause.**—Bradford discusses the relation of deformities of the foot to the wearing of improperly made shoes. The most common deformities, he says, are caused by crowding the toes together, as the shoe is always made narrower than the natural spread of the foot. This crowding results most injuriously on the great toe, which is pushed toward the middle of the foot and frequently partially dislocated. The boot is then pressed backward on the foot and, meeting the resistance of the head of the first metatarsal, develops, by irritating, irregular bony enlargements, as well as thickening and irritation of the skin. This will result from a loose boot as well as from a short or tight boot. The injurious effect of the shoe is increased by the custom of a stiffened toecap, which prevents the stretching of the leather and acts as a clamp, holding the toes together, when they would naturally spread in walking. The remedy of the present prevalence of shoe deformities must come by educating the public demand, as has been accomplished in an improvement in the shape of corsets and the more general use of less harmful waists. Bradford is convinced that this is the result, largely, of the increasing athletic activity of women, and partly by a better knowledge of the human figure. It should be the custom for all people to furnish themselves with working and dress boots, and to relieve the foot from all pressure when at leisure, wearing moccasins or Turkish slippers. The working shoes of women should be like those of men, giving freer play to the foot. Children should wear moccasins, sandals and loose, light boots and shoes.

19. **Osteo-Arthritis of the Spine and Urinary Disease.**—In his attempts to find a definite cause for obscure pain, which was supposed to depend on hypochondriasis or neurasthenia, Chute examined with great care all urinary patients who complained of pain for which there was no evident cause. The only abnormality he could find in some of these patients was a stiff lumbar spine, treatment of which gave relief from the pain in a certain number of cases. A continued study of this subject has convinced him that this pain of osteo-arthritis of the spine is an element which must be taken into consideration in the diagnosis of a certain number of cases which present themselves to men interested in urinary disease. He applied the term osteo-arthritis of the spine to those chronic, non-tuberculous processes which are characterized clinically by more or less stiff or immobile spines, usually presenting considerable spasm of the back muscles and often accompanied by local or referred pain. He has observed two sorts of pain, one, which is local, referred to the spine or vaguely to the back in the lumbar or sacral regions, and is to be attributed to sensitive vertebral articulations. The second pain is referred to the distribution of certain of the nerves arising from the lumbar or sacral plexuses, and probably is due to the presence of an inflammatory exudate about the spinal articular processes, which exudate exerts pressure on the nerve roots as they pass out between the laminae. The local pain may, under some conditions, be confounded with the pain of movable kidney, prostatitis, or vesiculitis. The patients who present themselves with a pain of this sort have, as a rule, suffered from previous attacks of urethritis or other urinary disease. When, on examination, a stricture, a prostatitis, or some pathologic condition is found, the pain is supposed to depend wholly on this. In the absence of such findings, the pain is likely to be considered neuralgic or neurasthenic. Therefore, these cases should be examined carefully with reference to the presence of any disease of the urinary tract. In the mildest cases, improved hygiene and phosphate of soda may be all that is required. In most cases, however, something is required which will support the

spine or even partially or wholly immobilize it. In some cases seen by the author, strapping the back with strips of adhesive plaster has been sufficient. In some, a wide, heavy canvas belt has relieved the pain, while in others a plaster or leather jacket has been required. The duration of treatment may vary from a few weeks to many months.

22. **Therapeutic Value of Colorado Climate.**—Byles emphasizes the fact that a sick man in Colorado needs medical care just as much as he does in the East, and that the same medical care, aided by the atmospheric conditions of the place, will, in suitable cases, result in much greater benefit to the patient in Colorado than the one in the East. The benefit of Colorado climate to a tuberculous patient depends very much on a proper understanding on his part of the kind of life he should live there. A tuberculous patient will do better in the East with plenty of food and home comforts than in Colorado on a starvation diet. He had better live out of doors in the East than shut up in a stuffy room in Colorado.

24. **Caisson Disease.**—Aldrich discusses the clinical history of this affection as he has found it in a study of over 50 cases.

- 37 Management of Accidental Wounds. S. S. Wilson.

32. **Variola Hybrida.**—Mansfelde maintains that the recent epidemic of so-called smallpox is not the classical disease, but a modified species. In observing several hundred cases, he recognized at least four distinct varieties of smallpox (sub-species), as well as various types of each variety. Persons contracting the disease developed the same variety of smallpox as had the patient from whom the disease was contracted. "Each variety bred true to seed." Mansfelde considers that glycerinated lymph is a chemically changed virus, which has not the protective power of spontaneous cowpox virus or human virus; and that the latter, taking the possibility of transmission by it seriously, is safer than glycerinated lymph.

34. **One-Minute Form of Anesthesia.**—This method of anesthesia was introduced by Sudeck. He pours three to five grams of ether into the cone and after the patient has taken 10 to 15 deep inhalations, the operator can begin. Clifford terms this method "one-minute anesthesia," since in many cases the operation can be started in about a minute after the first inhalation is taken. He has used the method in about 200 cases and cites a number of them to illustrate what can be done. One difficulty in using the method is to decide when to begin and when, during the operation, to give more or less of the anesthetic. To get the best results, not only as to safety, but efficiency, the patient must be kept in the narrow zone between the stages of sensibility and excitement. He has the patient count after the anesthetizer, who occasionally changes the order of the numbers, and the minute the correct answers cease the anesthetic should be stopped and the operation begun. During the operation the anesthetizer should frequently urge the patient to count, and, if he responds, a little more anesthetic should be given, but not otherwise. If signs of excitement or resistance appear, stop the anesthetic and the operation for a minute or so, until the patient will count again. The advantages of the method are: (1) The decrease of danger; (2) the saving of time; (3) the saving of pain; (4) comparative absence of after-effects, vomiting is very rare during or after the anesthesia, and where nausea occurs after it is over, it is of short duration and very trifling compared with that which follows the deeper form. The disadvantages of the method are: (1) That it sometimes fails to work. According to Gifford, this simply means that the patient has to be pushed along into the ordinary deep stage, and, therefore, the objection is not serious. (2) That if the plan of making the patient count, off and on, during the operation is followed, it interferes with the quiet and order in the operating room and with any teaching which the operator may wish to carry on during the operation.

41 and 42.—See THE JOURNAL of October 8, page 1079.

43. **Elaterium in Edema.**—Sewall believes that elaterium, aside from its action on the excretory functions of bowels and kidneys, directly excites absorption of fluid from the tissue spaces. Whether this effect is brought about by a sudden increase of osmotic pressure of the blood or through some specific stimulation of the capillary epithelia through which endosmosis is accelerated, is a question for definite investigation. He has found that the action of elaterium seems to be cumulative over considerable intervals of time. One or two small doses daily may finally produce a physiologic effect or give rise to intolerance. The drug may appropriately be used in most cases of edema, barring those in which there is a tendency toward enteritis. If it is attempted to obtain therapeutic results without nausea or griping, elaterium will be found irregular and unreliable in its action. Sewall suggests that possibly better results will follow the use of its active principle—elaterin. He has given elaterium in doses of three thirty-seconds (3/32) of a grain, on two or three successive days, every hour until nausea is produced, with most excellent result. Out of 20 recorded cases, elaterium disagreed—produced nausea, or rarely griping—in about one-half. In most instances the diminution of dropsical accumulations under its influence was attended with purgation. The favorable results secured through the use of elaterium, supported by appropriate other treatment, were of a strikingly durable character.

 50½ Fifty Years in Medicine. John D. West.

49. Exophthalmic Goiter.—Wright's case is that of a girl aged 16, with the following history. When she was about 8 years old, there was first noticed a protrusion of the left eye, with pronounced nystagmus of both eyes, and defective vision, much worse in the left eye than in the right. When she was 13, it was discovered that she was entirely blind in the left eye. Both eyes were very much protruded, the left more than the right; there is pronounced external squint of the left eye. The pupils are normal. When the right eye is exposed, there is consensual reaction of the pupil of the left eye. An ophthalmoscopic examination showed complete atrophy of the disc of the left eye, with large retinal veins and small arteries. The right eyeground appeared almost normal. The interesting features in this case, says Wright, are the age and the loss of vision.

51 and 52.—See THE JOURNAL of July 2, pages 66 and 67.

53. Roentgen Ray in Dermatology.—Frank gives a general clinical and statistical résumé of his experience in the treatment of various forms of dermatoses by the *x*-ray. He is in accord with others as to the value of the *x*-ray in the eradication of epithelioma and cancerous degeneration of the skin, and that its value becomes more doubtful where the lesion is more deeply seated, involving the subcutaneous structures. Acne in its various forms has tenaciously resisted the most patient and persistent course of treatment. Frank does not hesitate to affirm, however, that the *x*-ray will accomplish what other measures have often failed to accomplish. Ten cases of chronic eczema of the palms of the hands were treated successfully with the *x*-ray; three cases were followed by a recurrence, which again readily yielded to a few renewed treatments. Similar good results were obtained in a chronic vesicular eczema of the hands due to wild ivy poisoning of 10 years' standing, in two cases of eczema of the auditory canal, and a number of similar, localized chronic conditions that had baffled ordinary therapeutic measures. In cases of hypertrichosis, the danger to the patient, the discomfort and the time consumed tend to discourage the use of the ray. More gratifying results were obtained in a few cases of syphilis of the most rebellious type, with multiple follicular abscesses. Frank attributes this not to the bactericidal influence of the ray, but to its complete depilatory action. In psoriasis, of which he has treated a few cases only, he has succeeded in causing the infiltrations to disappear without difficulty, and so far without a recurrence. In keloids and cicatrices, he has

found the action of the Roentgen ray a most pronounced one, the lesions disappearing after about fifteen treatments. A few warts were beneficially acted on in like manner. Frank concludes that in the *x*-ray we possess a valuable adjunct in the treatment of dermatoses, but unbounded enthusiasm for the results obtained should not blind us to the equally good results obtained by the ordinary and harmless methods. A combination of the *x*-ray with the ordinary methods of treatment enhances the therapeutic value of the former.

 64. An Improved Apparatus for the Treatment of the Deformity of Hip-Joint Disease by Weight and Pulley Extension. Albert H. Freiberg.

55. Mechanical Treatment of Pott's Disease.—Taylor cites 11 cases treated by mechanical support and usually by fixed plaster-of-Paris jackets for from four to eight years, after which, if the patient was considered free from active disease, a laced plaster-of-Paris corset was usually substituted. In the upper dorsal and cervical regions a jury-mast was added. One case was treated by the Taylor brace, and one by the Knight brace throughout; in several cases a Knight brace was used in the later stages. The jackets were changed every 10 or 12 weeks, unless the patient absented himself contrary to orders. Patterns were taken with the lead tape, and transferred directly to the pages of the histories by pencil in the usual way, the patient being in the prone position. The ages varied from 2 to 8 years; six patients were 3 years or under. In no case had the symptoms attracted attention for more than one year; in seven the duration was given as six months or under. In most instances the general condition, when observed, was good or fair and the deformity slight or moderate. Three had complicating bone disease, one in the radius and maxilla, one in the hip, and one in the knee. Two cases had spinal abscesses, one of which receded without opening. In none was paraplegia noted. In many instances the notes are defective as to the exact condition of the patient after the 10-year period. All but one or two were still under treatment and wearing support of some kind at the time of the last note. Of the cases which had left off support, one relapsed after a fall; in two support was reapplied after a year or two owing to pains, and but one was known to be cured, having been without support during eight years. In every case but one the final result showed a considerable increase in deformity. In this case, after an initial increase, there was a final decrease and practical obliteration of all deformity. The results as to deformity may be summarized as follows: Good, 1; fair, 5; poor, 5. The results in all cases but one was a marked kyphosis, and in about half the cases a large and disfiguring kyphosis. Taylor considers this group of cases as far too small to be more than suggestive, nor is it an indication of average results. At the same time, it bears out the writer's general impression that, while the ordinary jacket treatment in dispensaries affords great relief and is productive of much benefit, it does not usually quickly arrest the disease nor prevent very serious and disfiguring deformity even in young patients seen in the first few months of the disease and in otherwise good condition, and also that the results are far inferior to those obtained in private practice.

57. Upper Dorsal Pott's Disease.—For the treatment of this condition, Young recommends an apparatus which is made

over a cast which includes the head, neck and trunk. The patient is placed face down on a frame, stockinette is securely applied to all these parts and a plaster-of-Paris cast is made. From this an exact counter-cast is made, and from the counter-cast the felt or celluloid cuirass is constructed. The head portion is made removable from the body portion, but the entire cuirass is secured and reinforced by steel. The cuirass is secured to the body by broad webbing into which elastic webbing has been incorporated, and shoulder straps and a frontal band complete the outfit. It is applied with the patient lying on the face and secured in position before the patient is turned over. While the cuirass is being prepared, or if any indications occur for recumbency, the patient is placed in bed, on a wire frame bent backward, felt pads are placed under the deformity on either side and the patient is secured to the frame immovably by means of a specially constructed wheel couch. The patient can be taken into the open air daily. This couch permits the patient to lie in the full extension position. The advantages of this apparatus are that the deformity is reduced, that the paralysis quickly disappears, and that there is a complete restoration of function.

60. Typhoid Coxitis.—Porter says that involvement of the hip in the course of typhoid enteritis is an infrequent complication, one which usually develops late in the disease or even during convalescence. The pain is often severe, though the patient may only complain of slight pain or discomfort about the joint. Swelling develops slowly, and, on account of the thickness of the muscles about the joint, may progress to a considerable degree before being noticed. The first thing to call attention to the joint may be the fact that the patient can not lie on that side, or that he keeps the thighs flexed. The one peculiar thing about these hip infections, says Porter, is the tendency to spontaneous dislocation of the joint, and it is this feature which makes typhoid coxitis such a serious condition. Little is known about the bacteriology of the condition. It is believed that the synovitis is sero-fibrinous in character and that, besides causing a distension of the joint, it produces an inflammatory softening of the acetabular margin and the pressure of the head of the femur, by contraction in a flexed and abducted position, causes a pressure atrophy of the outer part of the acetabular rim, permitting the head of the femur to slip slowly out. Early evacuation of the joint is the only satisfactory treatment. Two illustrative cases are cited.

61. Cure of Chronic Bursitis.—The operation advocated by Hoffmann consists of puncturing the bursa, thoroughly scarifying its walls, expressing its fluid contents, bringing its walls in contact and holding them so by means of a compress until their raw surfaces have grown together and have thus obliterated the cavity. It is especially adapted to the treatment of the condition known as housemaid's knee. An ordinary tenotome, having a long shank, or an especially devised instrument, is passed into the distended bursa at its base. With the sharp edge, its entire inner surface is marked with many fine cuts, after which the instrument is withdrawn and the bursa evacuated of its fluid contents through the small skin incision. A thick, wide pad of gauze is placed over the bursa and firmly bound down with strips of adhesive plaster overlapping one another and completely encircling the limb from an inch or two above the upper margin to the same distance below the lower margin of the bursa. Over this a muslin and a crinolin bandage are applied. A pad of cotton should be placed within the popliteal space beneath the plaster, to protect the prominent ham-string tendons and overlying skin from undue pressure. The raw bursal surfaces should be kept in contact until firm union has occurred. Two weeks are sufficient. The adhesive plaster strips should be renewed or re-enforced whenever they appear loose; as a rule, every two or three days. No anesthetic need be given, nor need the patient be confined to bed or even use crutches during the after-treatment. In the past nine years, Hoffmann has operated on 104 cases of house-maid's knee. In two, the operation had to be performed twice, and in four three times,

while in 98 it was primarily successful. The scarification must be thorough, the withdrawal of synovial fluid complete, and the compression quite firm to assure success.

63. Treatment of Round Shoulders.—Lovett presents a method of treatment which, in his hands, has produced improvement in cases of the resistant type, which had been, for the most part, for many years under gymnastic or mechanical treatment without marked benefit. The method consists of forcible hyperextension of the dorsal spine with forcing back the shoulders and, while the patient is held in the corrected position, a corrective plaster jacket is applied embracing the shoulders. The apparatus used consists of an oblong gaspise frame of the ordinary pattern. Fastened to this near the middle and hinged so as to be raised to any degree is another section of gaspise lying on the frame proper and of the same shape and size as the upper half of the frame. To this movable section is fastened, at right angles to it and movable on it, a gaspise bridge rising about 18 inches from the movable section. When prepared for use, two strips of webbing, lying one over the other, run from each of the buckles at the bottom of the frame. The lower pair of these strips is tightly drawn and run to the buckles at the end of the movable section. The upper pair is loosely fastened to the bridge over the movable section. The cross-pieces are tightened and the patient laid face downward on the webbing strips. The thighs are flexed and the feet rest on the floor so that the lumbar spine is flattened. Two pieces of webbing are passed over the mid-dorsal region side by side, tied to the lower non-movable frame on each side. These furnish the resistance for the straightening of the spine when the upper end of the frame is lifted, carrying with it the head and upper chest. The upper part of the frame is lifted after the patient is in place and as much force is exerted as seems advisable. The movable part of the frame is finally raised and fastened in place and a plaster jacket applied. In three or four weeks this is replaced by a brace, and corrective exercises are begun. The brace used has some modification of the tempered uprights in common use. All that one can hope from this method, says Lovett, is to restore to the dorsal spine a more normal range of hyperextension and then to educate the muscles to retain the improved position. His results have been extremely gratifying.

18. Chorion-Epithelioma Following Hydatidiform Mole.—A case is reported by Savage, occurring in a woman, aged 50, the mother of eight children, the last born seven years ago. For the last few years menstruation had occurred irregularly, at intervals of from two to eight weeks, and it was scanty.

For two months she complained of dyspnea and progressive wasting, with pains, tenderness and swelling of the abdomen, especially on the right side. The breasts had been getting larger; there had been no vomiting, but the patient could not eat anything. On examination, the pulse and temperature were found raised and the general condition was bad from weakness and anemia. The abdomen was enlarged by a tumor rising up out of the pelvis and reaching to one finger's breadth of the umbilicus. It was higher on the right side. A fluid thrill was felt in parts and it was somewhat tense. A souffle was heard all over it, but not a fetal heart sound. A blood clot lay in the vagina, the vaginal walls and cervix were swollen and edematous, the veins of the vulva were enlarged. The tip of the finger could be inserted through the internal os, but only a soft, doughy mass was felt. Ballottement could not be obtained. The tumor was made out to be uterine, but the nature of the enlargement was not clear. As the general condition was bad, and as the examination brought on hemorrhage, Savage inserted some gauze into the cervix and gave ergot in the hope that the uterus might empty itself. On the following day he removed, by means of a finger and a blunt curette, about four and a half pints of cysts of the hydatid mole, mixed with blood and clot; the cysts were of varying sizes, up to that of a small walnut. The uterus contracted down to about four inches in its cavity length. After the operation, hemorrhage of slight amount lasted for five days; convalescence soon took place. One month afterward, a continuous slight blood discharge commenced, lasting a fortnight. Later, profuse hemorrhage occurred, rendering the patient anemic and faint. The vagina was promptly plugged with iodoform gauze. On examination, nothing was felt by the abdomen. The uterus was found to be somewhat enlarged, thickened, and it felt heavy; the cervix was opened enough to admit the tip of the index finger; both lips were edematous. Eleven weeks after the removal of the mole, Savage performed a vaginal hysterectomy, and five months afterward the patient was in excellent condition, with no sign of recurrence. Microscopic examination of the tumor showed it to be a chorion-epithelioma.

19. Chorion-Epithelioma.—Martin's case gives the following history: Patient, 50 years old, had eleven children and three miscarriages. For twelve weeks she had constant hemorrhage through the uterus. There was no other discharge and the blood was never offensive. There was some shortness of breath on exertion, but otherwise the patient felt well. The examination of the abdomen was negative. Per vaginam, the uterus was found enlarged, the cervix soft, spongy and granular, but without any growth or ulceration. It was patulous, but did not admit the finger. The uterus felt as large as the body of a uterus two months pregnant. It was quite mobile and there were no signs of disease of the uterine appendages. A diagnosis of cancer in the body of the uterus was made, and a vaginal hysterectomy was performed in the usual way. On laying open the uterus, it was found to contain a soft, friable, fungating growth about the size of a small hen's egg, growing from the endometrium. The patient made a good recovery. The microscope disclosed a typical chorion-epithelioma.

20. Malignant Chorion-Epithelioma.—The history of Wilson's case differs from the two preceding ones in that the patient was only 22 years old and single, and succumbed to the disease one year after she was delivered of a hydatidiform mole. The physical findings were the same as in Martin's case.

21. Decidua Malignum.—The case of Windsor and Fairbairn followed a full-term delivery. Recovery from the confinement was not complete, the patient remaining anemic and feeble, and throughout the illness there was some sanguineous discharge. About six months after the confinement, the uterus was found enlarged, and later the discharge increased and became offensive. A vaginal hysterectomy was performed, convalescence from which was complicated by the development of a subclavicular abscess, and six weeks after the operation the patient died, with symptoms of severe paroxysmal headache,

abdominal pain, vomiting, and symptoms of general collapse. The microscopic findings were typical.

23. **Infantile Syphilis.**—Still says that in the treatment of this condition there is little choice of drugs; the only question is in what form should mercury be administered, in what dose, and for how long. In his opinion, gray powder is the best. Combined with aromatic chalk powder, a dose of half a grain can usually be given three times a day without causing diarrhea; but if there is any looseness of the bowels, Dover's powder may be given with the gray powder in doses of 1/4 of a grain for infants over 3 months of age and 1/4 of a grain at the age of 6 months. He has also used the liquor hydrargyri perchloridi, but found that it is more liable to cause diarrhea; an infant a month old can take from 5 to 10 minims three times a day. Inunctions of unguentum hydrargyri may be used either alone or, in severe cases, in addition to the internal administration. A piece of the size of an average green pea—a rough measurement of 15 grains—is gently rubbed over the abdomen or the inside of the thigh or arm at night and left covered over with a flannel bandage until the following morning, when it is washed off; this to be repeated every night until the skin shows signs of irritation, as it occasionally does. Still says that he knows of no condition in which there is anything to commend the intramuscular or intravenous injections of iodine or mercury for infantile syphilis. They involve an absolutely unnecessary infliction of pain and an equally unnecessary risk of troublesome inflammation. Iodids should be used internally in addition to mercury. The disappearance of symptoms is no indication for discontinuing treatment. It should be continued for at least six months after the disappearance of active symptoms, and it may be necessary to continue it for a year or more, if symptoms tend to recur when treatment is omitted.

26. **Perchlorid of Iron in Blood Poisoning.**—Latham again calls attention to the efficiency of the tincture of the perchlorid of iron and chlorin in the treatment of various forms of blood poisoning. The most judicious plan is to give moderate doses, cautiously watching their effect and administering them more frequently if the patient will bear them. If not, continue moderate doses and, if further antiseptic action is required, give chlorin water or euclorin internally, alternately with or in the intervals between the doses of iron. The chlorin water is prepared by adding 20 grains of powdered chloride of potassium and one dram of strong hydrochloric acid to 20 ounces of water. (The author fails to mention doses.)

46. **Torsion of Spermatic Cord.**—Vanvets concludes from a study of 44 recorded cases that if the testicle is retained, it is impossible to reduce the torsion by manipulation. If the condition has lasted more than 24 hours, castration is the only recourse. If the testicle is in the scrotum, reduction of the torsion by manipulations may be possible if done early. If not successful in the first few hours, surgical intervention is required.

58. **Intraperitoneal Rupture of Bladder.**—Seventy-five cases of surgical intervention on this account are analyzed from the literature, and 3 unpublished cases added. There were 44 recoveries and 24 deaths, a mortality of 43.5 per cent., and during the last ten years of only 20.5 per cent. The symptoms, etc., are studied in detail. Laparotomy and suture are the only treatment.

59. **Exclusion of Kidney.**—This work issues from Jaboulay's clinic and 2 cases of exclusion of one kidney are reported. The results demonstrate that this is a harmless operation, which fact has been further confirmed by numerous experiments on animals. The indications in one case were a suppurating lumbar fistula, pyelonephritis and incipient cystitis. The patient was practically cured by ligation of the ureter from the infected kidney.

78. Serum Treatment of Puerperal Fever.—After ten years of testing the various makes of antistreptococcus serum, Bumm finds that the serum prepared by inoculation with human material is the most effectual in controlling puerperal fever. He here reviews his experience in general and especially the results observed in 32 cases of severe puerperal infection. The impression derived is that a septic puerperal process, confined to the uterus, is unmistakably influenced by antistreptococcus serum injected subcutaneously. He shrinks from the intravenous route since observation of a serious mishap in one instance. In 4 particularly striking cases of high fever, but no phagocytosis, phagocytosis occurred 12 hours after the injection of serum, very intense, the leucocytes incorporating the streptococci with great avidity. The serum evidently sustained and re-enforced the natural defensive processes which, without it, would have been unable to cope with the infection. In order to keep watch of the phagocytosis induced by the serum, the secretions must be examined repeatedly, as the process occurs abruptly and does not last long. When the septic process has spread beyond the uterus, none of the serums available are powerful enough to affect it in the slightest. Consequently, their use should be restricted to the uncomplicated cases of septic streptococcus endometritis.

79. Movable Cecum.—Haussmann warns that a movable cecum may cause ileus and other disturbances attributed to other organs. Whenever he palpates an abnormally movable cecum, he always informs the subject of the finding and bids him call the physician's attention to the abnormal play of the gut.

81. Serum Prophylaxis and Treatment.—Wolf's conclusions from his extensive research and reasoning are to the effect that the best prospects from the use of bactericidal serums are from the standpoint of prevention. Especially in the streptococcus domain are the prospects most encouraging for successful preventive immunization. When general streptococcus infection is feared, as, for instance, after opening an abscess in the tonsils, after operations on the nose, after abortions, severe deliveries, etc., prophylactic use of the antiserum may prove very useful. From the therapeutic standpoint, we can hope for success only when the serum can be given during the stage of incubation, before the bacteria get the upper hand. Early diagnosis, during the phase of incubation, will enable serum treatment to be applied in time. After this is past, little can be hoped from it in the present state of our knowledge.

82. Quinin Prophylaxis of Malaria.—Ziemann's report states that 24 of the 25 control subjects who took no quinin had malaria fever, generally very severe, and the twenty-fifth had malaria in the latent form. Thirty-six per cent. died. Of 70 who submitted to an unsystematic quinin prophylaxis, only 6 died and only 6 had to be sent home on account of malaria (from Kamerun). Of the 69 who took systematic prophylactic quinin treatment, only 3 died and only 2 had to be sent home. The regular prophylaxis consisted of a gram or half gram dose of quinin every third, fourth or fifth morning, after breakfast, accompanied by 1 gram of potassium bromid, if the subjective disturbances were annoying. More seemed to depend on systematic regularity than on the dose or interval.

85. Intestinal Tuberculosis in Children.—Richter practices in a mining district and states that tuberculosis of the intestines and mesenteric glands is very prevalent among the children, especially between the ages of 1 and 4. The onset is frequently sudden; the children become emaciated, with a chalky pallor, diminished appetite, abdominal pains and tenderness in the umbilical region, headaches, restless sleep and occasionally slight evening fever. The glands in the neck become enlarged in the majority of cases. In exceptional cases, diarrhea is noted. The affection runs a chronic course, and when the subjective symptoms disappear, the child is left weak and pale for a long time. Only 7 terminated fatally out of a very large number of cases that came under his observation, all with the identical clinical picture. Improved hygiene has reduced the number of cases and recovery is more rapid. It seems as if the intestinal tuberculosis in youth confers immunity later to pulmonary tuberculosis, as the latter is comparatively rare among the miners and their families. The deaths from tuberculosis are only 6.86 per cent. of the total mortality, while the proportion in Berlin is 12.3, and in Breslau 14.53 per cent.

87. Orthodiagraphy.—The Greek term ortho means straight, and it has been applied to Roentgen inspection of the trunk from a point directly above. The views thus obtained offer many interesting peculiarities. Moritz describes them and explains the data thus obtained.

90. Symptomatology of Sclerosis of the Aorta.—Bittorf reviews in detail the various symptoms noted in 54 cases of sclerosis of the aorta. Subjective disturbances were not noted in all the cases, and they were generally due to the associated imperfect nourishment of the organs. To this cause he ascribes the palpitations, vertigo, especially when caused by abrupt changes of position or copious meals, buzzing in the ears, weakness in the arms, intermittent limping, etc. The average age was 55.6, but the syphilitics averaged ten years younger. The majority of the subjects were pale; a few had red faces. The heart was hypertrophied in 24, and this was suspected in 22 others. In 49 cases there was a distinct area of dullness corresponding to the shadow to the right of the sternum in dorsoventral fluoroscopy. The shadow on the left of the sternum is not accompanied by dullness, as the aorta at this point is too far below the anterior wall of the thorax.

92. The Pancreas in Arteriosclerosis and Its Relation to Diabetes.—In 9 out of the 18 cases of arteriosclerotic changes in the pancreas observed by Hoppe-Seyler, glycosuria had been evident in 9. The arteriosclerotic lesions were much more pronounced in the cases accompanied by glycosuria. The Langerhans islands were always affected in the latter, and

proportionately to the intensity of the diabetes. The lesions in the diabetic subjects always predominated in the tail of the pancreas. His experience corroborates the assumption that the principal difference between lesions originating in the vessels and those originating in the efferent passages is that, with the former, the sugar metabolism is disturbed, while with the latter the production of pancreatic ferments suffers most. Treatment of arteriosclerotic subjects with diabetes is pre-eminently dietetic, with mild laxatives, courses of mineral waters, iodine preparations in small amounts long kept up and arsenic as needed. The dieting should not be too strict, as a little sugar is better than loss of appetite and strength.

101. **Specific Action of the Precipitins.**—The "biologic blood test," or specific albumin reaction not only tells the species, but also serves to differentiate various kinds of albumin from the same species of animal. It is thus possible to distinguish between a solution of the white and the yolk of the egg, etc. The yolk gives a stronger reaction than the albumin, possibly owing to the larger proportion of lecithin or phosphorus.

Deutsche medicinische Wochenschrift, Berlin and Leipsic.

102. **Medicinal Action.**—Lewin warns against routine medication and routine disinfection, to the neglect of the fundamental principles of the action of drugs. Through-and-through contact is an indispensable condition for penetrating and durable action. The animal body casts off as rapidly as possible all foreign matter which it is unable to assimilate. Unless there is an affinity between the tissue and the drug, it is expelled without delay. Even when the drug is circulating in the blood, and is thus theoretically brought into contact with all the tissues, the contact is of the briefest. The drug is hurried along in the blood and expelled at the earliest possible moment by every available route.

103. **Quantitative Tests for Sugar in Urine.**—Citron lauds Fehling's test as the simplest and most reliable means to determine the amount of sugar in the urine. It should not be estimated by the color reaction, but by determination of the amount of unreduced copper sulphate in the filtrate. This is done by Lehman's technic, which is based on the fact that every molecule of copper sulphate liberates one atom of iodine. Allihn's tables show the amount of sugar which corresponds to the proportion of copper reduced. Thus modified, the test surpasses in delicacy the polarimetric test and should supplement the latter when other optically active substances are suspected. Even the novice can complete the test in five to ten minutes, and when large amounts are at hand, the test is still more rapid. Citron gives an illustration of the small case with automatic burette, vials, etc., which he has found most convenient for the test.

104. **Fixation Abscesses.**—Bröse reports a case of severe pyæmia treated by injection of 5 c.c. of turpentine oil in the left calf. The patient was a iii-para of 25, and the pyæmic process followed an abortion. No local process could be discovered and no micro-organism could be isolated from the blood, but the fever kept high and the general condition grew constantly worse. As the fixation abscess developed the fever subsided to complete recovery. The suppuration continued for some little time in the abscess after it had been evacuated. The pus was always sterile and no hyperleucocytosis was detected. Fochier, the originator of the method, seldom injected more than 2 c.c.; it is possible that the large amount used in this case may have been a factor in the results.

106. **Treatment of Fractures.**—Liermann advocates mobilization and massage of a fracture at the earliest possible moment.

This shortens the length of treatment and restores conditions to normal with remarkable promptness. The physician should be guided by the Roentgen findings, but he warns that the Roentgen plate should be regarded merely as a medical diagnostic aid. The plate should remain in the hands of the physician; it is generally unnecessary to have a finished picture made from it, and above all things, such a picture or plate should never be given to the patient for him to misconstrue. The best of all appliances for massaging and treating fractures is the "surgical hand," and the general practitioner should seek to acquire this. He gives the details of treatment of fractures on these principles, adding that the quiescence of treatment is to forbid the use of the limb at first, but to apply rational massage and mobilization during the bed-rest imposed. The effusion is much more rapidly absorbed and the strain of the muscles aids in restoring the fragments to place and in their consolidation.

109. **After-Effects of Chloroform.**—Vorderbrugge reports from Dantsic 2 cases of serious after-trouble from moderate use of chloroform. The subjects were children, 10 and 5 years old, and less than 30 gm. of chloroform in one case and less than 12 gm. in the other had been used. After some time symptoms of collapse were noted, fatal in one case. The necropsy revealed fatty degeneration in heart, liver and kidneys. In the other case albuminuria and hemoglobinuria were long persistent, but the child finally recovered. The hemoglobinuria suggests that the assumption may be correct which ascribes the injury from chloroform to destruction of the red corpuscles. Trouble may be anticipated after chloroform when the pulse shows great disturbance while the temperature remains approximately normal, with albuminuria and other signs of acute parenchymatous nephritis, vomiting, icterus and brain symptoms.

110. **Enterostomy in Prophylaxis and Treatment of Peritonitis.**—Gebhart attributes the serious outcome in many cases of diffuse suppurative peritonitis to absorption of the stagnating bowel contents in the paralyzed intestines. He cites 8 cases from his own experience in which he made a temporary opening into the bowel as a prophylactic or curative measure, and always with good results. He commends the procedure as a prophylactic operation in peritonitis of intestinal origin and in general sepsis and in all cases of paralytic ileus or occlusion of unknown etiology. Also as a palliative operation in case of debility forbidding further operation. It is sometimes advisable after perforation to suture the perforated point to the skin. The fecal fistula usually heals spontaneously, in from seven to eight weeks at farthest.

112. **Elbow Injuries Treated by Bardenheuer's Technic.**—Stolle gives radiograms of a large number out of the 140 cases he reports. The Bardenheuer technic method of extension in elbow injuries is described in detail and its application. The technic is easily comprehended from the illustrations. In 23 cases the dislocation was complicated by fracture in 14.

113. **Luxation of the Ulnar Nerve.**—Haim reports 2 cases and adds 12 new ones to the 40 collected from the literature in 1896. The subjects were all over 15 years old, and a congenital predisposition to extreme movability of the nerve was apparent in some, but cubitus valgus seemed to be the chief factor in its production during a traumatism. In 10 cases the luxation caused no symptoms of any kind. The pain is usually severe at the time of the accident, and dull pains persist with paresthesia in the arm or even paralysis. In treatment the preferable method is to fasten the ulnar nerve to the periosteum and adjacent connective tissue of the fossa between the olecranon and the epicondyle. Two cases on record were treated by resection of the nerve, and the condition was aggravated. The nerve becomes dislocated because it is too short, and resection is contraindicated.

115. **Forward Displacement of Urethra.**—Beck's technic for the treatment of hypospadias is well known in this country. He here emphasizes certain minor points which aid in the success. He has only had a single failure in his extensive experience, and in this case the patient tore out the catheter and suture himself the day after the operation. Beck has found the method applicable also to women and for various kinds of defects and injuries of the urethra.

119. **Blood Pressure in Spinal Anesthesia.**—In 16 cases in which spinal anesthesia was induced with a combination of suprarenin and cocaine, the blood pressure was found augmented at first, but later sank slightly below normal. In 12 others it remained high throughout. In 8 no influence was perceptible. In 9 there was a marked drop in the blood pressure to such an extent as to threaten collapse in some of the subjects. This was due probably to the combination of three factors, the cocaine, the operation for which it was injected, and the patient's excitement. The details of the 50 cases are tabulated. The work issues from Bier's clinic.

 136 Beitrag zur Statistik des Inoperablen Uterus-Carcinoms. E. Lilek.

128-130. **Hyperemesis Gravidarum.**—Graefe ascribes the incoercible vomiting to hysteria in many cases, and thinks that suggestion is an important element in treatment. The most important indication is the isolation of the patient. Zaborzky's experience has convinced him that it is due to a reflex neurosis in many cases. Interruption of the pregnancy does not always put an end to the vomiting. The vomiting persisted in 3 cases under his observation, all terminating fatally. The post-mortem examination disclosed a cancer in the stomach, yellow atrophy of the liver or inflammation in the intestines as the unsuspected cause of the vomiting. Baisch does not accept either of these theories altogether. He regards the hyperemesis as a reflex phenomenon, a motor or secretory disturbance of the stomach function, the irritation proceeding from the periphery and transmitted through the vomiting center. The uterus, the nerve centers in the medulla or the stomach itself may be the points where the exaggeration of the reflex occurs, and consequently treatment should be applied to correspond for each individual case. In his experience the cases with the gravest prognosis were those accompanied by abnormal sali-

vation. This is an objective sign of a severe central disturbance of the reflex excitability. In 2 such cases he interrupted the pregnancy, with a favorable outcome. The relations between the villi and the uterine wall are probably the primal cause of the disturbances. Suggestion is liable to reduce the reflex excitability in some cases. It is characteristic of hysterical vomiting that the digestibility of the food does not seem to have any influence on the vomiting.

135. **Stones in the Female Bladder.**—Zangemeister remarks that the clinical picture of stones in the bladder varies in men and in women. Foreign bodies are usually responsible for their formation, either as a nucleus or as inducing hemorrhages. Chronic catarrh of the bladder should always suggest the possibility of a stone, and the cystoscope be used, but x-ray examination is seldom necessary. Foreign bodies in the bladder should be removed as soon as possible, and no suture material should be used that is not readily absorbable. Colpocystostomy is easy, and the prognosis is so favorable that he prefers it as a routine procedure to sectio alta or even to dilatation of the urethra. The opening into the vagina heals rapidly. He makes a sagittal incision, cutting away from the sphincter. The details of 11 cases are tabulated. Out of 9,692 cases of stones in the bladder on record, only 205 were in women. The stone does not obstruct the urethra as it is so liable to do in men, and the vague pains from its presence are often referred to the genitalia and treated on a mistaken diagnosis. The disturbances are less pronounced than in men. The stone lurks in the side recesses and moves around so readily that it is difficult to palpate through the vagina. Incontinence may be the only symptom.

137-138. **Cinamic Acid in Treatment of Tuberculosis.**—Prym reports the results of treatment of 22 cases of tuberculosis according to Landerer's technic. He was impressed with the unmistakably potential action of the hetol on tuberculous processes, but found that this action was not always for the benefit of the subject. Sometimes, in the severer cases, the effect seemed to be injurious. Schrage's experience has been more favorable. He restricted the treatment—according to Landerer's directions—to beginning phthisis: uncomplicated, afebrile cases. He has been applying it during the last four years and asserts that with it the physician is certain to cure a certain proportion of the cases—not all. The effect is soon apparent in the cessation of the night sweats, increase in weight, and in the vanishing of the physical signs of the affection. A dozen cases are described in detail out of his large experience. The formula is: Natrii cinnamylci, 1 part (or 3 to 5 parts); solution natrii chlorati, (7 per cent.) to 100 parts. For intravenous injections he keeps the syringe and the solution in a small nickelin case in which everything is sterilized by steam generated by an alcohol flame an hour before use.

139. **Marmorek's Antituberculosis Serum.**—Frey has made more than 350 injections of this serum at Davos, his material embracing a dozen cases of tuberculosis. His experience confirms that of others in regard to the harmlessness of the serum. No symptoms of intoxication were observed, while the condition of the patients showed marked improvement. He urges further trials.

141. **Plant Dermatitis.**—Besides the primrose, Hoffmann has observed cases of plant poisoning due to the chrysanthemum,

the poison sumach, fresh squill roots, arbor vitae and the Japanese laquer derived from rhus vernifera. The subjects of these affections never connect them with their contact with the plant—the contact sometimes being of the briefest—and the differential diagnosis is, therefore, at times difficult.

147. **Conservative Surgery of Myoma.**—Henkel reviews the material, operations and remote results of the myomas observed at the Berlin gynecologic clinic. He adds in conclusion a theory to explain the symptoms observed after hysterectomy. The uterus may produce a substance which acts as a toxin unless neutralized by an antitoxin which is generated in the ovaries. The antitoxin may likewise have a toxic action in case it has none of the toxin to act on, as, for instance, when the ovaries are retained after the uterus has been removed. In regard to the preservation of the menstrual function he believes that it is a welcome feature of conservative surgery, but that it is not its chief purpose. The subjective results of enucleation are much better than those of the radical operations. Drainage is better when the capsule is removed with the tumor. Its removal is required also because additional myoma nuclei have sometimes been discovered in the capsule.

149. **Tuberculosis of Gravid and Puerperal Uterus.**—Kraus states that tuberculosis develops in the pregnant uterus as a chronic endometritis, spreading from the tubes over the surface, or as a military infection of the placenta and its point of attachment, the decidua vera persisting intact. No case has yet been recorded in which the military infection involved more than the placenta and its attachment. Military tuberculosis may develop in the puerperal uterus from some extragenital focus by way of the blood, or may spread from a tuberculous focus in the tubes.

154. **Plastic Fixation of Kidney.**—Mariani remarks that the conditions for successful fixation of a wandering kidney are that it should be fastened in its natural position, with some substance not foreign to the body, and not elastic, and that the organ should still have its normal limits of physiologic excursion. He has been trying on animals and on the cadaver a technic which answers these conditions much better than any other proposed to date, in his opinion. He exposes the twelfth rib and isolates it completely. Gauze is then worked under it and its periosteum incised lengthwise and detached from the bone. The rib is then resected about 4 cm. from its articulation. The periosteum rolls up into a large cord as soon as the rib is resected, and this cord of periosteum is drawn through the kidney and sutured to the muscles of the eleventh interspace. Four large dogs operated on by this technic bore the operation well. When killed two months later the kidney was found solidly attached to the cord of periosteum and to the muscles in the interspace; the periosteum was alive and the kidney normal except for a narrow zone around the periosteum in which the tissues appeared a trifle harder than normal. There was not a trace of supuration past or present nor of bone formation from the periosteum. The desired result had been attained beyond expectation.

158. **Roentgen Treatment of Leukemia.**—See abstract 97, page 1669.

160. **Intravenous Injections of Thymol in Staphylococcus Infection.**—The results of Fiorentini's experimental research are tabulated and demonstrate that thymol administered by intravenous injection seems to display an almost specific action against infection with the staphylococcus aureus. In the proportion of 10 cg. per kilogram it modifies and even arrests the progress of staphylococcus infection. It evidently does not destroy the cocci, but attenuates them to such an extent as to render them harmless. It is a substance not modified by the organic fluids and retains its specific action in the blood, where it induces a pronounced defensive reaction, causing hyperleucocytosis with polymucloisis. It shares with bichlorid this leucocytogenic property, but possesses it to a greater degree than the latter.

167. **Treatment of Pneumonia with Large Doses of Digitalis.**—Capuano reviews the history of this method of treating pneumonia and its mechanism, citing his own experiences. He has had occasion to treat 36 cases of lobar pneumonia during the last year and has given digitalis in all, according to age; the dose is from 4 to 5 grams for an adult. This was repeated for four or five successive days, and no signs of intolerance were apparent in any instance. By the second or third dose the temperature fell, the respiration became less rapid and the pulse subsided from 120 or 150 to 100, 90, or even less. When the pulse keeps high for forty-eight hours under these doses of digitalis the patient is inevitably doomed. This occurred in 3 cases in his series. The others promptly recovered, the crisis coming on by the fourth to sixth day. He explains the action of digitalis in these large doses as due to the hyperleucocytosis which it induces. All but a few of his patients were between 6 and 60 years old, the others still older.

168. **Intra-Articular Injections of Salicylates in Rheumatic Joints.**—Santini has followed Bouchard's method of treating rebellious articular rheumatism by injecting a 3 per cent. solution of sodium salicylate around the joint or joints most affected. He found it remarkably effectual, but discovered that the same or better results could be accomplished by injecting the fluid directly into the joint. He has treated 30 cases of articular rheumatism in this way and is enthusiastic in regard

to the numerous advantages and the harmlessness of this technique, if the usual aseptic precautions are adopted. In a number of cases the entire disease was arrested by this local treatment; in others it was attenuated and the most serious manifestations relieved. In case there is much effusion in the joint he aspirates a little before injecting the salicylate. The existing pain is usually relieved almost at once, the fever drops and the disease is aborted. The intra-articular injections do not display any efficacy in a couple of cases of tuberculous pseudo-rheumatism or gonorrhoeal arthritis. The literature on the subject and the history of these local measures are summarized, with theories to explain their action. He regards this application of the salicylates to combat the process where it is localized as a great advance in therapeutics, in cases rebellious to internal medication or as an adjuvant.

180. Bichlorid Intravenously in Ocular Affections.—Two years of research on more than a hundred rabbits have demonstrated that intravenous injection of corrosive sublimate has an unmistakable but moderate action in arresting or retarding an infectious process in the depths of the eye in the large majority of cases, both acute and chronic. The objections to this mode of treatment, however, and its occasional failures should cause it to be reserved for a last resort. Tumminia's experiments included tuberculosis and other infections.

181. Hot Baths in Neurasthenia.—Alessi noticed that his neurasthenic patients were much less irritable during the summer than in the winter, and felt better generally. This fact, in connection with others which he cites, suggested the propriety of stimulating the more sluggish metabolism during the winter by means of hot baths. He has found them of the greatest value for this purpose during the cold months. The bath is taken in the morning, the temperature of the water is as warm as is most agreeable to the subject, and he remains in it for forty minutes. He finds afterward that he is far less nervous and irritable and that he gets through the day comparatively without fatigue. Alessi ordered the baths merely to combat the symptom of irritability, and supplemented them by the ordinary measures.

182. Silver Fluorid in Stomach Affections.—Among all the silver salts the Italians prefer silver fluorid, which Paterno prepares in a durable 10 per cent. aqueous solution. Durante reported its powerful antiseptic properties in 1902, and since then a number of Italians have used it for various therapeutic purposes. Ferrannini has been making a study of the drug's action on the stomach, testing it on dogs with Pawlow fistulas and on other animals. He claims that his experiences have fully confirmed its power as an antiseptic and against fermentations, while it possesses the property of stimulating the motor function of the stomach, and slightly enhancing the proteolytic and coagulating power of the gastric juice. It also modifies the stomach lining, similar to the action of the silver salts in general. This will be found a valuable aid in

the treatment of chronic gastritis. He concludes that this drug in a 1 to 3,000 or 5,000 solution, is one of the best antiseptics and antifermentation agents known, whether used for lavage of the stomach or administered internally. He tabulates the findings of his various experimental tests *in vitro* and on animals.

186. Treatment of Cutaneous Tuberculosis.—Campana thinks that cutaneous tuberculosis should be treated by local excision or cauterization, that absorption should be promoted by administration of tuberculin according to the latest and most approved methods, and complications avoided by protecting the parts from septic invasion. He is convinced that the so-called recurrences are due to septic invasion of the part which thus invites renewed infection or arouses a latent one. The thorax should be immobilized to aid in the recuperating processes; and the excursions of the thorax should not be disturbed by use of the voice. Cold applications should also be made to the surface of the thorax on the affected side and the mouth should be kept in the nearest approach to a sepsis that is possible. Another measure is to have the patient breathe in an atmosphere impregnated with a medicinal spray. The intervals between the use of the tuberculin should be fifteen days at least. This allows time for the action of the tuberculin to be felt without disturbing the general health by its continuous administration. Given in this way it aids in the resolution of the inflammatory process, reduces the tendency of the tuberculous process to spread, and induces a slight degree of local immunity in the vicinity.

188. Collapse of Veins as Sign of Pressure in Right Auricle.—Abbruzzetti has been making a very thorough study of Gaertner's test of the pressure in the right auricle described in THE JOURNAL, xlii, page 687. He tested it on healthy subjects and under the influence of chloroform, alcohol, etc., as well as in a large number of diseases. His conclusions are that although it may serve in certain cases to determine the approximative value of the pressure in the right auricle, yet it is scarcely able to reveal chronic affections not appreciable by other means, and is of no use for the early diagnosis of disturbances in the heart and lungs. It may serve occasionally as an aid in the prognosis, but not when toxic phenomena predominate.

NEW PATENTS.

- Recent patents of interest to physicians:
772707. Drop stopper for bottles or the like. Martin Elfstrand. Uppsala, Sweden.
772802. Atomizer. George F. Hawley, Chicago.
772359. Fumigating device. John Hurley, Little Falls, N. Y.
772806. Combined support for garments and catamenial sacks. Elizabeth H. Johnson, Clayton, N. C.
772466. Vaporizer. James M. Locke, Faulkner, S. D.
772664. Truss. Frank L. Moynoux, Painesville, Ohio.
772666. Roentgen tube. Carl H. F. Muller, Hamburg, Germany.
772607. X-ray tube. Carl H. F. Muller, Hamburg, Germany.
772438. Vibrot. Charles F. Spillford, New York.
772450. Aseptic syringe. Herman A. Wulff-Lange, Paris, France.
773274. Stethoscopic instrument. Robert C. M. Bowles, Brookline, Mass.
773281. Container for radium and allied compounds. W. E. Everett, Tacoma, Wash.
773145. Fumigator. Bertram K. Hollister, Chicago.
772948. Invalid bed and lifter. Lewis C. Martin, London, Tenn.
772959. Medical battery. Leon W. Pullen, Philadelphia.
773229. Carbon analysis. George O. Seward, Hotcombs Rock, Va.
772993. Pocket fumigator. Frank E. Wolcott, Indianapolis, Ind.
774075. Apparatus for generating steam for medicinal purposes. Max F. Hentschel, Leisnig, Germany.
773774. Measuring bottle. Stanley Kosowski, Chicago.
- 773827 and 774118. Roentgen ray tube. Elin Thompson, Swampscott, Mass.
773828. Curative apparatus. John Titus, Oyster Bay, and W. Titus, Westbury, N. Y.
774151. Continuously producing and rectifying chloral. Jules A. Besson, Caen, France.
774378. Machine for decapping, filling and recapping capsules. Albert V. Carter, Syracuse, N. Y.
774572. Hygienic night stand. Narcisse Faucon, Dijon, France.
774317. Corn or union shield. Isaac A. George, Hastings, Neb.
774386. Vaginal syringe. Elmer E. Hall, Chicago.
774191. Clip for catamenial belts. Art. E. Luzzi, New York.
774529. Electrothermic and vacuum appliance. Charles C. F. Nieschang, Fort Wayne, Ind.
774282. Ear phone. Douglas E. Smith, New York.
773105. Electric baker for surgical purposes. Walter S. Edmonds, Newton, and C. A. Hogg, Boston.
773214. Flexible water bottle or pad. Wm. A. Galloway, Xenia, O.
774948. Sterilizing apparatus. Milo B. Perry, Chicago.
774773. Aseptic cartridge, etc. Wm. E. Ranz, Townsend, O.
772988. Suspendory. James C. Riley, Los Angeles, Cal.
772727. Design, water bag. Antonio C. Eggers, New York.

Address.

THE PHYSICIAN'S CALLING AND EDUCATION.*

BISHOP JOHN LANCASTER SPALDING.
PEORIA, ILL.

I have hope and wish that the nobler sort of physicians will advance their thoughts, and not employ their time wholly in the sordidness of cures; neither be honored for necessity only; but that they will become coadjutors and instruments of the divine omnipotence and clemency in prolonging and renewing the life of man.—Bacon.

Love for true, wise and heroic men and women is part of our love of life, which is a craving for more perfect and abundant life. They show us how blessed a thing it is to be a genuine man. They confirm our faith in the worth and sacredness of conscious existence, and make our standards of value real and palpable. They convince us that within and beneath and beyond all that appears is the creative Spirit who knows and loves and is good. They make it plain that he has not lost his cunning, but is still with us as he was with our fathers of old. They give us confidence that life shall not be emptied of its spiritual content; that a race which has learned to believe and hope, to think and do, can not descend into the sloughs of sensual indulgence and there lie in brutish indifference. What no one has done we imagine can never be done, and these sages and heroes reveal to us new possibilities. When they appear a new quality of life diffuses itself. They may do what all the world is doing, but it is not the same. They breathe a purer air, they are uplifted and borne on by higher thoughts and diviner impulses; they need not money nor recognition nor any kind of worldly success to make them our benefactors and masters. In their presence financiers, inventors and battle-winners dwindle. These deal with life's circumstances; they drink at the eternal fountain-head. Mental and moral force, like the physical, propagates itself, and the influence of the wise and good is transmitted to ever-enlarging circles. To hear of great achievements is to feel a new impulse to fresh resolve. We gain from them a higher conception of the meaning of life, and of the marvels that lie within the reach of whoever has faith and industry. So a noble man, though dead, still lives for those who knew him or get tidings of him, and he is often more helpful so than when he moved in bodily presence. So long as there are those who meditate and love the lives of noble and just men, the race of noble and just men can not perish.

Thanks to God who makes us and to the human heart by which we live, such men are found every-

where. Neither learning nor wealth nor high place is required that they may exist. Their power springs from within where great thoughts, high aims and loving dispositions are born and nourished. They may or may not have genius or fame. They may dwell in solitude or mingle with the restless crowds that pour through the thoroughfares of populous cities; they may be of exalted or of humble birth; they may follow the plow or sway the minds of listening multitudes. Their worth lies in themselves—in the spirit in which they act—and not in the circumstances by which they are environed. Whatever their worldly fortune, they are true to their deepest insight, pure in mind and heart, modest, unenvious, free from vanity, from the desire to shine and to become a theme for idle tongues, consenting to be made conspicuous only at the command of duty, happy in the good they do, not in the praise or the money they receive, holding themselves aloof from controversy and intrigue, intent on their own improvement and that of the environment in which their lot is cast, and rejoicing when leisure is given them to take refuge from the cares and labors their business or profession involves and imposes in the solitude and obscurity where best opportunity is afforded to grow in wisdom and in freedom.

Thoughts like these spring unbidden when we turn to the character and work of him to do honor to whose memory we have come together. He was fortunate in the circumstances of his life, but more fortunate in having within himself something higher and worthier than circumstances can provide. He was one of the happy and hardy band who are born where Nature holds her primal sway and challenges the soul to become itself; who from their earliest days are brought face to face with what is great and abiding, with the solid earth and the heavens made glorious by the rising and setting sun or beautiful by the waxing or waning moon, or sublime and awful by the intermingling mystic light of countless stars; who dwell with the changing seasons until all their thoughts and dreams are enriched and colored by the radiance and freshness of spring, by the abounding fragrant wealth of summer, by autumn's splendor and tranquillity, and by winter's white purity and crisp energy; who, felling trees or feeding kine, store for themselves a treasure-house of courage and firm resolve whence they may draw rich nourishment through all the coming years of toil and struggle. There is iron in their blood and the full, deep throb of conquering strength in their pulse-beat. Thrown back on Nature and on themselves, they are made aware of the almightiness of God revealing itself in both. It is he who, tossing the celestial orbs, as a child its toys, bids them spin forever in abyssal space; it is he who lifts the oceans on high and scatters them over the thirsty earth as a gardener waters

* Address at the memorial service for the late Dr. Nathan S. Davis, held in Powers' Theater, Chicago, Oct. 23, 1904.

his flowers. No man nor all the race of man has made the world in which these young souls live and are exalted and urged to high thoughts and deeds.

To the age of 16 young Davis worked in the fields, tilling, reaping and garnering, spring, summer and autumn; and when winter's frost made such labor impossible, he went to school. Little of the learning that is found in books could he, under such conditions, make his own, but the little he acquired gave him a thirst for more; and his father (his mother having died when he was but 7), persuaded by the youth's eager desire for knowledge, sent him to a seminary, where, however, he was permitted to remain but for a single session; and it was with this scant intellectual equipment that he began, in 1834, the study of medicine. It was only in the latter part of the eighteenth century that medical schools were founded in the United States—first in Philadelphia, then in New York, and later still at Harvard University; but even into the earlier half of the nineteenth century the custom of apprenticing students of medicine to practicing physicians still prevailed; and Davis' initiation into the science to which he had resolved to devote his life was made in the office of Dr. Daniel Clark, which he soon left for the College of Physicians and Surgeons of Western New York, where he was graduated in 1837, when he was but 20.

Here, then, is a country youth who, with scarcely any mental culture or intellectual discipline, quits the plow to take up the study of a learned profession which, to be mastered and followed with ability and skill, requires a large acquaintance with philosophy, history and natural science; and who, notwithstanding, within less than three years receives license to practice medicine, to experiment on the lives and fortunes of his fellow-men.

His talents, his industry and his earnestness were doubtless exceptional, but the social conditions which rendered such a state of things possible were primitive, not to say barbarous; and it is a convincing proof of Dr. Davis' strength of mind and character that he was not misled by his great gifts, to imagine that even genius can, without the best education, make a competent physician. His own lack of opportunity made him eager to provide opportunity for others.

He was a born teacher, and he had hardly begun to practice when he gathered in Binghamton a little following of medical students whom he instructed and inspired. In 1843 he was sent as a delegate to represent his county society at the annual meeting of the New York State Medical Association in Albany, and it was there that he made his first appeal for a higher standard of medical education. An individual may honor and serve his profession in various ways, but in none possibly so effectually as by creating a demand and providing opportunities for the more thorough education of its members. Dr. Davis' plea was not unavailing, and at the next annual meeting of the state society a call was issued for a national convention of delegates from medical colleges and societies throughout the Union to deliberate on the best measures to improve medical education. The outcome was the organization of the American Medical Association, a permanent body, whose influence for good has been and is deep and widespread. The defenders of dying causes may be heroes, but most fortunate are they who are called to do a work which the course of events furthers and prospers, whose issue is emancipation from ignorance, sin and suffering.

There is nothing in the history of the nineteenth century for which we may be more justly or profoundly thankful than for the rapid and wonderful advance made in the knowledge of the causes and cures of disease. From the time men began to think, they began to consider how sickness and death might be, if not overcome, at least mitigated or postponed; nor was their thinking altogether vain or profitless. The Egyptians and the Hebrews, still more the Greeks and the Romans, arrived at some insight into the laws of health and the treatment of disease. Hippocrates and Galen are great names, but their value for us is historic, not scientific. Hippocrates was born 400 years before Christ, and from that date to about the middle of the nineteenth century there was relatively but little progress in medicine. Here and there, indeed, we meet with physicians or surgeons of special ability or skill. Harvey's discovery of the circulation of the blood in the seventeenth century was important. Sydenham, by his insistence on the necessity of careful observation and on the healing power of Nature, rendered valuable service. In the eighteenth century Boerhaave, whose fame was probably greater than that of any physician who has ever lived, whose attainments were as surpassing as his character was benevolent and pure, contributed nothing of an essential importance to the science of medicine. In the eighteenth century, too, we have Dr. John Brown, whose teachings are said to have destroyed more lives than the wars of Napoleon, of whose school our own Benjamin Rush was a follower.

The most important contribution to medical progress in the eighteenth century was made by Jenner, when, in 1796, he introduced vaccination as a prevention of smallpox; for he not only discovered the means by which one of the worst scourges has been practically eliminated, but he opened the paths along which the most wonderful advance has been made. When Dr. John Hunter, whose pupil he was, said to him, "Do not think, investigate!" he announced the opening of a new era in medical history. The starting point was the systematic employment of scientific methods of research. Experiment as the best means of arriving at accurate knowledge is not a discovery of the nineteenth century, but the nineteenth century provided facilities and laboratories for scientific investigation, and so made it possible for medical students to observe, analyze and determine with precision the functions and conditions of the organs and tissues of the body in health, their pathologic changes, the causes of disease and the means of prevention or cure. The result was that in the nineteenth century medicine became a new science, which made most of what had been taught in the past a mere curiosity of literature. All the vital organs, all the phenomena of life, were examined in the scientific spirit, and as knowledge grew it was perceived that a single organ might afford sufficient matter for the study of a lifetime.

Many physicians consequently limited their field of investigation to the diseases of special organs, or to the diseases of women or of children, and to the labors of these specialists is due much of the progress which has been made in the ascertainment of fact and in the best methods of treatment. The greatest medical triumphs were won in the realm of the infinitesimal beings that, unseen, swarm and multiply within and about us everywhere. Bacteriology was born of the philosophic doubt, which for ages had engaged the attention of acute minds concerning the origin of life. Is the living born

of the dead? For centuries the weight of opinion had inclined to give an affirmative answer, so far, at least, as the lowest organisms are concerned. The theory of spontaneous generation prevailed far into the nineteenth century. It seemed, indeed, to be an implication of the theory of evolution which tended more and more to take possession of the modern mind. It would have supplied the missing link in the chain of causation. Hence in scientific minds there was a bias toward its acceptance. It adapted itself to the pantheistic or materialistic world views which were gaining wider and wider acceptance. To doubt its truth was to retrograde. But the brutal fact established by scientific experiment showed the hypothesis to be a delusion, that the plain truth is that whatever has life is born of the living. Pasteur, probably the greatest benefactor of the human race in the nineteenth century, proved in 1861 and again in 1876, that the theory of spontaneous generation is without foundation in fact, and contrary to all the evidence which scientific research can adduce. The consequence was that bacteriology became a science, and the causes of all the phenomena, whether of health or of disease, began to be sought for in the activities of living organisms, the smallest known, and belonging for the most part to the vegetable kingdom. They upbuild and they break down all the larger forms of life. They are the mighty armies on whose banners is inscribed the axiom, "Who despiseth small things shall little by little be brought to ruin."

Bacteriology has furnished a solid basis for preventive medicine, which has conferred and is capable of conferring more and more as its principles receive wider application, benefits on mankind, that make the triumphs of industrialism of minor importance.

More than 250 years ago, Descartes, the most original mind of the modern age, who, more than any other thinker, has determined the course both of speculative and of scientific inquiry, declared that if any great improvement in the condition of mankind was to be brought about, medicine would provide the means, and what he foresaw we see. The discovery that nearly all the worst diseases which afflict the human race are due to the action of minute organisms directed the attention of educated physicians to the exclusion of these organisms, or, if this be impossible, to investigations which should show how their baneful action might be prevented. The cause which creates a disease being known, the physician's business is to learn how to remove it or to neutralize its effects. Bacteriology has revealed to us the infinitesimal organisms that produce many of the gravest maladies to which man is subject—Asiatic cholera, diphtheria, typhoid fever, typhus fever, yellow fever, smallpox, the bubonic plague, tuberculosis, pneumonia, hydrophobia, leprosy, venereal diseases, puerperal fever and malaria. These are all germ diseases which it is possible to prevent or cure. Some have ceased to be a cause of alarm to the civilized nations—smallpox, for instance, Asiatic cholera, typhus fever, the bubonic plague and puerperal fever. When vaccination is rightly employed, smallpox wholly disappears. When filth and overcrowding are abolished, where there is good sewerage and pure drinking water, typhus fever, Asiatic cholera, yellow fever and diphtheria will hardly be found. The bubonic plague has no terrors for the peoples of Europe and America. Puerperal fever, which formerly destroyed each year the most precious lives of thousands of mothers, is now almost unknown, the mortality from

this cause being only about .07 per cent. Physicians themselves carrying the infectious germs from bedside to bedside were the agents of death, which ignorant and heedless physicians are always in danger of becoming.

When it became scientifically certain that many of the worst diseases are produced by bacteria, it was plain that the principal occupation of the physician and surgeon should be concerned with the exclusion of poisonous germs or with the means by which their baneful action might be suppressed. This led to the employment of antiseptics and antitoxins. The miracles of modern surgery are due not so much to the superior skill of our operators as to their knowledge of the means by which inflammation and suppuration may be prevented. Sepsis is a Greek word which means putrefaction, and antiseptics is the science and art of preventing putrefactive processes. The appalling death rate following surgical operations thirty or forty years ago, is not to be ascribed to imperfect anatomic knowledge or lack of manual skill, but to infection caused by disease-producing germs which, introduced into the body by contact with the air or with any object whatever, in which they had not been destroyed, multiply and sow the seeds of death with incredible rapidity. Asepsis, based on the germ theory of infectious diseases, now enables the surgeon to operate with comparatively small risk in cases in which formerly the dread of some form of blood poisoning deterred him from attempting to save his patient. Surgery has consequently become a new and most beneficent art, anesthesia rendering the operation painless, while asepsis excludes infection. The progress of pathology and therapy, if less striking, is not less real, and will doubtless in the next quarter of a century overshadow the triumphs of surgery. The field in which it works is vaster, and its methods reach deeper, touching the roots of the ills from which relief is sought. The living body has within itself a greater or lesser power to resist the attacks of the foes to health, and there have never been lacking practitioners or schools to teach that in the treatment of disease the chief reliance is in the healing force of nature. The blood and tissues, in their normal state, have a germicidal efficacy which varies with the special diatheses of individual constitutions. There are vigorous natures which seem to have the power of resisting the action of all poison-producing bacilli, while others afford no hold to certain specific germs. In our cities the bacteria of tuberculosis, pneumonia and influenza are in the air and are inhaled by all, but fortunately they find a suitable lodging place in but comparatively few. Then there is in the blood a regular army of white cells or leucocytes, whose function is to repel and destroy the intruding enemy. They are the divinely appointed defenders of life's fortress, to whom the secret of Nature's medicinal power is entrusted. They change or neutralize the toxins generated by the poison germs, and elaborate antitoxins; and when the victory has been gained and recovery has taken place, the patient has acquired at least a temporary immunity from the disease which has been eradicated. Insight into this fact has led to the discovery and employment of serum therapy, whose efficiency has wrought a transformation in medical practice, and promises, as knowledge grows, yet greater things. In one who has had the smallpox the conditions which favor the spread of the poison have been destroyed. The question suggests itself whether by introducing into the system the specific poison in a milder form, equal immunity may not be acquired. This methodical doubt led Pasteur to the discovery of

serum therapy, which by the injection of the serum of the infected blood prevents or cures the disease. Its efficacy in the treatment of diphtheria, hydrophobia and various diseases of animals has already been abundantly proven, and there is good reason to believe that the research of specialists will enlarge the field of its prophylactic or curative power, until it shall be universally recognized as the opening of a new epoch in the history of medical science and practice, an epoch in which new and accurate knowledge of the causes and nature of disease shall lead to new and efficacious methods of prevention or treatment. Drugs will not be discarded, but their action will be scientifically investigated and confidence in their therapeutic value will diminish.

It was Dr. Davis' good fortune to begin the study of medicine when this great transformation was about to take place; and, like the good, wise and far-seeing man he was, he understood that the physician could no longer be permitted to be but an empiric.

From the early years, when he helped to found the American Medical Association, to the close of his long life, he was the tireless champion of higher medical education. He thoroughly understood that a science which embraces the whole of human life, physical and psychical, can never be mastered by those whom mental culture and discipline have not prepared for its study. Men of exceptional talent and industry may surmount obstacles which for the many are insuperable; but the standard of professional attainment must necessarily remain low so long as a proper preliminary education is not required of all who offer themselves for matriculation. The physician who is not also a scholar may be a more or less successful practitioner, but his influence will be confined, his methods mechanical and his interests narrow. The doctor, the lawyer and the minister of religion can do but inferior work, unless to a knowledge of their several sciences they bring the insight, the wide outlook, and the confidence which nothing but intimate acquaintance with the best that has been thought and said can confer. The more accomplished the specialist, the greater the need of the control which philosophic culture gives.

The lack of opportunity for his own mental training made Dr. Davis the more eager to provide it for others. His life in Chicago was identified with the educational, moral, scientific and sanitary history and progress of the city. He was among the first to urge the need of a supply of pure water and of an adequate system of sewerage; and in a course of public lectures he showed how this might be accomplished. With the money charged for admission, he laid the foundation of Mercy Hospital. He was a Methodist, not a Catholic, but his vigorous mind and noble character taught him that prejudice is ignorance or imbecility, and that where suffering is to be relieved, where good is to be done, all, save the blind or the perverse, are drawn together to help and to cheer. The more angels, the more room, and the greater the misery the more do noble natures feel that there is place for all who have good will and the desire to serve. Great minds and loving hearts offer boundless hospitality. When the Chicago Medical College was founded, its more exacting requirements for admission and graduation could not but win the sympathy and approval of Dr. Davis, and, heedless of the loss and sacrifice, he resigned his professorship at Rush to take one in the new institution, of whose faculty he continued to be a member for more than forty years.

He was a leader in the organization of the Illinois State Medical Society, of which he was elected president, and which he served as secretary for twelve years. For six years he was editor of THE JOURNAL of the American Medical Association, which he placed on a solid financial basis. If genius be exceptional capacity for work, Dr. Davis had genius. His industry was tireless, his painstaking unwearied. In the midst of the onerous duties of a large private practice, in the midst even of unremitting ministrations in times of epidemic, he still continued to teach, to write, to edit, co-operating meanwhile in any movement for the common good to which his attention might be called.

He was one of the founders of the Northwestern University, the Chicago Academy of Science, the Chicago Historical Society, the Illinois State Microscopical Society, the Union College of Law, and of the Washingtonian Home.

"The essence of greatness is the perception that virtue is enough," says Emerson in his fine way. Perception, indeed, is not and can not be the essence of anything, but he who has insight into the fact that the end of life is moral, is conduct and character, understands wherein the essence of greatness consists. It lies, like the kingdom of heaven, within. Title, office, possessions may or may not be its accompaniments. Vast knowledge even gives no assurance of its presence; for it is what a man believes, hopes, loves, admires, yearns for and does rather than what he knows. Only they whose existence is upborne and illumined by a high and holy purpose are interesting or have intrinsic value. The rest are busy with what they shall eat and wear, with how they shall be housed and attended, and pass their existence on the low plain of appetite and vain desire. Dr. Davis was more than a learned and skillful physician; he was a genuine man filled with religious and moral fervor and zeal. He might have grown rich, but he died poor. He felt like Agassiz, that he had no time to get money. Had he possessed the wealth of the founders of universities, his chief significance and value would still have lain in himself—in his rectitude of purpose, in his desire to teach men how to live, in the simplicity and honesty of his life, in his love of truth and justice, in his high-mindedness, purity and benevolence, in his freedom from envy, jealousy and pettiness.

In every profession there are men without principle or character who prefer success to virtue, whose predominant passion is greed, who to get money are ready to prey on the weaknesses and miseries of their fellows, who, like the ghouls that gather wherever great calamities befall, consider the helplessness and sufferings of their fellows but opportunities for plunder; and since a man is willing to give all he possesses for health, and since whoever can pay can advertise, the healing art offers the most inviting field for these hyenas in human shape; and therefore the medical profession, more than law and quite as much as the sacred ministry, is most commended and honored by men who to scientific attainments add the essential and abiding worth of moral character. If it be true that an orator is first of all a good man, one who inspires confidence, who is himself more eloquent than words can be, it is also true that a physician should first of all be a man of moral worth, of principle, of probity, of honor, of benignity and heroic unselfishness. If confidence in him as a man be lacking, the wise will hesitate to put trust in the exercise of his professional knowledge and skill; and confidence is half the cure, since in his power to inspire hope, a cheerful and brave spirit, lies, in most cases, the

secret of a physician's success. Boerhaave, whose reputation surpasses that of all other physicians, to whom letters addressed "to the most famous physician of Europe" were sure to be delivered, wrought, it is said, more cures by his presence than by his remedies. However great one's science or skill, the foundation of the trust we place in him must be laid by his moral worth. Knowledge does not of itself determine will or form character, and one may know many things and be only the greater villain.

The trend of the most recent theory and practice in education is to lay chief stress on intellectual ability and technical skill, and to hold lightly the convictions of those who are persuaded that human life is essentially conduct, and that the everlasting fountain-head by which right doing is fed is religious faith, which alone can build the foundation of a rational belief in the absolute worth and sacredness of man, as revealed by his origin and destiny.

The ideal is that of the calculating understanding in the service of the senses. Get money, and whatever is desirable shall be thine. Succeed, by fair or foul means, and the world will do thee homage. Make thyself able, strong and skillful, and thou shalt have small need of virtue.

Dr. Davis was a lover of knowledge, a life-long student, a chief promoter of medical organization in this country, and the tireless, persuasive advocate of the need in his own profession of higher and more thorough education. His mind was vigorous and alert, his intellectual curiosity drew him ceaselessly to scientific inquiry, his temper was judicial, his power of diagnosis was exceptional; but his religious, virtuous life, his sobriety, his tolerance, his largeness of thought and sympathy, his independence, his sense of justice, his desire to be of help, his fearlessness in the assertion and maintenance of right, his indefatigable zeal for the promotion of temperance and morality—his character—gave him a distinction which belongs to but few in any profession. He himself is greater than his knowledge, than his deeds, than his reputation. "The chief need," says Seneca, "is of great teachers." Dr. Davis was a great teacher, and, like all teachers of essential vital truths, his highest lessons are taught by his life more than by his words.

In the midst of the crowd of adventurers, of the rabble of fortune seekers, in which he found himself when first he came to Chicago, he walked the narrow path among them like a ministering spirit, but not of them; and when the town of twenty thousand had grown to be a city of a million and a half of inhabitants, he, where all had changed, remained steadfast, true to God, to himself and to the service of his fellow-men, faithful to the old principles which assert religion, conduct and character to be the aim and end of life. For him duty is a divine impulse, and honor, the finest sense of duty. The patient who called him became as sacred in his eyes as is the penitent in the presence of the priest. What he learned was as though he knew it not. The body is not separate from the soul, and, like it, is sacred. He who ministers to the infirmities of the one, helps the other. The physician and the priest are near kin, and in all ages have been held to be so, though like near kin they have had their quarrels. Both recognize that moral good is the essential good; that if men had but virtue enough, they would have health and happiness enough.

Progress in etiology and diagnosis has confirmed the

belief that the root of evil lies not in the stars, but in ourselves.

Men are most prone to lie to themselves, and most willing to be lied to, when there is question of their health and morals. They will lay their infirmities and faults to anything in the wide universe but themselves. Whether there is question of medicine or of religion, their unwillingness or inability to employ the right preservatives or remedies lies in their unwillingness or inability to lead right lives. We make ourselves the victims of greed, lust, gluttony, drunkenness, envy and hate, and find what comfort we may in denouncing doctors and priests. And doctors and priests, who, if they are not better, are worse than laymen, are forever tempted to palter, to flatter, lacking the courage to unveil truth to the easily shocked eyes of lechers, drunkards, gluttons, thieves and tricksters, if, having money and position, they can make or mar. They are forever tempted to prove false to their deepest knowledge and insight, to compromise where compromise is betrayal, to indulge where indulgence is ruin, to administer palliatives when there is no hope but in radical change. This false and cowardly attitude undermines character, confuses knowledge, and destroys the power to inspire confidence in those who are ill that they shall be made whole.

In the presence of the all-pervading self-indulgence and self-deceit which lust and pride and greed beget, we are made conscious of the transcendent worth of a man like Dr. Davis.

In him the average sensual man, who is every man, can find little comfort. He sees the fact and speaks plain. Between him and the possibility of quackery there lie infinite worlds. Between him and the expert who values his professional ability chiefly for its power to exact large fees, there lie infinite worlds. Between him and the crowd of the prosperous, who believe that a man is worth not what he is, but what he possesses, there lie infinite worlds.

Into the valley of the Mississippi, made fat and fertile by the slow but ceaseless action of natural forces during epochs of indefinable length, there has come suddenly a race, provided with the highest religious, moral and scientific power, a race of exceptional vigor and of most fortunate historic experience. In brief time we have developed here a material civilization whose wealth and promise is a world-wonder. What hitherto it had taken thousands of years to bring about, has been accomplished in half a century. But we ourselves have not grown as our prosperity has increased. We have succumbed to our success. We have vast riches, and all the comfort, luxury and display which money provides, but our thoughts are superficial, our sympathies shallow, our desires selfish or sensual, our aims and ambitions vulgar.

Like those who, in the midst of unending waters, die of thirst, we, having all that earth's bounty can give, have lost the secret and the art of leading a worthy and a happy life, because we have ceased to be either willing or able to believe that souls live by faith, hope, love and imagination, in the light of high ideals, and in the glow and warmth of self-devotion to what is forever true, and good and fair. We measure human worth by mechanical standards, the value of life by the opportunities it affords for the indulgence of appetite or vanity. We are feverish, restless, timid and uncertain. In our very strength and energy there seems to be something akin to disease. We can neither work nor play in moderation. The wisdom of those who are con-

tent with what suffices is in our eyes folly. Hence it is easy for us to become gamblers, promoters, givers or takers of bribes, drunkards, and suicides; and in the midst of the dazzling spectacle of our national progress, it is a question whether our millionaires or our toiling, hard-driven wage-earners, are more discontented and unhappy.

With us everything improves—mechanical devices, the breeds of domestic animals, the qualities of vegetables and fruits—man alone is stationary or retrograde, because his nature, being essentially moral and religious, the worship of vulgar success, the indulgence of appetite, the preference of the external and transitory to the real abiding world within, make religion and morality impossible.

From the midst of such a world, a man like Dr. Davis rises, like one inspired, to proclaim by word and deed, that righteousness is life, that the wages of sin is death, that whatsoever thing a man soweth that shall he reap, that sin or culpable ignorance or neglect, which is sin, is the cause of nearly all the diseases, ills and miseries by which we are brought to ruin.

To the learned professions especially his teaching and his example declare that they rest not more on a basis of knowledge and skill, than on a foundation of principle, honor and benevolence. His view is generous and comprehensive. Not for his clients alone does the lawyer exist, nor for his penitents, the priest; nor for his patients, the physician.

God makes sages and saints that they may be fountain-heads of wisdom and virtue for all who yearn and aspire; and whoever has superior knowledge or ability is thereby committed to more effectual and unselfish service of his fellow-men. If the love of fame be but an infirmity of noble minds, the craving for professional reputation is but conceit and vanity. To be of help, and to be of help not to mere animals, but to immortal, pure, loving spirits—this is the noblest earthly fate, this, the highest good fortune. In the light of this ideal Dr. Davis believed, hoped, loved, worked, suffered, died and triumphed. When the politicians, the captains of industry, the inventors of mechanical devices, the lavishers of millions to promote whatever ends, shall have sunk into oblivion or be remembered with the contempt of indifference, he shall remain as a witness to right human life, as an influence and encouragement to all who have faith in God, in truth, in justice, in plain, unselfish living, in brave endeavor, in purity and love; a principle of hope and courage, an inextinguishable light to beings who wander amid the labyrinths of time and space, and feel and are certain that their true home is with the Eternal Father who makes and upbeats the Universe that beings like unto Himself may be born and grow forever.

Before the Royal College of Surgeons of London, there is delivered an address, each year, to commemorate the life and work of John Hunter. Let the physicians and the medical schools of Chicago bear witness to their love of worth and appreciation of excellence, by making a similar foundation to perpetuate the memory of Nathan Smith Davis.

The Physician Should Insure His Life.—A physician owes much to his family. His peculiar life, his enforced absence, and his irregularity are exasperating in the extreme; therefore, he should offer reasonable compensation by definitely providing for accidents, illness, and death, particularly for the comforts of those who depend on him for their future existence.—*N. W. Lancet.*

THE SURGICAL TREATMENT OF BILOCULAR UTERUS AND BIFID VAGINA.*

H. W. LONGYEAR, M.D.

Gynecologist to Harper Hospital; Physician to the Woman's Hospital; Clinical Professor of Gynecology, Detroit College of Medicine; President of the American Association of Obstetricians and Gynecologists.

DETROIT.

My object in presenting this subject is to call attention to a simple operative procedure for the correction of one of the numerous forms of anomalous development of the female generative organs which result from faulty evolution in the process of development of the Müllerian ducts.

The strange silence of gynecologic literature appertaining to the therapeutics of these sexual deformities is remarkable, as it would seem that, where possible, their early discovery and correction should be aimed at, rather than allowing such abnormal conditions to continue as a serious menace to the health, and possibly the lives, of their possessors.

The bilocular, double, or septate uterus is usually attended with the same condition of the vagina, the latter being divided by an apparent continuation of the uterine septum into two lateral halves. The cause of the deformity being an arrest of coalescence of the Müllerian ducts, the result is one uterus and one vagina divided by an anteroposterior septum of fibrous tissue in such a manner as to cause the apparent duplication of the organs; thus, to correct the deformity and form one uterus and one vagina, as Nature intended, all that is necessary is to destroy the dividing septum in both vagina and uterus. When this is done, a vagina and uterus, both being rather more capacious than normal, will result, and the two small cervixes will be coalesced into one normal-sized cervix. The whole apparatus is thus placed in practically a normal condition, so that gestation and parturition may be assumed in a normal manner.

Others, no doubt, have worked this matter out as is here suggested and corrected the deformity by operative procedure of one kind or another, but beyond the destruction of the vaginal septum, I can find nothing recommended in the text-books, and so I present my method of operating, with report of two cases, which comprises my experience with this particular variety of malformation.

Care is necessary in the selection of the cases for operation, so that a bicornate uterus may not be mistaken for a septate uterus, as it is apparent that the division of the mistaken septum in the former would open the peritoneal cavity. The differentiation is easily made by conjoined examination, so that, with reasonable care, the accident is not liable to happen.

THE METHOD OF OPERATION.

The vaginal septum is first removed in the following manner: Two pairs of long pedicle forceps are made to grasp it along its entire length from the vulva to the two cervixes, one anteriorly and one posteriorly, close to the vaginal wall; the tissue between them is then entirely cut away with scissors and trimmed clear from between the cervixes at its upper end; the Paquelin cau-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

tery is then applied to the edges of tissue held in the grasp of the forceps, and the latter removed. This plan of removal of the septum insures a bloodless operation and can be accomplished much more quickly than if the parts are cut away and stitched.

The capacious vagina can now be opened widely with a retractor and the two small cervixes plainly seen lying closely against each other, with only the edge of the divided septum between them. Both are then dilated sufficiently to facilitate manipulation, the direction of each uterine canal ascertained, and, if necessary, a farther bimanual examination made to be certain as to the shape of the uterus. The dilator is then inserted, with one jaw in each os, and the Paquelin cautery knife thrust between them, cutting the septum to the depth of perhaps an inch. The dilator, which has acted as a shield to the outer sides of the cervix, is then withdrawn and the farther division of the uterine septum up to the fundus is completed with a pair of long, curved, blunt-pointed scissors. The cavity is then curetted, if necessary, and swabbed out with tincture of iodine and packed with iodoform gauze, the latter being continued into the vagina, which is also loosely packed with it.

At the end of four days the gauze is removed and daily vaginal irrigations of carbolic water, followed by sulphate of zinc solution, gr. 3 to 5 1, used till the parts in the vagina are healed.

The two cases which have come under my observation were discovered on examination to determine the cause of severe dysmenorrhea, both patients complaining of the persistently increasing pain from month to month.

In the first case only the vaginal part of the operation here proposed was made, and it was the experience with the case following the division of the vaginal septum that determined the trial of the extension of the operation to the removal of the septum in the uterus. The following are the histories of these cases:

CASE 1.—G. R., single, 20 years of age, but in appearance an undeveloped girl of 15. Breasts and labia small and genital hair scanty. Menstruation had occurred irregularly five or six times, each period being more painful than the last, and it was for this symptom that the girl's mother brought her to the clinic at the Woman's Hospital, Jan. 10, 1899.

Examination.—On examination under anesthesia the abnormality was discovered. The vulva was normal, the vagina was divided into two lateral parts by a firm anteroposterior septum which extended from the introitus to the vault, where, on each side of this dividing membrane, a small cervix uteri was felt, with the inner aspect of each lying closely to the septum and adherent to it almost to the os. On passing the sound along the finger into the two uterine canals, the left was found to deviate considerably toward that side, while the right was deflected but little from the median line. The left measured 2½ inches and the right 2¼ inches.

Each cervix was thoroughly dilated, and the patient directed to report occasionally for further observation and treatment. She was not seen again until June 13, 1902, when she presented herself again, through the courtesy of Dr. Samson of Windsor, Ont.

Her general development was then greatly improved in every way, and it was discovered that the members of the left side of her body were more largely developed than the right: the left breast, left arm, leg and thigh, as well as this side of the abdomen, being markedly larger than the opposite corresponding parts. The size of the hands and feet were not different. For several months she had had increasing severe pains at each menstrual epoch, which always began in the right hip and extended across the abdomen. On account of the limited room in the vaginal canal, due to the septum, bimanual examination was unsatisfactory, but a sensitive mass larger than an ovary

could be made out in the region of the right ovary, so its removal by abdominal section was decided on, as well as the ablation of the vaginal septum.

Operation.—At the Woman's Hospital, June 14, 1902. The vaginal septum was first removed in the following manner: Its whole length was grasped by two long pairs of pedicle forceps, one anteriorly and one posteriorly, from the introitus to the vault, cut away with scissors close to each forceps, and the edges thoroughly cauterized with the Paquelin cautery. On removal of the forceps no hemorrhage occurred. This left the cervixes projecting into a vagina which was rather wider than normal. The abdomen was then opened and a careful examination of the pelvic contents made. The double uterine body was nearly three inches in breadth at the fundus, the right side being somewhat smaller than the left, with a slight indentation marking the junction of the two halves. The left tube and ovary were normal; the right tube was normal, but the ovary was enlarged by a hematoma to the size of a hen's egg, and was removed.

Her first menstruation, while still in the hospital, was attended by the same pain in the back of the right hip. This same pain, occurring at the menstrual epochs, continued to increase in severity and duration after this operation, until Dr. Samson again returned the patient, Jan. 8, 1903, with the opinion that the woman would soon be dead, from either suffering or morphia, unless relieved.

Examination revealed no cause for the pain, but the condition being desperate, the removal of the remaining ovary was determined on for the purpose of bringing on the menopause. At the operation, which was performed at the Woman's Hospital, Jan. 29, 1903, nothing in the line of adhesions or other cause for the pain could be found, and the ovary was normal. It was noted that the right half of the uterus, the side from which the ovary had subsequently been removed, had diminished considerably in size.

A bloody discharge from the uterus, two days after the operation, caused the old pain in the hip, necessitating hypodermics for its relief, and ceasing with the cessation of the discharge. Four months after operation the patient reported no menstruation and no pain. Was becoming very fat.

After the experience with this case the query naturally rose as to the possible rôle the uterine septum had played in the causation of the dysmenorrhea, and whether its removal should not have been first attempted and the ovary left for the *dernier ressort*. It was decided to try it next time, not only for the relief of a possible dysmenorrhea, but for the purpose, as well, of placing the organs in a condition more nearly approaching the normal. Such an opportunity presented itself sooner than expected.

CASE 2.—W. M., servant, 21 years old, single, normally developed in every way. Menstruation began at 13 years of age, always painful, but lately much more so. Sought advice because of the severity of the pain, which was located in the hypogastric region, of a colicky nature, and active only during the first day of menstruation. Is well and strong between periods and able to work.

Examination.—Vulva normal; no hymen; two vaginal openings were found, divided by a thick, loose septum which adhered closely to the right side, and was not at first discovered by inspection. This septum extended from the entrance to the vault of the vagina, where a cervix uteri could be felt on each side of it. Vagina very capacious, each side receiving a large size bivalve speculum. Cervixes small and placed close to the septum. Sound passed 2½ inches in each side, the left deviating slightly to that side and the right a trifle toward it. Uterine body felt to be broad and freely movable. Appendages apparently normal.

Operation.—Harper Hospital, Jan. 26, 1904. Vaginal septum excised with scissors, between two forceps (anterior and posterior), and edges cauterized with Paquelin cautery. The two cervixes were then successively dilated, and, after introducing and opening the dilator, with one jaw in each side to act as a

shield, the cautery knife was thrust between them into the uterine canal to the depth of about one inch, thus making one os uteri and cervical canal. The dilator was then withdrawn and the balance of the uterine septum cut through by small successive snips with a pair of long, curved, blunt-pointed scissors. The hemorrhage was quite insignificant. Examination with the curette showed the endometrium to be in a healthy condition on each side. The uterus was then swabbed with tincture of iodine, washed out, and both uterus and vagina packed with iodoform gauze.

The patient suffered no pain or discomfort from the operation. The gauze was removed on the fourth day, and carbolic acid and sulphate of zinc douches used while she was in the hospital. She sat up on the tenth day, and was discharged on the fifteenth.

Result.—Reported at office, April 6, 1904. Had had two menstrual periods since operation, both being less painful and flow more free than before operation. Examination showed the vagina well healed; cervix showed no signs of the operation, except that the os was a trifle larger than is usual in a nullipara, and the remains of the vaginal septum could be discerned on its anterior and posterior aspects. The uterine canal was free, and no remains of the septum could be felt with the sound, excepting a slight projection of tissue of about a quarter of an inch at the fundus, which marked the point of insertion of the septum.

NOTE.—Sent, 30, 1904, patient very well in every way and not suffering from dysmenorrhea.

DISCUSSION.

DR. C. S. BACON, Chicago, said that the obstacle to labor from the septum in the vagina is easily conceivable, but that he can see no reason for cutting the septum in the uterus on account of the pregnancy or to relieve any disturbance during labor. Menstrual difficulties seem to have been the reason for the operation, and it certainly seems remarkable that without further attempts to improve menstruation, ovaries that apparently were normal should be removed. Hematoma of the ovary is not a sufficient reason for removing it; hence, the case is open to criticism. Dr. Bacon said that it is hardly conceivable that a septum can be the cause of difficult menstruation, unless it acts as a mechanical obstruction.

DR. L. H. DUNNING, Indianapolis, has seen cases in which a septum in the uterus and vagina acted as an obstacle to menstruation; both women conceived and were delivered without any operative procedure. In both cases the septum was torn during labor. The first case occurred early in his career and he concluded to leave things to nature, especially as the septum was very thin. The septum was torn in both uterus and vagina, and no accident followed. In the second case the septum was thick and there was a wedge-shaped piece of tissue running from the external os up the cervix. The patient refused operative interference, and she had a very hard labor. The descending head tore its way through the septum, and, incidentally, through the cervix. Dr. Dunning doubts whether it can be laid down as a general rule that the septum in the uterus should be removed by operation. Malformations of the uterus may be found more often than we think. He has seen eight cases, two of them uterus bicornis, and the others of various kinds.

DR. H. T. JOHNSON, Washington, D. C., has seen one or two cases of partial double vagina, in which the trouble was overcome by snipping away the septum. He recalled the case of a woman living in the country who had a miscarriage. She came to the city to be curetted, on account of a more or less continuous flow after the miscarriage. She recovered from the operation, went to New York, and remained there for several months. In the meantime her abdomen increased gradually in size, but as it caused her no inconvenience she did nothing about it. One evening, however, she had a very severe pain and was taken to the hospital of Dr. L. G. Wylie, who delivered her of a five months fetus. Dr. Johnson could not explain it at all, as he had curetted thoroughly. Later he received a letter from Dr. Wylie describing a perfect double

uterus. The patient had had a miscarriage in one side of the uterus while a pregnancy existed in the other, and it was fortunate that he did not get the curette into the pregnant side.

DR. J. H. CARSTENS, Detroit, said that he had had similar cases in his practice. Eighteen years ago he attended a lady who had had a miscarriage. There was nothing unusual about it, but after six or eight months she had another miscarriage, and after a time she had a third miscarriage. The placenta was retained and he was obliged to remove it. Then he found that there was something wrong. The placenta was over on one side, but during his manipulation he found a septum extending down to the internal os, the external os being normal and the fundus normal; the septum was the only thing abnormal. Some months later he dilated the cervix with sponge tents and removed the entire septum, making one uterine cavity. In about three months she became pregnant again and was delivered of a full-term child. After that Dr. Carstens had a case of septum passing through the uterus and vagina. He removed the septum so as to make only one cavity. In order to prevent adhesions of the uterine walls after removing a septum, he always swabs out the uterine cavity with strong carbolic acid. He has had several cases where he could not operate because of the shape of the uterus, the fundus being depressed, making a sort of bicornate uterus. In order to make an operation permissible there must be only one septum and a normally-shaped uterus.

DR. W. B. DORSETT, St. Louis, operated on a case recently and found a double vagina and uterus. The patient was very fleshy and it occurred to him that it would be a rather hazardous procedure to carry the incision all the way up to the fundus, as he might enter the abdominal cavity, or it might have been a case of bicornate uterus and not merely a septum in the uterus, so he divided the septum in the vagina and as far as the internal os into the uterus. Several years ago he was called in consultation in a case of labor with a septum in the vagina. The child's head had come down well until it met this band, which prevented its further descent. He cut it and the labor proceeded without further trouble. These septa are not alike. Sometimes they consist merely of mucous membrane, while at other times they may contain some circular and longitudinal muscle fibers and frequently troublesome blood vessels.

DR. H. W. LONGYEAR said that the case reported by Dr. Dunning shows the beneficial results following division of the septum. Removing the ovary in the first case to stop menstruation was not advocated as a method of treating these cases. The removal of a normal ovary is always a subject for difference of opinion, but here was a case of abnormality in every way. The whole individual was abnormal; all the soft parts were abnormal, and the excruciating pain necessitated the administration of morphin for two weeks out of the month; and she was not a morphin fiend. He had had the opinion of an excellent practitioner who had been her physician, and he had no hesitation about removing the ovary, because the woman was a wreck and would continue to be such, apparently so long as the menstrual epoch continued to recur. Removal of the ovary was the simplest way to stop it. He had nothing to guide him in the matter, as he could not find anything in the literature. He hesitated to continue the division into the uterus, for the reason that there might have been a bicornate uterus and he might have gone into the abdominal cavity. He has wished since that he had done the same operation in this case as in the later one, before any organic changes took place in the first ovary. The patient consulted him for the relief of dysmenorrhea, and that is how he discovered them, although he did not operate solely to cure the dysmenorrhea, but to put the patients in a normal condition. Dr. Longyear knows of one case like Dr. Johnson's where infection occurred. The physician thought that he had curetted away everything, but the woman became septic, and it was then discovered that she had a double uterus, and he had curetted only one side. On making a thorough examination he found that the other side contained septic matter so that she apparently had a double miscarriage.

A PLEA FOR CONSERVATIVE OPERATIONS ON THE OVARIES,

FROM A NEUROTIC STANDPOINT, WITH REPORT OF CASES.*

JAMES W. COKENOWER, M.D.

DES MOINES, IA.

The subject of ovarian neurosis is one of the most difficult the gynecologist has to deal with to-day, because of his inability to fix a standard from which to determine the beginning of surgical treatment. Hence the question is of diagnosis rather than of surgery, and the thing to decide is whether the woman's symptoms arise directly or indirectly from pelvic disease. This decided, the treatment is simplified, but should the pelvic disease not enter into the case further than one of many other factors, then it is not a surgical case, and should be treated accordingly; and it is this very factor which complicates the subject and has given discredit to legitimate surgery and brought to view the shining light of the operator, while the conscientious surgeon prevents damage to the patient and injury to his profession.

It is my purpose to emphasize the importance of a better knowledge on the subject of diagnosing such cases and point out the mistakes likely to occur in doing so, because no class of patients suffer more or longer with less prospect of relief than do these. They are fully convinced that, directly or indirectly, all their grief emanates from the pelvis, and oftentimes this idea is fostered and materially augmented by their friends. The headache, backache and tired feeling, combined with pain in iliac regions, are considered indications of pelvic disease, but when these symptoms are accompanied with disordered menstruation, dysmenorrhea and leucorrhœa, then there is no doubt about the diagnosis, especially if some kind friend or thoughtless doctor confirms their opinion.

The real cause frequently originates from abortions, gonorrhea, endometritis and pelvic inflammation, which keep up an irritable condition of the ovaries, and the woman suffers for years, and it is no wonder she is willing to resort to any means that will promise relief. However, the all-important question arises in all such cases as to whether surgery is an advantage or disadvantage, or whether it will do the patient harm or good. Opinions of leading gynecologists differ on this point, although the bulk of authority is against the assumption that pelvic disease is not the cause, but result of neurosis.

The intimate relationship existing between diseased conditions of the reproductive organs of the female and functional disturbance and organic changes in other parts of the body should be better understood; also that fermentation and putrefaction within the intestinal canal will produce autoinfection, and that intoxication will produce ptomaines and leucomains, which are the most prolific and common cause of nervous disease. We should know that excretions retained within the body, as well as waste tissue, are absorbed and bring about pathologic changes in the blood, which, in turn, causes malnutrition of nerve centers, and thereby materially interferes with and abridges healthy functions in all the vital organs.

Other causes than pelvic disease may operate to produce this abnormal nervous condition, we must admit.

and that the functional disturbances within the pelvis may be the effect and not the cause of the pathologic nerve state, is equally true.

Many surgical procedures, heretofore undertaken with confidence, have been sadly disappointing, and have utterly failed to relieve the condition for which they were advised. The neurasthenia and functional disturbances have remained, and both patient and surgeon have lived to regret the treatment adopted. Many operations which, a few years ago, were very popular with the profession for relief of supposed ovarian nervous troubles, have grown in disfavor, and are now seldom done, which ought to teach us all an important lesson not to take up fads, hobbies and phantom neuro-psychosis, but to take a broader and more comprehensive view of the subject and be less radical and more conservative in our treatment of such cases.

A few gynecologists condemn oophorectomy in neuroses, and deny the existence of genital neurasthenia. This is, in my opinion, an extreme view of the subject, and is as injudicious, in the face of clinical facts, as are the teachings of those who report such large numbers of these patients as cured by the removal of the ovaries.

The experiences of Liebermeister and Baldy coincide so nearly with mine that I quote, in abstract, from remarks made by them on the subject:

"On the one side we often see extremely nervous women, in whom the anatomic and functional conditions of their sexual organs are normal, and, on the other hand, all sorts of diseases of the sexual organs may occur, without the presence of nervous disturbances. Neurotic cases cured by local gynecologic treatment are rare. Many cases are cured in whom the sexual organs remain unchanged. The conclusion, then, must be that neurotic cases are rare that are wholly dependent on diseases or abnormalities of their sexual organs, and yet it is equally true that abnormal irritation of the same functions are conditions especially fitted to cause nervous manifestations."

I began five years ago to examine the right ovary in all cases of appendectomy in women, and was surprised seldom to find an ovary normal, from an anatomic standpoint, but many cystic ones and in some diffused edema. A few conservative operations were done on such ovaries with negative results, and now the ovary is removed or dropped back unmolested, unless prolapsed or congested, then suspension should be done.

Statistical reports of the surgical and non-surgical aspect of ovarian neurosis does not convince me that either extreme should be adhered to, and that an intermediate position is preferred between the two extremes, not laying down any specific rules to be governed by, but judge each case on its own merits.

During the past year several cases have come under my professional care, or have been seen in consultation, on which conservative operations on the ovaries had been performed with negative results, and now they seek a secondary operation for relief. I will report two of such cases which have occurred in my own practice, and two were from other physicians.

CASE 1.—Jan. 6, 1901. Mrs. B., aged 35; good family history. Examination showed she was suffering from metritis and prolapsed and diseased ovary; had severe pain in loin and back of head, which had existed for months without an intermission, producing a general hyperesthesia of the nervous system, insomnia, loss of appetite and emaciation. I put her to bed, using local and constitutional remedies for four weeks without satisfactory results. February 16 I removed the diseased ovary, and she had an uninterrupted convalescence. Her

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

nervous troubles seemed relieved for a few weeks, but gradually returned in an aggravated form; in fact, hysteria. Two years after the operation I saw her again, and symptoms were unchanged. I advised her to try medicinal treatment for a few weeks, and if the results were not satisfactory that she should have the uterus and right ovary removed; my advice was not carried out, and I have not seen her since.

CASE 2.—March 20, 1901. Miss S., aged 22. Her family history was negative, and so were most of her subjective symptoms; so far as contributing to the reflex nervous condition, eliminating a diseased condition of the left ovary, which an objective examination fully verified. An operation was advised as the best way out of her trouble; this was refused, although she had suffered almost continually, and often severely, for about three years.

I put her on a medicinal treatment, constitutionally and locally, and put her to bed for four weeks, and quiet for twice as many more, during which time the treatment was continued, but with negative results. June 25, 1901, I removed the left ovary and tube, both being badly diseased; the right ovary and tube and womb seemed normal. She had an uneventful recovery, and for a time seemed relieved; then her nervous condition returned and remained. She has repeatedly requested the right ovary and uterus removed, with hopes of relief; this was refused, because no conditions existed warranting such procedure, hence it is problematic how the case will terminate.

CASES 3 and 4.—Give similar histories of three and four years' standing and operations, by other gynecologists, of single and double oophorectomies failed to give relief, and the patients consulted me with a view of another operation, and, if I thought best, a complete hysterectomy. After receiving the full histories of the cases and making a thorough examination, and not finding pathologic changes warranting such a procedure, I declined to operate, and these, like the preceding two cases, must look for relief from other sources.

These cases go to show that relief in many cases is not secured from one or even two operations, yet many are benefited, and conservativeness should not be pushed too far, because cystic degeneration in many cases is progressive.

CONCLUSIONS.

1. Operations on the ovaries that preserve the menstrual and reproductive functions should be employed, when possible, in lieu of complete extirpation.
2. Healthy displaced ovaries may be anchored to posterior surface of the broad ligament or by shortening the infundibulo-pelvic ligament.
3. Sterile women and married women who are using means to avoid pregnancy are unfavorable subjects on which to do conservative operations on the ovaries.
4. Conservative operations should be avoided on all pus cases, as a general rule.

DISCUSSION.

DR. ROBERT T. MORRIS, New York City, said that the psychoses must be separate from the reflex neuroses. Patients have been operated on who should not have been operated on. Recently a surgeon said to a neurologist that he could clean out his office of patients if he were allowed to step in. To which the neurologist responded that he had no doubt of it. The fact of the matter is that neither was quite familiar with the work of the other. Many patients having a fundamental psychosis give pelvic symptoms. Patients classified as neurasthenias are often patients with a psychosis, with incipient melancholia and with pelvic pains. They must be classified carefully if physicians are not to be subjected to the humiliation of doing unnecessary and harmful surgery.

DR. A. GOLDSPOHN, Chicago, considers that the difficulty is one that is solved by making better diagnoses. The gynecologist, like all specialists, is often accused of finding too much in his sphere and, therefore, every other part of the body should be examined before the pelvis; of course, having

the history in detail. Gynecologic diagnosis begins, at least, with the mouth, and sometimes with the eye. The ophthalmoscope ought to be used occasionally to see whether there is an organic lesion of the eye, rather than to regularly use the uterine sound that leads the physician astray frequently in ordinary minor cases. Successful gynecologists must be general medical men first, and be able to distinguish the thoracic symptoms of abdominal or pelvic origin from those that arise from thoracic diseases. Likewise to distinguish the symptoms of kidney lesions, and of diseases of the bile passages and others which arise from traction on peritoneal structures, particularly the suspensory ligaments of the intra-abdominal organs, such as enteroptosis and gastroptosis, from the referred symptoms of pelvic disorders. After that, make a bimanual examination, but to do this thoroughly the physician needs practice quite as much as an average housewife needs to have practice on the piano in order to play that instrument respectably. This fact of cultivating the touch, of having developed eyes in the fingers, is not appreciated enough. It is not the size but the consistence of an ovary that is of importance. It may be twice as large as it should be and yet be healthy; and an ovary half the normal size may be the source of serious trouble and require extirpation more than many an ovarian tumor of the size of a fist. This examination should be impressed on the patient as being a difficult feat, for which she must be prepared. The surgeon should not stake his name and reputation on an examination which he makes on a case as it comes to him; with aggravated sensitiveness, with an abdomen full of feces and gas, and with the bladder distended. It is a mistake to attempt an examination under these conditions. Send the patient home with instructions to come prepared properly, and tell her that an anesthetic is sometimes necessary, although it is a disadvantage in that the physician can not tell when he hurts the patient or when he touches a tender spot. And, having enlisted her good will and intelligence to assist in this examination, try to elicit the facts. With such an examination, together with the subjective history and a complete knowledge of the patient's habits, occupation and surroundings, it is usually possible to discover the psychoses.

DR. W. H. HUMISTON, Cleveland, Ohio, stated that in cases of neuroses there is frequently found a leaky mitral valve, an enlarged heart, a prolapsed kidney or a dilated stomach, and the pelvic organs are found to be normal, although the patient may complain of backache and bearing-down sensations. The gynecologist shines in those cases of acquired insanity in women, with no family history of insanity. Repeated examinations have been made by men who have not the eye in the end of the finger, but when examined by a competent man it is found that the ovary is smaller than normal, hard, corrugated and occasioning continuous suffering. In these cases operative results are brilliant; the patient is restored to full mental faculties and her long suffering is relieved. Even in conjunction with the operation these other associated conditions are often found.

DR. F. F. LAWRENCE, Columbus, Ohio, said that this question seems to hinge on the meaning of the term conservatism. Every man who is doing operations tries to do what is right and what is for the best. The patient with a nervous disease should receive the advantage of exactly the same methods of treatment for relief as one who has no mental nor nervous disorder. The fact that a woman is insane is no reason why she should be denied relief from a gross lesion of any kind. In other words, the determination as to whether operative procedures should be adopted depends on the absence or presence of gross pathologic lesions, no matter what the lesion may be. True conservatism means to do promptly and thoroughly that which will replace a pathologic condition by a physiologic, or which will remove gross pathology.

DR. H. O. MARCY, Boston, emphasized the relation of pelvic disease to insanity. Several years ago he asked the late Dr. Bucke, who had charge of the insane asylum in Ontario, containing over 500 insane female patients, what he knew with reference to pelvic disease in these women. Dr. Bucke

said that he had never thought of that. Dr. Marcy advised him, on his return, to have all these patients examined carefully and to report results. Over one hundred of these women were operated on for serious pelvic disease, and over 70 per cent. were permanently restored to their normal mental condition.

DR. G. B. MASSEY, Philadelphia, called attention to the cataphoric diffusion through the vagina of mercuric ions, in inflammation in the pelvis. It does not matter whether this inflammation is in the uterus, in the tubes, in the ovaries or in the parametrium, it is still inflammation. There is something between these two alternatives of pelvic disease and psychosis that must be considered at times, and that is abdominal neurosis, not psychosis. Eliminate hysteria, exclude psychosis, and though hysteria is a manifold complex disease, it can seldom be mistaken, but do not treat cases of abdominal neurosis as hysterics. Do not put them in bed; it will make them worse. Correct the abdominal condition. Decide in every case the output of solids in the urine. See that there is no kidney constipation, and many of these cases will recover.

DR. D. H. CRAIG, Boston, said that in examining the ovaries of young women more healthy looking ovaries are found than in women a little older who have had nearly as smooth a life as the young women. On investigating the subject, it occurred to him that the ovary of a woman comparatively recently entered on her menstrual life is relatively sound, whereas the ovary of a woman who has menstruated for some years has a scar for each time an ovum has ripened and the follicle ruptured. At the middle or end of menstrual life, therefore, the ovary is a much scarred, contracted organ. In the average normal ovary there are from ten to eighteen graafian follicles in process of maturation, and many follicles attain a diameter of 2 cm. Dr. Craig has seen many a badly scarred ovary which gave no clinical symptoms but which was so apparently cystic that he put a cautery point or knife into the sacs of fluid and evacuated a great deal of material, dropped it back, and the woman went on comfortably. The question arises whether those scars were not the result of previously ruptured follicles and whether the "cysts" he evacuated were not maturing graafian follicles. After removing such ovaries, he has had them examined microscopically and in some instances his suspicions were confirmed. Many of the so-called cystic ovaries removed to-day, that have given rise to no clinical symptoms of ovarian disease, are not pathologic ovaries at all but are ovaries containing graafian follicles which are rather larger than common but are simply in process of maturation.

DR. COKENOWER does not believe that any one who has not been a general practitioner first should be a specialist in any line of work, especially gynecology, a fact that his consultation work with general practitioners and other gynecologists has verified. Physicians are too prone to limit their knowledge to their own subject, thus excluding much that is valuable in other subjects; hence, their observations should be more general and their work broader, thus producing better results.

MANAGEMENT OF THE ACUTE STAGES OF ABDOMINAL INFLAMMATION.*

GEORGE ERETY SHOEMAKER, M.D.
Gynecologist to the Presbyterian Hospital.
PHILADELPHIA.

Differential diagnosis is of the first importance, and will first engage the attention of the surgeon. This paper is concerned with the management of acute stages after the diagnosis is made, especially with the question of immediate operation, and only acute conditions will be considered. It may be necessary, clinically, to distinguish the following: Suppurative cholangitis;

suppurative cholecystitis associated or not with gallstones; acute suppurative pyelophlebitis; various kidney inflammations; peritonitis following the perforation of viscera or of cystic tumors; acute hemorrhagic pancreatitis; ureteral calculus. Among intestinal conditions may be found strangulated hernia; obstruction due to bands; intussusception; volvulus of mesentery or of intestine; acute appendicitis; thrombosis or embolism of mesenteric vessels or those of the spleen. Salpingitis, ovaritis, metritis; postpuerperal, traumatic or due to such infecting agents as the tubercle bacillus or the gonococcus.

Of these conditions certain ones do not call for operation, and are, therefore, to be distinguished. Acute suppurative pyelophlebitis, for example, the septic inflammation of the veins of the liver, is an invariably fatal disease. Fortunately, it is usually secondary to an infection along the portal tract, and is, therefore, preventable. A case reported by me was due to acute appendicitis, and another to postperitoneal infection caused by a common pin in the appendix. The primary condition might call for operation, but not the secondary, as the hopeless multitude of liver abscesses and the widespread engorgement of veins by virulent thrombi make radical treatment or even drainage impossible.

Extensive thrombosis of the mesenteric vessels and spontaneous gangrene of the intestine is beyond operative relief, but inasmuch as the area involved may be small enough to make resection feasible, exploratory operation would be indicated were the diagnosis made. It shares with acute pancreatitis certain crucial symptoms. Very sudden agonizing pain, usually above the umbilicus, vomiting, collapse and muscle rigidity. There may also be copious, loose, bloody or coffee-ground stools. The pulse is high and meteorism is very marked. Should the probable diagnosis of acute pancreatitis be made, there is some hope from early operation and thorough drainage. Osler mentions two cases which recovered after partial or total sequestration of the pancreas within an abscess cavity. The mistaken diagnosis of acute intestinal obstruction is very apt to be made in these cases.

Should acute necrosis of the spleen occur from occlusion of its blood supply operative extirpation would be probably useless, but theoretically it would be indicated.

There is a simulation of abdominal inflammation which deserves to be carefully considered, namely, pain referred to the epigastrium or appendix region in the early stages of pneumonia. In most of these rather puzzling cases, however, the real origin of the disease is in the appendix, and the chest symptoms are due to a secondary diaphragmatic pleurisy or to a septic pneumonia. When the onset has been distinctly abdominal, the later development of lung symptoms must not be allowed to befog the diagnosis of appendicitis. We come, then, to a group of conditions in which the treatment, at least, of all the graver types is operative, but in which the indications are to avoid operation in the acute stage, if possible, relieving by simple drainage if compelled to intervene. Operate radically after the primary stages of infection are past. To this type belongs salpingitis in all its forms, gonorrhoeal, traumatic, tubercular, post-puerperal; also cholecystitis, except the fulminating or gangrenous forms. The gall bladder is, however, like the appendix, much more liable to the treacherous, rapidly fatal conditions of profound infection

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

and will not bear at all a management which follows set rules and does not allow of variations.

There remains, then, by far the largest group, namely, that in which operation is indicated at the earliest possible moment of an acute onset. Appendicitis is here included, with some modifications in cases first seen in later stages, also intestinal obstruction, perforation of all viscera, and strangulated hernia. After perforation of any of the viscera, immediate and radical operation is indicated as soon as the diagnosis can be made, or, in severe cases, with very suspicious symptoms, even before the diagnosis is certain. The repair is to be made with as little handling of bowel as possible, the peritoneal cavity being carefully cleaned by sponging if the affected area is small, or by copious irrigation if there are no limiting adhesions and contamination is extensive. Drainage by tube and gauze follows, of the region affected and of dependent points.

Strangulated hernia, or inflamed irreducible hernia, both call for immediate operation, day or night. Patients with such disorders do not bear transportation well, especially if advanced in years. It is often wiser to operate in the patient's home than to invite disaster by transporting him to a hospital. Space forbids here any consideration of operative technic. The truest conservatism almost always calls for the total removal of the appendix as contrasted with a drainage operation in acute attacks. Gonorrheal tubes, if operated on at all, should both be removed into the cornu of the uterus.

MEDICINAL TREATMENT.

In cases where it has been decided not to operate, vomiting is best controlled by withholding all food, and, if necessary, by lavage of the stomach. Feeding by the rectum sustains the strength and rests the disordered digestive tract. Tympany may be relieved by hypodermic injection of salicylate of eserin, 1/100 gr., among other measures. Normal salt solution by the rectum or under the skin flushes the kidneys, relieves thirst, sustains the pulse and assists in the elimination of toxins.

The ice bag is probably the most useful local agent we have. Ichthyol may be applied to the skin under it. Flannel should always intervene to take away the sense of chill. My custom is not to use ice continuously, but two hours out of every three. Local sloughs have been reported as caused by its continuous use.

Opium in acute conditions is dangerous, because it masks the symptoms and has thus caused many deaths.

Acute cholecystitis, whether due to gallstone disease or to infection by specific organisms, such as the typhoid bacillus, may be cautiously watched through acute stages with everything ready for immediate interference if called for. Gangrene and perforation are not common, but they call for immediate operation at any time when they may be discovered.

APPENDICITIS.

Next to inflammatory disease of the pelvic organs in women, quite the most frequent cause of acute abdominal inflammation is appendicitis. As is well known, the pain and tenderness may be referred to the epigastrium or liver region, to the pelvis, or even to the left side of the lower abdomen. Should a patient have sudden severe pain in these regions, with chilliness, vomiting, a little fever and an anxious expression of the face, with muscular rigidity over the right abdomen in the lower quadrant, appendicitis is probably present. No matter where the pain may be referred, the muscular rigidity is always over the diseased organ.

When the attack of acute appendicitis is serious and decided, there is general agreement that the appendix should be at once removed. No time should be lost in obtaining a blood count, which can only corroborate what the clinical picture teaches. If taken, however, it will probably show a leucocytosis above 15,000, with a tendency to increase; but a high white cell count alone is not a good guide for or against operation, though it furnishes valuable corroborative evidence. Its absence need not be too highly regarded if other symptoms of gravity are present, especially an unsatisfactory pulse and a facies which shows anxiety, associated with sallowness or slight jaundice and duskiess. In profound toxemia the facial expression may be dull and listless.

Micro-organisms.—The organisms most frequently met in abdominal inflammations are the gonococcus, the colon bacillus, the streptococcus, the tubercle bacillus and staphylococci. The typhoid bacillus is occasionally found in pure culture in the gall bladder, as in one of my cases.

However difficult it may be to demonstrate it in the laboratory, there are undoubtedly stages of growth in which organisms vary greatly in their power to produce toxemias. Widespread as the colon bacillus is, it is only in some stages that it forms a highly dangerous infective agent. For example, in gunshot wounds of the healthy intestine, these bacilli escape into the peritoneal cavity without doing harm, if reasonably prompt suture of the openings and the toilet of the peritoneum is carried out. A similar amount of implantation of the same bacillus as it appears when migrating through the walls of a gangrenous volvulus gives rise to a rapid form of infection after an equivalent number of hours' residence in the peritoneum, which no amount of irrigation or cleansing is able to offset.

The comparison intended is the same as that which may be made between the organism of diphtheria demonstrable in the discharges of ozena, as compared with the same organism appearing in the infectious stages of true diphtheria. The same difference holds good in regard to stages of virulence in streptococci and the pus-forming organisms.

The deduction is this, that under the conditions which obtain when the bowel wall is acutely inflamed, especially where the blood supply is suddenly cut off, virulent states of previously benign organisms rapidly develop.

Most important in the case of appendicitis is the concealment under which this process at times proceeds. A history such as this is well known in the experience of every operating surgeon. A patient has appeared perfectly well till within thirty-six or forty-eight hours of the time he is brought for operation. For the first twenty-four hours of that time symptoms have been so mild as not to confine him to bed, and to his friends, or even to his physician, there has seemed little cause for anxiety. The temperature was not above 99, and there was little pain, though for a few hours in the beginning it had been severe. Only the pulse was suspiciously high. Twelve hours later the patient's condition had obviously changed for the worse; the pulse was 120 to 130 and feeble, the tongue dry, the face anxious and slightly jaundiced, or with a sickly pallor. In such a case the temperature may be from 99 to 101. Tenderness of the abdomen may be slight or severe, according to whether the entire area involved is gangrenous, or whether surrounding peritoneal areas are only inflamed. The skin becomes leaky, the pulse thready, rapid and running, the voice weak. The subcutaneous capillaries

are irregularly distended; there are mottled bluish patches about the abdomen and thighs; the mind, at first clear, becomes dull. The patient, who seemed so well after the first twenty-four hours, is at the end of forty-eight hours on the verge of the grave.

What has happened here is that profound toxemia has developed quietly, while the absence of marked pain or extreme degrees of temperature, vomiting or tympany has given the attendants a false sense of security. There may or may not have been a rupture of the appendix. There has been here the development of a highly virulent condition of the ordinary bacilli of the intestine. The products which accompany their growth are intensely poisonous. Absorption has taken place through portal vein radicles and has reached the liver, or post-peritoneal lymphatic channels have poured it into the great lymph streams. Whatever the route, the toxic dose received by the patient was sudden and overwhelming. In spite of operative removal of the appendix and drainage at this time, early in days but late in infection, there is little hope for the patient. It is the treacherous character of infection of the appendix, its power of remaining latent or concealed, and bursting forth into an overwhelming toxemia, that furnishes the keynote for the management of the disease.

If seen early, operate early and radically, in all except the simplest cases, without waiting for dangerous symptoms, when it may be too late. The management of late stages, seen only when late, presents special problems.

INFLAMMATORY CONDITIONS IN THE PELVIS.

The second most formidable infecting organism met with in acute conditions is the streptococcus. Especially as found in post-puerperal inflammations, it gives rise to many fatalities. The cardinal principles of management of such infections may be briefly summarized as follows: Avoid, if possible, opening the general peritoneal cavity. Thoroughly cleanse the vaginal and uterine field by gentle mechanical removal of debris without abrading fresh surfaces. Use tincture of iodine and loosely pack uterus and vagina with iodoform gauze.

If the conditions be not promptly arrested, open the vaginal cul-de-sac and isolate the uterine field by iodoform gauze, as advocated by Pryor. Should pus form in the pelvis, every effort should be made to drain it from the vaginal side to tide over the acute stages. Operate radically weeks or months later, if necessary, when much of the danger of peritoneal operative infection will have passed away. Acute symptoms, due to tuberculosis of the tubes and ovaries or of the urinary tract, are, if severe, apt to be due to mixed infection. It is wiser not to operate radically in the height of an inflammatory attack, but to tide over the acute period by ice externally and general measures, including good care and nursing. Pus is to be immediately drained away, for example, from the kidney, reserving nephrectomy for a later period.

Gonorrhea is the most common, and to life least dangerous, of the causes of acute abdominal inflammation, especially in women. Its results in producing permanent ill health are, however, appalling, and many deaths follow more or less indirectly. Immediately after a menstrual period, or immediately after childbirth, a fresh infection appears more liable than at other times to spread to the peritoneum and to give rise to serious lesions.

In the acute stage prompt attention will greatly modify the destructive process. Rest in bed, liquid diet,

saline laxatives, external cleanliness, gentle irrigation with lysol or potass. permanganate, 5 per cent. protargol solution to the urethra, will promptly ameliorate the external symptoms, and while these measures do not cure the tubal conditions, they lessen the tendency to reinfection and extension. Prompt amelioration of pain, temperature and tenderness should follow. According to Pryor, opening the vaginal cul-de-sac and packing the pelvic cavity with properly prepared iodoform gauze will prevent serious lesions of the tubes in nearly all cases if done promptly. Radical extirpating operations should never be done in the acute stages, especially of first attacks. Too long delay, however, may be worse, and if pus forms in quantity it must be evacuated by the nearest route; otherwise it may burrow or perforate into bowel or bladder. Gonorrheal cases are not favorable for partial operations, which aim to preserve organs. No greater contrast in the management of acute conditions exists than between that of acute appendicitis and acute gonorrheal salpingitis, or salpingitis due to cold or dampness while menstruating. In appendicitis, owing to the treacherous nature of the disease, operation is usually safer than waiting, and, except in the simpler cases, it should be done as early and as completely as possible, being followed by free drainage. The appendix can be removed in all but the most exceptional cases, and it should be done.

In salpingitis all palliative measures should be employed during the acute stage, and operation never undertaken then except for good reason. If necessary to drain a large pus collection, do it preferably by the vagina. In gonorrhea a few cures will be accomplished in this way, though the mortality of the subsequent major operations will be greatly lessened. It is possible thus to handle a series of pus cases with a mortality of 4 or 5 per cent. As bad pus cases formerly constituted the chief element in mortality in any series of unselected cases, a great gain has been made by the adoption of this plan of management, so that it is now possible to keep a general operating mortality well under 6 per cent. and to have a long series of cases without a death. The mortality in the simpler chronic gonorrheal salpingitis cases is almost nothing.

REMARKS.

No greater mistake can be made, however, than to make these rules apply rigidly to all cases. The surgeon must ever be on the alert for signs which call for immediate operative interference.

Of danger signals, the most important is the pulse. A rate high in proportion to the severity of other symptoms is very suspicious and should lead to the utmost vigilance. An ascending rate with a diminishing quality means danger, and this no amelioration of other symptoms should outweigh. The temperature is an unsafe guide in abdominal inflammation, as the gravest lesions may be accompanied by little rise and a fall may be deceptive. A simultaneous and continued rise of both pulse and temperature is always unfavorable. Leucocytosis above 15,000 with a tendency to rise usually points to operation. A decided fall in a patient evidently very ill is not a good sign. Other unfavorable signs are persistent vomiting, increasing tympany, sweating, thoracic respiration, increasing muscular rigidity, failure of peristalsis, local edema. Pain generally improves with the patient's condition. A sudden cessation in an otherwise ill patient may point to gangrene.

DISCUSSION.

DR. JOHN H. FISHER, Philadelphia, indorsed all that Dr. Shoemaker said on the management of acute inflammatory conditions in the abdominal and pelvic cavities, but emphasized that the tolerance of the peritoneum differs in various portions of the abdomen. It is more tolerant in the pelvis than in the upper portion. In acute inflammations in the pelvis acute symptoms should subside before operation. No risk should be run in appendicitis. The patient's life is not jeopardized by an early operation. In a gonorrhoeal case Dr. Fisher recently removed a large pus tube from one side. He thought of removing the other tube, but a physician present said that it was healthy and suggested that it be left. Dr. Fisher left it and the patient has since returned to have it removed. Gonorrhoea in a female, although it may appear to involve only the appendage of one side at first, always becomes bilateral, and during an operation, when one side appears to be healthy, it is best to remove the tube, leaving, if possible, an uninvolved ovary.

DR. F. B. DORSEY, Keokuk, Iowa, said that for a number of years it was his practice in gonorrhoeal patients to remove the tubes and to consider the patients cured, but on investigation he found that they have constant leucorrhoea. For the last four or five years, whether the trouble is unilateral or bilateral, he removes the uterus also, and the results have been very satisfactory. He can not recall a single death from a gonorrhoeal inflammation during the acute stage, except those who were operated on by other men during the acute stage. The acute symptoms should subside before operation. If there is a mixed infection, drain through the vagina until the primary attack has subsided, and then do a radical operation. In mixed infection there is trouble outside of the tubes, involving, perhaps, the broad ligament or some of the other tissues. We are not yet able to differentiate between a return to the normal and gangrene; nor can we diagnose, in some cases, the presence of pus in or about the appendix. Within the last three months in four patients with normal temperature he found pus.

DR. CHARLES L. BONIFIELD, Cincinnati, Ohio, declared it bad practice to remove both tubes and the uterus in every case because one tube is infected with the gonococcus. In the later cases he believes that one tube should be removed and the uterus curetted; part of the other tube and ovary may be removed and the woman will still be able to give birth to healthy children. In some cases, one appendage is removed and the woman is apparently cured of the gonorrhoeal discharge. Afterward she has another gonorrhoeal discharge and infection of the other tube. There is no proof that this came from the original infection, because one of two things is taking place—either the woman is a prostitute and has been exposed to gonorrhoea since the operation, or she is married and her husband has gonorrhoea. Dr. Bonifield has seen a number of such cases where a woman was infected several weeks after coming from the hospital. Many of these instances of persistent discharge from the uterus are due to the fact that the removal of the tubes was imperfect. In the early days the tube was tied off anywhere near the uterus. Now, the careful surgeon will not only cut off the tubes close to the uterus, but he will dissect out the horns and thus prevent secondary infection. The inflammation inside the uterus can be cured by repeated curettage and prolonged local application. Gynecologists make a mistake when they curette and promise the woman she will be well. She should be instructed to come back to the office for inspection a few weeks after the curettage, and often it is necessary to continue the local applications.

DR. SHOEMAKER said that in his service in the Presbyterian Hospital, Philadelphia, he had 83 consecutive operations with only one death. These included several cases of bad pelvic abscess, two from gonorrhoea with gangrene of the intestine, just on the point of perforation; but both cases got well, although they would have died if they had not been operated on. Sometimes he removes the uterus and sometimes he does not, but the cornua should always be removed. Leaving one tube

in the presence of the gonococcus is bad policy, unless there is a strong reason for making the effort, and we explain to the patient that she may require a secondary operation. He has tried the conservative method a number of times on gonorrhoeal cases and has been disappointed. Almost invariably he had to do a secondary operation later. An uninvolved ovary will not very often become infected.

ENURESIS IN CHILDHOOD.*

Assistant Pediatric Physician and Assistant Physician to the Children's Dispensary, University Hospital.

PHILADELPHIA.

Experience has taught that incontinence of urine, while not uncommon in adults, in women especially, is constantly noted in institutions for the treatment of children. During the past five years at the children's dispensary, University Hospital, we have found 85 cases of enuresis among 1,657 new patients treated, one out of almost every twenty children manifesting this condition, about 5 per cent. These figures tend to corroborate the statement made by Townsend¹ that, when the families of children applying for treatment at the Children's Hospital, Boston, were questioned, 21.5 per cent. of all children were found to have or to have had enuresis. Out of 1,500 children, however, he found but 25 with incontinence of urine, about 1.6 per cent, while Adams² reported 55 cases out of 19,261 children, about .25 per cent. It is probable that more of the children whom we saw suffered from enuresis, although the limited history taken failed to elicit this fact. Adding to these five cases recently observed in private practice, we have the honor to present 90 cases of enuresis in children, detailing our plan of treatment.

The incontinence occurred at night only in 53 cases; was both diurnal and nocturnal in 35 cases; and was diurnal only in two cases. Forty-seven patients were boys and 43 were girls. In 59 children the enuresis persisted from infancy, called by Townsend "primary" cases; in 11 cases it was first noted at 3 years; in four at 4, 5 and 6 years; in three at 9 years; in two at 7 years, and at 8 and 12 years, respectively, in one child, making 30 "secondary" cases. In one case the time of onset is unknown.

Twelve of the 90 children treated were of Jewish ancestry, six boys and six girls. All these boys were circumcised in infancy. Four other boys had also been circumcised, in only one of whom did the operation result in permanent recovery. Five children, four boys and one girl, made up an entire German family, two of the boys being twins. One boy was a Syrian, one girl Italian, and two boys were French; the others were all American born. The mother and six sisters of one boy were epileptics, and he also had epilepsy. It is interesting to note here that Trousseau³ believed enu-

resis to be more frequent among epileptics. The history of two boys showed tuberculosis, of two alcoholism, and of two hereditary syphilis, while one boy and three girls gave a decidedly neurotic family history.

Of the complications noted, chronic gastrointestinal indigestion was by far the most common, occurring in 38 cases, sixteen boys and twenty-two girls. Nasopharyngeal catarrh was noted in 17 cases, ten boys and seven girls; hypertrophied tonsils or tonsillitis in 8 cases, five boys and three girls; adenoids in 8 cases, four girls and four boys; enlarged cervical glands in four boys; otitis in one boy and three girls; eczema in two boys and one girl; hereditary syphilis in two boys; chorea in one boy and one girl; vulvovaginitis in two girls; oxuris in one boy and one girl; ascariides in one boy; asthma in one girl, and undescended right testicle in one boy. Masturbation is known to have been present in one boy only. Besides, two of the girls treated had recently been discharged from institutions in which enuresis is notably frequent.⁴ Morris⁵ says it occurs in one out of every twenty boys in reformatories, and is more common among colored than white children. This we cannot confirm, as only two of our cases occurred in colored children. But we should state that the ratio of white to colored children at the children's dispensary, University Hospital, is about 40 to 1. One girl had a rectal polyp, but its removal did not cure the incontinence, as occurred in Townsend's case.⁶ Of the eight children with adenoids, six had undergone operations for their removal without more than temporary improvement of the enuresis.

The question of the etiology of enuresis has received much discussion. Yet, in the majority of cases, the cause remains unknown. In many cases the condition was first noticed after some debilitating illness, such as the infectious diseases. In 27 of our 30 "secondary" cases, the cause of the enuresis was known. In these cases, as in the majority of cases in which the cause remains unknown, it seems probable that the tonicity of the vesical sphincter muscles is lowered; in some cases the entire musculature of the bladder walls decidedly needs toning. That, out of 90 cases, we only had 27 in which the cause was known, is directly contrary to the figures quoted by Townsend, who found some cause which could reasonably be held responsible in 69 per cent. of cases. Two of our cases resulted from being accidentally run over; 3 were due to cystitis, with osteoma and congenital malformation of the sacrum in one; one to diabetes mellitus; one to an old hemiplegia; and one to excessive acidity of the urine. Of the 19 cases in which enuresis followed some infectious disease, 8 appeared after measles, 5 after pertussis, 3 after scarlet fever, 2 after typhoid fever, and one after diphtheria.

In every case we attempted first to correct all errors in diet. Tea and coffee, fresh bread and cake and fried things were forbidden absolutely; nothing was allowed between meals except milk; no liquids were permitted after supper, and the fluid taken at that meal was limited to one cup or glassful. Cold sponge baths of two minutes' duration, followed by rubbing the entire body with a Turkish towel, were ordered daily on rising; and associated conditions, such as gastrointestinal or nasopharyngeal catarrh, otitis, tonsillitis, eczema, worms, etc.,

were given special attention. In a few cases a folded towel was fastened to the child's back, preventing sleeping on the back; in some cases, too, the foot of the bed was elevated, according to Stumpf's method.⁷ If analysis of the urine showed hyperacidity, potassium citrate was given. In all the boys the foreskin was stripped back regularly and adhesions freed, when this was possible; when there was phimosis circumcision was advised. In every case in which the presence of vesical calculus was suspected, skiagraphs were made or sounds introduced. Yet no calculi were discovered among our 90 cases, in spite of their recorded frequency. The one case in which vesical calculus seemed the most probable cause of enuresis failed to return for further treatment.

Tincture of belladonna was first prescribed, in ascending drop doses, beginning with three drops three times daily, increasing one drop a day. With this a bitter alkaline tonic was given before meals.

When as many as ten or fifteen drops of tincture of belladonna thrice daily failed to control the enuresis, aromatic tincture of rhus was tried, increasing gradually up to 30 minims a day. If this also failed, as it usually did, a solution containing 1/240 gr. of atropin and 1/480 gr. of strychnin to the drop was given. The initial dose was one drop a day, increased one drop daily until symptoms of the physiologic action of atropin or strychnin appeared, or the enuresis ceased. In one or two of these cases potassium bromid was also given. In a few cases the medicine was given after supper only; in some after dinner and after supper; but in the majority of cases, three times a day, with the largest dose always in the evening. In 13 cases electricity was tried, with or after aromatic tincture of rhus, with success in but one case.

On this treatment 67 out of 90 cases recovered, almost 75 per cent., in 53 of whom recovery is known to have been permanent. From the 14 other patients who recovered, nothing has been heard for varying intervals of time, though they had recovered when we last saw them. Nine patients were recorded as improved and seven as unimproved, three of whom had cystitis. In 6 cases the result of treatment remains unknown; one death occurred, from diabetes mellitus, almost sixteen months after symptoms were first noticed.

Of the 67 cases cured, 37 followed the administration of tincture of belladonna, in doses ranging from six to fifty-seven drops daily, and 23 the administration of the atropin-strychnin mixture, in doses varying from one drop (atropin gr. 1/240 and strychnin gr. 1/480) to thirty-three drops (atropin gr. 1/7 and strychnin gr. 1/14). In the last case no physiologic symptoms appeared, in spite of the massive dose. In two patients recovery resulted from diet and hygiene alone; in one it followed 15 grains of potassium citrate daily, besides; in another, 27 minims of aromatic tincture of rhus daily; in another, circumcision; in another, tincture of belladonna with potassium bromid; in still another, the atropin-strychnin solution, together with potassium bromid. In the children with chorea, one boy and one girl, no strychnin was given, but the dose of potassium bromid was greatly increased.

Of the 9 patients who only showed improvement, 5 were taking tincture of belladonna, 2 the atropin-strychnin mixture, one aromatic tincture of rhus, together with the application of electricity, and another the

5. Med. and Surg. Reporter, 1881, vol. xlv, p. 652.

6. Boston Med. and Surg. Jour., 1892, vol. cxxvii, p. 592.

7. Münchener med. Woch., 1895, vol. vi, p. 265.

atropin-strychnin mixture with potassium bromid. Of the 7 cases marked unimproved, 3 had cystitis, 2 were on tincture of belladonna only, 1 was taking the atropin-strychnin mixture, and 1 the tincture of belladonna and aromatic tincture of rhus.

The duration of treatment in the 67 cases which recovered was as follows:

Cases.		Cases.	
3 weeks in.....	16	16 weeks in.....	3
6 weeks in.....	11	1 week or less.....	2
2 weeks in.....	10	7 weeks in.....	2
8 weeks in.....	6	12 weeks in.....	2
4 weeks in.....	4	11 weeks in.....	1
5 weeks in.....	3	20 weeks in.....	1
9 weeks in.....	3	Unknown.....	2

Omitting the 2 cases in which the duration of treatment was unknown, this gives an average of five and one-half weeks of treatment for each child.

There was recurrence in 17 of the 67 cases which recovered, generally with the first cool nights in the fall; sometimes, too, whenever too great a quantity of fluid was ingested. In these cases some drops of the tincture of belladonna, aromatic tincture of rhus, or the atropin-strychnin mixture cured the condition in a few days.

Of the two boys with diurnal enuresis, one was cured on the atropin-strychnin mixture; in the other the result remains unknown. Of the 35 with both diurnal and nocturnal enuresis, 22 were cured, 2 improved and 5 unimproved, including 3 with cystitis, while the result was unknown in 2 and in 1 death occurred, from diabetes mellitus. Of the 53 with nocturnal enuresis, 43 were cured, 7 improved, 1 unimproved, and in 2 the result was unknown.

A review of the prolific literature on enuresis, now over three times as long as that reviewed by Adams⁸ in 1884, brought to light many ancient and modern methods of treatment. The majority of writers rely on belladonna or atropin, with or without strychnin, yet the lack of any uniform, routine mode of treatment for those cases in which the cause is unknown is a possible reason for failure. Thiemich,⁹ Reinach,¹⁰ Hippus,¹¹ and others consider the condition hysterical and urge suggestion and hypnotism in the treatment; Rousseau St. Philippe,¹² Gundobin,¹³ Perles,¹⁴ Freyberger,¹⁵ and others rely on aromatic tincture of rhus, while Thomson,¹⁶ Leonardi,¹⁷ Marchionneschi,¹⁸ Becchietti,¹⁹ Ademollo,²⁰ and others employ chloral. Electricity, quinin, other drugs and various operations have all been in vogue.

The idea that the child will outgrow the condition appears to us erroneous, especially as our oldest patient reached the age of 19 years before being cured. Circumcision has been advised in all cases with preputial adhesions of phimosis, but is very rarely permanently curative. More recently epidural injections²¹ have been employed with success. We tried to secure a patient

for this operation among those in whom our treatment failed, but were unsuccessful. The many other modes of treatment, subcutaneous injections of normal salt solution, cocaine, air, blisters to the perineum, rectal massage, etc., seem to us useless.

We conclude, then, from our results—almost 75 per cent. of recoveries—that our routine method of treatment is of decided value in enuresis. We would add, as a further step, based on the results achieved by others, epidural injections, when negative results have been obtained on the plan of treatment outlined above.

DISCUSSION.

DR. EDWIN E. GRAHAM, Philadelphia, emphasized the fact that treatment in enuresis should be kept up for a long time. These cases often drift from one clinic to another, and remain un cured because the treatment is not carried out systematically. The belladonna and strychnia are usually given in too small doses and not continued long enough; they should be given in increasing doses, and continued for weeks and even months and should not be discontinued as soon as an improvement or apparent cure takes place. After the cure has lasted for two or three weeks the dose can be gradually reduced.

DR. ISAAC A. ABR, Chicago, had an experience during the past winter in the treatment of enuresis which has been instructive to him. A little girl of 7 years had been under his care for a long time, suffering from nocturnal enuresis. The child was in excellent health, the urinary examination was negative and for the enuresis she was given 1/200 grain of atropin twice daily. She took this from the first of January until the middle of April. The enuresis improved very much, and the use of the medicine was continued. After the child had taken the drug for a long time, she complained one day at school of dizziness, and the mother noticed that she blushed frequently. About 2 o'clock one morning Dr. Abr was called to see her. The parents told him that for several hours she had been actively delirious. She was dreadfully excited, very voluble, and labored under the hallucination that the neighbor's house was on fire, and no amount of persuasion could convince her that her own home was not already aflame. Her pulse was between 80 and 90, and of good quality, the respirations were from 24 to 26 a minute, temperature normal; the pupils were dilated and reacted slowly to light, and the tongue and mouth were dry. After leaving the case that night it occurred to him that she had been taking atropin for her enuresis and that this might bear a causal relation to her delirium. The delirious condition continued more or less for four days, at the end of which time no further disturbances occurred. The case was undoubtedly a toxic delirium caused by the continuous use of atropin. He believes that this is a valuable point to be borne in mind in connection with atropin treatment of enuresis.

DR. MAURICE OSTHEIMER said that while symptoms of poisoning from the use of atropin in these cases are not at all uncommon, they never do much harm. In one instance a nurse accidentally gave a child a dram of a mixture containing 1/120 of a grain of atropin to the drop. The child recovered entirely from the effects of the overdose within twenty-four hours.

Antagonism of Alcohol and Strychnin.—Dr. J. M. French, in an article in *Merek's Archives*, says that few physicians recognize that there is an antagonism between alcohol and strychnin. He says that the keynote of strychnin is stimulation and that of alcohol paralysis. Strychnin increases the acuteness of touch, perception and also muscular resistance, while alcohol lessens the ability to distinguish heat and cold and makes the touch defective. Strychnin renders the sense of smell abnormally acute, while alcohol renders it defective. Dr. French concludes that, as the two substances are directly opposed in their therapeutic effects, their conjoint use is an absurdity and that whatever benefits may result from administration of strychnin are not observed when it is used as an adjuvant of alcohol.

HEMATURIA AS THE EARLIEST OR ONLY SYMPTOM OF INFANTILE SCURVY.*

JOHN LOVETT MORSE, A.M., M.D.,

Instructor in Pediatrics, Harvard Medical School; Assistant Physician at the Children's Hospital and at the Infants' Hospital.
BOSTON.

Very soon after the existence of infantile scurvy as a clinical entity was established, it was recognized that hematuria was a not uncommon symptom. All writers on the subject refer to hematuria as one of the symptoms, but very few lay any stress on it or emphasize its importance. Holt¹ says that it is seen in about 5 per cent. of the cases while Rotch² says that it has been noticed in a certain number and that it is well to examine the urine when this disease is suspected.

While all writers mention hematuria as one of the symptoms of scurvy, most of them give the impression that it is rather an unusual symptom and certainly not an important one. Very few call attention to the fact that it may be the earliest symptom, and hence, for a time, the only symptom. Holt¹ says that in rare cases hematuria has been the first symptom noticed; Williams,³ that hematuria may be the solitary sign of scurvy; and Barlow,⁴ that it may occur without limb symptoms and respond immediately to the addition of living food to the dietary. Carpenter⁵ has also referred to it a number of times in discussions.

It seems strange that the importance of hematuria as an early sign of scurvy has been so little appreciated, as some of the earliest writers called attention to it. Gee,⁶ in 1889, in a paper entitled "Bloody Urine of the Only Sign of Infantile Scurvy," reported two cases. Thomson,⁷ in 1892, reported a case of hematuria of a month's duration in a child of seven months. No other symptoms beside lassitude were noted, and recovery was rapid under antiscorbutic treatment. Barlow,⁴ in 1894, reported two cases of hematuria in infants in which there were no bone lesions, but excessive irritability, resentment to the slightest touch of the lower limbs and a certain amount of anemia. Both recovered rapidly under antiscorbutic treatment. A few similar cases have been reported since then, but in none has the importance of hematuria as an early or as the sole sign of scurvy been fully emphasized.

My experience leads me to believe that hematuria is not only a more common symptom of infantile scurvy than is generally supposed, but that it is comparatively often one of the earliest symptoms, if not the earliest, of the disease, and that it may be for a considerable time the only symptom. The following cases are examples:

CASE 1.—J. W. was an eight months' baby. He was never nursed, but was fed from the first on a pasteurized, modified milk, prepared at the Walker-Gordon laboratory. He did very well until he was about 8 months old, when he ceased to gain, and began to lose in color. September 27, when 9 months old, he began to pass bloody urine. It was red, slightly acid, of a specific gravity of 1008, and contained $\frac{1}{8}$ per cent.

of albumin. The sediment contained normal blood and a few small, round cells. There were no other symptoms except that he was rather more fussy than before. Nothing was found on physical examination to account for the condition of the urine. The hematuria persisted in spite of alkalies and urotropin. On October 17, nearly three weeks after the onset of the bloody urine, the nurse reported that his back seemed to hurt him and that he disliked to be bathed or handled. Physical examination failed to reveal any other signs of scurvy, but, as the combination of hematuria and tenderness suggested this disease, he was given orange juice. The tenderness disappeared in a few days and the urine was entirely free from blood by the first of November.

CASE 2.—Baby S. was the second child of healthy parents. She was healthy at birth and weighed about 10 pounds. She was fed on the breast for a few weeks, then on cereal milk for three or four months, and after that on Eskay's food. This was prepared with scalded milk. She was perfectly well up to eight months, except for occasional regurgitation. She had not vomited for three months. Her movements had always been normal in character, although she had recently been slightly constipated.

When she was 8 months old it was noticed that the urine stained the diapers. A month later a small specimen was taken to her physician, who found a little blood in it. The urine was not examined again until four days before I saw her, when she was 11 months old. At that time it was reddish, and undoubtedly contained blood, but as it was decomposed no microscopic examination was made. The parents said that the redness of the urine varied from time to time. She passed water frequently, but micturition was not painful. Her parents thought that the quantity of urine was not diminished and said that she drank a great deal of water. She perspired considerably, but had no fever. Tuberculosis of the bladder had been suspected and the urine examined for tubercle bacilli. None was found. Chronic arsenical poisoning had also been suspected. No examination of the urine for arsenic had been made, however. She had been pale for four or five weeks, and had not gained in weight for a number of months. During the last week her legs had been tender, and she had cried out when handled. She had been afraid of being touched for two days.

Physical Examination.—She was fairly developed and nourished, but markedly pale. There were no subcutaneous hemorrhages. She was very much afraid of being touched, and screamed when approached. The gums were not at all inflamed about the teeth. There was some tendency to hold the legs flexed at the hips and knees. Passive motions caused some pain, but were not limited. No enlargement of the bones was made out, and no local tenderness.

Treatment.—She was put on fresh milk, with lime water, and given two tablespoonfuls of orange juice daily. She began to improve almost immediately and was well in a few days. There was no recurrence of the hematuria.

CASE 3.—K. P., 15 months old, was the first child of healthy parents. He had never nursed and had never been able to take milk. Although large and fat, he had always been a little backward in development. For some months he had been fed on condensed milk and barley, with occasionally a little bread and cracker. About six weeks before I saw him micturition was said to have been painful for a day. The urine was examined a week later and a trace of albumin, a small amount of normal blood, and a very few fine granular casts found. He was given citrate of potassium, but there was no improvement in the urine, which continued to contain a trace of albumin and normal blood. Casts were never found again, and no bladder elements were ever seen. During the last two days the amount of blood had increased so much that the diapers were stained red. The urine was passed in sufficient quantity. Benzoate of soda and cystogen had been tried without relief. Acute nephritis or tumor of the bladder was suspected. Further questioning elicited the information that the legs had been a little tender since the beginning and that he had given up trying to stand. His appetite had been good.

6. Gee: St. Barthol. Hosp. Reports, 1889, vol. xxv, p. 85.
7. Thomson: Lancet, 1892, vol. I, p. 1292.

There had been no vomiting and the movements had been normal. He had lost a little weight and much color. He had had no fever at any time.

Physical Examination.—He was well developed and nourished. There was moderate pallor. The anterior fontanelle was widely open, the head somewhat square. There was a marked rosary and moderate enlargement of the epiphyses at the wrists. There were two lower incisors. The gums were normal. The kidneys were not palpable. The genitals were normal. No evidence of tumor of the bladder could be made out. He cried when his legs were handled. Both active and passive motions were free, however, and there was no enlargement of the bones. His eyelids were slightly puffy. Numerous ecchymoses, which had previously escaped notice, were present on the knees, forehead and body.

Treatment.—The diagnosis of scurvy was made and antiscorbutic treatment instituted. Recovery was almost immediate.

CASE 4.—J. S., 10 months old, had been fed for some months on a home-modified milk, pasteurized, and on the whole had done very well. About two-weeks before I saw him his mother noticed that the urine was bloody. She took it to her family physician, who examined it and found fresh blood, but nothing else abnormal. He did not understand the condition and gave nux vomica as a tonic. The urine continued to contain blood, the amount varying from time to time. About a week after the urine became bloody, the mother noticed that he disliked to be handled during his bath. She soon discovered that his legs and back were tender. This tenderness increased. The diagnosis of rheumatism was then made by the attending physician and tonics prescribed. The swelling of the gums had not been noticed.

Physical Examination.—He was rather pale. The gums were somewhat swollen and a little purplish about the four lower teeth. He held both legs slightly flexed at the knees and thighs. Passive motions were not limited, but caused considerable pain. There were no subcutaneous hemorrhages. The physical examination was otherwise negative.

Treatment.—The diagnosis of scurvy was made, and un-pasteurized milk, orange juice and beef juice ordered.

He was very much better in two days, and well in a week. The blood quickly disappeared from the urine and did not recur.

In these cases other symptoms of scurvy were present and revealed the nature of the hematuria. In the following cases hematuria was the only symptom. Their rapid response to antiscorbutic treatment, however, justifies the diagnosis of scorbutic hematuria in them also.

CASE 5.—L. P. was the first child of healthy parents. She had always been fed on pasteurized milk prepared at the Walker-Gordon laboratory. She had done very well until she was 6 months old, when she ceased to gain and lost her appetite. When she was 7 months old her mother noticed that at times the urine stained the diapers red. This staining was attributed by the physician in charge to uric acid. It continued intermittently for a month, when the urine was examined and found to contain fresh blood, but no casts. There were no other symptoms whatever, except failure to gain in weight. Orange juice was begun the next day. The urine was clear in less than two weeks and has so remained. The child also at once began to gain in weight.

CASE 6.—S. T., 6½ months old, had been fed for two months on a modified milk prepared with Mellin's food. She had lost her appetite and had not gained for over a month. Otherwise she had seemed perfectly well. When she was about 6 months old her mother noticed that the urine stained the diapers red or brown. She did not report it, however, until two weeks later. The urine was then red, alkaline, and contained ¼ per cent. of albumin. The sediment showed much normal blood, with an occasional hyaline cast and small, round cell.

The physical examination was entirely negative except for a slight rosary. Orange juice was begun at once. Improvement in the color of the urine was noticed in twenty-four

hours. It was clear in five days and so remained. The appetite also improved at once, and gain in weight began and continued.

CASE 7.—F. F., 10 months old, had been fed on Eskay's food for some months. The Eskay's food was boiled in water and then milk was added to the boiling mixture. This undoubtedly sterilized the milk. He had apparently done very well on this food, except that his bowels had been somewhat constipated. He had been unusually fussy for two or three days, and the day before had passed bloody urine in small amounts. The urine had continued bloody, and that morning there was a little puffiness about the right eye. Acute nephritis was suspected by his father, who was an apothecary, and by the attending physician.

Examination.—Physical examination showed nothing whatever abnormal, except a slight rosary and a slight swelling above the right eye. There were four teeth, but the gums were healthy. There was no tenderness of the extremities or pain on motion. The urine was red, acid, of a specific gravity of 1008, and contained ¼ per cent. of albumin. The sediment showed much normal blood and an occasional leucocyte.

Treatment.—The Eskay's food was continued, but was cooled before the milk was added. He was ordered orange juice and beef juice. He refused the orange juice, but took the beef juice very well. The urine was clear in five days.

In one of these cases the onset of the hematuria was accompanied by pain and tenderness in the extremities. In one the hematuria preceded any other symptom of scurvy by three months; in another by three weeks, and in another by one week. In three others in which the hematuria had been present for one month, two weeks and two days respectively, without any other symptoms, recovery was almost immediate under antiscorbutic treatment. These cases seem amply sufficient to prove that hematuria may be the earliest, and for a time the only symptom of scurvy.

The fact that all these cases were seen within three years goes to show that they can not be very uncommon. During the same period only one case of hematuria in an infant from any other cause was observed. This shows that scurvy must be one of the more common causes of hematuria in infancy. In fact, my experience leads me to believe that it is the most common cause of hematuria in infancy.

Few physicians realize, I think, that an uncomplicated hematuria in infancy may be due to scurvy or take it into consideration when seeking the cause of a hematuria. Certainly no one of those who saw the cases just reported had considered or even suspected scurvy as an etiologic factor. It is with the hope of again bringing the importance of scurvy as a cause of hematuria in infancy to the attention of the profession that these cases are reported.

CONCLUSIONS.

Hematuria may be the earliest symptom of infantile scurvy, and therefore for a time the only symptom. Scurvy is the most common cause of uncomplicated hematuria in infancy.⁵

DISCUSSION.

DR. LOUIS CURTIS AGER, Brooklyn, asked Dr. Morse which method of collecting urine from small children he recommends. There are various ways of doing it, but none is very satisfactory.

DR. WILLIAM L. STOWELL, New York City, said that the best method of obtaining urine from very young children is to pass a small catheter. He considers that the whole subject of disturbances of the blood, including cases of scorbutus and hemophilia, is still very much confused. It is very difficult to say which form of blood disorder we have to deal with, and what

the cause of it is. If there is a special germ it has not been found. Neither has a special remedy been found. Hemorrhage is an important symptom in most of these cases; the bleeding usually occurs in the skin or in the internal organs. The urine of young infants is too frequently neglected. If it was systematically examined in all cases, this symptom of hematuria would no doubt be more frequently seen. Hematuria in the adult may be caused by stone, but as this is comparatively infrequent in infants, the bleeding usually can be traced to one of these blood disturbances. Dr. Stowell's impression is that these blood disorders are due to a specific germ. Although one or two such micro-organisms have been claimed to be discovered, the findings lack confirmation. At present adrenalin seems to give the best curative results.

Dr. H. M. McCLANAHAN, Omaha, stated that hematuria may be the first and only symptom of infantile scurvy for a considerable time. This disease is wholly curable if it is recognized within a reasonable time, before secondary changes have taken place.

Dr. J. ROSS SNYDER, Birmingham, Ala., thinks that this symptom is likely to be overlooked unless careful search is made for it.

Dr. J. L. MORSE said that he had never found any difficulty in collecting the urine of babies. For little boys he uses a bottle with a wide mouth, which is tied around the waist with a band. In little girls one method is to place a rubber basin in the diaper. Another is to place the child on a Bradford frame with a vessel underneath to catch the urine, and a third is to fasten a tin cup against the vulva. In private practice he has found that if a child has not passed urine for a number of hours and is then held over a vessel, it will almost always be ready to urinate. The old-time method was to place absorbent cotton in the diaper. If it is absolutely necessary to find out about the urine he does not hesitate to pass a catheter.

important contribution to our knowledge of summer diarrhea has been made. Dr. Bassett will report the results of his laboratory studies separately. Dr. Winne, clinical assistant at the sanitarium, will discuss the results of a long series of observations made on the agglutination reaction of the organisms isolated, and of dysentery bacilli from other sources with the blood of the patient and with antidyenteric serum. In this paper attention is particularly directed to the clinical side of the problem, the causes predisposing to this malady, the nature and severity of the attack, and the more hopeful methods of prophylaxis and treatment. Especial reference is made to the use of antidyenteric serum. This study is confined to a consideration of positive cases; that is, to those in which the dysentery bacillus was successfully demonstrated in the stools. Other cases were treated during the summer, presenting similar symptoms, and which were, in all probability, infected with the same organism. However, it is thought that more convincing deductions can be drawn when only those instances are considered in which the etiology of the disease has been definitely determined. There were 43 of such positive cases. As is brought out in Dr. Bassett's report, they were all infected with the so-called "acid type" of the bacillus; that is, with the variety of organism which ferments mannite with acid production.² The more important features brought out in this study are presented as succinctly as possible in short tables.

AGE AND SEASON.

The ages of the patients in periods of six months have been averaged in the following table and grouped according to the season (fortnight) of the summer in which they have occurred.

A SUMMER'S EXPERIENCE WITH INFANTILE DYSENTERY.*

J. H. MASON KNOX, JR., Ph.D., M.D.

Physician in Charge of The Thomas Wilson Sanitarium, Assistant in Pediatrics, The Johns Hopkins University.

BALTIMORE.

INTRODUCTORY.

During the summer of 1902, C. W. Duval and V. H. Bassett, working in the laboratory of The Thomas Wilson Sanitarium under a grant from the Rockefeller Institute for Medical Research, were able to isolate the *Bacillus dysenteriae* (Shiga) from the dejecta of 42 infants suffering from diarrheal disorders. A careful review of the histories of these patients¹ led to the conclusion that this series of cases were identical clinically with several well-recognized types of intestinal diseases prevalent among infants during the summer months, and that this organism was associated with a considerable proportion of cases of so-called summer diarrhea. It was then hoped that further investigation would confirm these findings and establish a connection between this bacillus, for several years known to produce intestinal diseases in adults, and this widespread yearly epidemic among young children.

Last summer similar studies were carried on in several of our large cities, and again at The Thomas Wilson Sanitarium Bassett succeeded in finding the dysentery bacillus in the stools of a series of upward of forty babies. In general, the work of Duval and Bassett has received abundant verification, and it is felt that an im-

Age in months.	June.		July.		August.	
	1-15	15-30	1-15	15-30	1-15	15-30
Birth to 6.....17	0	3	5	7	2	0
6 to 12.....18	1	2	4	6	5	0
12 to 18.....6	0	3	1	2	0	0
18 to 24.....1	0	0	0	1	0	0
Older than 24... 1	0	1	0	0	0	0
	43	1	9	16	7	0

The tabulation indicates emphatically the great susceptibility of children during the first year to the invasion of the dysentery bacillus. The number of cases under six months about equal those in the second half of the year, while those under twelve months of age comprise 80 per cent. of the whole number. After the first year the susceptibility to these disorders is rapidly reduced, although the exposure to the infection is probably as great. The youngest patient in the series was six weeks and the oldest three years. In general, it may be said that the resistance of the body to the progress of the disease is somewhat increased in the later months of the first year.

A review of our cases indicates that the very young infant more often succumbs to the intoxication of the first infection, while a child a few months older may resist this danger only to yield finally to a severe inflammatory lesion of the intestinal wall. Certainly, other things being equal, the prognosis is materially better after the first year. That portion of the table which indicates the number of cases admitted each fortnight during the summer needs no comment. The summer of 1903, because of the absence of any excessive or continuous heat, was possibly not a fair average of the climatic conditions in Baltimore from June to September. Nevertheless, the times of greatest pressure for admission of diarrheal cases to the sanitarium corresponded

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

2. Lentz: Zelt. für Hygiene, vol. xli, p. 3.

closely to those in much warmer seasons. It is seen from this series that comparatively few infants are infected until the latter part of June, that the number increases through July, reaching its maximum in the second half of that month, and that in August there is a decline in the number of cases. These positive cases are far too few to admit of much generalization. It may be affirmed, however, that they agree closely with a similar series obtained in 1902,⁴ and it is of some interest to point out that both in the period of life in which the child is most susceptible and in the time of the year most favorable to the outbreak and spread of these specific disorders, there is entire accord between this illness due to the dysentery bacillus and the so-called summer diarrheas in general.

FOOD AND HYGIENIC SURROUNDINGS.

It has long been emphasized by physicians that the character of the baby's food and the care the child receives in the home have most to do with the presence or absence of diarrheal diseases. The importance of these factors has been clearly pointed out by Park and Holt in their extensive investigations in New York City during the past two years.⁵ In each case in the present series an especial effort was made to ascertain the nature of the previous surroundings of the patient, the kind of attention it had received and the character of its diet. This knowledge of the hygienic condition

of them belong to families having their own houses. There are but few large tenement buildings in Baltimore, and crowding usually takes place when several families live in one small house. (See the table below.)

The cow's milk "fair" referred to in the table was delivered at the home from a wagon or bought at a dairy store. In but few instances was bottled milk sold. Usually it was ladled out of a large can into a pitcher. This milk will average at the wagon about 500,000 bacteria to each cubic centimeter. The cow's milk "store" is milk bought for the patients at small grocery stores where there is no suitable refrigeration and where frequent contamination from dirty utensils takes place. This milk was found, in an investigation in Baltimore in 1901 by Bassett and myself,⁴ and in 1902 by Schorer,⁵ to contain from 500,000 to 25,000,000 bacteria to the cubic centimeter, and this number doubtless rapidly increases in the homes.⁶ The frequent use of preservatives in milk of this grade is well known. The "heating" mentioned usually means that the milk is scalded or just brought to a boil over the fire. In no case was steam sterilization or pasteurization employed. As would be expected, better hygienic surroundings, some refrigeration and an improved quality of milk were generally found in the same families. Several points suggested by the table are worthy of consideration, and are as follows:

FOOD AND HYGIENE.

Food at time of illness.	Total.	Hygienic condition.			Refrigeration.		Water with or between nourishment.		
		Good.	Fair.	Bad.	Ice.	No ice.	Boiled.	Unboiled.	Never given.
Breast, exclusive.	11	0	0	2	0	0	0	1	1
Cow's milk (fair) heated.	2	5	5	1	7	2	2	7	2
Cow's milk (fair) raw.	6	1	3	2	1	3	2	5	1
Cow's milk (store) heated.	4	0	0	2	0	3	2	0	0
Cow's milk (store) raw.	5	0	0	2	0	5	0	4	1
Condensed milk.	14	5	5	4	1	6	4	10	0
Table diet.	1	1	0	0	0	0	0	1	0
	43	12	18	13	10	19	8	30	5

in which the baby lived was acquired by questioning the mother as to the size of her house, the number of people sleeping in the room with the baby, her methods of bathing the patient and the preparation of its bottle. This information was compared with the appearance of the mother and child at the sanitarium and the care given to the baby by the mother during their stay. In many instances direct reports were also obtained from the district nurses employed by the sanitarium in the city. All these factors have been grouped under three grades—good, fair and bad. When these conditions are said to be "good," it is meant that the house is well kept and clean, that the child receives sufficient attention, and that the food is prepared in a cleanly manner. In this class are included several infants whose food was not suited in quantity or quality to their needs and who were fed irregularly. In the group called "fair," although there was some endeavor to care for and feed the baby, it suffered evidently from some form of neglect. When the conditions were designated "bad," the home was judged to be extremely dirty, ill-ventilated, and the attention given the baby reduced to a minimum.

It should be said that our patients as a rule did not come from the criminal or degraded classes found in our large cities. For the most part they were the children of the poorer working people, while about 20 per

cent. of them belong to families having their own houses. There are but few large tenement buildings in Baltimore, and crowding usually takes place when several families live in one small house. (See the table below.)

First, infants exclusively breast-fed seldom succumb to the dysentery bacillus, there being but two such cases in our series. Again, the division of the babies into groups according to the form of nourishment antecedent to their illness gives rather surprising results. Thus the number of infected infants in our series who received milk of a fair quality is 17, while there were but 9 who were given notoriously bad milk. These figures are in part accounted for by the fact that mothers of the better classes—those who procure fair milk for their children—are more apt to avail themselves of a distant sanitarium when their children fall ill than are the very poor.

That the number of the cases who were given their milk *boiled* should be greater than those who received it raw, is also unexpected and probably would not be the result in a larger series. It does suggest the possibility, however, that the infective agent may reach the baby by other means than in its milk.

Although but one child was fed exclusively at the table, crackers, bread, cake, often tea or coffee, were occasionally given to a dozen others.

The largest single group of cases—one-third of the whole number—had been nourished on condensed milk.

4. Maryland Med. Jour., xlv, 1902, p. 241.

5. Maryland Med. Jour., xlvi, 1903, p. 213.

6. Compare investigations made by Park and Holt, loc. cit.

In Baltimore condensed milk is largely used among the lower and middle classes as an infant food because of its cheapness. Fully one-half of the children admitted to the sanitarium have been fed on condensed milk during a large part of their infancy. The experience at Mt. Wilson lends support to the generally accepted decision that the resistance of children so nourished against many untoward influences is materially lessened.

The data under the head of "refrigeration" resolves itself into an inquiry as to whether the milk was kept on or near ice. It was impossible to ascertain the temperature of the milk, and it is quite possible that the association between it and the ice when present, may not have been an intimate one. The fact, however, that in a quarter of all the cases ice was provided in the home, indicates again that our patients did not come from the very poorest families.

The results of the tabulation of these cases with respect to the hygienic conditions pertaining at the homes, as this could be ascertained from the account and appearance of the mother, was also surprising, in that the number of ill babies brought up under good, fair and bad surroundings, respectively, was so nearly equal. It must be recalled, however, that these were all children of parents of moderate means, and in no case were the conditions of life so ideal as they may be in the homes of the rich. But after due weight is attached to these partial explanations, this discrepancy between the number of cases on the one hand, and the quality of the milk and the character of the hygienic surroundings on the other, makes it difficult to charge either to the milk or to the daily care of the infant alone this outbreak of diarrheal diseases due to the dysentery bacillus. A primary infection of the whole milk supply of the community with the specific organism is an impossible hypothesis, as our patients entered the sanitarium already ill from widely separated sections of the city and obtained their milk from a large number of remote sources. Moreover, most of it was boiled before using, and many fed exclusively on condensed milk received no fresh milk at all.

Negligence in the care of the baby, although a factor, is not a satisfactory explanation, in view of the fact that a considerable number of the ill children in the series had been well cared for. The nature of the disease itself predisposes an invasion of the intestines by the dysentery bacillus, the mouth being the chief portal of entry and food and drink the most probable means of conveying infection. Further evidence in this direction is evinced by the fact that in the homes of our little patients there were no others suffering from diarrheal diseases; that is, in almost every instance the illness of the baby was the first and usually the only case of intestinal disorder in the family.

If the disease were spread primarily by contact, either direct or indirect, from patient to patient, surely in a large percentage of cases similar antecedent illnesses in the household could be discovered. The nature of the outbreak of the disease suggests rather that the causal organism reaches the individual through a common carrier. Practically in large cities the water is the only material ingested by the whole population from a common source. This is particularly true of infants whose only food, milk of some sort, is derived, as has been said, from widely separated herds. Moreover, the biologic character of the specific organism places it in the typhoid-colon group of bacilli, which are introduced into the

human body most frequently by means of drinking water, and clinical experience indicates that diarrheal disorders among infants can best be controlled by certain precautions such as are found most efficacious in typhoid fever, without resort to the complete isolation necessary in the so-called contagious diseases.

An especial endeavor was, therefore, made to ascertain whether the water supplied to ill babies could possibly be charged with the carrying of the infection; that is, if all of it was boiled or unboiled. The results of the investigation for 1903 are tabulated in the third column of the table. This indicates that to 29 infants, out of a total of 43, or about 70 per cent., *unboiled* water was supplied regularly in the intervals between nourishments, or was used as a diluent of the milk. Eight infected babies, or 19 per cent. of all the cases, were said by their mothers never to have received any other than boiled water, while in the case of five infants it was denied that water of any kind was given. Of the eight cases given, according to the mothers' account, only boiled water, two lived under "good," four "fair," and two amid "bad" hygienic conditions. By careful questioning concerning the diet, it was discovered that four of the eight babies were given crackers or bread from the table, hence it is probable that in these instances unboiled water was also occasionally obtained. These results corroborate the experience of the previous summer, where, in twenty-eight instances in which definite information was obtained, unboiled water was supplied to twenty-six infants infected with the dysentery bacillus, four of whom were fed exclusively at the breast and four on condensed milk. While these cases are too few to warrant any sweeping conclusions as to the manner of the spread of these disorders, especially in the absence of a demonstration of the specific organism in drinking water, so far as they go they do suggest the possibility that the disease may be in large part water borne, and justify the adoption of stringent regulations preventing any but sterile water being supplied to babies, especially in the summer. The difficulty of isolating the typhoid bacillus in water shown to be contaminated is well known, and it is quite possible that the dysentery bacillus present in the water in small numbers has thus far escaped detection.

OTHER METHODS OF INFECTION.

Other methods of infection are of course recognized. Thus in hospitals where many sick infants are cared for, specific organisms may be conveyed from case to case by fomites or careless attendance. Sufficient attention has not been directed to the part played by insects, particularly the common house fly, in the spread of this malady in institutions and crowded communities. One can easily be convinced of this danger by an hour's observation in any children's ward where these pests are numerous. Without the most rigid surveillance by numerous care-takers, these flies often find access to the napkins of the infants, whence carrying the organism they may light next on the face, hands or bottle of a neighboring child. Two cases during the last two years, admitted to the sanitarium for other causes, became infected with the dysentery bacillus through flies.

CONDITION OF PATIENTS PREVIOUS TO ILLNESS.

Turning now from the home diet and environment of the patients, let us consider their actual physical condition before the onset of the specific illness. In reviewing the histories one is surprised at the small number of instances recorded in which acute sickness had anteceded the diarrheal attack. Thus bronchitis and

pneumonia were each noted twice and gastric colic once. These disorders all occurred several months before the intestinal disease and apparently had no association with it. There was but a single instance in which there had been an attack of diarrhea previous to the one from which the patient was suffering on admission; that is to say, the children were brought to the sanitarium during the course of their first illness.

The nutritional condition of the patients is not indicated by their freedom from previous acute illness. A small percentage only of the patients were "well nourished," 25 of the series showed pronounced stigmata of rickets, and 10 were markedly emaciated. These conditions had been brought about by food, improper either in kind or quantity, or both, and by insufficient care.

In but two instances could a history be obtained of any special indiscretion in diet before the onset of symptoms. In one of these, vomiting and purging began in a boy of 3 years, the oldest of our cases, after a meal of peanuts. This child was desperately ill with ileocolitis. The other instance was in a seven months' infant whose acute symptoms, ending in convulsions and death, followed the eating of a piece of banana.

In none of the other cases was there a history of any alteration in the diet of the patient to be obtained from the mother. Frequently the babies had not been thriving and had been losing weight, when, without any cause to which the mother could attribute it, the symptoms pointing to intestinal disorder set in. It would seem, then, that all young children are susceptible to infection with dysentery bacillus, but that its most numerous and least resisting victims are the infants whose vitality has been lowered by improper food and insufficient care.

TEMPERATURE.

A factor of undoubted importance in the spread of the disease in a community is the degree of atmospheric heat. It was found that the number of our specific cases was almost in direct relation to the height of the thermometer; that it could be predicted certainly that an increased number of babies infected with the dysentery bacillus would apply for admission after an unusually heated term. In this respect and in regard also to the nature of the cases most susceptible, our experience was identical with that of the great mass of clinical data for summer diarrheas in general.

DURATION OF SYMPTOMS BEFORE ADMISSION.

The difficulty of securing the admission of patients immediately after the onset of symptoms in any sanitarium distant from the city has already been pointed out. The tendency is for the mothers to attempt home remedies before medical aid is sought, unless the initial symptoms are very alarming. On account of this delay and the serious nature of the majority of the cases under observation, all methods of treatment are under considerable disadvantage. The series of cases have been divided into three groups, in reference to the duration of disease before admission, as follows:

1-10 days.	10-20 days.	More than 20 days.
13	11	19

But one case was seen on the first day and but four before the sixth day. Nearly half of the whole series came under treatment after three weeks of illness. Most of these were admitted in the latter half of July and in August.

LENGTH OF TIME UNDER OBSERVATION.

There was no fixed duration to the stay of the patients at the sanitarium. They were kept until it was

thought they were able to go home safely. Occasionally circumstances in the city required a return sooner than was advised. As a rule, the mothers preferred to have the desperately ill babies remain at the sanitarium until the end, notwithstanding a grave prognosis had been given. The time these 43 cases were under observation at Mt. Wilson varied from one day, in the case of a baby admitted in a comatose condition and which died the following morning, to forty-seven days, the average for the 43 cases being seventeen days. The more protracted cases occurred, as a rule, late in the summer.

CONDITION OF THE PATIENTS ON ADMISSION.

The condition of the infants admitted presented wide variations, and is of sufficient importance to tabulate:

CONDITION ON ADMISSION.				
Good.	Fair	Toxic.	Marantic.	Collapsed.
5	10	14	10	4

The cases whose condition was "good" presented few symptoms on admission other than diarrhea. Where the infants showed in addition slight constitutional disturbance, their condition was called "fair." The cases "toxic" on admission showed very marked symptoms of infection. The large marantic group has already been referred to. Four infants were admitted, pulseless at the wrist, and unconscious in profound collapse.

TYPES OF THE DISEASE.

A persistent effort was made during the last two summers to detect some signs or symptoms at the bedside that would differentiate the infants infected by the dysentery bacillus from other cases of summer diarrhea. Thus far, this effort has been quite futile, for the babies whose stools contained the specific organism presented no uniform clinical picture, but included rather all the varieties of illness that are commonly included under the designation "summer diarrhea." As was found also during the preceding summer, the cases could be divided broadly into two groups—one in which the chief symptoms were apparently due to the absorption of toxins from the intestinal tract, while in another form, in addition, the character of the stools or the autopsy findings indicated marked inflammatory lesions of the bowels.

The cases in the first group presented great variations in the degree of the toxemia, some exhibiting symptoms only of mild gastro-intestinal disorder, while in others the condition was one of profound poisoning associated with convulsions and ending in coma and death. No instance of typical cholera infantum was encountered.

A sharp line of separation can not be drawn between the two groups of cases above indicated. Usually the typical instances of ulcerative ileocolitis began as dyspeptic diarrhea. It was thought well to make use of the grouping, however, as it illustrates that the dysentery bacillus in the intestinal tract does not produce a simple, clear-cut, clinical disease entity, but rather that its manifestations are manifold, that it is responsible for a large train of symptoms which correspond accurately to those of the various diarrheal disorders common among children in the summer.

Our cases may be divided in accordance with the foregoing remarks, as follows:

	Mild.	Moderate.	Severe.
Cases presenting chiefly toxic symptoms,			
"dyspeptic diarrhea"	5	6	10
Cases of inflammatory or destructive lesion of the intestine, "ileocolitis"	0	8	15

To detail the clinical history and the bedside notes in each of our series would involve much valueless repetition. Later, in discussing the serum treatment, sev-

eral cases which serve as fair representatives of larger groups will be presented in full. Nearly all the babies exhibited nervous symptoms, as indicated by irregular and insufficient periods of sleep and by fretfulness. Less frequently increased drowsiness ending in coma was observed. Symptoms pointing to functional derangement of heart or lungs were not present, except when the child was *in extremis*. On the other hand, tympanites, usually of a moderate grade, was frequently observed, and tenesmus was a troublesome feature of the severer forms with ulceration. The symptoms fairly constant in all forms of these disorders were vomiting, diarrhea and elevation of temperature. A tabulation showing their frequency and severity has been arranged:

	Absent.	Moderate.	Severe.
Vomiting	9	22	12
Diarrhea	(1) 0	(2) 25	(3) 18
Fever	(4) 0	(5) 17	(6) 26

(1) Less than 4 stools in 24 hours.
 (2) Four to 15 stools in 24 hours.
 (3) More than 15 stools in 24 hours.
 (4) Temperature not over 99.
 (5) Temperature between 99 and 101.
 (6) Temperature higher than 101.

Of the group in which the fever was high,⁶ in thirteen instances the temperature showed marked daily variations. The nausea and vomiting was a frequent symptom at onset, but was also a troublesome feature in many of the severe cases throughout their illness.

There was always some elevation of temperature above normal, but the height of fever was of itself not a sure index of the condition of the patient. In many of the toxic cases the temperature curve remained continuously high unless reduced by sponging. Most of the instances in which the fever showed the marked daily intermission belonged to the "ileocolitis" group, having blood and pus in the stools. It is quite possible that the hectic character of the fever in these cases was due to a secondary infection. There is ground for the view that the destructive lesions, ulceration in the bowel in this form of the disease, are due to streptococci⁷ and other organisms superimposed on a primary infection with the dysentery bacillus. Much interest attaches also to the character of the stools of these cases, because from them information is obtained concerning the condition of the intestinal wall.

All the children exhibited more or less looseness of the bowels. The average number of stools in twenty-four hours in the cases where the diarrhea is described as "moderate" was about ten. In but one case was there but four stools, and in this instance the child passed shortly out of observation. In several children the number of stools reached forty in twenty-four hours.

A brief summary has been made of the presence in the dejecta of mucus, blood and pus as follows:

CHARACTER OF STOOLS.

	None.	Trace.	Moderate.	Much.
Mucus	9	4	20	9
Blood	15	10	16	2
Pus	10	11	15	8

It is, of course, recognized that such a division must be largely arbitrary, but it is thought that with a word of explanation it may serve to indicate the general nature of the discharges. The naked eye appearance of the fresh stools on the napkin, supported in most instances by a microscopic examination, formed the basis of the division. Thus when blood and pus are said to be "absent," it is not contended that no red blood cells or polymorphonuclear leucocytes whatever are present, but that neither of these elements could be detected macroscopically, and that they were only very sparingly found with the microscope. A "trace" of a "moderate"

amount of, or "much" mucus, pus or blood, on the other hand, indicates the detection by a simple inspection of increasing quantities of these materials, respectively, the naked eye appearance being corroborated with the microscope. Epithelial cells, swarms of bacteria, various crystals, curds and undigested food residue, fat droplets, and other elements found in normal stools were likewise noted in our examinations. Mucus was present in all cases, both mild and severe, whether belonging to the so-called inflammatory or toxic types. In the majority of instances it was present in considerable quantities. Blood, on the other hand, was not noticed during the entire course of the illness, either at home or at the sanitarium, in 15 cases, or 35 per cent. of the whole number, and only a "trace," often a mere fleck on the napkin, such as could result from a simple congestion of the mucosa, was present in ten additional instances. Blood frequently stained the napkins in 16 cases, but was present in large amount in but two instances. In no case was there active hemorrhage. No pus was present macroscopically in 10 cases throughout their sickness, and only a trace was noticed in the stools of eleven other babies.

These results substantiate the contention that the infection of infants with the dysentery bacillus does not necessitate a disease comparable with adult dysentery, but rather that not exceptionally, but frequently, this organism may produce a mild disorder.

COMPLICATIONS.

Complications were comparatively rare. Eclampsia occurred at the terminal event in three cases—one of severe dyspeptic diarrhea and two of ileocolitis. Bronchopneumonia was recognized but twice in our series; each time it proved fatal, in malnourished infants. One baby of two months died with symptoms of intestinal obstruction. No necropsy was allowed. A general pyemia proved in one instance a fatal complication. Frequent urine examinations and an occasional autopsy failed to disclose a definite nephritis in any of our cases.

RELAPSE.

In six instances a return of the disease occurred after the patient, being apparently well or improved, had been discharged from the sanitarium.

These relapses took place in the latter part of the summer, and after periods of from five days to three weeks from the return of the child to its home. In each case pure milk was provided at the house, and the environment of the baby made as healthful, by a visiting nurse, as the conditions at the home permitted.

The occurrence of relapse in these disorders is of the utmost importance, as it indicates the difficulty of setting a time when a case may be considered cured and become of no further danger to the patient or to others, and at the same time it suggests that one attack confers on the infant no immunity against a subsequent infection. In all six of the instances cited the second illness was more severe than the first. Three cases seemingly recovered from dyspeptic diarrhea, returned with symptoms of severe ulcerative lesions of the intestine. Probably from these infants the dysentery bacillus had never been completely removed from the intestinal tract, although present in too small numbers to produce symptoms, and only needed an opportunity to again set up the disease.

When we consider that the purest milk affords excellent culture material for the development of specific organisms already in the bowel, and also that because of the technical difficulties of their isolation a single negative examination of the stools is of little significance,

7. Blum: Arch. of Pediatrics, xxi, January, 1904.

the practical difficulties of dealing wisely with the question of relapse are greatly increased. Certainly it is true that a child once infected in hot weather should be carefully fed and kept under medical surveillance for several weeks after the abatement of all symptoms.

RESULTS.

The results of treatment in the series have been tabulated briefly with reference to the clinical forms of the disease which are still tentatively retained.

Toxic type—	Well.	Improved.	Unimproved.	Died.
Mild	3	2	0	0
Moderate	3	3	0	3
Severe	3	3	0	3
Inflammatory type—				
Mild	0	0	0	0
Moderate	3	1	0	4
Severe	2	1	1	10
	13	12	1	17

Of the 43 cases under treatment, 25, or 58 per cent., were cured or improved, and 18, or 42 per cent., died or were discharged unimproved, the mortality for the series being 39 per cent. It is striking that there should be such great disparity in the results obtained with the cases of the toxic type. Thus, of the 25 children improved at the sanitarium, in 18 were there no symptoms indicating marked intestinal ulceration, while these symptoms were present in 15 of the 18 fatal cases. Because of the established fact that the severer inflammatory forms begin often as mild toxic infections, the figures here tabulated argue strongly the importance of prompt abortive treatment.

The results can also be profitably tabulated with regard to the character of the diet previous to admission:

	Well.	Im- proved.	Unim- proved.	Died.
Cow's milk of all kinds, raw and heated	26	10	7	1
Condensed milk	14	1	5	0
Table diet	1	1	0	0
Breast exclusively	2	1	0	0
	43	13	12	1
				17

It is to be noted that of the 14 cases which had been previously fed on condensed milk, 8, or 57 per cent., died at the sanitarium in spite of treatment, and but one really recovered; while of the 26 cases given at their homes some form of cow's milk, but 8, or 29 per cent., died, 7 were improved and 10 were permanently cured.

It was found that the results of treatment were not appreciably affected by the character of the cow's milk supplied the babies before they came under observation; that is, that whether the milk had been "poor" or "fair," "raw" or "boiled" did not apparently alter the course of the illness after the disease was under way. On the other hand, these figures support the view already expressed that although condensed milk-fed infants may be less liable to become infected by the dysentery bacillus, especially if care is taken that all the water used is boiled, than are babies fed during the summer on cow's milk of poor quality; yet when the specific organism does find entrance into the body, the children reared on proprietary foods are more liable to succumb.

If future investigations should determine the dysentery bacillus to be, in small numbers even, a normal inhabitant of the intestinal tract of children, the danger of lowering the individual's resistance by condensed milk feeding will be still further emphasized. The fatal illness of the breast-fed child was that of a weak, emaciated baby nourished by an overworked, anemic mother.

The results of treatment with reference to the age of the patient may also have some interest:

	Well.	Im- proved.	Unim- proved.	Died.
Birth to 6 months	17	4	6	1
6 to 12 months	18	3	5	0
12 to 18 months	6	5	0	10
18 to 24 months	1	0	1	0
Two years +	1	1	0	0
	43	13	12	1
				17

Deductions must be warily drawn from such a small number of cases. Our experience would indicate that during the second six months of life the invasion with the dysentery bacillus is more likely to prove disastrous than at an earlier or later period. Thus, out of 17 cases under 6 months, 10 were bettered and 1 unimproved, with 6 deaths, a mortality of 34 per cent.; but of 18 cases between 6 and 12 months of age, only 8 were bettered, none improved, and 10 died, a death rate of 55 per cent. The difference is to be accounted for in part at least by the fact that the untoward effects of improper artificial feeding are most in evidence in cases with weakened constitutions, rickets and the like, during the second half year of an infant's life. For a large part of the period preceding the mother is able to nurse the child and so carry it along for several months in good nutritive condition. Should the infant survive the first year it can then assimilate more readily the ill-assorted mixtures often provided for it as food. Of the 18 cases older than one year, but one, aged 13 months, resulted fatally, of ileocolitis.

(To be Continued.)

THE TREATMENT OF PURULENT CONJUNCTIVITIS.*

MYLES STANDISH, M.D.

Ophthalmic Surgeon Massachusetts Charitable Eye and Ear Infirmary; Professor of Ophthalmology, Dartmouth College; Assistant Professor of Ophthalmology, Harvard Medical School.

BOSTON.

The treatment of purulent conjunctivitis will always be of great interest to every practitioner in ophthalmology, and when the chairman of this Section asked me to read a paper on this subject I acceded, and the more willingly because the Massachusetts Charitable Eye and Ear Infirmary has a separate building, isolated from the main structure, which is devoted exclusively to the treatment of contagious diseases of the eye. For five years all cases of purulent ophthalmia applying to the institution for treatment have been promptly admitted to this building. The result has been that there has been brought together in the records of this pavilion a large number of cases, and this paper is chiefly a study of these records, to ascertain if possible which methods of treatment have been the more successful.

In looking over thirteen text-books published in the last twenty years, I find recommended the following measures for the treatment of purulent conjunctivitis: Cleanliness, iced compresses in the stage of swelling, with topical applications of nitrate of silver, solutions of the bichlorid of mercury, solutions of permanganate of potash, chlorinated water, iodoform and boric acid. Can these methods of treatment be improved? If so, by what means? This paper is an attempt to answer these questions.

Corrosive sublimate, permanganate of potash, iodo-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

form and chlorinated water have all been tried in the balance and found wanting. Therefore, for many years a solution of nitrate of silver has been the only topical application accepted for the treatment of this disease.

Purulent ophthalmia is due in the majority of cases to gonorrhæal infection. If sought for, the gonococcus will be found in from 60 to 65 per cent. of the cases.

A differential diagnosis in a case of purulent conjunctivitis between a typical gonorrhæal infection and one produced by the staphylococcus, streptococcus, or Klebs-Loeffer bacillus is not difficult, when the case has fully declared itself, but in the earlier stages absolute dependence must be placed on the bacteriologic examination, without which even the most expert are liable to be deceived. Thus in the last twenty months there have been admitted to the Gardner Building 91 cases under 5 years of age, in which it was thought probable that the infection might be gonorrhæal or diphtheritic. The bacteriologic examination on entrance showed the infection to be Klebs-Loeffer bacillus in 2 cases, streptococcus in 1 case, staphylococcus in 17 cases, and the gonococcus in 64 cases, and 6 cases in which the infection was not determined except in so far as to prove it was not gonorrhæal. In 1 case of staphylococcus infection there was ulcer of the cornea on entrance, and in another case a "steamy cornea" and a membrane on the palpebral conjunctiva. The diphtheritic cases under the use of antitoxin were both discharged with clear cornea. The cases of staphylococcal infection also did well, as is almost always the case under any rational treatment.

Our disasters occur in the treatment of cases in which the gonococcus is the causative agent. Therefore, this paper resolves itself practically into the treatment of gonorrhæal ophthalmia. It is a well-known fact that this infection is less difficult to manage in so-called cases of ophthalmia neonatorum than in the adult, but in both classes the virulence of the infections may vary greatly. It is not necessary for me to enter elaborately into the methods of caring for gonorrhæal ophthalmia. The first essential is cleanliness. This can only be obtained by frequent washing of the lids with the removal of the pus, so far as is practicable from the conjunctival sac.

When nitrate of silver was relied on for the direct treatment of the disease the manipulations necessary to properly apply it and to wash off the excess of the solution greatly favored injury of the cornea with subsequent infection and ulceration, and cases where eyes were lost or vision destroyed were often due to this process. Of late years there have been presented to the profession silver salts, not so irritating as nitrate of silver, and much more easy of application. A solution of protargol or argyrol can be applied by simply pouring the liquid between the opened lids; moreover, the specific gravity of these solutions is such that, sinking to the bottom of the cul-de-sac, pus and mucus are floated to the surface and can be removed much more easily without the manipulative dangers to which patients were formerly exposed.

Two years ago, in a paper read before the New York County Medical Society, I made a comparison of results obtained in cases of ophthalmia neonatorum treated by nitrate of silver and protargol. I was able at that time to find 50 cases in the records of the Gardner Building in which the nitrate of silver had been the agent relied on. Of these 50 cases, there were three that had clear cornea on admission, which subsequently

developed ulceration of the cornea sufficient to interfere with vision. This showed 6 per cent. of unsuccessful cases. I found on the records at that time 150 cases in which protargol was the only remedy used. Among this number there were also 3 admitted with clear cornea, which subsequently developed ulcers that greatly injured or destroyed sight. This gave 2 per cent. of unsuccessful cases. The protargol solution used was increased from 4 per cent. in the beginning to the habitual use of a solution of 20 per cent. and in the last 50 cases treated no baby with clear cornea on admission had any corneal complications.

The 50 cases in which nitrate of silver was used were in the hospital an average of twenty-three and one-half days, and the last 50 cases above referred to were in the hospital an average of sixteen and one-half days, making a difference of one week in the time of treatment. Since that paper was written argyrol as the local application in these cases has been largely used in the Gardner Building and I have been able to find on the records 64 cases of ophthalmia neonatorum with gonorrhæal infection, which entered with clear cornea in which it was depended on as the principal agency. All of the 64 cases were discharged with clear cornea, and the average stay in the hospital was eighteen and two-thirds days. I also found on the records 9 cases in which it was noted on entrance that the cornea was "hazy," in only one of which did any ulceration of the cornea follow. These cases, although naturally more serious, only remained in the hospital an average of twenty-two days. During the same period 9 cases entered which already had corneal lesions, in only one of which was the eye lost. From these cases it will appear that either of the modern silver salts gave much better results than was ever obtained from the use of nitrate of silver.

The routine treatment has been to wash the edges of the lids with a solution of boric acid once in half an hour, to put when necessary a little vaselin along the edges of the lids to prevent them from sticking together and to instill a solution of protargol or argyrol freely between the lids at intervals of from every hour to once in four hours. As has been before stated, the solution sinking to the bottom of the cul-de-sac floats to the surface the pus and mucus which can be easily removed with a very slight amount of manipulation. In no case has it been necessary to do a canthoplasty to relieve the pressure on the globe, and in no case has cold been applied at any time during the treatment. Cases in which there was "hazy" cornea as above noted have often had pilocarpin in 0.5 per cent. solution instilled once a day. Atropin has rarely been applied except in cases where the cornea was involved and no case was discharged until two negative smears had been examined under the microscope on successive days. From this it will be seen that in 114 consecutive cases admitted with clear cornea and treated with protargol or argyrol, no case has developed corneal ulcer, nor has any untoward incident occurred, and in 9 cases admitted with the cornea already threatened, only one ulcer developed. These results are surely brilliant as compared with those obtained before all the cases were admitted to the house and before modern silver salts were used.

The real value of any method of procedure in gonorrhæal ophthalmia is the result obtained in gonorrhæal infection in the adult. During this same period there have been admitted to the Gardner Building 89 cases of gonorrhæal ophthalmia in individuals over five years

of age, of whom 48 were treated with protargol and 37 were treated with argyrol exclusively. In studying the relative value of the agents used, it is necessary to divide these cases into two classes: 1. Those admitted with clear corneæ; 2, those in which the corneæ were involved on entrance. The latter group includes, of course, all degrees of corneal lesions from the smallest infiltration to almost total ulceration.

It is obvious that from results obtained in this latter group very few deductions can be drawn, therefore the results obtained in the first group are of the most importance.

In the 48 cases treated with protargol the solutions used were 10 per cent. in 28 cases; 20 per cent. in 18 cases, and 30 and 40 per cent. in one case each. Of the 33 adult cases which were admitted with clear corneæ, 21 were discharged without corneal lesion, or 66 per cent., and of the 27 cases which were admitted with corneal lesions, or developed ulceration of the cornea, four eyes were lost.

It will be seen from the accompanying tables that the percentage of successful cases was much greater with the 10 per cent. solution of protargol than in any other group. In this group there were 28 cases, 18 of which were admitted with clear corneæ, 14 being discharged without complication—about 78 per cent.—and of the 14 cases in which the corneæ became involved only one eye

RESULTS OF TREATMENT OF GONORRHEAL OPHTHALMIA WITH PROTARGOL AND ARGYROL.

Per cent. used	Entered with clear cornea	Discharged with clear cornea	Entered with corneal lesion	Discharged with leucoma	Lost or total leucoma
Protargol.....10	18	14	10	13	1
Protargol.....20	12	5	6	10	3
Protargol.....30	1	1
Protargol.....40	1	1
	32	21	16	23	4
Argyrol.....13	2	2
Argyrol.....25	12	8	7	6	5
Argyrol.....50	9	6	7	7	3
	23	16	14	13	8

was lost. With the 20 per cent. solution 12 entered with clear corneæ and 5 only escaped corneal infection, or 42 per cent., while of the 13 cases in which the cornea was attacked three eyes were lost, or had total leucoma. It is perhaps interesting to note that all four of the eyes lost entered with clear corneæ.

Of the 37 cases in which argyrol was used, the solutions were 15 per cent. in 2 cases; 25 per cent. in 19 cases, and 50 per cent. in 16 cases. Of 23 admitted with clear corneæ, 16 were discharged without corneal lesion, or 69.5 per cent., and of 21 cases in which corneal lesions were present on entrance, or subsequently developed, eight eyes were lost, three of which entered with clear corneæ. It will be noticed that the results obtained with the 50 per cent. solution were no better than with the 25 per cent. solution.

It would appear from the above tables that while the percentage of successful results with the two agents was not materially different in cases which entered with clear corneæ, that once the cornea has become involved, protargol seems to control the case more effectively. The advantage of argyrol is that it is practically unirritating and is much better borne by the patient.

One other factor in the treatment of gonorrhœal ophthalmia to which I wish to direct your attention is the inadvisability of cold at any stage of the disease. Of the before mentioned thirteen text-books published in

the last twenty years, ten advise the application of cold during the stage of swelling as a routine procedure. The statements made were generally of the following character:

"Iced compresses should be used during the stage of swelling;" "cold during the stage of swelling, then heat;" "iced compresses during the stage of swelling for an hour at a time, omitting an hour, and so on continuously;" "cold applications should be abandoned when the cornea has a steamy look; heat is then resorted to;" "iced compresses should be used until the discharge begins," that is until the growth of the gonococci has been well developed. And it was a fair inference from the context that the limited time allowed for the use of the iced compresses was due in each instance to the opinion of the author that cold was inimical to the nutrition of the cornea. If this is true a strong case must be made in favor of their use before they should be habitually employed. In these cases, as in the preceding, the value or detrimental effects of cold can only be determined by considering the cases that were admitted to the hospital with clear corneæ. Among the 85 cases which I have reported above as treated with protargol or argyrol, there were 17 cases admitted with clear corneæ which had cold applications made, of which 10 were discharged without corneal lesion, which gives 59 per cent. of successful cases. During the same period 38 other cases entered with clear corneæ and were treated without the applications of cold, of which number 28 were discharged without corneal lesion. This gives about 74 per cent. of successful cases. If the difference between 59 per cent. and 74 per cent. was due to the application of cold, it is surely inadvisable.

These cases were treated with cold, not because they were more virulent, but because the physician treating them habitually used cold applications in the initial stages of gonorrhœal ophthalmia. The records do not state in every case the length of time the cold was employed, but the average time in which a definite statement was made was three and three-eighths days. There is no reason to suppose that it was continued over a longer period in the remaining cases. I have taken considerable trouble and time to ascertain the fact that the treatment otherwise than the application of cold was practically the same in all the 55 above cases. The ages of the patients were four between 5 and 20, ten between 20 and 30, one between 30 and 40, and two between 40 and 50. In each decade of life, it is roughly 25 per cent. of patients admitted with gonorrhœal ophthalmia having clear corneæ, therefore the results can not depend on any difference in corneal nutrition between youth and middle life.

The rationale of the cold applications is somewhat difficult to see. If it is done merely to reduce swelling of the lids, ought not heat to be employed instead? Elsewhere heat promotes absorption in edematous conditions. If it is done, as I have heard it stated, for the sake of inhibiting the growth of the gonococcus, it does not seem to be any more rational. Neisser, in his recent article in *Kolle and Wassermann's* work, states that the growth of the gonococcus is inhibited when the temperature is reduced below 86 degrees Fahrenheit, and it is improbable that in any case the application of iced compresses to the lids could reduce the temperature below 86 degrees. As a matter of fact, since this paper has been under consideration, I have had a virulent gonorrhœal case admitted to my service in which there was considerable, although not excessive, edema of the lids. A large slough of the cornea had already oc-

curred. In this case finely broken bits of ice wrapped in a thin layer of absorbent cotton were kept continually on the lids until the pain was sufficient to cause their discontinuance—a matter of twenty-two hours—and this was repeated after an interval. I caused the temperature in the conjunctival sac to be taken every hour. It is plotted here for the sake of brevity with two-hour intervals. It shows that before the cold applications were made, the temperature was 100 degrees, that during the application of cold the temperature fell to 98 degrees. On the removal of the cold the temperature rose to 99.5 degrees, and on the cold being renewed it was reduced as before.

From this chart, it will be seen that the utmost reduction of temperature obtained was only 2 degrees, being 12 degrees above the temperature which Neisser states is necessary to prevent the growth of the gonococcus. In the above-mentioned article, it is also stated that the growth of the gonococcus is inhibited by a temperature of 107.6 degrees Fahrenheit, but that inhibition is not so marked when the gonococcus is present in living tissue. Therefore, whether the application of heat would be beneficial must be determined by the clinical results obtained in cases where it is used. On this point, unfortunately, the records of the Gardner Building furnish us with no statistics. In this connection it is well to call attention to the fact that in the above reported 114 consecutive cases of ophthalmia neonatorum in which the cornea did not become involved, cold was used in no instance.

Chart showing result of applications of crushed ice. Observations taken at two-hour intervals. I. A., ice applied; I. D., ice discontinued on account of pain.

From the above facts it would seem that the application of cold is at least of doubtful value and that probably its effect is harmful.

CONCLUSIONS.

Recognizing the fact that final conclusions on any method of procedure can not be drawn from any limited number of cases, it would appear that so far as the evidence presented above goes, the following conclusions can be deduced:

1. That the newer silver salts are more easily applied, safer in use and produce better results than nitrate of silver.
2. That in cases of ophthalmia neonatorum either protargol or argyrol is an entirely satisfactory agent.
3. That in cases of gonorrhoeal ophthalmia in the adult, the results obtained when treatment is begun early are approximately the same with either preparation, but when once the cornea is involved, protargol appears, in these cases at least, to have afforded a better ultimate outcome.
4. That the application of cold during the stage of swelling in gonorrhoeal ophthalmia is a dangerous procedure and should be abandoned.

DISCUSSION.

DR. CASEY A. WOOD, Chicago, said that in the early days attempts were made to abort gonorrhoeal ophthalmia; hence the enthusiasm for nitrate of silver in strong solutions. The main reason for the retention of that treatment was that it did work which could be seen. In recent years a treatment not so irri-

tating in character has been used. To his mind the chief consideration in the prevention of serious consequences is the cornea. He said that he believes that strong nitrate of silver solutions are occasionally harmful because of their irritating character. Ulcer of the cornea has been caused by eagerness to get at the root of the disease in this fashion and secondary troubles have been produced which are worse than the original infection. Another matter of importance is that of irritating the infant and so making him cry. The moment a child is made to cry the lids become congested, their sharp margins are pressed against the cornea and, in its macerated condition, the anterior corneal epithelium is easily removed. Nitrate of silver applications make the child cry. Dr. Wood differed from Dr. Standish regarding the application of cold. Dr. Wood believes in it if judiciously applied. It may not affect the bacteria in the tissues that form the sac, but it makes the patient more comfortable, and this is of particular importance in the case of children. Dr. Wood agreed with Dr. Standish as to the cleansing of the eye. The sac can not be entirely sterilized nor even thoroughly cleansed, and when the discharge has been carefully washed off from the edges of the lids the physician has done about all he can in that respect. In Dr. Wood's opinion it is dangerous to do so much cleansing as is advised by some of the text-books; that is, with the aid of retractors, eversion of the lids, the use of irrigators, etc. Dr. Wood thinks that argyrol is a better preparation than protargol. It has a somewhat anesthetic effect on the cornea and conjunctiva and makes the patient more comfortable, which are distinct advantages, aside from any bactericidal property it may possess. Another remedy that has been somewhat overlooked is hydrastin. Dr. Wood uses the mixture introduced some years ago by Dr. X. C. Scott without the deodorated tincture of opium, and feels sure that it possesses valuable properties in the second and third stages of the disease.

DR. MAITLAND RAMSAY, Glasgow, Scotland, considers Dr. Standish very fortunate in having been able to collect and to study so many cases of purulent ophthalmia in the adult, for in Scotland, although unfortunately ophthalmia neonatorum is always to be found, gonorrhoeal ophthalmia in the adult is a comparatively rare disease. Dr. Ramsay always taught that in the early stages of purulent conjunctivitis in the adult, when the pain is severe and the chemosis and inflammation are intense, the judicious use of ice locally affords great relief, but that whenever purulent discharge is established, cold is harmful and hot applications are more grateful to the patient. Dr. Standish's statistics, however, prove that corneal complications are more serious in those patients treated by cold than in those where iced applications are not employed, and if that be so, it becomes a matter for serious consideration whether the relief from pain which is brought about by the use of ice is not purchased too dearly if it is to be followed by greater destruction of the cornea.

DR. A. W. CALHOUN, Atlanta, Ga., emphasized the danger of argyrosis from the use of protargol. He has seen a discoloration following the free use of protargol which does not occur with argyrol. Weak solutions of these salts are very beneficial, whether the ulceration is the result of conjunctival infection or not.

DR. FRANK C. TODD, Minneapolis, stated that for the past four years he has been using protargol at the Minneapolis City Hospital and has had about 30 cases in which the protargol, or argyrol, has been employed. He has compared the treatment with protargol by the same nurses that were taking care of other cases being treated with nitrate of silver and found the results very much in favor of the protargol. In any statistics it must be borne in mind that cases vary, and that the treatment the patient receives from the nurse has a great deal to do with the result. Cases treated with silver nitrate showed that in about 30 per cent. of the cases the cornea became involved. In his treatment with protargol there was only one case in which the cornea became involved after the treatment

had been instituted and that was attributed to the too long continued use of cold applications. Cold was usually applied for the first day or so and in this case he neglected to order it discontinued, with the result that the cornea became involved. Regarding the comparative value of the two salts, he did not feel that the statistics would be of sufficient value, as they only cover about 30 cases to date, and so he undertook the experiment of using protargol in one eye and argyrol in the other. The solutions used were 50 per cent. in glycerin with each remedy, and were used the same number of times each day (from one to three applications daily) and the other treatment, which consisted in the use of cold applications for half an hour at a time every two hours during the first day if there was swelling of the lids, and the frequent use of boric acid solution for irrigation, and in certain cases, atropin. In all these cases the eye treated with protargol progressed faster and recovered quicker than the eye that was treated with argyrol. There was so much difference that there can be no mistake, and in some of the cases, when the protargol eye had been cured and the discharge continued from the argyrol eye, protargol was substituted for argyrol with immediate improvement in progress.

DR. JOHN E. WEEKS, New York City, agreed with Dr. Standish in regard to the cleansing of the sac, except, perhaps, that he prefers to wash away the secretion a little more thoroughly. This can be done without any danger by gently opening the lids and permitting the solution to flow in, thus irrigating the conjunctival sacs. The use of specula and lid retractors is harmful. The cleansing should be done very frequently in adults as well as in children. Dr. Weeks uses argyrol in the strength of 35 per cent. The applications are made about every two hours. The growth of the gonococcus ceases when the temperature is from 88 to 86 F. or below, but from 96 to 88 F. the growth is inhibited to some extent. Dr. Weeks has taken the temperature of the conjunctival sac in making cold applications in the ordinary way—that is, with pieces of gauze transferred from the ice to the eye every minute or minute and a half—with the result of reducing the temperature of the conjunctival sac to 92 F., which is low enough to prevent the growth of these organisms to some extent. This is one of the reasons why he advocates the use of cold to an extent, not sufficient, of course, to interfere with the nutrition of the cornea. He employs it for three hours at a time; he allows an interval of an hour and then resumes the applications for another three hours. Cold used in this way will not interfere with the nutrition of the cornea. Another reason is that advanced by Dr. Ramsay, namely, the relief from the intense suffering. The patient is given a high degree of comfort by the use of the ice compresses.

DR. HIRAM WOODS, Baltimore, stated that he had seen a number of cases of ophthalmia which Dr. Standish was treating in the manner described, and was impressed with the thorough cleaning the eyes got from the simple method of removing such secretion as adhered to the margin of the lids, separating the lids, and pouring the heavy protargol solution into the palpebral fissure. Dr. Woods indorsed the opposition to the introduction between the lids, for cleansing purposes, of toothpicks, probes, etc., armed with cotton. He has seen these things abrade the cornea and open a way to infection. Dr. Woods considers that cold promotes comfort, yet, if it retards cure, it should be abandoned. He mentioned 10 cases of purulent ophthalmia in children under 7 years of age recently treated with argyrol. All were of gonorrheal origin. In one case a 25 per cent. solution was used every third hour. In the others a 50 per cent. solution was employed twice a day. All the cases were cleaned with sterile water every hour. No case was lost. The average duration for the 10 cases was eight and a half days.

DR. H. H. SEABROOK, New York City, stated that he is an advocate of the use of cold, and has even used it after the cornea has been involved, and he has seen a cloudy cornea

clear up under its use. Dr. Seabrook asked if cold, presumably by its effect on the circulation, will not lower the temperature sufficiently to affect the growth of the gonococci in the lids, how does it become dangerous to the nutrition of the cornea.

DR. J. L. THOMPSON, Indianapolis, said that, until ten years ago, a case of ophthalmia neonatorum was rarely ever lost. Under silver nitrate treatment, Dr. Loring reported a case many years ago where both eyes were lost, and that was considered a most remarkable case. A great majority of cases will be saved by the mildest treatment imaginable. Dr. Thompson treated every case for a while with hydrastin, but he had one very bad case in an infant where a croupous membrane formed, and that case was lost, though subsequently treated with silver nitrate; one case in his whole life.

DR. S. O. RICHEY, Washington, D. C., said that he has tried all these new salts, and is still wedded to the nitrate. The difference in irritation is due largely to the amount of silver contained. He reverted to the use of the nitrate after trying all the other salts. Of course, solutions must be modified according to one's own judgment and experience. The effect on the mucous membrane is that of constructive metamorphosis. The unfortunate cases are mainly due to the fact that cold is used where one should increase nutrition. The tissues must be helped to resist the germs; not given something to impair nutrition.

DR. J. WALTER PARKE, Harrisburg, Pa., mentioned the last four cases he had treated in adults, one of which had a perforated cornea. His plan of treatment was lifting up the lid and, with a large pipette, washing out the eye thoroughly every thirty minutes, with 25 grs. each boric acid and sodium bichlorate, then dusting in a mild antiseptic powder after the irrigation. This controlled the discharge and at the end of a week it had ceased entirely. It acted better than any of the solutions he has ever used. He still employs the nitrate of silver in varying strengths once daily as an application to the lids.

DR. NELSON M. BLACK, Milwaukee, Wis., said that in several cases where destruction of the cornea had commenced the use of argyrol or protargol in an oily medium has given very good results. The oil lubricates the lids and the already partially destroyed epithelium is not further irritated by their movements. The argyrol, too, is not so easily washed out of the sac, so that the bactericidal action is continuous. The eye is first washed out, thus removing the secretion and after each washing an application of the argyrol in sterilized cod-liver oil is made.

DR. MARK D. STEVENSON, Akron, Ohio, called the attention of the section to the use of alphozone in solutions of 1:2,000 to 1:500. It is a powerful antiseptic, unirritating, and causing practically no discomfort. In small children and nervous people especially, it is well to wash and irrigate the eye by means of cotton that has been dipped in the solution to be used. By this simple means the eye and adjacent parts can be thoroughly cleansed without any danger of injury. The use of an irrigating apparatus and eye droppers is often harmful by removing some of the corneal epithelium, thus opening up new avenues for infection.

DR. LEARTUS CONNOR, Detroit, Mich., was impressed with the relative value of these new silver salts by a microscopic study of three cases occurring at the same time and under much the same conditions. One case was treated with nitrate of silver, one with protargol and the other with argyrol. In the case treated with argyrol, the gonococci diminished more rapidly than in either of the others. Some years ago, Dr. Connor saw disastrous effects follow the use of cold and since that time he has employed heat, not warmth, habitually. When the eyes are kept clean, without damage to the cornea, they tend to get well without other treatment. He has never seen harm result from the use of silver salts when used judiciously. An eye may be destroyed by the use of large amounts of nitrate of silver as the nitric acid is set free by the decomposition of the salt. The new organic salts, however, do not require so much care, as they are devoid of

destructive acids. The eye should be cleansed every five or ten minutes, day or night, in severe cases. With argyrol there is no discomfort to the patient.

Dr. E. E. HOLT, Portland, Maine, considers that it is cleanliness that has the best effect in the treatment of any case. Four years ago he advocated the douche. When the pipette, or irrigator, is used, and cleanliness is not obtained, it is because of the method. He is in the habit of using a Davidson syringe, using the smallest tube, at the outer canthus, and using a quart of water at a time and repeating this as needed every one, two or three hours, day and night. The time between the douchings may be employed in using cold applications and antiseptics. He allows the eye to get dry from wiping it with lint or absorbent cotton and exposure to the air, so that the tissues will not be soaked with moisture all the time.

Dr. MYLES STANDISH, Boston, said that he has never seen a case of argyrosis in acute gonorrhœal ophthalmia, either from nitrate of silver, protargol or argyrol. When it has been used in other cases, not acute, he has seen argyrosis with all three remedies. Much handling is dangerous in cleansing the eye. With a particularly careful and well-trained nurse more handling may be permitted, and he considers a properly trained nurse as important in these cases as in any case in medicine. In reply to a question, Dr. Standish said that the cornea derives its nutrition not from direct blood supply, but through the lymph channels, and anything that delays the passage of fluid through these channels must increase the danger to the cornea.

TUMORS OF THE EYE AND ORBIT.*

H. V. WURDEMANN, M. D.
MILWAUKEE, WIS.

There is no more interesting and outré subject¹ in the category of diseases than tumors of the orbit. A large proportion of these are seen and dealt with by the physician and general surgeon, rather than by the special practitioner, as the subject is intimately connected with neoplasms in other portions of the body, and in many cases is but a complication of other serious diseases. It has been deemed well to make a somewhat different classification from that hitherto used by Bull, Buller and other writers who have considered this subject as a whole.

CLASSIFICATION.

To accord with the demands of modern pathology, these tumors should be considered from their place of origin as follows: 1, Intraocular, which in the third stage involve the orbit and which are here but briefly considered; 2, primary in the orbit, to which this paper mostly relates; 3, secondary to neoplasms in the neighboring structures and sinuses; 4, arising from metastasis; 5, pseudoneoplasms.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

1. My original intention, in the preparation of this paper, was to make a collection of photographs and specimens for a pathologic exhibit for the Section. Realizing that no one man's experience would be sufficient to cover all phases of the subject, I corresponded with more than a hundred ophthalmic surgeons of experience, a number of whom have kindly aided me to amass the interesting collection herewith displayed. I was surprised that many, even some of great experience and long years of practice, had little or no experience with this subject. Many others had not secured photographs or saved specimens. The rather extensive collection of photographs and specimens herewith displayed have been obtained through the courtesy of comparatively few of our American ophthalmologists. I do not intend in this paper to make an exhaustive study, but reserve the privilege of putting more time on the work and eventually publishing a brochure, in which I shall attempt to exhaustively treat the subject and to reproduce many of the photographs and specimens herewith presented.

In accordance with modern pathology, I herewith submit the following as a skeleton on which I propose later to build up a more exhaustive article:

1. Neoplasms may commence in the eyeball and extend to the orbit in the third stage. Of these, lipoma and cyst of the conjunctiva are rare and non-malignant, while glioma and sarcoma are common and very malignant.

2. Primary orbital neoplasms may be properly described under the heading of the tissue in which they arise:

(a) Those arising in the mesodermal tissue, of which sarcoma in its various forms is most common. These are round, spindle, fibro, myxo, cysto, cylindro and plexiform. The so-called benign growths are mainly lipoma.

(b) Angiomata in its several varieties, including the nevus maternus, telangiectasia, cavernous angioma and lymphangioma.

(c) Pulsating exophthalmos and orbital aneurism.

(d) Tumors proceeding from the orbital walls; osteoma, osteosarcoma and cysts, the latter due to extension.

(e) Tumors of the optic nerve and sheaths, which are myxomatous, endothelioma, angiosarcoma, sarcoma, primary glioma, tuberculous disease, gummata, metastatic sarcoma.

(f) Tumors arising in the lacrimal gland: Hypertrophy, cyst, dacryops, adenoma, myxomatous and myxo-spindle, lymphosarcoma and epithelioma, carcinoma, eyelidroma, lymphadenoma and chloroma.

(g) True cysts, under which we may likewise place extravasations, dermoid and cystoid growths.

3. Extending from the frontal, ethmoidal, maxillary and sphenoidal sinuses, tumors are mostly sarcoma.

Extending from the skin: Fibroma, neuroma, sarcoma, adenoma, gumma, rodent ulcer, carcinoma, epithelioma. Extending from the conjunctiva and cornea are the tumors of the same variety.

4. Metastatic sarcoma and carcinoma. The sarcomata of the orbit sometimes give rise to metastasis in the brain and abdominal organs, but the converse is supposed to occur, especially with carcinoma.

5. Exophthalmos from pseudoneoplasms.

(a) Orbital effusions, hemorrhages.

(b) Orbital inflammations: Phlegmon and cellulitis, which may be primary or metastatic; inflammatory hypertrophy.

(c) Orbital protrusions from inflammation of the neighboring sinuses.

(d) Orbital anomalies, encephalocele.

PROGNOSIS.

As regards the treatment and expectation of life in the case of malignant intraocular tumors, the prognosis is favorable in the majority of cases if the eye be enucleated sufficiently early, the growth returning in the orbit in the others, the large majority of which die from the effects of extension of the secondary orbital growth.

In the case of primary tumors of the orbit—those of benign nature, by pressure on the globe and optic nerve, give rise to disturbances of motility, exophthalmos, diminution of vision and blindness, but, as a rule, are carried for many years without danger to life, the deformity being the main complaint. These benign growths should be mainly treated by excision, and in many cases it is not necessary to remove the eyeball.

The diagnosis of primary malignant growths arising

in the orbit is usually made too late to save the life of the patient by any treatment or operation, but we are happy to state that there have been a number of cases of undoubted sarcoma, and even of carcinoma, which have been subjected to thorough exenteration in which the tumor has not recurred and the patient's life preserved to the natural limit. Several cases are known to have been cured by the use of the Röntgen ray, without any operation, and in others, in which the neoplasm was removed, secondary treatment by the x-rays seems to have ensured its non-recurrence. The x-ray certainly relieves the pain and seems to hinder the development of these growths.

In the rare cases of metastasis into the eyeball or orbit, or where the growth has primarily occurred in the orbit and is accompanied by metastasis into other organs, the removal of the primary focus or secondary growths will not prevent recurrence. Extirpation even seems to increase the rapidity of the reformation.

We are happy to state that within the last few years a number of lives have been saved by early diagnosis, operation and the use of the Röntgen ray, which in previous years would have been classed as inoperable or subjected too late to the formidable operation of exenteration.

DISCUSSION.

DR. CHARLES S. BULL, New York City, stated that his experience has been largely in this variety of orbital tumors, and he has come to hold a very positive opinion on this matter. If the tumor develops within the orbital tissue proper, or is connected with the periosteum of the orbit, or with the sheath of the optic nerve, and on removal can be shown to be encapsulated, the prognosis is almost always a favorable one. If the tumor is not encapsulated, whether it has originated in the tissue of the orbit itself or in the periosteum of the bony walls, or in connection with the sinuses in the vicinity of the orbit, the prognosis is always unfavorable. Each operation for the removal of such a growth can never be a complete operation, hastens its return or recrudescence, and by so much shortens the life of the patient. In these cases of really inoperable tumors the matter should be fully explained to the patient, the reasons for the unfavorable prognosis plainly stated, and the patient should be told frankly that while an operation will give temporary relief from the symptoms, the recurrence of the growth will be hastened and his life will be shortened, and the patient should decide whether the operation shall be done. When the tumor starts elsewhere and involves the orbit secondarily, it should be classified as inoperable, in so far at least as the knife is concerned. These cases may very properly be subjected to the x-ray treatment. Dr. Bull has seen three cases within the year in which the application of the x-rays produced apparently marvelous results in the disappearance of the tumor and the relief of the painful symptoms. Sufficient time has not yet elapsed to enable him to pronounce the cases cured, but the relief from pain alone would justify a resort to this treatment for these hopeless cases, even if a cure can not be promised.

DR. E. C. ELLETT, Memphis, Tenn., mentioned two cases of tumor of the orbit presenting some peculiar features. The first was one of melanotic sarcoma of the choroid, occurring in a negro child aged 3. The parents noticed "something wrong" with the appearance of the eye in August, 1903, and when Dr. Ellett saw it in February, 1904, the tumor had burst through the cornea. Enucleation was not permitted until March 30, when the growth was found to have invaded the nerve and to have burst through the sclerotic near the posterior pole. Sections showed the nature of the growth and the infiltration of the nerve. Recurrence took place in two months and further operation was not advised. The second case was that of a girl, aged 14, who had just noticed a hard tumor at the inner angle

of the right orbit. This was in 1898. The tumor was 12x8 mm. in size, very hard and smooth, and lay just within the internal canthus. There was no pain or tenderness. The only other abnormality was an enlarged middle turbinate body on the right side. In one year the tumor had increased 4 mm. in width and there was epiphora. In two years it was 15 mm. wide by 12 in the vertical diameter. Operation disclosed a bony tumor, which proved to be a cyst, with smooth walls, containing about an ounce of grumous mucus. A probe could be passed backward $1\frac{1}{2}$ inches, down and back 2 inches, and up and down 1 inch. The bony front walls of the cyst were broken in, the wound was closed and in a few days the enlarged middle turbinate was removed, giving an opening into the cyst cavity from below. This remains open, there has been no increase in four years in the tumor, which is much smaller than before the operation, the epiphora ceased entirely, and there is no visible scar. The tumor was evidently a mucocele of the anterior ethmoidal cells.

DR. L. WEBSTER FOX, Philadelphia, said that his experience in x-ray treatment of these conditions has been considerable. His attention was first called to the treatment in conditions of epithelioma of the lids. A year and a half ago he had a case of sarcoma of the orbit; the diagnosis was confirmed by several colleagues and by the microscope. The case received 48 applications of the x-ray before the disappearance of the growth. There was no recurrence. The treatment has been continued about once in every two or three weeks. Dr. Fox's experience has been that in the so-called inoperable cases it is practically useless to perform any operation. It gives relief for the time, but at the end of a year or more the patient dies of metastatic trouble with the internal organs. He emphasized the fact that the x-ray seems to prevent the development of new growths and also relieves pain.

DR. J. F. KLINEDINST, York, Pa., related the history of a case of sarcoma of the orbit in a boy, aged 14, strong and healthy, whose father stated that for two months the right eye had turned upward slightly. There was no impairment of vision, nor ophthalmoscopic changes. On palpating the lower lid a small, round, semi-solid growth could be felt. There was no exophthalmos. Dr. Klinedinst made an incision in the lid, went in below, and found that the growth was encapsulated. The growth was found to have a semi-solid appearance and was removed in sections. Dr. Klinedinst enucleated what he supposed to be its attachments. Four or five weeks later the boy returned with the growth larger than it had been before operation. Then Dr. Klinedinst referred the case to a general surgeon, who opened up the orbital cavity and removed the inferior orbital ridge. The growth had extended into the antrum, which was opened, making a thorough operation and removing the floor of the orbit. The growth was examined by a skilled microscopist and found to be a round and spindle-celled sarcoma, probably of orbital origin. The patient made an excellent recovery, and there is no evidence of a recurrence of growth.

DR. J. O. McREYNOLDS, Dallas, Texas, said that according to his observations, gliomata of the retina nearly all recur. With regard to melanotic sarcomata of the choroid, as a rule, they do not so frequently occur. In one case the patient died a few years later from metastases in the internal organs. Dr. McReynolds said that in Dr. Würdemann's paper an error was made through oversight on his part in not reporting more accurately the case of the little child. He did operate on the case, but it recurred. It was a primary orbital sarcoma. They are almost certain to recur unless encapsulated. With the epitheliomata and carcinomata, his experience with the x-ray has been more satisfactory than in the cases of sarcomata. He has seen marked improvement with its use in a case that was inoperable.

DR. C. F. CLARK, Columbus, Ohio, asked if, with the x-ray, any one had succeeded in a case of glioma. He had a case some time ago in which the x-ray had no effect whatever, although persisted in. He has had success with it in cases of epithelioma.

DR. H. V. WÜDEMANN said that benign neoplasms may be removed generally without the loss of the eye, but there is sometimes loss of function, paralysis of the recti muscles, or, as in a case of his, optic neuritis. He believes, in contradistinction to Dr. Bull, that all tumors of the orbit that are supposed to be malignant when small should be operated on, and later subjected to the x-ray; benign tumors should be extirpated if they interfere with function. Since the use of the x-ray several cases of sarcoma have been cured without operation. Glioma seems to have been favorably affected by the x-ray in a case of his; the child is still alive, although an exenteration of the orbit was done last July. It stopped the pain and the child has been free from pain since.

POST-OPERATIVE INFECTION OF THE EYE.*

JOSEPH A. WHITE, A.M., M.D.

Professor of Ophthalmology and Associate Professor of Otolaryngology in the University College of Medicine; Senior Surgeon to the Richmond Eye, Ear, Throat and Nose Infirmary.
RICHMOND, VA.

The subject of infection of the eye following operations that expose the interior of the globe to the possibility of bacterial invasion, such as cataract extractions, needle operations and iridectomies, is one of doubtful interest in these days of modern antiseptic methods, because such an unfortunate result of an operation is regarded askance, as if it could only have happened through neglect of well-established precautions by the operator.

I suppose this accounts for the fact that it is hardly mentioned by our latter-day text-books, it being taken for granted that if these precautions are taken, it is hardly worth the space or time to discuss a bare possibility, as the space is needed for what is more commonly met with. Moreover, when it does occur it is practically regarded as a hopeless affection, not remediable by any known methods of treatment, and this pessimistic aspect of the subject may also account for its practical neglect.

In order to get some idea of the frequency of post-operative infection I wrote a number of letters to prominent ophthalmologists in different parts of the country, because I was not satisfied to base a paper of this kind on my own individual experience. Their replies would seem to confirm the statement above, that it is a rare trouble in these days, although the frequency of it seems to differ in the experience of different operators. Some of them have had no infection in any operation for years past, although one adds that in his early days of practice its occurrence was too often for his peace of mind. Others have had one-half of 1 per cent. based on a large number of operations, and the highest percentage given by any one gentleman was between 3 and 4 per cent., the general average being between 1 and 2 per cent. Going back to old records of cataract extraction twenty-five years or more ago. I find that the percentage of infections after operations was considerably higher, in some instances as high as 10 to 20 per cent., the difference being due, undoubtedly, to modern antiseptic methods.

The text-books of that time and previous years lay great stress on careful watchfulness for the advent of this complication, and warn us to look for an infected flap in from twelve to twenty-four hours after an operation, although they give different causes for it. Some

state that it commences in the iris, some that it comes from conjunctival or lachrymal secretion, while others give constitutional causes for it, but all suggest the same treatment, viz., atropin, hot fomentations and the pressure bandage. Where it was diffuse it was considered hopeless, as it always ended in panophthalmitis. In circumscribed infection of the wound the suggested remedies were supposed to be valuable in arresting its progress.

Over twenty years ago Abadie claimed that post-operative suppuration was always due to infection of the corneal wound by microbes, and was in no way dependent on the patient's condition, nor on the manner of incision, whether with or without a conjunctival flap; that the only way to lessen the frequency of post-operative infection was by thorough antiseptics. From different authors it seems that post-operative trouble may arise from conjunctival, lachrymal or nasal secretions; that the presence of capsule or cortex remnants in the wound, or the exposure of the vitreous from rupture of the hyaloid predisposes to infection; and that people with diabetes, senile marasmus, or septicemia, or with suppurative foci anywhere about the human system, whether ulcers or abscesses about the limbs or body, or aural discharge, were much more liable to infection. Added to this, improper asepsis in the operation, and we would have all possible causes for this serious complication.

In examining the reports of many thousand cataract extractions in the last thirty years, I find a steady decrease of this trouble. For example, in a report of 200 cases in 1877 by one of our best-known ophthalmologists there were twenty-five cases of post-operative infection, of which eighteen had a negative result, 9 per cent. Two years later in 100 extractions there were eight cases of the same trouble with negative results, 8 per cent. Two years later again in another hundred cases we find only two cases, 2 per cent. Still two years later in a hundred cases we find only one case, 1 per cent. Since then this operator and others have recorded a like series with no infection. A report of 1,400 cases between 1868 and 1883 showed about 4 per cent. of post-operative infection, while a series of 1,000 operations between 1891 and 1895 showed less than 1 per cent. of infection.

Taking all the reports I can find since then, running into the thousands, and from correspondence, there has been no improvement over this. No methods have been suggested that exclude entirely this fatal complication, and it seems to remain at about 1 per cent. on the general average. Now, is this steady improvement in barring infection due to the manner of operating or to the method of technic? From the advent of Listerism to the great improvements in what we may call modern operative technic there has been a gradual reduction of suppurative complications in all kinds of surgery; and statistics, unless absolutely valueless, have been given to show the same results in eye surgery.

From Horner's first brilliant results with antiseptics down to to-day, we find by examining thousands of cataract extractions a steady decrease of infection, although even 1 per cent. is too much, considering the uncertainty of the treatment. It is one of those troubles where the old adage that prevention is better than cure certainly applies, because, as far as treatment is concerned, there has practically been no improvement in the last twenty-five years, there being no remedies to-day on which we can place any reliance. It is more than twenty years ago that it was suggested to apply the actual or galvanocautery to the corneal wound as soon as signs of infection

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

presented themselves. In cases of circumscribed infection I must say it has proved its value and in some rare cases of diffuse infiltration it has been claimed that it arrested the process, but I doubt if we have gotten any further in reaching a satisfactory treatment in the last two decades in the attempt to combat this most fatal of post-operative complications.

The experience of those with whom I have corresponded has not lessened this uncertainty. New remedies have been experimented with and new methods of treatment have been tried with uncertain if not barren results. Most ophthalmologists to-day, once infection has set in, regard the case as hopeless; as one of them aptly said, his only remedy was Christian resignation, and I wondered if he had his patients equally well educated in that respect. Cauterization with the actual or galvanocautery, pure carbolic acid, and saturated solutions of nitrate of silver; subconjunctival injections of mercury (the cyanid and bichlorid), injections into the anterior chamber of chlorin water, 25 to 50 per cent. solutions of argyrol, bichlorid 1 to 5,000 and 1 to 1,000, and formalin solutions 1 to 10,000.

In addition to these methods the open treatment of the eye with repeated cleansing with antiseptic washes, bichlorid, boracic acid, formalin and argyrol solutions and with antiseptic salves, such as bichlorid and iodosal. Powdered iodoform seems to be in favor with some writers. Internally, saline purgatives, iodid of potash, salicylate of soda, quinin and calomel in small doses, and mercurial inunctions cover the whole range of treatment. They dilate extensively on these methods of treatment; none of which, in my opinion, have been demonstrated to be satisfactory. I should think that on account of the nature of this process, which is at first an infiltration of the edge of the wound, usually starting in the corner but at once involving the deep layers of the cornea, causing necrosis, that the most rational treatment would be to reopen the wound, fill the anterior chamber with a 50 per cent. solution of argyrol, apply the galvanocautery to the edge of the wound, trusting to prevent the migration of bacteria into the deeper tissues, and treat the case by the open method (Heinemann) with argyrol, sterile washes or antiseptic salves as may appear best to each operator. Some authors do not hesitate to inject into the anterior chamber a 1 to 1,000 solution of bichlorid, just as they inject it into the conjunctiva in these cases. Pflüger, Abadie, Darier, Deutschmann and quite a number of prominent ophthalmologists claim great things for this method. Some consider this solution too strong, because it would probably damage the endothelial layer of the cornea, but it has good authority and wide experience for its use.

But, all things considered, we must place more dependence on prevention than on any curative treatment, and this brings up the question of the most rational methods of asepsis in ophthalmic surgery.

Since Abadie's insistence on thorough antiseptic preparations for the operation to make it as aseptic as possible, many observers and writers have suggested different methods for getting as sterile a field for operative work on the eye as is claimed for operations elsewhere, by neutralizing, as far as practicable, the effect on the wounded eye of the secretions from the conjunctiva, lachrymal sac and nose. Many have claimed and still claim, that it is impossible to sterilize thoroughly the conjunctival sac (Gayet), and in the face of this impossibility limit themselves to the simplest kind of antiseptic, flushing the eye with sterile water, normal salt solu-

tion, solutions of boracic acid, or a weak solution of bichlorid of mercury. Others prepare the patient in advance by some of the suggested methods of sterilizing the conjunctiva, doing what can be done to obtain a sterile field without doing harm to the tissues. They flush out the nose and nasopharynx with a solution of permanganate of potash, 1 to 1,000, or any other antiseptic solution, and clean the eyelids and lashes frequently for several days before the operation, in addition to flushing the eyes with boracic acid, or normal salt solution.

If there is any discharge present from the conjunctiva or lachrymal sac, argyrol seems to be in special favor just now in doing away with this. If there is any oozing from the canaliculus, some operators tie the canaliculus with a suture to prevent the secretion from the sac emptying on the conjunctival surface. If there is any mucocele of the sac, and applications fail to get rid of the secretion, the sac is destroyed.

The whole question of the preparation of the patient by antiseptic measures I find depends altogether on the opinion of the different operators as to the possibility of sterilizing the conjunctival sac, and as to the effects of the chemicals used for that purpose. And here, therefore, it might not be amiss to refer briefly to the conditions that confront us.

It is claimed that the conjunctival sac is rarely, if ever, free from bacteria, that being such a good receptacle for everything that floats in the atmosphere it necessarily has the best chance of collecting foreign material. Moreover, it is rubbed by dirty hands and soiled handkerchiefs and so constantly brought into contact with so many things that might carry infection by the majority of people, that it is an easy matter to introduce foreign matter, and if this is of a deleterious nature, it has the best chance for propagation in its folds and crypts.

Moreover, it is the outlet for any pathogenic organisms in the lachrymal sac or duct, and indirectly through these passages from the nose. It would take up too much time to go into all the different species of bacteria that are found in the conjunctiva, but we know that we have many kinds, both harmful and harmless. Among these, according to different authors, is the pneumococcus of Fraenkel, one of the commonest habitants, and by Gifford supposed to be the cause of catarrhal conjunctivitis. Weeks,¹ however, lays this same trouble at the door of a small rod-shaped bacillus to which he has given his name, and his contention is supported by other investigators, particularly Moran and Beach. It is questionable whether this bacillus is found in the normal conjunctiva. Among other harmful bacteria found are the bacillus coli communis, which Randolph has also found in the pus from a case of panophthalmitis, the staphylococcus pyogenes aureus, the staphylococcus pyogenes albus and the micrococcus pyogenes.

We have, then, a great number of harmless bacteria in the conjunctiva which do not produce pathologic changes, but may under certain conditions produce toxins which aggravate pre-existing trouble. We have also harmful bacteria present in the conjunctiva which do not produce any trouble unless the soil is specially ripe for it. In other words, where the vital resistance is normal, no trouble follows their entrance into the conjunctiva, but any lack of vital resistance will result in inflammatory reaction.

1. Dr. Weeks claims that the pneumococcus is found in a healthy conjunctiva, but requires special surroundings to develop any pathogenic conditions, whereas, his bacillus is not found in a healthy conjunctiva and immediately produces trouble as soon as it is lodged in the eye.

And lastly, we have a third species of bacteria, such as Weeks' bacillus, and gonococcus which produce trouble as soon as lodged on the mucous surface.

Of course, the presence of these bacteria requires important consideration when we are about to do surgical work. Their presence may be perfectly harmless until surgical intervention brings about a new condition of affairs, resulting in harm from previously harmless inhabitants of the conjunctiva. Naturally, if we can remove these possible sources of post-operative trouble from the conjunctiva by any means, mechanical or chemical, we will establish that cleanliness or aseptic condition which all surgeons are constantly striving after.

But can this be done in ophthalmic work? Theoretically the same principles should be applied to eye operations as to any other wound treatment, absolute cleanliness so far as practicable, and if possible, the elimination of the causes of purulent inflammation, viz., pyogenic micro-organisms, irrigation with sterile fluids to remove mechanically bacteria present in the conjunctiva, and the use of an antiseptic application that will destroy germ life without damaging the mucous membrane or lowering the vitality of the tissues.

It is questionable whether we ever succeed in producing strict asepsis, although the presence of pyogenic germs does not always excite suppuration in a wound. The living tissues have a certain resisting power that is frequently stronger than the attacking force, in which case the onslaught fails and we have healing without reaction; if this resistance is lowered sufficiently the attack prevails and we have infection. Hence it is that the conditions existing in different individuals would give different results with the same germicidal agent; it would give a sterile field for operation in some and not in others. Laboratory experiments with the same agent could not represent exactly the action of the chemical on the living tissues, as they are made with the conditions fixed and known, while the conditions of the living tissues can only be imperfectly known and their resistance power, or vital force, absolutely unknown. Even in laboratory experiments observers differ, and therefore give us conflicting reports in regard to the germicides experimented with. Sublimate solutions, 1 to 1,000, 1 to 2,000 and 1 to 3,000, have apparently produced different effects on pus cocci according to different writers, due probably to a difference in the technic of the methods employed, or to the failure to preserve the same temperature.

In ophthalmic practice the strength of the sublimate solution generally employed for irrigating and cleansing the eye is about 1 to 5,000. This is supposed by most writers to kill pus cocci in about three minutes. Some use it stronger, some weaker. Some have discarded bichlorid solutions altogether and use only sterile water, because, they claim, that a solution strong enough to kill pyogenic organisms in the conjunctiva will cause too much irritation of the eye and lower its normal resistance, and that a sterile solution of any kind will answer to cleanse the conjunctiva mechanically, as that is all that can be accomplished.

Now, we all know the difficulty of disinfecting the skin. But we also know that the skin can be disinfected by antiseptic dressings kept in contact long enough to accomplish the result. Why can not the conjunctiva be rendered sterile by the same means? For some years past I have been experimenting along this line. As aqueous solutions could not be kept in contact with the conjunctiva I resorted to vaselin as the menstruum instead

of water, and bichlorid as the chemical. I made an ointment of 1 grain of bichlorid of mercury, 5 grains of chlorid of sodium and 6 ounces of vaselin. The salt is added to prevent albuminoid deposit. The vaselin is boiled. The bichlorid and salt are dissolved in a few minims of water and added to the boiling vaselin. After boiling, the bichlorid vaselin, 1 to 3,000, is put away in jars until used. I find it a good menstruum for atropia, eserine, cocain and other medicaments used in eye affections instead of dissolving them in water. In all cases of discharge from the eye, mucus, mucopurulent or purulent, I find it valuable as a dressing, the conjunctival sac being filled with it as often as needed.

In cataract operations I prepare my patient as follows: The night before a bath and a purgative are given, eyebrow, lids and lashes are cleansed thoroughly by soap and water, followed by a bichlorid solution, 1 to 1,000 and alcohol, the conjunctival sac is thoroughly irrigated with a bichlorid solution, 1 to 10,000, and filled with the bichlorid vaselin. A sterile pad and bandages are then applied to the eye, and it is not opened again until the patient is put on the operating table. The bandage is then removed and the sac irrigated anew with a weak bichlorid solution, 1 to 10,000. The sac, being kept filled with this sterile preparation for twenty-four hours after thorough irrigation, is much more likely to become sterile and remain so than if merely washed out. No organisms can live in this medium, as bacteriologic investigations have proven. The only defect in the technic is that the sterilizing medium is not applied often enough. The eye does not retain a particle or sign of the vaselin in even a few hours after, except that the lid is somewhat greasy. But if the contact for a few hours succeeds in destroying or preventing the development of germ life, there is no chance of infection from without while the eye is kept sealed, although there is always danger of infection from within, if there is any pathologic condition with purulent secretion, or any affection of the lachrymal sac, or a purulent rhinitis.

This method of sterilizing the conjunctiva is on the same principle as the disinfecting of the skin. Laboratory experiments with this same preparation on the skin have proven its efficiency. All germs are destroyed by it in a short time, even the germ of anthrax.

Over 500 cataract extractions have been made at the Eye Infirmary with this method, with but one case of infection of the wound, and that limited to one corner. This occurred on the fifth or sixth day and was due probably to outside infection caused by the patient's carelessness. I mention this apparent clinical demonstration of its value for your consideration. You can decide its value. I would say here that the eye is dressed with the same preparation each time the bandage is removed after operation.

I have never seen any marked or annoying irritation from this application, except once or twice, in hundreds of cases, possibly running into the thousands, and because of this fact I have never been able to understand how others get so much irritation from the use of the bichlorid. I believe that the bichlorid in the salve is absorbed just as the atropia or eserine or cocain is, and that it thereby helps to render the corneal tissue to a certain extent immune against infection. This is a speculation, of course, but why should not the bichlorid be absorbed as readily as the other remedies whose effects prove that they have passed through the cornea?

Dr. Stuart MacLean, professor of bacteriology at the University College of Medicine, examined twelve cases

of cataract before and after the use of this application. These cases were in the hospital. In all twelve, except one, he found bacteria in the sac before the patient was prepared for operation, twenty-four hours after the use of the vaselin, when the eye was opened on the operating table, the cultures taken from the eyes showed no growth in the tubes except in one case where a slight growth developed on the fifth day. The tubes were kept in the incubator from three and one-half to five days.

In eighteen of the cases taken at random from the clinic out-patients to see the effect of the ointment, bacteria were invariably found prior to the application, and only four of them showed growth from the cultures taken twenty-four hours after the application. Three of these four cases were dirty negroes of the lowest type, two of them with phlyctenular keratitis, and one with chronic glaucoma and inflamed conjunctiva with constant secretion. All these showed staphylococcus pyogenes, whether aureus or albus was uncertain by the microscope, as no plate cultures were made.

The other one was a case of capsulotomy in which the cultures showed a number of micro-organisms (possibly saprophytes), which Dr. Hoen, the bacteriologist of the Pasteur Institute of Richmond, said could not be morphologically classified. He reported that the chief organisms found were a very thick, jointed bacillus, varying in length, and as many as five or six in a string (possibly the bacillus mesentericus vulgatus, or the bacillus hirsutus); another very slender bacillus, somewhat resembling the tubercle bacillus; a third, short, thick and nearly oval in shape (possibly the pneumonia bacillus), and the fourth a long, slender, thread-like organism resembling the leptothrix buccalis, which has been found in the lachrymal passages. Clinically the case did well and had no trouble. In this case the presence of the micro-organisms was probably due to a defect in the technic.

The following cases showed no growth after the use of the ointment: Three of phlyctenular keratitis, two of catarrhal conjunctivitis, three of superficial corneal ulcer, one wound of the eye with prolapsed vitreous, one iritis, one capsulotomy, and two of foreign body on the cornea.

In the twelve hospital cases only one showed a growth, but the conjunctiva in all of them was in a normal condition, there being no pathological alteration in the eye apart from the cataract; whereas in the outdoor cases nearly all had some trouble of the conjunctiva either primarily, as in phlyctenular keratitis and catarrhal conjunctivitis, or secondarily as in corneal ulcer, iritis, wounds and so on. Notwithstanding only four in the seventeen showed a growth in the culture taken twenty-four hours after the application, and these the very worst of the whole number.

While I do not consider the number sufficient to draw any definite conclusions, they certainly help to support very strongly the clinical results given above as to the efficiency of the application in sterilizing the conjunctiva. I think, therefore, that this method is worth a trial in our effort to get an aseptic condition in ophthalmic surgery.

DISCUSSION.

DR. S. D. RISLEY, Philadelphia, said that one never feels sure that the most faultless diagnosis is going to result successfully because of the danger from this lack of sterilization of the operative field. He thought it reasonable that the bichlorid of mercury, or any other agent of that kind, placed in the sac in an unctuous medium would have a longer opportunity for effect

than when used in solution. He is convinced that the free use of bichlorid of mercury immediately preceding the operation and then followed with a solution of cocain disturbs the integrity of the epithelium of the cornea and often does harm. For some time he has been avoiding the use of these methods just preceding the operation, and has been using only boracic acid, or sterile salt solution, or water, in preference to bichlorid of mercury. He is always careful to mechanically sterilize the edges of the lids and the openings of the meibomian glands by scrubbing them with a pledget of cotton dipped in boracic acid solution, or salt solution. In suspicious cases, where there has been some disease of the lachrymal sac or nasal passages, he treats the sac or passages with an antiseptic solution, dilating the punctum and washing out the sac with the aid of the lachrymal syringe, and immediately after the operation dusts the inner canthus with iodoform. In cases where, notwithstanding the precautions taken before operation, we find the lids swollen at the first dressing, with possibly a gray membrane formed, he scrubs them with a pledget of cotton dipped in boracic acid solution, or perhaps even with bichlorid, and then applies a weak solution of nitrate of silver (2 to 5 gr. to the ounce) to the edges and every portion of the wound. He has not used any of the modern silver salts on the conjunctiva in these cases. He has injected a weak solution of nitrate of silver into the sac, allowing it to remain there a moment and then washing it out again with salt solution. Only rarely in the last fifteen or twenty years has he had any serious infection of the wound after operation. He believes that infectious processes result often unexpectedly. The operation is attended by many persons, of the condition of whose respiratory passages nothing is known; they cough and spread into the atmosphere around the patient various organisms and these doubtless often settle on the instruments or on the conjunctiva of the patient.

DR. HERMAN KNAPP, New York City, stated with regard to infection following cataract operation, that not everything is infection that looks so. One such condition is that of the exudate sometimes seen in the anterior chamber after extraction. It is seen in syphilitic subjects and in cases of traumatism especially. It differs from a real infection in that the edge of the lid is not swollen. The conjunctiva is swollen and there is this exudate in the anterior chamber, which fills it more or less and which fills often not only the anterior chamber but the vitreous as well. He has seen it occur in cases with gonorrhoea. Recently he saw such a case; it looks exactly like ophthalmia, except that the lids are not swollen. The conjunctiva was swollen and the whole anterior chamber filled with a yellowish-white exudate. He sent the patient into the hospital for treatment. This spongy exudate is sometimes described as gelatinous. It coagulates in the lower part, and in the upper part of the chamber is an area which is perfectly clear. From day to day the exudate grows less and disappears entirely, leaving no trace. It is the same in the vitreous chamber. Actual infection probably comes from the lachrymal sac and to be safe the sac should be extirpated, which can be readily done.

DR. F. C. ARD, Plainfield, N. J., said that he has had two cases this year of the spongy iritis referred to by Dr. Knapp. The first case followed a cataract extraction by the combined method. After the exudation in the anterior chamber was absorbed he found the vitreous filled with floating opacities, and the best vision he could get with a suitable correction was 20/200. The second case was one of injury in the ciliary region caused by a tack. The condition looked very serious, as all these cases do, but in a few days the nature of the case was apparent, and a diagnosis of spongy iritis made. When the spongy material in the anterior chamber was absorbed he found the vitreous filled with a yellowish exudate, and the patient is to-day blind in that eye. His experience in these cases has led him to give a much more guarded prognosis than is given by Dr. Knapp in his article on this subject in Norris and Oliver's System of Diseases of the Eye.

DR. J. A. LIPPINCOTT, Pittsburg, Pa., said that he has used the method described in the paper in every case of cataract extraction since Dr. White suggested it to him several years ago, and he is satisfied of its efficacy. Spraying the nostrils with a

solution of permanganate of potassium is useful, and he still practices that procedure, but it is not absolutely preventive. In his opinion the prophylactic power of the bichlorid ointment is due to its remaining in the lachrymal canals, partially plugging them, and thus presenting a mechanical as well as chemical barrier to the entrance of germs from the nasal passages.

Dr. E. E. HOLT, Portland, Maine, stated that he has had one suppurative in 200 cases. He is still, however, very much in favor of the method and uses it in every case.

Dr. C. R. HOLMES, Cincinnati, said that it was his misfortune, early in his career, to lose a case from an infected tear sac, and that led to his following the method of extirpating the sac and gland. He would refuse to operate where there is a purulent inflammation in the tear sac unless he could extirpate the sac. He has performed this operation in a patient over 80 years old with perfect success. He long ago abandoned the idea of trying to clean the mucous membrane that has not shown any inflammation prior to the operation, as he thinks that this only sets up an irritation that gives a good chance for infection. He does not use anything at all except sterile water, or a saturated solution of boracic acid.

Dr. V. T. CHURCHMAN, Charleston, W. Va., said that since Dr. White spoke to him several years ago about this method of preparing sterilized sublimated vaselin, he has used it in every case on which he has operated since. He had infection in only one case and that subsided promptly on following up the treatment.

Dr. J. L. BORSCH, Philadelphia, said that one point not brought out is the cleansing and sterilization of the lashes prior to operation. He does not believe it is the proper thing to use very strong solutions in sterilizing the conjunctival sac; they seem to make infection more probable. De Wecker simply cleanses and sterilizes the lids and lashes with cyanid of mercury, 1 to 100, then flushes the conjunctival sac with a boracic acid solution and follows this with a douche of sterile distilled water. Dr. Borsch follows this method and finds it entirely satisfactory.

Dr. F. P. LEWIS, Buffalo, N. Y., said that he has had in two cases a suspicion of infection, one from the sac and the other from without. He has wondered, in view of the success of the Cr d  method, that the silver salts have not been more used in these cases. With that idea in mind some years ago he made it a routine practice, in attempting to thoroughly cleanse the eye, to use a solution of 2 or 3 per cent. protargol in the eye just prior to operation. It is non-irritating and Cr d 's experiments have shown that there is certainly a lessened probability of infection in gonorrhoeal ophthalmia. It would seem reasonable, therefore, to suppose that like protective results might be expected in operative cases. Since using it he has had no infections.

Dr. J. A. WHITE said that the actual treatment of the infection itself and how to get rid of it is just as much in the dark as it was before. Each one has his own methods for the prevention of infection. He thinks that in his case the infection came from within, perhaps because he did not investigate the condition of the nose properly before operation. He included cleansing the lashes in the prior cleansing of the eyelids as given in the paper, viz., scrub with 1 to 1,000 bichlorid, and then wash with alcohol before applying the ointment to the eye and lids.

Honest Experts Wanted.—Dr. S. Solis-Cohen read a very interesting paper at the pharmaceutical meeting in the Philadelphia College of Pharmacy, November 15, on "The True Scope of Scientific or So-Called Expert Testimony in Trials Involving Pharmacological Questions." He said that the expert should distort, magnify or minimize nothing, assert as positive nothing doubtful, throw doubt on nothing certain, and say nothing he would not defend before a learned society. He further said the expert's efforts should be bent to elucidate truth and not to score points for either side. The court should restrict examination to matters having actual bearing on the case at trial; but the testimony of the expert should be given only with reference to scientific accuracy, and not with reference to its effect on the verdict.

SEPTIC THROMBOSIS OF THE CAVERNOUS SINUSES.

WITH A REPORT OF THREE CASES.*

E. C. ELLETT, M.D.

MEMPHIS, TENN.

CASE 1.—J. W., white, male, age 15, of good family history and previously healthy; was taken sick Aug. 2, 1898, with pain in and around the right eye. This pain was severe, but I was not able to ascertain if it was accompanied by other local symptoms, or if there was fever. The pain was relieved by acetanilid, but returned next day, and there was then swelling over the brow and fever.

Examination.—These symptoms persisted, and he was brought to Memphis on the fifth day of his illness and was placed in the care of a general practitioner. There was a fluctuating swelling over the frontal region, extending up to the hair and down to the root of the nose. This was incised at its upper border and pus escaped. On the next day an incision was made above the root of the nose for better drainage. On the ninth day of his illness I was asked to see him on account of an involvement of the eyes, especially the left. I found the two openings as described, discharging pus from a common cavity. The eyelids were swollen till the eyes could not be voluntarily opened. A fluctuating swelling was seen at the upper and inner corner of the right orbit, and the left eye showed exophthalmos, with fixation of the ball, edema of the conjunctiva and ulceration of the cornea at its lower margin. The pupils were normal. The skin was of a pale yellow, temperature 103 to 104 degrees, and a small abscess was found over the left parietal region. The pulse was rapid, mind clear. In other words, there was general septic infection, apparently having its origin in the right frontal sinus.

Operation.—Under general anesthesia the abscesses were freely opened, the left frontal sinus opened and found full of pus, the lining thickened, and an opening in the septum between it and the right sinus. The sinuses were cleaned out, thrown into one, and opened freely into the left nostril. Pus was present in the right orbit, none in the left. The operation was done at 11 a. m. and the collections of pus being liberated and provision made for drainage, a hopeful view was taken of the case. We did not recognize the fact that we had to deal with anything more than the accessible foci of suppuration. At 2 p. m. the temperature was 105 degrees, and briefly, all the symptoms grew worse. A general surgeon was called in consultation and could suggest nothing further than repeated exploration of the left orbit for pus, which was never found. Stupor developed and on the fourteenth day of his illness a right hemiplegia appeared. The patient was then comatose, and without further change in the local symptoms except a spread of the corneal ulceration in the left eye, he died on the fifteenth day of his illness. No autopsy was performed.

CASE 2.—N. G., white, male, aged 27, was seen in consultation with Dr. W. T. Michie, through whose kindness I am permitted to report the case, on June 20, 1903. Six days previously he had consulted Dr. Michie for a phlegmonous inflammation of the right ala nasi of two days' duration. It had started as the common furuncle in this situation usually does, but was, when seen by Dr. Michie, so severe and so painful that a general anesthetic was given and a free incision made. On the following day the nose was red and swollen to the root, and both eyelids somewhat swollen. On the next day the symptoms were all worse, with elevation of temperature, swelling of the right eyelids, nose, forehead and right side of the face and neck. In the mouth a right peritonsillar swelling was seen. All the swellings were edematous rather than inflammatory.

Examination.—When I saw him on the eighth day of his illness there was a swelling and redness of the nose and right lid, and slight swelling at the inner angle of the left orbit.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

The peritonsillar swelling persisted, as did the edema of the right side of the face and neck. There was right exophthalmos, the orbit being tense, and conjunctiva edematous (right), but the ball itself was normal, the pupil reacting and motion being unimpaired. Temperature 102.5. He had had several chills. I gave my opinion that a septic thrombus existed in the right cavernous sinus, just beginning to involve the left one, and that the patient would die. I saw him again on the eleventh day of his illness. He was then unconscious, but could be roused to answer questions. Incisions into the peritonsillar swelling had evacuated a quantity of dark blood, but no pus. The temperature was running from 100 to 102.5 degrees, the pulse was rapid and weak, respiration 50. He was restless, tossing from side to side and pulling at the bed-clothes. No signs of consolidation in the lungs could be made out, though there must have been one or more metastatic abscesses. There was double exophthalmos. On the right side the conjunctiva was hemorrhagic, slight dilatation of the pupil, and divergent squint (oculomotor paralysis). The left eye was normal except for edema of the lids and conjunctiva, and a black, dry slough in the center of the upper lid the size of a dime. A similar large area was seen on the bridge of the nose and a large oval bluish spot on the forehead. The edema of the right side of the face and neck was worse. The patient died at 7 o'clock that evening. No autopsy.

CASE 3.—G. W., white, male, aged 27, consulted my associate, Dr. Farrington, on Oct. 2, 1903, with a small pustule at the end of the right nostril. This was gently ruptured, swabbed with bichlorid of mercury and a wash of the same solution given for use at home. The next day the parts were still inflamed and the process was repeated. On the 4th he was seen by his family physician, Dr. Malone, who was at the house to see our patient's child. The nose was still red, swollen and painful, and learning what had been done, Dr. Malone did not give any active treatment, but on the following day, October 5, the symptoms not abating, Dr. Malone made a free incision of the inflamed area under local anesthesia. There was no evidence at this time of any extension beyond the nose, but on the 6th the morning temperature was 102 degrees and the lid of the right eye was swollen. That evening the temperature was 104 degrees and the pain was intense. On the morning of the 7th Dr. Farrington saw him with Dr. Malone and made the diagnosis of septic thrombosis of the right cavernous sinus.

Examination.—The patient was removed to our infirmary, where I saw him at 2 p. m. on this, the fifth day of his illness. The nose was red and swollen, and there were several small superficial pustules at the end. The lid of the right eye and the skin of the forehead were edematous, a phlebitis of the supraorbital veins could easily be made out, the conjunctiva of the right eye was chemotic and swollen and the ball fixed, pupil slightly dilated and vision obscured as by a white mist before the eye. The lids of the left eye were slightly swollen at the inner corner. Temperature 104 degrees, pulse 112, mind clear.

Operation.—Under chloroform the nose was freely incised and some pus escaped. The right orbit was incised, but no pus was found. Six drams of antistreptococci serum was administered, but had no effect and was not repeated. The treatment was symptomatic, and no material change could be suggested by any of several consultants, among them Dr. A. J. Ochsner of Chicago, who was in the city attending a meeting of the Mississippi Valley Medical Association. On the sixth day the conjunctiva of the left eye became edematous, the temperature remaining high and the pulse rapid. That night the patient began to sink rapidly and became delirious, and next morning (seventh day) was weaker, with temperature 105 degrees, cold extremities and active delirium. The right eye was divergent with dilated pupil. Death at noon of the seventh day. No autopsy.

It is a question whether this is the proper place to report cases of this condition, but I do so because these cases were seen by me on account of apparent eye symptoms. Moreover, the disease is rare, and as this rather

large number of cases have fallen under my notice, I venture to relate them for the purpose of calling attention to the condition.

The literature on this subject is not abundant by any means. Dwight and Germain¹ append an extensive bibliography to their report of 4 cases, and were able to find 178 cases, with their 4, making 182. I would refer those interested in the literature to this article. The importance of the condition lies in its great mortality, only 14 of these 182 cases recovering. In septic cases the prognosis is always bad. Since this collection of cases others have been reported by Day,² Lodge³ and Finlay.⁴

Day's patient was a child of 11, suffering with chronic purulent otitis media and mastoiditis, both of the right side. Five days after operation the right eye was swollen, and thirteen days later the left eye was similarly involved. Fluctuations in the temperature seemed to be due to retention of pus in the mastoid wound, and though both cornea ulcerated the child recovered, leaving the hospital at the end of four and one-half months. Largely on account of recovery, Day thinks the thrombi in the cavernous sinuses must have been non-infective and ultimately absorbed. Its association with mastoid disease he regards as a coincidence. The lateral sinus was not involved, though cases have been observed where the infectious process spread from this sinus to the cavernous by way of the superior petrosal.

Lodge's case was a married woman, aged 41. The trouble originated in the left peritonsillar region, spreading to the cavernous sinus of the left side by way of the pterygoid plexus. Pus was found on incision back of the last molar tooth, and later a purulent discharge came from the left nostril. The antrum of Highmore was healthy. Autopsy verified the diagnosis, there being septic thrombi in both cavernous sinuses and pus distributed pretty well over the base. The sphenoidal sinus was full of pus, other accessory sinuses healthy. He thinks there was a primary marasmic thrombus of the pterygoid plexus which became infected from the mouth.

In Finlay's case all the symptoms pointed to mastoid and lateral sinus disease, complicating acute otitis media. On the operating table a swelling under the left superior orbital margin led the operator to diagnose a complicating thrombosis of the cavernous sinus. The lateral sinus was found healthy and the mastoid practically so. Autopsy showed a purulent clot of the cavernous and circular sinuses, extending to the left ophthalmic vein, and pus in the sphenoidal and posterior ethmoidal cells. No symptoms of nasal disease had ever been complained of. Finlay remarks that "one can scarcely seriously contemplate reaching the local lesion through the orbit or by means of a craniectomy."

By far the most lucid and satisfactory exposition of the subject that I have seen is in McEwen's "Progenic Diseases of the Brain and Spinal Cord," and what can be said on the subject in general is excellently said by him.

The cause of this condition, i. e., septic thrombosis of the cavernous sinus, is any infected lesion in the area drained by the ophthalmic vein or its branches. Pustules on the face, nostrils, eyelids, etc., purulent affections of the accessory sinuses, nasal, pharyngeal or

4. Archives of Otolaryngology, vol. xxxii, p. 419.

buccal cavities, facial erysipelas, infected wounds of this region, etc., may be the cause. Here we encounter the first important point, which is the necessity of care and cleanliness in dealing with pustules or other infected lesions of the face. Two of my three cases resulted from lesions which the rhinologist sees almost daily and which most of us have personally experienced.

The symptoms naturally divide themselves into (1) the local and (2) the general. The general symptoms are those of sepsis under any and all circumstances. The local symptoms may, following McEwen's scheme, be divided into (a) those due to venous obstruction, and (b) those due to pressure on the nerves. Venous obstruction causes edema and chemosis of the affected area, viz., the orbit, the skin of the nose, forehead, cheek and sometimes fauces, pharynx and neck. We have seen in Case 2 that necrosis of the skin may ultimately result. The exophthalmos, which is a prominent symptom, is due to engorgement of the tissues of the orbit.

Pressure on the nerves causes characteristic symptoms. The nerves involved are the second, third, fourth, sixth and the ophthalmic division of the fifth. The visual disturbances are usually very marked, due to pressure on the optic nerve and edema of the retina, while the motor disturbances are most pronounced in the parts supplied by the third. We have seen the dilated pupil, divergent squint and ptosis in the cases reported. The ophthalmoscope shows dilated and tortuous retinal veins and edema of the retina. The disturbances due to pressure on the fifth are variable.

A very important and characteristic symptom arises from the fact that while the trouble is unilateral at first, the thrombus soon spreads to the other sinus, and obstruction and other symptoms appear in the areas drained by it. The edema of the lids of the second eye, beginning at the inner canthus, and not due to direct extension, the parts at the root of the nose lying between the eyes being normal, is very characteristic.

The diagnosis must be made from tenonitis, orbital cellulitis and facial erysipelas. If attention is once drawn to the condition under consideration the diagnosis is not difficult, and it is for the purpose of calling your attention to it that I have presented this report.

The prognosis in septic cases is, I believe, uniformly bad. In one of the series reported by Dwight and Germain, operation was performed and they think the results are promising. Hartley demonstrated its feasibility in Knapp's well-known case, but the question is probably one for the general surgeon, and no general surgeon who saw any of these cases entertained the idea of operative treatment. Since the prognosis otherwise is absolutely bad, it seems to me proper that operation should be tried. Other than this the treatment is supporting and symptomatic.

Dwight and Germain stand alone in their advocacy of operation, but it is to be hoped that their encouraging results will lead others to give the matter a trial. There is nothing to lose.

DISCUSSION.

DR. S. D. RISLEY, Philadelphia—I have often been surprised that thrombosis of the cavernous sinus does not occur more frequently. I have a suspicion that it occasionally occurs without being recognized. For many years there has been a recognition of the fact that abscesses about the face were dangerous, probably without recognizing the probability of thrombus of the sinus. A few years ago I saw an aged man who had an abscess of the lachrymal sac on one side. A homeopathic surgeon operated on it. Just what he did I do not know, but in forty-eight hours the patient died with symptoms

of thrombosis of the cavernous sinus. I have seen one case of thrombosis. A small abscess occurred at the superior aspect of the malar bone, becoming evident on a Thursday; on Friday there was severe headache, which increased in severity, and on Saturday there was an edema of the left eyelid, with slight proptosis. On Sunday morning there was edema of both lids, the exophthalmos rapidly increased on both sides and the pain became violent and was rendered worse by cold or hot compresses. In this case 200 Swedish leeches declined to draw blood and artificial leeches had to be used. The abscess proved to be of streptococcal infection. Ether was administered and exploration of the orbit was made, but no pus was found there. On Sunday afternoon, the pain being violent, a hypodermic of morphia was given and the patient was immediately relieved from pain and passed into sleep which ended in profound coma that lasted until death the following Wednesday, five days after the onset of the small abscess on the malar bone. This was situated within the area drained by the cavernous sinus. These cases suggest the importance of consideration of this subject. When we have an infectious process the area of which drains into the cavernous sinus we should be on our guard for thrombosis of the sinus.

DR. L. A. PREFONTAINE, Springfield, Mass.—About six weeks ago I was called to see a young man who three weeks previously suffered from a febrile disease, which was thought at the time to be pneumonia. A week before he had severe pain in the back of the head, in the right thigh and in the right ear. The pain continued and a discharge from the ear began at the end of forty-two hours. Seventy-two hours later I was sent for. He then had a purulent mastoiditis, with a temperature of 103, pulse 120, and some delirium, and more severe general illness than would be accounted for the mastoiditis alone. I operated on the right mastoid and exposed the sinus, which was normal. Five days later there was swelling of both lids and some exophthalmos. Two days later I found him delirious, with temperature 104, pulse 90, and marked bilateral exophthalmos; I made the diagnosis of double cavernous sinus thrombosis. Death followed in two days. No postmortem.

DR. H. S. MILES, Bridgeport, Conn.—I would add one case, which began in a small abscess in the right nostril. It was opened, the pus examined and found to be of staphylococcus origin. The patient became worse, and on the fourth day was unconscious; the lids were swollen and there was some exophthalmos. No pus was found in the orbit. On the fifth day the patient died.

DR. E. C. ELLETT—My only object in presenting this paper is that these cases are apt to be seen by the ophthalmologist, and should be borne in mind. The diagnosis is easy if attention has been called to the trouble.

PRESBYOPIA.

E. J. GARDINER, A.B., M.D.

Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College.

CHICAGO.

Not long ago a number of medical men were gathered after luncheon at one of the down-town clubs. They were all about the same age—somewhere between 45 and 50—and were amusing themselves by gently twitting one of the number who was wearing his first glasses for presbyopia. This twitting led to a discussion, brought about by my defense of the wisdom manifested by the victim in wearing glasses for reading. A test was made *in situ* with small print, which revealed that every man present was presbyopic. This was not surprising, but the interesting feature to me was, first the aversion they all had to admit the presence of presbyopia, and then the reasons advanced for not using glasses for its correction. No one, of course, wishes to admit a failure of the faculties. That a perfectly normal change, brought about by a maturing

process in the eye, that is slowly but constantly working in everyone—showing its effects in some individuals at 20—and producing a defect so easy to remedy, should not be remedied is certainly a prejudice as curious as it is widespread. Further, if the necessity to use glasses for reading were necessarily the stamp of old age, we might hesitate to accept this symbol of our infirmities, but the emmetropic, the normal eye, reaches this condition at from 40 to 45, hardly a time of life for a healthy man to number his infirmities. When properly examined, the whole matter presents such a different aspect from that of the infirmities of age that I have thought that a brief résumé of the subject would not be without interest to the practitioner.

An apology is here entered for presuming to take the time of the busy reader with an article elementary in its nature, and in which nothing new is set forth. But it is universally admitted that even the elements of ophthalmology bear so distinctly the stamp of specialty that little attention is paid to them by those who do not expect to treat diseases of the eye, and a teacher's experience in post-graduate work has clearly demonstrated to me that the subject of accommodation is one of those simple things that are frequently taken for granted without distinctly understanding the mechanism thereof.

The process by which the eye adjusts itself to see distinctly objects within its range of vision is called accommodation, and the factors that participate in this act are mainly the ciliary muscle and the lens. The former by contraction, when an object approaches the eye, allows the lens by virtue of its elasticity to assume a more convex form, especially the anterior surface, thereby adding to itself the equivalent of an extra lens, or lens power, thus throwing on the immovable retina a clear-cut image. The distance from the farthest to the nearest point at which an object can be distinctly seen is called the region of accommodation; and the power that enables the eye to adjust itself to objects within this region is called amplitude, or range of accommodation.

Unlike the rest of our faculties, which gradually develop from childhood to maturity, the power of accommodation begins to decrease from our tenth year, and gradually diminishes until at the age of 75 it is abolished. The result of this diminution of power is that the near-point gradually recedes from the eye. At about 40 it reaches a point where objects are distinctly seen by the normal (emmetropic) eye at a distance of 22 centimeters, 9 inches, only by bringing into action the full remaining power of accommodation. The amount of accommodation that an emmetropic requires to see distinctly at this distance is equal to a lens of 4.50 dioptres, hence we say that the accommodation is equal to 4.50 dioptres. At this arbitrary point Professor Donders places the beginning of presbyopia.

The word "presbyopia," from the *πρεσβυς*, old, and *ὄψις*, the eye, is in reality a misnomer. It has been handed down from antiquity when the process of accommodation was unknown, and was based on the fact that the sight for near objects usually fails in old age, and glasses were needed for work. When Donders satisfactorily explained the process of accommodation the word lost its real meaning, for he demonstrated that one individual may become presbyopic at 30, while another may reach the mature age of 80, and not be at all presbyopic. For lack of a better, he retained the word, and unfortunately to it the old association of age infirmity still clings.

The following table, giving the power of accommo-

dation from the age of 10 to 75 is quoted by Landolt from Donders' classical work and rendered into the metric system. I have added the approximate distance in centimeters for the near-point:

Age.	Amplitude of Accommodation.	Near point in centimeters.
10	14.00	7.00
15	12.00	8.00
20	10.00	10.00
25	8.50	11.50
30	7.00	14.00
35	5.50	18.00
40	4.50	22.00
45	3.50	28.50
50	2.50	40.00
55	1.75	56.00
60	1.00	100.00
65	0.75	133.00
70	0.25	400.00
75	0.00

This remarkable and rapid diminution in the accommodation power is due to the rapid loss of elasticity of the lens substance which prevents it from assuming a sufficiently convex form.

In connection with the range of accommodation there is another fact to be considered. Repeated experiments have proved that the smallest angle under which objects are perceived by the retina is one of five minutes. On this basis Professor Snellen made a series of test types, each letter of which at a given distance subtends an angle of five minutes. No. 1, at 12 inches, subtends therefore the same angle as No. 20 at 20 feet, etc. It of course follows that when the eye can no longer focus at 12 inches the inclination is to remove the object farther from the eye, in which case the angle becomes less than five minutes, consequently it can no longer be seen distinctly. The following paragraph printed in diamond type should be read distinctly at 12 inches. A young emmetropic can read it at 8 inches.

The Gallic tribes fell off and sued for peace.

So far the word presbyopia and the popular interpretation of it exactly agree. An individual with normal vision becomes presbyopic at 40 or 45. But the application here ceases. The accommodation power decreases in eyes of all forms by exactly the same amount. Consequently in ametropia the near-point must be differently affected. A couple of examples will make this clear.

A hypermetrope of 4 dioptres, in order to see distinctly objects at a distance, is obliged to use 4 D of accommodation. At 30 years of age he has, according to Donders, 7 D. of accommodation power. Of these 4 D. are used to correct the hypermetropia. Consequently, he has but 3 D. remaining, his near-point is at 33 D.; hence he is presbyopic at 30.

Let us take another case. A myope of 5 D. has his far-point at 20 centimeters (8 inches) from the eye. At 40 this accommodative power is only 4.50 D., but he needs none of it, because his far-point is at 20 centimeters (8 inches), and there is no presbyopia. If his myopia is over 7 D., he will never be presbyopic.

It is, of course, evident from the preceding remarks and examples, that while the range of accommodation decreases equally in all cases, the different forms of error of refraction constitute the main desideratum in its effects on the eye, and consequently the measurements of the static refraction should precede any attempt to correct the presbyopia.

It is foreign to the object of this paper to enter into any details regarding the correction of presbyopia. But one important fact should be borne in mind, viz., that the occupation of the patient, the distance at which his work is held, and the size of the object that he is obliged to see, determine the amount of correction to

be given regardless of age. It would, of course, be absurd to prescribe for a clerk, who works at a desk standing, on books that he can seldom bring closer than 50 centimeters (20 inches), a pair of glasses that would oblige him to have his work at 25 centimeters (10 inches). It would be just as absurd to prescribe for a person working on very minute objects that must be seen under large angles, a pair of glasses that would bring his near-point 50 centimeters (20 inches) because a small object the size of diamond print could not be seen distinctly at that distance.

I am now arrived at the main object of this paper. That there exists a widespread prejudice against wearing glasses is too evident to need proof. That the evil moment is postponed in most cases of advancing presbyopia until the near-point has receded to such a distance from the eye, that it simply becomes a question of splicing the arm or of wearing glasses, is likewise certain. Are there any evil effects caused by this postponement, and if there are, what are they?

It must be admitted that in the majority of cases little or no permanent harm seems to follow this wilful disregard of Nature's demands. This is partially due to the fact that in most instances when the near-point recedes so that small print and objects are not distinctly seen, and a sense of fatigue ensues when the eyes are used, larger print is substituted which can be held at a greater distance; and when necessity compels to read small print, a cursory glance and a guess are accepted as a solution of the problem. But Nature is a strict banker. She soon complains of small balances and rebels against overdrafts. It is seldom that she accepts without protest the use of the full quota of nerve energy, consequently the practitioner should be on his guard for vague headaches, pain in the back of the head, sense of fatigue in the same region, that make their appearance in early middle life, around the age of 40 or even earlier. Headaches that make their appearance toward the middle or latter part of the week with no asthenopic symptoms, after Sunday's rest, in people engaged in a business requiring the constant use of the eyes at close range, should arouse suspicions; they are frequently caused by advancing presbyopia.

While it has been admitted that in the majority of cases slight damage seems to result from the neglect of presbyopia, the fact should not be lost sight of that uncorrected errors of refraction are a fruitful source of eye diseases, and there can be little doubt that directly or indirectly they exert an influence on the nutrition of the lens. The efforts to accommodate even in uncomplicated presbyopia, while not so continuous as are the efforts in errors of refraction, nevertheless are productive of the strained condition, and coming at a time of life which predisposes to such diseases as glaucoma, cataract, etc., should not be overlooked as possible factors in their etiology. The preponderance of cataract patients, seen in the clinic over those seen in office practice, may be partially accounted for in this way: The former being culled from the poor and ignorant, who pay little attention to their eye defects, and the latter from wealthier better educated people who give their eyes more thought and attention.

Another practical point, and one that I think is more important than the former, is the question of efficiency. Here the prejudice against glasses and the inference that the use of glasses implies failure of sight, has reached the point where a workman, especially in skilled labor, does not dare to use glasses at his work, because he fears discharge, based on inefficiency. Con-

sequently he bungles along, not seeing distinctly what he does, to the great detriment of his work. Could there be anything more absurd? Not long since I had occasion to watch a carpenter at work putting a lock in the door. He could not see the slot in the screw heads, and bungled and scratched the lock until the screwdriver fell into the slot. He was a man of 50. My reading glasses were a revelation to him. "They are fine," said he, "but I don't use them at my work. They would discharge me." The application does not cease here. It is unquestionable that good eyesight greatly enhances the efficiency of everyone who has to use his eyes in close work. It follows that lack of good eyesight impairs the efficiency. Let us look at this matter by the light of Donders' table. With the exception of myopic eyes, at about 40, objects begin to blur at a distance of 12 inches from the eye. At 45, objects small enough to subtend only at an angle of five minutes only (diamond print) are not distinctly seen. Are individuals who are called on to work on small objects justified in attempting to do so without proper glass correction? I should very much dislike to be forced into having any operation performed on my eye by an oculist of over 40 years of age, whom I knew not to be myopic, who did not wear glasses for close work. Can a dentist of the same age see the details of his work, often done in minute cavities and with rather poor illumination? Are there not parts of the field of operation in general surgery where objects are found that come under angles not to exceed a five-minute limit?

These are important practical questions. The only way to overcome the difficulty is to use properly adjusted glasses for close work, and the only obstacle in the way of adopting the remedy is a prejudice based on either vanity or ignorance.

36 Washington Street.

DENGUE IN THE ISTHMIAN CANAL ZONE.

A PRELIMINARY REPORT.

RICHARD LIGHTBURN SUTTON, M.D.

Assistant Surgeon, U. S. Navy.

UNITED STATES NAVAL HOSPITAL, BROOKLYN, N. Y.

To the average North American physician, unless he be located in Mexico or in one of the extreme southern states, "breakbone fever" is so rare a disease that a case of it would probably pass unrecognized. The practitioner in the tropics, however, usually receives an early introduction to the affection and the acquaintance becomes in time an intimate one.

Persons who have previously resided in a cold or temperate climate appear to be especially susceptible to the infection, and it is for this reason that it is so prevalent among fresh drafts of men sent into warmer climates for duty.

It is not my intention to take up a general discussion of the disease here, such information being readily obtainable from any standard work on tropical medicine. The type usually encountered in Central America, however, I am informed by competent authorities, differs so much from the affection which is found in the far East, or even in Cuba, that it is only by a close and prolonged study of cases that the two classes may be identified as representing one and the same disease.

The "dandy fever" of the isthmus, while simulating the typical clinical picture in various respects, differs from it greatly in others. For example, in many instances there is a total absence of the erythematous condition constituting the so-called primary eruption. In

others the face, instead of assuming the characteristic bloated and congested appearance, is excessively pale, the sclera of the eyes being bluish in color, with absolutely no enlargement of the capillary vessels. A hyperemic or catarrhal condition of the pharyngeal mucous membrane is not present in a large percentage of patients. One point particularly noticeable in these instances is the presence of, or predisposition to, intestinal diarrhea. Jaundice is extremely rare. Only twice have I seen that significant discrepancy between temperature and pulse which is considered almost pathognomonic of yellow fever. Joint pains have been prominent in but one case, although a continuous, severe pain in the back is almost invariably present. A dull, throbbing, frontal headache is an extremely frequent symptom. The clinical picture presented strongly reminds one of an attack of influenza in a rather plethoric subject.

Arterial pressure is high, averaging, in the first stage, about 180 mm. of mercury (Riva-Rocci), and gradually returning to normal as the temperature and pulse come down.

Chart 1.

Chart 2.

Chart 1.—One of several charts in which the secondary rise was almost or totally absent.

Chart 2.—A typical dengue chart. Case admitted at height of primary fever.

During the second exacerbation, the vascular tension does not follow the temperature curve so closely, but remains somewhat lower, comparatively speaking. The period of defervescence after the primary fever is short, from twenty-four to fifty hours, and leaves the patient in a weakened but fairly comfortable condition.

Often there is no secondary rise, but one can never feel absolutely positive, unless the beginning eosinophilia ushering in convalescence is recognized, that the patient was not just at the end of a light initial stage when he first came under observation.

The terminal fever comes on about the fourth day more frequently than at any other time, and, in the greater number of cases, the temperature reaches a point fully as high, if not higher, than at the onset.

The terminal eruption has been typical in only about 1 per cent. of the cases and is usually totally absent.

Of the sequelae none have proved to be more stubborn or difficult to combat than the neuralgic affections of the sciatic nerves. Experience has shown that the only hope of cure in these cases is removal to a cold climate,

the earlier the better. When this is done the sciatica is much more amenable to treatment than when it has occurred primarily in the North.

Adenitis has been met frequently, in fact it is a question whether the so-called "idiopathic" tropical bubo is not often dependent on an initial attack of dengue for its causation.

The blood destruction is comparatively slight, probably because of the brevity of the fever, and the hemoglobin index is more often 1+ than otherwise.

The results, in detail, of the blood and urine examinations, together with a report on experimental inoculation by mosquitoes, will be embodied in a future paper; the data has not yet been sifted down and arranged for publication.

In every instance a careful and prolonged search is made on three successive days immediately following admission for the plasmodium of malaria. Stained (Wright) specimens only are employed. From quite an extensive experience it has been found that this method is the quickest, simplest and most accurate, allowing, as it does, a differential leucocytic count to be made from the same slide.

Cigarette paper and needle smears have given the best satisfaction, and a large drop is used in order to get a working area of good size, thus simplifying and rendering more certain the search for malarial organisms.

In the cases where an undoubted diagnosis of dengue is made, quinin in heroic doses, either hypodermically or by the mouth, has had absolutely no effect on the course of the disease.

Phenacetin and like antipyretics affect the temperature curve but little. Their use, however, combined with external complications of cold, affords great comfort to the patient.

The severe supraorbital headache, due, for the most part, to ocular congestion, is more readily relieved by an ice bag over the upper face and forehead than by the administration of analgesics.

In my opinion, the essential symptoms, in the order of their value, are: 1. Sudden onset. 2. Severe and continuous supraorbital headache. 3. Deep congestion of face and neck. 4. Backache and pain of an excruciating character in the loins.

An exhaustive blood examination, preferably by the aid of reliable stains, should always be made in order to partially check the possibility of pernicious malaria.

In uncomplicated dengue the mortality is practically nil. In a series of considerably over one hundred cases I have not seen a single one in which a serious symptom at any time became manifest.

One attack undoubtedly has some immunizing effect, although some of our men have suffered from it twice within a period of a few weeks. Adult natives seldom contract the disease, while it is seen frequently among the children. Newcomers, especially if from our northern countries, seldom escape.

There is good reason to believe that dengue was formerly a much more serious affection in this region than it is now. French physicians in the city of Panama, who have practiced on the isthmus for many years, claim that the disease is identical with the "Chagres fever," which was looked on by the ignorant natives with such superstitious dread. Its mortality was placed at 50 per cent., in reality it was probably much lower.

Dengue has already played an important part in increasing the ratio of sick days among the men stationed in our most recently acquired territory, and, although

the hygienic measures now being brought to bear on the canal zone will be of almost inestimable value in stamping it out, we may expect to hear of this disease much more frequently in the future than we have in the past.

New Appliance.

APPARATUS FOR HANDLING COMATOSE PATIENTS.

CHARLES S. WHITE, M.D.
House Surgeon, Emergency Hospital.
WASHINGTON, D. C.

In every hospital doing emergency work the problem of moving unconscious patients through dark, narrow halls and down flights of uncertain stairs confronts the surgeon almost

Orderly using sling.

daily, and to facilitate the handling of such cases I have had made a simple belt or sling.

This is made of heavy canvas, 30 inches long and 10 inches wide. Each extremity is sewed securely about an iron rod three-eighths of an inch in diameter. The iron pieces have their ends bent squarely in a rectangular form, leaving sufficient space to fasten leather straps 11 inches long, each pair of which join at a metal ring about 2 inches in diameter. The sling is completed by a strap riveted in one ring, a buckle in the center, and connected with the other ring by a snaffle.

The illustration shows the manner of using it. By rolling a patient first to one side, then to the other, it is placed under him, the strap thrown over the shoulder and snapped, the whole process requiring less than a minute. If the patient is unusually large the sling can be adjusted by the strap which goes over the shoulder. One arm is slipped under the patient's neck, the other under the knees.

The chief use of this apparatus is in moving comatose cases in crowded dwellings, and this latter term includes some modern apartment houses. The advantages are:

1. The weight is properly distributed on the person carrying the load; much of it is placed on the muscles of the back, where it belongs.

2. One person can do the work usually required of two or more.

3. It may be applied quickly.

4. The cost is trifling and it is simple in construction. We have used this sling for several months and find it indispensable. The ambulance driver has carried patients weighing 170 pounds or more from the second and third floors with less exertion, he says, than in the usual manner with the assistance of another person.

A STUDY OF EIGHTEEN CONSECUTIVE CASES OF WHOOPING COUGH TREATED BY THE ELASTIC ABDOMINAL BELT.

THERON WENDELL KILMER, M.D.

Assistant Attending Physician to the Out-Patient Department of the Eables' Hospital.

NEW YORK CITY.

The article with the above title appeared in THE JOURNAL, Dec. 10, 1904, page 1749, without Figures 1 and 2. This omission was due to an oversight and these two illustrations of the belt as applied in whooping cough are shown here. The method of application was described in the article.

Fig. 1.—Stockinette Band.

Fig. 2.—Elastic Abdominal Band.

Sanatoria in Germany.—The annual meeting of those officially interested in the sanatorium movement in Germany was held at Berlin, May 20, in the main hall of the parliament buildings. It was announced that there are at present 69 sanatoria, with 5,800 beds, for working people insured against sickness. In addition, there are 25 private sanatoria which receive these patients. Nine more are in process of construction and a number are projected. To date, 30 millions of marks, or about \$7,500,000, have been spent for sanatoria for pulmonary affections. The central committee has spent about \$300,000 for the same purpose. It was proclaimed that the antituberculosis dispensaries, with medical and hygienic supervision of the patients at their homes, are as important as the sanatoria in the campaign against the disease, but they must act in co-ordination with other institutions, sanatoria, etc. Berlin is planning a system of such dispensaries throughout the city, all under one management, with special attention to tuberculous children. Funds have already been partly provided for this purpose by the departmental sickness insurance company. It was explicitly stated that these specialist dispensaries must not be connected with a polyclinic nor encroach on the sphere of the physician in any way. Wolff described how the polyclinics are already doing work that could be transferred to a special dispensary to the advantage of all. A school sanatorium is projected by the Charlottenburg city authorities, to be open all the year.

TRANSPLANTATION OF TUMORS.

After so many years of painstaking but fruitless studies of tumors by the ordinary microscopic methods, there seems little hope of discovering their specific cause in this way, and we must look for future progress chiefly along other lines of research. What line of research will be successful is the interesting question. Will it be one that is still unemployed, or is it perhaps among those newly brought to light? The recently developed methods of observation of bodies hitherto classed as "ultramicroscopic" seem rich in possibilities, for they represent simply an extension of methods, now familiar, which have been employed with success in solving so many problems. It has long been thought that in diseases apparently infectious, in which bacteria and protozoa could not be seen, the difficulty lay in the limit of magnification possible for our microscopes. The investigators who hold to the animal parasite etiology will hope for progress through development of the methods devised in the Ann Arbor laboratories, for the growth of trypanosomes on artificial media. But it is probably a long step from the cultivation of the hardy rat trypanosome to the isolation of so elusive an organism as the hypothetical cancer parasite.

In the meantime, a fruitful field of research seems to lie in the study of tumors inoculated from one animal to another for several generations. Here the principles involved are such as have been employed in bacteriology, the chief difference being that living animals are employed instead of test tubes for the inoculations and transplantations. Among the most successful of these experiments are those of Leo Loeb, working with a sarcoma of the white rat, and Jensen, who transplanted a carcinoma for many generations in mice. This last series is of particular importance, for, in general, experiments with sarcoma have been more successful than carcinoma, and the close resemblance of sarcoma and granulation tissue leaves always some room for argument. A valuable series of successful transplantations of sarcoma in the dog has recently been reported from Ehrlich's laboratory by Stricker.¹ The original tumor was a round-cell sarcoma, primary on the penis of a 7-year-old dog, and it was transplanted successfully to thirty-one other dogs, and passed through several generations. The development of metastases in several of

the inoculated dogs, as well as other features of its growth, leave no question regarding the sarcomatous nature of the tumor. Age or race of the dogs seemed to have no influence in the success of the transplantations. The latent period between the time of inoculation and the development of a demonstrable tumor was usually about three weeks, while death occurred in from three to five months. One of the most suggestive results obtained was that dogs that had once been successfully inoculated with the tumor later showed themselves immune to further inoculation, and Stricker promises further experiments on this important subject. So far, these experiments, like others of the same nature, have failed to show any results that are positively for or against the parasitic theory. Stricker found that he could get successful transplantations with tumor cells kept twenty-four hours at 13 C., or for two hours at 50 C. Jensen found in his experiments that exposures at -10 C. and +46 C. did not prevent successful inoculations; higher and lower temperatures were found detrimental. As it has been found that testicular and salivary gland cells of rabbits will withstand similar temperatures without losing their vitality, the conclusion might be reached that all successful transplantation tumors are the result of the growth of the implanted cells. On the other hand, it is equally possible that the cancer parasites, if such there be, have powers of resistance quite similar to the cells in which they grow.

The possibilities of securing successful transplantations of tumors are not great. Stricker made seventy-nine inoculations of sixteen malignant and of six benign tumors from dog to dog, and six inoculations of two malignant tumors from cat to cat, without success. Inoculations of tumors from one species of animals to another by different experimenters have been fruitless, although the literature contains some questionable reports of inoculation of malignant tumors from man into animals.

An interesting experience of Vischer² may explain some of these supposedly positive results. He inoculated fragments of melanosarcoma into animals, and after a time observed what seemed to be pigmented tumors growing in the animals. These tumors, however, did not progress and kill the animals as would true malignant growths. Microscopic examination showed what might readily be mistaken by the inexpert for pigmented sarcoma, but which was really granulation tissue growing among pigment granules left from the original inoculated material. The sarcoma cells had all been absorbed, but the pigment was insoluble, and, acting as a foreign body, led to proliferation of the connective tissue. What seemed to fully establish the success of the experiment, an apparent secondary growth in a regional gland, turned out to be a gland that had received considerable of the pigment by way

1. Zeitschr. für Krebsforschung, 1904, vol. i, p. 413.

2. Beitr. zur Klin. Chir., 1904, xlii, 617.

of the lymphatics, and, as a result, had reacted by proliferation. Similar appearances were afterward produced by the injection of pigment particles into experimental animals. In the light of this experience Vischer has reviewed the literature critically, and comes to the conclusion that there is no certain instance of successful transplantation of sarcoma from man to animals, any more than there is of carcinoma.

ACCURACY IN MEDICAL WORK.

In a recent address Cabot¹ expresses the opinion that the use of exact methods in diagnosis, the use of instruments of precision, and the keeping of full and accurate records, will in future times be regarded as the most striking characteristics of the progress of medicine in the last fifty years. In other words, the tendencies in the medicine of to-day are all in favor of more accurate methods. As a result of these tendencies, certain changes have occurred, according to Cabot, both in medicine and in the physician. In medicine exact methods have led to the abandonment of many of the loosely applied terms which uneducated men have so long used as a cloak to ignorance. The gradual disuse of the term "diathesis" to describe certain obscure symptoms, the disappearance of the word "bilious" from our vocabulary, the absence from modern diagnoses of such diseases as congestion of the brain or liver, and the reclassification of the multitudinous affections formerly grouped under the general head of rheumatism, have all been due to modern methods. As a result of this vigorous pruning in the field of medical terms and of the careful reclassification which many great groups of diseases have undergone, the dividing line between knowledge and ignorance has been sharpened, and we are able to see much more clearly where our future work must be concentrated.

Cabot seems to think that one of the most valuable results has been the building up in us of habits of mind which are distinctly antagonistic to habits of deception. He describes the hazy condition of mind of the physician who has made an inaccurate or slovenly observation, and suggests that such an individual falls into the habit of drawing on sources other than facts, in order to clear away the haze, when he comes to state his results. The habit of accurate observation, on the other hand, says Cabot, teaches us to lean on fact, to analyze and deduce from fact, and to avoid embellishment and unwarranted assertion. We may charitably call attention to the fact that in a man of careless habits of thinking, this may be such a gradual self-deception as not to involve any moral turpitude—save for the "sin of ignorance," as it has been called. In other cases, it is lying for the physician to give expression to such inaccuracy. Whether or not we agree with Dr. Cabot's explanation of the development of lying or truth-telling tendencies, we must deplore any deception.

whether the physician himself be a fellow-victim of his ignorance or his patient be the dupe of his deceit. We are not here discussing the withholding from patients of facts that would be harmful. This is to be done tactfully and without false statements, as Cabot has elsewhere pointed out.

The effect of accurate methods on the physician has not been one of unalloyed benefit. Of the unfavorable results of the accurate methods, perhaps the most prominent one is the tendency to use instruments of precision in place of a brain instead of in conjunction with a brain. As Cabot truly says, it is the brain behind the instrument which is the achieving force. Again, it must be pointed out that accuracy is only a relative term, and that there is a limit of error both in the instrument and in the observer. Furthermore, accuracy is relative not only to the limitations of the instrument employed, but also and chiefly to the purpose desired. We can not be accurate in everything; we must be accurate somewhere, and the wise physician is he who knows when and where to be accurate, and when and where to get along without accuracy.

There is a tendency to separate the laboratory man from the clinical man, which is to be deplored. The most complete view of a case is one including a consideration of both the purely clinical and the laboratory facts, and if these two sets of facts are to be interpreted by two distinct men the interpretation is much more apt to be faulty than if the same man does both the clinical and laboratory work. This view is a rational one and its practical realization is perfectly feasible. The modern tendency to distinguish between laboratory and clinical diagnosis is certainly detrimental to the best interests of the patient, and, as in the end this is a point to be considered, it should be the aim not only to train the student to do his own clinical laboratory work, but also to impress on him the necessity of becoming proficient enough in it to be able to intelligently interpret the laboratory findings in his own cases.

PROGRESS IN THE CHEMISTRY OF THE ALBUMINS.

Through a long series of researches it has now been definitely established that the complex molecules of the various albumins consist of long chains of interlinked simpler molecules of the amino-acid type. Systematic degradation by chemical or physiologic methods breaks up the complex molecule into its ultimate fragments; the number and character of the fragments in the various albumins are rapidly becoming known to us. On comparing individual albumins marked differences in ultimate constitution are found; the albumin of muscle is different from that in milk, while both of these are in turn different from that obtained from maize. The holding, for example, in arginin, one of the fragments most widely distributed in the molecules of various albumins, may vary enormously, for while some albumins may contain as much as 83 per cent. of arginin,

1. California State Journal of Medicine, December, 1904.

others may contain only 40 per cent., others only 20 per cent., and still others as little as 1.8 per cent.; even albumins from the same muscle may vary in their arginin content. One mode of difference among the albumins consists in inequalities in the variety of the ultimate fragments of which they consist; thus, while the molecule of ordinary serum albumin contains no less than seventeen or eighteen varieties of elementary fragments (amino-acids), the molecules of the relatively simple protamins contain only four or five such varieties. On the other hand, the more complex proteids like the nucleoproteids, the mucins and hemoglobin contain, besides a highly complex albumin molecule, other bodies like the phosphorus-holding nucleic acid, the sulphur-containing chondroitin or the iron-bearing hemin.

The simple group of albumins known as the protamins, discovered by Miescher in the testicles of fish, have been studied most thoroughly by Kossel and his pupils with surprisingly interesting results. It is easier with such simple bodies than with more complex ones to determine the nature of the groups entering into the constitution of the molecule, to ascertain the mode of union of these groups with one another, to estimate the relative amounts of each present, and to draw conclusions as to the positions they occupy in the chain which represents the whole molecule. Thus salmin, derived from salmon sperm, has been shown to consist of only five varieties of constituent fragments, namely, urea, diamino-valerianic acid, serin, mono-amino-valerianic acid and prolin, there being about ten molecules of the first variety of fragment, ten of the second, two of the third, one of the fourth and two of the fifth in each molecule of salmin. Clupein, from the herring, is a little more complex, containing still another amino-acid, namely, alanin, while scombrin from the mackerel is simpler, containing only four varieties of constituent fragments—urea, diamino-valerianic acid, alanin and prolin. The urea and diamino-valerianic acid in these molecules lie adjacent to one another in the chains; indeed, they are regarded as being united to form a higher unit, which is no other than arginin. All the protamins are rich in their holding in diamino-acids (hexone bases), and this accounts for the strongly basic properties which they manifest.

The ordinary albumins, such as serum albumin and serum globulin, differ from these simpler protamins, chiefly in that they contain, in the first place, a much greater variety of ultimate constituent fragments, and, in the second place, a very great number of the less basic mono-amino-acids. As has been pointed out, the protamins contain mono-amino-acids, singly or in pairs; the ordinary albumins contain often ten or more different mono-amino-acids, and not only those of the monobasic series, but often also dibasic amino-acids, like aspartic acid and glutaminic acid. Moreover, the carbon atoms of these constituent amino-acids may be

arranged as straight chains, or the chains may be branched; the groupings met with may belong to the fatty-acid series, or they may be aromatic bodies containing closed rings; not infrequently a heterocyclic group is encountered, as in prolin and in histidin.

This richness in form presented by the different albumin bodies is undoubtedly of great importance in connection with the different parts they play in metabolism. Normal physiology begins to assume a new aspect in the light of these new facts, and it is reasonable to suppose that pathology will ultimately be correspondingly benefited. Indeed, already advances in pathology are being made along these lines. We called attention in a recent issue to Neuberger's demonstration that in amyloid disease the new substance is formed by a transformation of albumin through which its holding in diamino groups is increased. Kossel and Wakeman have shown that in liver necrosis there is an abnormal partial decomposition of proteids as a result of which the liver becomes poorer in bodies rich in nitrogen, especially in arginin. Further, in diseases in which abnormal proteolysis occurs, certain of the constituent amino-acids may be given out in the urine; thus Ignatowski has demonstrated the presence of glycocoll (amino-acetic acid) in the urine of gouty patients, and other investigators (Abderhalden and Barker) have isolated from the urine of dogs poisoned by phosphorus no less than four such amino-acids, namely, glycocoll, leucin, tyrosin and phenylalanin.

The studies made of tumors and rapidly growing young tissues rich in nuclei have shown further the heaping up in them of certain richly nitrogenous organic bodies—combinations of phosphoric acid with the purin bases (xanthin, guanin, hypoxanthin and adenin), and such pyrimidin derivatives as uracil, thymin and cytosin. In the nucleins we have to deal, as Kossel has emphasized, with organic molecules which contain chains of atoms in which there is a tendency for nitrogen and carbon atoms to alternate with one another. It is not impossible that such an intramolecular arrangement stands in some important relation to the mechanisms of growth.

The various analytical studies outlined above have been happily supplemented by synthetic researches. Emil Fischer of Berlin and Curtius of Heidelberg are already far on the way toward the synthesis of the albumin bodies. Not only have nearly all the constituent fragments of the albumin molecule been synthesized, but it has already been possible to unite two, three or more of these amino-acids artificially into chains—the so-called dipeptides, tripeptides and other polypeptides. A chain of eight amino-acids, an octopeptide, has even been obtained by Curtius, at least in the form of its ester. These polypeptides behave in many ways like natural bodies, are split similarly to the albumins by digestive ferments, and, indeed, may be regarded as very simple albuminous substances.

THE PROGRESS OF ORGANIZATION.

The rapidity with which the state societies all over the country have accepted the recommendation of the American Medical Association and have adopted a uniform plan of organization is both remarkable and pleasing. The most hopeful did not dream that so much could be accomplished in four years, and that in less than this time three-fourths of the state societies would have been reorganized and would be working under the same plan. Four, Alabama, Connecticut, Massachusetts and Pennsylvania, already had the essential features of the new plan in their organic law, so that these may be considered as part of the great body working under a uniform plan as though they had adopted all the non-essentials. Aside from the above—and New York—the only states that have not finally acted on the matter are Georgia, Idaho, Maine, Montana, Nevada and Wyoming. These will probably take final action at the next annual meeting, and as there is practically no opposition in any of these states, we may confidently hope that at the next annual session of the American Medical Association, all but one state will have adopted the essentials to uniformity of organization. The only state that has refused to reorganize is Virginia, but the members of that association will reconsider when they realize the great advantage to the physicians of the whole state—not necessarily to the members of the state society—of the county society plan.

While all this has been accomplished, it simply means that the frame-work for the structure is complete and that the important work of finishing the structure is yet to be done. In some states, steady and efficient work has been going on since they were reorganized, and in some it may be said that practically every county has a society, and that consequently there is brought within the reach of every country practitioner a chance to join the organization and to obtain all its benefits, without sacrificing time and money to go to some distant place of meeting. In other states, especially in those that were only organized last year, little has been done in this line thus far, although in no state can it be said that something is not being accomplished. The great trouble is that this work is voluntary, and volunteers, men who are willing to sacrifice themselves for the good of their profession, have not come forward; but there are such men in every state, and in nearly every county, and when their attention is called to the need for their services they will be found ready to volunteer. The principal trouble to-day is that the great majority of the members of the profession do not realize what is being accomplished in this work and what are the possibilities for the future: how to reach these men and how to get them to take hold is a problem of the day. We hope that these words may be read by many such, and that they will take up the task. Meanwhile, the work being accomplished by Dr. J. N. McCormack is bearing fruit, for as he goes to various sections of the different states, he reports that men are

being found everywhere who give evidence of interest in the work and of being anxious to co-operate, who before this had given no thought to the matter, and, in fact, in many instances, knew nothing about what was being done.

In the meantime, while the work of organization is going on in some parts of the country, in other parts, where organization is more or less complete, the fruits of such an organization are to be seen. In other words, good work is being done, not only from a scientific but from a utilitarian point of view.

MORE CASES OF POISONING FROM WOOD ALCOHOL.

During the mobilization of the Russian troops at Dorpat this summer, a number of men and women celebrated the occasion by partaking of a local beverage known as Kuntzen's balsam. This is made from alcohol, water, peppermint leaves, salvia, lavender, etc., and, like our Jamaica ginger, is much affected by the Livonians as an internal remedy. Like it, also, this balsam is employed as a beverage when other alcoholic drinks are not readily obtainable. On this occasion, however, just as in the Stryker's farm holocaust, the drink was mixed not with ethyl but with methyl alcohol, probably of the "deodorized" variety, so well known in the United States under the name "Columbian spirits." Of the participants in the Dorpat debauch, sixteen men and one woman died and three men became blind.

A more recent Associated Press dispatch reports from Kiew the death of twenty people (about the same number as in New York) from drinking methylated brandy. Now that this adulterant of alcoholic mixtures is becoming popular in Russia, we may confidently expect the same experience this country is passing through—the substitution of a deadly poison for grain alcohol in the manufacture of our flavoring extracts, essences, drugs, beverages, perfumes, liniments and other mixtures.

In spite of the widespread use in Russia of methylated mixtures for making varnishes, for burning in spirit lamps, and for other manufacturing and household purposes, not a single case of death or of blindness occurred from their internal use until 1904. Thus we have to this date, in Russia alone, at least thirty-seven cases recorded, and there are probably many others. The reason, as shown conclusively by the Buller and Wood¹ articles, is evident. The introduction into Russia and the general employment of "purified" or odorless wood alcohol is a comparatively recent event. Previous to this year, the wood alcohol in common use was the ordinary article, of a vile odor and decidedly repugnant to the taste; it was not in use as an adulterant because its presence could easily be detected, nor as a beverage because no one had the hardihood to drink it, even when disguised with fra-

1. Poisoning by Wood Alcohol. THE JOURNAL Oct. 129, 1904.

grant oils. Now, to quote the circular descriptive of "eagle spirits" and "lion d'or," two of the many names under which "deodorized" methyl alcohol poisons the people of this country, "they are in every respect genuine substitutes for grain alcohol for all purposes connected with the arts and manufactures."

At present before Congress is a bill (H. R. 9303), introduced by Mr. Boutell of Illinois, to provide for the reduction of the tax on grain alcohol to a point where it can compete with the untaxed "higher grades" of odorless wood alcohol. Another bill (H. R. 9302) will, if it carries, "free from tax alcohol made unfit for use as a beverage." Such a provision is active in Germany, where sixty millions of proof gallons are annually used for industrial purposes, against five millions in the United States. These bills ought to have the support of the medical profession, not only because they would enormously stimulate the manufacture of an agent that can be used for a hundred good purposes at present rendered impossible by the high tax, but because they will effectually prevent the poisoning constantly going on in this country.

THE SERUM-TREATMENT OF TYPHOID FEVER.

At the Seventh French Medical Congress recently held at Paris Professor Chantemesse¹ reported the results obtained during three and one half years in the treatment of 545 cases of typhoid fever with serum obtained from a horse rendered immune by injections of soluble typhoid toxin. There were among these cases 22 deaths (4 per cent.), while in the hospitals of Paris generally there were among 3,199 cases from April 1, 1901, to Oct. 1, 1904, 581 deaths (18 per cent.) It was found that intestinal perforation was not diminished as a result of serum-treatment to the same extent as were other causes of fatal termination. As the intestinal lesions are the initial alterations, it is important to inject the serum early. Perforation of the bowel was observed in no case treated with serum during the first week of the disease. Cold baths are given when the temperature is high.

GOOD INTERPRETATION OF LAW IN IOWA.

The Iowa legislators who framed the medical-practice law of that state obviously intended it to guard the public against unqualified persons who might profess to heal disease. This intent seems to have been grasped by the Supreme Court of Iowa in two recent decisions. In one case the irregular practitioner was apparently an eye specialist, prescribing spectacles, exercise and diet, while the other was a magnetic healer, claiming to cure practically all human ailments, but especially cancer. The defendants had been acquitted by the lower courts on the misconceived ground that, as they gave no medicine or drugs, they, therefore, did not need to take out a license under the state law. The Supreme Court reversed these acquittals, and holds that the defendants violated the law. The ground

covered by the decision seems sufficiently comprehensive to include nearly every form of quackery, and to make it impossible to thus impose on the credulous and ignorant in Iowa. It is hoped that this precedent will be followed in other states where quackery of this kind has had too free a field. It gives us confidence in the general good sense as well as in the legal knowledge of the courts. We trust that there will always be as much good sense and legal knowledge shown in future cases involving the protection of the public health.

TO PREVENT SELF-ADVERTISING.

There are few things that will injure a physician in his own locality so much as having his name appear in local newspapers. One of the commonest charges made in our societies against individual members is that of advertising. We may call it jealousy, envy or what not; that it is true is well known. Very often notices appear in lay papers without the knowledge or consent in any way of the one mentioned. Such can not be helped. When, however, such occurrences take place often there is always good ground for suspicion. Many county societies have discussed the question of prevention, believing that prevention is better than punishment after the deed has been committed. One way recommended is that which has been referred to in our columns on two or three occasions. Among these was the action taken by the Orleans Parish Medical Society, which passed a resolution¹ to the effect that "copies of all articles appearing in the daily press of this city relating to members in this society shall be placed by the secretary in a scrapbook, which shall be kept on the president's desk for the inspection of members. The book shall be indexed. Any member whose name shall appear therein will have the privilege of attaching thereto a written explanation." This week we record the action of another society² which adopted a similar measure. We can not but believe that this idea, if carried out, will result in great good. It may be easy for an individual to explain how it happened once or twice, but not when it has occurred scores of times.

A TRUE PATRIOT.

That a physician should take an interest in public affairs and should do his duty as a citizen interested in the maintenance of good government and public morals, has always been advocated by THE JOURNAL. Under normal conditions he is honored for so doing. The public appreciates good service of this kind, and he does not lose, either professionally or financially, on account of his public spirit. Occasionally, however, in abnormal communities, one may suffer for well-doing, and virtue be its own and only reward. Hurley, Wisconsin, appears to be such a place. Chiefly owing to the efforts of a public-spirited physician, an appalling state of official moral rotteness was exposed, resulting in the interference by the highest state authority, and in the removal from office of certain of the offending officials. Public sentiment, however, was

1. See page 1905.

1. THE JOURNAL A. M. A., Aug. 27, 1904, p. 615.
2. See page 1878.

strongly with the offenders. The physician was removed from his position as health officer, was reproved publicly by the common council, and was boycotted by the public to such an extent that he found it advisable to remove to another locality. There was nothing, so far as known, alleged against his character nor against his competency as a physician. It was simply his well-doing that was his undoing in that community. On the whole, we feel like congratulating him for being thus persecuted for righteousness' sake, and we trust that he will receive his reward in this life as well as hereafter. As for the community where such things can be done, the best that can be said is that it is a good place to leave.

THE OLLIER MONUMENT.

The unveiling of the statue of the late Professor Ollier in the city of Lyons last month¹ is a matter of some significance, illustrating the well-known saying that science knows no national boundaries. Delegates from surgical societies from various parts of Europe were in attendance to do honor to the distinguished surgeon. It was throughout an international affair, for the statue itself had been paid for, as our readers know, by contributions from all parts of the world. Notable among the delegates was Professor Lassar from Berlin, who represented the German Surgical Association, that body wishing to offer its tribute through a personal representative and through one of its most eminent members. This is another proof that the strained relations which have existed between Germany and France since 1870, and which, unfortunately, had to some extent involved the feelings of eminent medical men, are now disappearing. Germany has less to forgive and forget than has France, but that fact has not diminished the significance of the gracious tribute thus offered, and we trust that when the opportunity occurs the medical profession of France will not be found wanting. In this connection it may be remarked that the municipality of Lyons has, perhaps, done more in the erection of memorials to men eminent in medicine than has almost any other city. It is adorned with statues of Claude Bernard, Bonnet, Petit, Gensoul and others, and streets and squares have also been named after medical men. France honors its medical luminaries as perhaps no other nation does.

THE PURE-FOOD BILL.

President Roosevelt's message is notable among similar documents for the attention which it gives to matters bordering on medical and sanitary science. As medical men we can heartily approve what he says in regard to the dangers of urban concentration and crowded tenement districts, child labor, etc., but we wish that he had made insistent mention of the importance of passing the pure-food bill left over by the previous session, and really the most important measure now before Congress. The poisoning of the population for profit by mercenary manufacturers is in its way a much

more vital question than any mentioned in the message. We do not know what the program of the Congressional leaders is. It is said by newspapers, with what truth and authority we know not, that, beyond the passage of the usual ordinary and extraordinary appropriation bills and some special colonial legislation, little will be done. If such is likely to be the case, it will be well for the medical profession to use its best efforts to insure the inclusion in that little of the passage of this salutary act. There should be no difficulty, but as we know there are powerful influences working against it, and unless every effort is made against them, they may succeed. We spoke at some length on this point last spring and gave the bill in full.¹ The latest suggestion on the prospects of the bill is that its provisions may be limited to apply only to pharmacopoeial preparations, and that in such case the powerful antagonism of the nostrum manufacturers will be removed and the bill easily pass. It is a reflection on Congress that such a statement can be made, but the power of moneyed interests over our lawmakers has been too often exposed to require any beating about the bush in the discussion of the subject. It remains to be seen what the individual members of the profession have done and will do. During the long time that has elapsed since the bill came before Congress there has been ample time for each physician to let his representative in Congress know of the feeling of the local profession on the subject, and to emphasize the great economic and hygienic importance of the bill. There remains time now to exert pressure, and thereby to favor good legislation, to protect those who are daily being injured by impure foods, and incidentally to show the interest of the profession in public welfare.

Medical News.

ILLINOIS.

Hospital Dedicated.—St. Joseph's Hospital, Elgin, was dedicated with solemn ceremony by Archbishop Quigley, December 13.

Personal.—Dr. Charles B. Johnson, Champaign, whose term of office ends December 31, will be succeeded by Dr. Ralph E. Niedringhaus of Granite City.—Dr. Benjamin F. Elfrink, Chenoa, who has been ill with septicemia, has been taken to Chicago for hospital care.

The Ottawa Tent Colony.—Dr. J. W. Pettit has issued a leaflet giving a brief report of the results obtained in the Ottawa Tent Colony established by the Illinois State Medical Society for the treatment of tuberculosis, not for gain nor as a charity, but on a nearly a self-supporting basis as practicable. The total admissions thus far have been 59, of which 24 were advanced cases. Of these 6 improved, 3 are convalescent and several are still under treatment. The incipient cases all made remarkable improvement from the inauguration of treatment.

Smallpox.—During November 225 cases of smallpox were reported from 12 counties, with 25 deaths. The disease was reported in the following localities:

Clark County, Martinsville Township; Cook County, Chicago, La Grange, Morgan Park, Orland and Riverside; Green County, Roodhouse; La Salle County, La Salle; Logan County, Elkhart; Macon County, Decatur and Oakley; Madison County, Granite City, Venice and Alton; Montgomery County, East Fork Township, Filmore and Irvin; Pike County, Griggsville; Saline County, Galatia and Ledford; Sangamon County, Springfield; St. Clair County, East St. Louis and Belleville and vicinity of O'Fallon.

Cook County Hospital Staff.—The new president of the board of county commissioners has announced that with the aid of

1. THE JOURNAL, Dec. 10, 1904, p. 1800.

1. THE JOURNAL, April 2, 1904, pp. 894 and 910.

Drs. Frank Billings and Fernand Herroin he has evolved the following plan for selecting the attending staff of Cook County Hospital:

A staff of seventy-one physicians and surgeons to be appointed by the president and confirmed by this board, the said appointments to be made as recommended by a nominating commission of twenty-five doctors of medicine selected by the president, the term of service of the commission and of the staff members to be six years, vacancies during this period to be filled in the same manner as original appointments are made.

Members of the attending staff shall be ineligible to reappointment for six years succeeding their term of service, except upon a two-thirds affirmative vote of the nominating commission. There shall be no money paid to the members of the staff for work at the county hospital. Strict attention to all duties will be required. The president, for cause sufficient to himself, may reject the name of any eligible submitted to him by the nominating commission. The nominating commission shall serve also as a consulting staff under specified conditions, but shall receive no pay in either capacity.

Chicago.

Deaths of the Week.—During the week ended December 10, 512 deaths were reported, 35 of which, however, were "hold-overs" from November, making the net deaths 477 and the annual death rate 12.89 per 1,000. Pneumonia heads the list with 85; consumption follows with 65; then come heart diseases and violence, 50 each, and Bright's disease, 41.

Coroner's Annual Report.—In Cook County during the year ended November 30, the annual report of the coroner states, 5,960 deaths were investigated, of which 575 were due to the Chicago fire, 426 to suicide and 382 to railroad accidents. He recommends that the following causes of accidents and crime receive attention: Carelessly operated railway excursions, the carrying of concealed weapons, grade crossings, overcrowded and wretched street car service and giant firecrackers.

INDIANA.

Osteopath Discharged.—The three criminal charges against E. S. Morrow, an osteopath of Columbus, practicing medicine without a license, have been dismissed for lack of prosecution.

Personal.—Dr. Caleb A. Pritchard, Gosport, who had the misfortune to be passing when the Farmers' bank was about to be robbed, was seized by the robbers, bound and gagged and carried into the bank building.

Society Meetings.—The Fort Wayne Academy of Medicine held its annual meeting November 14, elected the following officers: President, Dr. Alfred Kane; vice-president, Charles G. Beall; secretary, Dr. Adam L. Schneider, and treasurer, E. P. Weaver, and adopted the following resolution:

Resolved, That copies of all articles appearing in the daily press of this city relating to regular physicians of this city shall be placed in a scrap book, which shall be kept on the secretary's desk for the inspection of members.

All articles appearing between meetings of this society shall be read at each meeting, and any member whose name shall appear therein will have the privilege of attaching thereto a written explanation. The book shall be indexed.

The Fort Wayne Medical Society, the Medical Society of Allen County, met December 6 and elected the following officers: President, L. Park Drayner; vice-president, Dr. Maurice I. Rosenthal; secretary, J. Clifford Wallace; treasurer, Dr. William P. Whery, and Dr. Kent K. Wheelock, censor, to serve for three years.

MARYLAND.

Still in Jail.—Dr. Joseph C. Ohlendorf, convicted of manslaughter in the death of Madge Hale in Prince George County by an alleged criminal operation, is still in jail. The judge decided that it was not within his province to release him in habeas corpus. The court has, however, granted him a new trial because of faulty indictment.

Personal.—Dr. Frederick G. Mitchell, Verona, Baltimore County, will retire January 1 and devote himself to agriculture. Dr. Rudolph B. Tensler of Virginia, now superintendent of St. Luke's Hospital, Tokio, Japan, is touring the country in its interests and has recently visited Maryland.—Dr. Josiah S. Bowen, Mount Washington, has been elected president of the Kappa Psi, a medical and pharmaceutical fraternity.

Rare Books.—A remarkable exhibition of rare medical books was made at the Johns Hopkins Hospital Historical Club by Dr. F. P. Henry of Philadelphia, December 12, viz., First Book on Diseases of the Eye, by Benvenuto Grassus, 1474; First Medical Dictionary, Synonyma Simonis Genouensis, 1473; First Book on Diet, by Isaac, 1487; second edition of First Book on Diseases of Children, by Paulus Bagellardus, 1487. Dr. Harvey Cutting spoke on "Dr. Garth: Kit Kat Poet, 1661-1718."

Maryland Society for the Prevention of Tuberculosis.—This society was organized at McCoy Hall, Johns Hopkins University, December 13. The society was recommended at a meeting of prominent citizens held recently under the auspices of the State Tuberculosis Commission and is indirectly a result of the exposition held in Baltimore last winter. Dr. William Osler presided and addresses were made by Dr. E. O. Otis, president of the Boston society, and by Drs. William H. Welch and W. S. Thayer. All citizens who are interested in the prevention and control of the disease are eligible for membership. The new society has two general plans in view: To educate the people and to secure proper legislation. The great interest shown by the public here in the exposition last winter gives reason to hope for very large results from such an organization as this.

Baltimore.

Expelled.—Dr. Nathan Herman has been expelled from the Baltimore City Medical Society for unprofessional conduct.

Much Diphtheria.—The health commissioner calls attention to the unusual increase in the number of cases of diphtheria in the city, as shown by the December records. An average of 9 cases a day is reported.

Personal.—Dr. R. Tunstall Taylor sustained a compound fracture of the left arm December 9, while getting off a street car.—Dr. Irvin H. Elderdice has sued the United Railways and Electric Company for \$50,000 for injuries received in February, 1903, through alleged negligence of the company.—Dr. Tregant Burrow, who has been traveling in Europe, returned December 7.—Dr. B. Merrill Hopkinson has been elected president of the Baltimore Athletic Club for the thirteenth consecutive annual term.

Osler Testimonial.—A meeting to further this movement was held by the Baltimore City Medical Society December 6. Addresses were made by Drs. Edward N. Brush and William H. Welch. Great interest is being manifested in it all over the country. Dr. John H. Musser of Philadelphia has accepted the chairmanship of the national committee, composed of 100 prominent physicians throughout the country. The governor of Maryland is the national treasurer, and Dr. Henry Barton Jacobs, secretary. About \$10,000 has already been subscribed here. Dr. Osler was consulted as to his preference and expressed himself in favor of a building to be erected here for the accommodation of the valuable medical library of the Medical and Chirurgical Faculty of Maryland, so largely the result of his own interest and effort. The city will be divided into districts and a canvass made. Dr. Osler has greatly endeared himself to this community and the movement is by no means limited to his own profession. The bankers, druggists, lawyers, merchants and other professions and trades have appointed committees to take subscriptions among themselves.

MASSACHUSETTS.

Will Soon Begin Operations.—It seems likely that soon the actual start will be made on the Peter Bent Brigham Hospital, for the United States Court of Appeals has sustained the will. Efforts are being made to have a considerable part of the great hospital which this \$5,000,000 will make possible, devoted to the care of consumptives.

Bequests.—Boston hospitals have recently received many large bequests, as follows: New England Hospital for Women and Children, \$16,000, one-half to be used for the training school for nurses and the remainder for general expenses; from Charles E. French the Massachusetts General Hospital will get \$10,000; the House of the Good Samaritan, \$1,000; Carney Hospital, \$1,000; Boston Children's Hospital, \$500, and the New England Hospital for Women and Children, \$500.

Dr. Abbott's Successor.—Dr. Charles Harrington, assistant professor of hygiene at Harvard University Medical School, has been appointed to succeed the late Dr. Samuel W. Abbott as member of the State Board of Health. Formerly he was chemist for the State Board of Health. He has been teaching for 21 years in Harvard University Medical School, and for 15 years has had charge of the milk inspection of the Boston Board of Health. He is well known as a writer on hygiene and on food and drug analysis.

Hospitals in Peril.—The New England Baptist Hospital narrowly escaped a serious fire December 10. The hospital is located near the top of the steepest and highest hill in Boston, so that it was fifteen minutes after the alarm before the first engine reached there. Meanwhile the janitor and nurses, bravely working with fire extinguishers, had subdued the fire, which

had started in a drying closet. The loss was not more than \$600, and none of the 30 patients was at all harmed. The fire again calls attention to the danger of all the neighboring buildings, two of which are the Charity Club Hospital and the Cushing Hospital, and the urgent need that fire apparatus be located nearby. Repeated petitions to the city government have invariably met refusal from one branch or another.

MICHIGAN.

Cornerstone Laid.—The cornerstone of the new building for the Michigan College of Medicine and Surgery, Detroit, was laid with elaborate ceremonies, December 13.

Purging Battle Creek.—In an effort to clean out the abortionists, whose work has made Battle Creek notorious, the Physicians' Business Association has ascertained that 32 unregistered practitioners were plying their trade in the city. Warrants have been sworn out for these irregulars and seven were issued on the first day.

Comparative Morbidity.—For November, 1904, compared with the average for November in the ten years, 1894-1903, smallpox, puerperal fever, cholera infantum and inflammation of brain were more than usually prevalent, and bronchitis, pneumonia, intermittent fever, diphtheria, erysipelas, remittent fever, cholera morbus and whooping cough were less than usually prevalent.

In Trouble.—Drs. John T. Hoffman and Otto F. Toepel, Detroit, coroners of Wayne County, have been asked by the governor to resign. Both are under the ban for contempt of court.—Dr. Wallace E. Newark, Charlotte, who pleaded guilty to performing a criminal operation, was fined \$600, and paid the amount.—Dr. Bert H. Ling, Germfask, convicted of practicing without a diploma and fined \$12, has been arrested and placed in jail on account of failure to pay the fine and costs.—Dr. Otto T. Toepel, Detroit, was fined \$250 and sentenced to 30 days in the county jail for contempt of court, December 6. He will appeal.

The Most Dangerous Communicable Diseases.—Meningitis was reported present in Michigan during November at 6 places; whooping cough at 18 places; measles at 35 places; pneumonia at 59 places; diphtheria at 87 places; smallpox at 99 places; scarlet fever at 105 places; typhoid fever at 161 places, and consumption at 247 places. Meningitis was present at 1 place more; whooping cough at 6 places more; measles at 6 places more; pneumonia at 30 places more; diphtheria at 24 places, smallpox at 20 places, and scarlet fever at 23 places more; and typhoid fever at 21 places and consumption at 56 places less in 1904, as compared with the preceding month.

College Merger.—According to the Detroit *Journal* for December 8, a proposition has been made to merge the Detroit College of Medicine into the University of Michigan Department of Medicine and Surgery. It is claimed that the clinical facilities at Ann Arbor are insufficient for the third and fourth-year students, and that under the new plan the first two, or possibly the first three years' work would be done at Ann Arbor, and the last year or two at Detroit. It is understood that those in control of the Detroit College of Medicine are willing to surrender its charter to the board of regents of the university so that it will go out of existence as an independent institution. Ann Arbor papers express the sentiment there as being almost wholly against the project.

MISSISSIPPI.

Smallpox.—The physicians of Montgomery County have discovered a large number of smallpox cases, fortunately of mild type, near Stewart. Quarantine has been instituted and vaccination ordered.—Several cases are reported in Clarksdale.

Free Clinic at Biloxi.—A free clinic has been established at the Biloxi Sanatorium, to be called the Lopez Medical and Surgical Clinic, in memory of the late M. L. Lopez, who was vice-president of the sanatorium and took great interest in the institution from its inception.

Sanatorium Rebuilt.—Last spring the Biloxi Sanatorium was entirely destroyed by fire. On the site of the old building a new one has been erected and is now open. It has been built especially for sanatorium purposes, and is well equipped. Located on Mobile Bay, it has the advantage of an excellent winter climate.

NEW JERSEY.

Personal.—Dr. Frank N. Robinson, Camden, has gone for an extended visit to Los Angeles, Cal., on account of ill health.—

Dr. Byron C. Pennington, Atlantic City, was recently admitted to the German Hospital, Philadelphia, suffering from uremia. He is slowly convalescing.

Work at the Cooper Hospital.—The work done at the Cooper Hospital during the month of November is as follows: Seventy-one patients were admitted to the wards; 114 were treated in the wards; 317 new patients were treated in the out-patient department, and 1,187 revisits were made.

Medical Society Election.—At the regular meeting of the Camden City Medical Society, December 6, the following officers were elected: President, Dr. Paul M. Mearns; vice-presidents, Drs. Harry H. Sherk and Edward A. Y. Schellenger; secretary, Dr. Vernon E. De Grofft; treasurer, Dr. William H. Pratt; historian, Dr. Daniel Stroek, and librarian, Dr. Joseph H. Wills.

NEW YORK.

The Boy Wonder Must Serve His Term.—John Welchers, otherwise termed "Antonius, the Boy Wonder," of Buffalo, who claimed to cure by the laying on of hands, etc., and who was convicted and sentenced to imprisonment for one year for conspiracy, will have to undergo the sentence, as the Court of Appeals has decided against him.

Crusade Against Insanitary Tenements.—The Niagara Falls Board of Health has adopted ordinances similar to those used by the Buffalo Department of Health, which will give larger power to the health board. One of the first crusades will be directed against the insanitary tenements in the so-called "tunnel" district and occupied by negroes, Italians and Hungarians, where there is an increasing amount of typhoid fever.

Sanitation in Small Places.—A conference of the local health officers throughout the state was held in Albany, December 15 and 16. An urgent appeal was made to all health officers to attend, as small places are exposed to more danger from the outbreaks of epidemics than large ones. The sanitary conditions of the smaller towns are not so carefully guarded nor the health officers so well equipped for their work as those of the cities, and these conferences are intended to awaken greater interest among local health officers.

New York City.

Personal.—Dr. Kenkichi Rokkukun, physician in the suite of Prince Fushimi, has visited Ellis Island and made minute observations of every department of the emigrant reception depot.

The Mosquito Convention.—The second annual convention of the National Mosquito Extermination Society was held in Manhattan and Brooklyn on December 15 and 16. The sessions were open to the public.

Brooklyn Hospital Incorporated.—The Samaritan Hospital was incorporated December 8. This hospital is the outgrowth of a dispensary started several years ago. Two lots have been purchased and hospital buildings will be erected as soon as the necessary funds have been raised.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended December 3, 378 cases of diphtheria, with 30 deaths; 326 cases of tuberculosis, with 165 deaths; 200 cases of scarlet fever, with 10 deaths; 155 cases of varicella; 85 cases of typhoid fever, with 17 deaths; 83 cases of measles, with 6 deaths, and 13 deaths from cerebrospinal meningitis.

Tramp Steamers Suspected to Be Infected.—The British steamship *Coronation*, which arrived at quarantine December 7, had one of the crew ill with a disease resembling bubonic plague, but bacteriologic examination failed to reveal any traces of the plague.—The tramp *Coulston*, from Java, also detained because several of her crew had died of cholera on the voyage, was permitted to come to her pier, but the Chinese crew is held at Hoffman Island.

Permanent Tuberculosis Exhibit.—Dr. James E. Newcomb, in a recent address, urged most vigorously as a means of educating the public a permanent tuberculosis exhibit similar to that of Berlin, containing illustrations of the ravages of the disease, models of the breathing apparatus, showing the effect of tuberculosis on man and animals, collections of sputa receptacles gathered from various countries, disinfecting apparatus, illustrations of the methods of study of the tuberculosis bacillus, charts showing the effects of good housing in reducing the amount of the disease, etc.

Bellevue Diet Kitchen.—This week a scientific diet régime will be opened at Bellevue Hospital. The food served to the patrons will be cooked under perfect sanitary conditions and patients

will be served with the food best calculated to help them contend with the disease with which they are afflicted. There will be a separate dietary for children and adults. Hitherto there has not been much discrimination in the matter of food given the general run of patients. The establishment of the new cooking plant will not cost more than \$500 and it is estimated that it will not cost more than \$50 a month additional than the existing kitchen. The medical staff agrees that the proposed scientific system will benefit the patients and may tend to lessen the death rate.

The Pure Milk Crusade.—The work of the inspectors of the health department in the upstate counties has already resulted in evidence which would seem to be sufficient to convict one of the largest milk distributing companies in this city. In this case the inspectors found that skim milk was being shipped and that a considerable supply of formaldehyd was kept on the premises. Dr. Darlington says that when the evidence is complete he will revoke the license of the company. Hitherto these large companies have paid the fines and in the long run adulteration was profitable to the dealers, but if the companies are forced out of business it would prove a more serious matter. The health department is determined to make the punishment so severe that it will not pay to tamper with the milk. A number of persons charged with this offense were disposed of this week in the Court of Special Sessions in Brooklyn. The fines ranged from \$5 to \$100, and one offender who was unable to pay the fine went to jail for thirty days.

OHIO.

Post-Graduate School Incorporated.—Papers of incorporation were signed November 23 for the Toledo Post-Graduate Medical School. Drs. Herbert E. Noble, Addison D. Hobart, A. C. White, G. Albert Gorsuch and Alvin G. Snyder, signed the application.

Injured.—Dr. Edward W. Baehr, Cincinnati, physician for the Robinson circus, was shot and seriously wounded by a negro in Bainbridge, Ga., October 27. He has been removed to his home in Cincinnati.—Dr. John H. Rodgers, Springfield, fell down stairs at the Arcade Hotel, November 28, straining his hip.

Personal.—Dr. Harry L. Woodward, Cincinnati, has been appointed to succeed the late Dr. John E. Jones as physician to the Widows' and Old Men's Home.—The board of medical directors of the Cincinnati City Hospital has elected the following staff: Drs. Joseph Eiebborg, George A. Fackler, Edwin W. Mitchell, Oliver P. Holt, Herman H. Hoppe, Frank W. Langdon, N. Pendleton Dandridge, Joseph Ransohoff, Edward W. Walker, John C. Oliver, Albert H. Freiberg, Charles E. Caldwell, August Ravogji, Charles S. Evans, Samuel E. Allen, John W. Murphy, Robert Sattler, Derrick T. Vail, William H. Taylor, Charles A. L. Reed, George M. Allen, John M. Withrow, Charles L. Bonifield, Sigmund Stark, Allyn C. Poole, B. Knox Rashford, Henry W. Bettman, Arch. I. Carson, David I. Wolfstein, John E. Griewe, William H. Crane, James W. Rowe, Frederick W. Lamb, Alfred Fiedlander, Horace J. Whitacre and Frank E. Fee.—The Columbus General Hospital Company, at its meeting held November 11, elected the following officers: President, Dr. Sherman Leach; vice-president, Dr. Robert C. Tarbell; secretary, Dr. John H. J. Upham, and treasurer, E. W. Christy.

PENNSYLVANIA.

Philadelphia.

Bequests.—By the will of Rosanna Carson von Phul the Northern Home for Friendless Children and the West Philadelphia Hospital for Women receive \$2,000 each.

The Philadelphia County Obstetrical Society elected the following officers: President, Dr. Richard C. Norris; vice-presidents, Drs. Wilmer Krusen and F. Hurst Maier; secretary, Dr. Frank C. Hammond, and treasurer, Dr. John W. West.

Pathologists Meet.—The monthly meeting of the Pathological Society was addressed by Dr. Victor C. Vaughan of the University of Michigan, Dr. Charles Harrington of Boston and Prof. C. B. Cochran of West Chester, chemist to the State Dairy and Food Department. The question of the relation of food preservatives to the public health was discussed. A reception followed at the University Club.

Health Report.—The deaths from all causes aggregated 453 for the week ended December 10, compared with 426 last week and 496 for the corresponding period of last year. Of the deaths, 59 resulted from pneumonia, 11 more than were caused by consumption; 48 were due to tuberculosis, 23 to cancer, 41 to heart disease, 16 to apoplexy, 33 to Bright's disease, and 85 to acute inflammation of the respiratory tract.

Site for Oncologic Hospital.—The trustees of the American Oncologic Hospital have selected a site for the institution at Forty-fourth and Chestnut streets. The building is a large brick and stone structure and will be at once equipped for use. The hospital will be opened as soon as this work is completed. The following staff has been elected: Attending physician, Dr. Boardman Reed; attending surgeons, Drs. Addinell Hewson, G. Betton Massey and Howard R. Swayne.

Personal.—Dr. John H. Musser addressed the Medical Society of the District of Columbia, Washington, on "The Symptomatology of Arteriosclerosis," November 18. A reception was given in his honor by the society in the evening.—Dr. John B. Chapin, superintendent of the Pennsylvania Hospital for the Insane, who recently fell and sustained a fracture of the right wrist, is gradually improving.—Dr. Thomas G. Ashton has been appointed adjunct professor of medicine in the Department of Medicine of the University of Pennsylvania.

November Hospital Reports.—There were 289 new patients admitted to the wards of the Pennsylvania Hospital; 1,254 new patients were treated in the dispensary, 4,663 visits were made to the different dispensaries of the institution.—Frankford Hospital admitted 25 new patients to the wards and treated 865 patients in its dispensaries.—During the month 5,315 patients were treated in the Medico-Chirurgical Hospital.—There were 94 patients admitted to the Germantown Hospital and 1,162 were treated in the dispensary.—St. Agnes' Hospital admitted 154 patients to the wards and 3,506 were treated in the dispensary.—At St. Mary's Hospital 151 patients were admitted to the wards and 2,610 were treated in the dispensaries.

TENNESSEE.

New Knoxville Hospital.—Plans have been accepted and contracts awarded for the new Tennessee Medical College Hospital, to be erected at a cost of \$30,000.

Thrice Arrested.—Dr. James L. Jackson, Chattanooga, has been thrice arrested and thrice fined for selling cocaine unlawfully. He paid the accumulated fines and costs, amounting to \$281.

Personal.—Dr. Henry J. Kelso, for several years secretary of the Knoxville Board of Health, has resigned and Dr. William R. Cochrane has been elected his successor.—Major Frank P. Robinson, chief surgeon at the Soldiers' Home, Johnson City, has resigned.

Smallpox.—On account of the prevalence of smallpox in Mount Pleasant, a proclamation was issued December 1 requiring every one to be vaccinated within three days and providing fine for non-compliance. The smallpox in the state is reported by Dr. J. A. Albright, secretary of the State Board of Health, to be confined practically to Mowry and Dyer counties.

WISCONSIN.

Must Pay for Alleged Mistake.—In the case of Paul Parkhurst against Drs. Thomas W. Nuzum and Arick Sutherland of Brodhead, where the complainant claimed \$10,000 damages on the ground that the defendants had operated on the wrong foot, thereby crippling him for life, the jury awarded the complainant \$10,000.

Personal.—Dr. Henry E. Twohig, Fond du Lac, has returned from Europe and will locate in Marinette.—Dr. D. J. Twohig has located in Fond du Lac.—Dr. Charles A. Hayes, Chippewa Falls, has been appointed superintendent of the Chippewa County Asylum, vice Dr. Philo E. Lindley.—Dr. H. Schafer, formerly of Kiel, has returned from Europe and has located in Appleton.

Society Elects Officers.—At the annual meeting of the Waukesha County Medical Society, held in Waukesha December 3, the following officers were elected: Dr. Henry G. B. Nixon, Hartland, president; Dr. Benjamin U. Jacob, Waukesha, vice-president; Dr. Maybelle M. Park, Waukesha, secretary; Dr. William B. Campbell, Menominee Falls, treasurer; Dr. Thomas Tomelty, Big Bend, censor, and Drs. Albert J. Hodgson, Waukesha; Michael R. Wilkinson, Oconomowoc, and Laurel E. Youmans, Mukwonago, committee on health and legislation.

GENERAL.

Going to Panama.—About 75 delegates to the fourth Pan-American Medical Congress at Panama, January 2, will sail from Baltimore December 27 on the steamer *Atkos*, which has been specially chartered for this purpose.

Use of Adrenalin to Conceal Trachoma.—Officers of the Public Health and Marine-Hospital Service have noticed that on

verting the eyelids of immigrants in several cases a peculiar blanché appearance was observed. On investigation this proved to be due to the use of adrenalin. It was found that in mild cases of trachoma this drug will obliterate all traces of the disease for about one-half hour.

Neurology at Pan-American Congress.—An invitation is given to all members of the profession interested in neurologic and psychologic medicine to attend the neurologic section of this congress, Jan. 2-6, 1905, at Panama, to present papers or other communications in the line of the section's work, by Dr. C. H. Hughes, 3857 Olive street, St. Louis, secretary of the section of nervous and mental diseases.

Hawaiian Medical Association.—The annual session of the Hawaiian Territorial Medical Association was held at Honolulu, Nov. 20-22, 1904. The session was well attended. The following officers were elected for the ensuing year: President, Dr. J. T. McDonald; vice-president, Dr. J. H. Dinnegar; secretary-treasurer, Dr. St. D. G. Walters; executive committee, Dr. J. T. McDonald, Dr. J. H. Dinnegar, Dr. St. D. G. Walters, Dr. H. C. Sloggett, Dr. George W. Herbert.

Health of Manila.—The report of the Board of Health for the Philippine Islands for August states that there were 535 births in the city of Manila during that month. There were 1,032 deaths of residents and 68 deaths of transients; 544 of this number died without medical attention. Seven hundred and eight of the total number of deaths occurred in children under 2 years of age, and two of the deaths were of persons whose ages were given as 120 and 109 years respectively. During the month there were 4 deaths from smallpox and 7 from plague.

International Medical Congress.—Dr. J. H. Musser, president of the American Medical Association, at the request of the secretary of the International Medical Congress, which meets in Lisbon in 1906, and on approval of the House of Delegates, has appointed the following members of the American Committee of Arrangements:

Drs. Frank Billings, Chicago; Herman M. Biggs, New York; Herbert L. Borrell, Massachusetts; William T. Councilman, Boston; Wm. H. Carmalt, Connecticut; Richard C. Cabot, Massachusetts; N. S. Davis, Jr., Illinois; Chas. H. Frazier, Philadelphia; R. H. Fitz, Massachusetts; E. B. Foss, Missouri; Chas. Lyman Greene, Minnesota; Ramon Gutierrez, New York; H. A. Hare, Pennsylvania; L. Hektoen, Chicago; Edward Jackson, Denver; E. J. Janeway, New York; A. Jacobi, New York; George B. Johnston, Richmond, Va.; W. W. Keen, Philadelphia; Howard A. Kelly, Baltimore; Chas. Kellock, South Carolina; L. S. McMurry, Louisville, Ky.; James H. McBride, California; A. T. McCormack, Bowling Green, Ky.; K. A. Mackenzie, Portland, Ore.; John Herr Musser, Philadelphia; J. B. Murphy, Chicago; R. Matas, New Orleans; William Osler, Baltimore; Chas. Powers, Colorado; J. P. Roberts, Pennsylvania; W. L. Rodman, Pennsylvania; M. H. Richardson, Boston; Chas. A. Reed, Ohio; H. M. Sherman, San Francisco; Frederick C. Shattuck, Boston; Geo. H. Niramons, Chicago; Chas. G. Stockton, New York; Geo. Sternberg, London, E. C.; Victor Vaughan, Ann Arbor; John A. Witherspoon, Tennessee; J. Collins Warren, Massachusetts; J. C. Webster, Chicago; Wm. H. Welch, Baltimore; John A. Wyeth, New York.

The Surgeon Generals of the Army, Navy and United States Public Health and Marine-Hospital Service.

The presidents of the American Ophthalmological, Otolological, Gynecological, Physiological and Pediatric societies.

The presidents of the American Dermatological, Laryngological, Surgical, Climatological, Neurological, Medico-Psychological and Orthopedic associations.

The presidents of the Association of American Anatomists, Association of American Physicians, American Association of Genitourinary Surgeons, American Association of Pathologists and Bacteriologists, New York Academy of Medicine, College of Physicians, Philadelphia, Cook County Medical Society, Chicago, and the Society of Medical Improvement, Boston.

Panama Canal Employes.—We have received the announcements of the U. S. Civil Service Commission concerning the examinations for appointments at the Panama Canal. A number of positions, including sanitary officers, are excepted from the necessity of examination. These sanitary officers, we understand, are chiefs and probably all surgeons under them are required to pass competitive examinations. Announcement is made of examinations Jan. 18, 1905, for surgeons, physicians, pharmacists, hospital internes and trained nurses. These examinations will be held at the 184 cities of the country at which civil-service examinations are regularly held. Some of the details are as follows:

Surgeon.—Age limit, 25 to 50 years; salary, \$250 per month. Examination in anatomy, 15 per cent.; surgical bacteriology, 5 per cent.; surgical pathology and diagnosis, 15 per cent.; surgical practice, 40 per cent.; surgical gynecology, 5 per cent.; and practical experience, 30 per cent. This element will be rated on the statements made in the application and accompanying vouchers. Special attention will be given to the quality of the applicant's experience, and applicants who have had extensive work in large hospitals will receive special credit.

It is the desire of the Isthmian Canal Commission to appoint in this position only surgeons of thorough training and wide professional experience.

Physician.—Age limit, 25 to 50 years; salaries, \$150, \$200 and \$250 per month. Examination in letter-writing, 5 per cent.; anatomy, 5 per cent.; therapeutics, 5 per cent.; physical diagnosis (including questions relating to tropical diseases), 25 per cent.; general pathology and practice (including questions relating to tropical diseases), 25 per cent.; bacteriology and hygiene, 5 per cent.; obstetrics and gynecology, 5 per cent.; practical experience, 25 per cent.

The element of practical experience will be rated upon the statements made in the application and accompanying vouchers. Special attention will be given to the quality of the applicant's experience, and applicants who have had experience in hospitals particularly in the treatment of tropical diseases, will receive special credit. Only those who have had extensive hospital experience and are familiar with the treatment of tropical diseases, will be selected for appointment to the highest classified positions. Promotions may be made in the discretion of the Isthmian Canal Commission from the lower to the higher positions in this grade.

These examinations are open to all citizens of the United States who comply with the requirements. Applicants should at once apply either to the United States Civil Service Commission, Washington, D. C., or to the secretary of the board of examiners at the places mentioned in the accompanying list, for application form 1312. No person will be appointed for service on the Isthmus who is not physically sound and in good health. No application will be accepted unless properly executed and filed with the commission at Washington. The exact title of the examination desired should be used in the application. As examination papers are shipped direct from the commission to the places of examination, it is necessary that applications be received in ample time to arrange for the examination desired at the place indicated by the applicant. The commission will, therefore, arrange to examine any applicant whose application is received in time to permit the shipment of the necessary papers. Further information concerning conditions of employment under the Isthmian Canal Commission is given as follows:

LENGTH OF SERVICE.—The construction of the Panama Canal may extend throughout a time-period of eight or more years, according to the details of the project yet to be adopted.

OPPORTUNITIES.—The civil service of the Isthmian Canal Commission offers excellent opportunities to qualified persons, both in the matter of salaries and promotion. Under the operation of the civil service law it is contemplated that promotions will be made on the basis of merit from the lower to the higher positions.

MEDICAL ATTENDANCE.—Medical attendance, medicines, and care of hospitals when sick, are furnished to the employes of the Isthmian Canal Commission without cost. Well-equipped hospitals will be maintained at Ancon, adjacent to Panama, and at Colon. In meritorious cases sick leave on pay may be allowed, in addition to the regular leave of absence, not to exceed thirty days for employes who are from the United States, or fifteen days for employes who are residents of the Isthmus.

ACCOMMODATIONS FOR EMPLOYES.—The Isthmian Canal Commission furnishes quarters to its American employes, or at its option, to the married employes, which has tentatively been fixed at 8 per cent. of the salary. The commission proposes to maintain a civil commissary department on the Isthmus, which is soon to be established and the advantages of which are to be made available to the married employes of the Isthmian Canal Commission.

TRANSPORTATION TO THE ISTHMUS.—The Commission furnishes its employes free transportation to the Isthmus from either New York, New Orleans, or San Francisco, and, also, free return transportation on completion of satisfactory service.

LEAVE OF ABSENCE.—The employes of the Isthmian Canal Commission are allowed six weeks' leave of absence annually on full pay. This leave of absence is not granted until after eight months of satisfactory service. In visiting the United States on leave of absence, the salaries of the employes are granted the special rates to the above-named ports. (The prevailing special rates are \$25 between New York or New Orleans and Colon, and \$70 between San Francisco and Panama.) The special rates also apply when members of the family of an employe accompany him to the Isthmus.

All inquiries concerning examinations for competitive positions under the Isthmian Canal Commission should be addressed to the United States Civil Service Commission, Washington, D. C. Further communication relative to service, situation, climate, and conditions on the Isthmus should be addressed to the Isthmian Canal Commission, Washington, D. C., by whom the foregoing details have been furnished.

CANADA.

Medical.—Dr. A. M. Campbell has been appointed superintendent of the Winnipeg General Hospital in succession to Dr. Halpenny, who has taken up private practice.

Toronto Home for Incurables.—According to the thirtieth annual report 111 patients are in that institution, 38 having been admitted during the past official year; 36 deaths occurred and 12 patients left the institution very much improved. Paralysis and rheumatism affects many inmates. Of the 111 in the institution, 39 are paralytics and 27 have rheumatism.

District of St. Francis Medical Association.—The regular meeting of this association was held in Sherbrooke, Quebec, November 9, when the following officers were elected: President, Dr. F. J. Austin, Sherbrooke; vice-president, Dr. S. A.

Banfill, East Angus; secretary-treasurer Dr. I. J. Williams, Sherbrooke; council, Dr. J. O. Camirand, Dr. L. C. Bachand and Dr. R. A. D. King.

New Brunswick Provincial Hospital.—A special commission has just completed the examination of all the inmates of the New Brunswick Hospital for the Cure of Nervous Diseases. The institution has been overcrowded for some time, there being 554 patients in the main building. The object of the commission was to effect the removal to outside homes of those patients who were harmless and thus to leave more room for those acutely insane. The commission consisted of the new superintendent, Dr. J. V. Anglin, Dr. G. A. B. Addy and Dr. A. F. Emery, all of St. John. Dr. Anglin will seek reform in the method at present in vogue in the admission of patients to this institution. Hereafter patients will have to wait until they receive instructions from the superintendent that they can be admitted.

Hamilton (Ontario) General Hospital.—The Hamilton General Hospital wants to erect a new wing and has appealed to the Ontario government for \$50,000. The governors thought they had a claim on the government, because it had offered \$100,000 to the Toronto General Hospital. They stated that their annual grant only amounted to \$2,000, the balance of the maintenance fund being raised by the taxes of the ratepayers, and this annually amounted to \$30,000. The premier pointed out to the deputation that the succession duties brought into the treasury of the province about \$250,000 annually, to which the government added \$850,000, and the \$1,100,000 thus obtained went back to the hospitals and other charitable institutions. It was true that the government had promised to aid the Toronto General Hospital to the extent of \$100,000, but the proposed grant was entirely for medical educational purposes.

Handsome Gift for New Alexandra Hospital, Montreal.—The Alexandra Hospital in connection with the Montreal General Hospital, or in connection more particularly with the Protestant Hospitals of Montreal, for the care of contagious and infectious diseases, should have been ready for occupation by the first of next year, but beyond securing a site very little advance has been made. Recently a public meeting was held in Montreal following a conference between the trustees of the hospital and the hygienic committee of the city council for the purpose of eliciting public sympathy and aid in the prosecution of the work. Lack of funds prohibited the trustees from carrying out the construction of the hospital; but, as \$62,500 is now subscribed, the construction of the hospital will proceed at once; it probably will be ready for patients by September, 1905. Toward the building fund Mr. James Ross, Montreal, contributed \$25,000. The approximate cost of the institution, including the land, will be in the neighborhood of \$200,000.

FOREIGN.

Plague in London.—A member of the crew of the steamer *Weybridge* from the River Plate, which arrived in London November 30, was found by bacteriologic examination to be suffering from plague.

Bubonic Plague in Argentine Republic.—The existence of bubonic plague in Salto has been officially declared. The Public Health Reports state that the government of the republic has ordered prompt and vigorous sanitary measures to be enforced, intending, should it become necessary, to close public schools and churches. The minister of war has ordered the troops in that district to aid in enforcing hygienic measures.

German Anti-Charlatan Society.—Drs. G. Platau and C. Reisinger have been publishing since October, 1903, a periodical entitled *Hygienisches Volksblatt*. It is the official organ of the *Deutschen Gesellschaft zur Bekämpfung des Kuppelschertums*, and is designed to enlighten the public in matters of hygiene and to warn against irregular methods. The name has been changed to *Hygienische Blätter* as the periodical enters on its second year.

Popular Vote on Restriction or Non-Restriction of Irregular Practices.—Our exchanges state that the canton of Zurich, Switzerland, is soon to cast a popular vote on the question whether all restrictions to the practice of medicine should be removed. Professor Krönelin and the members of the profession generally have been earnestly at work to prevent such a lapse from the higher ideals of civilization and the lay press has seconded their efforts. As the question is to be decided by popular ballot, there is considerable apprehension in regard to the outcome.

Awarding of the Five Nobel Prizes.—The cable brings word from Stockholm that the Nobel prizes for 1904 were duly awarded on the anniversary of the birthday of the founder of the prizes, December 10. The prize in medicine was bestowed on Prof. J. P. Pawlow of St. Petersburg, whose recent research on the physiology of the digestive processes has revolutionized many of our conceptions and established a scientific basis for empirical experiences and observation. An institute was erected at St. Petersburg exclusively for his experimental work, and it is the Mecca to which many a scientific pilgrimage has been made during the last few years. The twenty-fifth anniversary of his entering on his professional career was celebrated last February, when a fund was endowed in his name for a prize for research in physiology. The prize for chemistry was given to Sir William Ramsay, professor of chemistry at London. The prize for literature was divided between a French poet and a Spanish dramatist. The peace prize was conferred on the Institute of International Law, and the prize for physics on Lord Rayleigh, professor of natural philosophy at the royal institute. The particulars of this great endowment, founded by the discoverer of dynamite, were given in *THE JOURNAL*, vol. xxxix, page 1600, and elsewhere.

Correspondence.

Graduates of Medical Schools.

WASHINGTON, D. C., Dec. 1, 1904.

To the Editor.—My attention has been directed to your note on page 1307 of *THE JOURNAL*, Oct. 29, 1904, on "Graduates of Medical Schools," in which the deductions drawn from the result of state board examinations in 1903, from the standpoint of a Philadelphian, are quoted. It is true that taking the statistics collectively the showing is very favorable to the Philadelphia medical schools, but is it really fair to individual schools to institute such a comparison?

Reference to the table on page 515 shows, for example, that the percentage of failures of Washington graduates varied from 0 to 30, and that the percentage of failures among graduates of Baltimore medical schools varied from 0 to 55.8. The deductions of the Philadelphian, if applied to the graduates of the New Orleans medical schools, would show that the percentage of failures was 71.4 when, as a matter of fact, one of the two schools graduated all the unsuccessful candidates.

I am of the opinion that valuable conclusions can be drawn from the results of the state board examinations as to the efficiency of the medical schools, when accurately reported and analyzed, but it is obviously our duty to study the records before condemning or recommending any particular school to prospective students.

GEO. M. KOBER, M.D.

EDITOR'S COMMENT.—Our correspondent probably realizes that the note referred to was copied from another publication. The table from which the information was derived, and which appeared in *THE JOURNAL* Aug. 13, 1904, gave the facts concerning individual colleges, but the writer of the item referred to grouped certain colleges in the same city.]

Care of a Diphtheria Epidemic.

MR. WASHINGTON, MD., Dec. 7, 1904.

To the Editor.—In *THE JOURNAL* Dec. 3, 1904, p. 1709, it is stated that diphtheria is prevalent in East Coventry and in the northern section of Chester County. I write this in order that the medical profession of that community may profit by our experience here and so be enabled to stamp out the disease.

In this community of 1,400 inhabitants this terrible disease has been epidemic for the past 16 months. The disease has attacked all classes. Last winter the school in the immediate neighborhood was closed two months on account of this malady.

At the beginning of this school term it was thought that the trouble might be gotten rid of by the public schools. The trustees of our school, one of whom is our most eminent physician, consulted the school board and the county commissioners and made special arrangements with the State Board of Health for the taking of the cultures from the throats of the pupils of this school and of another school about two miles distant, where the disease had now got a foothold, and caused the school to be closed. The cultures have been taken nine times and in one school the percentage was 3.2 more than in the schools of New York City. In the other school, where the attendance was very much smaller owing to the number of cases in the

school, the percentage ranged from 5 to 25, which was a very large percentage.

When cultures from a child's throat were found to be positive, that child was sent home, and also other children of the family if there were any, and not allowed to return until cultures were declared negative. This, of course, decreased the attendance. There were some parents who did not approve of the method and were opposed to it and were trying to have it stopped when the county commissioners stopped it. If it were possible for the physicians of the locality above mentioned to make some such arrangements, I think that they could stamp out the disease in a short time.

JOSIAH S. BOWEN, M.D.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

SPECIFIC TREATMENT FOR TUBERCULOSIS.

NEW ORLEANS, Dec. 5, 1904.

To the Editor:—A recent article in THE JOURNAL (November 26) on the use of serums in tuberculosis and the discussion that followed, shows that up to the present the administration of toxins and antitoxins in the treatment of this disease has been unsatisfactory. Antitoxins have been discarded and, with the large majority of the profession, tuberculin and similar preparations have little vogue. That the serum treatment of pulmonary tuberculosis has so far been futile may be due to the fact that the well-established disease is nearly always complicated with streptococcal or staphylococcal infection, or both. There are different families of staphylococci and of streptococci, and this difference may extend to the tubercle bacillus itself. This suggests that in so long drawn out a condition as chronic tuberculosis an antitoxic serum might be obtained exactly adapted to each individual case by using the blood of a horse immunized to the mixed infection of the secretion obtained from the patient himself. 2. This would certainly be an expensive method of treatment, but if there is anything in the antitoxin treatment of disease, theoretically, at least, an effective one. And there are those who can afford not to consider expense when the life of one they love is in the balance.

A. NELKEN.

ANSWER.—Theoretically Dr. Nelken's proposition sounds well enough and, granting the correctness of his premises, the resulting serum should be effective. Closer examination of the problems involved shows, however, so many difficulties in the way that the practical use of this treatment is very remote indeed. Extensive experiments in immunization of horses and other animals with tubercle bacilli and streptococci would have to be carried out in order to determine under what conditions potent antisera are obtainable, if at all. By the way, right at this point it may be well to emphasize that it is not strictly correct to speak of all antisera as antitoxic serums. In the case of many pathogenic organisms, e. g., typhoid bacillus, dysentery bacillus, streptococcus, it has not yet been possible to obtain true antitoxic serums, because these organisms so far as we know now do not owe their pathogenic effects to toxins in the strict sense, namely, readily diffusible toxic substances with which it is possible to produce by immunization specific antitoxins. So far antityphoid and antidyenteric serums are essentially complex bactericidal serums, while the mechanism of action of antistreptococcus serum, so far as it has been determined, in animal experiments, is perhaps even still more complex. In the interest of clearness it is therefore best to speak of antitoxic serums only when we know that it actually concerns antitoxins in the limited scientific sense. Those who are interested will find these distinctions more fully outlined in Dr. Rickett's article in THE JOURNAL, May 21, 1904, p. 1336, entitled "Our Serotherapeutic Measures." Returning to Dr. Nelken's suggestion, we would say again that the only way to proceed is to experiment. First, it must be shown unequivocally that it is possible to obtain antitubercle and antistreptococcus serums, whatever their nature, by means of organisms derived from human beings. Secondly, should the results of these experiments warrant further effort, work should then be directed to shorten to the greatest possible extent the time intervening between the patient's coming under observation and the production of the serums, so that the disease could be attacked at the earliest and hence most favorable period possible. And lastly would come the actual trial of the treatment in carefully selected cases under simple but favorable and easily reproducible conditions so that it might be possible by comparison to form a definite idea as to the effects of the treatment.

RECIPROCITY.

FINDLAY, OHIO, Dec. 12, 1904.

To the Editor:—1. Do Ohio and Pennsylvania state boards reciprocate? 2. When will the good time of emancipation come to the

physicians of this great and goodly land, giving them perfect freedom to go wherever they will after having once been pronounced legally qualified to practice in any one of the states? 3. Could not the American Medical Association and other societies secure a federal law granting to all physicians, legally qualified, the right to practice anywhere in the country? 4. Would not a national board of licensure be more effective, with state boards subordinate, in bringing about all the results aimed at by the several states and in much more quickly securing those results?

W. C.

ANSWER.—1. No. 2. When we get more uniformity in our medical laws or uniformity in examinations. The states having a high standard will never reciprocate with those having a low standard of entrance requirements. The states having a low standard will not accept a certificate of a board whose standard is high, because the latter will not accept that of the former. 3. No, the matter comes under the police powers, and this, according to the constitution of the United States, rests with the individual states. 4. Yes, but only a voluntary board could exist; at least as a legal institution, for the reasons given in reply to question 3.

BURNS FROM HOT-WATER BOTTLES—OVARIOTOMY FOR EPILEPSY.

CHICAGO, Dec. 5, 1904.

To the Editor: Have any articles appeared in THE JOURNAL or elsewhere or in any of the text-books on surgery regarding accidental burns produced by hot-water bottles or rubber bags of hot water, when applied to a patient after being operated on? 2. Can a patient be burned by either of these forms of bottles containing hot or warm water when applied externally to a blanket that envelops a patient? 3. If, so, which form of bottle would be most likely to produce a burn? 4. Are there on record well-authenticated cases resulting in the cure of epilepsy in the female, without complications, in which the operation of clitoridectomy or ovariectomy has been performed? 5. Are either of these operations justifiable in a typical or simple case of epilepsy without complications, or are either of these operations frequently advised or performed for the relief or cure of this disease? LISTON HOMER MONTGOMERY, No. 92 State St.

ANSWER.—1. Yes; cases have been reported briefly, but we are unable to give names of references in which reports appeared. Reports of these cases may be found in hospital and in other records. 2. Yes; serious and even fatal results may occur. 3. A bottle which may be carried by straps or handles so that the excessive heat is not noticed in handling it. Further, a bottle of shape or kind as to rest more closely against the patient. 4. No. 5. No.

BURLESQUE NUMBER OF THE WOCHENSCHRIFT.

CHARLOTTESVILLE, VA., Dec. 5, 1904.

To the Editor:—Kindly refer me to some one in this country from whom I can get a copy of the burlesque number of the *Münchener medicinische Wochenschrift* and the price.

THOMAS J. BUTLER, Univ. of Va., P. O.

ANSWER.—This burlesque is published annually on the anniversary of the Munich Medical Society. The present number is the seventh thus issued, the anniversary being the seventieth of the society. It is expressly stated that this burlesque is not for sale separately, and that it is not even sent to subscribers for the *Wochenschrift* unless they are medical men. Consequently the libraries, like the Newberry Library at Chicago do not receive this 20-page burlesque number unless prescribed by some medical friend, as received on his private subscription. Dr. B. Spatz is the editor, Arnulfstrasse 26, Munich, Germany. In commenting on a previous number of the burlesque, THE JOURNAL remarked that its fun almost repaid one for the study of German, and the present number is even better than its predecessors. Perhaps some subscriber who sees this will loan our correspondent his copy.

PHYSICIAN MAY OMIT CHARGE FOR EXAMINING ANOTHER PHYSICIAN.

MILWAUKEE, Dec. 7, 1904.

To the Editor:—1. Is it right for one physician examining another physician for life insurance to give the applicant credit, with the knowledge and consent of the company, for the usual examination fee? 2. Can the examiner logically argue that the company pays him, when, as a matter of fact, the company simply fixes the rate high enough to cover this fee?

RALPH ELMERGREEN, M.D.

ANSWER.—1. Yes. 2. He can. He gets the fee from the company.

BOOKS ON URINALYSIS.

Pa., Dec. 5, 1904.

To the Editor:—Will you kindly inform me regarding the most practical books on the clinical examination of the urine and blood? I want a book which treats not only of all the methods of examination, but the significance of each abnormal element when present, etc.

T. H.

ANSWER.—Ewings's Clinical Pathology of the Blood; Cabot's Guide to Clinical Examination of the Blood; Ozden's Clinical Examination of Urine and Urinary Diagnosis; Croftan's Urinology.

—
 FEE FOR BLOOD COUNT.

ESCANABA, MICH., Dec. 8, 1904

To the Editor:—Will you kindly tell me the usual fee for a blood count, i. e., the leucocytosis only? M. P. FENELON

ANSWER.—\$5 to \$10.

—
Marriages.

Doc C. Hoyt, M.D., to Miss Belle Claire Chamberlain, both of Chicago, December 1.

GRACE MAE HARCOURT, M.D., to Jonathan Hoag, Jr., at Baltimore, December 8.

JOHN DARST, M.D., Houston, Texas, to Miss Julia Holmlund of Mason City, Iowa.

CHARLES W. ZELLER, M.D., Defiance, Ohio, to Miss Therese Cunningham, October 14.

VINCENT SHEPHERD, M.D., to Miss Marium Palmer, both of Dupont, Ind., November 30.

FELLOWES, DAVIS, JR., M.D., to Miss Gertrude Agostini, both of New York City, December 7.

CHARLES MACDONALD, M.D., Chicago, to Miss Clara Middleton of Oak Park, Ill., December 1.

CORNELIUS D. MACKAY, M.D., to Mrs. Mary Louise McMannany, both of Chicago, November 24.

L. A. VANDERHOOF, M.D., Byron, Ill., to Miss Vergne M. Culver of Lawrence, Mich., November 24.

WILLIAM Y. WARD, M.D., to Miss Maude Alice Peterson, both of Duplex, Texas, November 24.

RANDOLPH TUCKER SHIELDS, M.D., to Miss Ellen Randolph Page, at Winchester, Va., December 7.

THOMAS H. CULHANE, M.D., Peoria, Ill., to Miss Zana May Eastman of Chicago, at Ottawa, Ill., November 23.

WILLIAM LESTER SOUTHER, M.D., Rocky Hill, Ky., to Miss Ethel Pearl Jones of Chattanooga, Tenn., December 7.

FREDERICK ERNEST SCHACHT, M.D., Burlington, Wash., to Miss Sophia Gloria Wiese of Minneapolis, Minn., at St. Louis, November 26.

—
Deaths.

Webster Bodine Lowman, M.D. Jefferson Medical College, Philadelphia, 1867, a member of the American Medical Association; vice-president in 1886, and president in 1899 of the Medical Society of the State of Pennsylvania; one of the organizers of the Cambria County Medical Society, its secretary for several years, and three times its president; surgeon to the Pennsylvania System and the Cambria Steel Company since 1876, to the Lorain Steel Company since 1888; surgeon to the Cambria Hospital since 1884; one of the incorporators of the Conemaugh Valley Memorial Hospital Association, and consulting surgeon to the hospital, one of the most prominent surgeons of western Pennsylvania, died at his home in Johnstown, December 5, from chronic nephritis, after an illness of about one year, aged 63.

William E. Carroll, M.D. College of Physicians and Surgeons in the City of New York, 1884, of Newark, N. J., a member of the American Medical Association, Medical Society of the State of New Jersey, Essex County Medical Society and Newark Medical Society; surgeon to the Woman's Hospital, Newark, and one of the most prominent physicians in the city, died at St. Michael's Hospital, December 2, from pneumonia, after an illness of one week, aged 57.

John T. Wills, M.D. Kentucky School of Medicine, 1890, a member of the American Medical Association, and the Denver City and County Medical Society; one of the founders of the Bank of Grand County, Colo., proprietor of the Sulphur Springs Mercantile Company, and county judge of Grand County, died at his home in Sulphur Springs, December 2, from consumption, aged 44.

Martin L. Gerould, M.D. Harvard University Medical School, Boston, 1866, acting assistant surgeon United States Navy during the Civil War, died at his home in Kirkwood, Mo., De-

ember 4, from heart disease, after an illness of five years, aged 63.

Louis J. Steuber, M.D. Rush Medical College, Chicago, 1891, formerly of Lima, Ohio, but recently appointed chief medical officer of a sanitarium at Sour Lake, Texas, was found dead in his bed in San Antonio, Texas, December 8, from heart disease, aged 36.

Carlos L. Chambers, M.D. Rush Medical College, Chicago, 1882, of Kasson, Minn., a member of the American Medical Association, died in a hospital at Minneapolis, December 6, after an operation.

Nelson S. Witting, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1870, of Marinette, Wis., died at a sanitarium in Oshkosh, Wis., after a long illness, aged 71.

Wilford Hickham, M.D. Medical College of Indiana, Indianapolis, 1883, died at his home in Spencer, Ind., November 23, from disease of the stomach, after an illness of three weeks, aged 46.

Caswell J. Graves, M.D. Transylvania University Medical Department, Lexington, Ky., 1848, died suddenly from angina pectoris at his home near Payne's Depot, Ky., December 4, aged 77.

Tobias Jurim, M.D. Vienna, Austria, 1894, of New York City, died at the home of his father-in-law in New York City, December 7, from carbolic acid, taken with suicidal intent, aged 33.

Claude H. Burke, M.D. University of Virginia Medical Department, Charlottesville, 1896, of Burketown, Va., died in Abiquiu, N. M., November 30, from tuberculosis, after a long illness.

John T. McColm, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1877, died at his home in Gravity, Iowa, from cerebral hemorrhage, November 27, after an illness of three days.

James E. McClellan, M.D. Long Island Medical College Hospital, Brooklyn, N. Y., 1868, died at his home in De Ruyter, N. Y., November 24, from diabetes, after a long illness, aged 68.

John Davis, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1863, died at his home in Gomer, Ohio, December 4, after an illness of 13 days, aged 67.

Charles O. Belden, M.D. College of Physicians and Surgeons in the City of New York, 1882, of Litchfield, Conn., died at the Hopeworth Sanitarium, Bristol, R. I., November 27, aged 46.

Nelson J. Bird, M.D. Faculty of Medicine of Queen's University, Kingston, Ont., 1860, of San Francisco, died suddenly from acute gastritis in Fresno, Cal., December 2, aged 71.

Dennis O'Donoghue, M.D. Medical College of Alabama, Mobile, 1874, died at his home in Charlotte, N. C., December 3, from pneumonia, after an illness of one day, aged 74.

William E. Sitzer, M.D. Trinity Medical College, Toronto, Ont., 1894, died at his home in Ida, Mich., December 6, from pneumonia, after an illness of one month, aged 36.

Martha Cornelia Holmes, M.D. Women's Medical College of Pennsylvania, Philadelphia, 1886, died at her home in Waterville, Conn., December 5, after a short illness.

William H. Warder, M.D. Rush Medical College, Chicago, 1892, fell dead on the sidewalk in front of his residence in Chicago, December 12, from heart disease.

Charles Wilbur Edgington, M.D. Starling Medical College, Columbus, 1895, died at his home in West Union, Ohio, from tuberculosis, November 27, aged 37.

B. Thomas Marshall, M.D. St. Louis Medical College, 1865, died at his home in Woodville, McCracken County, Ky., December 8, from paralysis, aged 65.

Andrew J. McCaughy, M.D. University of Louisville Medical Department, 1884, died at his home in Linton, Ind., November 29, from typhoid fever, aged 49.

Asa A. Bennett, M.D. Philadelphia, 1861, died at the home of his brother in Roscoe, N. Y., from asthma, after a long illness, November 19, aged 69.

Calvin S. Acker, M.D. Rush Medical College, Chicago, 1885, of Arkansas City, Kan., died at his home in Kay County, December 8, from consumption.

Joseph Fuqua Bass, M.D. Jefferson Medical College, Philadelphia, 1860, died at his home in Richmond, Va., December 6, after a long illness, aged 62.

William J. Proctor, M.D. Trinity Medical College, Toronto, Ont., 1892, died recently at the Kindred Hotel, Valley City, N. D., after a brief illness.

George Gordon Kyle, M.D. Starling Medical College, Columbus, Ohio, 1880, died suddenly at his home in Riverside, Cal., November 29.

Hugo W. Kohler, M.D. Marion-Sims College of Medicine, St. Louis, 1892, died at his home in St. Louis, Mo., December 5, aged 40.

George N. Lowe, M.D. Northwestern University Medical School, Chicago, 1887, died recently at his home in Fort Pierre, S. D.

Joseph C. Anderson, M.D. Ohio, 1873, died at his home in Cleveland, December 5, from pneumonia, aged 58.

Benjamin H. Thurman, M.D. Georgia, 1833, was murdered near his home in Cheraw, S. C., November 29.

Kittie Waldo Higgins, M.D. Illinois, 1901, died at her home in Denver, Colo., December 4.

Deaths Abroad.

R. Langerhans, M.D., author of numerous works on pathology, died at Berlin, November 21, aged 45. He was Virchow's assistant from 1885 to 1894, and since then has been prosector at the Moabit Municipal Hospital.

K. Stellwag von Carion, M.D., the well-known ophthalmologist at Vienna, died there November 22, aged 81. He has published numerous manuals and other works on his specialty, and was professor of ophthalmology until retired on reaching the age limit. His name is connected with a sign for goiter, etc.

Book Notices.

A HAND-BOOK OF SURGERY. For Students and Practitioners. By Frederick R. Griffith, M.D., Surgeon to the Bellevue Dispensary, New York City; Assistant Surgeon at the New York Polyclinic School and Hospital. 12mo. Volume of 579 Pages, Containing 417 Illustrations. Philadelphia, New York, London: W. B. Saunders & Co. 1904. Flexible Leather, \$2.00 net.

This book is intended to serve as a working guide in surgery for both the student and the general practitioner. It outlines briefly and in a systematic way the principles and practice of surgery, giving the essentials, as a rule, with extreme conciseness and commendable clearness.

REGIONAL MINOR SURGERY. Describing the Treatment of Those Conditions Daily Encountered by the General Practitioner. By George Gray Van Schaick, M.D., Consulting Surgeon to the French Hospital, N. Y. 226. Price, \$1.50. New York: International Journal of Surgery Co.

This little handbook discusses the treatment of those conditions which are daily encountered by the general practitioner and which, while comparatively trivial, may by careless or bad treatment result in the gravest possible conditions. The book well fulfills the promise of the preface, and that it is of value to the general practitioner is evidenced by the necessity of a second edition in so short a time after the appearance of the first.

EXAMINATION OF THE URINE. By G. A. de Santos Saxe, M.D., Pathologist to the Columbus Hospital, New York City. Fully illustrated, including 8 Colored Plates. Flexible Leather. Pp. 391. Price, \$1.50 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

Undoubtedly this manual states well the principal facts in regard to examination of the urine, but it is not apparent that its author has written it because he had anything new to tell or because old facts and principles have been considered from new or unusual points of view. There is a short chapter on "The Diagnosis of Functional Efficiency of the Kidney," in which only the general principles of cystoscopy, etc., are stated. Of the pathogenic germs that may occur in urine only the gonococcus and the tubercle bacillus are fully considered from the point of view of their demonstration. The book comes in a convenient form with flexible covers.

APPLETON'S MEDICAL DICTIONARY. An Illustrated Dictionary of Medicine and Allied Subjects, in Which Are Given the Derivation, Accentuation and Definition of Terms Used Throughout the Entire Field of Medical Science. Edited by Frank P. Foster, M.D. Half-Leather. Pp. 1991. Price \$10.00. Thumb Index, \$11.00. New York and London: D. Appleton & Co. 1904.

This work is practically Foster's Encyclopedic Medical Dictionary under another name, and revised and modified. Some

illustrations are new and original, but many are taken from the older work. It is accurate and up to date in most respects. Beside the Greek or Latin derivation of the word the French and German equivalents are given. In words of Greek origin the rules of the Greek language are adhered to in spelling, for example, "rachitis" is spelled "rhachitis." It seems to us, however, that in such words as hemorrhage and hemorrhoid it is better to replace the diphthong by an "e," thus keeping pace with progress in the development of the language. In an appendix are to be found a list of the chief initial and terminal parts of compound words and a pronouncing list of proper names. There are also a list of abbreviations and a table of weights and measures. The work shows the result of careful revision, as the most recent words are to be found in it.

FRIEDBERGER AND FROHNER'S VETERINARY PATHOLOGY (Authorized Translation). Translated and Edited by M. H. Hayes, F.R.C.V.S., with Notes on Bacteriology by Dr. G. Newman, D.P.H. Vol. 1. Cloth. Pp. 519. Price, \$4.00 net. London: Hurst & Blackett, Ltd. Chicago: W. T. Keener & Co. 1904.

The original of this book is the authoritative work on veterinary medicine in Germany. Its French translation has been made a text-book on this subject in French veterinary schools. This volume in particular will interest physicians because it deals with the infectious diseases of animals. Owing to the undesirable limitation often placed on the term pathology, especially in this country, in which it is frequently employed as synonymous with pathologic anatomy, it is necessary to state that this work deals fully with the clinical aspects of veterinary diseases, that it is in fact a work on veterinary medicine. The translation is a welcome addition to English literature because it places within easy reach comprehensive and authoritative information concerning diseases of domestic and other animals, a subject of increasing interest and importance to human medicine.

LECTURES TO GENERAL PRACTITIONERS ON THE DISEASES OF THE STOMACH AND INTESTINES. With an Account of Their Relations to Other Diseases and of the Most Recent Methods Applicable to the Diagnosis and Treatment of Them in General; also "The Gastro-intestinal Clinics," in which All Such Diseases are Separately Considered. By Boardman Reed, M.D., Professor of Diseases of the Gastro-intestinal Tract, Hygiene and Climatology in the Department of Medicine of Temple College, Philadelphia. Illustrated. Cloth. Pp. 1021. Price, \$5.00 net. New York: E. B. Treat & Co. 1904.

This is a bulky volume of 1024 pages, containing 82 lectures on the diseases of the inner lining of the gastrointestinal canal. There is no discussion of the diseases of the pancreas or of the liver. There is no author's index and the style is rather prolix. Frequently material previously published in articles in medical journals is introduced and there is, on the whole, good room and good reason for condensation. There has been given entirely too little attention in this book to the recent work of Pawlow and others on the various digestive ferments. Nevertheless the general practitioner will find much in these pages that will help him to care for chronic dyspepsies and nervous invalids with gastrointestinal affections. The author lays special stress on treatment.

A TEXT-BOOK OF MATERIA MEDICA. Including Laboratory Exercises in the Histologic and Chemie Examinations of Drugs. For Pharmaceutical and Medical Schools, and for Home Study. By Robert A. Hatcher, Ph.G., M.D., Instructor in Pharmacology in Cornell University Medical School of New York City; and Oswald Solimann, M.D., Assistant Professor in Pharmacology and Materia Medica in the Medical Department of the Western Reserve University of Cleveland. Illustrated. Flexible Leather. Pp. 400. Price, \$2.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

This book is written with the object of making the laboratory method of study of this subject popular. The interest in this proverbially dry subject can no doubt be stimulated by objective work. The author is to be commended for his successful venture in giving to the student a practical guide for the study of drugs and their derivatives. The book is divided into three parts. Part one deals with the systematic study of crude drugs. A brief and concise blank form is given which outlines the method of study and describing the drug. Part two considers the plant histology. The first chapter gives a very complete description of the technic necessary for preparing specimens. The section is well illustrated with simple drawings. Part three is a study of the chemical exercises in materia medica. In this section the student is directed to study the

essential connection between materia medica and chemistry. Considerable space is devoted to suggesting an outline for the analysis of unknown drugs. The book is well written, the classifications are good and the book is to be recommended as a practical guide in the laboratory study of materia medica.

WEATHER INFLUENCES. An Empirical Study of the Mental and Physiological Effects of Definite Meteorological Conditions. By Edwin Grant Dexter, Ph.D., Professor of Education at the University of Illinois. With an Introduction by Cleveland Abbe, LL.D. Cloth. Pp. 286. Price, \$2.00. New York: The Macmillan Co. London: Macmillan & Co., Ltd. 1904.

The author offers this work, not as a final word, but as a suggestion for further investigation. The field he enters is not without interest to the popular mind nor without possibilities to the investigator, but it certainly is a field of scientific research hitherto unentered to such an extent. Five of the chapters have, in substance, previously appeared in print; the rest of the material is new. The work will be of interest not only to the casual reader, but particularly to medical men, although it presents facts which, in the main, are well known by physicians. But here they are collected and presented in sequential form. It is the author's aim to set forth the influence of weather on human passions, crime and mental growth and development. Among subjects considered are the sources and nature of weather proverbs, animal weather lore, the weather lore of the "skye influences," the weather and its effect on crime, insanity, suicide, drunkenness, etc. In the preparation of this work the author has availed himself of the assistance of school teachers, wardens of penitentiaries, superintendents of public schools and of asylums for the insane, officials of the United States Weather Bureau and others.

STRABISMUS, OR SQUINT, Latent and Fixed. A Supplement to the Errors of Refraction. By Francis Valk, M.D., Professor of Diseases of the Eye, New York Post-graduate School and Hospital. Cloth. Pp. 171. Price, \$1.75. New York and London: G. P. Putnam's Son. 1904.

While we agree with Edward Jackson that much ink and paper have been wasted in vain attempts to elucidate the many problems that arise in connection with oculo-muscular anomalies and that much of the literature of heterotropia is valueless, it is a praiseworthy task to have stated, as Dr. Valk has done, the principal facts, theories and hypotheses that constitute our present knowledge of squint. Dr. Valk has done some original work in this department of ophthalmic surgery, a fact that gives him a special claim to speak with authority. We agree with him in always preferring, in heterotropia or heterophoria, either shortening or advancement, with or without tenotomy, to tenotomy alone. The various "tucking" operations, however, do not, in our judgement, have a place in ophthalmic surgery, i. e., there does not appear to be a muscular anomaly requiring operative interference whose readjustment can not be more successfully and more neatly accomplished by the average operator through the medium of an advancement, or a shortening without "tucking." We would draw Dr. Valk's attention to one statement in which we think he is in error. On page 121 he says: "I refer the reader to cases of congenital absence of the outward movements of the eyes—seeming convergent squint—where I think the check ligaments may have a very important influence, as in these cases there is a very decided limitation of the outward movement of the eye without any evidence or history of paralysis. I do not think this has been suggested before." This fact has been discussed by Motais and Maddox. Dr. Elliott Colburn of Chicago, writing in the *Ophthalmic Record* for January, 1897, also describes, in an illustrated article, the relations of the check ligaments to convergent squint with limitation of the outward excursion of one eye. The publication of Dr. Valk's book is justified by recent advances in "ophthalmic myology," as Savage phrases it, and the work will be a valuable addition to every ophthalmic surgeon's library.

ADOLESCENCE, ITS PSYCHOLOGY AND ITS Relation to Physiological, Anthropology, Sociology, Sex, Crime, Religion and Education. By G. Stanley Hall, Ph.D., LL.D., President of Clark University and Professor of Psychology and Pedagogy. Vols. 1 and II. Cloth. Pp. 590 and 784 respectively. Price, \$7.50. New York: D. Appleton & Co. 1904.

The importance of puberty and adolescence as a critical

period is becoming more and more recognized. There have been many important contributions to the subject, but the two volumes of the present work constitute by far the most elaborate and complete study that has yet appeared. The author, moreover, believes that he has opened a new line in his genetic ideas of the soul, which pervade the work and "mark an extension of evolution into the psychical field" that is of the utmost importance. How far his conviction in this regard is supported by the facts is a matter that must be estimated by competent authorities, and only after a very careful perusal of the work. The idea that the development of the individual and the race can best be elucidated by careful study of childhood and adolescence is not entirely new, but Dr. Hall has certainly given us more suggestive points and worked out his theory more elaborately than perhaps has been done by anyone heretofore.

Of the nearly fourteen hundred pages that compose the two volumes, several hundred in the beginning are devoted to physical changes, normal and morbid, that take place during the period of adolescence, including under this designation the period from the first indications of puberty to full maturity. This covers a range of from five to fifteen years at least, and may be extended still farther into early adult life. The growth of the body from early infancy to maturity forms the subject of the first chapter, and the special importance of favoring conditions during the development of sexual maturity are specially emphasized. It is at this period of stress that variations and reversions are liable to occur, and the equilibrium of the organism is most seriously disturbed. In the second chapter the details of growth of parts and organs during adolescence are taken up, and the importance of training to prevent abnormal tendencies is pointed out. It is at this time that mental and bodily culture is the problem of life. Next follows a chapter on the growth of motor power and function, a subject that is, when one considers it in all its relations, one of the most important of those discussed in the work, and involves as much as any other, perhaps the future of our race. The value of various forms of exercise, the importance of the play element, are all fully treated. Dr. Hall considers this one of the greatest problems of our present civilization. The "basal activities that shaped the body of primitive man have been suddenly swept away by the new methods of modern industry." There is here, perhaps on his part, a slight lack of recognition of the fact that human evolution proceeds through local and individual degenerations, a fact well illustrated by the evolution of the human jaw and teeth, and pointed out by Talbot, whose important work on dental deformities is not referred to by the author. We doubt whether mankind will ever be so specialized, as, for example, the soldier ants, but we do not know what physical changes future social evolution may bring forth. In any case, we can not exclude the possibility of further local arrest of development in the future evolution of the race. This chapter is, perhaps, one of the most practically important in the work, and is well worth careful perusal by teachers as well as by physicians.

The chapter on diseases of body and mind is a very good general résumé of our modern knowledge concerning these disorders as they affect the growing youth; especially that portion treating of the mental disorders of the period. One would hardly, however, appreciate the actual rarity of juvenile paresis from Dr. Hall's remarks on the subject, and its importance is, perhaps, overestimated by him as a disorder of adolescent life. He follows largely the ideas of Kraepelin, but holds that the term dementia precox, which became so popular under the inspiration of that author, is not altogether satisfactory, and that there are two important links missing in our knowledge of precocious mental decay. These links are knowledge of the actual changes that occur and lack of sufficient record of the earlier symptoms before the full recognition of the disease. He believes also that it is important that teachers and others who have to do with youth should be acquainted with these morbid forms, and wide-awake to the earliest and mildest of these symptoms. It is of the

utmost importance, he holds, to the study of normal genetic psychology that a careful study should be made of these types of premature decay. The failure of normal youthful development into a sane maturity he thinks will be the real cause of any possible future degeneration of the human race.

The chapters on juvenile criminality, sexual development and periodicity are noteworthy discussions of their subjects that can not be noticed in detail for lack of space. Like the other chapters in the work which have special medical bearings, they give evidence of careful study on the subjects on the part of the author, whose conclusions are generally those that may be accepted as agreeing with the consensus of opinion of those most qualified to judge. The chapter on adolescence in literature, biography and history, which concludes the first volume, is an interesting bit of literary criticism. The author holds that ephemic literature should be recognized as a class by itself and have its own place in the history of letters and criticism.

The second volume contains the discussion of the more particularly psychologic and sociologic aspects of adolescence. It is not less interesting and even more suggestive than the part already noticed. The author seems to favor the idea of the pre-existence of the soul, at least to a certain extent, as elucidating the problems of genetic psychology, and holds that the undue interest in its future has been one of the drawbacks in its study. He is particularly severe on certain methods in education, and is not at all a partisan of co-education. The ultra-feminization of the high schools is one of the leading modern evils, and the effect of the higher education of the adolescent female is, he believes, disastrous to fecundity, and is, therefore, a race danger. The statistics that he has collected appear to favor these views. It is fair to say, however, that there are experienced educators who do not agree with him as to the unavoidable evils of co-education. Boys and girls, according to Dr. Stanley Hall, require a different discipline, moral regimen and moral atmosphere and different methods of work. While co-education may tend to a refinement of manners on the part of the boys, he does not consider this an unmixed advantage. The boy of 15 who is a perfect gentleman has, he believes, something the matter with him. The brute and animal element should, he thinks, be allowed to work itself off in a normal way. On the other hand, the bachelor woman has overdrawn her account with heredity, so that in the full development of her type she is sterile, and this he calls the very apotheosis of biologic selfishness. The concluding chapter on adolescent races and their treatment is an interesting one, though some may question the author's views in some particulars. The typical savage is not always a perfectly lovable creature, and when sophisticated with the average un-Christian civilization which he meets, is still less of one. It may be a question also whether the term adolescent is properly applied to all the inferior races, and whether some of them are not rather in a state of permanent infantilism. Kipling's characterization as "half devil and half child" seems sometimes to close observers the most correct, and it is doubtful whether the world's progress is consistent with their continuation in their autochthonous development. Dr. Hall's quasi-condemnation of certain missionary methods is hardly fair, considering the fact that they have constantly to contend with the active hostile influences of civilization itself. There is very much, however, of truth in his remark that there is need of study of methods in mission work to avoid mistakes that may otherwise be made.

In conclusion, we may say that these two volumes form a treasury of facts and well-digested opinions that should be utilized, not only by physicians, but by teachers and parents generally. It is one of the most fruitful and suggestive works that has of late appeared. It has its drawback to the general reader in the richness of its philosophic vocabulary, and few persons of average culture will be able to interpret some of the terms which the author uses with such freedom; even with the aid of the latest dictionaries it is somewhat difficult. Fortunately, however, the context generally supplies the deficiency.

Miscellany.

Hospitalization of Contagious Diseases.—At the hospital connected with the Paris Pasteur Institute all kinds of contagious diseases are received and taken care of in the same pavilion. About 2,745 patients have thus been sheltered since 1900, including 524 cases of smallpox, 443 of diphtheria, 163 of erysipelas, 136 of measles, 7 of declared hydrophobia, and 192 mothers of sick children or the children of sick mothers. During this entire time there has been contagion of others only in 8 instances—5 of smallpox, 2 of erysipelas and 1 of diphtheria. The mortality has been 18 per cent. in smallpox, 11 per cent. in diphtheria, 2.17 per cent. in scarlet fever, and 6.75 per cent. in erysipelas. The hospital is on the cell or box plan, each separate chamber containing but one or two beds at most, with an entrance on the central corridor and also on a large piazza to be used when it is desirable to shut off the chamber from the rest of the building. There are six "boxes" on each side of the corridor. The walls between them are of glass. Each "box" is cemented and can be washed with the hose. Each has its independent supply of hot and cold water, electric light and gas, and when it is desirable to isolate the nurse with the patient two cells can be thrown into one. Each patient entering the hospital is vaccinated if there are any cases of smallpox in the hospital and each child receives a preventive injection of 5 c.c. of antidiphtheria serum if there is any diphtheria. The dishes, linen, etc., used for each chamber can be disinfected on the spot and none are ever taken out of the pavilion. Every morning and usually evenings, too, the floor is wiped up with a cloth wet with 1 to 50 javel water or a 1 to 200 solution of cresylene. Twice a week the floor of the entire hospital is washed with water and black soap. The erysipelas infection was traced to a rubber comb imperfectly sterilized with sublimate. Since then metal combs have been used and boiled. The cases of contagion of smallpox all developed after an incubation, showing that they must have become infected the first day or possibly before entering the hospital. The case of diphtheria was contracted from some doll's clothes brought from outside to a child. Infection in one case was traced to the cord with which the blind was raised and lowered in the convalescents' room. Martin describes the functioning of this contagious diseases pavilion in the *Bulletin de la Société Méd. des Hopitaux de Paris*.

The Comparative Intellectual Powers of the Two Sexes.—The *Lancet* says that a comparison between the mental attributes of the two sexes has practical as well as scientific interest, for from the economic standpoint it is obvious that the world's intellectual work must eventually fall into the hands of those of either sex, who, by reason of their mental capacities, are best fitted for this purpose. The comparisons drawn by Dr. J. de Kőrösy, the director of municipal statistics at Budapest, are certainly deserving attention, if only for the extensiveness of the observations on which they are founded. As director of municipal statistics he has had opportunities of comparing the examination records of nearly 1,000,000 children, girls and boys, who have received their education both in elementary and in higher grade schools. As gauged by successes and failures the comparison is greatly in favor of the girls, and even as regards proficiency in arithmetic, a subject usually regarded as the special prerogative of boys, the balance of proficiency inclines obviously to the side of the girls. The intellectual superiority of girls, as revealed by the test method applied by Dr. Kőrösy, is so unexpected and so entirely opposed to the teaching of the world's history that we naturally turn to other possible sources of explanation apart from inherent intellectual superiority to reconcile pre-existing conception with the statistical figures drawn from the Hungarian archives. The vulnerable features of these statistics, if, indeed, inferences drawn from the intellectual capacity of the girl can be applied to that of the grown woman, is that they refer to a period of life which both in boys and girls is subject to disturbances, sexual and otherwise. These disturbances are so fundamentally bound up with the general development of the organism, intellectual and organic, that it behooves us to be particu-

larly careful in making any sort of a comparison between the two sexes. The unexplained factors which apparently conduce to a form of intellectual precocity in girls, taken in conjunction with the biologic tendency for the establishment of an inverse relationship between the rate of organic development and the duration of a physiologically useful life, may offer some explanation of the fact that nearly the whole work of human progress can be traced to the maturer activities of the male and not of the female intellect.

Best Method of Artificial Respiration.—Experiments to test the amount of air which can be made to enter the lungs in the prone and in the supine positions are reported by the London *Lancet* as having been made by E. A. Schäfer to determine the effectiveness of the methods of performing artificial respiration, of Howard, Sylvester and Marshall Hall. The subject was a youth, the amount of whose tidal air in natural respiration was examined in the supine and the prone positions. With a respiration-rate of 13 the average amount of exchanged air per respiration was 489 cubic centimeters and per minute 6.460 cubic centimeters in the supine, and with a respiration-rate of 12½ it was 422 cubic centimeters and 5.240 cubic centimeters in the prone posture. The subject was then tested by the Sylvester method (supine). With a respiration-rate of 12.8 per minute an average of 178 cubic centimeters of air was exchanged per respiration and 2,280 cubic centimeters per minute, or slightly over a third of the normal exchange per minute for the individual. With Howard's pressure method (intermittent pressure applied to the lower ribs), the subject being in the supine posture and the average respiration-rate being 13.6, the average exchange per respiration was 295 cubic centimeters and per minute 4.020 cubic centimeters. In the case of the Marshall Hall method, "the patient is laid prone and rolled over to one side and back again, and so alternately. When in the prone position, pressure was exercised upon the back of the chest." Here, with an average respiration-rate of 12.6 and allowing for the rolling-over movement, the exchange per respiration is put at 254 cubic centimeters and the rolling without pressure at 192 cubic centimeters. In the prone pressure method, the one advocated by Schäfer, the compression is obtained in the same way as in Howard's method, but the patient lies prone with a coat folded beneath the lower part of his chest. The respiration-rate being 13, the average exchange per respiration was 520 cubic centimeters and 6,760 cubic centimeters per minute. It is clear that the experiments narrated above show that only in the case of the last method can an amount of tidal air be forced into the lungs which equals the normal exchange. Schäfer investigated these methods, and his conclusions refer to these methods alone, and he is mainly concerned with the resuscitation of the drowned; still, the fact that one method stands a long way in front of others as regards the amount of air which it effectually exchanges places that method first in all cases in which it is essential to empty and to fill the lungs rapidly. The prone posture is not one which is so easily to be employed in cases of suspended respiration in chloroform poisoning, but is undoubtedly the best in cases of drowning, as it not only gives the most free ventilation of the lungs, but also efficiently drains the air passages of water. Even in cases of suspended respiration under anesthetics when the operation has been commenced and is not one involving celiotomy, there appears no insuperable objection to turning the patient face downward while artificial respiration is carried out in the manner suggested.

Association News.

Portland Special.

Physicians in the East are planning a delightful itinerary in connection with the trip to Portland next year. It will include stops at Niagara Falls, Lake Minnetonka, Yellowstone Park, and Butte, Mont. The return trip will include stops in San Francisco, Los Angeles, Sacramento, Salt Lake City, Glenwood Springs, The Garden of the Gods, Denver and Omaha. The

expense is estimated at \$325 for each person. This will include all expenses except hotel bills at Portland and San Francisco. Information concerning this trip can be obtained by writing Dr. F. H. Wiggan, 55 West Thirty-sixth street, New York City.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. A., week ending Dec. 10, 1904:

Van Dusen, James W., asst.-surgeon, granted thirty days' leave of absence.

Appel, Daniel M., deputy surgeon general; Appel, Aaron H., surgeon; Metcalfe, H. F., asst.-surgeon, and Vedder, E. H., asst.-surgeon, called from San Francisco on the *Lagan*, en route to Manila.

Woodson, R. S., asst.-surgeon, will proceed to Hot Springs, Ark., for treatment.

Banister, J. M., March 21, 1905; Raymond, H. I., March 21, 1905; Bradley, A. E., April 21, 1905; Richard, Charles, May 12, 1905; Gibson, R. J., May 12, 1905, and Egan, Peter R., May 19, 1905. The above named surgeons are relieved from duty in the Philippine Division, to take effect on the dates opposite their respective names, and will then proceed by the first available transport to San Francisco, and on arrival report by telegraph to the military secretary of the Army for further orders.

Pollhemus, A. S., surgeon, retired from active service on account of disability incident to the service.

Johnson, R. W., surgeon, when services are no longer required at Louisiana Purchase Exposition grounds, will proceed to Fort Crook, Neb., for duty.

Fuller, Leigh A., asst.-surgeon, relieved from duty at U. S. Army General Hospital, Fort Bayard, N. M., and ordered to Fort Clark, Texas.

Arthur, Wm. H., and Glennan, James D., surgeons, appointed members of an Army retiring board to meet at War Department from time to time.

Geer, Charles C., asst.-surgeon, is directed to report in person to president of an Army retiring board, War Department, for examination by the board.

Wythe, Stephen, contract surgeon, granted an extension of one month to his leave of absence.

Rietz, Hugo C., dental surgeon, returned to Fort Sheridan, Ill., November 30, from temporary duty at Fort Brady, Mich.

Chambers, William H., dental surgeon, returned to duty November 26 at San Francisco from leave of absence.

Oliver, Robert T., examining and supervising dental surgeon, granted leave of absence for one month.

Dickenson, Clarence F., contract surgeon, granted leave of absence for three months, with permission to visit the United States.

Enders, William J., contract surgeon, left Fort Morgan, Ala., December 3 on leave of absence.

Wall, Francis M., contract surgeon, arrived at Fort Morgan, Ala., December 3 for temporary duty.

Boak, S. Davis, dental surgeon, returned to duty at Fort Slocum, N. Y., December 2 from leave of absence.

Shellenberger, James E., contract surgeon, returned to duty at Fort Sam Houston, Texas, December 2 from leave of absence.

Mason, George L., dental surgeon, granted an extension of twenty-three days to his leave of absence.

Lauderdale, Clarence E., dental surgeon, returned to duty at Fort Sam Houston, Texas, December 3 from leave of absence.

Brooks, John D., contract surgeon, left Fort Meade, S. D., December 4 on leave of absence for one month and fifteen days.

Navy Changes.

Changes in the medical corps of the Navy, week ending Dec. 10, 1904:

Wheeler, F. W., surgeon, detached from the *Philadelphia*, ordered home and granted sick leave for three months.

Seaman, W. P. A., detached from the *Wabash* and ordered to the Navy Yard, Boston.

Brownell, C. B., surgeon, detached from the *Amphitrite*, December 20 and ordered to the *Itora*.

Urie, J. F., surgeon, sick leave extended three months from Dec. 9, 1904.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ended Dec. 7, 1904:

Gassaway, J. M., surgeon, granted extension of leave of absence for one day November 27.

Carmichael, D. A., surgeon, to proceed to Washington, D. C., for special temporary duty. To proceed to Evansville, Ind., for special temporary duty.

Cumming, H. S., P. A. surgeon, granted leave of absence for seven days.

Von Esdorf, R. H. P. A. surgeon, relieved from duty in connection with the exhibit of the Service at the Louisiana Purchase Exposition, St. Louis, Mo., and directed to proceed to Washington, D. C.

Billings, W. C. P. A. surgeon, granted leave of absence for ten days from December 23.

Holt, J. M. P. A. surgeon, granted leave of absence for one day, Nov. 25, 1904, under Paragraph 191 of the Regulations.

Ebersole, R. E., asst.-surgeon, granted fifteen days' extension of leave of absence from December 6.

Stiles, Ch. Wardell, zoologist, granted leave of absence for three days from Nov. 30, 1904, under Paragraph 191 of the Regulations.

Ballard, J. C. A. A. surgeon, granted leave of absence for three days from Dec. 9, 1904.

Echemendin, D. M., A. A. surgeon, granted leave of absence for thirty days from December 1.
 Goldsborough, B. W., A. A. surgeon, granted leave of absence for two days.
 Safford, A. V., A. A. surgeon, granted leave of absence for nine days from December 10.
 Gahn, H., pharmacist, granted leave of absence for fifteen days from December 8.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Dec. 9, 1904:

SMALLPOX—UNITED STATES.

California: San Francisco, Nov. 19-26, 1 case.
 District of Columbia: Washington, Nov. 26-Dec. 3, 1 case.
 Illinois: Chicago, Nov. 26-Dec. 3, 12 cases, 2 deaths.
 Indiana: Hammond, Nov. 23-30, 1 case.
 Kentucky: Louisville, Nov. 24-Dec. 1, 6 cases.
 Louisiana: New Orleans, Nov. 26-Dec. 3, 4 cases, 2 imported.
 Michigan: Nov. 26-Dec. 3, Detroit, 1 case; Grand Rapids, 1 case; at 62 localities, Nov. 19-26, present.
 Missouri: St. Louis, Nov. 26-Dec. 3, 22 cases, 5 deaths.
 New York: Elmira, Nov. 26-Dec. 3, 1 case.
 Ohio: Zanesville, Nov. 12-19, 1 case.
 Pennsylvania: Philadelphia, Nov. 26-Dec. 3, 1 case.
 South Carolina: Georgetown, Nov. 30-Dec. 6, 2 cases.
 Tennessee: Memphis, Nov. 19-Dec. 3, 1 case.
 Wisconsin: Milwaukee, Nov. 19-Dec. 3, 39 cases.

SMALLPOX—FOREIGN.

Belgium: Brussels, Nov. 12-19, 1 death.
 Brazil: Pernambuco, Oct. 15-31, 48 deaths.
 France: Nov. 12-19, Lyons, 1 case; Paris, 16 cases, 3 deaths.
 Great Britain: Nov. 12-19, Dundee, 1 case; London, 1 case; Manchester, 18 cases, 18 deaths; Glasgow, 1 case; Newcastle-on-Tyne, 6 cases, 1 death; South Shields, 2 cases; Leeds, Nov. 19-26, 1 case; West Riding, including Dewsbury and environs, Oct. 1-31, 137 cases.
 India: Bombay, Nov. 1-8, 2 deaths; Madras, Oct. 29-Nov. 4, 1 death.
 Italy: Catania, Nov. 17-24, 2 deaths; Palermo, Nov. 5-12, 9 cases, 6 deaths.
 Russia: Nov. 5-12, Moscow, 2 cases, 2 deaths; St. Petersburg, 7 cases.
 Turkey: Constantinople, Nov. 13-20, 30 deaths.

YELLOW FEVER.

Brazil: Pernambuco, Oct. 15-31, 1 death.
 Ecuador: Guayaquil, Nov. 8-16, 1 death.
 Mexico: Coatzacoalcos, Nov. 19-26, 1 case, 2 deaths.
CHOLERA.
 Russian Empire: Astrakan (suburb), Oct. 14-16, 3 cases, 2 deaths; Baku, Oct. 11-18, 60 cases, 24 deaths; Morsha, Oct. 8-17, 51 cases, 23 deaths; Samara district, Oct. 10, sporadic.

PLAGUE.

Brazil: Pernambuco, Oct. 1-31, 1 death.
 India: Bombay, Nov. 1-8, 52 deaths.
 Japan: Formosa, Sept. 3-10, 1 case, 1 death.

Medical Organization.

Arkansas.

EIGHTH COUNCILOR DISTRICT MEDICAL SOCIETY.—At the second meeting of this organization, held at Little Rock, December 6, Dr. Stroder U. King, Little Rock, was elected president; Dr. James H. Voris, Conway, vice-president; Dr. Roscoe L. White, Little Rock, secretary, and Dr. S. Paul Vanghter, Little Rock, treasurer and librarian.

Maryland.

CAROLINE COUNTY MEDICAL SOCIETY.—This society was organized at Denton, November 23, on the standard plan. Dr. Charles M. Ellis, Elkton, was made temporary chairman, and Dr. Fred. N. Nichols, Denton, temporary secretary. The following officers were elected: Dr. Enoch George, Denton, president; Dr. James R. Phillips, Preston, vice-president; Dr. Fred. N. Nichols, Denton, secretary, and Dr. Theodore Saulsbury, Burrsville, treasurer.

PRINCE GEORGE COUNTY MEDICAL ASSOCIATION.—On November 26 this society, at a meeting held in Washington, D. C., adopted the standard constitution and by-laws and elected the following officers: President, Dr. L. A. Griffith, Upper Marlboro; vice-president, Dr. William O. Eversfield, College Park; secretary, Dr. William H. Gibbons, Croom; treasurer, Dr. Arthur O. Etienne, Berwyn, and censors, Drs. Charles A. Fox, Beltsville; Nelson A. Ryan, Bowie, and Van Lear Perry, Hyattsville.

North Dakota.

CASS COUNTY MEDICAL SOCIETY.—At the meeting of this society, held in Fargo, December 28, the standard constitution and by-laws were adopted.

South Carolina.

LAURENS COUNTY MEDICAL SOCIETY.—At a meeting held in

Laurens, November 28, over which Dr. Job J. Boozer, Clinton, presided, and Dr. Rolfe E. Hughes, Laurens, acted as secretary, the society was reorganized with the following officers: Dr. Job J. Boozer, Clinton, president; Drs. William H. Dial, Laurens, and John H. Miller, Cross Hill, vice-presidents; Dr. A. J. Chrystopher, Laurens, treasurer, and Dr. Rolfe E. Hughes, Laurens, secretary.

Texas.

TARRANT COUNTY MEDICAL SOCIETY has been incorporated at Fort Worth by Drs. Isaac L. Van Zandt, Preston L. Hooper, Edgar D. Capps and others, without capital stock.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.
 Western Surgical and Gynaecological Association, Milwaukee, Wis., December 28-29.
 Pan-American Medical Congress, Panama, Jan. 2-6, 1905.
 American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Nov. 23, 1904.

John B. Murphy in the Chair.

Symposium on Criminal Abortion.

THE DUTY OF THE MEDICAL PROFESSION IN RELATION TO CRIMINAL ABORTION.

DR. C. S. BACON estimates that from six to ten thousand abortions are induced in Chicago every year, a majority of which are married women. To collect data on the subject, to call the attention of the profession to it, and to exercise an influence toward restraining the evil and checking the debauchment of the minds of the profession and the community, a committee of the Council of the Chicago Medical Society was appointed about a year ago. This committee has now arranged for a symposium as a feature in its work of education.

From the medical and social sides of the problem, four reasons are given for repressing the practice of abortion. (1) It is an injury to the embryo or fetus destroyed, for the fetus is a living, human, independent being, and has the right to existence which belongs to all human beings, and it should be protected in this right. (2) It is an injury to the mother, for it is an unjustifiable risk to her health and life. (3) It is an injury to the relatives of the unborn child and to the mother. (4) It is an injury to the state. According to the common law, the fetus is not considered a being until after quickening, and therefore it is not a crime to destroy it. After quickening, its destruction, either by the mother or by a third party, is a misdemeanor, but not a crime punishable by imprisonment. According to the Illinois statutes, which take the place of the common law, there is no distinction between an animate and an inanimate fetus, and the induction of abortion is punished by imprisonment for from one to ten years. The consent of the mother does not absolve the third party who does the act. Intent is the essence of the crime, and the efficiency of the means employed is not considered. If the mother dies, the act is murder. Notwithstanding the prevalence of the crime, there are practically no accusations nor indictments for abortion unless the mother becomes seriously ill or dies. Even in the latter case her relatives generally try to prevent any investigation in order to shield her reputation. The influence of the physician should be exerted to persuade the injured mother or her friends to act. In case of her death, it is his duty to report the case to the coroner as he would any other case of homicide. If a case comes to trial, it is necessary that the physician know the rules of procedure of courts and the rules of evidence. In Illinois no communications to physicians are privileged. Attention is called to the great importance of a dying declaration, which may become the chief factor in producing the conviction. It must be voluntary, made when the patient has given up hope

of recovery, and should state that a certain individual has committed the act.

To illustrate some of these points, Dr. Bacon reported a case of successful prosecution of a midwife for manslaughter. It showed the necessity for obtaining unimpeachable evidence of the existence of pregnancy, and the importance of the dying declaration. Dr. Bacon also called attention to the need of maternity asylums for the unmarried.

MORAL AND RELIGIOUS OBJECTIONS TO ABORTION.

REV. PETER J. O'CALLAGHAN, of the Order of Paulists, said that it was one of the triumphs of the ancient church to have practically eradicated the crime of abortion, and that the Roman Catholic Church stands to-day where she stood a thousand years ago. She declares that no man has the right to destroy, by any direct act, the life of an innocent human being. In the face of a sentiment which has persuaded a large section of the medical profession that direct abortion is sometimes not only justifiable, but even commendable, that church has unflinchingly declared that the direct taking of an innocent human life is always murder, no matter what be the stage of its existence. In 1884 her authoritative teaching body was asked whether it was safe to teach, in Catholic schools, that the operation of craniotomy is sometimes justifiable. The answer was that it was not safe so to teach. In 1889 the same body was asked if any operation at all looking to the direct killing of the child *in utero* was justifiable. The question was also answered in the negative. Again it was asked if this should be done when absolutely necessary to save the mother, and in 1895 this question was answered in the negative. Again, the formal question was asked, if, in extraterine conception, any operation be justifiable which meant the death of the child. This was answered in the negative.

This church, therefore, has constantly said that no one has a right on any occasion to procure directly, by any act of his, the death of any human being. It maintains the right of the unborn child to live just as much as the right of the mother to live. If one or the other must die, or both die, and if both die without act of ours, the responsibility is not ours. Such, said the speaker, is the position of the Catholic Church. Although these are not dogmatic definitions of Roman Catholic doctrine, they are the authoritative decisions of that church on the question of abortion. The reason for the uncompromising position in this matter is found in the decalogue, "Thou shalt not kill." Principles of conduct can not be arbitrarily confined to particular cases. If it is right to take human life to save the mother's life, it is right to take a human life to save a mother's honor. If it is right to destroy the unborn child in order to avoid the suffering that shame brings, it is right to destroy a child whose birth would mean for others the sufferings of poverty. If there is such a thing as therapeutic abortion that is commendable, Father O'Callaghan thinks that there is no such thing as a criminal abortion that is reprehensible. Legislators may determine that some conditions justify abortion, while other conditions do not, but their judgment will not control the consciences any more than their present laws inconvenience the majority of those that are now guilty of what is called criminal abortion.

CRIMINAL ABORTION AS IT COMES BEFORE THE CORONER'S OFFICE.

MR. JOHN E. TRAEGER, coroner of Cook County, said that before his advent in the coroner's office he had little or no opportunity to know to what extent criminal abortion was practiced, especially in a large, cosmopolitan city like Chicago. He found, after investigation, that many of the abortions are induced by midwives who make a specialty of it, and whose business cards announcing their vocation could be found in some of the houses of ill-fame in the city, being distributed by the landladies or inmates to the men, who might some time want that kind of service. In consulting the records of the office, he found that there had been very few persons held to the grand jury, and fewer still ever convicted of the crime of criminal abortion. This news discouraged him, and he made up his mind to devise some way to stop it. During the past

four years, with the assistance of the state's attorney, four of those midwives were sent to the Joliet penitentiary. The first year of his term, he investigated 42 cases of criminal practice; the second year it fell off to 27; last year it was further reduced to 18; but this year it would reach 35, which is an increase of nearly 100 per cent. He held six midwives and one physician to the grand jury this year, and had already convicted two. In investigating the cases of abortion that came to his office, he finds that the cause for the act differs in almost every case, that is, among married women; in some cases on account of poverty, in others on account of children coming too fast, and the society woman, who has not time to devote to maternal cares; and last, but not least, the dwellers in modern flats. It has got so nowadays that a married couple with babies is denied admission to an apartment house or flat building, and it is his opinion that the attitude of landlords in refusing to rent to families with small children and in allowing that impression to go out broadcast is indirectly the cause of much of the criminal practice in Chicago. He thinks the discussion as to the causes of the practice and its cure can be safely left to physicians. He thinks that it is the duty of physicians, and that it is his duty to try to check the practice—their's by advice to the women who come to them for assistance, and his by punishing the guilty who have violated the law.

THERAPEUTIC AND CRIMINAL ABORTION.

DR. CHARLES B. REED stated that, in the advance of moral feeling, the opinion has developed that in certain cases where the lives of both mother and child are imperiled and one can be saved, the child should be sacrificed, since the value of the mother to the State is far greater than that of the unborn babe. Hence, where certain diseases or complications appear in or exist during the course of gestation and threaten the integrity of the case, a broad human sentiment now permits, nay, even demands, the destruction of the fetus. When this situation eventuates before the viability of the child, it is recognized as a prophylactic or therapeutic abortion, and becomes a justifiable measure in the presence of such conditions as hyperemesis gravidarum and eclampsia, which do not yield to treatment. In certain cases of beginning and advanced pulmonary tuberculosis, cardiac disease, insanity, severe nephritis, or serious and irreducible uterine displacements with dense adhesions, the operation is justly performed. In cases of absolutely contracted pelvis, where the patient refuses cesarean section, abortion is sometimes desirable, although the relative dangers of the two operations do not greatly differ in skillful hands. The results of therapeutic abortion, when executed in a careful, scientific way, are generally good, and the indications for its performance are found both in and out of marriage.

Abortion in all its phases is necessarily more common in the married state, and it has been said that almost half of all child-bearing women have an abortion before the thirty-fifth year. It is also true that the medical man is most frequently approached by married women who desire the removal of the socially inconvenient egg. For this situation there is no excuse. When the product of conception is deliberately destroyed for social reasons only, and without physical justification, in a woman married or single, it constitutes a criminal offense before the human and moral law. It is ignorantly maintained by many that the dislodgment of the egg before quickening is in no sense reprehensible, because it is thought that the egg is not alive. This is a distinction of degree only, and a species of special pleading, for the fertilized egg contains all the hopes and possibilities of a mature fetus, and, while quickening usually occurs at the sixteenth week, the fetus is practically fully formed at an earlier period. The normal attitude of the enlightened professional man is hostile to abortion. It is well attested that nearly all of the desperate and fatal complications found in abortions occur in criminal cases. The deaths from such attempts are frequent, and embrace a large range of causative conditions, among which as the most important are perforation, peritonitis, septicemia,

pyemia, tetanus, endometritis, endosalpingitis, air embolism, abscesses, pneumothorax, thrombophlebitis, phlegmasia alba dolens, etc.

Legal restrictions are relatively recent in origin, but none the less drastic. It is not the murder of a living child which constitutes the offense, but the destruction of gestation by wicked and unnatural means. The moment the womb is instinct with embryo life, gestation has begun, the crime may be committed. The liability of the mother, in the eyes of the law, is the same as that of the third person, and in many states is made equally culpable with the act. In Illinois, the attempt is punishable by imprisonment in the penitentiary for from one to ten years, and if the death of the mother results therefrom, it constitutes murder. But the law, unsupported by popular sentiment, has proved ineffective, and in many cases no attempt is made even to secure its enforcement, and the abortionist rests in security. It devolves on the physician to keep the light before the public mind, not only in general, but in particular instances.

The artificial conditions which drive unmarried girls to abortion should be everywhere strenuously opposed, and even illegitimate motherhood might soon become a bearable penance. Let the legal and moral enactments be what they will, a broad humanity demands the protection of the mother and the illegitimate unborn babe. Maternities should be established and maintained, and homes and places of refuge founded and supported for the woman awaiting confinement. There should be charity for the unfortunate girl who, with unreasoning animalism, attempts to escape exposure and humiliation by abortion. Teach chastity, teach restraint, but, above all, protect the devoted victim of her own strength, or weakness, from yielding to the eternal dominant impulse, and enable her to pass through her gestation and delivery free from the lofty scorn of an unsympathetic sisterhood.

CRIMINAL ABORTION AND NEWSPAPER ADVERTISING.

DR. RUDOLPH W. HOLMES said that he has become convinced that abortions among the better classes are essentially brought about by social causes. He believes that where one abortion occurs from the diverse pathologic causes, many more are produced by the abortionist's instruments, drugs, or other measures. Education is absolutely indispensable to a proper realization of the heinousness of destroying the unborn child; the physician is the one, above all others, who may be the most influential in deterring women from having their desires fulfilled. Well-directed arguments concerning the dangers of having the operation done are, to his mind, more effective than too strong presentations of the moral aspect. So soon as the physician presents to the woman that she is doing a criminal offense, is breaking a moral law, he arouses her enmity from the suggestion implied that she is immoral or a criminal.

The common law, which is founded on ancient and medieval customs, has fostered the belief that the fetus did not have life until quickening was noted by the mother. To this day the states of Connecticut, Mississippi, Minnesota, Arkansas and Oregon accept this obsolete interpretation of the common law in their statutes; other states and most countries, by legislative action, have removed such absurd qualifications as "quick with child" from their statutes defining criminal abortion. Although this really nonsensical belief that the fetus is endowed with life by the accidental circumstances of the mother feeling fetal movements has been done away with in medicine, law and theology, the laity still tenaciously adheres to the old idea. The present law in Illinois, as in nearly all other states, makes a great distinction between an abortion which does not destroy the life of the mother, and when she dies: the former is the felony of abortion, the latter is the felony of murder. Such a law is discriminative, as infanticide is murder, so should feticide be murder; the abortionist, directly, maliciously, with "malice aforethought," deliberately kills the fetus, while it is far from his intention to kill the woman. Dr. Holmes is positive that the daily papers, magazines, and even some so-called religious papers

are most fruitful means of disseminating the knowledge concerning the means for producing abortion, by covertly suggesting where the appliances may be obtained, the drugs bought, or even the instrumental methods which may be carried out. There is hardly a daily paper in Chicago which does not regularly print a list of advertisements of professional abortionists. That a veiled advertisement may be brought in as evidence of the criminal intent of the abortionist has been amply settled in Massachusetts, and would undoubtedly be accepted in the courts of other states.¹

Dr. Holmes briefly reviewed the laws concerning the sale of abortifacients, and stated his belief that the time has come for this society to take an active part in aiding the prosecution of notorious abortionists. This may be accomplished in various ways: 1. By bringing moral suasion on newspaper management, so that they will refuse all advertisements of a suggestive nature; a committee of this society might act as an advisory board of censors. 2. By working in friendly conjunction with the State Board of Health, Chicago Department of Health, the state attorney's office, and with the coroner. If work is carried on along these lines, he thinks an enormous amount of data would be collected which would be of inestimable value to the several legal bodies.

THE COMMON AND STATUTE LAW OF ILLINOIS.

MR. J. M. SHEEAN, attorney for the medicolegal committee, briefly reviewed the history of criminal abortion. According to the ancient English common law, fetal life was held to begin only at the quickening, and until such time no offense could be considered committed by an operation. No offense of any kind, with the woman's consent, was recognized as punishable. If, without the mother's consent, abortion was induced, simple assault was punishable. This law remained until a short time prior to the separation of this country from the mother country. Then certain statutory enactments were passed in England which did not become laws in this country, but which were followed in many of the states. It was made an offense, a misdemeanor, merely to commit abortion or to induce premature delivery, even though the child had not quickened. In addition, there was a provision, if the death of the mother resulted, murder was the crime committed by one who was either the principal or accessory. In Illinois, which adopted the common law, so far as it existed up to 1607, this condition was found, until the first criminal code was enacted, that abortion was defined in a manner slightly different from the crime as it exists on the statute books to-day. Until 1867, the crime of abortion in Illinois was defined as follows: "Whoever, by means of any instrument, medicine, drug, or other means whatever, causes any woman pregnant with child to abort or miscarry, or attempts to procure or produce any abortion or miscarriage, unless the same be done for *bona fide* medical or surgical purposes, shall be imprisoned in the penitentiary."

This statute remained until the year 1867; in 1867 the legislature changed the statute, and enacted it as it now stands on the statute books, and in lieu of the words "for *bona fide* medical or surgical purposes," the provision of the Illinois statute is, "Unless same were done as necessary for the preservation of the mother's life." In interpreting the words, "necessary for the preservation of the mother's life," it has been held that it must be an actual physical necessity; that is, the mental depression which may come because of the unfortunate condition of the mother; the threats of suicide, the probability of insanity, the nervous condition in which the mother at that time finds herself because of her surroundings, because of brooding over her condition are not within the medical law; they are not conditions that will justify a physician or surgeon in saying that it is necessary for the preservation of the mother's life that her child should be destroyed. The courts, in interpreting these words, have properly held that it must be an actual physical condition which renders improbable the continued life of the mother unless the life of the child be destroyed. Whether practical

1. THE JOURNAL, June 23, 1900, p. 1612.

enforcement of the law as it stands is to be brought about is dependent on public desire, public demands. Mr. Shecan said that the law itself is as far advanced as is the public conscience. Indeed, it is further advanced, apparently, than the public demand for its enforcement would require, and so, if anything is to be accomplished, it is not by making appeals to the legislature for a modification of the laws nor for a more stringent law, but public conscience should be so stimulated as to require and demand that the law, as it stands to-day, should be strictly enforced.

SHALL COMMUNICATIONS OF PHYSICIANS BE PRIVILEGED?

DR. HAROLD N. MOYER said that unquestionably the privileged communication or medical secret has stood in the way more largely than any one factor in the prosecution of the abortionist. The common law never had but one privileged communication, and this was not the result of a statute, but simply grew up as a part of the practice of courts, namely, a communication between an attorney and his client was regarded as privileged. Dr. Moyer quoted the Roman law, the French law and the New York statute in regard to privileged communications. The New York statute reads: "A person duly authorized to practice physics or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity." He said that this statute might put an onus on the physician. The privileged communication does not apply to this state, a fact not generally known to the profession. The communication of a patient to a physician is absolutely unrestricted and open to the inquiry of the court, and this absolves a physician from all legal responsibility in case he goes into court with questions of this kind.

Some years ago Dr. Moyer urged a member of the legislature to obtain the enactment of a statute making the communications of physicians privileged ones. He regretted he made such a request, and is glad that it bore no fruit, and if to-day he heard of any attempt to have the legislature pass such a law, he would do his best not to have it passed. Such a law, he said, is not useful to the community, and imposes an extraordinary burden on the profession in some particulars. The courts will protect physicians. A communication made under the seal of the confessional is not a privileged communication in this state, yet he has never heard of a court in Illinois that has attempted to invade the sanctity of the clergyman's office. The courts are capable of protecting physicians against the wrongful use or abuse of medical evidence, and the matter could be safely left to them.

DISCUSSION.

MR. FLETCHER DOBYNS, assistant state's attorney, said that the state's attorney can do nothing in prosecuting abortionists until he has complete evidence, and prosecutions frequently fail because evidence has not been properly obtained. He referred to the manner in which evidence should be prepared. The court instructs the jury that every material allegation in the indictment must be proved beyond reasonable doubt. It must be proved that a woman was pregnant, and that an operation was performed to induce abortion. It must be proved that such an abortion was not necessary to save the life of the mother, and that she died as a result of it. It is absolutely necessary for a physician in making his examination to make it carefully and exhaustively and to preserve his data, so that he can refresh his mind, and be able to take the stand and say with absolute accuracy and certainty that the woman was pregnant. This would help the state's attorney in proving to the jury beyond a reasonable doubt that pregnancy did exist. The next point to prove to the jury is that it was not necessary to perform an abortion to save the life of the mother; and the physician must be able to take the stand and to tell the conditions he found, the treatment of the patient, and to give his reasons clearly to the jury to show why it was not necessary to induce an abortion to save the life of the mother. Furthermore, it is necessary to show that death resulted from the operation by which the abortion was produced.

The symposium was further discussed by Dr. M. O. Heckard, Mr. H. H. Hart, Mr. Charles Allen, Dr. Lucy Waite and Dr. Rosalie M. Ladova.

Travel Notes.

XX.

GRANT MEDICAL COLLEGE AND THE HOSPITALS OF BOMBAY.

NICHOLAS SENN, M.D.

CHICAGO.

MARSEILLES, FRANCE, Oct. 3, 1904.

Bombay, with its 800,000 inhabitants, is the commercial metropolis and medical center of India. The city has many and varied medical institutions that awaken the interest of the professional visitor. The most important among these is the Grant Medical College, the largest medical school in India. For sixty years it has been the Mecca for native young men in that part of India who were desirous of entering the ranks of the medical profession. Thousands of graduates have left its doors well prepared to serve their countrymen as reliable and competent physicians. From a modest beginning it has developed into a great medical school with an attendance of more than 600. The personnel of the students is an interesting one. The mixture of colors, from the almost pure white of some of the Eurasians to the coal black of some of the Hindus, and the variety in dress, from Parisian to the most picturesque costumes makes up an interesting picture for the foreigner.

The Mohammedan population of India is large but, as a rule, its young men manifest little desire for a higher education and the number of medical students from this source is small. On the other hand, the Hindus take kindly to the professions of law and medicine and the bulk of the medical students is recruited from the high caste Hindus. The Parsee element of the population is well represented in the medical schools, and the strange headdress of the males of these people figures conspicuously in all the classrooms.

The female medical students number about sixty and, with the exception of two or three white women, they are Hindus, Parsees and Eurasians. What are known as half-castes in Ceylon are designated in India by the more euphonious word, Eurasians, meaning a mixture of Europeans with Asiatics. The female medical students have won for themselves here, as elsewhere, an enviable reputation as enthusiastic, hard workers, who, when the time for graduation comes, are never found at the undesirable end of the class. Their subsequent professional career is often, however, a very checked one. Some receive hospital positions with small salaries, rupees 100 to 200 (\$32 to \$64) a month; others enter private practice, but seldom meet with great success; some marry, and not a small percentage sooner or later abandon their profession and turn their attention to some other vocation.

The professors are selected from the Indian Medical Service with special reference to their aptitude to teach the different branches. The principal chairs, medicine, surgery and obstetrics, are occupied by men who have had an extensive experience, while the primary branches, especially pathology and bacteriology, are usually taught by the younger members of the service. Native graduates hold subordinate positions in the teaching force as assistant professors, instructors, demonstrators, tutors, etc. The professors who belong to the civil branch of the Indian Medical Service receive a salary accorded to their military rank and in addition they receive some remuneration from the college for their services to that, for instance, a lieutenant colonel who has been in the service for 20 years may have an annual income of \$4,800. In the event of his death, his widow receives a pension of \$750 a year and each of his children \$150 a year, the sons until they reach the age of 21 years and the daughters until they become married. The pensions are provided by a fund to which each officer contributes. When an officer gets married he pays into this fund 2,000 rupees (\$640), and 1,000

rupees (\$320) after the birth of every child. At the end of 25 years, on retiring, he receives a pension of \$2,500 a year. The teaching duties of these men are so exacting that they are given but a slight chance to increase their income by private practice, which is, however, permitted.

The original Grant Medical College, so called in honor of one of the former governors of Bombay, is a substantial, venerable, two-story stone building. With the increasing demand for space, additional buildings have been erected. The anatomy building (Fig. 1.), now nearing completion, is a two-story, massive stone building, with marble floors: the upper story is the dissecting room, which is flooded with light from all directions. It is unquestionably the finest dissecting room in the world. Connected with it is a small separate building, covered with wire screen for the purpose of excluding vultures and crows, in which the bodies are prepared and the bones of the dissected subjects are cleaned and mounted.

The chemical and pathologic laboratories are inadequate for the present requirements and it is hoped that separate buildings will soon be erected for each of these very important primary branches. With an ever increasing attendance, the lecture rooms will also soon become too small. The curriculum of study for the M.B. and B.S. degrees extends over five years and includes the following studies:

First Year.—Biology, botany, chemistry, practical chemistry, materia medica, practical pharmacy.

Second Year.—Anatomy, botany, chemistry, practical chemistry, materia medica, practical pharmacy, physiology.

Third Year.—Physiology, histology and practical physiology, anatomy.

Fourth Year.—Medicine, surgery, pathology, hygiene, diseases of women and children, demonstrations in pathology, clinical practice in medical, surgical and obstetric wards. Attendance at male and female out-patient rooms. Attendance at pathologic room.

Fifth Year.—Surgery, medicine, diseases of women and children, operative surgery, clinical practice in medical, surgical, obstetric and surgical wards, attendance at pathologic room.

A glance at this curriculum shows what attention is paid to the primary branches, especially chemistry, anatomy and botany, the last of these entirely ignored in most of our medical colleges and the first and second only too often treated in a stepmotherly way. The students are not pestered with unnecessarily frequent examinations, as only two examinations a year are held, at the end of each semiannual term.

The military pupils, of whom there are now 86 in attendance and who finish their studies in four years, have a somewhat different curriculum of study to follow. It is as follows:

First Year.—Anatomy, descriptive and surgical, dissections, anatomy and physiology, materia medica, chemistry and practical chemistry, compounding dispensary.

Second Year.—Anatomy, descriptive and surgical, dissections, anatomy and physiology, materia medica, chemistry and practical chemistry, compounding dispensary.

Third Year.—Medicine and clinical medicine, surgery and clinical surgery, diseases of women and children, hygiene, pathology, hospital practice and out-door dispensaries, post-mortem examinations.

Fourth Year.—Medicine and clinical medicine, surgery, clinical and operative surgery, diseases of women and children, practical toxicology, clinical, medical, surgical, obstetric, and ophthalmic wards.

Fourth year students and third year military pupils attend in rotation at the male out-patient rooms as arranged by their teachers. Female pupils attend at the female out-patient rooms. Four and five didactic lectures, from 10 to 3 or 4 p. m., are delivered daily except Saturday, on which day only two lectures are given, during the forenoon. The clinics in the Jamsjee Jeejeebhoy Hospital begin at 7 or 7:30 a. m. and are held daily. This is the hospital in which the clinical teaching in medicine and surgery is done exclusively. The present teaching staff consists of eleven professors, one demonstrator and eleven tutors. Lieut.-Col. H. P. Dimmock, I.M.S., is principal of the school and professor

of obstetrics, gynecology and diseases of children, and Lieut.-Col. Quicke, I.M.S., is professor of surgery, operative surgery and surgical anatomy.

The final examination in this college appears to be quite a severe one, as every year only about 45 per cent. of the candidates for graduation are recommended to the Bombay University, with which the college is affiliated, for the degree. Those who fail may come up again for examination at the close of the next or of any other subsequent term.

The military pupils are prepared for the assistant surgeon branch of the Indian Subordinate Medical Department. They must be of European or Eurasian parentage, not less than 16 and not more than 18 years of age. They must pass a satisfactory physical examination and are examined in the following subjects: English.—Handwriting, dictation, composition, explanation of idioms and grammar questions. History and geography.—The outlines of English and Indian history, and the elements of physical and general geography. Mathematics.—Arithmetic: The four simple rules, vulgar and decimal fractions, reduction, practice, proportion, simple interest, extraction of square root. Algebra: The four simple rules, proportions, simple equations; Euclid, first book. Vernacular.—Hindustani, colloquial.

They are educated at government expense. Pupils who obtain less than 33 per cent. of marks in each subject of their final examination will be liable to removal from the college.

Fig. 1.—Anatomy Building, Grant Medical College.

Such pupils, however, will be allowed to remain for a further period (to be fixed by the principal in each case) in the college to continue their studies at their own expense. Military assistant surgeon graduates from this department of the college are employed in hospitals of British troops and in military and civil appointments; those in civil employment being available for military duty in time of war or other urgent necessity. This branch of the military medical service is entitled to the following pay:

1. Senior assistant surgeon, with honorary rank of captain, 400 rupees (\$128).
2. Senior assistant surgeon, with honorary rank of lieutenant, 300 rupees (\$96).
3. Assistant surgeon, first class, 200 rupees (\$64).
4. Assistant surgeon, second class, 150 rupees (\$48).
5. Assistant surgeon, third class, 110 rupees (\$35.20).
6. Assistant surgeon, fourth class, 85 rupees (\$27.20).

In addition to this pay they receive allowances when on special duty, and traveling expenses, and pensions on retiring from the service. Retirement is compulsory at the age of 55 years.

PATHOLOGIC MUSEUM.

The pathologic museum of Grant Medical College contains a very large amount of material illustrative of tropical diseases. It is the result of accumulation of specimens for 60 years and should contain more than it does, but the opposition to postmortem examinations is so violent and persistent

that permission is only seldom obtained. No Parsee corpse has ever been touched by a pathologist except under medico-legal pressure. Not many years ago a postmortem was made on a Mohammedan and when the fact became known it gave rise to a riot in the hospital grounds, which it was found difficult to suppress. Since that time the Mohammedans employ a salaried guard, who watches the approach of grim death in the hospital, and, if the patient is a Mohammedan, he sees to it that the corpse escapes the postmortem knife. The Hindus furnish the material for the museum almost exclusively.

This unreasonable objection to postmortem examinations by a large proportion of the population of Bombay has seriously interfered in collecting a larger material. A catalogue of specimens in the Pathologic Museum was prepared by Capt. G. F. Gordon, I.M.S., in 1903, and was published by the government in the form of a well bound and well printed book of 247 pages. I will quote here a description of only a few of the most interesting specimens:

Pneumonic Plague.—The lung is solid throughout, greatly enlarged, and the visceral pleura covered with slate colored blotches, which are subserous hemorrhages. This specimen was from a patient aged 26, who was ill about three days. One section of the lung was filled with light colored masses, which were surrounded by areas of acute congestion. The lower were more markedly affected by consolidation than the upper lobe. There were several hemorrhages in the cellular tissue of the posterior mediastinum, and the other viscera were acutely congested.

Syphilitic Fibrosis of the Lung.—A portion of the left lower lobe, showing broad bands of fibrous tissue running through it, the largest proceeding from the base of the lung in an upward direction. The section shows very little lung parenchyma, and that in a most condensed state. Numerous openings of vessels and dilated bronchi are seen, closely agglomerated from the shrinking process which has gone on. The affected portion of the lung seems to be shut off from the more healthy part by a broad band of fibrous tissue. The specimen was taken from a man whose leg was amputated for chronic ulceration; a Hindu aged 40 years. There were a few caseous nodules in the right lung; the capsules of the liver and spleen are greatly thickened, especially of the latter. There was a gumma in the spleen; both testicles had undergone fibroid degeneration with thickening of the tunica vaginalis. There was a left hydrocele.

Aneurism of the Heart.—At the upper posterior part of the left ventricle, immediately to the right of the mitral valve, is a pouched condition of the septum measuring fully 1 3/4 inches across at its mouth and an inch deep at the deepest part. The pouch is lined with thick, opaque endocardium. The right group of chordæ tendinæ is thickened. There is thickening and contraction of the mitral orifice. In the right ventricle is a patch of opaque endocardium at a point covering the pouch in the septum. The patient was a male Mohammedan, aged 60; ill for weeks. The aorta was atheromatous; a breaking down gumma was found in the liver, the capsule of which was extensively scarred. The right kidney was atrophied and contained sand-like calculi; left kidney hypertrophied; fibroid left testicle; ulceration of large intestine. It is suggested that it is a case of syphilitic myocarditis, with resulting fibroid degeneration causing weakening of the septum.

Malarial Hepatitis.—Section of a highly pigmented liver, which is hard and has a mottled appearance on the surface. The surface of the section is granular. Such livers are, as a rule, slightly enlarged, uniformly tender, associated with slight jaundice, some evidence of bronchitis at the base of the right lung, and therefore they are often difficult to distinguish from cases of hepatic abscess.

Hepatic Abscess.—This shows the upper surface of the liver, where an abscess had burst through the diaphragm. There were three large abscesses in the right lobe. One had intricate connection with the diaphragm, which formed the upper wall of the abscess cavity. In this were two minute perforations, which communicate through the thickened pleura, with a

pneumonic patch in the base of the right lung. The patient was a Mussulman, aged 28. The illness commenced with an attack of dysentery, three months prior to admission. No signs of dysenteric ulcerations were found in the bowel at the postmortem examination.

Enormous Calculus of the Bladder.—This stone (uric acid and urates) is probably one of the largest stones ever removed from the human bladder. About half of the stone is shown in the central compartment and the fragments are grouped around it. The operation in this case was performed in 1876 or 1877 by the late Apothecary White at Tando Aylhar Dispensary, near Hyderabad, in Sindo. The patient was a man 25 years old and had suffered from symptoms of stone since childhood. An attempt was made to extract it by the lateral operation, but this being unsuccessful, the suprapubic operation was performed. Even now it was found impossible to extract the stone. By means of some improvised instrument (a craniotomy forceps), the stone was broken in pieces and removed. The patient lived for about twelve hours after the operation. The weight of the stone was 30 ounces and 95 grains.

Ainhum of the Small Toe.—This curious condition generally commences on the inner and plantar surface of the little toe. It begins as a narrow groove on the skin, which slowly deepens. The groove involves the whole circumference of the digit, the distal portion of which swells up as if it had been constricted

Fig. 2.—Madura foot. Amputation by Professor Quicke.

by a ligature. The digital portion finally becomes a round, dangling mass and, after some years, drops off. The fourth toe is next affected, and so on.

Mycetoma or Madura Foot.—The shape of the foot is characteristic (Fig. 2). The disease is absolutely localized to the foot, the circumference of the leg above the ankle not being increased. The skin of the foot is covered with pellets, some of which have been cut across to show the yellow fatty material of which they are composed. A window has been cut on one side of the foot. A capsule of thick, dense, fibrous tissue envelopes the foot and this hardened tissue is honeycombed with small cavities, which lodge the yellow bodies in the interior of the bone, which has fallen away from the tissues and which can be seen riddled with large communicating cavities. The specimens were obtained by amputation and presented to the museum by the operator, Prof. Quicke (Fig. 3).

Anesthetic Leprosy.—A dissection of a leprosy foot made by the late Dr. Van Dyke Carter. The nerves are considerably thickened, especially on the plantar surface. The great toe has been lost, and all the digits, except the middle one, are partially absorbed.

Guinea Worm.—This is a long, thin worm from 12 to 40 inches long. The female only is known as a parasite in the human body. It wanders into the loose subcutaneous tissues

of the leg, scrotum and sometimes the upper limb, and there generally forms an abscess or it may form a vesicle from which the extremity projects, when it can be gradually removed by slow traction extending over some days, the protruded portion being wound round a stick.

Jamsetjee Jeejeebhoy Hospital.—The Jamsetjee Jeejeebhoy is one of the oldest and best known of the many Bombay hospitals. It bears the name of the Parsee who built it at his expense and presented it to the government in 1845, the same year that Grant Medical College opened its doors to medical students. Mr. Jamsetjee Jeejeebhoy was a poor man, but made a fortune by buying and selling bottles nearly a century ago, hence the hospital is still well known under the name of "Bottle Hospital." Mr. Jamsetjee Jeejeebhoy was knighted by Queen Victoria in recognition of his many deeds of charity, and a full size statue of stone in a half reclining position in the main entrance hall of the hospital does honor to the memory of its founder. The hospital is for the exclusive use of the native sick poor and is maintained entirely at government expense. The hospital is an immense one-story stone building, with accommodations for 360 patients. It is an old-fashioned structure, which lacks many of the important

into an operating room supplied with the most primitive outfit for asepsis. What this hospital is sadly in need of is a new and separate operating theater and a more complete set of surgical instruments. It is a great injustice to the surgical staff to be obliged to perform 5,000 operations annually under such trying circumstances. All hospital surgeons in India confess that it is extremely difficult to prepare a native for operation. A patient recently admitted to the surgical wards of Professor Quicke for the purpose of undergoing an operation for the radical cure of an inguinal hernia, brought with him the following sources of infection: Scabies, ringworm, diffuse furunculosis and pyorrhea alveolaris. (Fig. 3.)

The nursing of this institution leaves much to be desired. The trained female nurses are inadequate in number, and it is only recently steps have been taken to organize a training school. Most of the nursing is done under their supervision by male and female ward attendants. The house staff, consisting of three medical officers of the Indian Subordinate Medical Department, is made up of a house surgeon and two assistant house surgeons. The house surgeon has charge of the property, his work being largely that of an executive officer, but, in the absence of the regular attending staff, he attends to the emergency cases, medical and surgical. The first assistant surgeon has charge of the drug room and dispensary, and the second assistant attends to the admission of patients and makes the preliminary examinations. The fourth and fifth year students do much of the dressing, under the supervision of the house surgeon and attending staff, and they assist at operations. The bedside clinics are an important feature of the clinical teaching in this, as well as in all other medical colleges in India. The attending staff of this hospital consists exclusively of the clinical teachers of Grant Medical college.

(To be Continued.)

Fig. 3.—Keloid of punctured lobe of ear. Excision, with good cosmetic results, by Professor Quicke.

features of a modern hospital, and it is about time that it should give way to a new building better adapted for present requirements.

Three new two-story stone pavilions were opened in 1892, the Sir Dinshaw Petit Hospital for diseases of women and children, the Bai Motlaibai Maternity and the Ophthalmic Hospital, each with a capacity for about forty patients. These new buildings are modern in their construction, are well furnished and have excellent little operating rooms. The nursing is also better than in the old hospital. About 800 women are delivered annually in the Maternity Hospital, and two students attend each case; this gives them an excellent opportunity to become conversant with practical obstetrics. The most careful aseptic precautions are employed and sepsis in in-patients is almost unknown. The delivery room has all the austere appearances and simplicity of an operating room. Two women were in labor when I visited this department of the hospital.

Professor Dimmock showed me a number of interesting cases on which he had recently performed major gynecologic operations. In the old building, a small ward has been converted

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Urticaria.

The treatment of urticaria, according to the *Med. News*, consists of purgatives, intestinal antiseptics such as salol, benzozaphthol and quinin or alkalies. The following is recommended locally:

R. Acidi carbonici (puræ).....	.5ss	2
Glycerini5iiss	45
Aque5v	150
M. Sig.: Apply locally.		

Lotions containing chloral in strength of 5 to 200 are also recommended. As an ointment the following:

R. Zinci oxidi3ss-3i	2-4
Cocaine hydrochlor.....	gr. v-x	30-60
Lanolini5i	30
M. Fiat unguentum. Sig.: Apply locally.		

If the pruritis is rebellious an application of a paste or a plaster as a protecting envelope will be necessary. Edema of the glottis is a serious complication and requires hot applications to the neck, hot foot-baths, hot fumigations and the administration of ether, spiritus etheris compositi and acetate of ammonia. In some cases tracheotomy is necessary. In chronic urticaria the diet should be carefully guarded, and wine should be prohibited. The bowels should be moved daily and alkalies and intestinal antiseptics given, such as charcoal, sodium bicarbonate and magnesia. Sufficient elimination by the kidneys should also be secured.

Thrush.

The following combinations are recommended by *Rev. Francis de Med.* in the treatment of thrush:

R. Sodij bicarb.	5i	4
Sodij boratis	3ss	2
Syr. idææ	3vi	24
M. Sig.: To be used as a mouth wash. Or:		
R. Glycerini	3vi	24
Amyli		
Sodii boratis, aa.	5i	4
M. Sig.: Apply with a camel's hair brush.		

Carbolic Acid Poisoning.

Chas. V. Burke, in *N. Y. and Phila. Med. Jour.*, states that Epsom and Glauber's salts are of no value as antidotes of carbolic acid poisoning. He regards alcohol as of great value and if given promptly and followed by lavage, will save life. The stomach tube should be fairly stiff, as some force is required to introduce it, as the mucous membrane is roughened and dry on account of the caustic effect of the acid. The swallowing reflexes are also abolished and there is more or less spasm present. A weak alcoholic solution should be used for the washing. He, therefore, recommends whisky in as large quantities as can be borne, introduced by the stomach, hypodermically and by rectum.

Aborting Buboes.

The following ointment is recommended in aborting buboes:

R. Ung. hydrarg.	}
Ung. belladonnæ	
Ichthylol	
Lanolini, aa.	

M. Fiat unguentum. Sig.: Apply locally on gauze and renew once a day.

Burnside Foster, according to *Buffalo Med. Jour.*, recommends that the patient be put to bed, a calomel purge administered followed by calcium chlorid, grain 1/12 (.005) every three hours. An ice-bag should be placed over the bubo. By this treatment the bubo is aborted within a week.

Horwitz recommends that a small opening be made into the bubo with a very small bistoury and peroxid of hydrogen or mercuric chlorid, 1 to 5,000, be injected. After the cavity is cleansed it is filled with sterilized vaselin containing 10 per cent. of iodoform and an ice pack applied.

Dysentery.

The prophylaxis of the treatment of dysentery, according to Kolbassenko in *Med. News*, consists in:

1. Avoiding overexertion.
2. Supplying most nutritious diet.
3. Drinking the best water possible.

In moderate cases the patient should be placed on a mild liquid diet and a warm abdominal bandage applied, saturated with alcohol. The following emulsion should be given:

R. Tinct. iodidi	gtt. viii	50
Olei ricini	3iv-3vi	15-25

M. Sig.: At one dose, to be repeated two or three times a day.

By administering the iodine in the castor oil it reaches the intestine better and the iodine is liberated.

After the acuteness of the attack has subsided the author recommends the following suppository:

R. Ichthyolei	gtt. ii-viii	12-50
Xeroformi	gr. v-viii	30-50
Bismuthi subnit.	gr. xv-xx	1-130
Antipyrini	gr. vi	35
Lanolini		
Olei theobromati, aa q. s.		

M. Fiat suppos. No. i. Sig.: One or two such suppositories to be inserted daily.

Where there is a great deal of intestinal irritability, grain 1.3 to 1/2 (.02-.03) of the extract of opium or belladonna may be added. Ichthyol is considered as a local astringent and disinfectant, antipyrin as an astringent, antiseptic and analgesic.

Warm injections of water containing a few drops of creolin are also highly beneficial.

Chronic Blepharitis.

The following combinations are recommended by *Amer. Med.* in the treatment of chronic blepharitis:

R. Ung. hydrarg. rubri.	gr. iss	90
Plumbi acetatis.	gr. 3, 4	95
Adipis benzoinati	gr. lxxv	5
M. Sig.: Apply locally once or twice daily. Or:		
R. Zinci oxidi		
Plumbi acetatis, aa.	gr. 3 4	95
Olei amygdalæ dulcis.	gr. viiss	50
Liq. petrolati	gr. lxxv	5
M. Fiat unguentum. Sig.: Apply locally.		

Congenital Syphilis.

A. Ravogli, in *Critic and Guide*, states, in speaking of the treatment of congenital syphilis, that a syphilitic must be nursed only by its own mother. Nurse girls must be cautioned against kissing the babe in the mouth. In this connection several cases are mentioned where syphilis was contracted through carelessness or ignorance.

The treatment of congenital syphilis, both local and constitutional, is similar to the acquired.

When the little patient is covered with eruptions it should be bathed in a solution of mercury bichlorid every day for ten or fifteen minutes. The solution should be prepared by dissolving from two to four tablets of seven grains of mercuric chlorid in six gallons of warm water in the bath, making a 1 to 12,000 strength solution.

THE CORYZA.

To relieve the coryza the nurse should be directed to remove the purulent secretion with a wet rag or cotton and inject by an ordinary glass dropper a solution of mentholated sodium bicarbonate:

R. Sodij boratis	3ss	2
Mentholi	gr. i	96
Aq. camphoræ		
Aque dest., aa.	3iiss	45

M. Sig.: To be injected into the nostrils while the babe is held in the erect position in order to prevent choking.

FISSURES AND MUCOUS PATCHES.

Fissures and mucous patches around the nose, on the lips, tongue and genitals, should be touched with a 3 per cent. solution of silver nitrate, and afterward washed with sterilized water to remove the excess of silver.

Ulcerated surfaces and excoriated papules are usually dusted with calomel and covered with dry absorbent cotton. If the dry dressing is non-indicated on account of forming crusts, the following salve is recommended by the author:

R. Hydrarg. precip. alb.	gr. iv-vi	25-40
Bismuthi subcarb.		
Zinci oxidi, aa.	3ss	2
Acidi carbolicæ	gtt. vi	40
Liq. petrolati	3i	30

M. Fiat unguentum. Sig.: To be applied locally.

In cases of ulcerated cutaneous gummata the employment of emplastrum hydrargyri is preferable. In some cases the application of iodoform powder, iodoform gauze or iodoform salve is valuable.

CONSTITUTIONAL TREATMENT.

As in acquired syphilis, mercury is indicated in these cases, administered by ingestion, subcutaneously or by inunctions. In cases with secondary symptoms, when the general nutrition is not too much affected, mercury administered by ingestion is preferable. Calomel is in this way recommended, giving it in doses of 1/10 grain (.006) two or three times a day combined as follows:

R. Hydrarg. chloridj mitis.	gr. ii	12
Sodij bicarb.	gr. x	65
Sach. albi.	gr. x	65

M. Fiat chartulæ No. xx. Sig.: One powder twice daily in a little water or milk.

Mercury may be given in the form of the gray powder, one grain (.06) four times a day.

If the patient is troubled with diarrhea when calomel is given, then mercurial inunctions should be resorted to as follows:

R. Ung. hydrargyri
Lanolini, aa ʒss 15

M. Fiat unguentum. Sig.: Twenty grains to be rubbed daily into the soles, palms, back, axillæ and thighs alternately. After the inunction has been applied the area should be covered with a piece of lint to maintain the ointment in contact with the skin.

In grave cases of congenital syphilis deep injections into the muscles are advised. The gray oil in five drop (.30) doses of the 20 per cent. solution has been so administered once a week injected into the gluteal region.

Potassium iodid is recommended along with the mercurial treatment, especially when the tenderness of the joints shows epiphysitis or periostitis, given in doses of from 10 to 20 grains (.65-1.30) daily.

As soon as decided improvement has taken place the mercurial preparations may be substituted by a ferruginous tonic, in order to correct the anemia and to improve the nutrition of the patient. The specific treatment must be carried on for a year or longer, changing the preparations as necessary.

PROPHYLAXIS.

When symptoms of congenital syphilis appear in a newborn babe the parents should be placed on specific treatment. The mother should take antisyphilitic treatment for four months during her pregnancy in two or three periods. The effect thus produced on the fetus is very great and produces a wonderful diminution in the ravages of the disease.

Medicolegal.

May Recover Damages for Second Miscarriage.—The Court of Civil Appeals of Texas says that, in *Rapid Transit Railway Company vs. Smith*, the wife of the latter party was injured, June 8, in a collision of cars. She was pregnant at the time, and the accident caused her to miscarry the next day. In the following November, having again become pregnant, she miscarried again, which the physician said was the probable result of the accident; and the court does not think that the allegation of a second miscarriage, November 15, was too remote for a recovery.

Confinement of Person Acquitted of Crime for Insanity.—Chapter 1 of the Public Laws of North Carolina of 1899 provides that: "When any person accused of the crime of murder shall have escaped indictment or shall have been acquitted on the trial on the ground of insanity, * * * the court before which such proceedings are had shall in its discretion commit such person to the Hospital for the Dangerous Insane to be kept in custody therein for treatment and care as herein provided," etc. In holding this statute unconstitutional, the Supreme Court of North Carolina says, in *re Boyett*, that the right and duty of the state to provide for the care and treatment of its insane, with such confinement and restraint of their liberty as may be necessary for that purpose, was conceded. It is made the duty of the General Assembly to do so by Sec. 10, Art. 11, of the Constitution of North Carolina. It was also conceded that the state may, pursuant to general laws, and after proper judicial proceedings, confine insane persons for their own protection and that of other persons. It is also true that, to meet sudden emergencies, and prevent either self-destruction or injury or harm to other persons, an insane person may be restrained temporarily without adjudication of his insanity. The writers and courts have not undertaken to define the limitations of the power which the state has to deal with these unfortunate people, except by the announcement of general principles essential to their welfare and the protection of the public. This court does not propose to discuss this delicate subject. A very different question is presented when the legislature undertakes to confer

on courts discretionary power to confine persons in asylums or hospitals and makes no provision for notice or adjudication before the order for confinement, or for review of such discretion after the person is committed. It is well settled that a person acquitted by a jury on the ground of insanity existing at the time of the commission of the act is entitled to all of the protection and constitutional rights as if acquitted on any other ground. The fatal infirmity in the statute under consideration is that the power to commit is vested in the court to be exercised "in its discretion." No provision is made for notifying the person whose liberty is involved, nor is the court required to make any investigation either by itself, by examination of witnesses, by calling to its aid medical experts, or otherwise. It may be that the wisdom of the legislature will find, within constitutional limitations, a remedy for the objectionable features of the statute. The court does not wish to be understood as saying that a person acquitted of a grave crime on the ground of insanity may not be detained for a reasonable time, so that by some appropriate proceedings the condition of his mind may, either under the direction of the judge presiding or some other judicial officer or commission, be examined into for the purpose of ascertaining whether his own safety and that of other persons or the public generally requires that he be committed to the hospital for treatment and care. It is well settled that it is not necessary that a jury trial be had; it is sufficient if the inquiry be had in some way and by some tribunal conforming to the constitutional requirement of due process of law. Another and equally fatal objection to this particular statute is that it provides that a person acquitted of a capital felony and committed to the hospital can not be released except by an act of the legislature. It is a fundamental principle that every person restrained of his liberty is entitled to have the cause of such restraint inquired into by a judicial officer. The judicial department of the government can not by any legislation be deprived of this power or be relieved of this duty.

Validity of Health Laws—Compulsory Vaccination.—The public health law of New York provides that "no child or person not vaccinated shall be admitted or received into any of the public schools of the state, and the trustees or other officers having the charge, management or control of such schools shall cause this provision of law to be enforced. They may adopt a resolution excluding such children and persons not vaccinated from such school until vaccinated." The question was presented by the case of *Viemeister vs. White* whether the legislature was prohibited by the Constitution from enacting that such children as have not been vaccinated shall be excluded from the public schools, the Constitution requiring the legislature to "provide for the maintenance and support of a system of free common schools, wherein all the children of this state may be educated." The Court of Appeals of New York upholds the law. It says that a statute entitled a health law must be a health law in fact as well as in name, and must not attempt in the name of the police power to effect a purpose having no adequate connection with the common good. When the sole object and general tendency of legislation is to promote the public health, there is no invasion of the Constitution, even if the enforcement of the law interferes to some extent with liberty or property. The right to attend the public schools of the state is necessarily subject to some restrictions and limitations in the interest of the public health. A child afflicted with leprosy, smallpox, scarlet fever, or any other disease which is both dangerous and contagious, may be lawfully excluded from attending so long as the danger of contagion continues. Public health, as well as the interest of the school, requires this, as otherwise the school might be broken up and a pestilence spread abroad in the community. So a child recently exposed to such a disease may be denied the privilege of our schools until all danger shall have passed. Smallpox is known of all to be a dangerous and contagious disease. If vaccination strongly tends to prevent the transmission or spread of this disease, it logically follows that children may be refused ad-

mission to the public schools until they have been vaccinated. It must be conceded that some laymen, both learned and unlearned, and some physicians of great skill and repute, do not believe that vaccination is a preventive of smallpox. The common belief, however, is that it has a decided tendency to prevent the spread of this fearful disease and to render it less dangerous to those who contract it. While not accepted by all, it is accepted by the mass of the people, as well as by most members of the medical profession. It has been general in New York state and in most civilized nations for generations. It is generally accepted in theory and generally applied in practice, both by the voluntary action of the people and in obedience to the command of law. Nearly every state of the Union has statutes to encourage or directly or indirectly to require vaccination, and this is true of most nations of Europe. It is required in nearly all of the armies and navies of the world. Vaccination has been compulsory in England since 1854, and the last act upon the subject, passed in 1898, requires every child born in England to be vaccinated within six months of its birth. It became compulsory in Bavaria in 1807; Denmark, 1810; Sweden, 1814; Württemberg, Hesse, and other German states, 1818; Prussia, 1835; Roumania, 1874; Hungary, 1876; and Servia, 1881. It is aided, encouraged, and to some extent compelled, in the other European nations. It is compulsory in but few states and cities in this country, but it is countenanced or promoted in substantially all, and statutes requiring children to be vaccinated in order to attend the public schools have generally been sustained by the courts. A common belief, like common knowledge, does not require evidence to establish its existence, but may be acted on without proof by the legislature and the courts. The fact that the belief is not universal is not controlling, for there is scarcely any belief that is accepted by every one. The possibility that the belief may be wrong, and that science may yet show it to be wrong, is not conclusive; for the legislature has the right to pass laws which, according to the common belief of the people, are adapted to prevent the spread of contagious diseases. In a free country, where the government is by the people through their chosen representatives, practical legislation admits of no other standard of action. While the court does not decide and can not decide that vaccination is a preventive of smallpox, it takes judicial notice of the fact that this is the common belief of the people of the state, and with this fact as a foundation it holds that the statute in question is a health law, enacted in a reasonable and proper exercise of the police power.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia, December 3.

- 1 *Presence of Tubercle Bacilli in the Urine of Patients Suffering with Pulmonary Tuberculosis. Randle C. Rosenberger.
 - 2 *The Roentgen Treatment of Malignant Disease of the Breast. Charles L. Leonard.
 - 3 Review of Some Malignant Cases. Charles L. Leonard.
 - 4 *Status of Our Knowledge of Sero-Therapeutics. D. H. Bergey.
 - 5 *Concerning the Suppression of the Acetone Bodies in Diabetics. Heinrich Stern.
 - 6 *A New Reflex: Paradoxical Flexor Reflex. Alfred Gordon.
 - 7 *Operative Technic in Stone in the Ureter. J. P. Crawford.
1. Tubercle Bacilli in the Urine.—Rosenberger examined the urine for tubercle bacilli in 25 cases of pulmonary tuberculosis in which there was positively no involvement of the genito-urinary tract. A few isolated tubercle bacilli were found in only three cases, and no clumps nor groups of bacilli were observed, as are usually seen in cases of tuberculous cystitis, nephritis, etc.

2.—See abstract in THE JOURNAL of September 24, page 908.

4. Present Knowledge of Sero-Therapeutics.—Bergey calls attention to the fact that recent investigations appear to indicate that a class of immune serums must be formed which

possess properties that are entirely different from the antitoxins and the bactericidal immune serums in that they are neither antitoxic nor bactericidal in their action. The best known of this class of serums are the pneumococcus, the staphylococcus and the streptococcus serums. Bergey cautions that too much should not be expected from the therapeutic application of these serums, and says that it is evident that we have a great deal to learn as to the best method of preparation of these serums as well as to the character of the serums themselves and the manner in which they bring about curative results.

5.—See abstract in THE JOURNAL of November 5, page 1410.

6. Paradoxical Flexor Reflex.—Gordon has observed a new reflex in cases, the history of which points to organic disease of the nervous system, and especially of its motor tracts; it is always associated with exaggerated knee-jerks; in some cases the Babinski reflex is present, in some not. In a majority of cases Gordon found the sign on the side, where the Babinski was either absent or slight, although in a certain number of cases it was present alongside of a Babinski. It was present in obscure cases in which the Babinski was absent. The reflex is elicited in the following manner: The patient assumes the prone or sitting position, with the feet on a stool. The feet are slightly rotated externally to obtain complete relaxation of the muscles of the leg. The examiner must place himself to the outer side of the leg; the thenar and hypotenar muscles of his right hand are placed on the inner surface of the tibia of the patient and the fingers pressed deeply on the middle or the lower portion of the calf muscles so as to transmit the pressure to the flexor muscles of the deep layer; sometimes pressure must be combined with lateral movements of the superficial muscles. If the reflex is present, extension of the great toe or of all the toes will be noticed. Gordon examined 30 cases, 2 of spastic paraplegia, 3 specific meningomyelitis, 2 of traumatic myelitis, 1 of ataxic paraplegia, 2 of spinal syphilis, 3 of transverse myelitis, 1 of amyotrophic lateral sclerosis, 3 of cerebrospinal syphilis, 12 of hemiplegia, 1 case of rigidity of the spine with cord symptoms, and 1 case of paresis, with the following result: In 12 cases the reflex was present, together with the Babinski. In 10 cases the Babinski was present, but the paradoxical reflex was absent, or vice versa; and as in 9 cases the Babinski was distinct but the paradoxical reflex slight on the same side, it is seen that in 19 cases, against 12, the two reflexes showed a tendency to replace each other. Only in 6 cases were both reflexes absent at the same time. Gordon has given this sign the name of "paradoxical flexor reflex." He also examined a great number of patients showing an involvement of other portions of the nervous system than the motor tract, also a great many normal individuals, and found that the reflex was inevitably absent in all these persons.

7. Operative Technic in Ureteral Stone.—A positive diagnosis having been made of stone in the bladder area by means of the Roentgen ray, Crawford advises its removal by means of a suprapubic cystotomy rather than by the usual extraperitoneal operation. In the case cited of ureteral stone, Crawford dilated the mouth of the ureter with the end of the index finger, constantly teasing the sphincter for nearly an hour until sufficient dilation was obtained to permit the delivery of the stone, which was one and three-eighths inches in diameter, without laceration of the bladder wall.

8. Treatment of Epilepsy.—Hamilton is convinced that

many apparently hopeless cases of epilepsy can be greatly benefited, if not cured, by carefully following ordinary hygienic rules and such means as favor the elimination of waste and toxic products, the institution of proper mental occupation and the avoidance of stress and strain. Hamilton inclines very strongly toward the belief that toxemia, either of gastrointestinal origin or due to the introduction into the circulation of certain familiar cocci, or the generation and accumulation in the blood of cholin, the result of the breaking down of nerve tissue, enters more largely into the pathogeny of epilepsy than is generally supposed. He says that regulation of the diet should include a consideration of the idiosyncrasies of the patient, but nitrogenous food should be interdicted as far as possible. No large quantity of food should be given at any one time. If intestinal autotoxis exists, cholagogues and appropriate ferments, as well as antiseptics, should be prescribed. Everything possible should be done to prevent the lighting up of gross intracerebral pathologic processes and the resulting formation of cholin. The equilibrium of the arterial pressure should be everywhere maintained. Bromids should be given only in doses sufficient to diminish the activity of the cortical motor cells.

10. **Henoch's Purpura.**—Smith cites two cases of this affection. The first, a boy, aged 9, developed purpural spots on the legs and abdomen two days after a blow on the abdomen. The purpura became general, there were severe abdominal pains, and the albuminous urine contained blood. The onset of symptoms pointing to intestinal obstruction necessitated the performance of a laparotomy. The intestine was found collapsed and ecchymotic. The bowel was lifted up and douched, and the abdomen was closed with as much normal saline solution in it as it would hold. The bowels resumed their peristaltic action, and all the other gastrointestinal symptoms gradually abated, but the patient died one month later from a renal involvement, which was not relieved by decapsulation of both kidneys. The second case, a boy, aged 16, was very similar to the first case and was treated in the same manner. Improvement followed and the patient was discharged cured four weeks later. Smith believes that an exploratory laparotomy in cases presenting grave abdominal symptoms, even though purpura may exist at the time, is not only permissible, but indicated. Therefore, Henoch's purpura is not to be regarded as entirely a medical disease. An interesting fact in Smith's cases was that filling the abdomen with salt solution was followed within a few hours by a resumption of intestinal peristalsis and improvement in all the other abdominal symptoms.

11. **Infant Feeding.**—The method of preparing milk for infants is described by Glazebrook as follows: For children under 3 months of age, the top 9 ounces of a quart bottle of milk, that has stood until the cream has separated, are removed by means of the Chapin dipper, and 6 ounces of this are diluted with 24 ounces of dextrinized barley water, for the preparation of which explicit directions are given. One and a half ounces of sugar of milk are also added. A good average milk contains in the top 9 ounces about 12 per cent. fat, 4 per cent. proteid, and 4 per cent. sugar. When diluted as above, the result is: Fat, 2.4 per cent.; sugar, 6 per cent.; proteids, 8 per cent. Any desired strength of these ingredients may be obtained by using more or less of the 9 ounces of milk. For older children, the top 16 ounces are removed. These contain about 8 per cent. fat, 4 per cent. proteid, and 4 per cent. sugar. To 10 ounces add milk sugar and barley water as before. The mixture contains: Fat, 2.35 per cent.; sugar, 6 per cent., and proteids, 1.2 per cent. By adding 1 ounce of sugar to every 25 ounces of food, the sugar percentage is always 6, a good average amount. The percentage of fat and proteid may be varied by using more or less of the top 16 ounces of milk. Glazebrook also says a word in favor of condensed milk, especially in those cases where the infant, owing to careless or ignorant feeding, does not seem to tolerate fresh cow's milk in any form. He has used it in a great many cases which were given up as

hopeless, and improvement was almost immediate. This may be explained by the fact that the vacuum process of condensing milk seems to make the curd more assimilable, or it becomes more friable. In order to get the percentage of fat and proteid in correct relation to each other, top milk or cream should be added to an equal amount of condensed milk.

- 20 *Misocainia in Medicine. Achilles Rose.
- 21 A New Case of Chloroma with Leukemia, with a Study of Cases Reported Since 1893. George Dock and Aldred Scott Warthin.

14. **Spark-Gap Radiations.**—Supplementing a "preliminary note" as to the "rays" given out by his "ultra-violet" condenser spark-gap lamp, Piffard says that these rays exert a very powerful influence on the skin; and that the reaction is similar in character to that of the α -rays and of radium, and that it appears much more promptly. Like them also, it may produce a curative or a destructive effect, according to the intensity of the spark and the duration of its application. He says that if the appliance be used with a coil, the single Leyden jar should be employed, with inner armature connected with one of the secondary terminals and the outer armature with the other terminal of the secondary of the coil. The lamp is then connected directly to the secondary by its cords. He prefers an interrupter adjusted to give a current of from 5 to 6 amperes through the primary of the coil. The armatures should not exceed 40 square inches of foil in each. This is for the three-spark lamp. For the one-spark "ionizer" a lesser amount of energy is preferable. The first application should never exceed 10 minutes. If the apparatus is connected with a static machine, two Leyden jars are used, the armatures of which should each have a foil surface of at least 100 square inches. The outer armatures of the jars should be connected together, and the lamp terminals connected to the pole pieces of the static machine. The first application should not exceed 15 minutes, with the spark from 15 to 20 millimeters for the lesion.

15. **Extrauterine Pregnancy.**—Lemann believes that this disease is a far more frequent one than is generally supposed, and that our knowledge of it is very indefinite and unsatisfactory. By maintaining an attitude of alertness and by carefully investigating all conditions of menstrual irregularities and colicky pains, Lemann thinks it possible to make an accurate diagnosis and thus save the lives of some patients who otherwise would perish. If the diagnosis is obscure, but there is present a boggy or fluctuating mass on either side of the uterus, an exploratory operation, either through the abdomen or the vaginal fornix, is justifiable.

16. **Pancreatitis.**—Haggard's article is a complete and thorough review of the entire subject.

17. **Laundry Hygiene.**—Wile has studied this question with reference to infection of employes from patrons' clothing, and the infection of patrons through their own clothing handled by the laundry employes suffering from some infectious or contagious disease. The results of his study demonstrate the hopelessness of arriving at a satisfactory solution of this problem. It appears, however, that laundering is an efficient hygienic method of promoting cleanliness without marked danger to the patron and with comparative safety for the employe.

20. **Misocainia.**—Rose offers this term as a substitute for that proposed by Lombroso, *misoneisus*, meaning the deep-rooted inclination of mankind to combat new ideas. He calls attention to the rôle misocainia has played in the history of medicine, and cites a number of instances, such as the introduction of calisaya bark by Juan del Vejo, the discovery of

the circulation by Harvey, percussion by Auenbrugger, Semmelweis's work in connection with the etiology of puerperal fever, and others.

27 *An Accident with the Antrum Trocar. Benjam Douglass.

27. **Epilepsy.**—Ranney's experience in investigating the causes of epilepsy for nearly twenty years has led to the following conclusions: Epilepsy is not necessarily an organic disease; hence, there is always hope of a radical cure. A very large proportion of epileptics suffer from some type of reflex, ocular, abdominal, genital, or other local sources of nervous irritation. Of these reflexes, the eyes are unquestionably the most frequent source of trouble. No medication should ever be employed to control epileptic convulsions until every possible exciting cause has been intelligently sought for and scientifically combated. The refraction of all epileptics should first be carefully determined under the influence of a mydriatic and, if necessary, corrected by properly prescribed glasses, before positive conclusions are arrived at regarding any mal-adjustment of the eye muscles, from which a large proportion of epileptics unquestionably suffer. After the correction of errors of refraction by glasses for a time, the tests for mal-adjustments of the eye muscles should again be made. Ranney considers this step of vital importance, and insists that it should always be done most accurately and scientifically, as one radical and permanent cure of epilepsy without drugs offsets a thousand failures. The percentage of cure of chronic epilepsy under skillful eye treatment will naturally be modified greatly by the abnormal eye conditions found, the physical condition of the patient, the amount of drugs that have been given, and the complications that may co-exist with eyestrain. To colonize epileptics or to place sufferers of that type in private sanitariums without any investigation of the eyes and eye muscles, can not be too strongly condemned, says Ranney. He thinks that a large percentage of epileptics suffer from eyestrain (if there be first deducted from the total number the comparatively small number of cases that owe their epileptic seizures directly to some organic lesion of the brain or to a depression of the skull). The duration of eye treatment in epilepsy varies from three months to three years. Most of the work is done during the first six weeks; but long intervals of rest, between the successive operative steps that are commonly demanded, often extend the period of treatment considerably whenever the convulsive seizures are not totally arrested.

25. **Home Treatment in Pulmonary Tuberculosis.**—Craig reviews the benefits accruing to tuberculous patients from a residence in a comparatively warm, dry and equable climate, especially that of lower California and Arizona, and compares these with the conditions obtaining in the home treatment of tuberculosis. He says that when carried out under intelligent direction, the results obtained from climatic treatment are in such marked contrast to those secured where patients lived in boarding houses and hotels, that the most skeptical will be convinced of the advantages of the former over the latter.

27. **Accident with Antrum Trocar.**—Douglass reports an instance where the instrument designed by him perforated the outer wall of the antrum with the result that when water was injected it passed directly into the tissues of the cheek. The patient was put to bed, ice cloths were applied and within forty-eight hours the water had been absorbed without any reaction occurring. In explaining this unusual accident he assumes that the needle was not pushed through the nasal wall in the proper place, or that the antrum was very small

or entirely absent. He advises caution in the use of the trocar.

29 Pulmonary Tuberculosis and Sanatorium Treatment. Vincent Y. Bowditch.
30 *Mechanical Restraint and Seclusion of Insane Persons. Charles W. Page.
31 *Pott's Disease Treatment at a Late Stage. Remarks on the Pathologic Anatomy. E. W. Taylor.

28. **Unavoidable Calamities Following Surgical Operations.**—The conditions discussed by Richardson are suppression of urine following hysterectomy; infection of the knee-joint, general septicemia and death following arthrotomy; post-operative hemorrhage; phlebitis following abdominal operation and after operations on the uterus or ovaries with subsequent pulmonary embolism; septic meningitis following myectomy, and sudden death from pulmonary embolism after abdominal operations; fatal capillary hemorrhage following operation on jaundiced patients, and postoperative death for which no adequate cause can be found. Six illustrative cases are cited, distributed over a period of fifteen years, and among some five thousand abdominal operations. Richardson is of the opinion that these disasters can not be foreseen and prevented, and that such cases must be looked on as the hazard of any surgical operation.

30. **Mechanical Restraint and Seclusion of the Insane.**—Page denies these methods of treating the insane. He says where restraint is permitted the general spirit of the management breathes coercion, antagonism and enforced submission. When non-restraint is the undeviating rule, tact, persuasion and sympathy soften and mellow every act towards the patients. The employment of mechanical restraint gives the attendants a wrong sense of their personal power over patients, such a physical advantage that they instinctively incline to self-assertion; to issue peremptory commands; to use ill-considered, irritating speech; to make threats; in short, to intimidate all but the most quiet patients. His experience in an insane hospital has convinced him that being in earnest is the solution of the non-restraint question. The ruling authority over and above the nursing staff must be in earnest; and this signifies clear insight as to the evil and its remedy; certainly as to what can be done with the insane by virtue of patience, sympathy and tact; with determination, watchfulness, faith and enthusiasm.

31. **Pott's Disease.**—The case cited by Taylor is interesting from the fact that the disease developed in an adult male, aged 45, following an attack of typhoid fever, that the process in the spine progressed steadily to involvement of the cord, resulting in a practically complete paraplegia, and that persistent treatment produced a definite amelioration of the condition in spite of the serious damage to the cord, as shown at the postmortem held five years after the onset of the trouble. Although the patient was otherwise non-tubercular, there was tuberculous disintegration of the lower thoracic vertebra; constriction of the lumen of the spinal canal; wide-spread degeneration and deformity of the cord at the level of the eleventh dorsal vertebra; secondary degeneration above and below this level. There was no intradural tuberculosis. The onset of the disease was rapid. There was marked predominance of motor over sensory symptoms in spite of extensive degenerations in the sensory areas. The extreme local injury to the cord was suggestive of a myelitis.

38. Study of Gastric and Duodenal Ulcer.—Howard's study is based on a series of 82 cases of round ulcer that occurred in the Johns Hopkins Hospital during a period of about fifteen years, or 0.18 of the total number of cases admitted. In this series there were 7 duodenal ulcers. As compared with gastric cancer, the respective incidences were 1 to 225 and 1 to 56 general admissions. In the hospital mentioned, gastric ulcer is, relatively, as common in men as in women, the contrary to the usual idea. In the male the percentage of greatest frequency was between the ages of 40 and 50, a decade later than usual; while in females it was, as usual, in the third decade. The cases were relatively more frequent in the colored race than in the white, the ratio being 4.5 to 1. Ulcer is also, relatively, more frequent among the Germans. Vomiting occurred in 85.3 per cent.; pain in 82.9 per cent., and hematemesis in 75.6 per cent. In 36 cases there was a loss in weight of more than 10 pounds, and in 9 of 40 pounds or more. Hyperchlorhydria was present in only 17.6 per cent. Heredity played little or no part. In 47 of the cases there was a definite history of previous stomach trouble. In the majority it was described as indigestion. There was a positive history of trauma in 7 cases. In 53.6 per cent. of cases there was a history of the use of alcohol, and in 19.5 per cent. to excess. In 15.8 per cent. there was a definite history of syphilis—either recent or old. Tuberculosis in one or another of its manifestations was present in 13.4 per cent. of the cases. Arteriosclerosis was present in 48.8 per cent.; to a marked degree in 22 per cent. In 50 per cent., pain was the chief complaint; in 47.5 per cent., stomach trouble; in only 6 per cent. was the history of vomiting of blood volunteered by the patient. Only 8 cases (9.7 per cent.) might be termed acute; the remaining 74 existed for periods ranging from two months to twenty years. The blood picture was one of chloranemia (hemoglobin, 58 per cent.; red blood corpuscles, 4,071,000; white blood corpuscles, 7,500). Hemorrhage was the cause of death in 8.5 per cent. of the total number of cases, and in 29.5 per cent. of the fatal cases. Perforation was rare (3.6 per cent. of the series). General peritonitis occurred in but one instance (1.2 per cent.). Ulcus carcinomatosum was rare—4.8 per cent. of the series. The average duration of the disease for the entire series was 4.1 years. Howard concludes that operation is indicated in all cases of perforation or perigastric adhesions and in cases of copious or recurring hemorrhage, when medical means have failed after a fair trial. The results obtained in the 82 cases are tabulated as follows: Died, 24 (29.3 per cent.); well, 14 (17.1 per cent.); improved, 39 (47.6 per cent.); unimproved, 3 (3.6 per cent.); not treated, 2 (2.4 per cent.). In the cases that received treatment there was a mortality of only 18.8 per cent.; and in those receiving medical treatment alone, 8.6 per cent. Eleven of the 24 fatal cases died from some intercurrent affection, the ulcer being recognized only at autopsy. There were 16 deaths among the males and 8 among the females.

39. Intermittent Hyperchlorhydria and Recurrent Vomiting in Children.—The object of Snow's paper is to direct attention to the curious symptom-complex called cyclic, periodical, or recurrent vomiting of children, with the idea (1) that the condition is not as rare as is generally supposed; (2) that it is relatively easy of diagnosis, an examination of the vomited matter being most important; (3) that at least in some cases the gastric irritability is due to an intermittent hyperchlorhydria, a secretory neurosis, causing the sudden hypersecretion of free hydrochloric acid and gastric juice. Vomiting is the main symptom of the malady and the subject, except for the attacks, is in perfect health. The vomiting attacks occur at irregular intervals, begin with slight premonition, continue usually a few days, and cease suddenly, leaving the patient with an unimpaired appetite and digestion. Snow advises that the alkaline treatment should always be tried, although it is difficult to estimate the effect of treatment in an affection that may terminate spontaneously at any time. In dangerous conditions nutrient enemata, chloral by rectum, and hypodermics of morphin and strychnin may tide the patient over a dangerous crisis.

40. Medical Treatment of Gastric Ulcer.—The therapeutic indications are formulated by Lambert as follows: First.—To assist nature in the process of repair. (a) By regulating the diet. 1. To protect the ulcer from mechanical injury and consequent further extension of the ulceration. 2. To keep the ulcer at rest. (b) By administration of drugs. 1. To stimulate cicatrization. 2. To cover and protect the ulcer from chemical irritation. 3. To neutralize the gastric acidity, whether due to the normal acid or to any of the abnormal acids of fermentation. (c) By improving the general health, by careful feeding and hygiene. Second.—To prevent loss of flesh and strength by feeding through other channels than the stomach. Third.—To combat individual symptoms and complications as they arise. Lambert lays great stress on rest in bed and milk diet. During the rest the patient should receive daily alcohol spongings and baths, and mild forms of massage to the arms, legs and back. Rectal feeding is begun as soon as the patient is settled in bed, nothing but water and pieces of ice being given by mouth, for from four days to a week, according to the severity of the case. The treatment of complicated as well as of uncomplicated cases is discussed in detail by Lambert, but nothing new is offered. During the past 10 years 52 cases were admitted to the hospital, 4 being relapses of cases previously treated. Of the 52 cases, 11 died, a mortality of 21.15 per cent. Thirty-five cases were treated in the medical and 17 in the surgical wards. Of the former, 30 had hematemesis, 2 of whom died; 3 abandoned treatment in from 2 to 4 days, and the remaining 2 were cases of relapse, occurring without hemorrhage. Of the 17 cases admitted to the surgical division, 3 were admitted moribund, suffering from a general perforative peritonitis, and all died without interference. Of the 14 cases operated on, 1 died after an operation to relieve a cicatricial stenosis; 2 cases were operated on for gastralgia, and in both healed ulcers only were found; 3 cases were operated on for hemorrhage, and of these 2 recovered and 1 died. Eight cases of peritonitis due to a perforated ulcer of the stomach were operated on, with a mortality of 50 per cent. Lambert concludes that the statistics of these few cases do not allow of any particular generalization, except to emphatically point out the fact that surgical procedure, in certain cases, offers the only road to recovery.

41. Surgical Treatment of Gastric Ulcer.—Blake considers the surgical treatment of phases of gastric ulcer, namely, perforation, cicatricial contraction and obstruction, hemorrhage, and chronic gastric ulcer, *per se*, and concludes that it should be, at least, largely surgical. Surgical treatment, he says, should be instituted not as a last resort but before the starvation, the long suffering from pain, dyspepsia, and fermentation absorption have reduced the patient until he is beyond surgical help.

46. **Acute Lobar Pneumonia.**—Robinson urges that judicious rational treatment should be begun immediately and continued during the attack. The most useful single agent, as a preventive and curative, is creosote, used preferably as inhalations, properly given and continued for a sufficient length of time. Extremes of treatment in any direction, whether toward the use of so-called specifics or the employment of certain drugs, notably digitalis and strychnin, should be strictly avoided.

47.—See abstract in THE JOURNAL of Sept. 24, page 909.

49. **Diagnostic Value of Leucocytosis.**—McCaskey considers a routine enumeration of the white cells in the peripheral blood of sufficient importance to be made a regular procedure, so far as possible, in all cases. A single leucocyte count is entirely insufficient as a basis of conclusion in any given case, and should be followed up by several made under different conditions. An increase beyond 10,000 or 12,000 leucocytes in the peripheral blood indicates varying grades of intoxication with chemotactic substances of some sort or another. The leucocytes indicating suppuration are the neutrophils, while the eosinophiles indicate particularly cutaneous affections or parasitic diseases. Lymphocytosis signifies an irritative lesion of the lymphatic apparatus. Therefore, a differential count should be made in all cases to determine the type of cell which has been the subject of the principal increase, where such increase exists, and such records carefully kept and collated as a basis for the determination of the clinical significance of leucocytosis in the future. In the diagnosis of malignant disease, McCaskey has found a leucocytosis to be of very subordinate value, and when present is probably not due to the malignant disease *per se*, but to co-existing chemotactic toxins.

51. *A Contribution to the Study of the Prognosis of Syphilis. Noah E. Aronstam.

51. **Prognosis of Syphilis.**—According to Aronstam, syphilis is a curable affection, provided treatment is begun early and as faithfully and persistently carried out. He says that at least three, if not four, years of continuous treatment is required to bring the morbid process under control, with all dangers of recrudescence eliminated. The indications of the total cessation of the destructive condition consist of the absence of all manifestations and lesions for a period of not less than two years, a steady gain of body weight, or at least no loss of same, and the propagation of healthy children. Unfortunately, concludes the author, these indications are, at the present juncture of our knowledge of the prognosis of syphilis, far from positive and reliable.

56. Cortical Reflex of the Pupill. O. Haab.

52. **Melanosarcoma of Limbus.**—Bell reports a case of alveolar melano-sarcoma of the limbus. The iris and fundus were normal and the vision was 20/20 plus. There was paralysis of the external rectus muscle and a consequent diplopia. The preauricular glands on the left side were the only ones that were enlarged. The eye was enucleated and all the external rectus muscle was removed. Healing after the operation was normal and uneventful. Bell has reviewed the literature on the subject very carefully and concludes that most cases of epithular sarcoma demand radical treatment just as soon as the diagnosis is confirmed microscopically. He believes that it is unfair to jeopardize the life of the patient by a compromise in the treatment in the way of an abscission because that operation is useless. In 44 cases of abscission, recurrences occurred in 36.

55. **The Gonococcus Theory.**—Urbahn, who has devoted considerable time to the study of the morphology and biology

of the gonococcus, says that this germ will grow in the ordinary nutritive media, but that glycerin-agar alone is not sufficient for a differential diagnosis. Jellied blood serum, in connection with glycerin-agar, may suffice to distinguish gonococci from similar cocci, especially from the meningococci and nearly related varieties. There appear to be bacteriologic differences between various stocks of gonococci, but it remains to be determined whether these differences exist clinically. Whatever other differences may be found, the three characteristics of form, staining, and relation to pus corpuscles must be possessed by all varieties of cocci to enable them to be classed as gonococci, and until it has been determined whether or not the gonococcus is a distinct variety with special characteristics, that name should be reserved for it alone, and the name pseudogonococcus be avoided.

57. **Embolism Following Operation.**—In order to obtain more definite information as to the occurrence of postoperative embolism and all factors connected therewith, Dearborn addressed a circular letter to twenty-five of the most prominent surgeons of Boston and vicinity. The replies to these letters appear to show that thrombosis and embolism are more common after operations in the pelvis than after operations in any other part of the body. Further, that it is possible that many cases of pleurisy, pneumonia and pulmonary abscess following operation are due to emboli. Large emboli almost always cause speedy death by syncope or asphyxia; very small emboli usually run a favorable course. Dearborn says that any sudden increase in pulse rate during convalescence, temperature remaining about normal, should remind one of the possibility of thrombosis, and that, if there are evidences of phlebitis or of thrombosis, absolute rest in bed must be insisted on.

58. **Uterine Tumors Complicating Pregnancy.**—Fairechild holds that the discovery of a tumor complicating pregnancy is no certain indication for an operative procedure even when it is first apparent that mechanical difficulties of a very grave nature exist, but a watchful care should be exercised, and when it is found in the first four months that the uterus can not rise into the abdominal cavity, or that an abortion is almost certain to occur, the abortion should be left to nature or a supravaginal hysterectomy made. If the uterus is advancing into the abdominal cavity, no interference should be permitted unless grave pressure symptoms should appear as a remote probability, amounting to almost a certainty, when a supravaginal hysterectomy may be made. If, in the later months of pregnancy, a tumor springing from the neck or the lower segment of the uterus threatens to block the pelvis and seriously interfere with delivery, the question of removing it may be considered in anticipation of labor at about the seventh month. In the great majority of cases, when the immediate and seeming dangers are past, the case will go on to the period of labor to be treated according to the indications present at that time, either through the spontaneous effort of nature or by some operative procedure, probably cesarean section and a Porro operation.

63. The Management of Typhoid Fever. George E. Petty.

64. *A Successful Treatment for Dellirium Tremens. George E. Petty.

62. **Review of One Thousand Consecutive Cases of Appendicitis.**—The following classification is made by Ochsner of these cases: Chronic appendicitis or interval operations, 540; mortality, .5 per cent. Acute appendicitis without perforation, 255 cases; mortality, 1.9 per cent (of these 6 entered the

hospital within 36 hours after the beginning of the attack). Acute appendicitis, perforated or gangrenous, without abscess, 55 cases; no deaths (of these, 5 entered the hospital within 48 hours after the beginning of the attack). Acute appendicitis, perforated, with abscess, 117 cases; mortality, 3.4 per cent. Acute appendicitis, with diffuse peritonitis, 33 cases; mortality, 30 per cent. Of the total number of 1,000 cases, 22 died, giving a mortality percentage of 2.2. Of the 255 acute appendicitis cases without perforation, 200 were operated on immediately on entering the hospital and 55 were treated by gastric lavage and absolute prohibition of food and cathartics of every kind by mouth, the nutrition being accomplished by means of small enemata. Of the 55 cases perforated or gangrenous, but without abscess, 21 were operated on at once and 34 were first starved until they seemed in a safe condition for operation. In most of these cases the appendix was completely surrounded by the omentum and held away from all other intra-abdominal structures. Of the 117 cases of acute appendicitis in which abscess had formed, 39 were operated on at once and 78 were treated by prohibition of all nourishment and cathartics by mouth until their condition seemed sufficiently improved to make the operation appear safe. Of the 33 cases entering with diffuse peritonitis resulting from perforated or gangrenous appendicitis, all were treated at first with gastric lavage and exclusive rectal feeding. Of this class, a number were in a dying condition when they arrived at the hospital, which accounts for the high mortality in this class of cases. Seven of these cases were not operated on for the reason mentioned, but they are counted among the deaths in order to include the entire mortality of all cases treated. Among the 3 deaths in 540 cases of chronic appendicitis, with interval operations, one case, a weakly woman, 27 years of age, who had been ill much of the time during her entire life, had an acute attack of appendicitis two years before entering the hospital and a second attack one year later, since which time she had never been free from pain. The appendix was adherent, partially obstructed at the cecal end, and contained a small amount of pus; pelvis secondarily infected, uterus retroverted and adherent together with ovaries and tubes in pelvis. The patient died four weeks after operation from exhaustion, probably due to absorption from the raw surface in the pelvis. Oschner suggests that if this case had been drained the patient would probably have recovered. The second case was that of a married woman who previously had suffered from puerperal infection, and for 12 years had constantly suffered from subacute appendicitis following an acute attack. This patient, too, died from exhaustion. In the third case the chronic appendicitis was complicated with a double pyosalpinx necessitating the removal of both tubes, the right ovary and the appendix. The patient succumbed to the loss of blood incident to the ligature cutting through the ovarian artery. Oschner feels that these three deaths could have been avoided if the operation had been confined to the removal of the diseased appendix. In the next group the five patients who died were operated on immediately on entering the hospital because their condition seemed to indicate that the infectious material was confined to the appendix. Oschner says that if these five cases had been added to the 55 cases of this group in which gastric lavage was employed and which received neither food nor cathartics by mouth, it is likely that 3, or possibly 4, might have recovered. In all these operations he endeavored to reduce the traumatism to a minimum. All unnecessary manipulations were avoided. The surrounding peritoneal cavity was protected with warm, moist gauze pads. In cases of circumscribed abscess the appendix was removed when it seemed as though this could be accomplished safely. Drainage was used whenever it seemed as though the peritoneum might not be capable of disposing of any infection which might remain. It is much better, says Oschner, to drain too often than to err in the opposite direction. Irrigation was not employed in any of these cases, because his experience was less satisfactory when this means was frequently employed. Oschner concludes from these observations that in the

treatment of acute appendicitis neither food nor cathartics should be given by the mouth, that large enemata should never be given, and that gastric lavage should be employed, especially in patients suffering from nausea or vomiting.

64. Treatment for Delirium Tremens.—Pettey advocates the free administration of veratrum viride and cites several cases in which results were extremely satisfactory. In cases where the administration of this remedy was begun within from four to six hours from the beginning of the delirium, the mind would be clear in from three to four hours, but in cases where the delirium had continued for a longer period a longer time was required to overcome it. A full initial dose should be given and then the dose should be repeated as often and in such quantities as are necessary to establish the full physiologic effect of the remedy. The pulse should be brought down to fifteen or twenty beats below normal and held there until the circulation has become fully equalized and the mind becomes clear. In the meantime, free purgation should be obtained to remove the toxic matter from the system and thus remove the exciting cause of the delirium. In one case, Pettey gave an initial dose of 12 minims (27 drops) of Norwood's tincture hypodermically. An hour later the effects of the drug began to be manifested, and in another half hour the patient was given 6 minims more of the veratrum. At the end of fifteen hours he awoke and had no further trouble.

1. Trypanosome Diseases.—Koch's paper is a historical review of the general morphology and symptoms of tsetse fly disease, surra, mal de Caderas, sleeping sickness, and a classification of trypanosome diseases, a review of immunization experiments and the prophylactic measures to be employed for the prevention of these affections.

2. Tick Fever.—Ross and Milne give the results of their observations in eight cases of fever following the bites of ticks, the *Ornithodoros savignyi*. These ticks are of a grayish-yellow color and vary in size up to the dimensions of a little finger nail. Their habitat is in the old and dirty thatch of huts and in the cracks of mud walls and mud floors, where they secrete themselves during the day, coming out at night to feed. The incubation period varies from one to five days. The most prominent symptoms of the fever are severe pains in the head, mostly in the occipital region, sometimes cough, pains in the back and the limbs, sometimes splenic tenderness, vomiting; pulse varies from 90 to 120; half of the cases observed had diarrhæa. The skin is hot and dry, the conjunctivæ are congested and the tongue is mottled with a slight yellow fur. All the cases seen by the authors made a good recovery, though the treatment is practically nil.

7. Treatment of Enteric Fever.—Caiger's paper considers this subject under the following headings: 1, Specific treatment; 2, antipyretic, and 3, antiseptic treatment. After re-

viewing the results obtained by the serum treatment of typhoid fever and by previous inoculation with attenuated cultures of the typhoid bacillus, and urging further investigations, the author says a word in favor of the cold bath as an antipyretic. But the principal topic of his paper is the use of the essential oil of cinnamon as an antiseptic. His results have been favorable. He has treated 147 cases with the cinnamon and of this number 14 died, representing a mortality of 9.5 per cent. After careful observation of the progress of the individual cases comprising the series, Caiger expresses the firm conviction that in the large majority of attacks the influence of the cinnamon was a good one, and that a certain proportion of the patients who recovered would not have done so had the cinnamon been withheld and the treatment conducted on purely expectant lines. The favorable effects which were noted as attending the administration of the drug were:

1. The temperature in the majority of cases ran at a lower level than is customary in enteric fever, the mean of the daily records taken every four hours approximating 101 instead of 102 or more during the full development of the fever. This effect was a good deal more pronounced in cases brought under treatment at a comparatively early stage of the disease.
 2. The patients remained for the most part drowsy throughout their illness, many of them evincing a constant tendency to sleep, as a result of which mental rest was secured and delirium was less frequent. Here, again, the good effect of early treatment was apparent.
 3. Intra-intestinal decomposition, as evidenced by abdominal pain, distension and fetor of the stools, was controlled to an extent which was really very striking. That the oil of cinnamon is especially efficient as an intestinal antiseptic is evidenced by the fact that, with the exception of several patients in whom the condition was present at the time of their admission to the hospital, no single instance of meteorism occurred among the 147 cases which were treated with it. To obtain the full effect of the cinnamon a dose of from 2½ to 5 minims of the essential oil should be given every two hours from the time the case first comes under treatment until the temperature has fallen to normal. Caiger is in the habit of continuing its administration every four hours during the first week of convalescence and then three times a day for a week longer. It is well, however, to give the drug in smaller doses to begin with so as to accustom the patient gradually to its very pungent taste. By commencing with a dose of 2½ minims and increasing it to 4 or 5 minims in the course of a few days, the likelihood of vomiting being induced by the cinnamon is materially diminished. Care should be taken that the quality of the oil is above reproach. The better quality oil is distilled from the cinnamon bark, and this only should be used. The oil distilled from the leaves of the tree should never be used medicinally. In view of the fact that in three instances progressive cardiac enfeeblement developed where there was no special reason to anticipate its occurrence, Caiger adopted the practice of giving a grain of sulphate of quinin with each dose of the cinnamon in all cases where a careful daily physical examination reveals a suspicion of cardiac failure. The result has so far been reassuring. Bacteriologic experiments have shown that an appreciable, though slight, inhibitory influence on the growth of the typhoid bacillus begins to be exerted by cinnamon oil in a dilution of about 1 in 26,000, and that when its strength approaches 1 in 1,000, its antiseptic effect is complete. The paper concludes with a consideration of the expectant plan of treatment, and the treatment of special forms of typhoid as well as the complications of the disease.

9. Methyl Oxid, Ethyl Chlorid and Somnoform.—Hewitt has made a very careful study of the anæsthetic effects of these substances, and his paper may be summarized as follows: When methyl oxid is largely diluted with air, the mixture does not produce a very satisfactory form of anæsthesia. Mixtures sufficiently concentrated to produce satisfactory anæsthesia are too pungent to be pleasant. As compared to the anæsthesia obtainable by customary means, that produced by methyl oxid is of like type and is not uncommonly followed by nausea and distress. Although a long administration may

lead to a long available anesthesia, unpleasant after-effects are liable to result. As with other anesthetics, it is difficult to produce a satisfactory analgesia. Ethyl chlorid is a useful anesthetic for certain cases. It is a fairly good substitute for nitrous oxid when this gas can not be obtained. It is, however, somewhat uncertain in its action. Its chief drawback lies in the frequency with which it produces unpleasant after-effects—headache, nausea, vomiting and an undesirable feeling of depression. As a routine anesthetic for short dental operations ethyl chlorid is distinctly inferior to nitrous oxid and oxygen, although it produces a longer anesthesia. In small children, who are about to undergo some brief dental or throat operation, and in those adults who are bad subjects for nitrous oxid or nitrous oxid and oxygen, ethyl chlorid will generally answer well. By adding ethyl chlorid to nitrous oxid a very deep form of anesthesia is induced with extraordinary rapidity, the method having the advantage of destroying consciousness more pleasantly than with ethyl chlorid alone. Somnoform does not produce such good results as pure ethyl chlorid and is distinctly more dangerous.

10. **Red Light in Smallpox.**—Nash reports three cases which he thinks were benefited by the red-light treatment. The first patient, an unvaccinated boy between 9 and 10 years of age, was admitted on the eighth day of the disease, when suppuration was imminent and the course of his temperature showed evidence of slight secondary fever, but even this, says Nash, was lessened by red-light influence. The second patient, a boy, aged 3 years, was vaccinated for the first time on the day of his admission to the hospital. The eruption appeared two days later, the initial symptoms being very severe. There was no suppuration, and on convalescence only five small scars were left. The third patient, a woman, aged 33, vaccinated, was admitted on the second day of the disease. There was no suppuration or secondary fever. These three cases were of the discrete type. By having red panes fitted to the windows ventilation was not interfered with, nor were red curtains hung about to exclude rigidly every possible ray of ordinary light. Such a procedure Nash considers both unhygienic and uncalled for.

13. **Application of Superheated Air to the Eye and Face.**—Oswalt's apparatus permits the local application of superheated air to any part of the face. His tests have shown that the open eye can tolerate, without injury, a temperature of 180 C. The sensitiveness of the lids is the only obstacle to still higher temperatures. The heat is supplied by a gas jet under a spiral tube connected with a rubber bulb. He has found this an effectual means of curing rebellious blepharitis, keratitis, chronic iridochoroiditis, and especially neuralgia and tic douloureux. Gautier presented the apparatus to the *Académie* and added that he could speak from experience as to its efficacy; it had relieved him of a neuritis of the brachial plexus which had proved rebellious to all other measures.

15. **Seaside Treatment of Scrofula.**—D'Espine reports the work done at the Dollfus asylum in Cannes since 1886. About 950 children have been received during this period, all but about 150 being scrofulous and tuberculous. The results observed proclaim anew the importance of the sea air and bathing for such children, combined with a mild climate which allows them to be out in the sunshine all day and to have the windows open at night. Tuberculous peritonitis also seems benefited by these factors.

17. **Operative Treatment of Diffuse, Acute, Otogenic Purulent Meningitis.**—The two cases of this form of meningitis, cured by lumbar puncture and drainage above and below, reported by Lermoyez at the International Congress of Otolaryngology last fall, are here described in detail and four imperative rules formulated: The necessity for opening and draining the middle ear, with exploratory craniotomy if required, renders necessary extensive petro-mastoid evacuation, exposing the dura. If this proves ineffectual the dura must be opened with an X incision, and, if necessary, this be supplemented by exploratory puncture of the temporal lobe, not deeper than 4 cm. This will drain the lateral ventricle if distended by an encysted hydrops, or it may evacuate some latent cerebral abscess. Lumbar puncture should be made and repeated. The fluid should be withdrawn in quantities of at least 15 c.c. at a time. In one of the cured cases four punctures were made in nine days. This measure is useful for the prognosis, as well as for the relief it affords, the removal of the toxic fluid and the stimulation imparted by the reproduction of the latter. The fourth and final rule is to respect the labyrinth, even when it shows evidences of necrosis. In the 2 cases necrosis was observed, but no attempt was made to interfere, and the process gradually healed spontaneously after elimination of some sequestra. The middle ear healed completely with no evidence of disturbances in equilibration.

20. **Serum Treatment of Typhoid Fever.**—Chantemesse obtains the serum by injecting horses with soluble typhoid toxin. Since his first communication in 1897 his total mortality has been only 4 per cent. During the same period the mortality in the 14 other hospitals of Paris, under like conditions, has been from over 13 to 26.8 per cent., averaging 18 per cent., while in the Bastion 29 under his charge the mortality has been only 22 out of 545 cases, that is, 4 per cent. He cites Murchison, Griesinger, Curschmann, Harte and Flint to the effect that perforation occurred in 2.6 per cent. of the 8,160 cases of typhoid in their statistics. Perforation occurred in his material in 1.6 per cent., that is, in 10 out of the 545 patients; 2 were successfully operated on. The proportion of perforations in the fatal cases is larger than in other statistics, which shows that the serum does not materially reduce the danger of this complication after the lesions are once established. The serum must be injected early to prove efficient. No perforation was noted in any instance in which the serum was injected before the seventh day of the disease. It stimulates the defensive processes in the spleen, glands and bone marrow, but it requires the co-operation of the organism to cure. The principles of its administration are diametrically different from those of antipyretic serum. With the latter, the longer the duration of the disease and the more severe, the larger the dose, but with the antityphoid serum, the sicker the patient, the smaller the doses should be. The serum treatment is combined with baths, as usual; in fact, the latter are particularly needed to control the slight reaction from the serum. Josias of Paris and Brunon of Rouen have used the serum in 220 cases and have witnessed a reduction of the mortality to a third of its former figure.

22. **Primary Mesenteric Thrombo-Phlebitis.**—Mignon reports a case with postmortem findings. The affection exhibits two distinct phases; in the first there are intermittent pains in the abdomen, alternation of constipation and diarrhea, and malaise, with or without temperature, corresponding to the degree of inflammation of the mesentery. The second phase is characterized by signs of intestinal occlusion, as the disturbance in the circulation of the mesentery paralyzes the intestine and entails gangrene, at certain points. The seat of the pain, usually in the left flank, and the absence of distension of the large intestine are valuable hints. After several days of vague symptoms the second phase developed in the case reported, and the operation was undertaken on the tenth day, the diagnosis wavering between ileus and an insidious epithelioma. The patient succumbed in stercoremic coma within twenty-four hours. Three years before he had been under treatment for phlebitis of the left internal saphena, but otherwise was healthy.

24. **New Method of Testing the Stomach Functions.**—Meunier remarks that a substance for testing the stomach functions should not be absorbable through the stomach mucosa nor modify the elements of the gastric juice in their secretion nor dosage, while it should be capable of exact and rapid dosage and should form with the test meal a homogeneous mixture. Mathieu uses oil and Sahli uses butter for testing the stomach functions, but neither of these substances blend homogeneously with the stomach contents, while they modify decidedly the gastric secretions. Meunier believes that a small amount of iron added to the Ewald test meal answers all the above conditions. After the test meal of 60 gm. bread and 250 gm. water, he gives 30 c.c. of a solution of iron containing 1 mg. of iron to the cubic centimeter. This gives a proportion of 1 mg. iron to 10 c.c. of fluid in the stomach content. The motor proportion, that is, the proportion between the volume of the meal evacuated from the stomach and the volume ingested, varies in the normal subject between .7 and .9. The secretory proportion, that is, the proportion between the volume of pure gastric juice and the volume of the test meal evacuated, ranges in health from 1.2 to 1.5. Each stomach seems to have a constant composition for its own secretion. The variations in the acidity in a single subject seem to be merely apparent differences, probably due to the secondary secretion of Strauss, Pawlow and Alder, or to dilution of the gastric juice. He follows the Mathieu-Remond technic for obtaining the diluted stomach content one hour after the test meal. The fluid is separated into two parts, one to be chemically analyzed, the other to serve for the color test for the iron. For example, 120 c.c. of fluid are found in the stomach after the test meal of 300 c.c., and colorimetric dosage of the iron in the stomach content shows that there are 4.8 mg. in the 120 c.c. of fluid. As each milligram of iron corresponds to 10 c.c. of the original test meal, we know that there can be only 10x4.8 mg., that is, 48 c.c. of the original test meal still in the stomach, and 300 minus 48 c.c., which equals 252 c.c., have passed into the intestines. The motor proportion is, therefore, 252 divided by 300, which equals .87 in this case. As 120 c.c. were found in the stomach, and as only 48 c.c. were due to the test meal, the remainder, 72 c.c., represents the pure gastric juice. The secretory proportion is, therefore, 72 divided by 48, which equals 1.5. In 57 subjects examined the results of these tests corresponded invariably with the clinical data and progress of the cases. He prepares the iron solution by dissolving 1 gm. of pure iron in 10 c.c. of hot distilled water to which 2 c.c. of pure sulphuric acid have been added. After it is dissolved he adds 2 c.c. of pure nitric acid. The solution is slowly evaporated to remove the excess of acid, and is then diluted with distilled water to 1,000 c.c. Part of the stomach content is mixed with from 8 to 10 drops of pure hydrochloric acid to each 20 c.c. of the fluid. Ten c.c. of this mixture are filtered on paper containing no iron and are heated to boiling, with 10 drops of pure nitric acid to peroxidize the iron. Distilled water is then added to bring the amount to 10 c.c. When cooled, 5 c.c. of a 1 to 20 solution of ammonia sulphocyanate are added and the filtered fluid is ready for color comparison with a 1 to 20 dilution of the

mother solution given the subject. Ten c.c. of this solution are diluted with 5 c.c. of the ammonia sulphocyanate solution and the colorimetric test applied as usual.

26. **Blood Count in Surgery.**—Tuffier reviews the symptomatic value of the blood count during the operation, in infections and suppurations, in intestinal surgery, in cases of cancer, hydatid cyst, chronic glandular disease and in gynecologic affections. His conclusions are that examination of the blood has become an indispensable part of the surgeon's acquirements. It is liable to render the greatest services if the findings are interpreted at the bedside and in a wise and prudent manner. His experience has been that in case of cancer there is a marked and progressive reduction in the reds, paralleled by reduction in the hemoglobin, without much disturbance in the corpuscular value. There is also a hyperleucocytosis of from 10,000 to 15,000 with polynucleosis: 70 to 80 per cent. of the neutrophile polynuclears. The proportion of sugar in the blood is also increased, to 3 per 1,000 in some instances. These findings are not invariable, but when noted are presumptive evidence of cancer. The hyperleucocytosis occurs earlier, more constantly and is more considerable in sarcoma than with other tumors. As a rule, in his experience eosinophilia with a leucocytosis of 10,000 to 12,000, and a normal proportion of reds, or slightly above normal, were found with hydatid cysts; anemia with polynuclear hyperleucocytosis with cancer, and pronounced hyperleucocytosis with intense polymleociosis without anemia and without eosinophilia accompanied abscesses in the liver.

27. **Traumatic Separation of the Epiphyses.**—Kirmisson's long address on this subject was followed by a discussion in which Frolich called attention to the nervous complications that may follow separation of an epiphysis. These have included in his experience radial paralysis, atrophy of the muscles of the shoulder and cubital paralysis. Willems remarked that radiography is of little use in the diagnosis when the subjects are under 4, on account of the preponderance of cartilage in the part. Bardesco reported a case of separation of the lower epiphysis of the tibia in a child of 2. It was not reduced, and fourteen years later the leg was found 6 cm. shorter than its mate, while the femur was 5 cm. longer. Reiboul has observed 2 cases in which the separated epiphysis had turned completely around, requiring incision and wire suture to restore it to place. Walther thinks surgical intervention should be the rule in recent cases. In 2 thus treated he found that the obstacle to reduction had been interposition of a fragment of bone or periosteum. Kocher urged the necessity for surveillance even after apparently perfect reduction. In one instance he found that the separation had recurred after reduction and apparent healing in a cast. The function of the limb did not seem to be impaired. Kirmisson reviewed the symptoms and diagnosis of separation of the lower epiphysis of the femur, upper and lower of the humerus, lower of the radius, upper of the femur and lower of tibia and fibula. The age and the site of the lesion near a joint should suggest the possibility of separation of the epiphysis. The after-results of such a lesion are still a matter of conjecture. Careful study of the cases, with radiography, watching them afterward for years, are the only means for determining the remote results of such an accident. Some of the epiphyses are more important than others in respect to growth later, especially the lower epiphysis of the femur, the upper of the humerus and the upper of the bones of the leg. The age has also a great influence, as the more ossification that has already taken place, the less the after-disturbances. At the same time, the nature and severity of the trauma, the intensity of the inflammation, defective reduction and extent of resection of bone are factors in the prognosis.

28. **Nail in Treatment of Femoral Hernia.**—Roux of Lausanne concludes the radical operation for femoral hernia by fastening Poupart's ligament with a double-pointed nail driven into the crest of the bone. He has been doing this for eight years, and in 56 cases, operated on more than three years ago, there has been recurrence in only 2. The total material thus

treated has been 130. If the opening is very large he uses two or three of the nails with a suture. None of the nails has worked loose. They are made of nickled steel, and are quite long.

29. **Lever for Reduction of Congenital Dislocation of Hip Joint.**—Mencière of Rheims uses an apparatus, constructed on the principle of the lever, in reducing a congenital luxation. The force applied acts on the lever, not on the femur, and hence there is no danger of fracture.

30. **Pain in Case of Wandering Kidney.**—The pain may be continuous, or intermittent continuous, with exacerbations, or may occur in separate attacks. The subjects sometimes learn to put an end to these attacks by twisting the thorax in a certain way, which seems to restore things to place, as they say. The presence of a tumor in the lumbar region is sometimes the only means to differentiate these attacks from liver or kidney stone colics. The variation in the size of the kidney is the best sign, the tumor in the lumbar region during the attacks vanishing with their cessation. Another diagnostic aid is the examination of the blood for cholemia and segregation of the urine, which, repeated if necessary and the findings carefully interpreted, will solve the problem in dubious cases. The polyuria that follows the reduction of the tumor or the spontaneous cessation of the attack of pain is probably due to reflex excessive compensatory functioning of the normal mate.

31. **Color Cystoscopy.**—Czerny emphasizes the diagnostic importance of what has been named chromocystoscopy (intramuscular injection of 4 per cent. indigo carmin. See THE JOURNAL, xlii, page 69) combined with catheterization of the ureters or segregation of the urine.

32. **Urethroscope.**—Luys of Paris reports important results from the use of his urethroscope, which allows powerful topical applications exactly at the points in the bladder where they are needed, sparing the sound mucosa.

33. **Tuberculosis of the Kidney.**—The experience of Pousson of Bordeaux has been that the mortality in 9 cases treated by nephrotomy was 22.2 per cent., while it was only 1.58 per cent. in 19 treated by nephrectomy.

34. **New Symptoms of Pyelonephritis and Pyelitis.**—Bazy adds to the usual symptoms 3 others not described in the textbooks: nocturnal incontinence, sometimes superposed on nocturnal pollakiuria; a bladder-kidney reflex consisting in pain in the kidney when the subject has a desire to urinate, and, finally, pain on pressure of a point two finger-breadths from the median line above the horizontal ramus of the pubis, sometimes radiating toward the ureter.

35. **Decapsulation in Nephritis.**—Pâtean of Paris reported 5 cases which demonstrate that decapsulation is liable to prove a life-saving measure or, at least, prolong life in certain cases of parenchymatous nephritis or nephritis in cardiorenal subjects. It must be done while the organism is still capable of responding, before complete collapse of the means of defense, while oliguria still persists, with albuminuria or hematuria, and medical measures have proved ineffectual. Other speakers emphasized the benefits of nephrotomy or decapsulation in hematuric nephritis. Nephrotomy relieves the congestion, and decapsulation renders the relief permanent by providing a new circulation. These procedures have also a powerful algostatic, hemostatic and modifying action on the secretion of the kidneys. Pousson has had 3 patients with nephrorrhagia from nephritis, lithiasis or tuberculosis of the kidney cured by mere incision.

36. **Conservative Operations in Renal Retention.**—Albarran reports 4 cures in 4 subjects with renal retention. The ureter was found emerging from the pelvis at an abnormally high level. He resected the pelvic pocket below the opening into the ureter, leaving the latter intact and raising the floor of the pelvis to a level with the opening, cutting away as little of the kidney tissue as possible, but making it slope down to the opening into the ureter. In some of the cases he fastened the kidney to insure this slope.

39. **Gravidal Pyelonephritis.**—Rochard gives the clinical his-

tory of a case of extremely severe bilateral pyelonephritis in a woman of 30 in advanced pregnancy. The symptoms were so threatening that she was placed on the operating table, but at the last moment operation was postponed and she was normally delivered of twins ten days later, with immediate cessation of all the kidney symptoms. In Kendirdjy's statistics there were only 2 deaths in 62 cases of gravidal pyelonephritis. Expectant medical treatment is indicated, but if the physician's hand is forced, instead of operating on the kidney, premature delivery should be the rule, as the survival of the fetus is very doubtful in such severe cases. Cova has reported 21 cases in which nephrectomy was done, with resulting abortion in only 5. The danger of involvement of the second kidney is so great that it seems to be preferable to remove the cause, that is, the compression of the ureter by the distended uterus, rather than to attack the kidney.

40. **Cancer Treatment of Cancer.**—Renault reviews the various communications published recently on this subject. His conclusions are that cancer seems to have an unmistakable influence on the cancer, soothing the pain, lessening the physical signs, improving the general health and encouraging the patient, giving him a hope of cure. Whether it cures or not is another question, but it certainly prolongs life. Thirty-six cases have been reported this year as practically cured.

41. **Brain Symptoms in Alimentary Tract Infections.**—Nobécourt relates that infants affected with gastrointestinal troubles are liable to develop symptoms suggesting meningitis: strabismus, vomiting, Cheyne-Stokes respiration and a suggestion of Kernig's sign. Lumbar puncture shows the cerebrospinal fluid normal, and treatment of the digestive apparatus soon restored conditions to normal in his experience.

44. **Heredity in Pathology of the Kidneys.**—Castaigne and Rathéry present clinical and experimental data and pathologic-anatomic findings which testify that infants born to mothers with diseased kidneys have morbid kidneys. This weakness in the kidneys is sometimes so pronounced that they are unable to functionate properly, and the infants succumb during the first hours or days of life. Examination of the kidneys of such infants has disclosed invariably pronounced diffuse nephritis. The infants with less severe disturbances survive but display a "renal debility," with a tendency to albuminuria at the most insignificant causes, and the same is observed in animals. The serum and amniotic fluid of women affected with nephritis contain nephrotoxins and the passage of these nephrotoxins from the mother to the fetus was abundantly proved in the researches. Every woman affected with nephritis has certain substances in her blood serum which are highly toxic for the kidney. As these substances pass readily from the mother to the fetus, the latter is thus being constantly laved in these nephrotoxic humors. They may be so powerful as to render the infant non-viable, or they may permit its survival, but with weakened kidneys, a candidate for kidney disease and its consequences later.

46. **Torsion of the Spermatic Cord.**—Lapointe has recently collected 43 cases of complete torsion of the spermatic cord and 7 of incomplete, recurring torsion. Mohr has also observed 2 cases of the latter and Lejars describes another. His patient was a young physician, robust and healthy, with the exception of a small left varicocele. About 10 a. m. one morning he was suddenly seized with intense pain in the sub-

umbilical region, growing progressively worse, localized along the spermatic cord and testicle on the left side. When seen an hour later the abdomen was found retracted, sensitive to pressure on the left side, the testicle swollen and red, the cord thick and extremely sensitive, and no trace of hernia. There was no tenesmus, the pain did not extend along the ureter, and the pulse was good. On the assumption of torsion of the spermatic cord hot fomentations were applied and morphin injected. In three hours the entire syndrome had subsided and there has been no recurrence of the trouble since. These incomplete, spontaneously curable forms of torsion can not be demonstrated anatomically. They may yield to external manipulations, but careful surveillance is necessary to prevent complete torsion with its sequence of hemorrhagic infarct of the testicle. Enderlen's experimental research has shown that the testicle may recuperate within sixteen hours, but if the torsion has lasted twenty-two hours, consecutive atrophy is inevitable. An operation may be indicated in case the attacks recur frequently, to prevent complete torsion.

48. "Paraffinage" in Hay Fever.—Bründel has treated 5 or 6 patients with hay fever by injection of paraffin under the mucosa of the turbinates as in the treatment of ozena. The induration that forms around the paraffin prevents access of blood and thus the excessive secretion in hay fever is permanently cured.

49. Congenital Dilatation of the Colon.—This is called Hirschsprung's disease in Germany, Mya's in Italy, and Chéineuse claims the priority for a French physician, Oulmont, who described it in 1843. He reviews the literature on the subject and mentions that simple fixation of the dilated loop, although theoretically inadequate, has given good results in practice in the hands of Woolmer and Trezibicky. Enteroanastomosis has also been successfully applied, but the operation of election seems to be colectomy, as a number of reported observations apparently establish. This intervention, however, should be restricted to severe, threatening cases after failure of dietetic measures and systematic efforts to control the constipation.

50. Modification of Operation for Retention of Testicle.—Ruff modifies the Katzenstein technic by suturing the inguinal canal in such a way that the seminal cord is compressed to a certain extent. This compression is only sufficient to induce slight venous congestion in the testicle. This makes it larger and heavier, which prevents its slipping back and, by the traction, gradually lengthens the seminal cord. He has operated in this way on one subject and the results are most satisfactory in every respect.

51. Plus Pressure Narcosis Through a Tube.—THE JOURNAL has described Kuhn's method of intubation through the mouth or nose, and the possibility of thus bringing the anesthetic into direct contact with the lungs while avoiding any action from it on the upper air passages. He is preparing a compendious work on the subject, and merely announces here that all surgeons agree in commending this method of narcosis. He has found that it is possible to combine this mode of administering the anesthetic with the plus atmospheric pressure used by Brauer and Petersen for intrathoracic operations, a modification of the minus pressure of the Sauerbruch air chamber. No chamber nor apparatus of any kind is needed, merely the long tube. It passes through a broad rubber band

which covers the mouth airtight and fastens at the back of the neck. The nostrils are also closed airtight. The lungs and bronchial tree thus communicate solely with the long tube, and the chloroform can be easily applied. The tube is then connected with an oxygen tank to induce the plus pressure according to the Brauer-Petersen technic.

52. Non-Operative Treatment of Hip Joint Dislocation.—Schanz, in examining a child with this deformity, found that the luxation became spontaneously reduced when the thigh was brought over the abdomen in such a way that the axis of the femur crossed the umbilicus. He has since systematically used this technic. The assistant stands on the affected side and holds this side of the pelvis firmly pressed against the table. The operator, on the other side, draws the thigh up as described, placing the joint in flexion and adduction, and then exerts traction in the direction of the axis of the femur. Sometimes it is necessary to supplement the above by inward rotation of the thigh. Deep narcosis is not necessary. In older children it may be advisable to press on the trochanter in the direction of the axis of the femur. The head of the femur is thus replaced in the acetabulum, but it only lies loose there. In order to hold it there, the leg has to be placed in the retention position, as with the Lorenz and Hoffa technics, that is, in extreme abduction. This is painful and requires a trifle deeper narcosis. He then applies a plaster cast for from three to six weeks, and after its removal keeps the child in bed, but lets him use the leg as he pleases. When he begins to sit up in bed, a Heuser walking chair is supplied until he can walk alone. Any movements that might jeopardize what has been gained are inevitably painful for the child, and consequently he carefully avoids them. The results from this technic have been so far superior to what he had previously realized that Schanz commends it to the attention of all.

53. Button for Gastroenterostomy.—Jaboulay's button was illustrated in THE JOURNAL, xlii, page 1324. He has used it in 200 operations on the intestines. The mortality in 100 cases of carcinoma was only 18 per cent.

55. Action of Radium Rays on Animal Tissue.—Werner has been experimenting with capsules containing 10 mg. of radium bromid. He found among other things that the intensity of the physiologic action of the rays is not proportional to their fluorescence-inducing properties, nor to the duration of the exposure, but seems to obey certain very complex laws. Exposures of from sixteen to twenty hours cause changes in the tissues over an area from four to six times larger than the areas directly exposed. The penetration is not increased. Preliminary application of eosin did not seem to enhance the action of the rays to any appreciable extent. He found it possible, however, to enhance their action by preliminary brief, repeated freezing of the skin with ethyl chlorid or ether, by repeated dipping of the part in water at a temperature of from 49 to 51 C., by application of eron oil, by moderate, repeated venous congestion (the rabbit ear is a good object for these tests), by vigorous but brief and repeated expulsion of the blood from the part, and by repeated slight mechanical injury. These predisposing procedures must be repeated until the tissues become hyperemic and hypertrophied, with leucocyte infiltration. The exposures are then followed by a more prompt reaction, greater extension of the alterations and greater penetration. If the preliminary procedures are carried too far the tissues seem to become tougher and their susceptibility to the radium rays is lessened. It was found that the sores caused by exposure to the radium were very difficult to infect. Also that the radium was unable to dis-infect already infected wounds. Lecithin was exposed for two or three days to the action of the radium rays and was then injected subcutaneously. There was only very slight local reaction and all traces of it soon vanished, but two or three days after the injection the spot presented the phenomena of a typical radium burn, passing through all the phases of redness, swelling, blister formation, and necrosis of the epidermis. These facts suggest that the action of radium is

essentially an intoxication from the products generated in the destruction of lecithin, in addition to disturbance of the assimilation by changes in the lecithin. This harmonizes with the fact noted that tissues in which leucocyte infiltration has occurred are especially susceptible to the radium rays. He queries, in conclusion, whether the exposed lecithin has an elective action on elements especially rich in lecithin. If so, this suggests its possible application in therapeutics of leucocyte infiltrations, tuberculides and malignant tumors.

56. **Stopper for Artificial Anus.**—Two soft rubber balls communicate with each other by a small, short tube. The smaller ball is inserted collapsed into the intestine, which brings the other ball close against the outside of the anus. The balls are then inflated, which plugs the opening completely and the balls keep their place and are held firm without a bandage of any kind. There is no undue pressure, and the subject can turn the stop-cock to let out the air and remove and replace the stopper without aid.

60. **Improved Technic of Extramedian Symphyseotomy.**—Döderlein is enthusiastic in his appreciation of Gigli's mode of sawing the pelvis, apart from the median line, as a safe and simple operation in case of contracted pelvis. He has performed the operation eight times, and has somewhat modified Gigli's technic. He prevents undue gaping of the wound by tying a rubber band around the pelvis. This allows the sawed surfaces to separate enough to allow the passage of the head, but no farther. After delivery, the rubber band is removed and strips of adhesive plaster applied circularly around the pelvis. He considers it advisable to prepare for this extramedian symphyseotomy in dubious cases, but not to undertake it unless, in the course of the delivery, it proves actually necessary.

64. **Absolute Percentage of Cures in Carcinoma Statistics.**—Waldstein proposes a simple formula by which the absolute percentage of cures may be determined. It will enable the remote results of various technics and operators to be accurately compared, and shows the fallacies of the present antiquated methods of comparative statistics. The formula is:

$$\text{Absolute percentage} = \frac{O(100 - M)D}{10,000}$$

O per cent. represents the proportion of operable cases; 100 per cent. minus M per cent. represents the per cent. that survived the operation, M per cent. representing the mortality percentage, and the remainder, after subtracting M. per cent. from 100 per cent., representing the survivors. D per cent. represents the percentage of permanent cures. O per cent. of all the cancer subjects are operated on. Of this O per cent., M per cent. succumb from the operation. That is, M per cent. of O per cent. succumb. Expressed mathematically this gives $\frac{MO}{100}$ per cent. The survivors are, there-

fore, $O - \frac{MO}{100}$ per cent. The permanent cures must, therefore, be a certain percentage of this last term. The absolute percentage of permanent cures will, therefore, be D per cent. of $O - \frac{MO}{100}$ per cent., which may be expressed: $\left(\frac{100O - MO}{100} \right) \frac{D}{100}$. This can be simplified to the formula first given above:

$$A \text{ (absolute percentage)} = \frac{O(100 - M)D}{10,000}$$

By substituting L for the survivors (100 - M), the formula can be still further simplified to $\frac{OLD}{10,000}$

If the above factors (except the mortality) were the ideal 100 per cent., then the final absolute proportion of permanent cures would be the ideal 100 per cent.

66. **Affections Due to Wearing Out of Nervous System.**—Edinger reiterates his former assertions in regard to the origin of certain nervous affections. He is convinced that the demands resulting from the normal functioning of the nerves cause a wear and tear which is not always replaced by normal repair. The nerve fibers become used up and their elements are not duly replaced. The cells of the organism are balanced so nicely that none can be destroyed but the neighboring cells proliferate to excess or usurp the place of the weaker cell. Edinger accepts this as the cause of a very large number of nervous affections from the mildest professional neuritis to tabes, paralysis, optic atrophy, muscular atrophies and combined sclerosis. The group also includes the majority of congenital nervous affections. The close connection between these affections is readily demonstrable and is further established by the transitional forms observed. He gives a number of striking examples to sustain this view and also cites the results of experimental research which further corroborate his theory that functional use may under certain circumstances entail the destruction of nerve tracts.

75. **Immunization of Cattle.**—Friedmann's announcements in regard to the value of turtle tubercle bacilli for rendering other animals immune to tuberculosis were summarized on pages 136 and 624 of vol. xlii. He has succeeded in rendering guinea-pigs immune to injections of virulent bacilli, and his experiments with cattle have been equally successful. A single injection confers a high degree of immunity on the cattle, and the turtle bacilli are apparently entirely harmless. These two points are the chief advantages of the turtle bacillus over others that have been used for this purpose. He describes experiences with prepared bovine serum, pig serum and guinea-pig serum in which he succeeded in protecting guinea-pigs by serum treatment against virulent infection.

82. **Cancer Research Committee.**—Von Leyden has founded a cancer dispensary on the principles of the tuberculosis dispensaries in vogue in France and elsewhere where the patients are taught the necessary hygiene and measures to take care of themselves and prevent contagion of others. The care over them is extended to their homes, families and even workshops. Special attention will be paid to x-ray and radium treatment

of cancer. Michaelis reported further successful inoculation of cancer in mice. Juliusburger has been sifting a life insurance material of 7,981 deaths from cancer during the fifteen years 1885 to 1899. The figures show that the number of cases of cancer among the well-to-do is much larger than among the working classes; also that the age limit is from 40 to 70 in the former and from 50 to 70 in the latter. The stomach and the genitalia are the most frequent sites. He was unable to detect any conclusive connection between trauma and the development of cancer. A hereditary tendency was apparent in 3 per cent. of the well-to-do subjects and in 18 per cent. of the others, the maternal influence being much more pronounced. There were more victims of cancer in good hygienic surroundings than in the reverse. Nothing was discovered in these thousands of cases that testified conclusively in favor of a parasitic origin.

93. Priority in Prophylaxis of Puerperal Fever.—Baruch quotes from a recent important German work by R. Dorn, "History of Modern Obstetrics," 1903, which seems to settle the Holmes-Semmelweis priority question in favor of Holmes.

101. Inherited Immunity Instead of Inherited Predisposition.—Effertz has been traveling unfrequented paths the world around for more than twenty-five years, and has been particularly interested in studying the comparative pathology of different generations and races. He regrets that this study is so neglected. The more interesting a locality in this respect, the fewer the physicians and the lower the standard of their intelligence. Men with brains like to live in the cities, and there is no ethnologic originality to be found in the towns. And yet the present generation is the last one in which such ethnologic studies are possible, as races are blending so fast; succeeding generations will have to go to the libraries and museums to study them. He has been much impressed with the variations in the frequency and virulence of the affections noted among various races. Others have explained this by "inherited predisposition," but he thinks that a much better explanation is an "inherited immunization." His idea is that all infectious diseases have a tendency to diminish in virulence. Diseases pass through three phases: The miasmatic phase, that is, when they are transmitted by insects able to travel over considerable territory. Then, as they become less malignant, they can be transmitted only by direct contact, and we say they are "contagious." Then, as they become still less

malignant, they require still more intimate contact for transmission, and we say they are "venereal." All infectious diseases are destined to disappear gradually from the earth, but they retire in good order, obedient to these laws of becoming more benign, more infrequent and more venereal. The cradle of a disease should be sought, therefore, in races which have passed through these stages and have acquired an inherited immunity, so that these races are most exempt from the disease. Immunization by saturation with the virus does not seem to impair the general health. "Nature strikes with her hand but cures with her feet." Effertz has been residing lately in a remote corner of tropical Mexico, and his articles on the amazing immunity of the natives to syphilis and to wound infections have been reviewed here (XIII, pages 745 and 988). Their bare legs always have some scratch or sore, and these small ulcerations in time have induced an immunity to wound infections. He thinks that their immunity to syphilis is also due to inherited immunization. There is an extremely mild venereal affection observed among them, and this, he thinks, is the relics of malignant syphilis in preceding centuries. It is liable to transmit malignant syphilis to foreigners. Diseases can be exterminated only by inherited immunization. This theory explains the successes of serotherapy. He urges other physicians to study these questions by races, generations and centuries. Nothing can be learned by study of a few individual families. He suggests a question blank as follows: Among what races do you practice? At what place? When did syphilis, smallpox, leprosy, malaria, whooping cough and measles first appear there? What is the virulence of these diseases among the indigenous race, among the Europeans and among other immigrated races? Do the natives go barefoot?

103. Life Insurance of Northerners in the Tropics.—Van der Burg reviews in detail the various findings in subjects who reside permanently or temporarily in the tropics, as bearing on the question of life insurance. Chronic diarrhea and psoriasis exclude the candidates. Latent malaria may be revealed by a dose of sodium sulphate. If recovery is not complete there is usually fever afterward, readily suppressed with small doses of quinin. Special examination is required of persons returning to a temperate from a tropical region, with particular regard to the manner in which they bear the change, and also in examining for symptoms not encountered in the temperate climes. The companies should refer such candidates to physicians who have practiced in the tropics, and especially in the particular regions whence the candidate comes. Nothing will take the place of the intuition of practical experience.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

RELATIONS OF PATHOLOGY.*

LUDVIG HEKTOEN, M.D.
CHICAGO.

Ostwald, the inspiring interpreter of the great principles of science, states:

We have just passed through a period in which all sciences have been isolated, a period of specialization, and we find ourselves in an epoch in which the synthetic factors in science are gaining a constantly increasing significance. . . . Everywhere the individual sciences seek points of contact with one another; everywhere the investigator determines the value which his special results may have in the solving of the general problems. In short, all sciences are tending to be philosophical. Nowhere is this tendency toward fundamental explanation so great as in biology.

PATHOLOGY A DIVISION OF BIOLOGY.

Disease is the common lot of all forms of life—high as well as low, animal as well as vegetable—and it is the special province of pathology, the science of disease, to study life in its abnormal forms and activities. Hence pathology is a division of biology, and it is, in fact, pathologic biology, but its relationships as such have not always been so clearly appreciated as they ought to be; in part, this may be explained on account of the very special stress placed on its direct application to practical medicine in the service of the art of healing. For this and other reasons pathology in many respects has remained somewhat isolated among biologic sciences. The early pathologists took the almost exclusive standpoint of human medicine, and for a long time the vast resources of general biology remained practically unused in the study of disease. On the other hand, owing to lack of appreciation of the fact that disease is a phenomenon of life and to the unnatural separation of the biologic study of disease from general biology, the subject of disease has rather repelled the student of biology, who, therefore, seems to have neglected to utilize fully the approaches offered by pathology to a better knowledge of the phenomena of life.

In view of the extent to which man has busied himself with the study of all forms of animal life in all accessible parts of the world, is it not rather strange and an evidence of lack of co-ordination that the occurrence of cancer throughout the whole vertebrate kingdom should have been made out definitely only during the last year? Yet this demonstration by the Cancer Research Fund in London, as well as the further demonstration that cancer has the same fundamental characters as in man when it occurs in fish, reptile and bird,

render it extremely improbable that either climate or diet of man has anything to do with the direct causation of cancer, thus, putting an end to much needless speculation and materially narrowing the scope of a most important inquiry.

PATHOLOGIC PROCESSES IN EVOLUTION.

In some quarters disease has been regarded merely as an expression of inferiority and weakness, and as part, at least, of the means by which inexorable Nature carries out the verdict of extermination. Parasitism, for instance, has been designated as a weapon to eliminate those who fall below a certain standard. Consideration of the nature of disease from this point of view gives to disease merely a negative evolutionary significance, as it would cause no new and better qualities in the descendency. Closer examination would tend to show, however, that processes of disease may have a different significance of a more positive nature in evolution. There are numerous simple as well as complex physiologic processes which, when set in motion by abnormal conditions, appear to be of advantage not only to the individual, but also to the species. As examples of adaptive processes, at first sight of more special individual advantage, may be mentioned regeneration, hypertrophy, the interesting adaptations to new and strange conditions of which bones and vessels are capable, certain phases of thrombosis, and even atrophy which has been described as the faculty of an organ to adapt itself to conditions of diminished nutrition, thus circumventing necrosis, a faculty of great advantage when the period of diminished food supply is only temporary.

No one can fail to see much that is useful and advantageous in the complex reactions to injuries observed in inflammations, the significance of which has been greatly broadened through the well-known comparative study of Metchnikoff. In the ease of immunity, natural and acquired, our wonder knows no bounds, so marvellous are the precision and scope of the protective reactions, concerning which so much has been brought to light in recent years and which lend themselves well to comparative studies.

In the case of degenerations and tumors it is not possible to recognize any direct or indirect advantage, and certainly no one has yet been able to see malignant tumors in such favorable light.

In the instances first mentioned the pathologic reactions have physiologic prototypes; they are adaptations of physiologic processes. Regeneration and growth are taking place constantly in health. Phagocytosis, on which so much stress has been laid in inflammation, is merely an exaggeration of normal nutritive processes in certain cells. At present the production of antitoxins and other antibodies is best explained as the result of special adaptations of normal stereochem-

*Address in the Section of Pathology of the International Congress of Arts and Sciences, St. Louis, Sept. 22, 1904.

ical mechanisms whereby nutrition is carried on. A very noticeable difference between the physiologic and pathologic manifestations of these functions is seen in their imperfections and shortcomings under many of the abnormal conditions. Incomplete regeneration resulting in the formation of scars often has many disadvantages. Inflammations frequently establish conditions in themselves fraught with dangers. The reactions of immunity may not neutralize quickly enough the toxins nor destroy promptly enough the invading organisms. Hence there is abundant scope for the intervention of the physician armed with all the various appliances of his art, some of the most useful of which are the products of artificially produced biologic reactions.

But after all, these individual organisms must enjoy the best chances for survival and reproduction that suffer least harm because best able to adapt themselves and to protect the life and function of their cells under conditions of disease. Just as there are variations in the limits of physiologic regulatory mechanisms, so also there are individual differences of degree in the power of adaptive and protective reactions to establish themselves in disease and permit continuance of life. In progressive evolution it naturally must be in the descendants of individuals with the best adaptive and protective powers that an increasing completeness and perfection of such powers will be found.

Viewed in this light, many processes of disease assume a significance of positive character in biologic evolution, a point of view that would tend to increase the interest in pathology among the biologists in general, and thus further its development along broader lines and lead to co-ordination of knowledge and broad and still broader generalizations as to the causes, nature and processes of disease. At present we may be said to be gathering materials for this broader comparative pathologic biology of the future in the same way as older naturalists gathered materials for the biologists of the present day.

PATHOLOGY AND RESEARCH.

In certain fields, at least, the student of the pure science of disease is primarily interested in the knowledge of disease for its own sake without much thought or immediate care as to any prompt, practical use to which such additions as he may make to this knowledge may be put. It is true here, as it is in general, that most things are done only on account of the results expected from them in the future, but immediate technical utility is not always the sole guiding principle of the investigator in pathologic domains. The history of pathology shows him that in this science, as well as in its synthetic sciences, all actual increase in knowledge eventually helps to relieve suffering. Everywhere the most intimate relations may be seen between the progress of medical knowledge and the progress of medical art. Like other sciences, pathology furnishes many examples of the rather unexpected importance and the even profound influence of the new observation, the new methods of study, the new point of view that at first seemed to have but limited significance. Indeed, some of the fundamental ideas of scientific medicine have arisen in this way. It has been well said that no knowledge of substance or force of life is so remote or minute, but that to-morrow it may become an indispensable need (van Hise). We in America have, therefore, much reason to rejoice because of the strong movement that is starting in the interest of scholarship and of research

in pathology, a movement that, of course, does not limit its influence merely to the advancement of knowledge, but exercises as well a powerful influence on the diffusion of knowledge. The man who is so full of enthusiasm for pathology that he will "burn his lamp for its advancement," is likely to be an inspiring teacher illuminating the older knowledge with the discovery of to-day and placing the new facts in their proper relations to what is already known and to what will be known. Medicine in this country has been so preoccupied with building up medical education for the training of physicians that comparatively little energy has been available for the upbuilding of medical science itself. Thus pathology in the universities has not been taught until very recently in such a way that graduate students might take it up as a branch to be followed through long stretches of labor. This is regrettable, but in some of our universities pathology is now placed on equal footing with other natural sciences and fully recognized as a proper field for work leading to higher degrees, and this is a much-desired progress in a most important direction. The direct interest now taken by many persons in medical research, the institutes and funds their munificence has established, are also having a most profound influence on the development of pathology in this country. Another mighty current in favor of this development has set in from the scientific work carried on in our various governmental and state institutions.

PATHOLOGY AND SYNTHETIC SCIENCES.

Let us now attempt to trace briefly the present relations of pathology to cognate sciences with the object of learning, if possible, in which direction the hope lies for greatest progress and to mark out the paths along which our investigators must journey in order to gather the best materials for that wider and larger pathologic biology on which we are still to work. The clearest conception of the rôle that the more important synthetic factors have had and are having on the development of pathology will be obtained through the historic perspective. In this way, too, it may prove feasible to show how some of the special problems have been solved and to bring into relief the great co-ordination of useful knowledge exemplified by practical medicine and the influence on it that various sciences have had and are having through the medium of pathology.

THE ANATOMIC IDEA IN MEDICINE.

Anatomy was the earliest biologic science to receive cultivation. The first laboratory for the training of students was the anatomic. One cause, at least for this, if not the cause, was the downright necessity for physicians to become closely acquainted with the structure as well as the functions of the human body. It is consequently not strange that pathology in the modern sense should begin as pathologic anatomy, that is, with the study of the grosser, evident alterations in structure that result from disease and on which, in turn, rest many of the disturbances of function observed in disease. In its earlier stages pathologic anatomy busied itself with the accumulation of a store of facts and observations gained almost wholly by the examination of human bodies after death. Morgagni was the first to attempt any generalization from this store of facts, and by correlating the anatomic changes observed after death with the disturbances of functions observed as clinical symptoms during life, he was able to draw conclusions of fundamental importance in regard to the seats and causes, at least in

certain phases, of disease. This is the first instance of synthesis on a large scale of two biologic sciences in the study of pathology, namely, the physiologic or study of function, and the anatomic or study of structure. Morgagni's conception of disease as inseparably connected with structural changes in the organs was designated happily by Virchow as the anatomic idea in medicine, and this idea, the greatest gift of anatomy to medicine, proved of incalculable service in turning the minds of physicians away from speculation to careful, objective study of disease during life, as well as after death. We catch an interesting glimpse of Morgagni's own point of view in the following quotation from his writings:

The various steps in progress ought not to be disregarded, for, in difficult research, we derive encouragement from the recollection that, although the exertions of an individual may not advance philosophy in any perceptible degree, yet, owing to the power of experiment and the successive influence of opinion the most obscure and apparently unsuccessful inquirer may prove the first or the connecting link in a series of most valuable discoveries.

CELLULAR PATHOLOGY.

The next advance was the result of Biehat's introduction of minute anatomy and the demonstration that the organs consist of tissues to which the seat of disease now was referred. Before long came the epochal development in botany, under the influence of Schleiden of the cell doctrine, which was applied by Schwann to normal animal histology, and by Virchow in 1858 to pathology, the direct outgrowth being the justly celebrated cellular pathology, beginning an era during which medicine has made greater progress than in all preceding time.

Physiologic and pathologic processes were traced to the elementary morphologic constituents of living organisms—the cells. The famous phrase of 1855, "*omnis cellula e cellula*," completed the liberation of medicine from abstract speculation already begun by Morgagni and greatly furthered by John Hunter, Bright, Addison and others in England, and by Laennec, Louis and others in France. "The physician grew from a schoolman into a scientific observer, and the surgeon who appeared on the scene in livery and without learning grew from a handicraftsman to be a man of science." Pathology became a natural science. What rich new fields were not open for investigation! A vast amount of material was accumulated from careful clinical and morphologic study of individual cases, and the basis thus laid for the construction of general laws and fruitful theories of disease. During the earlier part of this period attention was confined largely to man, but it also was often turned in the direction of animals in the effort to penetrate deeper into morbid processes; the experimental method was used to interpret correctly observations made in the clinic and in the postmortem room.

Of fundamental importance for all branches of medicine was the resulting organization of the teaching and investigation of pathologic anatomy. Following the leadership of Virchow in Berlin pathologic-anatomic institutes or laboratories were rapidly established and soon recognized as indispensably necessary for teaching, for research, and for direct assistance to medical practice. In the further course of development these laboratories have undergone various modifications and enlargements of scope, principally as the result of the advent of medical microbiology.

With surgery and the rapidly developing surgical specialties, pathologic anatomy—gross and microscopic—

soon assumed permanent relations of fundamental character. The anatomic study of the diseases in question was followed by great progress in treatment, and the exponents of these branches of applied medicine did not remain merely receptive of the work of others, but have themselves prosecuted diligently pathologic investigations of great value. Indeed, in certain special branches, especially ophthalmology, otology and dermatology, the clinicians have long been practically the sole occupants of the fields of pathologic anatomy of their respective parts of the body.

The close study of pathologic anatomy, being largely the study of the results of disease, stimulated also to brilliantly accurate diagnosis of certain internal diseases, which, unfortunately, in some cases, was coupled with a disheartening therapeutic pessimism. Said the therapeutic nihilist Skoda: "We can diagnose disease, describe it and get a grasp of it, but we dare not by any means expect to cure it." That some of the followers of cellular pathology in the narrower, dogmatic sense, believed that the innermost secrets of disease could be reached by morphologic methods, and that functional disturbances always could be adequately explained by morphologic means, may now be regarded as an instance of the tendency man frequently shows to approach his problems from the least accessible points. These unfavorable tendencies in pathology led to the following protest by Clark in 1884:

We are so much concerned with anatomic changes; we have given so much time to their evolutions, differentiations and relations; we are so much dominated by the idea that in dealing with them we are dealing with disease itself that we have overlooked the fundamental truth that these anatomic changes are but secondary and sometimes the least important expressions or manifestations of states which underlie them. It is to these dynamic states that our thoughts and energies should be turned; they precede, underlie and originate structural changes; they determine their character, course and issues; in them is the secret of disease, and if our control of it is ever to become greater and better, it is on them that our experiments must be made.

Fortunately, Clark's warning had been anticipated by development. Virchow himself long before repeatedly emphasized that pathologic anatomy can not deal forever with the product without searching for the cause that led to its production. It seems to me that the following highly remarkable statement in the prospectus of the first volume of *Virchow's Archiv*, published in 1847, shows that the founder of cellular pathology had a wonderfully clear vision of the rôle pathologic anatomy was to play in the evolution of pathologic biology:

The standpoint we aim to occupy is simply that of natural science. Practical medicine the applied theoretical, the theoretical pathologic physiology is the ideal we shall strive to reach so far as our powers permit. While we recognize fully the title and the independence of pathologic anatomy and of the clinic, they serve us pre-eminently as sources of new questions, the answers to which fall to the lot of pathologic physiology. Inasmuch, however, as these questions, to a large extent, may be formulated only through painstaking and comprehensive detailed study of manifestations (of disease) in the living, and of the conditions in the dead, we regard the exact growth of anatomic and clinical experiences as the first and most important demand of the present time. From an empiricism of this kind will result gradually the true theory of medicine, pathologic physiology!

MICROBIOLOGY, ETIOLOGY, COMPARATIVE PATHOLOGY.

It was reserved for etiology, the offspring of microbiology, "to lift pathology permanently out of the level

of a purely descriptive science, for, with the entrance of a dynamic factor, a causal element, under the guise of micro-organisms, the experimental era began definitely."

The coming of microbiology, long foreshadowed by ingenious speculations concerning infectious diseases, at once made pathology broader and definitely comparative in its scope, thus widening its relations to general biology on the one hand, and to preventive and curative medicine on the other. It will be recalled that the founders of bacteriology—Pasteur, chemist and biologist, and Koch, physician—both made their appearance in medicine as investigators of animal infections. Infectious diseases constitute a predominant part in the field of pathology, and deeper insight into their nature required simple, easily controllable conditions accessible to experiment and analysis. This became possible by the discovery and study of micro-organisms which could be used to set in motion the complex phenomena of disease according to the pleasure of the investigator. In animals the course of a disease may be cut short at any time for the purpose of investigation and better insight obtained into the evolutions of morbid processes. The disease may be studied in all its phases. Hence comparative pathology rapidly became the refuge of the investigator finding his way blocked by the necessary restrictions governing the study of human disease. The great influence of the comparative method of study of infectious diseases is well shown in the relatively advanced state of our knowledge in regard to those human diseases of this class that are readily communicable to animals as compared with our ignorance in regard to the cause of certain other human diseases which, so far as we know, are not transferable to animals.

As the secrets of the vast domain of parasitism were revealed and the teachings of specific etiology and pathogenesis became appreciated, there sprang up in the place of the therapeutic hopelessness, inspired by the study of pathologic anatomy only, an increasing interest of enormous consequences in preventive measures. This was the natural outcome of the persistent efforts now made to follow the chain of causation so far as it was possible to go; for it early became established that the farther back of the immediate causes of diseases we can come, the more easily and economically are they controlled, and, reversely, the nearer we approach the period in the evolution of disease characterized by open manifestations the more difficult is disease to overcome. Hence the newer ideas of cleanliness and of surgical asepsis, sanitary science and preventive medicine—all are the offspring of the study of microbiology and etiology in a wide sense. Indeed, the great principle of prevention may be applied with perfect success, even when the actual cause of the disease remains unknown. The discovery by Walter Reed, for instance, that the cause of yellow fever is conveyed by a certain kind of mosquito, made it possible to prevent this destructive disease with absolute certainty, by destroying the mosquito.

INTERACTION OF PARASITE AND HOST. BIOCHEMISTRY AND IMMUNITY.

But the fundamental problems of etiology are not wholly solved by the discovery of the causative agent, however important this step may be: for it remains to explain how normal function and structure are upset by the entrance of this new factor.

Now the study of bacteriology and comparative pathology has permitted a deeper penetration into the nature and mechanism of certain infections. The discovery of bacterial and other toxins, complex soluble and diffusible chemical substances, and of their wonderful influence on the metabolism of cells, opened new and rich fields that under the hands of keen investigators have furnished precious materials for the advancement of medical science along new lines. Henle had anticipated many of our ideas of the interaction of parasite and host, but especially interesting are the teachings of Bretonneau in regard to the specificness of infectious processes, and the words of his pupil, the great Trousseau, have proved themselves of prophetic significance:

There are (in infectious diseases) two factors; one is the morbid germ coming from without, and the other is the economy about to receive it; there is required a special aptitude for the organism to respond to the action of the stimulus . . . when there is no such predisposition the morbid germ perishes.

It was necessary to erect the great structure of cellular pathology and to make brilliant and epochal discoveries in morbid etiology before the suggestions in Trousseau's statement as to the interaction of host and parasite could be expressed in such definite terms and given such enlargement in scope as in the genial and heuristic side-chain theory of Ehrlich. According to this theory, a toxin is poisonous only when it unites chemically with some constituent in the cell of corresponding stereochemical configuration; if the cell does not contain this particular constituent the toxin is harmless; and when these constituents course in the blood as the result of reproductive processes in the cells they are protective (antitoxic), because they unite with the toxin and thus prevent the disastrous union of toxin with cells. In other words, the substance in the body which, when situated in the cells, is a primary essential for the toxic process, becomes a curative agent when it enters the blood stream (Behring).

Fortunately for the therapy and prevention of diphtheria, tetanus and a few other essentially toxic infections, these antitoxins may be caused to accumulate in large quantities in the blood of certain animals when artificially immunized by the injection of increasing doses of the corresponding toxin. It was a happy inspiration, indeed, that led Behring, Kitasato and Roux to use the antitoxic serum of immunized animals for curative and prophylactic purposes, thus turning to the common good this innate faculty of the animal organism to develop in so marvellous a manner its own resources.

Supported by numerous experiments among the most imaginative and interesting of modern biologic investigation, Ehrlich's theory has proven a veritable master-key to some of the innermost secrets of toxic and antitoxic action and immunity in general. The theory has been found adaptable to other closely related problems in chemical biology, and its signal usefulness in promoting investigation in this complex field on broad comparative basis places it among the great theories of science.

Ehrlich's side-chain theory has been applied with great success to the explanation of the action and the formation by the cells of the various lytic or solvent substances for animal cells, particularly red corpuscles, as well as for bacteria. The active hemolysins, bacteriolytins and cytolytins are formed by the

union of two distinct bodies, amboceptor and complement, whose properties and affinities are being studied most actively. These substances occur to a considerable extent in the blood of normal animals, and may be induced to develop freely under the stimulation of the injection into animals of large quantities of the cells or bacteria to be acted on. The fact that hemolytic substances, though of a somewhat different and apparently less complex nature, are produced by certain pathogenic bacteria of common occurrence, especially streptococci, has given us a new point of departure for the study of the anemia that develops in streptococcal and other infections. By the aid of Ehrlich's theory it has also proved possible to explain the mode of action of the toxic substances in certain venoms, and in this particular field highly valuable facts have been established by the work of Flexner and Noguchi and of Kyes. In certain phases the subject has been beautifully simplified by the work of Kyes, who succeeded in showing that a definite chemical substance, namely, lecithin, may act as a complement to amboceptors in venoms, with which it unites as a crystallizable "lecithid."

The extraordinary complexity of the chemical substances produced by cellular activity is further illustrated by the group of substances known as agglutinins, which have the interesting property of drawing animal as well as bacterial cells together into clumps. Agglutinins may be produced by bacteria as well as by animals. It is more than likely that certain forms of thrombosis met with in infections are caused by agglutination of corpuscles, a form of thrombosis which has been designated as agglutinative. Experimentally, such thrombi are produced with ease by the injection of various agglutinating substances. In animals as well as in man certain infections, e. g., with typhoid bacillus, are associated with the development of agglutinins having a specific effect on the bacterium causing the infection. Such agglutinins are being used everywhere for two purposes: (a) To determine the nature of the infection for purposes of clinical diagnosis (as in the agglutination test for typhoid first introduced as a clinical measure by Grünbaum); and (b) to identify certain bacteria and establish their relations to the infection.

Furthermore, it has been found that the serum of an animal treated with a proteid form precipitates with that one proteid, a property that within certain limits appears to be specific. This has led to the use of specially prepared precipitating serums for the diagnosis of different proteids, e. g., the detection of human blood for medicolegal purposes, and for the study of the genetic relationships of certain animals—a study that in the hands of Nuttall has given results of general chemico-biologic interest from an evolutionary point of view.

Reviewing these remarkable developments, one is profoundly impressed with the fact that at the same time as they constitute a most important widening out of biochemical science they have added greatly indeed to the permanent resources of practical medicine, emphasizing again in the clearest way the everlasting identity of the scientific and practical. Let no one, at least in the medical profession, ever doubt the practical value of the knowledge that ripens on the tree of science! These developments also demonstrate that there are other modes of progress toward knowledge of cellular activity and biologic mechanisms under path-

ologic as well as normal conditions than the purely morphologic highway, which hitherto had been followed with great persistence in pathology.

Here we are dealing with chemical substances and chemical and physical processes which ultimately will be interpreted in terms of chemistry and physics. Already Arrhenius and Madsen have attempted to show that the laws of mass action and chemical equilibrium govern the reactions between toxin and antitoxin, an attempt that has precipitated a sharp controversy with the Ehrlich school, which can not but powerfully stimulate continued work in this field. Recently we have learned, too, that many salts in ionizable solutions and also more complex substances combine in such a way with the complements in normal and immune serums as to hinder the union of complement and amboceptor necessary for lytic action. Perchance it is in this direction that we may look for some insight into the changes in physiologic mechanisms that permit various organisms to enter and set up disease.

It seems that in the chemistry of immunity we soon may expect most interesting developments. The fact that lecithin may act as complement, that it forms a crystallizable "lecithid" by union with the amboceptor of snake-venom; and, further, the evidence now at hand that colloidal silicic acid may play the part of amboceptor, warrant the hope that before long complete analysis and perhaps synthesis of lysins may become possible.

THE SYNTHESIS OF DIFFERENT METHODS IN SCIENTIFIC AND PRACTICAL MEDICINE.

In the majority of cases we owe our first knowledge of the existence of distinct diseases to clinical observation. By keen study physicians were able to distinguish even between more or less similar pictures, but the clinical picture has not always proved adequate for the determination of disease-entities. The clinical manifestations of certain diseases are so much alike that differentiation finally was accomplished as the result largely of the study of the more or less characteristic structural changes in the tissues of the body. In some cases differentiation could be made only after the discovery of the specific causative organism. This was the case with diphtheria. The clinical manifestations and the local anatomic changes in the throat caused by the bacillus of diphtheria may be reproduced in streptococcal and other infections. Now it is self-evident that the real penetration into the nature of a disease demands its complete separation from other, in certain respects, perhaps, more or less similar diseases. In the case of diphtheria, for instance, complete etiologic differentiation was essential in order that the real value of diphtheria antitoxin might be learned. It may be mentioned, too, that it required the discovery by Koch of the same bacillus in practically all forms of human tuberculosis before the doctrine of the dual nature of this disease, at one time advocated by Virchow on anatomic grounds, received its final overthrow.

In various local inflammatory diseases, such as pleuritis, pericarditis, peritonitis, meningitis, and in many so-called septic conditions, i. e., local infections with general intoxication, but with or without bacteremia, the same clinical manifestations and anatomic changes may be produced by different organisms. The diseases being different etiologically are consequently also in all likelihood different chemically in spite of their clinical and anatomic similarities, and for these rea-

sons deeper penetration into their nature as well as progress in direct treatment will depend largely on study of the organisms concerned and the products of their activities. Clearly an essential step in this direction is the differentiation of the diseases on etiologic grounds. Other examples of analogous nature could easily be cited.

Now, practically every disease, the nature of which we in some degree understand, may be cited in illustration of the close synthesis of clinical observation (clinical pathologic physiology), pathologic morphology, etiology and microbiology, experimental and comparative methods, and especially more recently of chemistry, in the development of our knowledge of disease. To the fullest extent this is true of certain infectious diseases. Starting with normal physiology and anatomy these have become the principal methods by which material is accumulated for that pathologic physiology which Virchow put as the chief end of medical investigation. And it is along this road, too, that the medical student passes to reach membership in the medical profession; for here also "ontogeny repeats phylogeny." Finally, these are also the very methods of procedure employed by the real physician in solving the problems of diagnosis and so of treatment presented by the individual patient, no matter to what specialty the case may be referred in consequence of the great differentiation of medical art with which we are familiar.

Practical medicine is availing itself more and more of the methods of scientific medicine. The laboratory is entering into closer and closer relations with the clinic. For the purpose of facilitating investigations as well as treatment, it has been found advantageous to include various laboratories in the clinic, and the use of laboratory methods has extended to all departments of medical practice, where their field of usefulness is constantly enlarging. How these methods may be made most easily available for the practitioner has now become a problem of real urgency. Pathology is consequently a great force in the interests of integration as opposed to differentiation in medicine; for pathology gathers under her wings, like a scattered brood, all the specialties which, in their respective fields, are using the same methods of investigation.

Whatever the rôle of pure morphology in the investigations of fundamental biologic problems—and it does not seem likely that it will lose greatly in significance in this respect so long as biologists regard the peculiar complexus of physical conditions called structure as absolutely essential to life—it always will maintain relations of fundamental importance in medicine. Medical and surgical diagnosis rests to a large extent on the recognition of the nature and cause of gross changes in structure and their consequences on function. To the surgeon pathologic anatomy is a guide whose minutest direction he must obey. Exact clinical observation controlled so much as ever possible by anatomic examination will continue, as emphasized by Chr. Fenger, the mainstay of medical progress in every locality.

The value of microscopic anatomy in the study of diseases of the blood, in the differentiation of new growths and in inflammatory products needs only mention. Many of the methods of microbiology are essentially morphologic. The established classification of bacteria is based on morphology, and the studies of the relations of micro-organisms to the cells of the body—often a matter of great importance—requires morphologic methods.

I believe there is no room for the opinion one occasionally hears expressed to the effect that the value of the usual methods of morphology and microbiology in scientific pathologic investigation has been exhausted. Of course the field can not be said to be so large as at one time, but there are still problems enough demanding the use of these very methods, refinements and improvements in which are constantly increasing their usefulness. Unquestionably advances in our knowledge of functional localization and in the tracing of conduction paths in the central nervous system of man will continue to depend in the main on the careful study of anatomic lesions and the functional and structural consequences. Blastomycetic dermatitis and paratyphoid fever are brilliant examples of "new diseases" recently established as the result of purely morphologic and microbiologic methods of study in fields long diligently explored. In trypanosomiasis and piroplasmosis of man and of animals we have other examples of interesting diseases, for the recent knowledge of the existence of which, as etiologic entities, we are indebted chiefly to clinical observation and morphologic studies of the blood. These facts indicate that microbic etiology may yet be forced to yield up hitherto carefully guarded secrets to more or less familiar methods or new modifications thereof.

In pathology, purely morphologic methods have surely as great importance in establishing etiologic relationships and as a means of orientation in various forms of investigation as they have in unraveling the intricate connection between structure and function. Progress in the domains of microscopic pathological morphology and progress in normal morphology will always be mutually helpful because pathologic cellular changes—necrosis, necrobiosis, degenerations and proliferations—are probably largely identical with normal cytomorphosis, being abnormal only as to time and place. A recent morphologic observation of great interest is that by Bashford and Murray of a process of conjugation in cancer cells. These observers found in cancer cells nuclear changes similar to those by which sexual cells are prepared for fertilization, and also fusion of nuclei equivalent to the process of fertilization known as conjugation. This discovery (if confirmed) will help to turn the search for the causative factor in cancer directly to the very processes in the cells themselves, a direction indicated already by the facts that cancer always "breeds true," that it is transplantable only within the species in which it originates, and that it behaves as an independent organism.

Undoubtedly the newer methods of study of recent microchemic reactions in normal cytology will prove valuable also in pathologic cytology. Perchance this synthesis of morphologic and chemical methods in time may give us some insight into the normal relations and time sequence of chemical reactions in biologic processes, normal as well as abnormal.

It proved to be an auspicious day both for chemistry and medicine when Pasteur conceived his biologic theory of alcoholic fermentation. Ludwig's prophecy of forty years ago that chemic physiology would largely prove a study of catalytic reactions has come true, and the cell is now no longer considered as a simple structure, but rather as a most complicated machine, the working of which for the most part is dependent on enzymes. Into the finer details of the manner in which these mechanisms may be disturbed under abnormal conditions we as yet have hardly been permitted to

penetrate, but the extensive recent researches dealing with the nature and mode of action of ferments in divers physiologic activities have awakened a lively interest in fermentations in pathologic processes which augurs well for the future.

Among the many intracellular ferments those causing self-digestion or autolysis of cells are thought to play an active and essential rôle in the removal of dead material, such as dead cells, necrotic tissue in infarctions and inflammatory exudates. Some idea of the fermentative activities in autolysis may be obtained from its action in pneumonia. In a few days autolysis may so alter a mass of exudate weighing several hundred grams that it is readily removed from the lungs by absorption and expectoration.

The biochemic mechanisms of normal and pathologic pigment formation have now been shown to depend on the action of oxidative ferments.

Cohnheim's demonstration that two enzymes, one coming from the pancreas and the other from the muscles, are necessary for the oxidation of sugar, appears to be a long step toward putting the pathogenesis of diabetes in an entirely new light. While these and other oxidizing ferments are the products of cellular activity, it at once suggests itself that they need not be the products of the cells of the same body which is later to use them, and the idea has been expressed that they may be introduced as needed much as antitoxins now are introduced (Long).

The results of the work of Croft Hill and of Kastle and Loewenhardt on the reversibility of ferment action have been eagerly grasped by pathologists and made to throw new light on the problems of fat absorption and translocation. Indeed, the newer chemic methods of study are changing completely our older ideas about fatty changes in the cells, ideas that were based almost wholly on morphologic appearances. Great progress has been made also in other respects in recent years from the application of the methods of physiologic chemistry to pathologic problems, but I must refrain from going into further details. As a result, the field of pure chemistry as an aid to medical diagnosis is enlarging, not merely as regards various analytical procedures for the testing of fluids and other substances, but the newer methods of physical chemistry, such as testing the solution content by electrical conductivity and cryoscopy have also been found useful in order to obtain information of help in reaching a correct diagnosis or a better understanding of the nature of the functional disturbance.

As indicated in the foregoing we are now at the beginning of an era of the application of physico-chemic methods to many problems in medicine, problems that at one time were regarded as approachable only by so-called biologic methods, and the number of problems that lend themselves promisingly to this form of treatment seems to be constantly increasing. I have referred already to their use in the study of chemic problems in immunity. The many fundamental problems connected with the constancy of osmotic pressure in the fluids of the body; the great influence of osmotic disturbances in the production of edema; the part played by inorganic salts in various phenomena and the interesting relations of ions to proteins; the physico-chemic properties of ions of various salts in relation to pharmacologic action—these are some of the questions that are being actively studied with results, in many cases, of far-reaching importance.

In many of its phases this departure is the outcome of the application by Loeb and others of general chemistry to biologic study, the results of which have been followed with increasing wonder as they have shown us the extent to which life phenomena can be controlled unequivocally by chemical and physical means. Many of the manifestations of life are physical in character, but biologists are agreed that the source of energy in life phenomena is chemical, and that general chemistry therefore must form the foundation of biology. From this it follows directly that the deeper, fundamental explanation of the mechanisms of pathologic processes also requires chemical and physical methods. Henceforth chemistry will play an increasingly important rôle in the efforts to reduce the phenomena of pathologic biology to simpler laws. We thus find that sharp lines of demarcation can not be drawn between normal and pathologic biology; for progress in one naturally exercises determining influence on progress in the other, and in both development is in the direction of closer synthesis with physics and chemistry.

Medicine has been called the mother of sciences, and not without reason. She gave to physics Galileo, Mayer, Helmholtz; to geology, Steno; to botany, Linnaeus; to biology, Huxley; but as pointed out by Sir Michael Foster, her children are ever coming back to help her. In medicine as a science and as an art many sciences converge—physical, chemical and biologic methods join hands for the advancement of knowledge and the relief of suffering.¹

THE RELATION OF THE PHYSICIAN TO SANITATION.

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON HYGIENE AND SANITARY SCIENCE, AT THE FIFTY-FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, AT ATLANTIC CITY, JUNE 7-10, 1904.

GARDNER T. SWARTS, M.D.
PROVIDENCE, R. I.

On the question of hygiene and sanitation much, if not all, of the practice of medicine rests. The nearer that the individual personally and the nearer the public or masses of individuals collectively live and conduct themselves in accordance with the conditions provided by Nature, so much less will be the need of med-

1. Of the various articles from which I have drawn freely in preparing this address I would mention the following especially: Barker, L. F.: The Unveiling of the Cell, THE JOURNAL A. M. A., March 1, 1902.

Welch, W. H.: Biology and Medicine, The American Naturalist, 1897, vol. xxxi, 756-760.

ical interference. What a sepsis is to the surgeon, perfect hygiene is to the medical practitioner. Unfortunately, however, under the stress of accomplishment of great results in every line of effort except that of health, Nature's pristine conditions are forgotten and abuse of all her natural laws follows.

In the effort of the ignorant mother to improve on the diet provided by Nature, she seeks to add to the infant's strength by feeding it with all sorts of indigestible foods. The woman of knowledge, striving for social eminence, forces on her infant a diet, scientific, perhaps, but precarious, and the child's start in life is made with the handicap of a weakened intestinal tract and softened bones, a system, which in the next few years, serves as a good nutrient pabulum for the growth of the numerous bacteria especially provided for the growing child.

As the child grows, lack of knowledge in quarantine precautions or false economy in municipal administration makes it possible for him to acquire the many communicable diseases.

Fortunately, the ancient superstition that it was desirable to have these diseases in childhood is passing, yet there are still medical men among the older members of the profession who, while they do not think it desirable to willfully expose a child to smallpox, believe that it is well to acquire measles, for the reason that a child is pretty sure to acquire it anyway, and if enjoyed in childhood the course of the disease will be milder than if undergone in adult life, forgetting that the sequelae from an attack of measles frequently incapacitates the child from full power of sight or hearing.

With the great advance made in the construction of school buildings and with the medical inspection of schools, one peril is minimized, but the stress and the demand made on the nervous system of an over-full curriculum has nearly reached the maximum of tension. To be sure, the development of the race in American precocity supplies the schools with nervous systems which are active and which possess a tensile strength which is increasing with every generation. Yet to this there must be a limit for practical utility.

Through the next stage of life the adolescent lacks a full understanding of hygiene, which should be taught more exactly, frankly and honestly at this period. He is exposed, if installed in college or separated from home surroundings in order to earn a livelihood, to the danger of alcoholic excess; less often to excessive use of tobacco, but always to the venereal peril which is treated with concealment by layman and professional.

Through adult life continuous demand is made on the system to do more than it is equal to. Overfeeding, on the one hand, and shortened periods for eating to gain time for work on the other, allows the normal functions little opportunity to produce a perfect constitution. If the digestive tract is not abused the nervous system is overtaxed.

The pitfalls are many, and the average man and woman succeeds in finding some one of them and Nature and her instructions are forgotten.

It is evident that the journey is perilous and a puzzle to one who stakes his intent on cause and effect, and he involuntarily quotes the statement that if he were God and if he had the making of man he would have made good health catching instead of disease.

But these dangers exist. Many, if not all of them, are avoidable, and the spread of many may be controlled. The health officer is the one appointed to see that the

means of prevention are applied. He does so in proportion as the knowledge of modern sanitation may be possessed by him, and to the extent that his superiors supply him with the power and the money to apply that knowledge.

For the purpose of obtaining the latest and most perfect knowledge of the laws of hygiene and sanitation, the American Public Health Association meets once a year. For a perfect understanding as to the best means of applying this knowledge in a practical way, the Conference of State and Provincial Boards of Health of North America meets once a year, and its membership is made up of the executive and active health officers of the states and provinces and the country of Mexico. By provision of Congress, an annual meeting is to be called by the surgeon general of the Public Health and Marine-Hospital Service with representatives of the health boards of the various states.

The power for good in this line of investigation and application of interstate sanitation and quarantine and in reference to health matters in the broadest sense is illimitable, and will probably serve the various states with much information and assistance, especially in the management of diseases transmissible from state to state, and which may be introduced into the United States from abroad.

The Bureau of the Public Health and Marine-Hospital Service has for its executive administration six divisions for working out different lines of work for national sanitation. These divisions are as follows:

- Division of Marine Hospitals and Relief.
- Division of Domestic Quarantine.
- Division of Foreign and Insular Quarantine and Immigration.
- Division of Sanitary Reports and Statistics.
- Division of Personal Accounts.
- Division of Scientific Research.
- Miscellaneous Division.

We also have for our instruction in sanitation this section, termed the Section of Hygiene and Sanitary Science of the American Medical Association.

With the existence of these three other organizations the question may be properly asked. What need is there of such a section? Whatever has been left undone by these three can be considered by this section.

It must be remembered that the American Medical Association is composed of practitioners, physicians and surgeons, who are interested in their work, to be sure, but, while they have a certain amount of knowledge of hygiene and sanitation, yet when questioned or when they meet with conditions calling for an opinion in reference to sanitation, whether it be a question of quarantine or plumbing, it will be found that their knowledge does not extend beyond the ordinary knowledge of the laity.

The instruction in hygiene given in the various medical schools, with few exceptions, is notoriously poor and inadequate. The students shirk attendance on a subject which does not appeal to them and is not popular, and for which they are not shown that there is any practical demand. This is frequently apparent in the examination papers presented and answered at the several state board examinations. On these subjects the markings are extremely low, and the applicants confess that the course given at college was not very interesting.

Of the graduates appearing for state examination at the present time are many able practitioners who still entertain the belief that sewer gas is capable of producing the specific diseases of typhoid fever, scarlet fever and diphtheria, and that malaria is produced by

the miasm or a condensed humidity arising from marshes.

To be well posted on sanitary beliefs and facts, necessitates that the practitioner be alive to the published matter on these subjects in the voluminous medical journals of the day. Radium and its uses may be interesting and require much attention to meet the queries of a curious public, but if the physician neglects the various articles on the mosquito theory of the transmission of disease, the rôle which the common house fly may play in the spread of various communicable diseases, or the bacterial possibilities in a vast number of diseases, he will be tripped by the heels with short explanation by his patients who, at the present day, are kept well posted by the lay press; and, as stated in the beginning of this article, he will find that medicine rests one of its numerous feet on sanitation, for cause, effect and treatment, for treatment in many cases consists of prevention. One may ward off a chill in malaria with quinin, but can not prevent the return of the disease nor the spread to others unless the mosquito is excluded.

From the small attendance at the last meeting of this Section it would appear as if there was little need of its continuance. This has long been my opinion. The failure of the Section to attract can not be ascribed to the failure to present good subjects and able papers from prominent men, but the subject here, as in the medical schools, is considered too remote from the researches of the physician on his daily routine work.

Other sections present more topics of general interest, and the members can not be in two places at once, although at the sessions of the American Medical Association this desire is strong. The organization is so broad that it is hard to live up to it all. It is worse than the three-ring circus with its continual whirl of changes.

The interest in the subjects presented at this Section is to the general practitioner no stronger than the interest of the laity for the same subjects. The average business man will give more attention to an address on the practical subject of purification of a water supply by filtration than will the practitioner, yet he, the shepherd and guide of his patients, should be thoroughly posted in such practical matters which influence the health, not of his patients alone, but of every citizen in the city using the water supply.

The advance in our knowledge of the bacteria has permitted of a more perfect understanding of the means of transmission of communicable diseases. Unless the general practitioner follows the reports of the medical journals giving the results of experimental investigation on these lines, he will find his system of quarantine somewhat antiquated with the visit of the live health officer of the present day. The old practitioner, believing in contamination of atmosphere either in gaseous combination or a chemical one or in some injurious combination, fears all air which may be in and even about a house where diphtheria or scarlet fever exists.

When acting as medical inspector for communicable diseases, I have met with the following conditions: In the back entrance of a house I have found chlorid of lime exposed in a plate or saucer; hanging in the doorway of the room occupied by the patient, sheets saturated with carbolic acid; reaching the bedside, a quantity of raw onions in a receptacle under the bed; hanging on a cord around the neck of the patient, a bag of camphor. An undoubted wealth of foul odors gener-

ated, evidently, for the purpose of stifling the miasm and catching the vicious microbe in his winged flight, even to the lower stairway and out the back door.

If these attempts were for the purpose of deodorizing one might have respect for the effort, and yet this method of purification, unless its purpose and the limit of its effect is understood, is liable to lead the attendant into a false sense of security.

The results of the investigations of our expert bacteriologists have shown that the presence of the moribific material or specific organism in diphtheria does not reach much beyond three feet from the mouth of the patient. The center of infection is in the throat, and may be communicated only from that point, hence the mouth, and utensils and hands coming in contact with the mouth, is the limit of the infectious material. Of course, these utensils may be transported to other rooms, and if used without washing, may be a distinct point of infection.

Unless there is coughing or expulsive respiration, or in cases where the attendant is a careless person, the secretion of the throat be smeared on the clothing, the possibility of carrying the disease is remote.

If the practitioner would concentrate his quarantine on the center of infection instead of laying so much stress on the observation of unnecessary rules and the use of disinfectants in places where they can not possibly find any contagion to disinfect, his results would be more satisfactory.

Among the communicable diseases which have prevailed from time prehistoric, the physician is brought into contact with the venereal group. While gonorrhœa and syphilis have been declining in severity for several generations, yet some of our colleagues can tell us of the ravages which these two diseases produce in the full light of civilization.

These diseases are preventable, yet they continue to thrive. It is the duty of health officers to check preventable diseases, but if they are not informed of the location of the disease it is impossible for them to check it.

The physician is continually cognizant of the location of these diseases and of the source from which they come. Some caution their patients as to the danger after the patient has already paid for his experience and knowledge. Why was he not warned before in some practical way?

The Conference of State and Provincial Boards of Health, at its meeting in Washington, adopted a form of letter, copies of which shall be furnished by boards of health to physicians.

It is hoped that the physician may be able to assist the health officers and the public by placing these few trite statements in the hands of their afflicted patients, and at least warn them against communicating their disease to others.

The physician will claim that he invariably cautions his patients concerning the means of transmitting these diseases, but in the embarrassment and excitement of the consultation it is doubtful if many patients remember much of what has been said to them. In the immediate danger which is presented to their own person they are apt to disregard the far-reaching possibilities of the spread of the disease from themselves, or if they do know, on partial recovery, will lapse from their previous good intentions and become careless.

If a circular can be presented to them which they may preserve and read in the seclusion and quiet of

their own rooms, the impression of what and how will be more firmly fixed in their minds. The health officers are prepared to furnish the means, and it is now incumbent on the physician to do his share of the duty in giving warning.

There is one other matter wherein the physician often fails in his duty as a sanitarian. On physical examination of a patient it is determined without doubt that the person is suffering from pulmonary tuberculosis and is informed that "he has some trouble with his lungs," but the physician has not the moral courage to tell him that he has consumption. He may be sufficiently sordid to fear that the patient will consult some one else, and the second consultant will deny the presence of lung trouble for his own gain. Others may prefer to put off declaring the presence of any tuberculous affection, hoping, perhaps, for favorable results under treatment.

The patient, having no knowledge of the pressing need of care and attention to his ailment, does not again consult a physician until forced to do so by the advancement of the disease, and perhaps after a sufficient period to have become a menace to the public.

Herein lies one benefit to be derived from the examination of sputum by health boards. The physician, having explained the necessity of making an examination of the sputum to determine the presence or absence of tubercle bacilli, is placed under obligation to report the result to the patient, for he will make inquiry as to the result. In many cases it may be the only object of the patient in returning to the physician. Feeling comparatively well they do not feel that they need treatment, but curiosity stimulates them to ascertain the result of the examination.

Having determined positively the presence of tuberculosis, the intelligent physician at once emphasizes the necessity of care on the part of the patient not to allow any secretions from the mouth or lips to be transferred to other mouths or throats either by kissing, testing the baby's milk for warmth by drawing on the bottle nipple, allowing others to drink from the same glass, the use of towels in common with others, and the danger of promiscuous expectoration.

Boards of health making examinations of sputum for physicians present to the physician, with each positive report of the presence of the bacillus of tuberculosis, a circular setting forth in simple language the method of communication of the disease and the care required to prevent it. The departments, in a note to the physician, express the hope that it will be possible to place the circular in the hands of his patient, or at least with some member of the immediate family. How far this request is complied with can not be known to the department at the present time, inasmuch as the inspectors may not as yet interfere with the case by calling on the patient for any general information, and fearing that the increasing willingness of physicians to report their cases to the department may receive a check. Any visitation at this time without the consent of the attending physician causes him to conceal his cases, and thus much headway is lost in the difficult effort of health boards to obtain limited restriction of the spread of the disease.

The time will come, however, when the physician will see the desirability of co-operating with the health department in the control of this disease. The strong opposition to this is shown in the refusal of physicians to report their cases of consumption. It is claimed by some that there is nothing to be gained by it. Let

the cases be reported and let the health department determine what value there may be in such a procedure. As a rule, health boards are not arbitrary in their administration. When they are seemingly so, the public and the majority of the profession agree with them. It is usually an individual who is offended. He does not believe in compulsory vaccination for school attendance. He does not see the need of quarantining a child recovering from diphtheria, prohibiting attendance from school, when, in his opinion, the child is physically well. He may believe in the Klebs-Loeffler bacillus as a causative factor in this disease, but he fails to see the possible connection between a patient who is able to be about and any other susceptible throat which may come in contact with the first case.

The physician can not understand why a patient shall object to use quinin for malaria when a majority of physicians have determined its value; yet he in turn fails to see that the health departments have had a long and varied experience with the methods of control of disease, have met more than his one individual case, and should have a better average knowledge of what to do.

If physicians would willingly report their cases of tuberculosis and designate in what particular cases the health boards could be of service in assuming the responsibility of instructing the ignorant classes, much could be done by judicious inspection, repeated from time to time, and by giving special directions how nutritious food may be prepared and the maximum of ventilation obtained under the most adverse circumstances.

The experiences of New York City, the pioneer in this movement, have shown what may be done as a beginning. Much has been accomplished, even in the face of fierce and continued opposition coming from medical societies.

It was not so many years ago that the profession opposed the compulsory reporting of scarlet fever, diphtheria and typhoid fever, yet the boards have shown, by persistent effort, the need of such reports, and also that they are disposed to act only in accordance with generally accepted views and knowledge of the methods of transmission.

Learning by constant experience, the various boards reduce the border of their cordon to within practical limits, placing as little unnecessary restraint on the quarantine as is found from experience to be safe. This varies with the period of experience in the observation of certain states and towns. The character of the population, the reliability of the medical profession and the character and severity of diseases vary with each locality.

Where it might be necessary and desirable to place a cordon of police about a limited district in the presence of smallpox, yet by experience it has been shown that in different localities, even in the same state, a perfunctory quarantine is all that is required, and that in some instances mild measures of restraint, even with the ignorant class, may serve the end better than by creating unnecessary opposition, which it may be absolutely impracticable to compete with.

In some cities, in exercising quarantine in the presence of diphtheria, the bacteriologic and laboratory findings control the time limit of restraint or isolation. Other municipalities, which have adopted the requirements of a negative culture from the throat or from the throat and nose before raising quarantine, have discov-

ered the impracticability of enforcing this rule in the majority of cases.

Boards are exercising their best judgment and experience both in requiring a prolonged quarantine on the one hand, and a limited one on the other. The first may later find that a short period will fill all practical requirements.

The city of Providence, R. I., was, I believe, the first city after New York to introduce the culture method in the exercise of quarantine. The pendulum swung to the extreme of requirements, and after averaging the period of detention in all cases of diphtheria, a minimum period of ten days after disappearance of the membrane was all that was called for, a negative culture for release not being required after that time. While this seems to the rigid adherents of culture requirements as extremely lax, yet the results have not been so alarming as would naturally be predicted. The only objection to this rule that has appeared is that the physician and patient make just as much fuss over a detention of ten days as they do over one of fourteen or twenty, and perhaps the health officer might as well impose the longer period.

I cite these varied methods merely to impress on the practitioner that the health officers of the present day are working on reasonable grounds and as the result of experience, and that they are not endeavoring to demonstrate an autocratic control. They surely have enough other troubles in their routine work not to stimulate unnecessary opposition from their ally, the medical profession.

There is one other relation which the medical profession holds to good sanitation and in which they might be of invaluable assistance to the health authorities, but in which their neutrality remains a stumbling block. I refer to the attitude taken by the profession in regard to the general milk supply.

A physician imagines that he is very particular about his food supply, especially the water and milk. His worshipping clientele and the public also support his imagination in this regard. If Dr. Puritan is taking his supply from Farmer Littleclean, the inference is direct that the supply must be beyond reproach, and the various patrons of Farmer Littleclean are buoyed up by the repeated assertion that Dr. Puritan has taken milk of him for many years. No matter if the milk sours, on ice, within a few hours of delivery to the consumer, yet it must be the best to be obtained, for the physician, the adviser in sanitary matters, has the same supply.

Fortunately in this matter, some of the laity are thinking for themselves; the beshrined tin god who has been for generations worshiped on a pedestal is now admired on a level ground with his patient. The respect due to his necessarily assumed but undelivered knowledge in the past is now supplemented by a request for assistance on the grounds of common sense and reason. The people are instructed by the sanitarian and the public press, and the journals of health departments present facts and figures showing the quality or lack of quality of the foods ingested by the public and showing the death rates which accrue from the ingestion of these foods, especially that most common one, the lacteal fluid of the common cow.

Perhaps one of the most surprising conditions of indifference to sanitary affairs is shown in the attitude or lack of attention to the filthy condition of the public milk supply. A food which is utilized for all conditions

of depressed states of the system, the only food of the infant, the selected nutrient in typhoid and other wasting fevers, this necessary adjunct to our life is accepted without question from whatever source the supply chances to come.

While in recent years specialists in children's diseases and certain men of adventure and independence have sought to encourage the production of milk, under sanitary conditions, yet the mass of physicians manifest no active interest in the encouragement of such a venture. In order to ascertain whether this statement had foundation, a few years ago I made inquiry of all physicians in good standing in my state concerning their knowledge of the general supply and their willingness to assist in a campaign for clean milk. Among the large number of answers received it was found that a small number were acquainted with the name of a dealer from whom they received their supply, and only a few knew the conditions under which the milk was collected and had visited the barns where the cattle were housed. Many knew that they were supplied with a good quality of milk because, forsooth, the farmer who supplied it was an honest person and had had a good reputation; he had been in business for a number of years, and while they were sure he would not water his milk, yet they were not quite sure that the jars in which the milk was delivered were free from sediment. In many cases it was admitted that the milk soured if kept over twenty-four hours, and sometimes it was found to be sour when delivered.

When asked if they would be willing to pay an advance of from one to two cents above the present price of milk, four or five were willing to do so, two or three of whom would discontinue this unnecessary expenditure as soon as the baby was old enough to take other food.

While the average physician is fully aware that the introduction of fermentative material strongly infected with bacteria of decomposition is hardly a proper food for an invalid, and that the feeding of cow-barn refuse, even to the healthy man, is hardly a sanitary measure, still they are not at all willing to assist the health officers in any genuine, active crusade to this end. Many states have required that the milk should have a certain standard of quality as regards fats and solids. Certain cities have made regulations requiring a license which shall be issued only to dealers who produce and collect their milk under prescribed sanitary conditions. Among these may be mentioned the city of Buffalo, and during the last month, in the city of Boston, regulations for the sale and care of milk require that the cows from which it is derived have, within one year, been examined by competent authorities and shown to be free from diseases dangerous to the public health. Milk shall not be stored in any building used for the stabling of animals, or for the storing of manure, or in any room used for domestic or sleeping purposes. All milk shall be strained, cooled or stored as soon as it is drawn from the cow. Milk kept for sale in any store shall be kept at a temperature not higher than 50 F., and shall be stored in a refrigerator which shall be kept tightly closed except when necessary to introduce or remove milk or ice. All utensils shall be cleansed or sterilized before being used again for the same purpose, nor shall any utensils be used to contain any other substance than milk. Every person engaged in handling the milk shall notify the board of health of the presence of any communicable disease with which he may be brought in

contact, and shall discontinue the sale of milk until authorized to resume the same by the board of health.

No milk or cream shall be sold which contains more than 500,000 bacteria to the cubic centimeter, and must be delivered at a temperature of not more than 50 F.

To the older practitioner and to the farmer these requirements seem to smack of cranky, scientific notions. To them it seems impracticable to accomplish these ends, and while they fully believe in their own minds that the dirty milk which they have supplied for years is good enough for any one, yet many of these men under this test will be found wanting.

The results of numerous tests have shown that the average bacterial efficiency may be quoted as follows: A certified milk produced and delivered under perfect sanitary conditions, working for asepsis under perfect cleanliness, should not contain over 10,000 bacteria to the cubic centimeter; many supplies contain less. The milk supplied from farms where the cattle are well fed and the stables kept fairly clean should not contain over 200,000, while the cheap milk found in stores will be found to contain 3,000,000 bacteria to the cubic centimeter. This variation is strong evidence that the hoped-for condition of a clean milk supply is within the bounds of possibility.

The farmers will make no effort to obtain this perfection so long as the respected medical profession is perfectly willing to purchase their goods. Health authorities will have difficult work in obtaining legislation to this end so long as the indifference of the profession continues. Medical societies may resolve and present their resolutions to the legislators, but so long as the physicians individually are willing to pay money for filth the farmer will continue in authority.

What can a health board do in the face of such parsimonious disinterestedness for the public weal? How can health boards appear before their legislators and ask for laws governing the production and distribution of milk, when the farmers in their filth are supported by the neutrality of the physician? If the physician is satisfied with a standard quota of cow dung with each delivery at his door, how much to his credit may be put on the balance of responsibility for the infant mortality rate?

Possibly the demand of sanitarians for clean milk, as well as for a standard of fats and solids, is too strenuous; perhaps their ideas are beyond the present age; perhaps they are not acting on experience. Surely those cities which have ordinances controlling the quality of milk delivered within their borders, have had experience, if their statistics of infantile mortality are reliable.

The physicians of the state of New Jersey are prepared to tell us whether a clean milk supply is a possibility, and whether it has any effect on the health of the people. There are physicians of the New Jersey type in some other states, but they are not sufficiently numerous to produce results and are handicapped by the mass of neutrals.

From vital statistics much data is obtained which assists the sanitarian in his work. If it may be ascertained which of the numerous diseases are the most common, his effort is at once to ascertain if this prevalence is dependent on any common condition, and if that condition is one amenable to change. This study finds its practical application in the suppression of communicable diseases. Many other diseases which are the cause of a large mortality may be found to be associated with

conditions in common, some of which would hardly be suspected of being causative factors. Such conditions of climate, water and food supplies, subsoil saturation and the presence of insects and their breeding-places may also be found as associate conditions. Increased infantile mortality may find its association with a poor milk supply, a continued rise of atmospheric temperature or possibly an overabundance and interference of so-called midwives.

That these statistics, compiled from both mortality and birth returns, are one of the greatest value, is admitted by several states, but one is surprised to find so few registration states in a country which is supposed to represent scientific advancement. Many large and prosperous states are entirely without any system of registration of births, marriages and deaths. Think of what a mass of useful material might be made available to the health officers of the state of Pennsylvania, and yet, except for registration in a few of the larger cities, no figures are available in that state.

Although sanitary authorities in non-registration states endeavor to obtain legislation to inaugurate a system of registration, yet there is little or no support from the medical profession. It is to be hoped that the Committee on Legislation of the American Medical Association will find it a part of their already active and earnest department to formulate a crusade to assist and stimulate the delinquent states in obtaining a thorough system of registration of births, marriages and deaths. This it can accomplish through the particular members of the medical profession whom they have learned from experience are the more active promulgators of new and advanced ideas in their respective districts.

In those states which have a working system of vital statistics, much improvement in methods and in accuracy of returns has been accomplished, but only by persistent work on the part of the state registrars.

It is admitted that imperfect statistics have little, if any, value, and may lead to unfortunate deductions. If the total number of either the deaths or the births is not obtained, the comparison of the two is useless. If only half of the persons dying are recorded as having died from certain diseases, the conclusions arrived at are deceiving. Vital and mortality statistics should rest on data known to be reliable and not computed on a rule of probability.

In states having perfected laws, provision is made that a return shall be made for each and every death, giving the cause of the death, yet it requires much diligence and harassing of undertakers and physicians to obtain complete and correct returns. In two states the law provides that the body of a deceased person may be disinterred on the order of the health department if the undertaker has failed to make a correct return of the cause of death before burial. Naturally but few disinterments have been required, inasmuch as one such case serves as a salutary restraint on a repetition of the offense.

A large number of causes submitted to the registrar as sufficient to produce death are of a character to make a thinking medical man smile, especially when it is the other fellow who signed the return. In some of his own returns he fails to find any humor whatever, and is perfectly willing to be placed on record as having tended a patient who came to his death by "cramps" or "spasms." If the return had been signed death by "colic," we might perhaps have circumscribed our area of possibilities and have eliminated epilepsy, puerperal

convulsions and the many acute diseases affecting the motor system. But with "colic" we have a fair chance to guess whether the case was one of appendicitis, peritonitis from septic infection or from violence, volvulus, impaction of feces, the passage of concretions from kidney or gall bladder, with possible rupture.

Of course, it is perfectly plain to him that the patient was jaundiced or that there was uric-acid calculi in the urine, but the last and most violent symptom was colic. In the case of an infant he ignores the gastroenteritis which caused the colic, or he has, perhaps, in this case signed the death return with convulsions as a cause. He will also forget that the intestinal indigestion causing the convulsions was the result of improper feeding. Hemorrhage alone is often given as a cause. The attending physician fails to give the source of the hemorrhage and the locality from which the blood came. The registrar is allowed to guess, or do as is done in all well-conducted offices of registration, politely addresses a note to a physician who is bankrupt as to diagnosis, and an inquiry is made as to whether the hemorrhage followed a coughing spell, or had he been treating a case of typhoid fever for a week or two, or if the hemorrhage had followed a confinement and if so what abnormal conditions were present; was the person a "bleeder" or was there a pistol in the case, and, if the latter case, was the wound self-inflicted, and if so, whether accidentally or with intent. We might go on citing these absurdities: "Heart failure," which even the laity smile at by this time; "natural causes" (i. e., one of the hundreds possible); "inanition" in a person over 5 years of age and under 50, etc.

It is believed that all physicians are ready and willing to assist in making the returns perfect. Those conditions arise from the result of habit and inattention, and forgetting that the registrar was not a consultant in the case.

If physicians would indicate in plain words on the return that the cause of death was unknown, or could not be determined, it is at once known that an effort was made to obtain some information as to the symptoms preceding death, but to say that the person died of "natural causes" indicates that he has not made any endeavor to determine a cause. If the best possible diagnosis available is given and one of the symptoms present, they would receive praise and gratitude and some slight salvation here on earth, for the registrar will rise up and call him blessed.

The majority of physicians believe in sanitation, and are willing to uphold the sanitary authorities. The young men who are taking up the profession of medicine come to the health department like a refreshing breeze on a hot summer day. The contention and opposition to reform which has come from the older members of the profession is mostly because the latter have not lived up to the advance of the times and must needs cover their ignorance as of yore with evasions and with mystification all that is new, even if based on logical experience. Here and there among the profession are men familiar to us all who are in medicine for what they can make out of it, by hook or crook. It is the natural disposition of this class to take a stand against any constituted authority, partly because it is contrary to their precepts to act on anything which is based on honesty and partly because by setting up opposition they hope to pose before their clientele as men of stamina and authority. Fortunately, it frequently happens that these obstructionists receive their just reward by

making and falling into pitfalls, but while they exist they prove a source of great annoyance to the officers who are endeavoring to do what is right by all.

This class is readily recognized by its attempts to conceal the presence of communicable diseases, either by suppressing comment or by submitting intentionally a false diagnosis for the purpose of favoring their patients. Unfortunately for them, in order to obtain the small advantage of seeming to comply with the desire of the patient to conceal the disease he must admit to the family that scarlet fever or diphtheria is actually present, and thus as the result of human nature, which can not possess an advantage over fellow-man without gloating over it, the secret is at once disclosed to the neighbors as a success, and the physician's integrity is at once at stake beyond the pale of that household, and for slight gain and with much loss to himself he has placed obstruction in the way of the health officer and endangered the public, not alone by possible carelessness in his self-imposed quarantine, but by setting an example to the large and ignorant immigrant class to go and do likewise. He is the one who will sign a death return as grip when tuberculosis was the cause, in order to conceal the fact from an insurance company.

It is this same man who, from arrogance alone, diagnoses smallpox as Cuban itch, chicken-pox or as a simple skin disease, until he becomes alarmed at the spread of the disease and his methods are discovered. He may never have seen a case of smallpox, yet trustingly declares his knowledge to be superior to the authorities. His disposition for opposition, his desire to appear different, independent and superior to any and all other practitioners, permits him to flaunt himself before the public and spread havoc with the gullible class. In his experiments for advancement when dealing with smallpox, his downfall is usually sufficiently severe to satisfy the spirit of justice in the mind of the health officer.

How far does the regular practitioner take part in the fight against such irregularities, how far does he help the health authorities in giving these men their rightful position before the public?

The natural result of years of training in ethical conduct toward our honest and respected brother practitioners, our meek and modest desire to hurt no one's feelings, leads us to extend the same considerate kindness to those who should receive no recognition in medicine. Here and there may be a man who has the courage of his convictions and jumps to the assistance of the health officer by placing these men in a proper light, but he is at once set down as a fighter, and obtains for his reward only notoriety or neglect from his brother practitioners, whom he is endeavoring to defend at his own expense.

This conservatism and desire to stand behind the screen and let matters work out their own salvation, or to avoid being found on one side or the other leads the majority of practitioners to avoid assertion of their individual rights as citizens and their advanced privilege as men of a profession, when any movement for the betterment of hygienic conditions appears before legislative councils. The sanitarians and the health authorities ask for forms of government which shall control the ignorant public in doing things which is for the betterment of their health. It may be a question of pollution of water supplies, the adulteration of foods, the controlling of trades from a sanitary viewpoint, but not a word is heard from the mass of the profession

A SUMMER'S EXPERIENCE WITH INFANTILE DYSENTERY.

J. H. MASON KNOX, JR., PH.D., M.D.

Physician in Charge of the Thomas Wilson Sanitarium; Assistant in Pediatrics, The Johns Hopkins University. BALTIMORE.

(Concluded from Page 1854.)

TREATMENT.

The treatment of these cases at the sanitarium followed in the main the usually accepted lines and will not be here detailed.

In all acute cases milk was stopped for varying periods, and boiled water, with or without egg albumin, dextrinized cereal waters or broths, and later whey, were substituted. Gastric lavage was resorted to occasionally, but in nearly all instances the colon was repeatedly irrigated. On admission the intestinal tract was usually emptied by calomel or castor oil. Of the several intestinal astringents which were tried none proved more satisfactory than bismuth subnitrate in large doses. As stimulants, whisky or brandy, strychnia, digitalin and atropin were found useful in the order named. Opium was sparingly employed.

who have at least the political influence of their individual vote in the election of a state or municipal representative. The average politician, with all his assumption and dignity of representation, has his weak point in the fear of a non-election, and he has, as a rule, some slight respect for the opinions of a profession which, maintaining its dignity, asks for something which is practical and honest. He may not be able in many cases where "graft" is involved to see the scientific advantages of legislative sanitation, yet he is not always able to resist a concerted movement of a profession which carries the dignity and integrity of the medical profession.

Most of the advance in medical and sanitary legislation has been the result of the persistent efforts of individuals, who for their pains have lost time, frequently reputation, with their fellow-practitioners, and are cited as cranks and individuals who are working for notoriety.

If members of the profession would assert their rights as citizens and demand scientific medical and sanitary legislation, they would come nearer to their duty. To be sure, they are willing to commend any effort to advance hygienic improvements, but they do not step out and give their support to the health officer seeking for the betterment of the public. They consider that he is employed for that purpose, and must accomplish everything by himself without the support of the profession. If he asks for assistance he may obtain it in the form of a petition signed by innumerable M.D.'s, but as all legislators know that a petition is always signed for convenience to get rid of the messenger carrying the petition, and that the petitioner is often willing to sign petitions for both sides of the question, a petition, no matter how large, is considered of little value. It is the personal presentation of views to the representative which is of value only, and it is the duty of every physician who is conscientiously interested in the advance of sanitation to personally assist any measure to that end.

In the organization of the American Medical Association this idea is coming strongly to the front, as may be seen in the vigorous manner in which the legislative committee of the organization has pressed the needs of legislation in certain lines.

As is to be expected, since much of medicine rests on hygiene and sanitation, this committee finds its work to be in the line of the improvement of laws governing the adulteration of foods, and the desirability of sanitary authorities having undisputed authority in the prosecution of the work of the Panama Canal. The numerical strength of this body should serve as a factor in influ-omendations made for the benefit of their constituents.

Much more evidence could be shown wherein the physician is closely in relation to the health officer and his daily works. It is evident that the more perfect the contact of the two and the greater the harmony that exists, the greater is the perfection in sanitary administration, and that all results in hygiene must rest on the perfection of the work by the man engaged in the practice of medicine.

Unprofitable Discussions.—Let every physician refuse to accept samples of secret medicines, refuse to waste time talking therapeutics with smooth-tongued salesmen. . . . The stereotyped reply, to all agents of secret nostrums, that I do not prescribe medicines of whose composition I am kept in ignorance, has saved me many hours for more advantageous professional work than conversation with men whom I despise.—Roberts, in *N. Y. Med. Jour.*

Serum Treatment.—Through the kindness of Dr. Flexner and the generosity of the Rockefeller Institute for Medical Research, the sanitarium was supplied with antidyenteric serum obtained from horses immunized against the organism, at Mulford's vaccine farm. The serum produced with both the "Harris" and "Shiga" types of the organism, i. e., those which form acid in mannite and those which do not, respectively, was sent separately. It had been found by Dr. Gay⁸ to possess exceedingly high protective power for susceptible animals.

Unfortunately, because of the distance of the sanitarium from Baltimore, but few early cases came under observation and so little selection of infants thought to be favorable for the serum treatment could be made. Eliminating a number of instances in which the serum was given when the patient was *in extremis* or when a serious complication obscured its action, 20 cases remain to be recorded, all of them suffering from infection with the dysentery bacillus, in which were injected varying amounts of antidyenteric serum.

It may be mentioned here that the serum in all cases was given under the skin, using simple antiseptic precautions. In no instance whatever did any local infection, or other untoward accident, follow the injection. The welt produced by the serum usually disappeared in a few minutes. Comparatively little pain was given by the injection after the initial puncture by the needle.

The more salient facts concerning the treatment of these 20 cases are given in the table opposite.

The cases are arranged in three groups, according to the action of the serum: thus, A, those in which the serum seemed helpful; B, those in which the effect of the serum was doubtful; and C, those in which the serum was of no benefit. The clinical numbers of the cases in the second column correspond to those in the report of Dr. Winne. The variety of the serum used is designated by "S" or "H." that is, the serum was produced from an organism of the Shiga (so-called *alkaline*) or Harris (so-called *acid in mannite*) type, respectively. The table shows that of the 20 cases in but 5, or 25 per cent., was the serum of apparent

benefit (Group A). To these 5 cases could be added 4 other infants who presented similar symptoms and whose blood agglutinated the specific organism. As, however, the dysentery bacillus, which was probably present in small numbers, was not isolated from the stools, these additional instances of the "favorable" effect of the serum are not included in the series. In 5 other cases, 25 per cent., the effect of the serum was uncertain (Group B). The improvement which followed could not be definitely attributed to its use. In the 10 remaining cases, 50 per cent., no permanent benefit was derived from the serum treatment (Group C).

It was difficult often to determine the part played by the serum, when during the period of its injection the diet was altered and other therapeutic measures employed, and it was only after weighing all these other factors that the distribution in the above groups is

GROUP A. CASES IN WHICH THE SERUM WAS HELPFUL.

CASE 1.—L. W., girl, aged 6 months. Admitted to the sanitarium June 2 because of malnutrition. Breast fed for one week only, afterward given cow's milk diluted with equal parts of water, whenever it cried. Had never thrived; no gain in weight for several weeks. There was a possible syphilitic taint. The patient improved slowly at the sanitarium, with several intermissions, taking milk formula. The stools were large, light in color, usually pasty in consistency, occasionally contained curds. Weight, 7½ to 8 pounds.

Serum Treatment.—The notes pertinent to the serum are, in brief, as follows:

July 18—Patient doing well.

July 19—Patient became fretful; refused nourishment, and mucus appeared in the stools.

July 20, a. m.—Twelve hours after last note the stools were increased in number and contained more mucus and some blood. Pulse weak. Patient drowsy and almost in collapse.

SERUM THERAPY.

	Name.	Clinical number.	Age in months.	Duration of illness before injection, in days.	Number of injections.	Total amount of serum, in c.c.	Duration of serum treatment, in days.	Variety of Serum.	General condition of patient at first injection.	Result of serum treatment.	Condition on discharge.
GROUP A Treatment Beneficial 5 Cases.	L. W.	123	6	1	7	120	20	S	Acute attack at sanitarium in marantic infant.	Favorable, fewer stools, brighter.	Unimproved.
	E. B.	171	14	9	7	110	14	S	Comatose, irregular pulse, mucus and blood in stools.	Slightly favorable, slow recovery.	Well.
	W. C.	195	4	4	5	50	7	H	Poorly nourished, collapsed, extremities cold.	Favorable.	Well.
	M. S.	222	2½	6	1	10	1	H	Poorly nourished, listless.	Favorable, brighter, recovery prompt.	Well.
	G. M.	300	5	10	5	60	8	H	Poorly nourished, collapsed.	Favorable, lower temperature.	Well.
GROUP B. Treatment doubtful. 5 Cases.	L. F.	160	17	25	3	30	4	H	Fair condition, numerous stools containing mucus and blood.	No immediate improvement.	Improved.
	H. G.	242	6	10	2	40	2	S	Fair condition.	Serum of doubtful effect.	Improved.
	R. C.	274	7	14	6	110	7	H	Collapsed, semi-comatose.	Action of serum, if any, slow, temp. reduced.	Improved.
	V. Z.	308	8	50	4	40	3	H	Poorly nourished, mucopurulent stools with blood.	Slow, doubtful.	Improved.
	I. R.	338	3	16	2	20	2	H	Poorly nourished, feeble.	Inert or slightly helpful.	Improved.
GROUP C. Serum treatment inert. 10 Cases.	S. O.	210	5	7	3	30	3	S	Emaciated, drowsy.	Serum seemed at first helpful, later inert.	Died.
	J. B.	221	2½	22	6	100	21	S & H	Poorly nourished, extremities cold.	Serum inert.	Died.
	M. S.	223	6	30	8	170	18	S	Collapsed, semi-comatose; poorly nourished.	At first helpful, then inert.	Died.
	D. J.	273	7	14	14	230	16	S & H	Furunculosis.	Inert.	Unimproved
	R. M.	278	3½	15	3	60	3	S & H	Emaciated, collapsed.	Inert.	Died.
	M. S.	287	4	30	13	200	20	H	Collapsed, drowsy.	Inert.	Died.
	W. W.	301	6	30	5	70	10	H	Emaciated, marked rickets, drowsy.	Improvement (?) first, inert later.	Died.
M. K.	309	12	22	7	90	11	S & H	Poorly nourished.	Inert.	Died.	
A. S.	330	9	17	3	40	3	S	Poorly nourished.	Inert. (Bronchopneumonia.)	Died.	
F. O.	333	12	30	4	60	4	S	Collapsed, sunken fontanelle, many stools.	Inert.	Died.	

suggested. Although the action of the serum in some cases of the Groups B and C seemed to be occasionally favorable, in none did it produce immediate and complete recovery, but it must again be recalled that almost without exception the babies brought to the sanitarium were of weak constitutions, ill adapted to resist disease or to respond to any serum therapy. In two-well-to-do children in Baltimore, injected promptly after the onset of illness during the summer, the serum was said to have a marked and early remedial effect.

A recital of the clinical histories of each of this series of serum cases would contain but little information not to be found in the table. In order to indicate more fully the effect, if any, of the serum treatment, two cases fairly illustrative of each group will be presented in some detail, after which attention will be briefly called to some suggestive features.

One hundred c.c. salt solution and 30 c.c. antidyenteric serum (Shiga) were injected hypodermically at 1 p. m. Milk stopped; no laxative or irrigation given.

Result.—In six hours patient's condition improved; took liquid well; stools contained no blood.

July 21—Baby had a good night. Seems much brighter and stronger; takes nourishment well. Stools fewer in number, containing less mucus and no blood; 20 c.c. antidyenteric serum (Shiga) injected at 2 p. m. Patient gained in strength slowly. Ten c.c. more of serum were given on July 26. Improvement continued for ten days, although the stools were mucoid.

On August 8 the child was again worse and blood reappeared in the stools. Twenty c.c. antidyenteric serum (Harris) were injected. In twelve hours the infant was much improved, the stools again fewer in number and free from blood.

There was little elevation of temperature during the illness. The child was taken home against advice on the following day.

This case is of interest because it was the only one of the series observed from the onset of illness. The infection was contracted at the sanitarium, house flies being the probable conveyors of the bacilli. Here there was an apparent prompt response to the serum given early in the attack, on the part of a markedly marantic infant.

CASE 2.—M. S. (No. 222), girl, aged 2½ months. Admitted July 7, suffering from diarrhea. Since first week of life had been fed on Eskay's food and condensed milk; rice water since present illness, which began six days before with vomiting and diarrhea. Stools, ten to twelve in twenty-four hours; fluid, with mucus and lumps; no blood.

Examination.—The infant was fairly nourished, but rachitic. The thoracic organs were normal. On admission the patient was listless, with signs of toxic infection.

Treatment.—July 8, noon. Ten c.c. of antidyenteric serum was injected. Shortly afterward an extensive erythematous rash developed, which spread rapidly from point of inoculation, involving nearly half the child's body. After several hours the erythema quite disappeared.

Result.—In twenty-eight hours, without other treatment, the child's condition began to improve. The stools became fewer and more fecal in character. There followed an uninterrupted recovery, which seemed definitely to begin with the injection of the serum.

The two following cases are fair instances of a second group in which the improvement can hardly be directly attributed to the use of the serum:

CASE 3.—E. F. (No. 160), girl, aged 17 months. Admitted June 23 because of "diarrhea and weakness."

History.—The clinical history was, in brief, as follows: At five months of age had summer complaint, followed by measles and bronchitis in the fall. Not so strong afterward. Breast fed until thirteen months; since, milk, with table diet. The present illness began three weeks previously with diarrhea. Stools at home were green, offensive, and contained mucus; no blood.

Examination.—On admission the child was fairly well nourished, anemic, with a daily range of temperature from 100 to 103.

Examination of the chest and abdomen negative. The stools were fourteen to twenty in twenty-four hours, and contained mucus, pus and blood.

Treatment.—Treatment consisted in a change of diet to a cereal water: whey was added later. Bismuth subnitrate was given by mouth, and occasionally whisky as a stimulant. Frequent colon irrigations, usually with tannin and soda solutions, were employed.

The child's general condition remained good, but there was no abatement of diarrhea or fever.

On June 27 antidyenteric serum (Harris), 10 c.c., was injected. This was repeated June 30 and July 1, 30 c.c. being given in all.

There was no immediate change in the patient's condition. The number of stools was not decreased and the temperature remained elevated for several days. On July 3 the symptoms began to abate. In forty-eight hours the temperature became normal, blood and pus disappeared from the stools, and they were reduced to four in twenty-four hours. The child made a slow but complete recovery.

In this case the action of the serum, if helpful, was not prompt. It seems possible that the recovery might have similarly followed without serum treatment.

CASE 4.—R. C. (No. 274), boy, aged 7½ months. Admitted July 13 because of "summer complaint."

No history of previous illness. After five weeks baby was fed on cow's milk diluted with boiled water. Present illness began two weeks before with vomiting and diarrhea. Stools, ten to twenty a day, consisting largely of greenish mucus. There was fever throughout the attack.

Examination.—The child was admitted in a markedly toxic condition, eye dull and sunken, fontanelle depressed, skin bluish and dry, abdomen scaphoid and doughy, heart and

lungs negative, temperature 101.5, pulse 150, of small volume and low tension.

Treatment.—Shortly after admission 20 c.c. of serum (Shiga) was injected. This was repeated daily, July 19 to July 29, using the Harris serum on and after July 20. A final injection of 10 c.c. was given on July 23—a total of 110 c.c. in seven days.

The morning after the first injection the child was less listless, but the temperature remained elevated, 101 to 102, and the character of the discharges was not altered. Calomel, change of diet and colon irrigations were also employed in treatment. On July 20 an infusion of 100 c.c. salt solution was given hypodermically.

Result.—The fever began to abate July 21, after which date it did not rise above 100. Some elevation of temperature persisted, however, for a week longer. The toxic condition cleared up slowly, but the mucus persisted in the stools and the appetite remained impaired.

The child was discharged August 2, against advice, as he was not considered "well." He died several weeks after his return home, apparently from a "relapse." Here the effect of the serum was probably beneficial.

The last two cases to be recorded represent a large group in the series, where the serum seemed to be quite inert.

GROUP C. CASES IN WHICH THE SERUM TREATMENT WAS OF NO BENEFIT.

CASE 5.—M. S. (Nos. 219 and 287), boy, aged 4 months. Admitted first on July 7 because of diarrhea.

Never ill before; artificially fed from birth with diluted cow's milk.

History.—Two weeks before admission the infant's stools became green and watery. A trace of blood was noted twice. No vomiting; no fever.

The symptoms yielded to a change of diet, and the patient was discharged apparently well in nine days. After five days at home the stools again became frequent and the child was readmitted July 22 in a much weaker condition. At this time there was no fever, and the stools contained mucus but no blood or pus, and the symptoms were those of intestinal indigestion.

Treatment.—On August 3 the patient grew suddenly worse. It became drowsy, the features were "pinched," the eyes sunken, and pulse weak and rapid. Stimulants were given and the serum treatment begun—10 c.c. (Harris). On August 5 two similar injections of 20 c.c. each, with 100 c.c. salt solution, were given.

The child's condition continued alarming until August 6, when for a few days the appetite improved and the infant seemed brighter. Further serum had been injected on August 6, 7, 8 and 10—50 c.c. in all.

Between August 12 and 16 the temperature, which had rarely reached 100, rose daily to 102, and the child became more listless. Serum was given August 13 and August 15, and following its use there seemed again some betterment. The temperature fell to 100, and nourishment was now readily taken.

On August 20 the infant again became worse, the temperature rose to 103. The stools were more frequent and contained considerable pus and blood. The patient from this time grew progressively weaker. The temperature remained elevated, with marked daily remissions, until the end, which occurred August 25. The blood and pus in the stools increased during the last days. The serum given at this time (60 c.c., August 20 to 24) seemed to have no effect on the general condition of the patient, the height of the temperature or the character of the stools.

Result.—In this case the effect of the serum was difficult to determine. Some improvement apparently followed its use August 6 to 12 and again August 16 to 20, but the betterment was of a transient nature, the serum being powerless to check the symptoms of toxemia or to cure the lesions in the intestines, as evidenced by the increasing amount of pus and blood in the stools. Two hundred c.c. of serum was given in twelve injections during 21 days.

CASE 6.—F. O. (No. 333), boy, aged 12 months. Admitted August 6, because of profuse diarrhea.

History.—The child had always been well except for an attack of pneumonia six months before, from which he had completely recovered. He had nursed for two months, and afterward had been fed with condensed milk, augmented later by some food from the table.

The present illness began four weeks previously with an unusually severe attack of vomiting and diarrhea, called cholera infantum by the attending physician. The symptoms abated and the child was thought to be "well," when a relapse suddenly set in two weeks before admission. The stools again became numerous, and now contained mucus, pus and blood.

Examination.—On entrance the child's condition did not suggest a very serious illness. He was fairly well nourished, with moderate rickety changes; eyes were bright; heart and lungs normal; abdomen markedly distended. There was a slight edema under the eyes, and on the dorsum of the hands and feet. Temperature, 99.8.

Treatment.—The intestinal tract was swept with calomel, followed by oil. The stools afterward continued frequent and mucopurulent in character, deeply tinged with blood.

Antidysenteric serum (Shiga), 20 c.c. was injected on the day of admission and repeated the following day, while on each of the two succeeding days 10 c.c. was given—a total of 60 c.c.

Result.—The condition of the child remained apparently little altered, though the temperature gradually rose to 103. The stools were not reduced in number by various astringents, and the child died suddenly in convulsion on the sixth day after admission.

In this case, in which the infection had occurred a month before, the serum seemed of no help whatever.

Several features suggested by the table and the illustrative cases cited deserve some additional emphasis.

DURATION OF DISEASE BEFORE SERUM TREATMENT.

A striking fact brought out in the series is the relationship between the beneficial effects of the serum and the promptness with which it is administered. Thus, the average duration of the illnesses in the three groups, A, B and C, in which the effect of the serum seemed beneficial, doubtful and inert, was 7.4, 15.8 and 21.7 days, respectively. The most definite and rapid response to the serum treatment was noticed in Case 1, which was injected on the first day of the intestinal disorder. In this instance in six hours, although the infant was in an advanced stage of malnutrition, there was a definite improvement in its general condition, the character of the pulse and the number and appearance of the stools. It is recognized, of course, that these diarrheal cases are more amenable to all methods of treatment early in their illness than later, and that in none was the serum alone employed. Giving due regard to the value of these older procedures, experiments on animals,⁸ as well as clinical observation,⁹ seems to indicate that any healing effect of the serum is exerted in proportion to the promptness with which it is given.

In this regard results with antidysenteric serum accord with clinical experience in the treatment of diphtheria or tetanus, where the brilliant cures which follow the administration of the proper serum in the early stages of the disease are not effected if the use of serum therapy is long delayed. It is quite possible that antidysenteric serum will not prove to have as high curative value as have the antitoxins against diphtheria and tetanus. The cellular toxins, to which that produced by the dysentery bacillus and the typhoid bacillus belong, have not lent themselves as readily as have the

soluble toxins to the formation of strong healing anti-toxins.

Conclusive evidence on this point will be obtained only by the careful observation of a large series of cases. The children presented in the present series can not be considered ideally suitable for this test, both on account of the weakened constitutions of many of them and because also of the long duration of the illnesses before the serum could be given.

THE TYPE OF ILLNESS.

A consideration of the serum cases with reference to the clinical types of the disease may indicate in what instances help may be expected from serum therapy. The results can be briefly tabulated as follows:

ACTION OF SERUM.

Toxic—	Helpful.	Doubtful.	Inert.
Mild	0	0	0
Moderate	0	0	0
Severe	4	3	1
Inflammatory—			
Mild	0	0	0
Moderate	5	0	2
Severe	11	2	3
	20	5	5
			10

Serum was not given to the small number of mild and moderate toxic cases in our series for several reasons. Three were admitted to the sanitarium before the arrival of the serum; others were convalescent from their acute symptoms; and in others the parents' permission which was always obtained before injection, could not be secured.

This arrangement of cases would suggest that the serum is helpful in toxic cases even though they be of the severe grade. In the inflammatory form of the disease, on the other hand, it is of little service if its administration is delayed. Thus, out of 16 cases belonging in this group, only 2 seemed aided by serum injection, in one of which it was given on the first, and in the other on the ninth day, while in the ten in which it seemed quite inert, usually more than a fortnight of illness had elapsed before it could be employed.

The inference from this standpoint is, that although more can be hoped from the antidysenteric serum in the treatment of the acute toxic cases than of those included in the so-called inflammatory types, that the promptness of injection is a more important factor than the clinical variety of the illness.

DOSAGE.

The serum was usually given in 10 and 20 c.c. injections at intervals of 12 to 48 hours, sometimes after a lapse of several days. Occasionally 30 or 40 c.c. was injected at one time. This amount was many times the preventative dose per body weight of animals, as determined by Gay.⁸ In no case was improvement seen from 40 c.c. when a smaller quantity had failed to produce any effect. It did not seem possible to establish any relationship between the dosage and the result. It is questionable whether much larger amounts, i. e., 200 c.c. injected at one time, would have been more helpful. Apparently most of the cases benefited by the serum were those in which comparatively small amounts were given early in the disease.

THE NUMBER OF INOCULATIONS.

The number of inoculations varied from 1 to 18, extending over periods as long as 28 days. As has already been indicated, a series of cases of long-standing ulcerative ileocolitis were repeatedly subjected to serum therapy, with quite negative results; and it is felt that any beneficial effect of the serum, if present, can be de-

⁸ Shiga: Deutsche med. Woch., 1901, No. 43, p. 45; also Krusa: Deutsche med. Woch., 1903, No. 1, p. 1.

terminated after the first or second injection. If there is then no betterment a continuation of the treatment is practically useless.

DURATION OF THE EFFECT OF SERUM.

It is well known that a single attack of summer diarrhea confers no lasting immunity on the infant, but rather seems to render it more susceptible to subsequent intestinal disorder.

The number of relapses already referred to in this series supports this view. In the light of these observations it is not surprising to find that the effect of the serum is a comparatively transient one. Rarely a single injection, as in Case 2, appeared to start the infant on a permanent convalescence; more frequently a slight betterment which followed a single injection proved to be but a trifling interruption to the progress of the disease.

If, then in a given case improvement follows the injection of the serum, this should be repeated until untoward symptoms are past. In several instances which had to be included among those in which the serum was doubtful or inert, the baby's condition brightened after the injection, and the treatment was not afterward given till the child again became alarmingly ill, when the serum, even in larger quantity, was of no benefit.

TEMPERATURE.

Of the effect of the serum on the temperature of the patient, no certain deductions can be made from our cases. Occasionally a drop in the temperature occurred shortly after the injection and apparently because of it. Examination, however, of a large number of cases discloses similar variations in the fever quite independent of serum therapy. Again, a gradual reduction in fever in a few instances appeared to follow the massed action of repeated injections of serum. In fact, the temperature, within moderate limits, in these disorders is no index of the condition of the patient, as many of the severest cases ran a comparatively afebrile course, and a further reduction in bodily heat may accompany a complete collapse.

NO COMPLICATION DUE TO SERUM.

Our experience would indicate that the injection of antidysenteric serum is a harmless procedure performed under antiseptic precautions. Once an erythematous blush, lasting a few hours, appeared on the body of an infant shortly after injection, and in one other case a moderate urticaria was noticed on the twelfth day following the serum therapy.

PATHOLOGY.

Of the fatal cases in our series, permission for autopsies was obtained in five instances. Two of the infants belonged clinically to the toxic, the remaining three to the ulcerative group. At the time of death two of the babies were fairly well nourished, two sparsely nourished, and one markedly emaciated.

Most interest attaches to the condition of the alimentary tract. Nothing of interest was noticed in the mouth, except the occasional presence of the thrush fungus. The conditions found in other parts were as follows:

Esophagus and Stomach.—In all cases the mucosa of the esophagus was smooth and pale. The stomach was occasionally found moderately distended with gas. It usually contained some residue of food or medicine mingled with a slight amount of mucus. Once it was found filled with watery fluid, and in one instance it contained bile. In one case several linear

areas of congestion 3 by $\frac{1}{2}$ cm. were noticed at the crests of the folds of the mucosa. No definite hemorrhage and no loss of substance was present.

Duodenum and Jejunum.—These portions of the small intestine showed little change. The mucosa in all instances was smooth and covered with a moderate amount of bile-stained mucus. There was no marked distension present and no infiltration of the intestinal walls. The jejunum was once found slightly injected.

Ileum.—Changes in the ileum were absent in but one case, where the mucosa was smooth and pale and there was no gross swelling of Peyer's patches. In the other four cases there were definite pathologic alterations in the ileum, particularly in its lower third near the ileocecal valve. In this portion of the ileum were found scattered through the mucosa irregular areas of congestion often in association with multiple minute hemorrhages. The mucous membrane was usually thickened. The most conspicuous lesions were in association with Peyer's patches and the solitary follicles. These were enlarged and congested and often covered with a yellowish-gray necrotic material. In three of the cases there was ulceration in the ileum. The loss of substance was usually, but not always, in the lymphoid structures. Some of the ulcers were quite shallow and difficult to distinguish; others were deep and punched-out in appearance. Often a single patch was the site of multiple ulcers which united into a larger one, with irregular but not overhanging edges. None of the ulcers extended deeper than the mucosa.

Large Intestine.—The lesions in the large intestine were, as a rule, more pronounced. They were found throughout its extent, but were usually more marked in the sigmoid flexure, rectum and cecum. The mucosa was usually found thickened and congested. Hemorrhagic areas, minute or more extensive, were scattered here and there throughout the colon, occasionally in connection with the solitary follicles. These lymphatic structures were usually swollen and stood out as raised translucent dots against the mucosa. Often they were surmounted by a cap of yellowish-white material.

Ulceration was present in several of our cases. The ulcers varied from minute losses of substance not infrequently situated at the summit of the solitary follicles and others deeper, with punched-out borders, to extensive irregular areas denuded of mucosa produced by the confluence and extension of numerous single ulcers. This process in one case was so extensive as to leave in places only scattered strips of mucosa intact. Even in these instances the ulceration did not extend deeper than the mucous membrane, nor were the edges undermined. In no case was there noted any definite pseudomembrane more than the necrotic tissue seen here and there over a swollen Peyer's patch or solitary follicle or areas of ulceration. Mucus or mucopurulent material, frequently containing blood, was always present in the colon.

It is of interest to mention that in this short series of autopsies in one case there were found in the whole gastrointestinal tract no gross lesions; in another only three or four tiny shallow ulcers, and that in still a third case, although there were several good-sized ulcers in the lower part of the ileum, the large intestine was apparently normal.

Microscopic Examination.—A microscopic examination of sections from various portions of the intestines adds comparatively little. In some instances the wall of both large and small intestine showed no pathologic alterations; in others there was a moderate congestion of the vessels, particularly those of the mucosa and submucosa, with occasional hemorrhage and some serous exudation into the tissues. In the lymph radicles, Peyer's patches and the solitary follicles, there was a moderate proliferation of the small round (lymphoid) cells. The most prominent feature, however, was the serous infiltration of the gland tissue separating these cells from each other, exposing the fine fibrous filaments of the structure and explaining its increase in size. There was little polymorphonuclear invasion.

The ulceration observed began usually in the lymphoid nodules in the intestinal wall. The loss of tissue was found

to be limited usually to the mucosa; less frequently was the submucosa in part included. The muscle layers in our cases were invariably intact. The appearance of the ulcers was as though the lymph nodules had simply frayed out at the surface. The material lining the ulcer was composed of necrotic tissue without any evidence of organization. No fibrin was present.

The condition of the other organs may be referred to:

Heart.—No changes of importance were noticed in the heart; the valves were delicate, the musculature occasionally somewhat pale. There were no antemortem clots.

Lungs.—There was bronchitis with small patches of bronchopneumonia in three instances, in which the diarrhea had been of long duration. In one case this pulmonary complication was the direct cause of death. When the illness was comparatively acute the lungs generally escaped any alteration other than a slight congestion.

Liver.—This organ in the cases examined was little if any enlarged and usually reduced in consistency. The surface was smooth and edges rounded. On section, in some instances the lobules were hardly to be distinguished, the whole surface presenting a homogeneous appearance; in others the cut surface was made up of minute purplish areas surrounded by a network of yellowish-gray lines.

Under the microscope marked cloudy swelling was present in all cases, with more or less congestion. In three instances the most noticeable change was a fatty degeneration of the liver cells. This in one instance was of very pronounced degree, nearly all the cell protoplasm being replaced by large and small fat droplets. In association there was considerable enlargement of the hepatic capillaries.

It is interesting to note that the clinical history and general condition of the infant in which the greatest degree of fatty degeneration was present were not unlike those of the one showing the least liver alteration. This rather common form of hepatic degeneration seems to be dependent on factors at present little understood.

Kidneys.—There were no gross renal lesions made out other than an occasional cloudiness of the cortex partly obscuring the glomeruli and more or less dilatation of the vessels. The minute changes, together with moderate acute congestion, consisted in a parenchymatous degeneration, particularly of the cells of the convoluted tubules, and were of marked grade in but two instances.

Spleen.—This organ in our series presented few alterations. Its consistency was somewhat increased and the pulp was slightly darkened. In most cases the glomeruli were easily visible. Under the microscope, except for some congestion, little of pathologic nature was detected.

Examination of the thyroid, thymus, pancreas and adrenal bodies failed to disclose any abnormality.

Lymphatic Glands.—The most conspicuous and constant feature in the autopsies was the enlargement of the lymphatic glands of the mesentery. Frequently glands connected with all parts of both small and large intestine were uniformly swollen; in others the enlargement was most noticed in the glands of the mesoecum and colon, and more particularly in those draining the severely inflamed or ulcerated portions.

The glands varied in size from 2 to 3 mm. to 1.5 cm. They were fairly firm, whitish pink in color, often with dots of hemorrhage on their surfaces. Under the microscope a moderate proliferation of lymphoid cells with dilatation of the blood vessels was found. The increased size of these structures, as in the lymphatics of the intestinal wall, was due to the distension of the lymph channels and the separation of the cellular elements from each other by a serous exudate. The reticular framework of the glands could in many instances be readily made out. Scattered throughout the pulp were many large epithelioid cells apparently coming from the walls of the lymph vessels. There was little increase in the number of polymorphonuclear cells.

The pathologic alterations here referred to agree in the main with those found by Howland in a larger series of cases and reported to the New York Pathological Society.¹⁰

It is evident that the dysentery bacillus does not always produce in the infant a uniform pathologic picture, but is capable of setting up alterations differing widely, both in severity and extent, from cases where the intestinal wall is practically unchanged to those in which large areas of the mucosa, particularly of the large intestine, is lost. The typhoid and diphtheria bacilli, the pneumococcus, the gonococcus, and many other organisms are now known to have a varied pathology, and the dysentery bacillus in its manifold manifestations is in agreement with facts recently learned concerning the activities of these other well-known pathologic bacteria.

It is well, when possible, to classify diseases according to their etiology. Hence the name *Dysentery infantum*, or infantile dysentery, has been suggested for diarrheal disorders in infants due to the dysentery bacillus. This term at once separates these cases from those of adult dysentery which present certain pathologic differences, and from the diarrheas in infancy due to other causes, either nutritive or bacterial.

SUMMARY.

The results of this study may be summarized as follows: During the summers of 1902 and 1903 epidemics of diarrheal disorders among infants and young children appeared in Baltimore. A large proportion of these cases properly investigated were found to be produced by the proliferation in the intestinal tract of the *Bacillus dysenteriae* (Shiga), the variety of the organism being the so-called acid strain; that is, the type of the bacillus which ferments mannite with acid production. In the histories of the patients, in the clinical manifestations of the disease, and in the pathologic lesions, the cases appear identical with those of epidemic diarrhea which have recurred for many years among infants in Baltimore and other American cities, and there is good reason for the confidence that the dysentery bacillus is an important factor of this great scourge among children.

The disease begins in June, reaches its height in July, and gradually declines in August, although sporadic cases occur throughout the year. The number of cases appears to be directly increased by excessively hot weather. Children under one year are most susceptible; those over three years are rarely attacked.

Babies exclusively breast fed are less often affected; most of the cases occur among infants artificially fed. The simultaneous outbreak of so many widely separated cases suggests that the causal organism does not reach the baby primarily through the milk, but rather through a carrier common to all, such as water, and an investigation of the water supplied the ill babies makes this hypothesis possible, though other sources of infection are recognized.

Ill-nourished children, particularly those fed on condensed milk, are less able to withstand infection by the dysentery bacillus, and form a large proportion of the fatal cases.

The cases can be roughly divided into two groups—those in which the symptoms of toxemia are most prominent and those in which there is evidence of a destructive lesion of the bowel.

Mucus was noticed in the stools in all cases. Blood was present in the discharges in moderate amount in but 42 per cent., and pus in but 53 per cent. of the cases. Many of the deaths occurred late in the summer in long-standing cases of ileocolitis with ulcerated intestines.

The keynote in the treatment is promptness. If the food can be stopped and the alimentary tract emptied within a few hours after the onset of symptoms, most infections can be aborted.

The results of antidyenteric serum treatment were disappointing. It, too, was apparently helpful in proportion to the shortness of the time which elapsed between the beginning of the illness and the injection of the serum. Its use is perfectly harmless under antiseptic precautions.

The prophylactic injection of the serum into susceptible babies may prove to be an advisable procedure.

The alterations in the body produced by the action of the dysentery bacillus may be those of an acute toxemia only, or in addition there may be set up more or less destructive lesions of the lower bowel. In this latter process streptococci and other organisms may play a part. The constant change noticed in all cases was the enlargement (serous infiltration) of the mesenteric lymph glands.

THE BACILLUS DYSENTERIAE (SHIGA) IN ITS RELATION TO THE DIARRHEAL DISEASES OF INFANTS.

A CLINICAL STUDY OF TWO HUNDRED AND THIRTY-SEVEN CASES.*

L. EMMETT HOLT, M.D.

Professor of Pediatrics in the College of Physicians and Surgeons. NEW YORK CITY.

The early history of the work done on the dysentery bacillus has been so often published that it need not be repeated here. It is to Duval and Bassett that the credit is due of first pointing out the fact that this organism played an important part in the diarrheal diseases of infancy. Working under the direction of Dr. Flexner at the Thomas Wilson Sanitarium, Baltimore, in the summer of 1902, Duval and Bassett studied 53 cases of diarrheal disease in infants and young children, in 42 of which they demonstrated the presence of the dysentery bacillus. After a considerable number of positive cases had been found, 25 cases were taken successively and from 19 of these the dysentery organism was isolated. They established the connection between the organism and the disease by obtaining positive agglutination reactions in a very considerable number of their patients.

In the autumn of 1902, at my suggestion, Dr. Martha Wollstein, at the Babies' Hospital, began a systematic study of the cases of acute disturbance of the intestine, and continued the investigations until the following May, in order to discover whether this organism would be found in winter cases as well. She studied, in all, the discharges from 114 patients, representing almost every phase of acute intestinal disorder; in 39 of the 114 cases the dysentery bacillus was found. It was never absent where the clinical picture was a definite one of acute disturbance characterized by the presence of blood and mucus in the stools.

In 1903, under the general direction of Dr. Flexner, the Rockefeller Institute undertook to continue this investigation by making simultaneous observations at different centers, with a view of throwing further light on the relationship existing between the dysentery bacillus

and diarrheal diseases in summer. Work was carried on in New York at the Babies' Hospital, Nursery and Child's Hospital, Vanderbilt Clinic, Pounding Hospital, Infirmary for Women and Children, Bellevue Hospital; in Baltimore, in the out-patient department of Johns Hopkins Hospital and the Thomas Wilson Sanitarium; in Boston, at the Floating Hospital, and at the Children's Hospital in Philadelphia.

The bacteriologic reports of this investigation have been edited by Dr. Flexner and have recently been issued. The present paper is a summary of the clinical reports of 237 cases in which the dysentery organism was present. These cases were observed by the following persons:

Drs. John Howland and L. E. La F6tra, Vanderbilt Clinic	62 cases.
Dr. Louise Cordes, Infirmary for Women and Children	26 cases.
Dr. Samuel Amberg, Baltimore	19 cases.
Dr. Louis M. Wariela, Bellevue Hospital	7 cases.
Dr. J. H. M. Knox, Jr., Thomas Wilson Sanitarium	43 cases.
Dr. Robert Hastings, Boston Floating Hospital	28 cases.
Dr. R. G. Freeman, New York Pounding Hospital	7 cases.
Dr. Dorothy Reed, Babies' Hospital	45 cases.

Several of these persons have already published their individual reports. It is the purpose of the present paper to combine the results of the investigations of the summer of 1903 to see what light they have thrown on our conception of summer diarrheas of infants, and especially what results have been obtained, and in the future what may be expected from the serum treatment.

Considerable new light has been thrown on the subject of diarrheal diseases in infants and young children by this investigation, although much still remains to be done. The summer was not a particularly fortunate one for such an investigation, as it proved to be an unusually cool season, and the diarrheal diseases were neither so frequent nor so severe as in average years.

Several points were prominently brought out by the different clinical observations:

1. The infection with the *B. dysenteria* occurs under quite a wide variety of conditions. It is seen in breast-fed infants as well as in those artificially fed.
2. It occurs (a) as an acute primary infection in children previously well; (b) as a subacute infection without previous acute symptoms; (c) coincident with or following other acute diseases, such as measles, pneumonia, etc.; (d) it is often seen as a terminal infection in children suffering from extreme malnutrition or marasmus.
3. It occurs as a mild intestinal disorder with few symptoms, and these hardly more marked than those belonging to intestinal indigestion; also with local symptoms of considerable severity, yet with very little fever or constitutional depression; and finally, in its most severe form, with both local and constitutional symptoms of great severity.
4. It is not a disease of any one locality, having been seen with great and about equal frequency in all the large cities—New York, Boston, Philadelphia and Baltimore—where investigations were carried on; the only variation in type being that in the warmer cities the proportion of severe acute cases was rather larger. Nor is the disease one of tenements and hospitals, a number of the cases observed being in children living under the best surroundings, even in the country. In its prevalence, it appears to be as widespread as are summer diarrheal diseases.

PREVIOUS DIET.

The clinical reports include observations on 237 cases. The previous diet was studied in most of these in the

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClannahan and John C. Cook.

hope of gaining some information as to the mode of entrance of the organism into the body. Of the cases observed, 26 were previously breast-fed. While in most of these the infection was a mild type, some were severe and even fatal. That these attacks were, as a rule, milder than most of those seen, may be in part at least explained by the better physical condition, and consequently the greater resistance of the breast-fed infants. That so many attacks were seen in nursing infants shows that we must seek for some other mode of entrance of the specific organisms than with the milk. Possibly it may be the water, although in this the dysentery bacillus has not yet been found. The practice of boiling water for the use of infants is seldom followed in the tenements, and water in some form was given to almost all the children. No special relation of the infection to any other food or any special kind of feeding could be discovered.

RELATIVE FREQUENCY OF INFECTION.

The relative frequency of infection with the dysentery bacillus as compared with other diarrheal diseases of infancy can not be definitely stated from these reports. In only two groups of cases were systematic examinations made of consecutive cases. In the others, the cases for examination were more or less selected, and hence it is impossible to draw conclusions from them as to relative frequency. The two groups of consecutive cases were those from the Vanderbilt Clinic, a summer series reported by Howland and La F etra, and those from the Babies' Hospital, a year-round series, reported by Reed. In the first group of cases the dysentery bacillus was found in 62 of 64 cases examined. They included every sort of intestinal disturbance attended by diarrhea. These figures, however, do not prove that in every instance this organism was the cause of the disturbance. In some of the cases the number of dysentery bacilli was apparently very small; sometimes only one or two colonies were discovered after a prolonged and careful search. But their presence even in such small numbers is interesting as showing possibly how mild attacks might develop into severe ones.

In this connection I should like to refer to some studies just completed at the Babies' Hospital by Dr. Wollstein on the stools of normal children. During the past winter and spring, observations have been made on 56 children with a view of determining (1) whether dysentery bacilli were present in the stools of normal infants; (2) whether they could be obtained postmortem from scrapings of the mucosa of children dying from other diseases.

Stools of 32 children, all under 18 months of age, were studied with great care by the following method: Patients who had been in the hospital several days and had been observed to have normal discharges were selected. The colon was washed out with one or two quarts of a saline solution, after which a cathartic, castor oil or citrate of magnesia, was administered. All stools passed in the next ten hours were studied. In no instance were dysentery bacilli discovered.

In a series of 24 cases studies were made of scrapings from the intestinal mucosa in children dying from diseases other than intestinal. In 21 no dysentery bacilli were found. They were present in 3 cases, but 2 of these presented rather marked evidences of inflammation of the intestinal mucous membrane, not suspected during life; while in the third a history was obtained of a previous attack of diarrhea, and this case showed swelling of Peyer's patches and some congestion of the mucous membrane of the colon.

In one entire year's service at the Babies' Hospital about one-half of all the cases exhibiting clinical evidence of acute disorders of the intestinal tract showed dysentery bacilli.

These observations indicate that dysentery bacilli are an important etiologic factor in the intestinal diseases of young children, both in winter and in summer; but that they are present in a much larger proportion of cases in summer than in winter.

CLINICAL TYPES.

Of the cases studied, 91 were classed as examples of severe infection. These were characterized by much mucus and generally blood in the stools, usually fever, but not always high, and by marked general prostration. There were 81 examples of moderately severe infection, in which there was much mucus and often blood in the stools, some fever but not much constitutional depression. There were 63 examples of mild infection, in which the constitutional symptoms were very few; blood was seldom present; there was little or no fever; but the stools almost always contained mucus. These figures indicate only that mild infections are very common; their relative frequency, however, is probably much greater than is stated here, since by several observers only severe cases were taken for examination.

The types of disease were essentially the same at all places where the observations were made. Infection with the dysentery bacillus was associated with almost every sort of intestinal disturbance accompanied by diarrhea, with, however, one notable exception, viz., the severe acute intestinal intoxication called "cholera infantum," with its sudden violent onset, protracted vomiting, high temperature, frequent serous discharges, great prostration, early collapse and often early death. There was only one case which at all approached this type, and this lacked some of the essential features. The infection with the *B. dysenteriae* is associated rather with the inflammatory forms of diarrhea, and of all degrees of severity, the mildest and the most severe, the acute, the protracted and subacute; occurring both as a primary disease and a secondary disease, often occurring in institutions during the summer as a terminal infection in infants suffering from marasmus, exactly as does bronchopneumonia under similar circumstances in winter.

Up to the present time the organism has not been found in cases of chronic intestinal indigestion in infants and older children, even though mucus was present in the stools in considerable amount. In this series of cases there were observed no chronic cases such as have been described in adults where bacilli were found after many months. The cases of long duration which were studied in infants were usually free from bacilli at the end, death being due to progressive marasmus.

The most characteristic clinical type and the one with which the organism was almost invariably found associated, was the acute febrile form with stools containing much mucus and usually streaked with blood. For these cases the term "infantile dysentery" would seem the only proper appellation. This type seems so distinctive that we may safely regard it as a separate and distinct disease.

TYPES OF ORGANISM.

Of the 237 cases studied clinically, the "Flexner-Harris" or "acid" type of organism was present in 207, the true Shiga in 23, and both organisms were present in 7. No difference could be observed in the clinical manifestations in the different forms of infection. Further-

more, the relative frequency of the different types was nearly the same in all places where the observations were made.

Whatever may be said of the dysentery of adults, it would appear from these data that in infants and young children, in our large eastern cities, it is the acid type of organism rather than the true Shiga with which we are chiefly concerned.

MORTALITY.

Of the 237 cases reported, 73 were fatal. This gives little idea of the gravity of the dysentery infection, since it is well known that the result in all forms of intestinal disease in infants depends on nothing so much as on the age and previous condition of the patients. Considerably more than half the total number, 139, were observed in hospitals. It was among these patients also that nearly all the deaths occurred, as might have been expected. The poor general condition of these patients and the late date of beginning treatment had most to do with determining the results. Again, in several it was noted that the patients recovered from the acute diarrhea but died subsequently from marasmus. Cases of this kind were seen in almost all the groups.

In all acute disorders of the intestinal tract complex conditions are present. No infection or intoxication can occur without producing marked functional derangement of digestion. In some cases the infection is slight, while the digestive disturbance is severe. The two bear a general but by no means a constant relation to each other. The child's symptoms may be due almost entirely to the indigestion and very little to the infection. These conditions stand in the way of success by serum treatment. While we may be able to combat the infection by the serum, it may be without any power to improve the digestive disturbance. It also has a bearing on the question of diet during the attacks.

DIET DURING THE ATTACK.

The necessity of stopping milk during severe acute infections is universally agreed on. There is, however, some difference of opinion in regard to the desirability of withholding milk from cases of moderate severity, without temper ture, where the disease seems to be limited to the large intestine. In these cases the symptoms from which the child suffer are chiefly those of wasting from chronic indigestion. There seems to be little doubt from the experience at the Babies' Hospital and Vanderbilt Clinic, that many of these cases do much better on a properly modified milk than on other substitutes employed, such as broth, barley water, albumin water, etc., with which the loss of weight is very rapid. In such cases the infection seems to play a minor part and the indigestion a major part, and, therefore, one should not have his attention too much on the presence of a specific infection, but should manage the child's diet according to general principles, as in other forms of acute or subacute intestinal indigestion. The mere presence of dysentery bacilli in the stools is, therefore, in itself no reason for withholding milk, and its intelligent use seems to give much better results than the substitutes usually employed.

PREVENTION.

The fact that the dysentery infection is contagious seems to be established, but how and to what degree is not yet proven. In four instances, small ward epidemics were noted. From present experience a high degree of contagion does not seem probable. The spreading takes place most likely through the discharges. This calls at-

tention to the necessity for disinfection and the closest attention to prevent contamination of food or water by persons handling the child's napkins. The rule followed in the Babies' Hospital is a good one for all institutions, viz., that the nurse in charge of the children's napkins shall not at the same time have anything to do with the food or the feeding.

SERUM TREATMENT.

In all there were 83 cases in which the anti-dysenteric serum was employed; 38 of these were fatal. On the whole, the results were disappointing. No unfavorable symptoms followed its use in any case. In a few instances eruptions, usually urticaria, followed, as occasionally after diphtheria antitoxin. In only 12 cases did a noteworthy improvement appear to follow its administration. A careful study of the cases in which the serum was used does not make the results quite so bad as at first appears. Too much evidently was expected. The physicians had in mind the striking effects seen after diphtheria antitoxin. These were observed in no instance, and it is doubtful if they ever will be. The conditions in the intestines are very complex and in no way comparable to those which are present in diphtheria. Great disturbances of digestion are in most cases present, and the consequences of this remain long after a specific infection may have disappeared. Difficulties were found in the use of the serum. The quantity in the strength in which it was used was large. The mothers of dispensary patients would not allow its use except in severe cases, and often would not return for a second dose. A brief summary of the cases seems desirable.

Freeman's Report.—Seven cases treated; all hospital patients; in 2 the attack followed measles; one child had diphtheria and pneumonia. In 4 cases no improvement. In 3 improvement apparently occurred, but 2 died later from marasmus long after the intestinal symptoms had disappeared. The only case which recovered was that of a nursing child. Full doses were given, all but one receiving from 5 to 10 doses of 10 c.c. each.

Howland's and La Vitra's Report.—Ten cases treated; all dispensary patients. Serum used only in the severe cases. Two children received but a single dose; result unknown, as they did not return; 2 died, one moribund when treatment was begun, the other recovered from diarrhea, but died long after from marasmus; 2 showed decided improvement after the serum. In the other 4, no apparent effects. Rarely more than 2 doses of 10 c.c. given.

Amberg's Report.—Ten cases treated; 2 hospital patients, 5 private practice, 3 not stated. Of the 5 severe cases, 3 ended fatally, 1 improved and 1 recovered; of the 6 moderately severe cases, 5 recovered, 1 improved. Only one case received an injection on the first day and one on the second day; 3 had been sick four to six days and 6 more than one week. Six cases received two doses and 4 five doses of 10 c.c. each.

Warfield's Report.—Seven cases treated; 2 observed in tenements, 5 hospital cases; 4 died. Two were moribund when the serum was given and one other had pneumonia; 3 apparently benefited by the serum. Two patients received but two doses; all the others received much larger quantities, one patient being given 150 c.c.

Hastings' Report.—Fourteen cases treated; all hospital patients. Serum was used only in the severe cases. Seven of these were fatal. Details of the fatal cases only are given; one of these was moribund at the time of the administration, one died in the seventh week of the disease; 5 were in poor condition at the time of the attack. No striking improvement seen in any case.

Know's Report.—Twenty cases treated; of these 9 were fatal. Three cases apparently improved from the serum; in 17 apparently no improvement.

Cordes' Report.—One severe case seen late, no apparent effect.

Reed's Report.—Fourteen cases; all hospital patients; nearly all severe infections. Temporary improvement seen in several, permanent improvement in none. In 9 cases only one 10 c.c. dose was given.

Such, in brief are the facts regarding the use of the serum in the 83 cases in which it was employed. That decided improvement appeared to follow its use in only 12 of the patients is not very encouraging. Several factors worked against success. In a large proportion of the cases it was used late in the disease. Again, it was as a rule used only in the most severe cases; and, finally, at the beginning of the season no rules had been formulated as to the size and frequency of doses, hence it is evident that many of the doses were too small. Four patients were moribund at the time the serum was given. Of the 83 cases, 67 were hospital patients, and all familiar with hospitals for infants know the class of patients referred to.

The conditions of success, however, are, first, that it must be used early, before serious lesions have developed or before the patient's general nutrition has been too profoundly impaired. The latter refers particularly to cases in young infants. The second point is that experience shows that the serum must be used in repeated doses, one or two doses given each day and continued for several days if the attack is severe. I can not myself feel from a study of these reports and from personal observation of some of these patients, that an adequate trial of the antidyenteric serum has yet been made. The favorable cases for its use are surely not the subacute infections, where the symptoms relate much more to the functional disturbance of digestion and the resulting impairment of the child's nutrition, than to the specific toxemia of the dysentery bacillus; nor again can anything be expected from it in attacks which develop late in a condition of marasmus in hospital patients. The promising cases are rather the sharp acute attacks with symptoms of severe infection occurring in infants or older children with some powers of resistance. In other words, in patients where the real problem is to combat the infection, and not to maintain the nutrition of patients, which even before the infection was a matter of the greatest difficulty.

Inasmuch as at present nearly two days are required for a bacteriologic diagnosis, and as the agglutination reaction is seldom present until the end of the first week of the disease, if used at all, the serum must be injected on a clinical diagnosis. Its use would then be indicated in children taken with acute intestinal symptoms with blood and mucus in the stools, or with very much mucus in the stools with fever and symptoms of general infection. The serum surely must be used early, and it must be given repeatedly, since what is desired is to stop a process and not to neutralize a toxin.

All rules as to dosage and frequency must at present be tentative. From the experience of the past summer it would appear that a dose of at least 10 c.c. should be used daily in a moderate case, this being repeated two or three times daily in a severe case.

Since we have no means at present of differentiating clinically the cases in which the infection is with the acid or Flexner-Harris and with the true Shiga type, it would seem best to use a serum from animals immunized against both types of the organism, or that from animals immunized against the acid type, since by far the largest number of cases in young children are of this variety. Although the serum obtained from ani-

mals immunized with true Shiga is not without some effect in infections with the acid type, and vice versa, this is much less than when the animals are injected with the special type of organism concerned.

A beginning only has been made with the use of the antidyenteric serum. A much more extended trial and on more carefully selected cases is necessary before definite statements can be made as to its value.

14 West Fifty-fifth Street.

SOME FINDINGS IN SUMMER DIARRHEAS OF CHILDREN.*

JOHN C. COOK, M.D.
CHICAGO.

These cases came under observation during July and August, 1903, and are reported to show the relative frequency of some bacteria not ordinarily given prominence in this relation. The study was begun with the hope of making some clinical deductions from the microscopic findings and to trace, if possible, any bacterial relations between the buccal cavity and intestinal disorders.

Twenty-nine cases in all were observed and cultures were simultaneously made from mouth and fecal discharges, and observed as nearly together as possible, but much of the work was not completed owing to the sanitarium closing before all the cultures were worked out.

No note will be made of the ordinary inhabitants of the canal, such as colon groups, staphylococci, etc., but only such as may have some pathologic bearing on the clinical findings.

Cases 1, 2 and 3.—Nothing of value was found, notwithstanding that there were some clinical features present, such as vomiting and loose bowels, which were found in other cases bacteriologically more interesting.

No. 4.—Breast-fed; aged four months; diagnosis of enteritis. Gave history of from five to six loose, offensive movements daily for four or five days; temperature from 96 to 100; vomited frequently. Cultures were taken from oral cavity and bowel movements, but nothing was found but pink yeast bacilli and staphylococci from the mouth.

No. 5.—Aged six months. Came to sanitarium July 27, with normal temperature and history of from three to five loose brownish bowel movements a day. On the fourth day after admission a curdy exudate appeared in the roof of the mouth and on the inside of the cheeks, and some on the outside of the gums, resembling thrush a little. With this came a slight rise of temperature and loose greenish movements, six to eight a day. This condition was not influenced by treatment for more than a day at a time, when it would lapse back to the same state, and the child died on August 18. Cultures from mouth and movements both showed *Bacillus pyocyaneus*. A postmortem was not permitted.

No. 6.—Entered the sanitarium July 6, with temperature 103; three or four loose green bowel movements in twenty-four hours; vomited once or twice. Child was 18 months old and fairly well nourished; had been nursed for first two months of life, when the supply failed; since had been fed on diluted cow's milk. Cultures from oral cavity showed nothing out of the ordinary. *Bacillus pyocyaneus* was found in the culture from bowel movements. Child left the sanitarium on August 4, not in good condition.

No. 7.—Aged nine weeks; normal temperature; partially breast-fed and partially on store milk diluted; frequent green bowel movements; vomited occasionally. *Bacillus pyocyaneus* in bowel movements only. Did not return.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

No. 8.—Aged eleven months; rachitic; came from day nursery. Had from three to four yellow sour movements in twenty-four hours; only vomited once in two or three days; had been fed on some proprietary foods; child was under observation for nearly a month and during that time had three to four movements a day, sometimes green, but mostly yellow or brown in color. *Bacillus pyocyaneus* was found in the dejecta only. Child was fed on milk, proteins 1, fats 3, hydrocarbonates 7. Gained rapidly and was discharged cured on August 29.

No. 9.—Aged ten months; ran a normal temperature after first twenty-four hours; two to four yellow bowel movements a day, only occasionally showing any green; did not vomit.

Nos. 11 and 12 were of no interest bacteriologically. No. 12 was colored and markedly rachitic.

No. 13.—Aged five months, was presented for treatment August 6, at 4 p. m. Temperature 99, and history of having been sick three days. Vomiting and frequent green offensive bowel movements. Child was given a bath and colonic flushing, and two ounces of barley water to drink. At 12 midnight, temperature was 104.6, pulse 150, respiration 72; child died at 1:45 a. m. A culture from the month grown on bouillon, developed the *Bacillus mycoides*. On interrogating the mother, she said the baby had been fed on one cow's milk, the animal being owned by one of the neighbors. The same day she brought some of the milk from which the baby had been fed the day before, also a specimen of milk scoured from the owner of the cow that day. Both contained *Bacillus mycoides*. Not being familiar with the bacilli, we believed we were dealing with an anthrax, so visited the cow and found her healthy and giving a good quantity of milk. The owner said the cow had always been well, but some of the neighboring children said it had been sick about a week before, so it would not eat for two or three days.

No. 14.—Aged four months. Came under observation August 7, with normal temperature and history of vomiting and loose bowels for past week. It had been fed on malted milk, barley water, oatmeal water and condensed milk. Temperature was normal for next four days, with one exception; on the third day it went to 101 and back to normal; three to four green, offensive movements a day, and vomited about once a day until fifth day, when it was sent home convalescent. *Bacillus pyocyaneus* was found in the fecal discharges.

No. 15.—Aged four months; temperature 100.2 Child had been sick one week; six to ten green, watery bowel movements in twenty-four hours, sometimes very offensive; vomited once or twice a day; catarrhal stomatitis and bronchitis; very emaciated, showing marked degree of starvation rigidity; improved during its stay at the sanitarium—three or four days. *Bacillus mycoides* and *Bacillus pyocyaneus* from mouth culture; nothing worthy of note developed from fecal culture.

No. 16.—Aged three years; well nourished; temperature 101. Child had a round white patch on inside of left cheek, size of a half dollar, resembling noma, which spread to roof of mouth on same side, causing necrosis of the soft parts, irregular in shape. This yielded in four or five days to local treatment—peroxid of hydrogen and saturated solution of chlorate of potash. Klebs-Loeffler bacilli were found from culture of mouth, no fecal culture being made. No paralysis resulted, and, notwithstanding that the child mingled freely with other children, there was no spread of the disease.

No. 17.—Aged six months; had pain in the bowels, green discharges containing undigested food; vomited some mucus. Temperature 99, increased steadily, reaching 104.2 on the fourth day, when it began to subside. *Bacillus pyocyaneus* was found in mouth and fecal discharges.

No. 18.—Aged eight months. Was one of a pair of twins, the other one having died two weeks before. Temperature from 97.6 to 99.2; had one or two daily, and about the same number of night, movements containing undigested food, yellow, turning green on exposure; vomited occasionally. *Bacillus pyocyaneus* was found from stool culture, also from oral cavity.

No. 19.—Entered the sanitarium August 14; aged ten months; temperature 102.4, which rose to 105 within the next

twenty-four hours. Child was having from eight to twelve green movements a day, containing mucus and undigested food; temperature ran from 102 to 105, with about the same number of movements a day for the next seven days, when temperature gradually subsided, but the number of movements kept up, with very slight disturbance to the stomach. Child retained food well unless given too much. Temperature did not go above 99.6, but there was little change in the number or character of the bowel movements until the 16th day, when she died. *Bacillus pyocyaneus* was found in the feces only.

No. 20.—Aged 14 months, entered the sanitarium August 10. Temperature 99.8, and varied from 98 to 100 until the ninth day after admission, when the temperature went to 103.6 about two hours before death. Child had from three to five movements daily, dark brown to green; vomited very little. *Bacillus pyocyaneus* was found in the bowel discharge but not from mouth culture.

No. 21.—Five months old, normal temperature; had frequent light green bowel movements; did not vomit; condition improved daily for three or four days, when she was sent home.

No. 22.—Six months old; was brought to the sanitarium for three or four days; temperature normal; had frequent dark brown movements; did not vomit. No bacteria found from either mouth or movements.

No. 23.—Only present once for treatment. Child was twelve days old; breast-fed; had from eight to ten loose yellow movements a day. No bacterial findings.

No. 24.—Seven months old. Child was brought for treatment July 22, with the following history. Had been fed on raw milk and Mellin's food; began vomiting this morning; later the bowels became loose, with offensive light-colored movements containing quantities of undigested food. If food was not immediately vomited, it passed through the bowels in from 20 to 60 minutes; temperature ranged from 98.6 to 100. The first day of illness she weighed 12½ pounds. Three days later her weight was 7 pounds. After forty-eight hours vomiting ceased and food was retained in the bowels long enough to nourish. In the course of a month the child weighed 12¼ pounds. *Bacillus mycoides* was found in the stools.

Nos. 25, 26 and 27 gave negative results, both from mouth and fecal cultures.

No. 28.—Eight months old. Child had been well until the last days of August, then began having loose green bowel movements, containing quantities of mucus and streaked with blood; vomited three or four times in first twenty-four hours; had been fed on dextrinized gruel with top milk; temperature went to 102; great prostration but rapid recovery. *Bacillus pyocyaneus* was found in the stool culture.

No. 29.—I saw child for the first time when it was three days old. It had vomited that morning and the mother said it acted sick; temperature 100; had been nursed since birth; mother's milk was still full of colostrum; towards night of the third day the child vomited several times and the bowels became very loose. I advised the breast-feeding stopped and the breast pumped out, and gave albumin water. The vomiting ceased as soon as nursing was discontinued, and by the fourth day the bowels did not move oftener than every three to five hours. Albumin water was continued until the morning of the fifth day, when the child was put on the breast, which it took willingly. After the third nursing it vomited, and by the middle of the afternoon the bowels had begun to run off and she vomited again. Nursing was again discontinued. A few small yellow blisters appeared on the head and face that afternoon. I advised the nurse to open them but by the next morning the upper third of the child, including the head and face, was covered with the same sort of a papular eruption and the bowels were very loose—three or four offensive watery movements every hour. The baby was kept nourished on barley and albumin water. A culture was taken from the mouth, also a specimen of milk was drawn aseptically and a culture made from it. *Bacillus mycoides* was found in both. The baby had a little temperature for a week, the pustules gradually drying up; the condition of the bowels had improved so much that we once more tried the

breast, with the same result as before. The child was then put on dextrinized oatmeal gruel with top milk, and it is now a well, strong child, having fulfilled the ordinary requirements of weight and measurements. This was the third baby in the family—a girl—the two older children being boys and both had been strong and nursed for a short time. No miscarriages or other evidence or history of syphilis. The mother had a small abscess in one breast before the milk was dried up.

THE RÔLE PLAYED BY THE BACILLUS PYOCYANEUS.

Holt speaks of pyocyanous infection in ulceration of the intestinal canal.

According to Sternberg, the *Bacillus pyocyanus* was obtained by Gessard (1882) from pus having a green or blue color, and since carefully studied by Gessard, Charin and others. This bacillus appears to be a widely distributed saprophyte, which is found occasionally in the purulent discharges from open wounds, and sometimes in perspiration and serous wound secretions (Gessard).

Morphology.—A slender bacillus with rounded ends, somewhat thicker than the *Bacillus murisepticus* and of about the same length (Flügge); frequently united in pairs or chains.

Biologic Characters.—An aerobic, liquefying, motile bacillus. Grows readily in various culture media at the room temperature—more rapidly in the incubating oven.

12	8	5	1	2	1	14	12	

Of the 12 cases with temperature above 100, 6 had *Bacillus pyocyanus* in stools; 5 had *Bacillus pyocyanus* in mouth; 10 vomited; 7 had green movements.

Of the 8 cases with *Bacillus pyocyanus* in the stools, 7 had green movements.

Of the 5 cases with *Bacillus pyocyanus* in mouth, 1 had *Bacillus Mycoides* in mouth.

Of the 14 cases that vomited, 6 had *Bacillus pyocyanus* in stools; 4 had *Bacillus pyocyanus* in mouth.

Of the 12 cases with green movements, 7 had *Bacillus pyocyanus* in stools; 4 had *Bacillus pyocyanus* in mouth.

Does not form spores. The thermal death point, as determined by Sternberg, is 56 C., the time of exposure being ten minutes. In gelatin plate cultures colonies are quickly developed, which give to the medium a fluorescent green color; at the end of two or three days liquefaction commences around each colony, and usually the gelatin is completely liquefied by the fifth day.

Pathogenesis.—The experiments of Sternberg, Lederhose, Bouchard and others show that this bacillus is pathogenic for guinea-pigs and rabbits. Subcutaneous or intraperitoneal injections of recent cultures—one cubic centimeter or more of a culture in bouillon—usually cause the death of the animal in from twelve to thirty-six hours.

More recently Donald R. MacIntyre¹ of Ann Arbor has shown that the *Bacillus pyocyanus* contains an in-

tracellular toxin, and his excellent article has shown that the toxicity of the powdered germ substance of *Bacillus pyocyanus*, when injected intraperitoneally into guinea-pigs in the proportion of 1 part to 50,000 parts of body weight, is surely fatal. When injected subcutaneously in guinea-pigs, even in as large a quantity as 1 part of the toxin to 10,000 of body weight, the only inconvenience that resulted was a slight swelling at the point of inoculation, followed by temporary loss of weight. Subcutaneous injections did not give immunity to subsequent intraperitoneal treatments.

THE BACILLUS MYCOIDES.

The *Bacillus mycoides* has been isolated from cow's and mother's milk and also found in the oral cavity and fecal discharges of children. When grown on agar-agar bouillon, it grows very much like the anthrax bacillus. However, after a few days' growth the bacterial cell seems to grow as a shorter rod and with a rounder end than that of the bacillus anthrax. When grown in beef bouillon, it grows as a flocculent mass on top of the liquid.

When from 1 to 3 c.c. of beef bouillon culture is injected into guinea-pigs there is a decided cellulitis in the tissues around the point of injection. Forty-eight hours later the animal showed a decided toxic condition, with languor, and did not take food, and in about two to seven days the entire body seemed to be in a bloated condition. When the bouillon cultures were filtered out and the solution injected free from bacteria, very much the same symptoms were present, with the exception of the cellulitis that was manifest in the injection of the solution containing the bacteria themselves.

None of the animals died that were inoculated with the growths in the bouillon. Injections beneath the skin from very recent cultures on milk produced no effect, but an injection of 1 c.c. of milk culture, twenty-four hours' growth, produced very much the same symptoms as those injected with the bouillon; and forty-eight hours' growth in milk showed signs of a more toxic condition. There was considerable swelling around the point of injection. Twelve hours after the injection was made the animal began to show symptoms of inactivity. In twenty-four hours it refused food and began to bloat. This increased to the fifth day, when it died in convulsions. The organism could not be found in the blood of the animal nor in any of the body tissue except the spleen, where it was found in considerable quantity.

These inoculations were made in six guinea-pigs. Three of them died within six days, one on the tenth day, and the other two recovered after a long time.

This organism has not been classed as pathogenic so far as I have been able to ascertain—that is, it does not produce any specific disease, still it appears to possess the power of producing a toxic substance in milk, resembling that of ptomaines.

The first twenty-four hours' growth in bouillon, gelatin or agar-agar has to such an extent the general characteristics of anthrax that I found it impossible to distinguish one from the other under the microscope. However, after forty-eight hours in agar the chain-like appearance which is seen in anthrax slides began to be broken up, and the ends of the rods of the *Bacillus mycoides* became more rounded in appearance and they soon lost a great deal of their resemblance to anthrax. In the cultures of the twenty-four to forty-eight hours' growth there is to be distinguished large refractive bodies in the cells of the bacteria which, from general appearance, might be taken for spores, but with the method of

staining for spores we were unable to decide whether or not these refractive bodies were spores. However, in old, dried-up cultures there is to be found nothing but the round or oval forms of the micro-organism, which has a great resisting power to heat and many of the antiseptic solutions.

THE MANAGEMENT OF SUMMER DIARRHEA.*

THOMAS S. SOUTHWORTH, M.D.

Attending Physician Nursery and Child's, New York City Children's and Minton Hospitals, Physician Out-Patient Department Babies' Hospital.

NEW YORK CITY.

Trite as may seem the subject, the first hot days of the summer call up a picture of the blanched and sunken faces of the sad little army which besiege the doors of our offices, hospitals and dispensaries in the lifeless days of summer. It is a smaller army than of yore, thanks to the agitation for pure milk and the ever-widening knowledge of the proper methods of prophylaxis and treatment, but the work of such discussions as will follow this group of papers has not yet been done nor will be done until human ignorance or human life disappears from the earth.

ETIOLOGY.

Believe as we may concerning the preponderance of etiologic factors—bacterial, dietetic or meteorologic—the fact remains that diarrhea among infants and young children leaps to the front with the inception of the warm season, and claims our attention as the most common disorder until the cooler weather of the early fall forces it again into the background. It shall be the purpose of this paper to inquire into the advances made during recent years in the prevention and treatment of this scourge and to set them forth as clearly as may be.

In the search for etiologic factors, much that is of scientific interest has been compiled concerning the influence of sustained high temperature of the atmosphere in producing this affection. This influence is variously explained, either as favoring the development and multiplication of hurtful bacteria which may gain access to the digestive tract, or else so lowering, by its prostrating effects, the resistance of the individual host as to render him less able to cope with the invasion. Both factors doubtless play their parts, and since we can not influence the weather bureau, we must needs profit by the suggestions which they furnish for intelligent prophylaxis.

PROPHYLAXIS.

Prophylaxis, which, after all, is the supreme ideal of medical science, may well begin long before the summer opens, and many a life sacrificed might be saved by proper preparation for the ordeal which is to come; diet should be regulated and simplified, over-feeding in frequency and amount corrected, digestive difficulties of all grades, however slight, overcome, anemia and the protean gradations of malnutrition and rachitis actively combated.

Whenever it is possible children of susceptible age should be sent early into the country where the days and more especially the nights are relatively cooler than in the city. If such removal is not feasible as in

the vast majority of families, the coolest and best ventilated rooms should be chosen for their occupancy, clothing should be as light as is compatible with proper protection from sudden changes, they should spend as much time out of doors as possible in the daytime properly protected from the sun's rays, on the shaded side of the street, in public parks and open spaces, beneath trees or along water fronts, if these be accessible, and at night they should sleep in well-aired rooms. The functions and cleanliness of the skin should be promoted by the morning bath and evening sponging with cool or tepid water.

It may be stated as axiomatic that the healthy child is less susceptible to diarrhea, or if attacked, far more amenable to prompt and intelligent treatment. While all breast-fed children do not escape, the number affected of those who are exclusively nursed is relatively very small, and the numbers increase in proportion to the administration of other articles of food, whence the time-honored dread of the dangers not of the first, but of "the second summer."

METHOD OF INVASION.

Squalor, carelessness, improper and injudicious feeding and contaminated milk are probably accountable for most of the trouble. Squalid environment, which usually involves the other causes, furnishes many of our cases, but it should not be forgotten that bacteria may gain entrance to the digestive tract, even among the well-to-do in other ways than through bad milk and uncleanly nursing bottles, and that thumb-sucking and the use of rubber-sucking nipples or "baby pacifiers" should be discountenanced as serious elements of danger.

The investigation carried on among the poor of New York under the auspices of the Rockefeller research fund and published by Park and Holt show that the purer and cleaner the milk the safer it is in the summer months, but since this safety is one of degree only, and since milk produced under ideal conditions is obtainable in but few localities and often at a cost too great for general use, it is a safe and conservative position to assume at the present day that, unless we are assured of the absolute freshness as well as the cleanliness of the milk supply, and furthermore, unless there be some valid reason for the choice of raw milk, the milk for infant feeding during the summer months should be subjected early to pasteurization or sterilization, according to the particular prejudices of the physician, in order to guarantee reasonable hope of protection to the infant.

The term summer diarrhea has been employed purposely in the title of this paper, because while looseness of the bowels may arise at this season from many different causes, and at their inception with varying severity of symptoms, the great majority of them hold possibilities of later serious developments and call for radical and earnest treatment at the outset, at which time remedial measures are almost sure to be effective. There is the greater need of emphasizing this point, because those cases which at once show serious symptoms are naturally more alarming, and in consequence receive attention, while those of the slighter and milder degree are more often neglected until secondary infections have become engrafted, which are of vastly more serious import.

Thus much of the bowel disturbance of summer is purely dietetic and digestive, due either to some special indiscretion, or, as so frequently, to the inability

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

of the child to digest, in hot weather, food with which on cooler days there was no apparent difficulty. Allow this, however, to advance a day or two without suitable treatment or change in diet, and the disturbed mucosa, secretions and contents of the digestive tract become a suitable field for the development of forms of bacteria which the system would readily cope with in health.

WITHDRAWAL OF MILK FROM THE DIET.

While uncleanly and infected milk is responsible for many cases, it is doubtless an error to ascribe all summer diarrheas to this cause, nevertheless it should be remembered that since milk is capable of superimposing additional disturbances in a considerable number of cases, it should be stricken from the diet for absolute safety. Although there are unquestionably exceptions to this rule, it may be asserted and reiterated with the utmost positiveness that no one of twenty remedial measures has such life-saving effects in summer diarrhea as the prompt and absolute withholding of milk and the removal of all milk residue from the digestive tract on the appearance of frequent disturbed stools. Could this one measure be made absolute in every household and institution of the country, the mortality from diarrheal diseases would become insignificant.

There are no reliable means of distinguishing the cases in which milk will or will not do harm. To give milk to the wrong child is to supply him with the materials for the elaboration of dangerous toxins and for the growth of countless myriads of destructive bacterial organisms. Were it proper to end this paper at this point, it would be with the firm conviction that the most important word had been spoken. It is not our good fortune, however, to see every case in the early stages, and there are other measures which must be carried out with intelligent understanding and common sense before the patient is restored to health.

Let us first have a clear appreciation of the conditions existing in the tract which we are to treat. If the diarrhea be of digestive origin we have a mucous membrane congested and irritated and a nervous and muscular mechanism endeavoring by increased and disordered action to throw off their contents, the by-products of those faulty chemical processes are causing the disturbance by contact or absorption. If the difficulty be from contaminated milk, the process is only dissimilar in that the special bacteria which have been introduced multiply rapidly in the favorable medium and add their toxic products to the disturbance of the tissues and by absorption to the general system.

Continue but for a time these derangements of function, during which much of the natural protective power of the bowels is in abeyance and the bars are down for invasion of the intestinal wall itself by pathogenic organisms feebly or actively opposed by the rallying leucocytes, and mucous and submucous tissues suffer severely in their integrity, as so often happens to the hard-fought battlefield of contending forces.

There would be less hesitation in instituting rigid initial measures could every man study, microscopically and macroscopically, the intestines of some of these old neglected cases, swollen, congested, ulcerated, and see through the microscope the epithelium swept away, the mucosa and its glands eroded, and the blood vessels and lymph spaces choked with what were the bodies of the living, the dying and the dead combatants.

TOXIC SYMPTOMS.

We have thus far spoken chiefly of the intestinal symptoms, but what of the effects of the toxemia on the

rest of the body—the high temperature, the vomiting, restlessness, thirst, emaciation and prostration, the results of toxic absorption and of continued futile efforts to eliminate poisons which may be constantly recruited if milk be continued in the diet, and which directly or indirectly causes the death of the patient.

RATIONALE OF TREATMENT.

The picture given above is a common one enough, but before outlining a plan of treatment which is both simple and, if instituted early, usually effective, it will be well as a preliminary to set forth in plain terms what it is proposed to do and the reasons for so doing. The diarrhea, or diarrhea and vomiting, are no less than efforts of the digestive tract to rid itself as quickly as possible of something which it reflexly discovers to be hurtful. So long as that something remains in the body, the diarrhea is conservative, and any attempt to check it completely defeats Nature's purpose and is injurious. We should rather aid Nature in expelling it, and then, if necessary, assist in closing the flood gates which have been so rudely opened that the closing mechanism is out of order. Moreover, if the offenders be the teeming bacteria of spoiled or infected milk, not only must these poison-producing hordes be driven out, but no additional quantity of milk, however small or however disguised, should be allowed to reach the bowels until the whole brood has been exterminated, other forms of nourishment being supplied in which they do not multiply. Diarrhea with or without vomiting has not, however, arisen without considerable irritation of the organs concerned, which renders them incapable of immediately resuming their usual functions, and that which we supply in the way of nourishment must be of the simplest and blandest nature, until the whole system has recovered from what is really a serious shock, and the tone of the digestive apparatus shows that it is again restored by the subsidence of previous symptoms and the return of normal appetite. It must be evident, from what has just been said, that the earlier such rational treatment is begun the less injury will have been inflicted, and other things being equal, the earlier and more certain the recovery.

TREATMENT.

We have thus seen that the immediate indications for treatment in a case of summer diarrhea are of a triple nature, and every mother, nurse and physician should know them by heart. They are to stop milk and substitute a bland diet, to thoroughly clean out the digestive tract, and then, and not till then, employ means to check excessive peristalsis and secretion of the intestines.

Removal of Cause.—Castor oil and calomel are both efficient in sweeping out the bowel contents, and each has its special indications and advantages. Where improper and undigested food is known to be the cause or there be blood or much mucus in the movements, castor oil one to two drams acts promptly and relieves irritation. Where there is vomiting, intestinal decomposition or considerable temperature from absorption, and especially when the trouble has existed some time, calomel may be preferable in doses of 1, 10 grain every half hour up to 1 grain. It is a gastric sedative and intestinal disinfectant, while it favors more normal hepatic action.

Lavage.—Where vomiting plays an important part gastric lavage with lukewarm water or solution of bicarbonate of soda (1 dram to 2 pints) may be most useful in cleansing the viscous.

Intestinal Irrigation.—I have found intestinal irrigation to be necessary less frequently than formerly, doubtless owing to rigid adherence to the rule of stopping milk at once, but it is of the utmost importance where the temperature is ominously high, the toxic symptoms pronounced, and in neglected cases. In conjunction with the administration of laxatives by the mouth, which should never be omitted, nothing compares with it when properly administered in promptness and efficiency in cleansing the colon and reducing high temperature. Plain water should not be used, but a normal salt solution (1 dram to 1 pint), employing a fountain syringe and a moderately firm catheter, number 14E or small rectal tube, introduced in the lithotomy position with hips elevated while the water is flowing, some nine or ten inches into the sigmoid flexure or beyond.

The irrigation should be thorough, at least two quarts being used, as it escapes at intervals beside the tube, and if the body temperature be high it may be cool, but if low and there be much weakness it should be warm. With much congestion evidenced by blood in the stools tannic acid (one teaspoonful to the quart) may be added with advantage. Irrigation gently and skillfully performed with an elevation of the reservoir of not over three feet does not increase prostration, but like other judicious hydrotherapeutic measures stimulates and soothes and is often followed by restful sleep. Retained fluid is, in part, absorbed greedily by the depleted tissues of the body and thirst is thus relieved.

Intestinal Sedatives and Disinfectants.—Medication of the disturbed digestive tract next demands our attention with the four-fold purpose of relieving irritation, restoring normal secretion, favoring disinfection and checking peristalsis, if excessive. The drug, which of all others has stood the test of time and experience in meeting the first three at least of these indications and often the fourth, is the subnitrate of bismuth, which is sedative, mildly astringent and disinfectant. It has the further advantage of being non-poisonous in the relatively large doses which are necessary. It is often given too timidly, and so ineffectually. Ten grains should be given every hour at first to children under one year of age until improvement occurs with the characteristic discoloration of the stools, then every two hours may be sufficient. It has been a matter of observation that where this discoloration which is probably caused by the action on the bismuth of hydrogen sulphid in the bowel, does not appear in the stools, it is ineffective.

This may be remedied when required, as suggested by Kerley, by giving lac sulphur in grain doses. The frequency of the movements often subsides under bismuth treatment alone, but where the number of the stools exceeds six or eight in twenty-four hours, and particularly if they be fluid and large, special medication may be necessary. Opium fulfills this indication, and should be given separately, so that its dosage and frequency may be regulated independently of other remedies. Dover's powders $\frac{1}{4}$ to $\frac{1}{2}$ grain every two to four hours stand first, and paregoric, minims 5 to 15, second for this purpose. We repeat that high temperature and foul stools indicating retained toxic products forbid locking up the bowels.

DIET.

The dietetic treatment of these cases is of an importance second to none. Looseness of the bowels without temperature or vomiting in an exclusively breast-fed

infant may allow of a continuance of carefully regulated nursing, but in all other cases milk, even breast milk, should be withheld until the disturbance has subsided or its simple character becomes evident. It would hardly seem necessary to specifically include whey, cream mixtures, sterilized milk, condensed milk and cereal foods containing dried milk in this ban were they not so frequently employed in such emergencies under various misapprehensions. Barley water plain or much better dextrinized, has stood the test well as a bland nourishment which taxes but little the enfeebled digestive powers. Its nutritive value is not high, but it serves the purpose.

Children seem to bear this diet with less loss of weight and prostration, if there be added to each feeding one-half to one teaspoonful of some preparation of the liquid peptonoid type. A good substitute, if dextrinized barley water is refused, is rice water. If these are both refused, I do not hesitate to use egg albumin water (white of one egg to one pint of boiled water, strained and salted), with the addition of a little brandy or the peptonoid preparations. I am aware that albumin water is not approved by some authorities, but beyond the fact that if made too concentrated it produces more odor, doubtless of proteid decomposition in the stools, I have not recognized other drawbacks. Beef juice, which as an animal proteid, should be open to similar objection, is often useful, although occasionally too laxative, which is likewise true of broths which we often have to employ, especially with older children. In addition to the fluid diet given at prescribed intervals plain water boiled and cooled should be given freely, since thirst is a common symptom, and because the maintenance of free renal secretions renders the patient less liable to kidney complications resulting from the elimination of the toxins.

To recur now to the more definite treatment of a given case, we will assume that the child receives dextrinized barley water, or a substitute, every two or three hours, according to its age. This diet should be maintained two or three or four days, or even longer, until the acute symptoms, such as fever, vomiting, frequent loose stools, etc., have subsided, and the visible improvement in the patient and a return of appetite give definite indication for a cautious return to a milk diet.

It is during this period that the anxiety and impertunity of the parents are most liable to overbear our judgment. In no class of cases is judicious starvation more important, or too early relaxation of our rules more disastrous. Breast milk may usually be resumed earlier than cows' milk, as easier of digestion, often on the second or third day, a few scattered nursings for short periods being first tried and these rapidly increased if there be no untoward symptoms. Cow's milk must be relatively longer withheld, and at the outset added to the other nourishment in small quantities, often only a teaspoonful to the usual bottle, never more than an eighth or a sixth of the whole, and the effect on the symptoms and stools carefully observed.

Experience teaches us to differentiate the gelatinous stool of barley water from one containing much mucus. It is a golden rule that appetite should always precede and exceed the amounts added. Several days should elapse of gradual increase in the strength of the food before it approximates that which the child took before the illness. It is often many days before the child can return to his old formula, and even then fat percentages frequently must be kept low lest they produce laxative effects. Some children must be kept on weak for-

mulæ until the end of the summer. In rare cases the addition of even small quantities of milk is not well borne until the cooler weather, and other forms of nourishment have to be continued in its place.

Severe and neglected cases may require stimulation in the acute period, with brandy or alcoholic solutions of peptones. Persistence of rather frequent loose or semi-solid stools, with fairly digested residue and with or without some mucus, but otherwise general improvement, if not readily overcome by the administration of opium, will often yield to 5 grains of tannalbin every four hours, or to three or four minims of dilute hydrochloric acid, combined with some digestive preparation. The routine use of some one of these digestive preparations may avoid disaster among the classes where we have reason to believe that the diet of the child will not be carefully guarded or our instructions for gradual resumption observed.

HYGIENE.

The hygienic rules which were laid down in the discussion of the topic of prophylaxis are of doubled importance in the treatment of the sick child. The patient should be bathed as often as required, not only for cleanliness, but for the reduction of fever, and for its well-recognized effects of quieting restlessness and improving cardiovascular tone. Fresh air and good ventilation should be insisted on in the sick room. In severe or desperate cases, if this is not possible indoors, the child should be kept out of doors, even at night. Trips on the water are well-recognized factors in saving life. A change from the city to country, seaside or mountain air is most salutary, provided it can be accomplished with a minimum fatigue, and for the latter reason long journeys are inadvisable.

Acute symptoms with temperature lasting over a week arouse grave suspicions of invasion and inflammation of the intestinal walls with their unfortunate sequences. Such cases pass into the class of ileo-colitis, demand special treatment by daily intestinal irrigation, and if recovery ensue, are slow in convalescing, since not the functions alone, but also the integrity of the bowel must be restored.

CHOLERA INFANTUM.

A few words should be added here concerning that really rare condition known as cholera infantum. The term has been grossly abused by application to all grades of summer diarrhea, thereby furnishing an excuse for cases lost, and enhancing the prestige of cases cured. The best clinicians of wide experience admit that they see typical cases but seldom, and it may be shrewdly suspected that modern treatment has decreased the number which present this picture.

The name should be reserved for those cases which, either at the outset or suddenly in the course of a milder attack, are seized with almost uncontrollable vomiting, hyperpyrexia, with very numerous large, almost clear watery movements, and consequent marked prostration and rapid emaciation as the fluids are drained from the tissues. It very possibly differs only in being a more intense intoxication. The most hopeful treatment is that by hypodermic injection of morphin sulphate 1/100 of a grain and atropin sulphate 1/900 grain, repeated at intervals until the profuse outpouring of serum from the intestine is checked.

CONCLUSION.

It will have been noticed that the subject has been treated in this paper without reference to special types

of bacteria causing the disturbance. Thrown into confusion by conflicting reports concerning the common occurrence of the various types of so-called Shiga bacilli, our knowledge is too chaotic to serve as a basis for classification. During the same summer of 1903, when Howland and Lafetra found Shiga types in 62 out of 64 cases of all grades of summer diarrhea from all parts of New York City, similar cases of all grades and from all parts of the city were being treated in my service at the out-patient department of the Babies' Hospital, according to the principles above outlined, with gratifying success. Although bacterial studies were not made of our cases, it is inconceivable that drawn from similar sources, they should not have shown, if examined, like findings.

Under this rational and scientific treatment, if directions are carried out, I expect recovery in all save a very few neglected or extremely marantic cases.

807 Madison Avenue.

DISCUSSION

ON PAPERS BY DES. KNOX, HOLT, COOK AND SOUTHWORTH.

DR. J. P. CROZER GRIFFITH, Philadelphia, believes that he has not yet proved the etiologic relationship of the Shiga bacillus to the various forms of diarrhea. This in no way detracts from the importance of the investigations. They have not yet been completed nor been carried far enough to make them conclusive. Further study is to be looked for. Dr. Griffith believes, in the early withdrawal of milk in these cases, whatever the cause of the diarrhea. Some French authorities treat their cases by the administration of water only during several days, and he has no doubt that this is preferable to the use of barley, rice or egg water, but he should hesitate to resort to it, because he does not think the average parent would be willing to carry out such instructions. We must not resort to the use of opium early nor, on the other hand, should we withhold it too long. It requires careful consideration in every case to know when to begin its use, but it is a most important and valuable drug in diarrhea.

DR. JOHN LOVETT MORSE, Boston, believes in giving an initial purgative, followed by withholding food but giving water. He has used the French water treatment for several years, and finds that the babies do better and have fewer complications if they are given as much water as they would have taken with their ordinary diet. Albumin water, barley water, etc., are but poor substitutes for milk, as regards their nutritive value. The white of one egg, for example, contains only two-thirds as many calories as one ounce of milk. The nutritive value of an ounce of albumin water, made as it usually is by mixing the white of one egg with 8 ounces of water, is, therefore, not one-tenth that of an ounce of milk. He believes that if milk is diluted to the same degree, it will usually agree with the infant as well as does albumin water. He favors the early use of milk in diarrhea, but he does not believe in withholding it so long as is often done.

DR. DAVID E. ENGLISH, Millburn, N. J., believes very strongly in the starvation treatment of diarrhea. He instructs the mothers to put an ounce of whole barley into a pint of water; this is boiled for fifteen minutes, strained through a sterile cloth and a pinch of salt added. This pleases the mother and does not harm the baby. He does not think babies are given a sufficient amount of salt.

DR. THERON W. KILMER, New York City, said that although care is usually taken as to the character of the milk or water fed to babies, it is often put into dirty and unsterilized nursing bottles. Every nursing bottle should be boiled daily for at least half an hour, and there should be as many bottles as there are feedings.

DR. R. B. GILBERT, Louisville, Ky., believes that the smallest perceptible amount of opium given in the diarrhea of infants is dangerous and injurious. If an anodyne is needed he prefers chloral hydrate. If the colon is flushed with a strong saline

solution the pain will be relieved without the use of an anodyne. He believes in the starvation, or rather the water treatment of infantile diarrhea; the use of the various diluted broths, such as barley water, amounts to little else. The water is improved, in his opinion, by aërating it.

DR. ROSA ENGELMANN, Chicago, said that physicians who work in the dispensaries and slums see other insects, such as fleas, bedbugs and cockroaches, that are not above suspicion as disseminators of disease. A possible instance of this came under observation not long ago in Chicago. In a large apartment house containing about twenty families five cases of typhoid fever were reported. The first case developed on the lower floor, and the second case on the same floor, in the apartment on the opposite side. The two families on the floor above moved away, leaving that floor vacant. In the course of a month the third case developed on the third floor, and subsequently two more cases developed on the fourth floor. The source of the infection could not be traced to the water supply (artesian), to the milk nor to the ice. It was learned, however, that this apartment house was absolutely overrun with cockroaches, contaminating the food supply. In the apartment house opposite, where there were no cockroaches, with the same water supply, no cases of typhoid fever were reported. It was unfortunate that none of the cockroaches was caught and allowed to run over a culture medium, and thus proved to be the source of the infection; since they, of all insects, are water inhabitants and consequently probable disease carriers. Investigation should be done along these lines, as has been done with fleas and bedbugs in respect to plague.

DR. WM. T. WATSON, Baltimore, said that the mothers in his practice are, most of them, very busy women, who can not afford to employ nurses. He likes to make things as easy for them as possible. He thinks that Dr. Kilmer's advice to boil nursing bottles for an hour is carrying precaution to an unnecessary extreme. Surgeons do not boil their instruments for an hour. According to Rotch, all bacteria are killed at a temperature of 154 F., and Abbott says that all pathogenic bacteria and their spores are killed by five minutes' boiling. Boiling for five minutes ought to be enough for the disinfection of bottles, which is merely surface disinfection. During the past few years Dr. Watson has been feeding an increasing number of babies on raw milk. The milk comes from the Walker-Gordon farm and is modified at home. Where the mothers are intelligent he finds no trouble to arise from feeding this milk raw. He asked Dr. Southworth if he considers this a rash practice.

DR. WILLIAM N. STOWELL, New York City, said that raw milk for infant feeding has been used at the Children's Hospital a portion of the time for the past six years. At present they are using the gravity cream from their own dairy. The milk was given raw, except in extremely hot weather, and he was surprised to see how weak children thrived on it.

DR. W. H. F. PARK, New York City, said that it has been proved that the *Bacillus dysenteriae* is the cause of infantile dysentery. He said he believed that the Shiga bacillus gives rise to typical symptoms. There are many different kinds of bacteria in the intestinal tract, and in every case of infantile diarrhea the special organism found should be clearly identified and labeled.

DR. J. H. KNOX, JR., does not think it is claimed by anyone that the *Bacillus dysenteriae* (Shiga) is the cause of every case of infantile diarrhea. The differences culturally between the so-called "acid" and "non-acid" type (to mannite) are not striking, no more so than differences known to exist between the various colon and typhoid bacilli. He said that it must be conceded that in their series the dysentery bacillus was found in the several varieties of intestinal diseases both mild and severe, called, clinically "summer diarrhea," and it is felt that it is responsible for a large number of these cases. The importance, however, of other bacteria should not be minimized. In many cases streptococci and other pathogenic organisms were present in the intestines. It may be that when there is evidence of ulceration we may often be dealing with a secondary infection

with streptococci superimposed on that by the dysentery bacillus.

DR. THOMAS S. SOUTHWORTH, replying to Dr. English, said he does not know how long a baby can live without milk or cream, but he does know that babies, depending on their age, have lived for weeks and months on food other than milk. In reply to Dr. Gilbert, he said that he has recommended the use of opium only for the control of excessive peristalsis in cases where the movements are more frequent than is necessary for a proper drainage of the bowel.

TREATMENT OF APHASIA BY TRAINING.*

CHARLES K. MILLS, M.D.

Professor of Neurology in the University of Pennsylvania; Neurologist to the Philadelphia Hospital.

PHILADELPHIA.

As long ago as 1880 I published an account of a case of aphasia greatly benefited by training which was largely of the patient's own initiation and conducted by himself.

The patient fell in an apoplectic attack, and was taken to one of the London hospitals, where he was seen by Dr. Sieveking and Dr. Broadbent. He was a right hemiplegic and was also totally aphasic and agraphic, but appeared not to have been word deaf, as he understood what was said to him. He had lost all ideas of numbers, but was evidently not word blind, as he understood from the first what he saw in print or in script. When he read aloud he had a marked form of paraphasia, his speech being of the jargon or gibberish type. Like many such patients, he read off this jargon as if to himself he were reading correctly. He could copy, although unable to write spontaneously. After a time he improved under rest and internal remedies. He then began, partly under direction, to try to improve his powers of speech and of writing. He was a man of considerable intelligence, of fair education and of great determination.

This man came under my observation about two years after the attack which caused his aphasia and accompanying condition, having returned to this country, and he remained under my care for several years, during which time he slowly but continuously improved until he became able to communicate both in speech and in writing without difficulty. When I examined him he could understand all that was said to him. He could answer almost any ordinary question, although he occasionally mispronounced and was at a loss for a word. It was particularly difficult for him to remember the names of individuals, although he could give a connected account of his former life. Specimens of his writing, of different dates, showed progressive improvement in writing, spelling and in the formation of sentences. He could count, repeat the multiplication table and add and subtract simple sums. He could name objects pointed out to him much better than when studied by Dr. Broadbent.¹ Instead of reading gibberish he pronounced almost every word correctly, stumbling only occasionally over a large word; each word was distinctly separated from the others, but he did not hesitate.²

In connection with this early recorded case I shall refer to a case treated by me during the past year, that of a well known physician, forty-five years old, residing in one of the Western States.

In July, 1902, he had an attack of right hemiplegia with complete aphasia, first consulting me eighteen months later. The paralysis, although still marked, was much improved. No loss of sensation and no affection of the bladder or bowels were present. The face was the seat of a moderate right-sided paresis, the tongue not deviating to either side. The deep and

1. Brain, vol. 1, January, 1879.

2. Mills, C. K., Med. Bulletin, Philadelphia, May, 1880.

superficial reflexes were of the usual type found in cerebral hemiplegia, exaggerated knee jerk with front tap and ankle clonus and the Babinski response being present on the right side.

When tested with Wyllie's physiologic alphabet it was found that he could repeat the vowels *i, e, a, o,* and *u* well, having been previously trained in their pronunciation, but he could not remember them from day to day. In like manner he could repeat the consonants of the alphabet, but could not recall them spontaneously. He was partially word deaf, having regained word hearing to some extent by time and training. He could understand most familiar expressions, but if a strange or unusual word were used he did not understand it. He was also partially word blind, having re-learned to read considerably before he was seen by me. With his left hand he was able to write the words that he could read. He could not understand the meaning of such prepositions as *of, to, and for,* if pronounced or read. He could not spontaneously write these words when asked, but could copy them graphically.

In connection with a study of his reacquisitions of language, particular attention was paid to the degree in which he regained different parts of speech. It was noticeable that in his efforts to talk he chiefly used his nouns and verbs, occasionally employing a pronoun. The words which expressed the qualities of things, which join and relate things to each other and to actions, in other words, adjectives, adverbs, conjunctions and prepositions, were still almost entirely eliminated from his vocabulary. Auxiliary verbs, like *to have, and to be,* in all their modes and tenses, were apparently without any meaning to him. The word *is* or *was* occurring in the sentence seemed to worry him. In brief, this patient was a hemiplegic aphasic, the aphasia having at first been both sensory and motor and nearly complete, an appreciable degree of recovery from his word deafness, word blindness and even motor aphasia having occurred under the method of training by repetition and by efforts at spelling, reading and writing.

With the assistance of Dr. T. H. Weisenburg and of the patient's secretary, a systematic and progressive course of training was at once instituted, this being continued under my direction for several weeks, and since up to the present time on similar lines at his own home. Letters, words and the names of objects were repeated by him after others or as the result of reading, in so far as he could do this, this being simply a continuation of the methods previously employed. In the next place the physiologic alphabet of Wyllie was employed.

Since becoming acquainted with this alphabet, in every case in which I have attempted to train or to have trained an aphasic I have made use of it, varying, of course, the sentences employed in illustration. A special effort was made to test it in the present case, as the patient saw at once its value and the method of adapting it to his own case. He was able to improve his manner of using the vocabulary which he had regained by the methods of repetition, to articulate and denunciate with more clearness, that is, with greater ease to make use of the words, sentences and phrases which he had from time to time reacquired. The physiologic alphabet, however, like the method of training by mere repetition from dictation, reading or otherwise, had its limitations with him. The patient could be carried only a certain distance by these methods, which it was necessary to supplement by others. The letters, words and physiologic sounds, or many of them, often could not be recalled even after they had apparently been thoroughly acquired, one of the chief reasons for this probably being that they were remembered only as separate entities and were not recalled in their relations to other words in description, that is, in phrases and sentences. After a time a phonetic reader was used to some extent.

In this book the sounds of letters and of their combinations are taught by special associations with objects, and in sentences which advance from simple to more complex forms similar sounds are repeated in various combinations. The sound

element rather than the meaning of the sentences is made the first object in the method of instruction, although the words, phrases and sentences employed have definite meanings and are spelled in the usual manner.

Much use was made of the dictionary, chiefly by the patient's own initiative. He made considerable advance by looking up the definitions of words and when he found words and expressions in the definition which he could not comprehend, these in their turn were looked up at the appropriate place. A language primer and a grammar were next employed, the patient being instructed much as a child would be in the nature and use of the parts of speech, in the methods of conjugating verbs and of giving the cases of nouns, attention being particularly paid to the repetition of illustrations of the manner of using what was being acquired. The patient, in other words, was retaught, insofar as possible, the grammar which he had learned in childhood and which had slipped away from him as the result of the cerebral lesion.⁴

After the patient's return to his home I received from time to time communications regarding him. He steadily improved though at first his progress was comparatively slow. Three months after his return his secretary wrote as follows: "Dr. X. continues to improve right along, and as he puts it, 'slowly, slowly up hill.' He impressed on me to tell you that if he were told anything of length or importance, he missed some of it at times, but if it were written and he could see it, he understood it all. He reads his papers and magazines alone now all of the time and understands fully."

Three months later she again wrote as follows: "At the present time there is a noticeable improvement since his stay with you. I am sorry to say that for more than a month his studies were very much neglected and interrupted, but he has now settled down to work again and we can see the improvement almost daily. The woman who is teaching him is under the supervision of one of the principals in the city schools who is a relative of Dr. X. They are working along original lines, taking up what seems to be of benefit. He is using more voluntary expressions every week, and a noticeable feature just now is that when we tell him to say a certain thing, instead of repeating it verbatim, he will express the idea in his own words. He reads a great deal and plays whist and other games aside from his studies. He has just finished transacting some business for the institution, the first which he has done of any importance since his illness."

I received a letter dated May 25, 1904, from a physician associated with this patient, which is so interesting in relation to this case as well as to the general subject of the treatment of aphasics by training, that I shall reproduce it in large part. After speaking of the doctor's steady improvement under the methods suggested and also of his own devising, the letter continues:

"Following out the suggestions you gave him, as well as an unusual originality in method which he has devised for himself, I believe the improvement will continue until the doctor will not be troubled to any appreciable extent at all. In order to give you a minute understanding of his present condition, I would like to call your attention to a few things, the import of which you will understand as soon as they are mentioned. In the first place, there has never been any particular affection of the memory. He recalls readily names, places, incidents of his past experience, and at times seems unusually capable in this respect, recalling and reminding others of the family of incidents which they themselves may have forgotten entirely. The word-blindness is improved considerably and is hard to detect unless special effort is made in this direction. The word-deafness, of course, is more pronounced than the word-blindness, as was the case when you examined him. His use of words to express an idea is much more general than has been the case heretofore. He now expresses in his own words answers to questions, in the form of a sentence rather than a single word; and it is noticeable that he is able to use a dif-

4. The reader is referred for further notes on the training of this case to Dr. Weisenburg's remarks in the discussion.

ferent word to express the same idea. For instance, if we ask him, 'Do you feel cold?' he answers, 'Yes, I feel chilly.' Or, if we mention the sun's 'setting,' in answer he would say that the 'sun goes down about 7 o'clock,' or something to this effect. Formerly he used single verbs and nouns to express his ideas without putting them into the form of sentences, often leaving out the smaller words, such as the articles, 'a,' 'the' and 'and'; but he now uses these words without omission, and at times makes a sentence of considerable length. These sentences are formed of his own volition and are not simply a repetition from having some one else urge him to talk. There has been no particular difficulty in having him repeat sentences at dictation; but this feature of his case in which he originates his sentences is one of the points which shows a marked improvement, and this rapidly increasing vocabulary which he is now using is due, as I have intimated, to a natural tendency toward recovery, and the painstaking and conscientious use of a small dictionary, together with a thorough systematic schooling in the use of words by means of a blackboard, writing, speaking, etc., which we have endeavored to carry out to the fullest possible extent. It is remarkable to see the interest and enthusiasm with which the doctor himself appreciates the improvement in his condition, as well as the possibilities of the future. In carrying out the idea here referred to we have him do considerable reading aloud, afterwards repeating the sentences he has read without being allowed to see the book or the blackboard. In regard to number work and mathematics in general, it is much more difficult for the physician to make himself understood than is the case in the use of words. I would say at this point that I believe he had more of a natural talent for language than mathematics as a student, which somewhat accounts for the seeming difference between language and mathematics in his present work. It seems to be harder for him to express the numerals used in mathematics than to express the words used in speech. We also have him do a great deal of writing, urging him to write his own ideas rather than simply copy something which has been written by others. On account of the slowness with which he has to write it is hard for him to keep pace with what he is thinking about at the same time, so that here again we notice a disposition to leave out some of the words in forming his sentences. On the other hand, when he cannot immediately speak the word he has in mind, he is able to write it at once. Oftentimes when hesitating for a word, before he is willing to wait until he can express it in speech, he will spell the word on a book, or table, or any place convenient where he can make the word so that it can be read. He is being taught along the line of what is known in the schools as the 'word method,' instead of using each letter as in the older method of spelling. It is exceedingly interesting to observe the quick perception with which he grasps a new word that he has not thought of or come across before, when using this little dictionary. After this word has been brought to his attention, and especially pronounced by him and used in a sentence, that particular word is added to his vocabulary for good and he can use it in the future without any trouble. There is no doubt but that the zone affected is becoming smaller and smaller, or else that the right side of his brain is being educated to take the place to some extent of that part affected on the left. As, of course, you will readily appreciate, it is extremely difficult for me to know whether it is really a smaller portion of the zone affected which enables him to show these signs of improvement or whether it is the education of the opposite hemisphere which is taking up the function of that part of the brain affected."

In the first of these two interesting cases the methods pursued were in part the same, and in both they were much assisted by the native intelligence and the determination of the patients. In the case recorded in 1880, the patient largely followed his own methods; procedures such as naturally suggested themselves to one who has lost language and wishes to recover it. He began by the repetition of letters and words, and then by combinations of the latter. He read aloud, correcting

himself and having others correct him. He copied words, phrases and sentences, keeping samples of his writing from time to time and sometimes securing the assistance and direction of others in correcting and in proving what he had done or tried to do. The inability to name objects by sight, the so-called optic aphasia, was, as in so many cases of aphasia, one of his chief difficulties, and this he slowly corrected by repeating after others the names of objects held before him, and later by calling up the names of objects before him unassisted. This at first required much effort. Summarized then, his methods were chiefly as follows: 1. The repetition of letters, words, phrases and sentences, recognized by him in reading or repeated by him after others; 2. The repetition of the names of objects seen by him, or the naming spontaneously of such objects either seen or made known to him through his other senses, as for instance, by touching or handling; 3. Writing, either copy, from dictation or spontaneously, slowly and patiently improving himself in this respect.

The various pedagogic methods of treating aphasics can be summarized as follows:

1. The method of repetition after others which later becomes that of spontaneous recall as the patient improves; and allied or assisting methods like reading aloud, copying and writing from dictation.

2. Phonetic methods such as the method of the physiologic alphabet suggested by Wyllie and the use of phonetic readers.

3. The employment of vision to assist in the training as when the aphasic imitates the movements of articulation, enunciation and vocalization as made by others or by himself, in the latter case observing these in a mirror.

4. The re-training of the patients in the grammar of language when the aphasic is educated and when not, reorganizing so far as possible such language as he originally had.

5. Various special methods suggested by different authorities, as, for instance, that of Goldscheider of training the patient to repeat meaningless syllables.

With regard to the method of training by repetition many directions and many illustrations might be given. Those furnished by Dr. C. L. Dana⁵ in a recent publication will answer as a basis for work of this kind, and I shall therefore, as they are brief, take the liberty of citing them fully. Such methods can be varied almost indefinitely.

1. Repeat five exclamatory words, such as: Ah, Oh, or another exclamation expressing joy, anger or other emotion.

Repeat after the teacher ten single monosyllabic nouns and pronouns.

Repeat ten polysyllabic nouns.

Repeat ten verbs.

In these latter exercises, each time a noun is named, let the patient see the object, feel it, and see the written or printed name of it on a piece of paper before him, thus stimulating his visual, auditory and tactile memories at the same time, as for example: Watch; pencil; pen; cane; box; book; and so on.

2. Repeat the letters of the alphabet, these letters being held in front of him.

Repeat the letters of the alphabet after writing and looking at each one.

Repeat the figures up to ten.

Repeat while looking at the written figures in front of him. Write and repeat these figures.

3. Repeat ten simple, qualifying adjectives, such as: White;

⁵ Studies from the Department of Neurology, Publications of Cornell University Medical College, N. Y., 1904, vol. i.

black; red; smooth; soft; rough. At the same time let him see the object and color, or feel the same.

4. Later let him try to repeat sentences of three words in which the noun is joined to the adjective, using the familiar nouns and the familiar adjectives already experimented with, thus: Pencil or pen is black; box is white; book is red; and so on.

5. If the patient ever had any musical capacity, have him sit at the piano and hum the notes of the piano, going through an octave, and then let him try to hum a tune, striking a note at the same time. Finally teach him to sing the tune through and then introduce the possible words. Some patients can sing before they can talk.

6. Copy sentences made up of the words he is being taught. Let him have an ordinary copy book and have the copy at the top of the page. Let him fill a page every day, trying at the same time to pronounce the words as he writes them. Have him copy first the familiar nouns, and then the simpler verbs, then the simple adjectives; finally let him copy sentences.

Take a small vocabulary and repeat from this, not trying to enlarge too soon.

A PHYSIOLOGICAL ALPHABET

I.—VOWELS.

y—i e a o u—w

These should be pronounced in the Latin manner, as *ea, eh, oh, oo, oo;* *y* and *w* are consonants, not vowels, but, as explained in the text, they have very close relationships to the vowels, initial *y* being very closely related to *i*, and initial *w* to *u*.

II.—CONSONANTS.

Voiceless Oral Consonants. Voiced Oral Consonants. Voiced Nasal Resonants.

	P	B	M
Labials. (1st Stop Position.)	(W)	W	
Labio-Dentals.	F	V	
Linguo-Dentals.	Th ¹ S	Th ² Z	
Anterior	Sh	Zh	
Linguo-Palatals.	T (L)	D L	N
(2 Stop Position.)		R	
Posterior	K	G	Ng
Linguo-Palatals. (3rd Stop Position.)	H or Ch	Y (R)	

The voiceless *W* and the voiceless *L* have been given above within brackets, the former being now almost confined to Scotland, and the latter being peculiar to Wales. The burring or uvular *R* is also given within brackets.

7. Write the letters of the alphabet, and as he writes them, try to repeat them. Do this without a copy, if possible. Then let him write words to dictation, using the same vocabulary above referred to. Finally let him try to write short sentences to dictation, then try to read them after he has written them, with assistance at first, then without.

8. Write numbers up to twenty and say them out loud when written.

9. It would do no harm and might be of some benefit to try the effect of hypnotic suggestion in helping him to get along in these exercises.

10. The patient should allow himself to be read to for a short time twice a day, and he should also try himself to read a quarter of a page every day.

Much attention has been given by a few of the writers on the subject of aphasia and its treatment to the methods of re-education in language by phonetic meth-

ods such as the proper use of the vowel and consonant sounds and their combinations in particular ways. Undoubtedly a knowledge of the best method of producing and using special sounds and phonetic associations, will be of value in the restoration of speech lost by an adult, or even by a child, as it is in the primary education of a child. Wyllie gives a physiologic alphabet with a series of simple sentences illustrating its use, which I have reproduced.

In this physiologic alphabet the exact methods of forming and using both vowels and consonants need to be understood. A little practice, however, and the knowledge of the principles of the formation of these sounds, as described by Wyllie, will enable this to be done. He discusses at length the manner in which the consonant sounds are formed by the movements and positions of the lips, teeth and tongue. He especially considers the so-called stop positions resulting from placing the tip of the tongue at various points, as

ILLUSTRATIVE SENTENCES

I.—VOWELS.

Even ancient elves are awed over oozing.

This sentence represents only long vowels. Their short equivalents can be represented, as shown by Mr. Pitman, by attaching the letter *t* to each vowel, thus:—

ēet, it, et, at, ut, ot, oot.

II.—CONSONANTS.

Peter Brown made white wax.

Fine villages.

Thinkest thou so, zealot?

She leisurely took down nine large roses.

Can Gilbert bring Loch Hourne youths?

on the teeth, and anterior, middle and posterior locations as regards the roof of the mouth. In each of these positions certain sounds, labial, labio-dental, linguo-dental, anterior-linguo-palatal, and posterior linguo-palatal, are formed by the action of air passing through the oral cavity and outlets. Practice with the table and the illustrative sentences given in it, or with others which can easily be formed on the evident principles involved will soon familiarize one with the methods of its use even without an understanding of all the technicalities in the production of voice.

With regard to motor aphasia and the method of training by repetition and by the phonetic method, Wyllie says that it is often advantageous to have the patient repeat spoken words, and he holds that it is largely in this way that he reacquires his speech. He

believes, however, that the process can be much expedited by having the patient in the first instance master the simple letter sounds such as are explained in connection with the discussion of his physiologic alphabet.

He gives an interesting and detailed account of the treatment of a case of motor aphasia, the patient not being agraphic, in which complete recovery was obtained by the method of repetition and of training in the use of letter sounds.

A young man of twenty-five with mitral cardiac disease, had had an apoplectic attack which left him a hemiplegic and motor aphasic. He recovered the power of saying yes and no about four weeks after the attack. Two weeks later he had for the first time replied in writing to a question, using his left hand for the purpose. He continued to answer questions in writing, at first with some difficulty and awkwardly because he was not naturally left-handed. He could however, always recall the words he wished to use in writing. His hemiplegia in large part disappeared first from the leg and later from the arm.

He came under the observation of Dr. Wyllie four months after the attack causing the aphasia; at this time having a slight right-sided facial paresis and a marked paralysis in the distal portion of the right upper extremity, these being the remains of his former almost complete hemiplegia. His aphasia was still marked, almost his only utterances being yes and no. He improved, however, somewhat rapidly in acquiring single words which he often mispronounced, but what he did say whether the pronunciation was correct or not, was distinctly articulated. Tested with the physiologic alphabet he could not repeat many of the consonant sounds. He could produce the middle vowel sounds ah and oh, but had difficulty with the sounds at the ends of the list, often converting *ee* into *ch* and *oo* into *oh*. A full account is given of the consonant letter sound which he pronounced both correctly and incorrectly, showing considerable deficiency, this often being of a peculiar character. The tests were made with simple syllables containing the letter sounds. He expressed himself very much better in writing, but even in this respect showed considerable deterioration as was proved by comparing his writing before his aphasia with recent samples. He could read silently, but was easily fatigued in so doing.

This patient made an unusually rapid recovery attributed in large part by Dr. Wyllie to the use of the physiologic alphabet. As the main object of this paper is to call attention to practical methods of treating aphasics, I shall cite here from Wyllie what is said of the exact method in which he employed this alphabet:

"We did not trouble the patient with the names of the letters, but taught him from the beginning the letter sounds of the physiologic alphabet. In doing so, we adopted what may be called the 'Mother's Method.' Beginning with the labials, we taught him to say *papa, apap, appa*, thus giving him the consonant P as an initial, a terminal and a mid-letter. Then we taught him to say *baba, abab, abba*; then *mama, amam, amma*; then *wee wee*; and so on throughout the alphabet. He was shown by 'lip-reading' how to place the lips, tongue, etc., for the pronunciation of each letter-sound."

He was then supplied with primers in which to study short sentences, gradually increasing their length, and in various ways he also practised speaking. Eight months after his apoplectic seizure he was able to articulate almost anything he wished to say, but it was necessary to do this slowly and carefully. His powers of writing which were always relatively good, were restored.

At my request Dr. T. H. Weisenburg has examined the recent German literature of the subject of the training of aphasics and as a part of the discussion of this paper we shall give especially the methods of Goldscheider⁶ and of Gutzmann.

Summarized, the methods of these German neurologists are much the same as have been indicated in discussing those pursued by Wyllie and by me. They have, however, some points of special value and a few of some originality. The methods used are those of the repetition, not only of letters, words and phrases, but somewhat after the manner embodied in the physiologic alphabet of Wyllie, the repetition of sounds in particular letter or syllable associations, combining vowels, for instance, with the labials, dentals and other consonants. Tongue exercises are practiced; tones are taught; the patient is made to imitate movements of articulation and enunciation by watching the facial movements of others, and to improve himself in the same respects by observing in a looking glass his own movements and expression in articulating; the association of vocalization with reading and writing as well as with speech is practiced, in other words, the patient learns to read aloud and also to repeat what he writes; geometric forms are taught; and the aphasic writes from dictation, from copy or spontaneously; words are associated, not only with their meanings, but a suggestion is made to repeat meaningless syllables in various combinations. The association of names with concrete objects is brought about by one of the well known methods of repeating the names of objects seen, handled or recognized through any of the senses.

Gutzmann teaches that sensory aphasia is more difficult to treat than motor aphasia, a statement with which I do not entirely agree. He recommends that the speech movements should be observed and fully remembered. It is well known that the words of a singer can be told by watching his expression and the movements of his mouth. Feeling the different vocal organs as the larynx, the lips and the cheeks, while one is speaking is of value. The education of the sensory aphasic is that of a child. An object is held in front of him, the name is told, a picture is shown, and the word is pronounced, spelled and written. Sometimes when a patient is able to read the meaning of the words from a speaker's lips, he is unable to derive their meaning from the written words. In such a case a better way is to write the words while observing the lips. Gutzmann has what he calls a "phonetic picture script (alphabet)" where the letters are indicated by the pictures of the lips, cheeks and the expression of the face.

With regard to the treatment of auditory aphasia, Wyllie cites approvingly the plan used by Schmidt in an interesting case of pure auditory aphasia recorded by the latter. In this case words were deliberately spoken to the patient and she was asked also to read aloud printed words, she not being word blind. At first she repeated with difficulty. Wyllie suggests that "probably the practice was imprinting the word-images efficiently in the uneducated auditory center, and at the same time establishing connections of the requisite intimacy, between these images and those of other speech centers."

It became a matter of interest to me in observing aphasics who were striving to recover their lost powers, to note the particular parts of speech which were most obscured and most difficult to regain, and also the particular difficulties which attended their reacquirement or prevented this. A patient who has so nearly lost language that he has only one or two recurring utterances, regains by repetition, and recall, word after word, especially nouns. Later a few verbs are acquired. Adjectives, adverbs, prepositions and ar-

⁶ Goldscheider, A.: *Handbuch der physikalischen Therapie*, part 2, vol. II, Leipzig, 1902; Gutzmann, H.: *Arch. f. Psych.*, vol. xxviii.

ticles, the parts of speech whose uses are to modify, limit, or express relation are so entirely lost to the patient as to cause, more than anything else, his difficulty in language. The same remark applies to conjunctions like *and* and *but*, and with a special force to the auxiliary verbs in all their modes and tenses. The meaning and use of such words or combinations of words as, *is* and *was* and *has been* are in eclipse or lost to a varying extent. The impairment or loss of the faculty of constructing sentences, or propositionizing in language is one of the most important, if not the fundamental defect. While thought is at times expressed by a single word, the sentence is the usual unit of thought expression, and the aphasic patient, or at least some aphasic patients, find their chief difficulty in regaining those parts of speech which are concerned with qualifying and correlating. The grammar of language no longer exists for them.

Considerations of this kind led me to the use of primers and grammars in the retraining of aphasics; and these with individuals previously reasonably educated are of great value. Patients should be taught the grammar as a child is instructed, in other words, by teaching him the meaning of the different parts of speech and the exact methods of using them in phrases and sentences. The significance and value of the qualifying, relating and conjoining parts of speech should be enforced by numerous examples. When the aphasic in his efforts to repeat after another or to respond to what another asks or indicates, uses incomplete sentences, the complete sentences should be given and explained. In every possible way the manner of using adjectives, prepositions, conjunctions and auxiliaries should be impressed. The patient with the book before him should be taught to conjugate verbs, decline nouns and pronouns, compare adjectives, and in other ways to go through the routine methods of studying language employed in the schools, these being modified by the particular requirements of the case. The dictionary can often be used as a valuable adjunct to the grammar, some patients taking a particular interest not only in reacquiring words in this way, but in thus learning their meaning and their uses as parts of speech.

A few words should be said about the general management of aphasics while attempts at their re-education are being made. It should not be forgotten that, owing to the impairment of their powers of communication with their fellows, they often tend to become irritable or emotional under strain, or even at times with little or no cause, although this is by no means without exceptions, as I have seen a number of instances in which the deprivation of language has been borne with patience. The instructor should be both patient and considerate. The aphasic should not be pressed too hard in the process of re-education. If the aphasia is of comparatively recent date, not improbably some dangers may be apprehended from too insistent methods of training. The limitations of each patient should be studied, and the crippled brain should not be exhausted and irritated by too prolonged sittings. Patients suffering from word deafness who are beginning to recover their cerebral hearing are at first easily exhausted and may become discouraged in this way, and the same is true, but probably to a less extent, of cases of pure motor aphasia. If the patient is given lessons in the repetition of letters, words or sentences, in reading aloud, in writing from copy or dictation, in the physiologic alphabet, in naming ob-

jects at sight, in the study of words in a dictionary or of parts of speech in a language primer or grammar; in whatever way the training is pursued, and whatever stage it has reached, the patient's powers of endurance and of further developments should be carefully studied and should be the main guide as to each succeeding stage.

When language is reacquired by an aphasic, how is this brought about? The answer to this question is not always easy. The basis of reacquirement may differ, and for several reasons: 1, Because of the difference in the original capacity and previous education of the aphasic; 2, because of the form of the aphasia; 3, because of the degree of destruction of the centers or tracts in the zone of language.

Everyone with experience among aphasics has noticed the difference in the time and in the completeness of the recovery in cases apparently equal in the original loss. This remark applies not only to those cases in which aphasia is the only symptom, but to the more numerous classes in which hemiplegia or hemiparesis is associated with the aphasia. A man of intelligence or education, or of both, and especially if he is endowed with a strong character, will often advance with great rapidity on the road to recovery. The previous business or mode of life of the individual, in persons of equal degrees of education, may also have much influence on recovery. One needs, indeed, only to recall and compare his hospital experience with his experience in private practice to appreciate the full force of these statements. In the nervous wards of the Philadelphia Hospital, where a number of aphasics of different types are always to be found, the majority of the patients have little or no education. Among these patients recoveries from aphasia are comparatively rare and are relatively incomplete, while better cared for private patients show much greater improvement and approach more nearly to complete recoveries when properly and persistently trained.

With regard to the type of aphasia, my personal experience, like that of others, has varied. Usually cases of pure sensory aphasia make rather rapid partial recoveries, at least this is true of cases with word deafness. Where sensorimotor aphasia is present associated with hemiplegia, the recovery from the aphasia is usually partial. It would seem probable that in many cases destruction of the cerebral areas for speech is incomplete, in these cases language being partially reacquired by calling into activity the unimpaired portions of these regions. The centers in the right hemisphere have a potentiality for speech which can be developed under necessity, but it is doubtless true, as Bramwell and others have pointed out, that the ability of the right hemisphere to take on the function of speech differs greatly in different persons.

In further illustration of some of the points given with regard to the training of aphasics, I would like to call attention to two patients who have been trained under my direction, in large part by Dr. T. H. Weisenburg, and who have made great improvement under the systematic efforts employed:⁷

The patient was a young man, painter by occupation, who had no history of syphilis, but had indulged in alcohol not infrequently to excess since the age of 15. When he was admitted to my wards at the Philadelphia Hospital, Dr. Weisenburg was the interne, and took charge of his training under

7. These patients were presented at the meeting of the section and a demonstration made of their improved ability in talking, reading and writing.

my direction. So far as his speech was concerned he was a typical instance of motor aphasia. He had no spontaneous vocabulary except the words yes or no, and his name, or a part of it, usually speaking of himself by his first name only. He could repeat single words if he took his time, but was easily confused. He could not read, although he was able to do so before his illness. He answered questions fairly well by pantomime. If given a start he could count from one to eleven, but forgot easily. He could not read aloud either script or text, although he seemed to understand them by sight. He was not word deaf. When he attempted to repeat what was said to him he did much the best as regards nouns and next as to verbs, but was unable to repeat a complete sentence, even a short one, by repetition. Besides his aphasia he suffered from a typical form of Jacksonian epilepsy. The spasm always began in the right side of the face, and sometimes extended to the right arm and even to the right leg. The initial phenomenon was always facial. The spasms frequently recurred. The eye examination showed no optic neuritis.

The training was confined to the method of repeating words from dictation and by having them pointed out in reading and writing, and to the method of Wyllie's physiologic alphabet. The man made slow but continuous improvement, until he left the hospital a few months after admission. During this time also the spasms practically ceased, the last seizures occurring at intervals of several weeks. When he left the hospital he continued to carry on his re-education at home, using a primer, and with the assistance of members of his family, re-studying the meaning and pronunciation of words and combinations of words.

He gradually improved till he could communicate spontaneously with others, but in a slow and halting manner, marked by the elision of a considerable number of words from sentences. Even the most careless study of the re-acquired language showed that the words chiefly at his command were, in the first place, nouns expressing the abstract; next, those of a concrete kind; next, verbs, and perhaps next pronouns. He very seldom put a sentence together unless it was a short one.

It is now about four years since this man was first attacked with his aphasia and Jacksonian spasms. Since he has left the hospital he has not had any recurrence of the convulsions. He has been able to earn money in various employments, as by peddling.

It is not improbable that a considerable part of his improvement has resulted from the use of iodids, although the method in which the case occurred would not seem to point to gummatous meningitis, but rather to a sudden hemorrhage localized to the left subfrontal convolution chiefly, perhaps invading slightly the lower extremity of the precentral gyre.

This patient can now communicate with others in an intelligible manner, although his sentences are incomplete. He can read aloud from a primer, and even from a book or paper sentences which are not too elaborate. He has made, in short, a degree of improvement commensurate with his original capacity and education, but not nearly so great as that of the highly educated physician recorded in this paper.

The second case is of so much interest in the study of aphasia that it is worthy of publication for its own sake, as well as to emphasize what can be gained by persistent training over a short period in cases of sensory or mixed aphasia.

The patient was a hotel keeper, aged 44. He was entirely well until November, 1903, when, after worry and hurry home, he was suddenly taken with severe headache and dizziness, but did not become unconscious and had no aphasia nor other objective symptoms.

After this, once or twice weekly he experienced severe attacks of headache, and on two or three occasions be-

tween November and February had attacks with dizziness. About the middle of February he had a sudden attack, in which he first called out, "Oh, my right arm," and very soon afterward became unconscious, remaining in this state for three days, with congested face and disturbed breathing. When he regained consciousness he was totally unable to speak except in jargon fashion, and could not understand a word that was said to him for a week. He was not, however, paralyzed in arm or leg, although he had difficulty in standing and in using his right arm. He could not carry it with precision to the place intended, as for instance, to his shoulder. Surely and gradually he re-acquired, although by no means fully, the power of speaking spontaneously or in response in conversation, using less and less of the jargon.

After his attack in February he had never been able to read the newspapers or anything else, as formerly, although evidently anxious to do this, as shown by his frequent efforts. It is interesting to note that he could read every word in the books in which he kept his accounts.

In testing him for his powers of word-seeing, letter-seeing and number-seeing, it was evident that he recognized some letters and some words much better than others. This was especially true with regard to words. He could always pick out words which had evidently been unusually familiar to him before his seizure; for example, the words whisky, brandy and beer in the hospital diet list were at once recognized, although most other words he could not tell, except in a few cases with difficulty. He showed curious variations in his ability to recognize words and letters, as when, for instance, he could spell out the word head, pronouncing all the letters except the d; sometimes he recognized a word without correlating it with its meaning. He had not only a well-known form of optic aphasia, that is, inability to indicate by name the object seen, but what might have been regarded the reverse of this, the inability to translate into meaning the word which he recognized. Sometimes when asked to spell an easy word, he did so correctly, and then would not be able to find the word in a page in which it was printed, although perhaps on the same page and nearby he would recognize another word of about the same simplicity. It happened at times that he could recognize a word on a page at one minute and a little later would be totally unable to do this. He made some curious mistakes in recognizing, or failing to recognize, parts of speech, as when he picked out *an* when asked to indicate *the*, although the latter word occurred several times on the page. Looking at *an* he would spell it out as if it were *the*.

Letters in a word like words on a page or in a paragraph were sometimes correctly recognized and sometimes not. He picked out some numbers on a calendar, and when asked to indicate other numbers he sometimes became confused. In some instances he would get at the number by starting with the units or numerals before the number and working up to it, as, for instance, when asked to indicate 15, he pointed to it and said, 12, 13, 14, 15.

It was noticeable in this man's case that if he were allowed to have his own way in talking spontaneously he apparently had very little difficulty in using language; for instance, when he was asked to count out money values he took notes of different value and various coins from his pocket, counted their number and talked about them almost as anyone else would.

Word deafness was a marked feature in the history of this case. At first, from what could be learned from members of his family, this was total. He had, however, slowly regained the power of recognizing some words and later some expressions, the improvement in this respect proceeding slowly when he came under my observation. In listening to others he was aided in his understanding of what was said by watching the facial expression and movements of the lips. I made frequent tests of his word deafness and found that it was partial and seemed to vary much from time to time. Another point of great interest was the fact that his word hearing powers were soon exhausted by efforts to communi-

cate with him. He would become confused and sometimes unable to comprehend what was said to him if the conversation were continued too long. He also became extremely confused if more than one person attempted to talk to him at the same time, or if a miscellaneous conversation were going on in his presence.

The patient stated that before he had the first attack in November, his hearing was different on the two sides. He heard better with his left ear than with his right; when he was a locomotive engineer he had often noticed this. Examination of his hearing with the watch tick showed on the right aërial conduction at 7 inches, and good bone conduction; on the left hearing was acute, hearing the watch tick at 41 or 42 inches; bone conduction was also good on the left. Such deafness as he had, except that noted for the right ear, was evidently cerebral and not peripheral.

With regard to his appreciation of tones and music, his daughter said that on several occasions during the first months after the apoplectic attack when she was playing the piano her father said that all music sounded alike to him. His wife also stated that he said to her on one occasion when he heard music, "It all sounds the same to me." Lately he had not said much about recognizing music. While at my office the patient's daughter played two or three familiar tunes, which he evidently recognized, and one of which he was able to hum in unison with the piano, but he could not recall the name of the song, although he said he knew well what it was; neither could he recall the words.

Careful examination of this man for reflexes, motor paralysis and hemianopsia was negative. Sensation in all its forms was retained, as was also stereognostic perceptions; he had, however, partial tactile amnesia as well as partial optic aphasia, not being able to name objects either through touch, manipulation or sight.

In brief, this patient was originally a total aphasic, the lesion being on the sensory side of his cerebral zone of language, probably near the position where the higher visual and higher auditory centers are coterminous, that is, about the caudal extremities of the first and second temporal convolutions. His early motor aphasia was simply due to the great general disturbance of his zone of language; his amusia also probably resulted from similar disturbance or from pressure rather than from direct lesion, as he recovered from this at a comparatively early period. Word hearing, word seeing, letter seeing and number seeing were the fundamental cerebral functions lost as the result of the destructive lesion. His partial recovery up to the time he came under observation was probably due largely to the recovery of power in those parts of the left cerebral hemisphere uninjured. The right hemisphere was also probably beginning to respond to the efforts at re-education, which he had pursued in an irregular manner spontaneously and with the assistance of those around him.

During a stay of less than a month in the Hospital of the University of Pennsylvania under a course of training which included some of the features of most of the different suggestions made in this paper, he made rapid progress, gaining steadily in his ability to understand spoken words, reading and writing and to carry on both responsive and spontaneous conversation. Although a man of quick perceptions and ready wit, he was not well educated. He had, however, been a fluent talker, and was able to write with fair correctness before his attack. He lost this power entirely, but is recovering it with considerable rapidity.

The following are two samples of his writing, the first made about three months after his apoplectic attack, and the second a few days later:

"Anie you to talk to last night me vhy did anie how long at this round time you whar is Chas Frindt did he work to fesh to me yet Anie did you teel about Dutch Rimling is he drink to fr him Anie you tell that to woking to me all to mutch calt whar is mind ducks thim ded or what happened."
"1904

Pheliaphet May 16,
Emma i will com from you at the Rehrig rail rod will com from 12.20 Right dont tell about the Boyes i will sneep Back on the holl Bor i haas mie things."

It must be remembered in passing a judgment on the man's improvement, as indicated by the above specimens of his writings, that he could not read or write a word a short time, probably only about three or four weeks, before the date of the first of these productions.

DISCUSSION.

DR. T. H. WEISENBERG, Philadelphia, stated that, under the direction of Dr. Mills, he trained three of the aphasics referred to in the paper. The principle of the methods employed was essentially the same in all the cases, but there was a wide difference in their application. In the first patient, a pure motor aphasic, Wyllie's physiologic alphabet proved of the greatest value, with the additional practice in letter and word writing and reading. The patient was sufficiently instructed in a short time to be able to carry on his studies by himself. Dr. Weisenburg did not see him afterward for over two years, when he told him that he was earning his living by street peddling, and that while selling his wares he could talk with but little hesitation. He still has difficulty in talking, but in view of the fact that he could say nothing but "yes, yes" when instruction was begun, the improvement is remarkable. This patient was young, fairly intelligent, and possessed of the greatest amount of determination. This last point is a very important factor in the prognosis. Dr. Weisenburg said that the second patient referred to by Dr. Mills was a sensory motor aphasic. A highly intellectual man, imbued with the determination to speak, he spent nearly all his time in study. The training was begun by a systematic instruction in sounds, first the vowels, then the consonants; the proper positions and relations of the mouth, tongue and lips were insisted on. After this point was firmly impressed on him and mastered by him, the improvement was rapid. Newspapers were read by another person, the patient following, all misunderstood words being explained by the use of a dictionary. Writing with the left hand, playing with pictorial cards, the reading of illustrated sentences, and drawing of geometrical figures were practiced and proved to be of the greatest benefit. Grammatical constructions were taught. The improvement was rapid. The third patient was a pure sensory aphasic, with little education and with much less intelligence and determination than the preceding patient. Here the training was difficult and consisted mainly in the repetition of letters, words and sentences, and the constant rewriting of the same; nevertheless, the improvement was considerable. Dr. Weisenburg said that from the experience he has gained, especially from these cases, that the method of training will largely depend on the form of the aphasia, and that most patients will be benefited if properly instructed. The mixed form is probably the hardest type to teach, although less progress was made for the time spent on the patient with pure sensory aphasia than on the others. The following brief résumé of the methods employed in training aphasics is taken from the *Handbuch der physikalischen Therapie*, Part 2, Vol. II, Leipzig, 1902:

Goldscheider insists that in the training of aphasics the mere repetition of words is not enough and that a systematic instruction is necessary. A beginning should be made by the simplest instruction of sounds as by the letters and short syllables. Gutzmann recommends a beginning with vowels, next the explosives and then to the first articulated P. The explosives are bound with the vowels, as Pa, Po, Pe, Ba, etc. Then come the nasal consonants, N and F and W, and so on in the list of consonants.

If the patient can not repeat sounds as they are he should be instructed to watch the mouth of the speaker and to try and imitate the sound thereby. If the patient is then sufficiently instructed he should next be taught articulation. Gutzmann also thinks that the comprehension of optic perception of speech movements can be greatly benefited by the patient watching articulatory movements in the looking glass, comparing this with illustrations at hand.

Goldschelder believes that systematic tongue exercises are of benefit, as the patient learns how to control accurately tongue movements.

If the aphasic has progressed sufficiently in the repetition and understanding of simple sounds, he should learn how to repeat sounds in a systematic manner, and by himself. This should not be always according to the alphabet, but should be changed. If the intelligence and the perception of the patient is sufficient, he should next be taught the different tones.

Further on, after the patient has learned to associate vocal sounds with speech movements, he should learn how to associate these with other perceptions, as writing and reading. This should consist in the copying of words, writing by dictation, or automatically. If there is paralysis of the right hand, the left hand should be instructed. The instruction should be systematic, as letters, syllables, words, sentences, etc. If there is optic aphasia, the patient should be instructed for forms as letters, as, for instance, he should be shown a letter from the alphabet, and should be made to remember it and to be able to point it out. Geometric perception should be taught, as this will help optic perception. Matches can be taken and figures built and the patient should reproduce them, or should do so by memory.

A number of aphasics are unable to read words, though they are able to perceive the letters of the word. These should spell a word loudly and be allowed to pick words from the alphabet, and should repeat the word until known.

It is also well known that a word can be better remembered, for instance, if impressed on more than one sense. So, a word heard should be repeated, written down, spelled, and so on. A patient should never be instructed for a long period at one time, and, again, should not entirely depend on the teacher, but should learn enough to write, spell, compute and observe movements in the glass by himself.

Next, the patient should be taught to repeat and remember short words. This should be done in a systematic manner and the words impressed by reading, writing and spelling.

Finger aids optic and acoustic perception by aid of fingers. Each finger is made to signify certain words or numbers, and as each number is called the finger is projected, and so forth.

The association of words with their meaning is now the next point to be desired. This can be accomplished in various ways, notably by holding an object in front of him, telling him what it is, making him repeat the word and asking him to spell it, and to pick it out by alphabet, until it is thoroughly impressed on his memory.

It is to be remembered that in aphasics the words for abstract objects and for the pure formal speech elements are in a large measure better controlled than for concrete objects. Therefore, the teaching of this is highly important.

To instruct the tones and accents of the words is very important. This is helped by declensions and conjugations very materially. A better way is for the patient to learn certain sentences, paragraphs, sayings, and to learn to repeat them properly, and also to be able to write them and to read them loudly. Goldschelder thinks that the best way is to memorize rows of meaningless syllables, the order of these being changed from time to time. By this method the patient learns to differentiate syllables, accents and tones, and learns to remember different shades of sounds. It is well known that it is more difficult to remember meaningless words than words with meaning, and that it is harder to remember words spoken than the meaning of them. Herein lies the value of this training.

The syllables ut, re, ml, etc., are taken and arranged in rows as shown below; the combinations may be changed indefinitely:

ut	re	ut	re	ml
ut	ml	ut	ml	re
re	ut	re	ut	ml
re	ml	re	ml	ut
ml	ut	ml	ut	re
ml	re	ml	re	ut

Dr. C. W. BURR, Philadelphia, said that the first case was a patient of his before he was a patient of Dr. Mills, so that he is able to certify and to state that there has been a very great amount of improvement in his speech since he saw him at that time. Dr. Burr considers that, so far as speech is concerned, these patients are in a state of childhood, and it seems to him that the only way to teach them is to proceed as if teaching a

child. Show the object, call the object by a certain name; write down the name of the object, let the patients draw pictures of it, and they will gradually learn what the object is. Dr. Burr does not think it a good thing to make them repeat monosyllables in order to educate the auditory centers, notwithstanding that high authorities approve that method. He believes it is much better to educate them in sounds that mean something—boy, bell, book, and so on. Dr. Burr said that it is very hard for us to say how much of the improvement is due to education and how much is due to the natural course of events. In a case of syphilitic brain disease, a case of this character, from the pure use of mercury, independently of instruction, may regain largely the powers of speech and writing. Unless specific disease can be excluded, it seems to Dr. Burr possible that some of the improvement is due, not to the training, but to improvement in the specific disease.

DR. W. G. SPILLER, Philadelphia, said that there are four factors to be considered in regard to the prognosis: Age; nature of the lesion; extent of the lesion; intelligence of the patient. He has never seen an adult who was aphasic, although there might be hemiplegia on the right side, provided the hemiplegia developed very early in life. At one time he examined 30 cases of hemiplegia developing in early childhood without finding any case of aphasia accompanied by right-sided hemiplegia. In cases where the lesions are in a limited portion of the speech area, there will be improvement in the natural course of events. Traumatic lesions, Dr. Spiller says, give better results, so far as aphasia is concerned, than hemorrhage into the brain or thrombosis of blood vessels. Seven years ago Dr. Spiller examined a man with distinct motor aphasia who has now entirely recovered. The aphasia was caused by an injury received on the head. Another interesting case was that of a man who received a blow on the head and had word deafness as a result. He was found to have a large cyst in the left temporal lobe. This man, by his own efforts, recovered partially from his word deafness. In a case due to trauma the aphasia may last a short time; if due to arteriosclerosis it may be of considerable duration.

DR. JOHN PUNTON, Kansas City, Mo., agreed with Dr. Mills that if complete success is desired attention must be paid to the co-ordination of the speech. Complete success is often impossible; patients never recover completely, and Dr. Punton does not believe physicians are warranted in holding out a prognosis of complete success in that sense. It seems to him that the nature of the lesion in the case should have something to do with the prognosis, as Dr. Spiller has said. In a large number of cases there is embolism and thrombosis, and whether their presence would have anything to do in determining a second attack. It seems to him that the extreme efforts the patient would put forth in trying to accomplish his end would have a tendency to induce a second attack. That is one of the things that text-books warn against.

DR. F. W. LANGDON, Cincinnati, Ohio, stated that erroneous ideas prevail in the profession on the subject of the function of Broca's or the third frontal convolution. It is not a motor speech center, and its destruction gives rise, so far as can be seen, to no defect of motion whatever. Dr. Langdon prefers to speak of it as a language construction center, where the words are thrown together in their proper relation, but the real motor center is the lower Rolandic region, where the movements of the face, tongue, lips and so on are directed. Dr. Langdon said that he does not consider that grammar has anything to do with the acquirement or reacquirement of language by a patient with motor aphasia. The acquirement of language and grammar is purely a memory process. The child raised in refined surroundings will acquire a very different language from that of a child raised in the slums; and with a child raised in the slums the language of the slums will occasionally crop out, in spite of education and grammatical training. Language must be looked on as a matter of pure memory and arrangement, independent of grammatical relation.

DR. C. W. BURN, Philadelphia, said that he did not mean that in a man whose brain was occluded through the obstruction of an artery due to syphilitic disease iodid of potassium would dissolve that softening and create a new brain, and hence bring about restoration of function. He meant that in syphilis there may be syphilitic arthritis, not sufficient to produce softening of the brain, but quite sufficient to interfere with the function and to produce aphasia which, under the administration of mercury and iodid, certainly does clear up.

DR. W. J. HERDMAN, Ann Arbor, said that this whole matter can be summed up in the simple statement that while educational methods are the best to employ when there is any capacity left after injuries or organic disease of the different sorts, yet it is this capacity for recovery that is really the condition which determines how far the recovery will take place. There are some cases in which one would not by any process of education expect any degree of improvement. There are other cases which do possess such a capacity for improvement, and the individual will no doubt, without any very great help, show progress for the better, but it is the physician's business to employ therapeutic measures so far as they are helpful. Whether it is called a "grammatical process" or not, there is no question that the aphasic, if he retains any capacity in language, retains the vertebræ of that language, and in order to make it more ornate and intelligible he must, of course, place on the vertebræ the soft parts. Dr. Herdman does not agree with Dr. Langdon that the instruction of the aphasic must proceed along the same lines as the instruction of a child. The whole possibility of development in an aphasic depends on what remains of what actually did exist there, and in arousing this into action again. If the capacity never existed it could hardly be expected that the patient could be educated beyond the stage of his former acquirements: if the capacity does, or did exist, then the process of a systematic attempt at education is exceedingly helpful.

DR. CHRISTOPHER C. HERSMAN, Pittsburg, said that it is true that language is used in spite of grammar, and that after language has been learned it is perfected by grammar. If the patient is word blind and has to be taught words, he also needs synthetic teaching, or instruction in synthesis, building up, as well as teaching the individual words, and while teaching him the words, if the construction is also taught, more thorough advance is made than by simply teaching him the words.

DR. CHARLES K. MILLS said that the method of re-educating the aphasic is not exactly that which is applicable to children. The aphasic has both an advantage and a disadvantage as compared with the child. His advantage over the child is that his brain was thoroughly organized and in some cases thoroughly educated before the occurrence of the lesion: his disadvantage is that the child in its education started out with a potential mechanism of speech not affected by disease. Dr. Mills, of course, has taken the nature and extent of the lesion into consideration. He has seen cases of gummatous meningitis with aphasia and without other symptoms, the aphasia disappearing under the action of iodid. The first patient may have had a specific infection, but there was something more, a destructive lesion of the language center, and it is for this that he requires re-education. Dr. Mills has seen uremic aphasia and aphasia due to all sorts of affections which are remedied and do remedy themselves in time, but the remarks here apply to cases not to be restored to speech by time or medication. Dr. Mills stated that one inference drawn from part of the discussion is that these patients would get well anyhow by the progress of time in proportion to their natural, plus their acquired capacity, before the aphasia: but this is not quite true, as he knows from a long experience. He used the term grammar in a rather broad sense, in order easily to convey his idea. The patient must be restrained in the use of language as he formerly used it. There is a grammar of the slums. If a child who lives in the Bowery and uses the language of Jimmie Fadden becomes aphasic, he must regain this particular sort of language. The method

of training must not be simply a method of memory. The patient must learn again the use of prepositions, adjectives, conjunctions, and auxiliaries, of all the parts of speech that go to make up sentences, and the methods of arranging these in sentences for the expression of thought.

THE CONTROL OF INTERNAL HEMORRHAGE BY DRUGS.*

THOMAS LUTHER COLEY, A.B., M.D.

Visiting Physician to the Methodist Episcopal Hospital,

PHILADELPHIA.

By the term internal hemorrhage, as used in this paper, I include all forms of bleeding in which the bleeding point is not within reach of direct topical application.

It will be my purpose to set forth the general principles on which rational medical treatment is based, and not to discuss the relative merits of surgical and medical means.

In the first place, it may be stated that we have no specific remedy for the control of bleeding, and secondly that the employment of many of the drugs recommended is not based on rational grounds. As will be seen presently various agents are advised for a similar condition which act antagonistically, so that if one does good, the other must do harm.

The preference given to many remedies by clinicians is too often based on insufficient data. The action on a small series of cases of certain character may not apply to all hemorrhagic conditions, and the tendency of the bleeding to cease from nature's efforts is so important a factor that we are never sure our drugs have exercised any influence whatever.

In order to discuss intelligently the control of internal hemorrhage, I shall state the following general principles:

1. The mere onset of hemorrhage does not necessarily indicate medical treatment. The general tendency of bleeding is to cease from natural causes, and often more harm than good is done by overdrugging.

2. All patients, bleeding from whatever cause, must be kept in a state of absolute rest and quiet, bodily and mental, so far as this is possible.

3. All forms of hemorrhage may be more or less benefited by what may be termed collateral treatment. Change of bodily posture as indicated, drawing the flow away from the bleeding point as much as possible, the use of cold, heat, counter irritation, ligature of the limbs, etc.

4. The drug treatment of hemorrhage includes:

- A. First, the use of hemostatics, acting locally when this action may be secured, as in certain forms of bleeding in the gastro-intestinal tract. Second, the use of internal hemostatics.

- B. First, the use of drugs for the purpose of lowering the blood pressure, by depressing the heart or widening the blood paths. Second, the use of drugs to produce a local constriction of the vessels around the bleeding point.

In the consideration of the action of drugs on the vasomotor system we face one of the great difficulties of our problem. Vasoconstrictors to be of value must possess an affinity for the vessels around the bleeding

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Sells-Cohen and O. T. Osborne.

point and there alone; otherwise a rise of general blood pressure will more than compensate the constricting action. The local constriction of the bleeding vessels may be brought about relatively by those vasodilators which act on the vessels of the general circulation, but do not dilate those of the bleeding area. The difficulties of the problem are obvious. Sollmann discusses briefly the selective action of dilators and constrictors, a knowledge of which is of paramount importance.

"The lungs are not much influenced by vasomotors. Hence dilatation would be indicated: Nitrites.

"The vessels leading to the brain are very subject to dilators, but not to constrictors. Neither measure would therefore be useful. If there is not naturally a showing, aconite would promise good results.

"The splanchnic area is the area most sensitive to vasomotor influence, and which reacts most promptly to either dilators or constrictors. The latter would be indicated: Strychnin or hydrastis.

"The skeletal muscles are not readily dilated nor constricted. Dilatation would be indicated: Nitrites.

"The uterus is strongly subject to constrictors. In postpartum hemorrhage, ergot; in menorrhoea, hydrastis and especially local treatment."

These general postulates urge me to controvert the internal use of all drugs producing a rise of general blood pressure, either directly as digitalis, or indirectly as the emetics, ipecac, etc., with the exceptions of ergot and hydrastis in bleeding from the uterus, and possibly in hemorrhages of the splanchnic area.

With these preliminary remarks I shall proceed to outline briefly the general action of some of the remedies advised as internal hemostatics. This will illustrate how widely at variance have been the views of clinicians as to the therapeutic indication in cases of bleeding as well as the lack of knowledge of drug action.

VEGETABLE AND MINERAL ASTRINGENTS.

Astringents of both classes have a distinct constricting action on tissues. They precipitate albumin and other proteids and are effective only when applied locally. The vegetable astringents owe their activity largely to their tannin content. Tannic acid is itself derived from the oak gall and seems to consist of an anhydrid combination of gallic acid (Cushny). The greater part of the tannic acid administered is decomposed in the intestine into gallic acid. Hamamelis, gallic and tannic acid are alone of interest to us in this group.

Despite the fact that these remedies are administered routinely for the control of internal hemorrhages there is no satisfactory evidence, whatever, that they are of any value. Tannic acid is found in the tissues in minute quantities as a gallate or tannate of soda and the traces are so minute that they can have no action.

The mineral astringents, notably the salts of lead and iron, are very commonly prescribed for their supposed internal hemostatic action. They are, however, valueless for this purpose, being absorbed in very minute quantities and having no predilection for the bleeding point. If they were capable of coagulating the blood after absorption and thus stopping hemorrhage they would certainly do so in the portal circulation and would not be carried to the bleeding point before they acted. . . . They never reach the blood except in forms in which they have no astringent nor styptic action (Cushny).

SUPRARENAL EXTRACT.

The local effect on the vessels of preparations of the suprarenal glands is most marked and they have the added value of not producing a rise of general blood pressure when locally applied. The extract has been used with satisfactory results in gastric hemorrhage and it may be injected into the uterus, rectum and bladder, but it is only useful where a local application can be made. There is no satisfactory testimony that the bleeding point can be reached through the circulation. Experimentally it has been determined that when a small amount of epinephrin is injected into the blood vessels of animals that there is a very rapid rise of blood pressure with a slow heart beat; further, it has a distinctly selective action, some of the vessels being affected very much more than others. In the organs whose flow of blood is regulated by the splanchnics the effect is most marked while the vessels of the lung and brain do not seem to be affected; those of the skin are much contracted, and those of the muscles scarcely influenced. The rise of blood pressure following the intravenous use of epinephrin (which is a very unstable product) would be a contraindication to its use in internal hemorrhage.

DIGITALIS.

Digitalis is sometimes prescribed to stop hemorrhage, but the flow of blood is increased through the contracted arteries and there is no evidence but that more harm than good would accrue from the administration of large doses of the drug.

ERGOT.

Ergot, on account of its selective action on the uterus, however uncertain the method of this action may be, has found an established place in the treatment of hemorrhage from this organ. The general action of ergot, which depends on its still doubtful complete composition, is not satisfactorily known. As a remedy in internal hemorrhage it may be said to be of doubtful value on account of its slow and lasting action. The rise of blood pressure which follows its use may or may not be general and may or may not affect the vessels of the bleeding area. If it is general, it would be harmful by more than counterbalancing the local contraction of the bleeding point and, further, if the vessels contracted did not include the bleeding area the rise of pressure would then be a counter-indication to its use. There is excellent reason for not using it in pulmonary hemorrhage, for pharmacologic studies have shown that it produces a distinct rise in blood pressure in the pulmonary artery.

OPIUM.

Opium, preferably in the form of morphin, is of great value in internal hemorrhage and this, not from any hemostatic action it possesses, or vasomotor effect, but because it allays the patient's restlessness and nervousness, thereby favoring clotting of the blood.

HYDRASTIS.

Preferably in the form of hydrastinin, has some reputation as an internal hemostatic, especially in menorrhoea. It is a distinct stimulant to the circulation, causing a prolonged rise of blood pressure and a slowing of the pulse after moderate dose. The cause of the increased tension is not settled; there is probably stimulation of the vasomotor center and the peripheral vessels

are contracted possibly by direct action on their walls. The drug might be used in hemorrhages of a slow, oozing character, but in no others.

IPECAC.

The use of emetics in hemorrhages, especially pulmonary, has not met with favor of late. Graves, Trouseau, Peter, Massina, H. Weber and others were strong advocates of the use of large doses of ipecac, it being claimed that there follows a diminution in the size and strength of the pulse, and, in addition, that the blood is expelled from the bronchi where it is likely to become the source of reinfection. The great liability of the retching to induce fresh hemorrhage is a strong contraindication to its use. In tropical dysentery the drug seems to be almost a specific; we are in doubt whether this action is due to the alkaloids or the large amount of tannin the root contains.

ACONITE.

Aconite in small doses produces a slowing of the pulse with the fall of blood pressure, and seems especially indicated in the so-called sthenic cases. Aconite slows the pulse in the same way as digitalis but does not accelerate the arterial tension as does that drug.

NITROGLYCERIN AND THE NITRITES.

This group produces a profound fall in blood pressure by the dilatation of the peripheral vessels. It is stated that the vessels of the abdominal organs and the brain are more affected than those of the extremities. This group has been recommended for pulmonary hemorrhage. It would seem, however, that the general widening of the blood paths, together with the fact that the heart beats more rapidly under the lowered pressure, would contraindicate its employment. The general widening of the blood paths will frequently increase the caliber of the vessels of the bleeding area.

THE ANTIPYRETICS.

Antipyrin, especially of this group, possesses valuable properties as a local hemostatic, and has been employed internally for its supposed general styptic action. There is no evidence, however, that it possesses such. The depressant action of these drugs on the heart, together with the sedation which they often produce, may be of slight value.

FORMALDEHYD.

As a remedy by irrigation in the necrotic forms of dysentery, weak solutions of formaldehyd have been used with success. It has also been employed in climacteric hemorrhage and in uterine hemorrhages of unknown origin, by intrauterine application of a 40 per cent. solution of formaldehyd. A few drops of a very weak solution have been recommended for internal administration in gastric hemorrhage, yet the drug is distinctly toxic and highly irritating.

STRYCHNIN.

The action of this drug in producing stimulation of the vasomotor center has caused it to be employed for abdominal hemorrhage, owing to the constriction of the arteries of the abdomen and the dilatation of the vessels of the skin. Since, however, the blood pressure is raised and the drug possesses the property of producing motor excitement, it would not seem to be indicated in hemorrhage unless the patient was in a state of absolute collapse. The heart rhythm is slower after its use owing to

the stimulation of the inhibitory center, but the rise of blood pressure would seem to more than counterbalance any good this might do.

ALCOHOL.

The use of alcohol in cases of hemorrhage is generally deprecated by recent writers. As a matter of fact, the whole problem of the action of alcohol is more or less *sub judice*. We know that in fevers it will frequently slow the heart, which action is probably brought about by lessening the cerebral excitement. This action might be of distinct use in hemorrhage. The drug in therapeutic doses produces but slight fall in blood pressure. There is some widening of the blood paths, but this is not great. Taking the evidence under consideration, the employment of alcohol in cases of severe hemorrhage (shock) may rest with the personal preference of the physician. A good deal has been said on both sides.

THE PURGATIVES.

The employment of purgatives is recommended in certain forms of bleeding, as in pulmonary and cerebral hemorrhages, as a satisfactory means of lowering the blood pressure. When the need is imminent, as in certain cases of apoplexy, venesection is preferable, and it is a mooted question whether the physical and mental strain induced by purgation in general will not more than compensate any good that may follow such treatment.

SALT SOLUTION.

Isotonic salt solutions (0.6 to 0.9 per cent.) are administered with excellent immediate results when the body has lost considerable blood or other fluid. Such solutions, by whatever route administered, are absorbed rapidly and are unirritating. The rapid improvement in the circulation which follows their employment is due to the mechanical effect of the increase of fluid, but they do not stimulate the heart directly.

CALCIUM CHLORID.

Within the past ten years calcium chlorid has gained considerable reputation as an internal hemostatic, it being claimed by Silvestri, Wright and others that its administration distinctly increases the coagulability of the blood. Wright, however, emphasizes the fact that after the dose is given in full dose for a number of days, from 30 to 60 grains, thrice daily, a reverse effect is produced. G. Gross and others have used calcium chlorid in bleeding from the uterus, administering it both internally and by vaginal douche. It is a common practice among surgeons to use it routinely for a few days prior to operation on such organs as the liver and pancreas, it being claimed that this checks the hemorrhagic tendency quite effectually. The clinical evidence of its value is far greater than the pharmacologic evidence, it being urged that the coagulability of the blood can scarcely be increased by the administration of the lime salts, since more is taken in the food than is sufficient for the organism, and the chlorid is not more easily absorbed than the combination present in the food.

GELATIN.

The Chinese and Japanese have used gelatin as a hemostatic for hundreds of years, and among western clinicians it has come into general employment since its recommendation by Dastre and Floresco in 1897. The drug may be used either by mouth or rectum, or hypodermically after thorough sterilization. It is

claimed by many to possess a coagulant action on the blood, but so eminent authority as Cushny states that there is no satisfactory evidence that the clotting is accelerated by its use.

In the articles whose authors concede the hemostatic action of gelatin there is not a satisfactory explanation for the effect. Zibell believes it to be due to the lime salt contained, .6 per cent. being found. This is a very small amount to account for such action. Edsall suggests that the increase in coagulability is brought about by the more rapid formation of fibrin ferments, owing to the destruction of the red blood corpuscles. Certain oils, notably turpentine and erigeron, while possessing no distinct hemostatic qualities, may yet act beneficially by their local constricting action in certain cases, as in intestinal hemorrhage of slow oozing character.

CONCLUSIONS.

In conclusion, it is necessary to bear in mind that the direct indications for treatment vary with the individual case. These indications include the source of the hemorrhage, the condition of the circulation and the amount of blood lost. In cases of total collapse, alcohol and strychnin would probably prove of value. Fainting from loss of blood may not in itself be an indication for medical treatment, for we know the value of this condition in inducing thrombosis.

The use of the vegetable and mineral astringents in those cases in which the bleeding point can not be reached directly, is highly illogical. The same is true of the use of the mineral acids. Aconite approaches the action of this group on the circulation, without the untoward local effects.

Ergot seems distinctively harmful in pulmonary hemorrhage, and from its action can scarcely prove of any value in other than uterine bleeding.

Hydrastis has some value in similar conditions. The susceptibility of the splanchnic area to vasomotor influence might be utilized by administering hydrastis and strychnin in bleeding of this region.

I have never seen noteworthy or conclusive results follow the employment of gelatin or calcium chlorid. Normal salt solution is undoubtedly a valuable agent, and immediate response often follows its use. I have had poor success with suprarenal extract administered for its internal hemostatic effect and believe that the indications for its employment are distinctly local.

There is great reliance to be placed on rest and quiet for the patient who is bleeding, and often this will suffice. Collateral measures, ligation of the limbs, change of posture, etc., are of great service. Next in importance I should place morphin to induce quiet. In those patients whose circulation is powerful, aconite is of unquestioned value. In gastric hemorrhage, there is a great tendency to employ the astringents. It is well to mention the impossibility of their reaching the bleeding point, the stomach being filled with blood and often with partly digested food. Suprarenal extract, while at times serviceable in such conditions, may fail for the same reason. Many of the drugs advised are nauseous and should be especially avoided; emetics or drugs disturbing the stomach are only likely to cause increased bleeding, owing to the physical strain of the emesis.

This very brief and incomplete review has been presented to emphasize the fact that we have not at hand a single internal hemostatic, the value of which is generally conceded; to show further that many of the

agents employed do far more harm than good; that many are positively dangerous, and that a careful study of the individual case will generally show that very little drug treatment is indicated or can in any way do good. The physician is not certain in a particular case whether he has in any way aided nature in her efforts to check the bleeding.

The claims made for suprarenal extract, gelatin and calcium chlorid have not, in my experience, been borne out by fact.

DISCUSSION.

DR. WILLIAM J. ROBINSON, New York City, agreed with Dr. Coley that opium or morphin is of great practical value in internal hemorrhage, especially combined with a little atropin. He considers ergot unsuitable in hemorrhages from the lungs because it causes a rise in pressure in the pulmonary circulation. In gastric hemorrhage good results may be obtained from large doses of bismuth subnitrate, half an ounce at a dose. The patient should be kept in a reclining position and the stomach kept at rest. Aromatic sulphuric acid as an astringent is not safe in pulmonary hemorrhage, nor in gastric hemorrhage. In some cases of epistaxis that show great resistance to treatment, the bleeding will stop after the application of peroxid of hydrogen. Applications of fluid extract of hamamelis generally will control hemorrhage. Two hundred c.c. of gelatin injected into the back stopped a pulmonary hemorrhage which had resisted all other treatment. The patient died a few hours later and the pulmonary cavity was found filled with a large recent clot, showing the effects of the remedy. A number of cases are on record in which the use of gelatin was followed by recovery. One case of hemophilia was cured by gelatin, the treatment extending over six months. Dr. Robinson called attention to the great value of veratrum viride in hemorrhages; it does not act as an astringent; it lessens the peripheral resistance and lowers the pressure in the area around the point of hemorrhage.

DR. WILLIAM F. WAUGH, Chicago, suggested the use of atropin in addition to other therapeutic agents, as by its means the blood is directed to the peripheral vessels and can not flow from the wound at the same time. The life of a boy, with a pistol wound and apparently dying of hemorrhage, was saved by giving nitroglycerin to attract the blood to the capillaries, and atropin was given to keep it there. This was all that was needed. The action of hydrastinin is so slow as to exclude its use in all hemorrhages except those due to capillary oozing; it is not to be relied on in sudden uterine hemorrhage.

DR. W. C. ABBOTT, Chicago, emphasized the value of morphin, especially when combined with a little atropin, in pulmonary hemorrhage. Atropin relieves pressure and the morphin relieves the irritation in the respiratory organs, and quiets the patient. Therefore, the dose of morphin should be very small and that of atropin relatively large in order to produce the best effect. It is probably the fact that the arterioles around the area of hemorrhage are contracted by the effort of Nature to stop the hemorrhage. There is also a mental unrest and fear of bleeding to death, which by suggestion increases the condition. The morphin, therefore, aids the atropin in drawing the blood away from the part. The combination has no hemostatic action in typhoid fever.

DR. HORATIO C. WOOD, JR., Philadelphia, said that in a case of external or of internal hemorrhage the object of treatment is to permanently close the bleeding points with a clot. Therefore, any drug which causes increase of blood pressure does harm. The only reason that more patients are not killed by ergot is because it is used in too small doses. Atropin is equally with ergot contraindicated in hemorrhage; it elevates internal pressure more even than does ergot. Nature stops hemorrhage by lowering blood pressure until the blood has had time to clot. For this reason aconite in small doses may be useful. Stimulants may be of value, not, however, to check the bleeding, but to sustain the heart. Dr. Wood believes that

gelatin is of great value in increasing the coagulability of the blood, and pointed out that all the colloid substances possess this property. One reason why gelatin sometimes fails is because it is not used properly. In a Philadelphia hospital, a patient with typhoid fever had hemorrhage from the bowels. One-half an ounce of gelatin was ordered given every hour until relieved. The next day the same hemorrhage was going on, and it was found that a tablespoonful of ordinary prepared gelatin had been given, which contains about 3 per cent. of gelatin. Half an ounce of the dry gelatin must be given in order to have any effect.

DR. HENRY W. COOK, Richmond, Va., emphasized the danger of giving stimulants to persons with hemorrhage. A patient who was very badly injured and in shock from hemorrhage was given adrenalin, which caused a rise of blood pressure, but disturbed the clot; bleeding returned and he bled to death in ten minutes. Vasodilators may push the patient over the border line and cause death. Tentative treatment until the patient is over the danger point is the best treatment.

DR. W. B. ROBINSON agreed as to the value of gelatin in increasing the coagulability of the blood. When administered to a dog, the blood drawn will coagulate in ten minutes, while the blood from another dog, without gelatin, requires half an hour. It should be remembered, however, that the gelatin should not be cooked when given for this purpose, as by cooking it is converted into a different substance.

DR. ABBOTT disagreed with Dr. Wood, who said that atropin is not a remedy to give in internal hemorrhage. Dr. Abbott said that his views were derived from experience at the bedside. The increase of pressure at the point of hemorrhage will be overcome, if there is dilatation elsewhere, by the use of atropin.

DR. C. E. DE M. SAJOUS, Philadelphia, asked if some of the authorities quoted do not state that the action of the atropin is exercised on the arterioles. He said that this would sustain the contention of Dr. Abbott. One would have, in that case, to recognize the fact that the arteries are supplied with a muscular coat while the capillaries are not, and that the bleeding area could thus be deprived of blood and the hemorrhage arrested merely through contraction of the arterioles.

DR. HORATIO WOOD, JR., replying to questions, stated that the effect of atropin is demonstrable by placing a canula in a dog's artery. After giving atropin the blood pressure goes up, because the small arteries in the interior of the body are contracted. Atropin acts particularly on the arteries and very little on the veins; but the great danger is from arterial hemorrhage. Too small doses have no effect.

DR. ABBOTT said that while Dr. Wood gives atropin and gets internal rise of blood pressure, he claims that vasomotor influence sends the blood to the periphery and equalizes the circulation throughout the body.

DR. O. T. OSBORNE, New Haven, Conn., declared that one of the greatest dangers in internal hemorrhage is the contraction of the peripheral vessels, due to the fear of death. Atropin and morphin will produce peripheral flushing and will always help these cases.

DR. T. L. COLEY said that while morphin has no specific action in cases of internal hemorrhage, it allays the patient's restlessness, thus inducing conditions favorable to clotting. The use of bismuth in gastric hemorrhage is open to the same objection as the preparations of iron. In the presence of masses of food particles and blood clots the astringent action would, in the average case, be valueless and the mechanical effect slight. Washing out of the stomach in cases of gastric hemorrhage to remove the offending material is a step too fraught with danger to be employed with safety. The use of atropin seems to Dr. Coley to be contraindicated from its physiologic action—the rise of blood pressure which follows its administration. Clinical evidence is extremely unreliable in estimating the value of any treatment for hemorrhage. It is very difficult to calculate the extent of internal bleeding or the effect of a given drug. In a case of intestinal hemorrhage in typhoid fever several drugs may have been employed and we do not

know which of these, if any, has produced a favorable effect. The spontaneous effort of Nature must not be overlooked. A second patient may recover from severe intestinal hemorrhage without having received any drug treatment whatever.

A STUDY OF APOCYNUM CANNABINUM.*

HORATIO C. WOOD, JR., M.D.

Demonstrator of Pharmacodynamics at the University of Pennsylvania.

PHILADELPHIA.

(Done Under a Grant from the National Academy of Sciences.)

Apocynum cannabinum, commonly known as Canadian hemp, has long been used by certain Indian tribes in the treatment of dropsies and as an antidote to snake-bite. The credit of being the first to call the attention of the medical profession to the value of this remedy appears to be due to M. L. Knapp who, in 1826, ascribed to it great value as a diuretic. In 1833 Griscom published the records of a number of cases of anasarca in which the drug had been used with marked benefit. Despite, however, several clinical reports confirming its utility, the remedy appears to have passed into comparative desuetude for a number of years, until in 1898 Dabney contributed a paper reviewing what was known of its physiologic action and describing a number of cases of various conditions of circulatory weakness from valvular lesions of the heart and of edema dependent on disease of the kidneys, which were benefited by the use of Canadian hemp. The evidence gathered from a review of the not very extensive literature on this drug, as well as from my own experiments, indicate very clearly that in *Apocynum cannabinum* we have a remedy of marked value, but which has not achieved such a prominent place among the practical therapeutic agents as it apparently deserves. It is strange how slowly the profession adopts new drugs, the evidence of whose value rests on the observations of experienced clinicians and scientific investigators, when compared with the avidity with which is taken up the products of interested pharmaceutical manufacturers, whose greatest recommendation rests on highly laudatory and widely distributed advertisements. The clinical evidence of the value of *Apocynum cannabinum* and the comparative poverty of studies of its physiologic action have made it appear worth while to study more exhaustively the effect of this substance on the animal organism, and especially on the circulation.

There are several representatives of the genus *Apocynum* indigenous to this country. It would seem, however, from the work of Griscom and Dabney that of this genus only the species of *Apocynum cannabinum* is of value in the treatment of dropsy, although some authorities ascribe similar virtues to *Apocynum androsaemifolium*. My experiments have been made with the fluid extract of *Apocynum cannabinum*.

CIRCULATION.

The changes in the circulation following the intravenous injection of moderate doses of fluid extract of apocynum consist in a marked slowing of the pulse accompanied with a rise of blood pressure. (Tables 1 and 2.) After large doses the pulse becomes exceedingly rapid, the pressure ascending as the result of the increased pulse rate still higher. (Tables 1 and 3.) There was no secondary depression of the circulation:

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Sells-Cohen and O. T. Osborne.

in those cases in which sufficient quantity was given to cause death the heart ceased with great suddenness. (Tables 4 and 5.)

After death the heart was always found in complete diastole. In one or two experiments mechanical irritation of the heart caused a few feeble contractions, but in the majority of the experiments in response to such irritation it passed into a state of fibrillary contraction. In one experiment in which the heart was exposed before the drug was given and directly observed under large doses, it passed into fibrillation directly on cessation of its beats without any stimulation.

Asphyxia causes progressive fall of pressure till death. Traube waves. Postmortem showed cord almost but not completely cut.

The slowing of the heart was immediately abolished by division of the pneumogastric nerve (Tables 5 and 8), and did not occur if the vagi had been cut before the drug was administered. (Table 6.) It is, therefore, due to stimulation of the inhibitory centers.

The inhibitory stimulation is so marked that it interferes or may mask the stimulant influence of the drug. Thus, in Table 1, the blood pressure arose only from 138 to 145 mm., while in Table 7 the pressure arose as the result of the first injection from 77 mm. to only 117, and a second injection caused even a fall of

the blood pressure. It is noteworthy that in both of these experiments the rate of the heart was extraordinarily slow, in Table 7 being reduced from the rate of 192 a minute to 24 a minute. That the failure of the pressure to rise under these circumstances depended on the slowing of the pulse is shown by the fact that after the disappearance of the inhibitory stimulation the pressure primarily ascends. Thus, in Experiment 7, as the result of the division of the pneumogastric nerves, the pulse rate rose from 24 to 180 a minute, and the pressure in the arteries was more than doubled, rising from 84 to 188 mm. (Fig. 1.)

Fig. 1.—A. Before administration of apocynum. B. After administration of apocynum, showing the changes produced in the circulation by apocynum, namely, rise of pressure, slowing of pulse and later increase in pulse rate and the late paralysis of the cardio-inhibitory mechanism. X. Stimulation of vagus.

The rise in the pressure in Table 1 can, I think, also be justly attributed to the increase in the pulse rate, evidently brought about by secondary paralyzant effect of the drug on the pneumogastric nerve, and not to the asphyxia. Immediately before the rise an attempt was made to practice artificial respiration by manual compression of the chest. Of course, this method does not guarantee that the animal was receiving enough air to prevent asphyxial stimulation of the vasomotor cen-

Fig. 2.—Showing the sudden cessation of the heart in fatal apocynum poisoning. The movements on the fall of the needle are due to respiratory efforts and are not pulse waves.

ters; nevertheless, the rise of the pressure and the time of its occurrence indicate clearly that it depended on the increased rate of the pulse.

The secondary increase in the rate of the pulse is probably due to a late paralysis of the peripheral terminations of the pneumogastric nerve, since electrical irritation of this nerve had no effect on the pulse rate. (Table 3.)

The rise of the pressure is not dependent on any changes in the respiration or motor excitement as it

occurred equally as marked in thoroughly curarized animals as in the normal dog. (Table 8.) According to Dotschewski,¹ the rise of pressure depends on a stimulation of the vasomotor centers in the medulla and spinal cord.

TABLE 7.—(Weight of dog 7.7.)

M'n. and sec.	Pressure.	Pulse in 10 secs.	
0:00	85	33	Spinal cord has been cut. Asphyxia.
0:10-2:30			
2:40	69	22	
8:10	77	33

Apocynin 1 per cent. solution in dilute sodium carbonate. (Fig. 6.)

My own results lead me to contrary conclusions, because I have found that after section of the spinal cord the elevation of the blood pressure is equally as marked, if not more pronounced, than in the normal animal. Thus in the experiment No. 5, in which the normal pressure was 135, but fell to 47, after division of the spinal cord, under the influence of apocynum the pressure arose to 197. That the cord was completely divided was verified both by postmortem examination and by the fact that neither irritation of the central end of the vagus nor asphyxia caused any elevation of the blood pressure. In the experiment No. 7 the result of the injection was the same. In this experiment, although after postmortem a small portion of the anterior part of the spinal cord was found not completely divided, the fact that neither irritation of the vagus nor asphyxia caused any rise in the pressure, shows that the vasomotor fibers had been completely divided. When we compare the effects of apocynum in the normal animal and after section of the spinal cord, it is seen that in the latter case the pressure arose not only a greater number of millimeters, but reached a point as far above the normal pressure as in the uninjured dog. Thus the average of rise in Tables 1, 2 and 3 in which the cord was not divided is 66.3 mm. above the normal, while the average in 5, 6 and 7 in which the cord was divided was 65.6 mm. higher than the pressure before the section of the spinal cord. It is evident, therefore, that destruction, at least of the medullary vasomotor centers, has no influence on the stimulant effect of the drug on the circulation. That the drug has a stimulant influence on the cardiac muscle, is evident from the

These figures refer to c.c. of fluid in the registering tube. The fall, for example, in Table No. 9, from 4.3 to 0.4 means that the kidney has diminished in volume to an extent of 3.9 cubic centimeters.

Fig. 3.—Crystalline body separated from apocynum cannabinum.

character of the pulse wave, and also from the fact that the frog's heart was arrested in systole.

It seems extremely improbable that any stimulation of the heart could be sufficient to explain such an enormous rise amounting to 156 mm. in one experiment (Table 5) as was obtained in these experiments if the blood vessels were relaxed, as, of course, they normally are after division of the spinal cord. Of course, these experiments do not prove that the drug has no influence on the vasomotor centers located lower down in the spinal cord, but these centers are so comparatively feeble that it seems unlikely that they play any great rôle in the marked elevation of the arterial pressure, especially in view of the fact that they did not respond to the stimulation of carbonic acid. It would, therefore, seem probable from these results that the rise of pressure depends on a simultaneous stimulation of the heart and of the muscular coats of the arteries.

My belief that there is a constriction of the vessels as well as a stimulation of the heart is further borne out by experiments made on the volume of the kidney. For this purpose I employed the well-known ocometer of Roy. With this method I obtained constantly a

1. I have not had access to the original paper by Dotschewski, which was published in the Russian periodical *Tratch*. In the abstract I have quoted from there were no details of the experiments by which he reached his conclusions. It is impossible therefore to explain the contradiction between his results and my own. Incidentally it may be mentioned that in all other points our conclusions are in accord.

diminution in the volume of the kidney betokening a corresponding lessening in the caliber of the renal capillaries. (Tables 9 and 10.)

If given in sufficient quantity, apocynum produces in the frog complete paralysis. Its action, however, on the nervous system is quite subsidiary to its effect on the circulation, for I found that after a dose sufficient to cause arrest of the heart, there was still a certain amount of voluntary and reflex power, and the motor nerve responded normally to electrical irritation for two hours after the heart had stopped beating.

ACTIVE PRINCIPLE.

In 1883 Schmiedeberg isolated two substances from *Apocynum cannabinum*, which he believed to be the active principles. Of these one was a glucosid, to which he gave the name of apocynin, the other he obtained as an amorphous substance, the chemical character of which he did not determine, and to which he gave the name of apocynin. I was kindly furnished by Merck & Co. with a substance labeled "apocynin," which, however, I found to be almost inert. It produces none of the characteristic changes in the blood pressure produced by the crude drug (Table 8), but when given in large quantities acted as a circulatory depressant. As Schmiedeberg did not give in detail the method he employed for isolating these principles, I was unable to make them for myself, and although I have applied to Merck & Co. for the glucosid, I have not received it.

Fig. 4.—c. l. Cut left vagus. c. r. cut right vagus.

Under these circumstances it seemed to me advisable to make an independent attempt to isolate the active principle for myself. This portion of the investigation was carried out in the chemical laboratory of Professor Marshall, to whom I desire to express my thanks for constant advice and assistance in the investigation. After trials with a large number of extracting substances, I finally obtained by extraction with benzole a crystalline body, contaminated, however, with a large amount of yellow resin-like material. Physiologic tests of these impure crystals showing they were active, I attempted to obtain them in a purer form. To accomplish this end, I first tried washing the mass with a large number of solvents, but the result from this procedure was negative, the crystals being soluble in all these solvents which took up the resin. Finally, by dissolving the mass with hot water and then allowing it to cool, the crystals separated out in a comparatively pure condition. After repeating this process several times I obtained crystals which, although not absolutely clean, were very nearly so. These crystals when tested physiologically arrested the frog heart in systole; a dose of 2 mg. per kilo in a dog produced distinct elevation of the blood pressure with slowing of the pulse; a dose of 1 cg. was sufficient to cause death

in a dog weighing 4.2 kilo with the characteristic and sudden arrest of the heart. (Fig. 3.)

These crystals were soluble in ether, chloroform, alcohol, acetone, benzol and hot water, and were insoluble in cold water, petroleum ether and carbon bisulphid; their melting point was 112 C. On making comparative tests with Merck's apocynin I found it had the same solubilities and had a melting point of 113 C. I am inclined to believe, therefore, that the crystals which separated are identical with Merck's apocynin, the slight difference in the melting point being explained by the contamination which was present in my crystals.

In view of the fact that Merck's apocynin was inactive, I am inclined to believe that the activity of the crystals I separated was due to the adherence of the active principle which I regarded at first in the light

Fig. 5.—Both pneumogastrics and the spinal cord are cut. A. Before injection. The failure of irritation of the vagus to produce rise of blood pressure shows complete destruction of cord. B. of a contamination. In support of this view are the following facts:

From 259 c.c. of the fluid extract I obtained 0.6 gm. of impure crystals, that is about 2.3 milligrams from 1 c.c. The dose of the fluid extract required to kill a dog is about 0.1 c.c. per kilo of body weight; if the activity of the plant depended on the crystals it would, therefore, require about 0.2 milligram per kilo to kill, but I found by experiment that with the impure crystals it required approximately ten times this amount. Moreover, the more I purified them the feebler did they become, so that with the purest crystals 43 milligrams

Fig. 6.—Showing the fall of blood pressure under large doses of apocynin; smaller amounts had no effect at all. I. Injected apocynin. X. Stimulation of vagi.

failed to kill a dog weighing 9 kilos, although it did cause a marked slowing of the pulse. Beside this, the original residue left after thorough extraction with a number of agents did not seem to be much diminished in its power, and the material which was separated during the course of the purification of the crystals and which I had regarded as an impurity was physiologically active.

The separation of the active principle from the residue left after extraction with benzol has been a difficult problem which I have not yet succeeded in solving. I have attempted to obtain the active substance of apocynum with a number of methods which have yielded me more or less concentrated preparations of

the active principle, but I have not yet succeeded in obtaining it in a pure form.

The addition of basic lead acetate produced a copious precipitate, but the active substance was not thrown down, passing over into the filtrate. After freeing the latter from lead by passing through hydrogen sulphid, and evaporating the resultant filtrate there was left behind a mass of thick syrupy consistence, which evidently was largely glucose, since it reduced Fehling's solutions and was also fermentable. In order to get rid of this sugar I took the filtrate resulting from the first precipitation from lead acetate, which still contained an excess of this reagent, and added ammonium hydroxid, with the hope that a portion at least of the glucose might be precipitated as a lead saccharate. Even by this means, however, I failed to get rid of all the glucose, so that I still had left behind a substance which could not be evaporated to dryness. This residue was extracted successively with ether, chloroform, benzol, acetone, amyl alcohol and petroleum ether without yielding any results.

Although I have not succeeded in obtaining the active principle in the pure form, I am, nevertheless, strongly inclined to believe that it is in the nature of a glucosid. This view is supported in the first place by physiologic evidence that all cardiac poisons which resemble digitalis in their action which have as yet been isolated have been glucosids. More important than this, however, is the following chemical evidence: I took 5 c.c. of the fluid extract, which had been freed from resin by precipitation with water, and evaporated off the alcohol, added to it some dilute hydrochloric acid and boiled fifteen minutes. The resulting fluid was neutralized with sodium carbonate and injected into the vein of a dog, with the result that there was neither elevation of the blood pressure nor slowing of the pulse.

DISCUSSION.

DR. CLEMENT B. LOWE, Philadelphia, stated that there is some uncertainty, when apocynum is spoken of, whether we are dealing with *Apocynum cannabinum* or *Apocynum androsaemifolium*, dog's bane. He went to a large drug house for some cannabinum, and found that it was androsaemifolium. He returned it and was told that they always supplied that preparation when apocynum was ordered. Dr. Lowe said that he is afraid, therefore, that Dr. Wood has been working with androsaemifolium. The two are very much alike, but differ microscopically in the arrangement of some of the bark cells, which in dog's bane are thick-walled and arranged in groups in a circle near the middle of the bark. It also responds differently to the phloroglucin test. To distinguish them is also more difficult because of the tendency of dog's bane and Canadian hemp to hybridize. A few years ago, when Dr. Lowe was out botanizing, he came across a plant that he could not understand; on studying it he found that it was a hybrid of these two species. The value of a bitter principle is that it causes an increased flow of gastric juice, just as it increases the saliva. Its bitterness is the important feature, and it is lost when disguised. If patients complain that it is bitter, tell them that is why it is given, and that the effect of the bitter can not be obtained without giving a bitter drug.

PROF. C. S. N. HALLBERG, Chicago, called attention to the fact that the alcoholic concentration has been on the market for twenty or thirty years. This preparation of *Apocynum cannabinum* is called "apocynin," and is prepared by precipitating a concentrated alcoholic tincture of the drug in water, following the usual eclectic method and nomenclature. It would be well to remember the fact that if any physician should prescribe apocynin he would probably get, in the vast majority of instances, the eclectic resinoid, instead of the glucosid recommended by Dr. Wood.

PROF. JOSEPH P. REMINGTON, Philadelphia, said that we are all very apt to believe that the active principles of the various drugs are either alkaloids or glucosids of a crystallizable character. We have been led to this idea from the fact that morphin, strychnin, codein and many others are crystalline. In a great many instances the active principles are not crystallizable. For instance, in cubeb and pepper oleoresins are the important constituents. He thinks that the active principle of the drug would be more likely to be a resinous substance, possibly left in the solution which Dr. Wood threw away, instead of the crystallizable principle. In determining these questions Dr. Wood has a much better opportunity of carrying on an investigation into their physiologic action than a pharmacist would have.

DR. H. C. WOOD, JR., said that he was supplied with fluid extracts of both cannabinum and androsaemifolium, but he had relied entirely on the statement of the pharmacist as to the identity of the fluid extracts. He stated that he did not throw away the residue after getting the crystals, and on subsequent trial he found that it had some activity. He said that the drug is useful in cases of dropsy, whether associated with cardiac weakness or hepatic cirrhosis. He hopes at a future time to bring some more accurate observations on the clinical uses of the drug. *

USE OF DIAPHORESIS AND DIAPHORETIC AGENTS IN OPHTHALMIC THERAPEUTICS.*

HIRAM WOODS, M.D.

BALTIMORE.

To properly estimate the therapeutic value of an agent, allowance must be made for the natural enthusiasm of those who introduce it and who often record results which later experience fails to confirm, and the tendency of certain things to remedy themselves, the exciting cause having been removed. Disappointment may ensue because too much is expected. Credit may be given when none is due. Truth lies between these extremes, and is to be reached, it seems to me, by finding out what one should look for, basing judgment on the physiologic effects of the remedy, and the teachings of clinical experience. An example of what one may, not illogically, term therapeutic enthusiasm and therapeutic chaos, is found in the statements of books on general therapeutics and those on eye diseases, regarding the use of diaphoretic agents in ocular affections. If we could accept, for instance, all of the following from Potter's "Materia Medica," pilocarpin would be little short of an ocular panacea. Says this writer: "Ophthalmologists employ pilocarpin with most excellent results in the amblyopia of alcoholism, and that from the use of tobacco, in detachment of the retina, chronic iritis, keratitis, glaucoma, hemorrhage into the vitreous, atrophic choroiditis, white atrophy, to promote resolution and absorption in inflammatory conditions with exudation." Bartholow and other writers indicate practically the same scope. The student turning from this general advice to special works will, I think, be disappointed if he expects to find specific and positive information as to what in this list is true and what is not. Most of our special writers indicate that diaphoresis has been recommended or may be tried in these conditions; but in no text-book with which I am familiar is there the positive teaching the subject deserves, and which is justified by our present knowledge. Scattered through current literature are many most interesting and in-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

structive articles, but they are so scattered that their usefulness is greatly lessened. The object of this paper and the paper by Dr. Woodruff is to set forth briefly what, in the opinion of the writers, may be theoretically expected in ophthalmic therapeutics from diaphoretic agents, and the extent to which their own and others' clinical observation confirm or contradict claims from time to time put forth for this method of treatment. I regret that my recent illness has prevented such a search of current literature as I wished to make, and confined me to articles at hand or with which I was previously familiar. Still they cover more or less completely the principles involved.

Normal sweating is the result of glandular secretion. Physiologists no longer hold that transudation from the cutaneous blood vessels is its most important element. Says Stewart in his "Manual of Physiology": "Though an actively perspiring skin is in health a flushed skin, the vascular dilatation is a condition and not the chief cause of the secretion." . . . "Even the sweating produced by exposure to high temperature is normally brought about by nervous influence and not by direct action on the secreting cells." How far is the profuse sweating from diaphoretic agents, or high temperature employed in baths or cabinets, to be attributed to secretion from nerve stimulation and how far to transudation from cutaneous blood vessels? That the sweat glands can be stimulated to such an abundant secretion as is observed seems almost incredible. Yet the great salivation, sometimes produced by pilocarpin, shows that glandular activity plays an important if not the main part.

Secretions, however, must ultimately be derived from the blood, and there is doubtless a large element of truth in Hansell's¹ statement: "The efficacy of pilocarpin is, I believe, to be attributed to the inordinate activity of the lymph system induced by its presence. By depriving the peripheral vessels of a large proportion of their fluid content, those of the internal organs meet the deficiency, thus eliminating morbid products together with physiologic excretions."

If the therapeutic efficacy of diaphoresis is due solely to this vascular effect, equally good results should follow similar action on other vascular areas, which, for our purposes, are essentially peripheral. Those of the intestines and the use of salines and hydragogue cathartics illustrate. The copious watery evacuations from these agents are not, however, at least in my experience, followed by anything like the results observed after the use of diaphoretics. Nor does emptying the cutaneous vessels, with compensative filling from internal structures, explain the good results of small doses of diaphoretic agents, which do not produce copious sweats.

There must be something besides this transudation from peripheral vessels, and, I think, we may well consider in this connection the nervous influence which lies behind the diaphoresis. Pilocarpin is the drug in most common use. It acts on the skin by its stimulating effect on the cerebrospinal nerves supplying the sweat glands. Another of its physiologic effects is its inhibitory and paralyzing effect on the vasomotor system. One is surprised—at least I was—to note the similarity between the physiologic effect on the eye of pilocarpin and the results of section of the cervical sympathetic nerve or ganglion, when reading the scholarly paper presented to this Section a year ago by de Schweinitz. If one has occasion to observe cases of bad effects from

diaphoretic agents—the nausea, vesical disturbance, cardiac weakness, etc.—he will find abundant evidence, that in both its stimulating and depressing effect, a diaphoretic has marked nervous influence. By its action on the vasomotor system dilatation of the small arteries, with lessened resistance to blood flow and heightened local temperature, are produced. It seems to me, then, that in estimating the cause of the efficacy of diaphoretic agents, we should count first, as Hansell has said, depletion of cutaneous vessels; and secondly, the action of diaphoretic agents, pilocarpin particularly, on the small arteries.

From this we can draw two theoretical conclusions which clinical experience confirms: 1. Diaphoretic agents should have their greatest efficacy in structures richly supplied by blood vessels. 2. This efficacy should show itself in lessening of hyperemia and removal of exudates.

Of ocular structures the uvea, and hence the vitreous, retina and orbital tissues seem to present most prominently the anatomic and physiologic characteristics. Certain lesions with which the use of diaphoresis has been associated can, I think, be excluded. Atrophy of the optic nerve, no matter what the primary cause nor how clearly it might have come earlier, under this plan of treatment, is out of the question; so is optic neuritis, dependent, as it nearly always is, on extraocular disturbance. An exception must be made here of certain retinal lesions which may be accompanied by more or less papillitis.

It is equally irrational, I think, to apply this treatment to choroidal atrophy, cicatricial changes in the vitreous or uvea following long-standing iridochoroiditis, "chronic iritis" (in the sense of irritative symptoms persisting after an iritis has recovered with synecchia, and to be distinguished from relapsing iritis), retinal detachment resulting from cicatricial contraction, primary glaucoma. All of these lesions are either essentially incurable or else are better treated in other ways. Whatever good seems to ensue in such patients from the use of diaphoretic agents is probably due to their influence on the choroidal circulation, and hence on the vitreous opacities; but the underlying diseases are not influenced, and in glaucoma time and possibly opportunity is lost.

In another class of cases there is little probability of good, because the tissues involved are not sufficiently vascular to respond. I allude to keratitis and affections of the sclera. In such of these cases as seem to have been helped, I incline to the opinion that a more careful diagnosis would have shown some form of uveitis underlying the superficial disturbance.

Excluding all the above, there are left many lesions which are most satisfactorily treated by diaphoresis. They are acute troubles in the uvea, retina, orbital tissue and toxic blindness. Uveal disturbance will be presented at length in the paper of my friend, Dr. Woodruff. I want, however, to mention in passing three observations made this past winter in cases of iritis. All three were of rheumatic origin, two private cases of my own, and one a hospital patient of my colleague, Dr. F. M. Chisholm. In both of mine, atropia seemed to dilate the pupil a very little, and then, in spite of pushing it to constitutional effects, using an eight-grain solution, and finally the atropia discs, I could not obtain further dilatation. One patient was in intense pain, the other suffered only moderately. The former was given a copious pilocarpin sweat. The latter was sweated, somewhat unintentionally on my part, by taking an unusually large dose of salicylate of sodium. In

1. Philadelphia Polyclinic, Nov. 20, 1897.

each instance, the day after diaphoresis both pupils dilated ad maximum. An interesting thing was then observed, viz., that there were no points on the lens surface indicating synechia. Apparently the pupil was kept small through intense iridic hyperemia, and dilated when this was relieved. Chisholm's case was similar in essentials, and had resisted eleven days of strong atropia. There were, however, marks of synechia.

A case illustrating the ease with which one can think he has obtained results which he has not is the following:

A young colored man came into my clinic two years ago with a history of defective sight for a fortnight, terminating in pain, which latter symptom led his physician to send him to a hospital. He was almost entirely blind. Pupils were immovable and a little larger than normal. Cornea were steamy, tension increased, nearly plus 2. I advised immediate iridectomy for glaucoma, which the patient declined. He was put to bed, eserine used locally, and he was given three profuse jaborandi sweats on successive nights. Vision improved, and the case proved to be one of choroidoretinitis with iritis in its later stage, and secondary glaucomatous symptoms. Later I found spots of deposits on the posterior surface of the cornea—so-called descemetitis. Probably I should have found them at first had I looked for them, but it was primary glaucoma, as first supposed.

In leaving the subject of uveitis, I want to urge the systematic study of Descemet's membrane for these spots. As de Schweinitz, Friedenwald and others have pointed out, they are present nearly always in disease of the uveal tract, and when found in connection with such symptoms, as in the case just narrated, or those of keratitis interstitialis or scleral affections, point to the uvea as the seat of the underlying disturbance.

A number of cases of detachment of the retina, cured by diaphoresis, have been recorded. The method employed in most of them has been to confine the patient to bed and administer sweating doses of pilocarpin daily or on alternate days for six to ten times. Some clinicians have advocated the use of small doses as equally efficacious, and have not thought confinement to bed necessary, except for two or three hours when the treatment was given.

An interesting discussion of the subject can be found in the Proceedings of the British Medical Association held at Montreal in 1897. Mittendorf claimed excellent results "in cases of opacity of the vitreous and especially if associated with detachment of the retina" from the administration three times daily "for a long time" of pills containing 1/100 of a grain each of pilocarpin. Holt of Portland and Burnham of Toronto advocated the use of small doses, preferably by hypodermic injection. The most striking report came from Nettleship, who had a man with complete detachment of the retina, high degree of myopia, and no light perception in either eye. He used pilocarpin, and the result was satisfactory. He could read large type, but he could not say he could hold that.

Many of the reported cases give little data regarding the history and condition of the eye, besides stating that the retina was detached. Alt of St. Louis, however, reported in this discussion the case of a girl with high myopia, in whom the retina had become detached, and had remained so for eleven years after the diaphoretic treatment. Like most oculists who read these reports six to ten years ago. I used the sweating treatment for retinal detachment as opportunity offered. In the class of detachments which is most numerous—in myopic eyes with choroidal atrophies and floating vitreous opac-

ities—my individual experience has been disappointing. It has sometimes occurred to me that maybe a warning given in 1892 by Spalding of Portland might be repeated. In an article in the *Archives of Ophthalmology*, advocating the use of pilocarpin in cases of hemorrhage into the vitreous, he speaks of the possibility of confounding the black appearance of the blood in the vitreous chamber with a detached retina, and insists on confirmation of the ophthalmoscopic diagnosis by field examination and demonstration of a scotoma. Be this as it may, I do not recall ever seeing in my own or the practice of colleagues a permanent cure of retinal detachment in a myopic eye with choroidal atrophy and floating vitreous opacities. Twice I have seen reattachment and improvement—very little—of the field; but they relapsed. Vitreous opacities improve, but this is not cure of the detachment. I have, however, seen three cases of reattachment in eyes which were not myopic and which did not show the chronic degenerative changes observed in the class just under consideration. Acute choroiditis was present in two of these cases, both hypermetropic, and exudate from the choroidal vessels seemed the only explanation of the detachment. Rest in bed with antisyphilitic treatment effected absorption in one. I saw the man several years afterward,

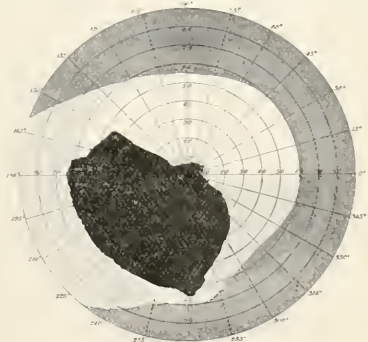

Figure 1.

and the retina was still attached, but that portion of the fundus was blind. Later the eye developed cataract. The patient was first seen in 1889, and disappeared five or six years ago. The other eye remained good. A second case presented, in hypermetropic eyes, double detachment following rapidly the onset of severe choroiditis with floating vitreous opacities. Cause was indeterminable. The case was reported in an analysis of choroidal cases at the Saratoga meeting of this Section in 1902. Pilocarpin was used, with rest in bed. The retina reattached, but there was no improvement of vision in the affected field. The only case in which I have seen apparent improvement of vision is now under observation:

A woman, 22 years of age, came into my clinic the second of last March. She had a positive central scotoma in the left eye. The right was normal. A detachment of the retina, apparently involving the fovea and upper and inner quadrant, was made out. Her scotoma on admission is shown in Figure 1, and was practically the same eighteen days later. She was kept in bed, with pilocarpin sweats three and four times a week for four weeks. At that time her scotoma was as seen in Figure 2, and central vision 20/30. I last saw her April 19, nearly three weeks after her discharge, and the condition was unchanged.

I confess to some misgivings of my own diagnosis, based on comparison of the fields at the beginning and end of treatment. While there certainly was a detachment and as certainly the retina became reattached, I am skeptical about the involvement of the fovea in the detachment. Central vision seems to have improved from nothing to nearly normal, with very little change in the periphery. It would be easy for the upper detached retina to overlap the fovea, and so shut off central vision, at the same time giving the appearance of involving the fovea. The cause of this detachment was a mystery. A few fine muscæ were in a clear vitreous, but there was no other evidence of choroiditis.

I have had no experience in the use of small doses of pilocarpin in retinal detachment, but in a single case of retinitis seen a few years ago I employed such dosage with good effect. The patient was a boy of 12 who presented in one eye a beautiful example of the exudative retinitis, arranged in radiating spokes about the fovea, described by Marcus Gunn at the Edinburgh Congress in 1894. A few small extravasations and mild papillitis completed the picture. Otherwise the boy was in health. Prolonged exposure to glare from snow was the only possible cause I found. After the mercurials and iodids had failed, the administration of

Figure 2.

pilocarpin in one-thirtieth grain doses cleared the exudates in a month.

The good effects accomplished by diaphoresis in general medicine in the treatment of nephritis, effecting elimination of products which should go off through the kidneys, suggests its usefulness in toxic amblyopia. I think one has to be very careful how he draws conclusions here regarding any remedy. For instance, when we were seeing methyl alcohol and Jamaica ginger cases in Baltimore, it seemed that pilocarpin was the only thing which did good, and that its effects were but temporary. Later we found that these transient clearings and cloudings were part of the toxemia. Again, when a toxic agent is withdrawn, the natural tendency is toward cure. Recently a saloon keeper, with typical alcohol amblyopia, came under my care. I wanted him to go to bed and sweat. He said he could not leave his business, but would let whisky alone. He did so, and with no other treatment than abstinence and epsom salts improved in a week from 2/200 to 20/100. Such observations naturally tax one's faith in the efficacy of drugs reported to have brought about identical results. Still, I had another case this winter, a physician, 33 years of age, with tobacco-alcohol blindness, who did

not improve for three weeks at his home in a neighboring state under abstinence and strychnia. He had 10/200 when I saw him first, and when he returned for hospital treatment. In two weeks under pilocarpin sweats he improved to 20/40. He wrote me recently that he had stayed well. There is, I think, no doubt that diaphoresis is effective in eliminating toxic products, and its employment in toxic amblyopia is not only justifiable but imperative. The fact that some cases do well without it is no argument against its use. It only calls for more exact study of cases before we make up our minds what we have accomplished by treatment and what has gone on without our help.

While orbital lesions logically come under the class of cases apt to be helped by diaphoretic treatment, I do not know of any special reports. Orbital diseases are, I think, among our rare observations, and when they occur usually indicate some other line of treatment.

Last autumn a woman, 41 years of age, came to my clinic with a right subconjunctival ecchymosis of the lower cul-de-sac. It presented an appearance different from that usually seen, in that the blood formed a definite tumor. She had 20/30 vision. The fundus presented evidence of former disseminated choroiditis. There was no doubt of syphilitic infection. She was put on specific treatment, with heat locally, and instructed to return in two days. When she did the blood tumor was nearly double in size, and there was slight exophthalmos. She was now urged to come into the hospital, as I believed the case to be one of syphilitic disease of the orbital vessels. She did so, and the exhibition of mercurials and iodids for a week did no good. The exophthalmos remained about the same, and the blood beneath the conjunctiva was not absorbed. The external rectus became paretic. I now put her on pilocarpin sweats, given alternate days. After three such treatments improvement commenced, and in a short time all traces of trouble, including that in the rectus muscle, had disappeared.

The case illustrates what has frequently been noticed before, that in syphilis diaphoresis, when indicated by the part involved and symptoms present, is a powerful adjunct to specific treatment.

CONCLUSIONS.

I would offer these conclusions:

1. The greatest utility of diaphoretics is in the acute congestive and exudative lesions of the uveal tract.
2. Diaphoretics are useful in retinal detachment produced by exudate from choroidal vessels during the course of acute choroidoretinitis. Judging from reported cases, they are also useful in the retinal detachment of high myopia. It is doubtful if restoration of function in the detached retina is usual or permanent.
3. Diaphoretics are useful in alcohol-tobacco amblyopia and probably in other forms of toxic blindness.
4. Diaphoretics influence to a slight extent only, if at all, lesions of the cornea and sclera.
5. Diaphoretics are useless in atrophic and cicatricial lesions.

842 Park Avenue.

The Physician as a Business Man.—Dr. C. U. Collins, in the *Medical Standard*, says that the physician must lay sentiment aside and, like the man in business, keep his income equal to or above his expenditure in order to maintain his credit. The business men from whom he buys expect him to be able to pay for what he buys. If he collects a goodly amount each year, it not only enables him to keep his family comfortable, but it also enables him to buy books, instruments and other accessories that make it possible for him to render better service to his patients, and this is a very good argument to give to his patients for collecting promptly.

DIAPHORETICS AND DIAPHORESIS IN OPHTHALMIC THERAPEUTICS.*

T. A. WOODRUFF, M.D.
CHICAGO.

The enumeration of the more important points in treating pathologic conditions of the eye by means of sweat baths and the most successful means for their application are here attempted. As in other organs of the body, the complete performance of absorption and elimination are constantly going on in the eye without any disturbance of its other functions. When this fails to take place deleterious products accumulate in the vascular and lymphatic systems from the non-elimination of poisons or toxins and pathologic changes manifest themselves.

On what disturbing influences these ocular diseases depend we are still in a large percentage of cases somewhat in the dark. Although syphilis and rheumatism frequently act as predisposing causes they can not be held accountable for all; many of them are probably the result of defective metabolism obscure in origin.

The inflammatory affections, in which we may expect to derive the most satisfactory results from the use of diaphoretics, are those involving the uveal tract. This portion of the globe, by reason of its abundant blood supply, is prone to inflammatory and degenerative changes which show themselves in the form of an exudative inflammation beginning usually in the choroid and less frequently as a catarrhal inflammation of the ciliary body. An endeavor is made by these means to eliminate the toxic or infectious products on which the lesions probably depend. Although a history of syphilis, either hereditary or acquired, can in many cases be elicited, it is not here that our best results are obtained from the use of the sweat-bath alone. It is indicated in just such cases, in conjunction with mercury or potassium iodid, not only as an aid to the absorption of these drugs, but by acting on the skin, helping in their elimination and rendering it possible to give much larger doses without experiencing their untoward effects. It is in those cases of exudative choroiditis which usually come on insidiously, without cause and in patients apparently in good health. The disease manifests itself by ciliary congestion without previous complaint from the patient, but on examination various changes are seen in the interior of the eyeball. The cornea is found to be hazy and on strong illumination Descemet's membrane is found to be covered with a number of opaque dots situated in its lower portion and arranged triangularly with the apex above. If seen in the early stages, and a view of the fundus can be obtained, a number of exudates can be seen situated in the choroid. The choroiditis is probably always the starting point of the uveitis, although in some cases the ciliary body seems to be the initial seat of the disease, beginning as a catarrhal inflammation of the glands situated in this region, according to Treacher Collins. Iritis is usually present, but in many cases is of the quiet variety, the pupil dilating readily with atropin and with little tendency to the formation of synechiae. The exudates become more abundant until covering Descemet's membrane and rendering the aqueous and vitreous humor cloudy and of such a density that all view of the fundus is obscured. Later on, permanent opacities form in the vitreous and atrophic areas form in the choroid.

While sweating as a means of treating intraocular diseases has been advocated by a number of authorities, it is most useful in exudative inflammations and especially in those of recent occurrence. Diaphoresis by means of pilocarpin has been successfully employed by a number of men of good repute in the treatment of various intraocular affections, especially the inflammatory diseases of the uveal tract, while some few have reported cases in which marked benefit has been derived from such treatment. Among others of the earliest writers who advocate this method of treatment may be mentioned Weber,¹ Scotti,² Schmidt-Rimpler,³ Landsberg⁴ and deWecker,⁵ who obtained favorable results, and in some cases where other remedies had failed, in cases of chorioretinitis with vitreous opacities, and recommended it as highly efficacious in the treatment of such disorders. Fuchs⁶ used the sweat bath promoted by pilocarpin for the absorption of serous as well as of organized fresh exudations, and reports having successfully treated several cases of detachment of the retina. In his experience it was ineffective in old opacities of the vitreous and in neuroretinitis. Of more recent date J. A. Spalding,⁷ Hansell,⁸ Burnham,⁹ de Schweinitz¹⁰ and myself¹¹ have written of the advantages to be derived from the use of diaphoretics in the treatment of certain exudative intraocular inflammations and as an adjunct to other drugs, especially mercury and potassium iodid, and in the elimination of the toxic and infectious products on which these diseases probably depend.

Although sweating is a useful remedy in many inflammatory affections of the eyeball, especially those of a low-grade character and those involving the internal structures of the globe, I by no means wish it to be understood that such affections are to be combated by this means alone, although a fair number of cases have been met with in which not only marked improvement has taken place without the use of any other medication, but the disease has been brought to a successful termination. In exudative choroiditis I have found diaphoresis usually assisted by the subcutaneous administration of pilocarpin hydrochlorate, very useful in the early stages before there is any involvement of the retina previous to the appearance of patches of atrophy, as in this advanced stage of the disease very little improvement of vision can be expected, but even then the further progress of the disease may be checked and useful vision be retained. It undoubtedly has a beneficial influence in the absorption of choroidal exudates and in allowing the affected tissues to resume their activity, and we can safely encourage the patient in the hope of a favorable termination of his symptoms.

In vitreous opacities very gratifying results can be obtained in many cases from the use of the sweat bath alone, the opacities becoming readily absorbed and the vitreous clearing up. In the recent cases, where the opacities are small, although the vitreous may be so cloudy that the details of the fundus are made out with

difficulty and visual acuity is very much lowered, there is usually a rapid clearing up of the exudates and visual acuity, if not fully restored to normal, may be greatly improved, so that useful vision is obtained.

In cases of long standing and where the opacities appear as large, dark, irregular masses, the degeneration has been too extensive to expect much improvement from any treatment, and in such cases the prognosis is less favorable. In elderly people, even when the disease is of recent occurrence, the prognosis is not so favorable, still the progress of the degeneration may be checked and absorption of a considerable portion of the exudate take place with retention of a useful amount of visual acuity. It is in the young individual that most favorable results are to be looked for.

In hemorrhage into the vitreous more favorable results are to be looked for where the extravasations are small, in which case complete absorption may take place. In the larger hemorrhages more permanent opacities are apt to remain in spite of treatment. In detachment of the retina I have not seen any favorable results from the use of diaphoretics.

In toxic amblyopia diaphoresis materially aids in the elimination of the toxic agent, but it is very difficult to estimate its true value as a curative agent, and as such its value is very doubtful.

METHOD OF ADMINISTRATION.

As to the technic employed in getting the patient into a profuse perspiration, the baths should be given when the stomach is empty, as being less liable to produce any untoward effects, this being especially the case when pilocarpin is to assist in the production of the sweat. The patient should be in bed and wrapped up to the neck in a blanket and again covered with at least four blankets. Under the latter half a dozen quart bottles containing boiling hot water should be placed. If used at all, pilocarpin should now be given hypodermically, beginning with one-tenth to one-eighth of a grain, the dose of which can be increased if considered necessary to produce a more profuse perspiration, but usually a larger amount of the drug is unnecessary and not at all essential to the success of the treatment. The patient is now given to drink at least a pint of hot water, weak, sour lemonade or tea. In a few minutes he should begin to break out into a profuse perspiration, which should continue for at least two hours, only stopping short of that time if he shows any bad symptoms. At the end of the sweat he should be thoroughly dried and the skin rubbed with alcohol and then allowed to rest the remainder of the day. This treatment should be continued at least every other day until twelve baths are taken. At an interval of two or three weeks a similar course of treatment should be repeated, and then continued at various intervals so long as necessary. It is important that the treatment be carried out systematically and at regular intervals if we desire to get results.

DISCUSSION

ON PAPERS OF DRs. WOODS AND WOODRUFF.

DR. W. B. MARPLE, New York City, agreed with Dr. Woods that if therapeutic nihilism is had, undue therapeutic enthusiasm is worse. Dr. Marple said in regard to the use of diaphoretics that the unwillingness of patients to undertake the treatment often deters physicians from using it in what would be suitable cases. The practice of Dr. Kipp in this regard is a most excellent one. When he has a case where he thinks it indicated, instead of going through the troublesome methods in the hospital he sends the patient to a Turkish bath establishment, and Dr. Marple thinks that is a very good idea. Diaphoretics are useful especially in cases of disease of parts

abundantly supplied with blood vessels; all forms of uveitis of an acute character. The more chronic conditions are not so much benefited. The unwillingness of the patients to subject themselves to the sweat-bath has led Dr. Marple to use the salicylates, and while the beneficial results may not be so great in this way, still they have a very useful action. He agreed that in most cases the withdrawal of the poison is the most important element, although he can readily see that the addition of diaphoretics may be of distinct advantage. He was recently interested in seeing a child who had been poisoned by instillation into the eyes of atropin drops. The child was violently delirious and it was not until it had been given a good sweat-bath that it quieted down and went to sleep.

DR. WALTER L. PYLE, Philadelphia, said that he is a firm believer in thermotherapy and in hydrotherapy, but he protested against the promiscuous employment of hypodermic injections of pilocarpin, and considers it a very dangerous procedure. He knows of one case in which the patient never recovered, and it seems to him that such a dangerous procedure should not be recommended. It is true that this patient had an advanced nephritis, but all these patients have either visceral disease or profound disturbances of the circulation or of metabolism. In his practice, to produce diaphoresis, he employs the Turkish bath, hot-water bottles, hot blankets, hot drinks, etc. There is one drug that he uses frequently—that is Dover's powder. He has never seen any bad results from it, and the patients all seem to do better when it is given. It has a quieting action that is beneficial. He is afraid of the massive doses of salicylates that are recommended by some to produce profuse sweating, although he generally uses one of the salts in rheumatic cases. Another point regarding the use of heat in his practice, when he can not dilate the pupil in the ordinary way, is to order hot fomentations and to instill the atropin solution hot.

DR. A. TIMBERMAN, Columbus, Ohio, said that in regard to the matter of undue enthusiasm for certain remedies, he thinks that some are not enthusiastic enough. One man thinks pilocarpin does no good and another pins his faith unreservedly to it. A patient with toxic amblyopia may get well without pilocarpin, and again he may not get well and the amblyopia may persist even though the toxic agent is withdrawn. A case of uveitis may progress for months without any apparent cause and get progressively worse and then, with the administration of these remedies, excellent results may be obtained. Recently a man who for six months previously had noticed a failure of vision in his left eye, consulted Dr. Timberman. He could make nothing out of the fundus appearance; there was a great black mass over the pupillary area which precluded any examination of the fundus whatever. He did not suppose he could do any good, but he put the patient to bed and gave increasing doses of pilocarpin. He always begins with small doses and runs up as high as the patient will stand. He is never afraid of the drug when he handles it himself. The results were very satisfactory.

DR. WENDELL REBER, Philadelphia, rose to the defense of pilocarpin. He said that it has the function of eliminating toxic material from the system and there is relatively little danger from its use if the condition of the patient's heart be studied beforehand and that, of course, is all important. He is careful to begin with 1/12 the first day, then 1/6 and on to 1/4. Treated in this way there is no danger. He feels that there is no more valuable adjunct to the treatment of iritis than pilocarpin. He agreed with Dr. Pyle that it is advisable to give stimulating drinks. In uveitis and in exudative choroiditis its value can not be overestimated. Patients who would not stand more than 20-gr. doses of iodid of potassium or sodium will tolerate much larger doses with pilocarpin treatment.

DR. S. C. AYERS, Cincinnati, said that for some years past he has been using the hot-air cabinets instead of pilocarpin. They produce a diaphoresis which can be regulated to any desired effect. They are entirely free from danger and the results are quite satisfactory.

DR. LEARTUS CONNOR, Detroit, Mich., declared that in the present condition of medical knowledge the use of hot air and

hot water has come very nearly to an exact science. The trouble is that physicians do not always have the appliances for using these in accordance with their advanced knowledge. The physicians in Boston about a year ago established an institution by which they are able on prescription to have hot water and hot air used exactly as they want it. And in many cities a similar plan might be adopted. They are the best diaphoretics and their intelligent use is without any risk. Where is the hospital that has proper appliances for the use of these valuable agents? In the conditions that have been mentioned, when Dr. Connor can secure the proper application of these remedies, excellent results have been obtained.

DR. E. E. HOLT, Portland, Maine, said that in the discussion of this subject in Montreal he referred to a case of myopia with detachment in which pilocarpin was used and there was a complete cure. There were eight diopters of myopia. He followed the case twelve years and there was no relapse in that time. He used hypodermic injections, beginning with small doses. He has never seen any bad effect from the use of pilocarpin.

DR. J. L. BORSCH, Philadelphia, stated that he has had most excellent results with pilocarpin injections, though, of course, cases must be thoroughly examined before instituting this or any form of treatment, and he would not advise the promiscuous injection of pilocarpin. He finds that cases of toxic amblyopia stand pilocarpin very well.

DR. F. BULLER, Montreal, said that he thinks there must be a certain amount of enthusiasm if anything is to be accomplished. Pilocarpin has been ably defended, but some unkind things have been said about the salicylates, and Dr. Buller thinks it only right that some one should defend them also. He has used the salicylates freely in uveal troubles and is convinced that they are very useful in these cases. Recently he had an illustration of this. In a severe attack of iritis following cataract extraction the patient was treated with the salicylates and with atropin, and in three or four days was entirely well. In another case, one of sympathetic ophthalmia, where the disease appeared to be steadily progressing in spite of everything, he put the patient on the salicylates and he commenced to improve immediately. The improvement was so marked that in a few days one could not tell from a casual glance that anything had been the matter with the eye, though it actually had been much inflamed for several weeks. Dr. Buller advocated the use of the salicylates at least in certain inflammatory affections of the uveal tract.

DR. HIRAM WOODS, Baltimore, said that when any one says that white atrophy of the optic nerve, choroidal atrophy and like destructive lesions can be cured by sweats produced by diaphoretics or by external agents, that person is indulging in a pretty gross form of enthusiasm. Dr. Woods agreed in general with Dr. Pyle concerning the dangerous possibilities of giving large doses of pilocarpin. A small tentative dose should be given at first, maybe not over a twelfth of a grain. Some patients are susceptible to the remedy and show marked reaction; others resist even large doses. Dr. Woods recently saw in consultation a young lady with acute otitis media, and was told that she had had no physiologic reaction from doses of a sixth, a quarter and a half grain. The patient's age is another consideration. The only serious depression Dr. Woods ever observed was in a man over 60 with organic heart disease, who never should have had the drug. Moderately severe vesical pains followed its use in another case, but these are the only instances of trouble Dr. Woods has observed. Dr. Pyle's method of using atropia in obstinate cases of iritis is most useful. Heat is certainly an adjuvant to atropin. Diaphoresis has not in Dr. Woods' experience helped senile or disseminated choroiditis. The exudative choroiditis, with deposits on the posterior surface of the cornea, so-called descemetitis, as described by Hills Griffith in Norris and Oliver's System, is the form of disease which is most benefited.

DR. T. A. WOODRUFF, Chicago, said that he has never seen any bad effects from the hypodermic use of pilocarpin. He always gives small doses unless it is difficult to get the patient

to sweat; then he increases the dose; generally gr. 1/10 to 1/8 is sufficient. He has found it unsatisfactory to give the patient the cabinet bath at home. In a hospital, with a nurse to handle the patient, good results may be obtained.

THE CONSERVATIVE MANAGEMENT OF LACHRYMAL OBSTRUCTION.*

S. D. RISLEY, M.D.
PHILADELPHIA.

It is by the request of the chairman that I venture for the third time to present my personal views as to the value of conservative methods in the treatment of lachrymal obstruction. Added experience has served to confirm the conviction that, in many cases, the practically incurable affections of the tear duct so frequently observed, have been produced through faulty technic or by the violent surgical measures adopted at the outset of treatment. In my early experience I approached the treatment of lachrymal retention with a doubtful prognosis; but of late years I entertain this feeling of doubt as to results only in cases which have already been subjected to some form of radical surgical treatment having in view the creation of a patulous nasal duct.

It is probable that a normal duct is never patulous, but that the tears escape into the nose from the lachrymal sac by capillarity aided by gravity, and possibly by muscular pressure on the sac exerted by the act of winking. It is the opinion of some that a vacuum is caused in the empty sac by this pressure and that the tears are sucked or drawn into it through the puncta and canaliculi from the lake formed at the inner canthus. The drainage system according to this view is therefore a pump forcing the tears forward into the nose.

The onward course of the tears may be obstructed in any part of the apparatus. The puncta, one or both, may be closed entirely or partially as the result of abnormalities or by chronic disease of the conjunctiva or lid margins; the lumen of the canaliculi at the same time may be obliterated or diminished; the lachrymal sac may be diseased and its cavity closed by hypertrophy or by the swelling of its surrounding tissue caused by a phlegmonous inflammation; or the peculiar tissue lining the bony nasal duct, may be so changed by disease as to close its caliber and so obstruct the escape of the tears from the lachrymal sac. Lastly, the form of the nasal duct may be such as to render it susceptible to obstruction by even slight causes. It is probable that the majority of cases of lachrymal retention belong to this last class.

When the cause of the retention lies in the puncta or canaliculi, gentle dilation after cocaineization is usually sufficient to effect a cure. If the sac is diseased it will usually be found necessary to slit the lower canaliculus to secure a more ready access to the sac and the nasal duct for the purpose of subsequent treatment.

In relatively few cases it will be found that the inflammation of the sac, dacryocystitis or blepharorrhea, exist without any marked stricture of the nasal duct. If any obstruction exists it is apparently due to swelling or thickening of the sac itself which readily closes the valve-like entrances to the duct. If the entrance to the duct is narrowed, the egress of the tears is prevented by the increased proportion of mucus or mucopurulent material formed in the sac, or entering it from the con-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and E. L. Randolph.

junction. After thorough cleansing, a few drops of a 4 per cent. solution of cocaine, followed by adrenalin, will contract the swollen or edematous tissues in a few moments, so that fluids will readily pass into the nose from the cannula of the lachrymal syringe, and that without first probing the nasal duct, a procedure which should be avoided whenever possible. When fluids can be made to pass into the nose freely, the inflammations of the sac and nasal duct will readily recover and I believe more speedily and with better final results than when the already inflamed tissues are subjected to traumatism by probing.

In purulent affections, the sac can be readily cleansed by solutions of peroxid of hydrogen and the inflamed surface treated by weak nitrate of silver solutions, sulphate of zinc or, in chronic affections, by solutions of tannin and glycerin, with iodine. These should not be allowed to remain in the cavity of the sac, however, but made to pass through it into the nose, and the surface subsequently washed with boracic acid or salt solutions. Many of these cases I often treat without ever passing a probe into the nasal duct.

In long standing disease, however, the lining membrane of the nasal duct becomes thickened and may quite close its lumen at one or more points in its course, usually at the bottom of the sac, i. e., at the entrance into the duct, or the entire course of the duct is apparently closed by swelling or a hypertrophy of the soft tissues, in which case probing becomes necessary. It should be undertaken with caution, having in mind the peculiar anatomy of the tissues lining the bony duct. A system of abundant veins surrounds the duct in its bony canal, which Dwight, quoting Heme, cites as an instance of what he calls compressible cavernous tissue, which gives support to the walls, and probably when congested can quite compress the cavity.

When we consider the variable and irregular form of the bony duct, it is obvious that the probe, impinging on a bony angle, may very readily be made to penetrate the soft tissue and so pass between it and the bony wall, causing profuse hemorrhage by injuring the bloodvessels, the traumatism doing more harm than the original disease. I am convinced by many of my earlier experiences that, in some cases which would have been readily curable by other and milder measures, more or less permanent and troublesome strictures of the lumen of the duct had been caused by this accident. It certainly can be avoided in most cases by filling the sac with cocaine solution and adrenalin chlorid, which, as the tissues contract, will pass into the duct, so that after the lapse of ten or fifteen minutes, the probe can be cautiously passed through the duct to the floor of the nose. Too fine a probe should not be selected. Numbers 3 and 4 of Bowman's series are less likely to penetrate the mucous membrane than numbers 1 and 2. The design in using the probe should not be to rend or tear a stricture, as in urethral surgery, but to compress the tissue between the probe and the bony walls of the canal, where it should be allowed to remain from fifteen to twenty minutes. By this means the absorption of the thickened tissue can often be effected, much as the indurated edges of a leg ulcer are reduced by firm strapping. After withdrawing the probe the duct may readily be treated with suitable astringent washes applied by aid of the lachrymal syringe.

I have found much caution necessary in slitting the canaliculus as a preparatory step to subsequent treatment. I invariably employ for this purpose the probe-

pointed knife of Weber, and am careful not to carry the incision into the sac, since to do so is to destroy the admirable function of the part, that of a pump.

The drainage duct throughout should be regarded not as an open drain pipe, but as a delicate and most ingenious mechanism, the operation of which may be readily destroyed by bungling interference. The canaliculus should therefore be slit only to its junction with the common canal. The probe or cannula of the lachrymal syringe can then be passed into the lachrymal sac and carried into a vertical position without the injury which would result from passing it through the uncut canaliculus.

Great care is often necessary to avoid passing the probe-pointed knife through the floor of the canaliculus at its junction with the common canal. I have many times seen patients where this has occurred and a false passage made. The results of this accident are extremely difficult to remedy, as I know from many attempts to do so; therefore it should be sedulously avoided. It can usually be prevented by carefully straightening the canaliculus by dragging the lower lid strongly toward the temple. The probe point of the Weber knife can then be carried forward to the nasal wall of the sac, when all tension on the lower lid will cease. In cases of acute dacryocystitis or phlegmon of the sac, with great swelling, the direction of the opening of the canaliculus into the sac is displaced, so that the operation of slitting should be deferred until the swelling has subsided under cold compresses, or by opening the abscess through the skin and by subsequent treatment through the incision. Without this precaution it is difficult to avoid making a false passage, which under the existing circumstances is likely to lead to a pus pocket, and subsequent contraction and permanent displacement of the opening into the sac. After the parts have gained their normal relation the canaliculus can then be slit safely and the final treatment of the sac and nasal duct conducted through it, and the opening through the skin be permitted to close.

There is another group of cases which present peculiar difficulties for their successful treatment, and while presenting the general characteristics of those already mentioned, are important because of their etiology.

Any careful study of the anatomy and physiology of the parts involved in lachrymal obstruction, and of the contiguous bony cavities in the anterior segment of the skull, either in dried or wet preparations, reveals marked variation in structure. One does not go far in such an investigation without being impressed by the idea that the anomalous relation of these anatomic structures may be in large measure responsible for the tendency to disease of the tissues composing the delicate lachrymal drainage apparatus.

It is obvious from any extended inspection of a collection of skulls that not only is the size and shape of the bony orbits modified by distortions of the skull, but the nasal passages and the accessory sinuses undergo marked variation in size and form, and in the relation of their walls to contiguous structures. In a number of specimens I have seen the direction, size and form of the nasal duct changed by the encroachment of the inner wall of the maxillary antrum.

In one patient, a woman, who had been treated for a long time by a general surgeon for lachrymal obstruction, I found that in his efforts to secure a passage into the nose the probe had been forced into the sac through

the floor of the canaliculus and thence downward through the walls of the maxillary antrum, failing entirely to reach the floor of the nose. In my efforts to relieve the condition I found that unless the point of the canula were carried beyond this false passage, the fluid from the lachrymal syringe would flow into the antrum. By changing the direction of the canula the contents of the syringe flowed freely into the nostril. She had suffered from a chronic rhinitis for many years and had a deflected septum and ethmoidal disease. Her lachrymal disturbance was no doubt primarily due to the nasal condition. By skillful treatment of these, and by simple syringing of the sac and nasal duct, a cure could readily have been secured; whereas a condition of affairs had been produced, which was curable only by some radical surgical procedure to which she would not submit.

In cases of blennorrhœa of the sac, with a large nasal duct through which a relatively large probe can be passed, I have usually found that the retention of tears was due to obstruction at the nasal end of the duct through disease of the soft tissues or some deformity of structure at this point. The passage to the floor of the nose does not always end with the bony duct, a fact which suggests both the futility and absence of any necessity for harsh probing or other surgical measures. In one case in which a No. 8 probe of the Bowman series passed without difficulty, and where washes flowed freely into the nostril, the patient nevertheless had constant retention of tears and mucus and a chronic conjunctivitis, which demanded more or less constant treatment. The bony duct was a short one, but opened as a narrow slit under a broad fold of membrane back of a scroll-like inferior turbinate, which hugged closely the wall of a very narrow nostril. In all cases of lachrymal retention, therefore, no study should be regarded as complete which does not include a careful inspection of the nostrils.

In this connection, however, it should be borne in mind that lachrymal disease is rare when compared to the great frequency of the affections of the nose. That the nasal disease does not more frequently cause obstruction of the outflow of the tears, I believe is explained by the protection afforded by the constant and ready exit of the tears under normal anatomic conditions of the lachrymal duct. Given cases of abnormal anatomic structure, as, for example, the absence of the valve-like fold protecting the opening of the duct, or a slit-like exit which is readily closed; or some of the abnormal irregularities in the course of the duct itself, and we have anatomic conditions which, even in health, introduce more or less difficulty in the escape of the tears and render such cases susceptible to closure by disease.

When we consider that the mucous membrane forming the nasal duct lies in a bony canal, which is subject to great anatomic variations in size and form, with great irregularities in its walls; that between the periosteum lining and the mucous membrane forming the tear duct, there is a small amount of intermediate tissue in which run veins of considerable size which are connected with the plexus of the inferior turbinates in the nose, it is obvious that we should at least hesitate before we plunge forcibly through this duct instruments which can only hopelessly injure the admirably contrived apparatus for the drainage of the tears. Such surgical procedure should be adopted only when other means have failed. My own experience seems to show that this is comparatively rarely necessary.

DISCUSSION.

DR. G. E. DE SCHWEINITZ, Philadelphia, stated that, in large measure, he agreed with Dr. Risley and commended the conservative measures which Dr. Risley adopts in the treatment of these cases. Dr. de Schweinitz considers it deplorable that epiphora alone has been made too often the indication for the introduction of probes, when in point of fact there has been no fault in the drainage system to account for the overflow of tears, which may be due to many causes—exophoria, uncorrected presbyopia, refractive error and some functional as well as organic nervous diseases. Such cases, to be sure, do not come into the discussion at the present time. In the presence of a stricture of the lachrymo-nasal duct, Dr. de Schweinitz thinks it may be necessary to use a probe, but his experience agrees with that of Dr. Risley, that large probes do not yield satisfactory results. So often continued overflow of tears is due to coexisting intranasal disease, and especially to obstruction at the intranasal end of the duct, that this region requires the closest scrutiny and the most accurate treatment. This often yields the happiest results and without the necessity of interference with the delicate drainage apparatus. In the presence of dacryocystitis, when the sac has been long inflamed and its walls are thickened, probing seems to be unnecessary when by the simple operation of extirpation of the sac a radical cure may be effected that is usually a satisfactory one.

DR. L. D. BROSE, Evansville, Ind., stated that there are some cases where he does not feel like trying conservative treatment. One is where one eye has been lost and there is a suppurative condition of the other tear sac. There the patient runs a risk of losing the other eye. Again, where the patient has had a severe septic ulceration of the cornea in one eye and the disease has been cured and then the same trouble starts in the other eye. In these cases the lachrymal sac should be removed. Where the sac is repeatedly inflamed and the probing is very painful, Dr. Brose resorts to the radical operation of removal of the sac.

DR. E. J. BERNSTEIN, Baltimore, said that he tried, in 12 skulls, to pass the larger probes and found three adult skulls through which it was impossible to pass them. In trying to pass the largest ones, he found that this was only possible by fracturing some of the small bones. This year he has had two or three cases which have been under the care of men using large probes for the treatment of chronic lachrymal sac troubles, in spite of which the tear drop had persisted. It was found on examination that there was an enormous hypertrophy of the turbinates which had been entirely overlooked. In some of the more chronic cases, Dr. Bernstein has been doing the radical operation of removal of the sac. Instead of doing the usual operation, as recommended by Petit, he goes through the skin only and lays bare the sac. In that way he dissects it out more readily and thoroughly.

DR. MAITLAND RAMSAY, Glasgow, Scotland, agreed with Dr. Risley regarding the conservative treatment of lachrymal diseases. Dr. Ramsay was taught to use probes frequently in these affections, but gradually, as his experience became greater, he has come to employ probes only in special cases, and to teach that the less probing the better in the treatment of diseases of the tear passages. Of course cases occur now and again in which there is an organic stricture in the nasal duct, which can only be overcome by the use of a probe. Under these circumstances it is his practice to administer an anesthetic (usually nitrous oxid gas), slit the lower canaliculus, pass a No. 6 probe into the nasal duct and then introduce a lead style, which is kept in position for at least 24 hours. At the end of that time the style is removed and the sac and nasal duct syringed thoroughly with an antiseptic solution. If the obstruction has been difficult to overcome, the style is reintroduced and is worn as long as may be necessary to effect a cure.

DR. SAMUEL THEOBALD, Baltimore, said that, from his point of view, one of these questions is as definitely settled as the other. A radical error is made in supposing that the normal condition of this apparatus can not be disturbed without

serious consequences. For the proper performance of its function it is not necessary to have a punctum or a canaliculus in its normal condition, nor is it necessary to have the valves which are commonly present in the nasal duct. Dr. Theobald does not know of any operation that gives more satisfactory results than slitting the canaliculus for eversion of the punctum. If it is necessary to preserve the normal state of these parts this certainly would not be the case. He has had considerable experience in the last twenty-five years or more in the use of the large probes and he states most emphatically that the normal physiologic function is not spoiled. He meets with patients whom, in some instances, he has not seen for ten or fifteen years and finds them absolutely cured. The ducts are pervious, as may be shown by the Valsalvan experiment. They may be abnormally pervious to air, but that is of no moment. Dr. Theobald considers Dr. Risley's experience singular in that all his troublesome cases had first been dealt with by other men, who had made them worse. He thinks that Dr. de Schweinitz uses probes of inadequate size.

Dr. E. E. HOLT, Portland, Maine, said that he interviewed the men at the Seventh International Congress, held in London in 1881, and that it was very interesting to learn what a difference of opinion existed in regard to the treatment of dacryocystitis. Dr. Holt's plan has been for the last twenty years, in cases of suppuration that he could not cure by syringing, to slit the canaliculus and pass the large Theobald probes and then to put in a lead style to fit the case. He does this to avoid repeated probing and he is so well satisfied with the treatment that he has followed it for years.

Dr. W. H. WILDER, Chicago, recalled a discussion some ten years ago in this section, when almost all the men advocated probing. At that time the conservative treatment of washing out the sac did not seem to be so well received. Dr. Wilder thinks, with Dr. Risley, that such conservative treatment in recent cases is the proper one and will prevent many from going on to impervious stricture of the duct. He is coming to believe that for those chronic cases that require regular probing, and that have received such measures from the hands of other practitioners, the most conservative treatment is the radical one of excision of the lachrymal sac and duct. If there is no need of the valves, or canaliculi, as Dr. Theobald says, then there is no need of the sac itself. When this is inflamed it is a constant source of irritation that is of itself enough to cause profuse lachrymal secretion. This all subsides when the sac is excised, and he does it more and more, not only for the relief of such irritation but for the prevention of infection of the cornea. A little method that facilitates the operation is to inject into the sac just before the operation liquid paraffin of a melting point of 112°, which is then chilled at once with ice; the dissection can then be carried on with greater ease and accuracy.

Dr. S. D. RISLEY stated that he has simply given his own experience and candidly stated his own judgment. The subject of probes, or of no probes, is not under discussion at all, as has just been pointed out by Dr. Reik. The cases where the probe does no good are those where the skull is very large. Under such conditions large probes may be useful, through pressure causing absorption of thickened tissue by stimulation. This is probably the only way in which probes do good. It is bad surgery to repeatedly pass large probes through a duct that is so small that the friable, bony structures must be crushed. Where the duct is large, the trouble is apt to be due to disease in the nasal passages at the lower end of the duct, which, through thickening of the surrounding parts, becomes closed, the lumen of the bony duct becoming secondarily involved by extension or through retained tears and the contents of the conjunctival sac. There are many cases that are stubborn in spite of and possibly because of continued probing which recover rapidly as soon as the probes are omitted and gentle syringing substituted. Given a case of acute dacryocystitis, if treated in the way suggested, often without even slitting the canaliculus, it will prevent them becoming cases of chronic blepharitis of the sac.

At one time in his clinic, Dr. Risley often found it necessary to have patients with lachrymal disease await their turn for the probes. There were not enough probes to go around. Now one rarely sees a probe in use in his clinic and the lachrymal cases no longer accumulate as in former years.

SOME INJURIES OF THE EYE IN THEIR MEDICOLEGAL ASPECT.*

JOHN JOHNSON KYLE, M.D.

INDIANAPOLIS.

For me to submit a paper on the medicolegal aspect of injuries of the eye in general would be rank temerity. My efforts will be especially directed to two interesting cases of injuries of the eye, with reference to the medicolegal aspect of one of them in particular.

Exaggeration of injuries and feigning seems to have taken its origin in the early dawn of man's existence. Erichsen, of London, in 1866 published six lectures on obscure injuries of the spine due to collision on railroads. Since that time thousands of cases of obscure nervous and physical disorders have been correctly and incorrectly attributed to trauma.

Unfortunately, it is necessary in a consideration of obscure sequences of accidents that we remember the weakness of human nature and draw conclusions from conditions as they really exist, rather than try to prove facts from abstract conditions.

The point I wish especially to make is that in cases of injury of the eye, obscure or otherwise in origin, occurring among employes of great corporations, soldiers, sailors, passengers of steamships or railways, we should exercise precaution in all we say regarding such injuries, not alone to patients, but also to interested corporations.

Wounds of the eyeball may be classified as direct and indirect. Direct injuries are punctured, contused, lacerated, incised and gunshot. Among the indirect are especially injuries from concussion, which may result from fall, blow on the head or gunshot wound. Direct injuries are of interest on account of their varied causes and the great spectacular forms presenting.

The greatest danger from such injuries is infection and sympathetic ophthalmia. The danger of infection is, as a rule at the present time, in direct ratio to the time the patient is seen by the surgeon. It may be a reiteration of an established fact that many foreign bodies strike the eye and even enter without bringing about inflammatory change, due to the early, careful and antiseptic treatment of the wound, to feeble pathogenic property of bacteria found in conjunctiva (Randolph) and to the bactericidal properties of the secretion of the eye. On the other hand, sterile bodies as copper may excite suppuration, as related by Leber, Kostenitschi, Kipp and Meyers (Baudry), the inflammation being of a chemical origin. Foreign bodies which are not susceptible to the chemical properties of the secretion or fluids of the eyeball may remain in the eye, innocuous for years and often a lifetime.

Injuries of the eye from cuts, foreign bodies or contusion are of greater interest when enucleation is not immediately indicated. With the introduction of the magnet favorable results in the extraction of steel and iron are daily recorded. Subsequent loss of eye months afterward from cicatricial irritation and inflammation may follow, as a report of the following will show:

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

Mr. A., an employe of the Atlas engine works, was referred to me by Dr. Dorsey, surgeon. Patient struck by particle of steel $\frac{3}{8}$ in. wide $\frac{7}{16}$ in. long, weighing $20\frac{1}{2}$ grains.

The track of the wound was through the upper lid, slightly below the supraorbital bone and in the median line; the object penetrated the orbit $\frac{1}{16}$ of an inch back of the sclero-corneal margin, making an irregular clear-cut antero-posterior wound. The large particle of steel was extracted by a Johnson magnet. Had we used the giant magnet the probability is that a great deal of the vitreous would have escaped, with possible collapse of the eyeball. As it was, there was but little loss of the vitreous. Two stitches were taken in the eyeball and three in the lid; healing by first intention took place with vision 20/30. No measurements, unfortunately, were taken of the field of vision.

Seven months after discharge of patient he returned and gave a history of slight pain and progressive loss of sight for a period of three months.

Vision was reduced to perception of light. The eye was very much injected, soft and tender to the touch. The iris was bulging on a line with the wound as though propelled by a foreign body. On account of the cloudiness of the vitreous, ophthalmoscopic examination was negative. Suspecting the presence of a melanosarcoma, enucleation was advised and accepted.

Operation.—On puncture of posterior chamber with needle previous to hardening with formaldehyd, a thin, turbid fluid of a reddish color escaped. On section, the retina and the flat portion of the ciliary body was found to be drawn into the scar two- to three-tenths of an inch. The gradual cicatricial contraction produced detachment of the retina and caused the lens and capsule to be drawn upward and by pressure at the point of contact, produced atrophy of the ciliary body and iris. The suspensory ligament at its lower portion was completely ruptured. Until fibrous tissue was fully formed in the scar there was no contraction or detachment and thus we had a good vision for a few months following the injury.

The lens is observed to be degenerated, the upper portion being filled with hyalin material. Cyclitis was in process of development, which in a short time would have brought about a general panophthalmitis.

As regards the magnet, I might repeat that Professor Schmidt-Rimpler prefers the large Haab magnet to the small Hirschberg magnet, except where foreign bodies are in the anterior chamber. If they are embedded in the iris, there is great danger, in using the Haab magnet, of pulling the iris out with the foreign body. In such cases Professor Schmidt-Rimpler¹ recommends exsection

of the iris, and that the Hirschberg magnet be used to complete the operation.

Wounds by contusion are of interest from a medico-legal standpoint especially when there is no hemorrhage into or rupture of the membranes of the eye. In such cases we may have a condition of traumatic anesthesia of the retina or molecular shock (Baudry) as described by Leber, Berlin, de Schweinitz and others, resulting in total temporary blindness or permanent partial blindness. In such cases we may have contraction of the field of vision, with good central vision and with total absence of objective symptoms.

The attending oculist or medical expert called by the court may be asked to testify in damage suits involving thousands of dollars, as to the existence of real or functional blindness.

Makin² in his interesting book relates a number of cases of contusion produced by bullets causing total blindness. In one case contraction of the field of vision resulted, with symptoms of a lesion involving the upper part of the uncinate lobe about the calcarine fissure. In this case in particular he says: "I feel satisfied that there is considerable loss of sight in the right field also, but the functional element obscures its exact nature."

Among the indirect injuries to the eye, I desire to dwell especially on those classified as due to concussion. It is difficult to always differentiate certain nervous conditions of the eye, classified as concussion, from those produced by contusion.

Concussion of the brain as described by DaCosta and others, "is a force that shakes, oscillates or jars the brain, giving rise to waves of cerebral fluid." Such waves may be transmitted to the fluids of the optic sheath, resulting sometimes in hyperemia of the nerve, either unilateral or bilateral, and occasionally passive blindness. Hysterical amblyopia may result from concussion of the brain, not alone from hysteria, but many latent nervous diseases may be hastened by concussion (Bailey).

To differentiate between feigning, hysterical amblyopia and concussion is indeed a difficult problem, especially when the blindness is bilateral. Blows or injuries on the periphery of the orbital wall or on contiguous bones of the face, may bring about concussion of the eyeball and nerve, producing temporary blindness and even slight permanent alteration of sight. Where we have no direct injury, vibratory force or possibly stunning is, without doubt, the cause of the loss of sight.

L. M., manufacturer by profession, while en route from Indianapolis to New York City, was, according to the history of the case, thrown violently from the train while in motion, striking on the forehead and bridge of the nose with sufficient force to cause unconsciousness for three hours. The man was brought to the city of Indianapolis the second day after the accident and confined in one of our hospitals. I saw him two days after the injury. The forehead and nose were badly contused and there was a slight bloody discharge from the nose. Eyeballs normal in appearance. Conjunctiva slightly edematous, tenderness along supraorbital ridge.

The patient said he could not see; could open eyelids normally; no muscular insufficiency of any kind could be detected. Pupils reactive to light. Examination of fundus showed nothing abnormal. Pulse at this time was 60, temperature slightly subnormal, breath fetid.

On the fourth morning the patient said he had suffered, during the night, a great deal of pain at the back of his head. Optic nerves were very much hyperemic and congested. On the seventh day, in addition to the eye symptoms, the patient complained that he could not hear in right ear; tuning fork C, 512 was heard for four inches through the air. The con-

1. Amer. Jour. of Ophthal., February, 1904.

2. Surgical Experience in South Africa.

gestion of the optic nerves after five days began to clear up. In a few days the nerve was quite normal. About this time the patient claimed he could not open his eyelids. The eyeballs were much deflected, resembling paralysis of superior oblique muscles, so much so that ophthalmoscopic examination of the nerves could be made only with great difficulty. The case continued in this condition for six weeks, when I lost track of the patient. At my last examination I emphatically told patient there was no excuse for his not seeing.

Because I, unguardedly, some twenty days after the accident, told the patient and his attorney that atrophy of the optic nerves would probably follow the congestion, the patient brought suit for \$100,000 on account of blindness. Six weeks after the injury I read in the paper of a sudden miraculous return to sight in the right eye of my patient, superinduced by accidentally striking his head against some object. Ten days after this injury, in the presence of a number of oculists of our city, Dr. J. L. Thompson conducting the examination, the patient was anesthetized and right eye bandaged up. On his partial return to consciousness, he said that he could see out of the left eye.

One year afterwards suit was instigated and damage was awarded to plaintiff for \$2,000 on grounds of temporary blindness. As a witness in the suit, I testified that during my observation of the case objective symptoms indicated vision, while subjective symptoms indicated blindness. The temporary congestion of the nerve and early action of the case would indicate blindness from concussion. The concussion may have produced hysterical amblyopia. On the other hand, many symptoms of the case would indicate feigning blindness, a proposition advanced by the defendants.

It must be remembered that many remote conditions may result from concussion. These conditions, according to Walsham, occur more likely in those with predisposition to nervous diseases. Among the remote ocular conditions mentioned are optic neuritis and atrophy.

In conclusion I want to say that I believe it unfortunate that in damage suits the real physical condition of the patient is often obscured by both the attorneys for the plaintiff and the defendant. Only such evidence as may appeal to the jury is too often brought out.

To give a history of the case, with complete and accurate conclusions, too often subjects the physician to ridicule, detracting proportionately from the value of his testimony. It is for this reason that we are compelled for self-protection before a court of justice to volunteer no information and answer questions as briefly as possible.

DISCUSSION.

DR. H. M. STARKEY, Chicago, agreed that these cases of injury are most perplexing; not only the cases where damage is sought for injury, but the pension cases. Every case that comes to the Pension Bureau with loss of vision from injury or when applying for pension is viewed as a case of probable malingering, and it is the rule of the Pension Bureau where there is no physical condition to account for the blindness to reject the claim. As a rule, this is undoubtedly right, but still there are cases where that is not justice. There are cases in ordinary practice where there is no reason for the patient to want to appear blind, and where no physical reason can be found for the reduction or loss of vision. Dr. Starkey has had several such cases, in neither of which was there injury to the eyeball. The first patient was a man aged 30, who first came to him November 4, 1901, having suffered injury sixteen days previously from an explosion. The eyes escaped because of very thick glasses which he wore, being a myope of high degree. The lashes and other hair on the face were singed. Vision in one eye was 20/20 and in the other 20/50 at times, but he would see for a moment and then lose the sight suddenly. Vision improved in this case gradually to 20/30. The second case was that of a young man shot at from a distance of seven feet with a thirteen caliber ball. The bullet struck the border

of the orbit, but did not penetrate the eyeball. It was extracted from near the ear and sight was permanently lost.

Dr. J. L. THOMPSON, Indianapolis, stated that the patient mentioned in the paper was brought to him some weeks after Dr. Kyle had examined him. It was a very difficult case to examine, as he persisted in closing the eyes, and when the eyelids were lifted the eyes were forcibly turned downward. The pupils responded to light promptly, but that may take place when the patient is not pretending blindness. It is never wise to give an opinion hastily in such cases, because there is no certain test which is proof that a patient can see when he persists he is blind in both eyes, especially if he persists in shutting his eyes and looking down when his lids are raised. Dr. Thompson made several appointments with the patient's brother-in-law, who is a physician, and who was very honest about the matter. Five or six subsequent examinations were made at stated intervals, when drawings were taken of the fundus of each eye, with extreme difficulty. After some weeks the patient claimed that sight returned to one eye, but that he could see nothing with the other. This made the case a very easy one. A prism was placed before the seeing eye, the lids of both eyes were lifted by an assistant, when it was plainly evident that he could see with both eyes. Dr. Thompson did not inform the relatives of his discovery, but told the patient's brother-in-law that he must be examined under chloroform to determine as to the paralysis of the superior recti muscles, and of the upper lid muscles. All the physicians who had examined him previously were present when the chloroform was administered. As he was recovering objects were held above the eyes and he raised the eyeballs and lids with ease. The seeing eye was closed and he recognized the physicians with the blind eye and called them by name. The relatives were told that it was a case of hysteria, thinking thereby to let him down easily, supposing that would be the last of the case, but many months afterward the jury found that the hysteria was caused by the injury and awarded him several thousand dollars.

DR. H. V. WÜRDEMANN, Milwaukee, declared that, to be of use to the jury, the testimony of the medical expert, more particularly as to ocular injuries, should not be alone confined to the ocular lesion that may be present, and the effect of that lesion on the sight, not only the visual acuity and all the other visual factors, but also to their effect on the earning capacity of the individual. Of what does it avail the jury to tell them that a man has suffered from paralysis of the inferior rectus muscle, or that he has a hemanopsia? The testimony should, if possible, show that there is some actual lesion and should be described in plain language. In loss of vision from injuries attended by internal lesions which cause damage to the optic nerve, it is very difficult for the expert to demonstrate this to the jury. In the collection of the Supreme Court and Appellate Court judgments in the last ten years Dr. Würdemann has found but few cases in which the damage was not awarded except for loss of an eye or some great internal injury. They run from \$150 for a black eye to \$12,000 for loss of both eyes. Physicians should testify regarding the permanent results of the accident where possible. The medicolegal relation of these cases is not alone that which deals with the patient and his loss of earning ability, but also to the party causing the damage and to the physician or consultant who has seen the case previously. Dr. Würdemann has been in a considerable number of damage suits, and found that there is generally some blame attached to the physician who attended the case. This is especially true of the fourth of July accidents.

DR. EDWARD JACKSON, Denver, in reference to the detection of simulated blindness in both eyes, said that he believed that the plan suggested by Priestley Smith several years ago will be found always satisfactory. It is a prism test, not based on diplopia, but on the behavior of the eyes when both are open and a sufficient strong prism is placed before one. A person with binocular vision can not avoid the movement of one eye to escape diplopia when the prism of 8 or 10 degrees is placed before it with the base toward the temple. If there is vision in the two eyes there will be movement in the eye

before which the prism is placed. The patient can not overcome the impulse of attempting simulation. There may be a form of hysterical blindness in which the eye movements are under the subjection of some inhibitory influence, the same influence that causes the inhibition of the visual centers, in which this test would not work, but voluntary simulation can always be detected in this way.

DR. JOHN J. KYLE agreed with Dr. Würdemann that the jury would rather see the injury or result of injury than have the physician tell them about it. He was on a case a few weeks ago where a woman claimed damages for deafness, alleged to have been caused by a fall from a street car. From examination we had to deal with a case of labyrinthine disease. The attorneys for the woman wanted to prove that there was a perforation of the drum, which the woman did have. They wanted this fact brought out, instead of the fact that there was a labyrinthine trouble, knowing the jury could fully realize the danger of a perforated drum, and could form no conception of any trouble of the labyrinth, and by insisting on this point they secured damages.

IS BILATERAL OPERATION FOR CATARACT EVER JUSTIFIABLE?

AND IF NOT, HOW SOON AFTER THE OPERATION ON THE FIRST EYE IS IT SAFE TO EXTRACT THE SECOND CATARACT?*

A. W. CALHOUN, M.D., LL.D.
ATLANTA, GA.

An exhaustive review of text-books, medical journals, special periodicals and pamphlets revealed a total lack of literature bearing on this subject, and a letter of inquiry, sent to forty-one competent and experienced oculists in different sections of the country, showed the greatest diversity of opinion; about an equal number being on each side of the question.

This paper, therefore, is largely based on a personal and clinical experience of more than fifteen hundred cataract operations.

I can conceive of no circumstances that would justify me in making bilateral extraction of cataract. There are so many sources of infection and so many opportunities for it, that we can never be sure that an eye will not be infected during or after an operation, however careful we may have been in our work, or however perfect the patient's local, mental or physical condition may have been. The difficulty of cleansing the conjunctival sac is well-known. Indeed, the assertion has been made that the sac can not be made aseptic.

The intimate connection, through the lachrymal canal, between the nasal mucous membranes and the conjunctiva, renders the latter peculiarly susceptible to all the irritations and inflammations of the former, and every operator must recall to mind cases of infection traceable to this source. Regardless of the great advance made in the operation for cataract and its after-treatment, in spite of every precaution, suppurative occasionally occurs, and will continue to occur. A distinguished surgeon recently stated to me that he had seen suppurative occur thirty days after a seemingly successful extraction.

More frequently an iritis springs up, not necessarily fatal to the eye, but most distressing to the patient, and equally discouraging to the surgeon. Unexpectedly and without apparent cause, an anomaly in the healing pro-

cess sometimes becomes a menace to the eye after extraction, adding another danger as to infection, and this would necessarily interfere with the normal process of healing in the fellow eye. I have had cases take not only days, but weeks, for the thorough healing of the corneal wound, there being all the while slight, gradually diminishing seeping of the aqueous through the wound. Some remote or hidden constitutional weakness was no doubt the cause of this. Such a case is a decided disturber of the surgeon's peace of mind, and would be suggestive of grave disaster in a case of double operation for cataract. Therefore the possibility of infection alone, should cause the too enthusiastic surgeon to pause and seriously consider, before proceeding to the bilateral extraction.

How absolutely helpless a patient must feel, with both eyes operated on at the same time; and if a severe form of iritis or other serious inflammation should set up in one or both eyes, there would certainly be great mental depression; and a cheerful and hopeful spirit is a mighty force in aiding recovery from any ailment.

A certain amount of experience, arising from the patient's peculiarities and from possible complications, is always gained by making the single operation, whether the results be good or bad, and the use of this knowledge would surely be a valuable guide, and increase the chance of success on the second eye. Not infrequently it has happened to the most experienced and competent oculist that an eye has been lost after extraction through inflammation or other mishap—whereas later on, guided by his first experience, the other eye has been operated on by the same surgeon with perfect success. Now and then it happens that an eye lost through violent inflammation following a cataract operation, requires to be enucleated because of the sympathetic irritation, before we dare proceed with the operation on the other eye. It is easy to predict what would have happened to the fellow eye, had bilateral extraction been performed in such an instance. In this connection I would say that sympathetic ophthalmia is not a frequent, but a distinct element of danger, to be reckoned with in considering the double cataract operation.

Accidents and the patient's disturbed mental condition following cataract extraction, are contraindications to the bilateral operation. The unmanageable patient tossing from side to side of the bed, displacing his bandage, striking the eye with his hand, springing suddenly up in bed and by a strain disturbing the corneal wound, coughing, sneezing, etc., are actual occurrences in the hands of every experienced operator.

I once had a patient, who from a violent fit of coughing, sneezing and vomiting, had a profuse intraocular hemorrhage with complete emptying of the contents of the ball. If one could be happy under such circumstances, I was reasonably so, when I reflected that the other eye had not been touched. Loss of the vitreous, hemorrhage, panophthalmitis following accidents, glaucoma and possible sympathetic inflammation, with infection from many sources, constitute a chapter of possible accidents with such dreadful results, that I feel warranted in asserting that it would be unwise and unjustifiable to extract both cataracts at the same time.

Mental disturbances after cataract operations are of sufficient frequency to cause the surgeon some concern. Occasionally, after several days of confinement with both eyes bandaged, the patient becomes melancholy, has hallucinations and, in rare instances, becomes violent and ungovernable. This condition generally passes

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

rapidly away on uncovering the other eye, even though this is practically blind, and getting the patient into the fresh air. One such patient threw himself through a window, carrying sash and glass with him, while in this temporarily perturbed mental state. Another, who had been a sleep walker in his boyhood days, eluded his attendant and climbing through a second story window, leaped to the ground below. Again, I would say, there is some comfort in such cases, when we consider that only one eye has been operated on.

On one occasion Mr. Nettleship, a surgeon of vast experience, after having extracted one cataract under general anesthesia, turned to his class and remarked: "Now, gentlemen, what a temptation the opportunity presents to extract the other. But, gentlemen, never do so, until your patient has fully recovered from the first operation."

Looking at it from every point of view, to my mind, the extraction of cataract is one of the most important of all surgical operations, the whole future of the patient depending on its successful outcome. Answering from the standpoint of the patient, would one of us willingly submit to the bilateral extraction? I would myself unhesitatingly cry out "No!"

The second part of my subject is quickly answered. "How soon after the operation on the first eye is it safe to extract the second cataract?"

There are competent surgeons who maintain that it is not wise to operate on the second eye at all, if good results follow the first operation. There are good reasons for this conclusion. The frequent disturbance of muscular equilibrium, the confusion due to unequal vision in the two eyes, constitute reasonable grounds for advising against the second operation, provided the first has been a success.

My rule, however, is to operate on the second eye if the patient desires it, but I do not urge the operation. Circumstances should always guide us in selecting the time for the second operation, but except for some special reason, I prefer to wait six or eight weeks, when the first eye has recovered from all reaction, and the general health of the patient has been thoroughly restored. There can be no rule; each case must be its own law, but I am convinced of the fact that in ignoring the patient's desire for haste, we are but adding to his chances of successful results.

DISCUSSION.

DR. J. M. RAY, Louisville, considers that the majority of ophthalmic surgeons will agree almost entirely with Dr. Calhoun. Fortunately, as a rule, cataract matures in one eye before it does in the other, and so one cataract can be extracted before the other requires operation. Early in his career Dr. Ray became prejudiced against the double operation, and while he has seen it done once or twice he has not attempted the procedure. He sees no reason, however, why, in six or eight days after a perfectly smooth operation, the second eye should not be operated on, if the anterior chamber has perfectly reformed and if there is no reaction. The only class of cases to be excepted are those in which it is necessary to give a general anesthetic. In persons under 50 it is wise to urge the removal of cataract in the second eye, but at another time, while in persons over 70 Dr. Ray is inclined against operation on the second eye, because they can get all the vision necessary with one eye. In cases between these ages he generally leaves it to the patient to determine.

DR. J. L. THOMPSON, Indianapolis, said that before he knew so much about it he had almost phenomenal success in operating on both eyes at the same time. He operated on eleven persons with excellent results. One old gentleman of 87 lived

to 106 years and 3 months old and read until he died. But Dr. Thompson would not do the double operation now under any circumstances. Two of his patients went quite insane for a while, but there was a good result finally. Afterward Dr. Thompson changed to operating on the second eye eight days after the first, and now that is not correct. The patient may appear well and then in twelve or fourteen days some inflammation show itself, so that he does not now operate on the second eye until three months after the first operation, and, where one eye has been lost, he always does a preliminary iridectomy and then waits six weeks before extracting the lens. He thinks very much is to be gained by this preliminary iridectomy.

DR. HOWARD F. HANSELL, Philadelphia, said that during last winter he reported to the Ophthalmic Section of the College of Physicians the results of seven cases of bilateral operation. Since then he has operated on five more patients. His experience leads him to believe that the operation is not only justifiable but advisable in selected cases. The risk to vision is no greater, indeed less than that incurred by two single operations. His practice is to fully explain the situation to the patient and allow him to decide, since the procedure is one of choice rather than of necessity.

DR. LEWIS H. TAYLOR, Wilkesbarre, Pa., stated that he believes that we are never justified in operating on the second eye at the same time as the first. He mentioned one case in which the patient had been operated on in a neighboring city by a good surgeon, who performed a successful operation, and in spite of that fact the eye was lost. Iridocyclitis set up and the eyeball had to be enucleated. When the time came for operating on the second eye, knowing this history, Dr. Taylor felt a little afraid and advised the patient to go to New York, which he did, and was operated on there by one who has had the largest cataract experience of any of us, the second eye being lost in the same way as the first. Now, had that patient been operated on the first time in both eyes nothing, in his opinion or in that of his friends, would have exonerated the surgeon. Dr. Taylor always advises the patient to go home and remain some time until everything has quieted down before having the second operation.

DR. PETER A. CALLAN, New York, thinks that Dr. Calhoun is a little too radical. Dr. Callan has never hesitated to perform a double cataract extraction, and so far has escaped disaster. There is no question but that Dr. Callan's stand, in the main, is correct, but if all his ideas are followed out no eye would ever be operated on; that is to say, there are so many difficulties that one would rarely operate at all. Dr. Callan never hesitates, if the patient desires it, to operate on both eyes if the conditions are such as to justify it. He does not think that any fast and fixed rule can be made. As to the patient being satisfied with removal of the cataract from one eye, he thinks that is a mistake.

DR. C. F. CLARK, Columbus, Ohio, declared that he does not think that a physician is ever justified in being influenced by what the patient desires. The physician must decide that on his own responsibility on medical grounds, and if the second operation is desirable it should be done, but the responsibility should not be shifted to the patient.

DR. E. E. HOLT, Portland, Me., stated that he used to operate on both eyes, but for the last four or five years he has absolutely refused to do so. He never had a bad result, and often looks back on his experience now and wonders that he did not. He remembers going to a neighboring state and operating on two patients in this way in one day. One was 92 years old, and the patient wrote Dr. Holt letters for four years after the operation. But, while he has never had a bad result, nothing could induce him to do the double operation now.

DR. A. W. CALHOUN stated that his early experience was very much like that of Dr. Thompson. In the beginning, he operated on both eyes, but later he made up his mind never to do it again. He saw in the hands of a friend a case in which both eyes went wrong, and since then he has not done the double operation. Dr. Calhoun said that it is possible for suppuration of the wound to take place, or a slow form of

iritis may spring up within two weeks or more after the operation. To operate on the fellow eye after a week or ten days and then have an iritis occur in the first eye would be very bad. Another thing is that these patients are very liable to have conjunctival troubles make their appearance from one to three weeks after the operation. For these reasons Dr. Calhoun has come to the conclusion that it is best to wait six or eight weeks, or even longer.

A NOTE ON THE OPERATION OF GASTROENTEROSTOMY.

B. G. A. MOYNIHAN, M.S., F.R.C.S.
LEEDS, ENGLAND.

I am prompted by the report of a discussion on various gastric operations, which was published in *THE JOURNAL of the American Medical Association*, Sept. 17, 1904, to send a brief description of the operation of gastroenterostomy as I now practice it. The papers and the contributions to the discussion in *THE JOURNAL* are of the highest merit; and the distinction and the wide experience of all those who joined in the debate make the opinions therein expressed worthy of serious thought. The fact that there was not a little difference of opinion as to the mere mechanics of the operation of gastroenterostomy is my excuse for this paper.

I propose briefly to describe the method of gastroenterostomy by suture which I now adopt. It is modified in some slight degree from that which I mentioned in a paper I had the honor to read in May, 1903, before the American Surgical Association.

We may assume that any method of intestinal anastomosis must possess certain attributes which are of primary importance. These are:

1. Simplicity. The simplest surgery, provided the desired purpose is accomplished, is the safest surgery.
2. Rapidity. The quicker an anastomosis is completed the better.
3. Absence of exposure of viscera. In all abdominal operations there should be no unnecessary exposure nor handling of any part; while the manipulation of the area of anastomosis is going on, all other parts should lie within the abdomen and out of sight.

4. Perfect security of apposition immediately on the completion of the anastomosis and for a length of time sufficient for sound healing of the united viscera.

I believe that the method of gastroenterostomy by simple continuous suture with the aid of clamps fulfills all these essentials with perfect success.

TECHNIC OF OPERATION.

The operation of gastroenterostomy is performed in the following manner: The abdomen is opened about three-quarters of an inch to the right of the middle line, and the fibers of the rectus are split. After the peritoneum is opened, the great omentum and transverse colon are lifted out of the abdomen and turned upward over the epigastrium. The under surface of the transverse mesocolon is exposed, and the vascular arch, formed mainly by the middle colic artery, is seen. A bloodless spot is chosen, a small incision made in the mesocolon, and the finger passed into the lesser sac. The opening of the lesser sac is not always quite easy, and this is more particularly the case where there are adhesions between the transverse mesocolon and the stomach. It will be found of advantage to seize a small portion of the mesocolon in a clip, at a point near the spot selected for the opening. On drawing the clip away from the stomach the mesocolon is put on the

stretch; a snip of the scissors by the side of the clip opens the lesser sac at once. The opening in the mesocolon is then gradually enlarged by stretching and tearing until the fingers can be passed through it. It is occasionally necessary to ligate a vessel. The left hand of the surgeon now makes the posterior surface of the stomach present at this opening, and with the right hand the stomach is grasped and pulled well through. A fold of the stomach, about three to four inches in length, is seized with a clamp (a modification of Doyen's clamp), whose blades are sheathed in rubber tubing. The clamp is applied in such a way that the portion of the stomach embraced by it extends from the greater curvature obliquely upward to the lesser curvature and toward the cardia. This is accomplished by applying the clamp obliquely, the tip of the blades pointing to the patient's right shoulder and the handle to the outer side of his left hip. It is important that the point on the greater curvature held by the clamp should be the lowest point. This is made certain before the stomach is turned over to reach its posterior surface, by observing that point which lies lowest in the abdomen. When the posterior surface is exposed, special care is taken that this lowest point is fixed in the end of the clamp.

The duodenojejunal angle is now sought, and readily found by sweeping the finger along the under surface of the root of the transverse mesocolon to the left of the spine. The jejunum is then brought to the surface, and a portion of it, about two to five inches from the angle, is fixed in a second pair of clamps. The two clamps now lie side by side on the abdominal wall, and the portions of stomach and jejunum to be anastomosed are well outside the abdomen, embraced by the clamps.

It is most important that precisely the right portion of the jejunum should be selected for the anastomosis. Almost all operators select a point far too low down. I decide on the point for the anastomosis by grasping the jejunum in my fingers and pulling it taut from the flexure. The jejunum while so held is laid against the posterior surface of the stomach and the fingers are moved along until they grasp the point which reaches exactly to the greater curvature of the stomach. The clamp is then applied so that this portion is the lowest piece (the piece that is most distal from the flexure) embraced by it. The result is that the jejunum from the duodenojejunal angle to the anastomosis forms a straight line, not a curve. The relation, therefore, is that which approximates most nearly to the normal. It is, I believe, the sagging of the jejunum, when a point eight to twelve inches or more from the flexure is used for the anastomosis, that is responsible for regurgitant vomiting.

The stomach, with the exception of the part embraced by the clamp, is returned to the abdomen through the upper part of the incision. The whole operation area is now covered with gauze wrung out of hot sterile salt solution, the clamps, with the stomach and jejunum which they embrace, alone being visible outside the abdomen. A continuous suture is then introduced uniting the serous and subserous coats of the stomach and jejunum. The stitch is commenced at the left end of the portions of gut enclosed in the clamp, and ends at the right. It begins on the stomach in that part which is nearest to the cardia and to the lesser curvature, and on the jejunum at that point which is nearest to the duodenojejunal flexure. The length of the sutured line should be at least two inches; its average length is two and one-half or three inches.

In front of this line an incision is now made into

the stomach and jejunum, the serous and muscular layers of each being carefully divided until the mucous membrane is reached. As the cut is made, the serous, muscular and submucous coats retract and the mucous layer points into the incision. The cut edges of these coats are loosened all round from the underlying mucosa. An ellipse of the mucous membrane is now excised from both stomach and jejunum, the portion removed being about one and three-quarters or two inches in length, and rather more than half an inch in breadth at the center. The gastric mucosa shows a marked tendency to retract; it is, therefore, seized with a pair of miniature (French) vulsella on each side. No vessels are ligated, as a rule. The cut surface of the bowel and stomach may occasionally ooze slightly; this can be checked at once by tightening the clamps one notch.

The inner suture is now introduced. It embraces all the coats of the stomach and jejunum, and the individual stitches are placed close together and drawn fairly tight, so as to constrict all vessels in the cut edges. This suture begins at the same point as the outer one, and is continued without interruption all round the incision to the starting point, where the ends are tied and cut short. It will be found that there is no need to interrupt the stitch at any point, for there is no tendency on the part of the sutured edges to pucker when the stitch is drawn tight. It is indeed a positive disadvantage to interrupt the suture anywhere, for by so doing the hemostasis is not so secure. The clamps are now removed from both the stomach and the jejunum, in order to see if any bleeding point is made manifest. Very rarely—about once in ten cases—a separate stitch at a bleeding point is necessary. The outer suture is now resumed and continued round to its starting point, being taken through the serous coat about one-sixth of an inch in front of the inner suture. This outer stitch is also continuous throughout; when completed, the ends are tied and cut short, as with the inner stitch. There are thus two suture lines surrounding the anastomotic opening—an inner hemostatic, which includes all the layers of the gut; and an outer approximating, which takes up only the serous and subserous coats.

For both stitches I use thin Pagenstecher (celluloid) thread. The needle used is of a special pattern, being rather more than half a circle and having a slot-eye for easy threading. In introducing the stitches it will be found a great advantage to draw lightly on the thread between the needle and the last stitch. A little ridge is thus raised up both in the stomach and in the intestine, and into these ridges the needle passes quite readily. There is, then, no need to dip down, as it were, to pick up the gut on the point of the needle.

The gut is lightly wiped over with a swab, wet in sterile salt solution, and the stomach and transverse colon and omentum which had been replaced within the abdomen are now withdrawn.

With the left hand holding these and the right holding the jejunum, the slit made in the mesocolon is seen to embrace the line of suture snugly. Two or three interrupted sutures are now introduced which unite the margins of the slit in the mesocolon to the jejunum close to the suture line. As a rule, I use three stitches, one on each side, and one at the lowest point of the anastomosis. The result of this is that the line of suture in the anastomosis is not seen from below. It is everywhere closely embraced by the edges of the rent in the mesocolon, and it is thereby considerably reinforced. Leakage from the suture line or yielding of it is vir-

tually impossible; it has never occurred in any of my operations. If it were possible, it would be rendered very much less likely by this little modification.

There are one or two fears entertained with regard to the operation of gastroenterostomy which may be dissipated. The first of these refers to regurgitant vomiting. Regurgitant vomiting is a thing of the past. In over 100 consecutive cases I have never seen any vomiting except that due to the anæsthetic, and very rarely that. There can be no question that patients after gastroenterostomy vomit less than patients after any other abdominal operation. This may be due to the very slight exposure and handling of parts or to the fact that a new and free road from the stomach is now open. In my early cases I noticed regurgitant vomiting of a severe type in three patients; on two of these I operated a second time, performing entero-anastomosis.

Regurgitant vomiting is prevented in the operation I describe by attention to three points:

(a) The anastomosis is made very high in the jejunum; there is no loop.

(b) The anastomosis is made at the lowest part of the stomach.

(c) The patient is propped up in bed as soon as he begins to come round from the anæsthetic.

The second of the fears is that which has reference to the subsequent narrowing of the new orifice. This fear is ill founded. When narrowing and closure of the new opening occur I believe that they are due to imperfection in the method which has been used. By the operation as now described, a large opening, not a slit, is made between the two viscera. The free removal of the mucosa (which I was the first to practice and for thought of which I am indebted to the Murphy button, which "stamps out" a piece of the stomach wall), lessens the likelihood of closure. This alone, however, could not prevent it. In addition to this removal of mucosa, it is necessary to make the opening of large size; of a size, too, that is not always the same, but is proportioned to the size of the stomach. When a greatly dilated stomach is operated on and a free outlet made from it, it is obvious that, under the new conditions, the stomach will speedily lessen in size. As it does so, the new orifice lessens also; moreover, some cicatricial contraction in the orifice occurs. The result will be that the anastomosis becomes less than it was when the surgeon left it. It is absolutely necessary, therefore, that when a very large stomach is operated on the size of the orifice should be large.

By the method I adopt, an opening of any size can be made, and on one occasion, when dealing with an amazingly dilated organ, I made the anastomosis four inches in length. Dr. W. J. Mayo has often expressed the opinion that contraction in the new anastomotic opening is due to a renewed patency of the pylorus. Anyone who has seen Dr. Mayo at work, who knows his vast experience, and who realizes the wonderful accuracy of his judgment, will not be eager to dissent from him unless strongly convinced of the accuracy of his own observations. In the opinion which I have just quoted I can not acquiesce. I have seen an anastomosis which I have made (on reopening the abdomen for another purpose) after two years, and though the pylorus was, and always had been patent, there was no appreciable shrinkage in the size of the opening. In two recent cases I have repeated this experience. Marked shrinkage in the size of the anastomotic opening is due, therefore, I believe, not to any condition of closure or

patency of the pylorus, but to errors in the making of the opening. The new orifice should always be large, and when occasion demands it, should be as much as four inches in length. For this reason a transverse incision in the jejunum, as made by Mikulicz, is undesirable. The opening when so made can not be longer than the diameter of the jejunum, and this size even in an ordinary case is not enough.

Such additions to operations as enteroanastomosis closure of the pylorus, etc., are entirely unnecessary. If the operation is properly performed there is no loop; the two branches which are to be joined in an entero-enterostomy do not, therefore, exist.

The average time needed for the performance of the operation, from beginning to end, is between twenty-five and thirty minutes. I have done the operation in seventeen minutes, in twenty-one minutes, and perhaps a score of times in less than twenty-five minutes. But these times are exceptional, and were due to the need of haste, owing to the poor condition of the patient. The usual operation lasts twenty-five to thirty minutes.

Finally, I venture to urge that those surgeons who are undertaking operations on the stomach in large numbers will give this method of mine a reasonable trial. It is the simplest of all methods, rarely offers any difficulty, and has been attended by most satisfactory results. I can not think that elastic ligatures and twines or any mechanical appliances possess equal safety or simplicity. I have performed gastroenterostomy in 162 cases of ulcer of the stomach and duodenum (excluding hour-glass stomach, for which a double operation is often necessary). In 20 cases the operation was done for acute hemorrhage (with excision of ulcer in 2) with two deaths. In 142 cases of chronic disease there were two deaths.

The two deaths in the acute hemorrhagic cases were due to great collapse at the time of operation and were the result of an unsuccessful attempt to save lives doomed, without doubt, unless operation could save them. The deaths in the chronic cases were due, the first to a hernia of all the small intestine through the opening in the mesocolon (this is prevented now by the stitching of the mesocolon to the jejunum); and the second to failure of the kidneys.

Clinical Report.

A LAYMAN'S TREATMENT OF A URETHRAL STRICTURE AND RETENTION OF URINE.

C. J. RINGNELL, M.D.

Surgeon to the Swedish Hospital.

MINNEAPOLIS.

Many curious incidents occur in the practice of medicine and surgery, but the one which I am about to relate is certainly unique.

Condition on Admission to Hospital.—One evening, some time ago, I was called to the hospital to attend an old man who had been brought in from the country suffering from some trouble for which prompt relief was necessary. On approaching the bed I noticed the odor of gangrene and decomposed urine; the patient had an anxious look about him; he was excited at intervals and at times delirious; tongue was coated and dry; there were sordes on the teeth, and the lips were parched. The respiration was labored; pulse small, wiry and rapid; temperature 100 F. The trouble was evidently of a grave nature.

History. From the young man who had brought the patient to the hospital I gleaned the following history of the case: The patient was a widower, aged 64, and lived a hermit life by one of the beautiful lakes not far from this city, cultivating a few acres of land and amusing himself with fishing and hunting whenever a change was desired. His health had always been good, with the exception of an old urethral stricture of which only his most intimate friends had any knowledge. (I mention this because no one but the young man who told me these facts had any idea of the condition the old gentleman was in just before being brought to the hospital.) The old fellow's neighbors were few and far between and so at times he would get lonesome and wander away to the city; there his old habit of indulging too freely in strong drink would return, and, as alcoholic drinks and old strictures are generally incompatible, trouble of an annoying nature invariably ensued. On such occasions a physician was generally consulted, and a catheter brought the desired relief. This operation had been repeated so often that the sufferer had acquired some knowledge of its execution, but at times the technic would be faulty. Rubber catheters, straws, and various other objects of a similar nature had been employed in the execution of this delicate operation. Before leaving the city after the last visit, a good-sized flask of whiskey had been procured. Feeling tired and weary on his arrival home, after the troublesome journey and "good time," the color of the flask soon began to change. Beer and various mixed drinks are fairly efficient diuretics, and as overstimulation at times produces a certain amount of anesthesia, the bladder soon became overdistended and the muscles, instead of relaxing, contracted. The old stricture also refused to relax, and right here the trouble, which proved so stubborn and refused to yield, although the most extraordinary treatment was resorted to, commenced, for which my services were sought. The catheter could not be found, so various sizes of straws were collected and manipulated in the usual manner; but the old stricture was firm and refused to let Nature's instruments pass. It was now far into the night, and no physician could be reached. The kidneys continued their work, and the bladder was filling up rapidly. Relief must come soon!

The Patient's Treatment.—There was no one to consult with, and a new line of treatment, which finally proved disastrous, was instituted. Some years ago, while drilling and blasting ledges of rock in a stone-quarry, the power of gunpowder had been observed. Why should it not work here. The ammunition box was secured and a few cartridges emptied of their contents. The urethra, from that incompressible stricture to the meatus, was carefully filled with powder; a lighted match was applied, and an explosion occurred, shattering the urethra and surrounding structures completely. But relief from the original trouble was only partial. The mutilation produced by the explosion brought on hemorrhage, extravasation of urine, septic inflammation and, finally, gangrene.

Hospital Treatment and Results.—Three days after this heroic treatment he was found and sent to the hospital. The gangrene had already invaded the scrotum and abdominal parietes, and treatment would, in all probability, be of no avail. Under other anesthesia, the gangrenous parts were removed, the bladder drained through the perineum and antiseptic dressings applied. The patient rallied after the operation, but the septic intoxication was too pronounced, and death ensued the following day.

Country Practice.—In 1871 Germany was a nation of 39,000,000 inhabitants, of whom 60 per cent. were engaged in the agricultural pursuits. In 1900 it had increased to an empire of 58,000,000 inhabitants, of whom 35 per cent. were engaged in agriculture and 65 per cent.—nearly two-thirds—in industry and trade. The above statistics suggest the inquiry whether a similar change has taken place in the United States. If so, this has considerable bearing on the proportion of country practitioners then and now.

GOVERNMENT CONTROL OF VACCINE VIRUS.

It is seldom that the good effects of legislation are so quickly seen as in the results following the act of Congress, approved July 1, 1902, regulating interstate traffic in vaccine virus, antitoxin and analogous products.

In accordance with the provisions of this act and the regulations framed thereunder, the Surgeon General of the Public Health and Marine-Hospital Service is required to cause an inspection of the establishments manufacturing vaccine virus for interstate sale, and the director of the hygienic laboratory, of that service, is required to buy vaccine virus on the open market from time to time, and examine it to determine the presence of impurities or lack of potency. The laboratory examinations are made in accordance with the usual bacteriologic methods, and primary vaccinations in children are made to determine the potency of the virus and to study the character of the "takes."

We learn that it has been over a year since any great number of bacteria have been discovered in a vaccine point or capillary tube, and the bacteria that are present are of the harmless variety. The frequent inspections which, by the law, are required every year of the vaccine establishments by officers of the national health service and the almost constant laboratory examinations of the vaccine virus sold by druggists, have enabled the Federal Government to obtain a firm grasp on the vaccine situation of the country. The notable improvement in the quality of the vaccine virus is not only manifest in the lessened impurities, as shown by laboratory tests, but fewer infected "takes" are reported.

These results are especially gratifying, and recall Rosenau's¹ work in 1902-03, before the passage of the act above mentioned, at which time the many sore arms were readily accounted for by the serious contaminations found in vaccine virus produced by irresponsible manufacturers. Rosenau showed at that time that "green" virus was sold on the open market, and that manufacturers did not give sufficient attention necessary to the production of a clean product. Within a few months following the enactment of the law, four firms went out

of business, not having been able to comply with the modern requirements.

There is still one phase of the vaccine problem peculiar to the United States that needs the attention of the government. Greater care must be exercised by manufacturers in shipping their product from place to place. We know that milk, fruit, meat and all perishable products are shipped in refrigerator cars or under special conditions, and it is not too much to ask that similar precautions be taken in the transportation of vaccine virus—equally perishable and equally important. Much of the vaccine virus found on the market is impotent, because it has been sterilized in the baggage or mail car by too close proximity to the steam coils. Vaccine virus is particularly susceptible to a temperature above the body heat, and must be kept in a cool, dark place in order to retain efficiency. We understand that the Surgeon General of the Public Health and Marine-Hospital Service is giving attention to this phase of the question.

DUPLICATE TWINS AND DOUBLE MONSTERS.

From the lay point of view, the humorous complications which might and do occur in connection with duplicate individuals, seem to have found most favor, and since the time of Shakespeare and his "Comedy of Errors," we not infrequently find the twin both in literature and the drama. Even in medical works the similarities of twins rather than their dissimilarities have been noted and commented on.

Recently, H. H. Wilder¹ has completed an elaborate study of twins, in which he not only discusses their method of origin, but also considers their similarities and dissimilarities from a new point of view, namely, the resemblances and differences of configuration in the skin patterns of the palms and soles. As Wilder shows, there are two types of twins—those in which the pair are invariably of the same sex, and are characterized, especially as children, by their marked resemblance to one another, and those in which the pair may or may not be of the same sex, and are not more alike than children born of the same parents at separate births. The first class of twins Wilder calls duplicate twins, and the second class fraternal twins. From his investigations into multiple births, in which more than two children are born at a time, Wilder concludes that the same rule in a modified form holds good here. In the case of triplets, for example, two of them may be duplicate twins, and the third different, i. e., fraternal, or all three may be fraternal.

Wilder's studies of the finger and foot prints in duplicate and fraternal twins bring out many points of interest. He finds that in duplicate twins, with some minor exceptions, the finger and foot prints are the same in the two individuals down to, but not in-

cluding, the minutiae. He thinks that this difference in the minutiae is due to the fact that influences acting after birth may modify them, while the main patterns already exist at birth. In fraternal twins the foot and finger prints are no more alike than is usually the case with different members of the same family. Curiously enough, in the duplicate twins the index-finger pattern in one of the twins may be exactly reversed in position to that of the other twin; that is to say, the pattern in one twin may face toward the radial side, and in the other toward the ulnar side of the hand.

Wilder's explanation of the two forms of twins leads us into the field of experimental embryology. He thinks that in the case of the fraternal twins we are dealing with two distinct ova which became fertilized at the same time, and this view is borne out by the fact that twins of this sort usually have separate placentae. In the case of duplicate twins, we are dealing with a single egg fertilized by a single spermatozoon, which, after fertilization, begins to divide in the usual manner. After the first cleavage of the egg, the two resulting blastomeres become separated, and each develops into a separate child. That this actually does occur in some of the lower forms of animal life has been abundantly demonstrated by experimental methods, and that it is probably what occurs in duplicate twins is shown by the fact that such twins have each a separate chorion and placenta. In the case of duplicate monsters, which are very closely allied to duplicate twins, we have a partial instead of a complete separation of the two original blastomeres. The fused portions of the two blastomeres give rise to a single individual, while each separated portion gives rise to a separate individual. We can easily see, following this explanation, how in some instances double monsters are fused at the head, in other instances at the feet, and in other instances at the midportions of the body, this depending on the portions of the original blastomeres which were separated. Besides bringing out these many interesting facts, the study shows how few cases of twins there are which are adequately studied, and suggests a fruitful field for the general practitioner, who alone is often able to follow twins over the long period of years which must elapse to make such studies of value.

THE MODE OF ACTION OF ANTISTREPTOCOCCUS SERUM.

In 1895 Denys and Leclef immunized rabbits by injecting them with small but gradually increased doses of a virulent streptococcus, and succeeded in getting animals that were resistant to about one thousand times the minimum fatal dose for their organism. At about the same time, Marmorek, Roger and also Denys and Leclef immunized horses and mules against these organisms, and each of them obtained an antiserum that had some protective properties against the particular strain of streptococcus used in preparing the serum.

Since that time many other experimenters have prepared antistreptococcus sera which protected laboratory animals against many times the minimum fatal dose of the streptococcus used in preparing the serum, but it is still an open question whether or not any of these sera protects against a streptococcus coming from a different source and rendered virulent for an animal of a different species. Some investigators, as Van de Velde, Tavel and others, believe that antistreptococcus serum for clinical purposes must be prepared, not by injecting the animal with one strain of streptococcus, but with a mixture of cultures of many different strains of this organism. They hold also that the streptococci must not be passed through animals before they are used in immunization, but must be used as they come from the human body. This entire question is, however, still in a very unsettled state and needs to be investigated further.

The exact mode of action of antistreptococcus serum has also been made the subject of careful studies by Denys and Leclef, Bordet, Neufeld and Rimpau, Besredka and others. We know that antidiphtheria serum and antitetanus serum contain a true antitoxin for the soluble toxins of these organisms, and the neutralization of the toxin by the antitoxin may be likened to the neutralization of an acid by a base. Careful investigations have shown that there is another class of antisera which do not contain antitoxin, but are destructive of the bacteria. These are the so-called bacteriolytic sera, of which antidysentery serum is a good example. It has been shown conclusively that antistreptococcus serum is not a bacteriolytic serum, because streptococci multiply rapidly in it, and it is not likely that this serum is of the nature of a true antitoxin, because nobody has as yet succeeded in preparing a strong soluble toxin of streptococci. Some samples of antistreptococcus serum do, however, possess protective properties against these organisms, and they seem, therefore, to represent a third class of antisera. Bordet was able to show that there is more active phagocytosis of streptococci in the peritoneal cavity of a rabbit that had been injected with a dose of antistreptococcus serum than in the peritoneal cavity of a normal rabbit.

In the normal rabbit hardly any of the virulent cocci were taken up by the phagocytes, and the rabbit soon died of streptococcus infection, while in the treated rabbit all of the cocci were taken up, and if the dose was not excessively large the animal recovered. In test-tube experiments the addition of antiserum to a mixture of leucocytes and virulent cocci aids phagocytosis, but there is no lysis of cocci by a mixture of immune serum and normal serum. The filtered broth cultures of a virulent streptococcus do not prevent phagocytosis of the non-virulent streptococci. Bordet concluded from his experiments that the antistreptococcus serum stimulates the phagocytes so that they will take

up the virulent cocci. This conclusion was also reached by Besredka in a very recent paper on antistreptococcus serum. These experimenters do not believe that antistreptococcus serum is of the nature of an antitoxin, but that it is a stimulant to the phagocytes.

Whether or not this view is correct can hardly be stated positively at present, but the experiments of Denys and Leclef,¹ and very recently those of Neufeld and Rimpau,² make it seem very probable that another explanation is the correct one. It has been shown by these investigators that leucocytes from an immune rabbit, and also those from a normal rabbit, suspended in immune serum, take up and destroy many virulent streptococci, while neither the leucocytes from an immune rabbit nor those from a normal rabbit in normal serum will take up the virulent cocci, unless immune serum is added. If now the leucocytes are treated for twenty minutes to half an hour with immune serum, centrifugated out and washed in salt solution and then suspended in normal serum, it is found that they do not take up virulent cocci which are added to the suspension. If, however, the virulent cocci are treated with immune serum, then washed in salt solution and added to a suspension of leucocytes in normal serum, they are readily taken up by the leucocytes. These experiments show that the streptococcus immune serum does not bring about a change in the leucocytes, by virtue of which they are enabled to take up virulent streptococci, but that it has a direct effect on the cocci, changing them in some way so that the leucocytes will ingest them. It is not probable, therefore, that there is a stimulation of phagocytes, but the immune serum seems to neutralize something (toxin?) in the bacterial cells which protected them against ingestion by the leucocytes. Heating the antistreptococcus serum to 59 C. for one-half hour does not deprive it of its power to change the virulent cocci so that they will be taken up by the leucocytes, and hence Neufeld and Rimpau conclude that the serum owes this property to the presence of an amboceptor, or a substance having the nature of an amboceptor. This conclusion can, however, not be accepted without further proof.

In general, this view seems to be the correct explanation of the mode of action of antistreptococcus serum, and it becomes even more plausible when we recall the experiments of Wright and Douglas³ on the rôle of the body fluids in phagocytosis of less virulent bacteria. They have shown that washed human leucocytes do not ingest any bacteria unless the latter have been treated for some time with normal serum, or are added to leucocytes suspended in serum. We see, therefore, that phagocytosis of non-virulent bacteria by human leucocytes and phagocytosis of virulent streptococci by rabbit leucocytes, aided by immune serum, are two closely analogous phenomena.

ENURESIS IN CHILDHOOD.

Involuntary discharge of the contents of the urinary bladder is physiologic in infants, ceasing at varying times in different individuals. Control of the sphincter of the bladder by day is acquired earlier than such control by night. Intercurrent disease may delay the manifestation of continence. When the lack of control persists beyond the third year it may be considered abnormal, and it is then designated enuresis. In the absence of disease of the nervous system the disorder has been thought, on the one hand, to be merely a functional disturbance, or, on the other hand, to be a symptom or a sequel of underlying or antecedent disease. The distinction between functional and organic disease is, however, only one of degree, and while tangible evidence demonstrative of a pathologic basis is not obtainable in every instance of enuresis, it must be inferred that some morbid process or abnormal condition is present, often, perhaps, undiscoverable by present means of investigation. Testimony to this effect is given by Dr. J. C. Rey,⁴ in a recent communication, in which he details the results of a careful study of the state of the bladder and of the urine in 52 cases of enuresis in children during a period of five years. It was found that in the overwhelming majority of cases in which disease of the central nervous system, idiocy, infantilism and athyresis were not etiologic factors, the cause of the disorder could be traced to disease of the bladder or adjacent organs.

In order that enuresis, which may be considered physiologic in the first ten months of life, shall persist beyond this time and even after the third year, there is necessary, in the presence of an otherwise normal nervous system, and in addition to the direct or indirect irritation of the bladder, a certain degree of enfeeblement or deficiency of the will. This latter, likewise physiologic in infancy, may persist in consequence of habituation to the enuresis from vesical disturbance due to disease of the bladder or to some peculiarity of the urine. Such impairment of the will may persist longer than the affection of the bladder. The sudden improvement that follows application of the faradic current, epidural injections and the like, under such circumstances is readily explained on neurotic grounds; but, when the vesical irritation persists, all educational and antihysterical measures will prove futile. The cases in which enuresis appears to be the only symptom of hysteria in children are likewise readily explained in a similar manner, unless the disorder can be attributed to the existence of a cystitis or urethritis or their consequences, namely, residual hyperesthesia of the bladder and the neck of the bladder.

In order to clear up the etiology of enuresis, it is necessary, in all cases that continue under observation for some time, to make frequent chemical and bacteriologic examinations of the urine, and to take note, more

than has been the practice in the past, of the frequent occurrence of catarrh of the bladder in infants, and, when possible, especially in girls and older boys, also to make endoscopic examination of the bladder.

NON-FATAL RUPTURE OF AORTIC ANEURISM.

Although rupture of an aneurism of the aorta is generally fatal, the resulting hemorrhage has, in rare instances, ceased, and the mortal issue has for the time been deferred. In one instance on record, life was prolonged for as long as five years and in another for two years. Under such circumstances the cessation of the bleeding must be attributed to a plugging of the opening by a portion of the clot contained in the aneurismal sac. A case of the character under consideration is reported by Dr. Charles H. Melland.¹ A laborer, 56 years old, was admitted to the hospital with a history of having coughed up a large amount of blood. He was apparently moribund, but as the bleeding had ceased, two pints of normal saline solution were introduced into the median basilic vein. The patient rallied rapidly, and great improvement took place in his general condition. This persisted for three weeks, when death resulted from another hemorrhage. Necropsy disclosed a sacculated aneurism as large as a hen's egg, arising from the convexity of the arch of the aorta immediately beyond the left carotid artery. The sac was almost filled with firm, laminated clot, and posteriorly it extended between the trachea and the esophagus. The trachea wall had been thinned and the blood had escaped through a small slit.

THE TREATMENT OF HEMOPHILIA.

Nothing is known of the essential nature of hemophilia, and the disorder has proved most rebellious to treatment. The affection is believed to be due to disease of the blood or of the vessels, or of both. It occurs almost exclusively in males, although it may be, and usually is, transmitted through females. In view of this fact Dr. Lachlan Grant² argues that the blood or the tissues of the female must be the seat of some restraining influence which, he suggests, may emanate from the reproductive center, perhaps an internal secretion; for example, that of the ovaries. In accordance with this reasoning, he proposes the internal administration of extract of ovaries, mammary gland or other tissue peculiar to the female as a therapeutic procedure for the control of the bleeding in cases of hemophilia, and he relates a case in which he was able to put the suggestion to practical test. A boy, eight years old, with a hemophilic heredity, bled freely and obstinately from a wound on the sole of the foot inflicted by a piece of glass, despite active treatment, including pressure and local applications of adrenalin hydrochlorid. Finally, after the patient had become anemic and the prognosis grave, extract of ovarian gland was given in doses of two and a half grains thrice daily, with the result that the bleeding soon ceased, while improvement in both the general and the local

condition also ensued. Of course, it is not to be concluded from the foregoing report either that the reasoning put forth is correct, or that the result attained was really due to the treatment instituted. Nevertheless, the experience gained in this case is at least sufficient justification for the further use of ovarian extract in cases presenting the hemorrhagic diathesis.

PHYSICIANS AND RECIPROCITY.

The physician, because of the nature of the work required of him, may usually be expected to have his wits about him. We have read of the physician who, receiving a large plumber's bill and being scandalized by some of the time-consuming methods of that tradesman, paid the bill and bided his time. Being the family physician of the plumber, he was called one day and went without medicine case or instruments. On finding what was the matter, he went home for his case, and included in his bill a liberal charge for this procedure. The plumber remonstrated, but when it was explained to him that the physician did not know what tools he wanted until he saw the patient, the plumber grasped the situation and paid the bill. From across the water comes the news of another bright physician, one able to appreciate the possibilities of reciprocity when the circumstances made it necessary. A physician received a box of cigars by mail with a bill therefor and with a letter, stating that, although the physician had not ordered the cigars, yet the maker took the liberty of sending them, convinced that he would find them excellent. The cigars were good and the physician smoked them. When the box was empty he sent the maker several prescriptions, accompanied by a bill for the same, which amounted to the same as the bill for the cigars, and accompanied by a letter stating that, although the cigarmaker had not asked for medical advice from him, yet he took the liberty of sending him some prescriptions, convinced that he would find them excellent.

ELECTRIC POSSIBILITIES.

The future uses of electricity, as described by Nikola Tesla, are interesting to contemplate from the standpoint of fiction, whether one is prepared to accept the statements as plausible or not. In a recent article in the *Electrical World and Engineer*, Tesla announces that "many thousands of simultaneous telegraph and telephonic messages, through one single conducting channel, natural or artificial, and without serious mutual interference, are certainly practicable, while millions are possible." We should certainly welcome this wholesale elimination of telegraph and telephone wires which form such networks in our great cities and which are often a menace to life. This elimination would certainly be a step in advance from the standpoint of municipal art. Tesla further announces the possibility of collecting electric energy all over the globe in small amounts, and by it running clocks and all the common machinery. Thus the physician will only have to tap the atmosphere, so to speak, by having the proper sort of a gatherer of electricity, to which he may attach his

1. *Lancet*, Nov. 19, 1904, p. 1414.

2. *Lancet*, Nov. 5, 1904, p. 1279.

centrifuge, his bone drill, etc. But this is not enough. Tesla declares that "this planet, with all its appalling immensity, is to electric currents virtually no more than a small metal ball," and when "the first plant is inaugurated it will be shown that a telegraphic message, almost as secret and non-interferable as a thought, can be transmitted to any terrestrial distance." Finally, "the sound of the human voice, with all its intonations and inflections, can be faithfully and instantly produced at any other point of the globe, or the energy of waterfall made available for supplying light, heat or motive power, anywhere—on sea or land." "I am hopeful," says he, "that these great realizations are not far off, and I know that when this work is completed they will follow with mathematical certitude." For a vision from a visionary mind, this is almost incomparable.

THE INFLUENCE OF DISEASE OF ONE KIDNEY ON THE MOLECULAR CONCENTRATION OF THE BLOOD.

Some doubt yet exists as to the value of cryoscopy from the diagnostic and prognostic points of view, and as to the validity of conclusions to be drawn from studies of the molecular concentration of the blood, as determined from the freezing point of the urine, and it is to be feared that the hopes aroused by the earlier investigations on this subject will not be realized. The freezing point may be reduced, among other causes, by disorders that cause interference with the circulation, such as uncompensated cardiac lesions and disease of the blood-vessels and the liver; also as a result of the presence of large tumors, especially in the abdomen, interfering with the circulation and giving rise to symptoms of stasis and exerting pressure on the ureters. It has been thought that if in the presence of disease of the uropoietic system the molecular concentration of the blood is increased there must be disease of both kidneys, while if the freezing point of the blood remains normal the urinary passages or at most only one kidney is affected. Evidence is, however, not wanting that disease of both kidneys may be present without increase in the molecular concentration, while disease of one kidney may be attended with such increase. A demonstrative case belonging to the latter category has recently been placed on record by Drs. A. Loeb and C. Adrian.¹ A man, fifty years old, presented symptoms of malignant neoplasm of the left kidney, with increase in the molecular concentration of the urine from both kidneys and reduction in the freezing point of the blood. On account of this fact, in conjunction with the debilitated state of the patient, operation was decided to be inadvisable and death took place in the course of six months. On postmortem examination the left kidney was found to be the seat of carcinoma, while the right was quite healthy. In explanation of the cryoscopic findings in the foregoing case it is suggested that the rapid growth of the neoplasm in the left kidney caused the entire burden of the secretion of urine to fall within a relatively short time on the right kidney, whose functions were interfered with by the existence of the carcinomatous cachexia.

NURSING AND PATRIOTISM.

In the early part of 1904 the War Department sent out—through the various training schools for nurses and through other available means—circulars requesting the registration of such trained nurses as were willing to hold themselves in readiness for government service in case of war. Of these circulars, according to the leading organ of the nursing profession, only six were returned to the War Department up to a recent date; that is to say, only six trained nurses in this country were willing, or took the trouble to announce themselves as willing, to serve their country in case of its need. The requirements of the registration were not onerous. All that was asked was a statement that the nurse would hold herself in readiness and would make periodical reports as to residence and condition of health. In case the services were needed there was the assurance of continuous and fair pay and support, with duties confined to base hospitals, and ample opportunity for interesting and profitable experience. As female nurses are not wanted at the front, the element of danger is practically eliminated from this kind of military service, except, of course, the danger of contagious or epidemic disease, and from possible change of climate. As the *American Journal of Nursing* says, there is no doubt that in case of war the government would be overwhelmed with applications of volunteer nurses, good, bad and indifferent. The enthusiasm of the moment would be sufficient to insure this. It would be a very different thing, however, if there were a selected list of well-accredited, competent persons to call on in emergency. The saving of expense, disappointment, and even of possible scandal, would be almost incalculable. It is to avoid the possibility of embarrassment by applications from discreditable persons that this waiting list was proposed, and it is, moreover, in the interest of the nurses themselves that they should not be misrepresented by such persons in the case of the country's need. It is a pity that the trained nurses of the country have not made a better showing of their patriotism and philanthropy than seems to have been the case.

THE PURE-FOOD BILL.

The pure-food bill now before Congress is one of paramount interest from a medical view-point, as evidenced by the fact that nearly 3,000 individual physicians and hundreds of medical societies have written to Senator Heyburn and to their various senators asking for the enactment of this piece of legislation. We trust that they may be rewarded for doing their duty by seeing the bill become a law. So far, there has been no direct opposition to the bill, as its virtues are fully recognized. Several members of the Senate, however, have claimed that certain terms and clauses are vague and indefinite, and are calculated to give the courts trouble in placing the responsibility where adulterated or misbranded goods are sold. In the interests of the drug trade and of the proprietary medicine concerns, it is desired to restrict the term "drug" to substances and preparations described in the United States Pharmacopeia, but as Senator McCumber¹ of North Dakota

1. Berliner klin. Wochenschrift, Sept. 26, 1904, p. 1021.

1. Congressional Record, Dec. 13, 1904, pp. 198, 199.

says: "The bill does not prevent a man from buying what he desires to eat, or what he desires for a drug; it simply declares that he shall be protected in buying what he does want, either for food or in the drug line." No honest dealer or manufacturer should object to a bill of that kind; nor should he object to putting a label on his products, stating plainly their composition. Senator McCumber¹ argues: "The government passes stringent laws with reference to counterfeiting. Those laws provide that if I pass a counterfeit coin the penalty may be ten years' imprisonment. If the government, therefore, compels me to use coins of absolute value and integrity, then, I submit, it is incumbent on the government to protect me in securing goods of absolute integrity, so far as in its power. . . . It seems to me that if it is an injury to the country to flood it with spurious coin, used in the purchase of good goods, it is equally an injury to the country to flood it with spurious goods to be traded for good coin." Because of the alleged lack of clearness in some respects, it is said that the bill is not likely to become a law at present. This is much to be regretted. The adulteration of foods and drugs in this country has become an evil of great magnitude, and one with which the individual states seem to be unable fully to cope without the aid of a Federal law. If the objections to the bill on the ground of indefinite phraseology are founded on fact, no time should be lost in rewriting those portions. If, on the other hand, these objections are instigated by some person or persons desiring to delay the passage of the bill, they should be overruled and the ulterior motives given publicity.

Medical News.

CALIFORNIA.

Warrants Issued.—The executive committee of the San Francisco County Medical Society has obtained warrants for the arrest of ten individuals who, it is alleged, are practicing medicine without having first obtained licenses, as required by law.

"Quaker Doctors" Assistant Sentenced.—Fred S. Walton, an attaché of the "Quaker doctors" who have been operating in California, was found guilty December 10, at Fresno, of obtaining money under false pretenses, and was sentenced to imprisonment for 150 days.

Personal.—Dr. James R. Curnow, San José, has broken down from excessive study and has gone to a sanitarium for needed rest and change.—Dr. J. Walter Key, San Francisco, was seriously injured by the explosion of a shotgun, November 26.—Dr. Herman E. Mueller, Oakland, has returned from abroad.

State Board Asks Power.—The secretary of the State Board of Health has prepared a series of bills to be introduced at the coming session of the legislature. The object of these measures is to give the board increase of power, which is greatly needed, to provide for thorough registration of births and deaths, and of data with relation to disease, also to create a system of local sanitary inspection. The board has not power essential to make it a useful arm of state government. It will ask the legislature to reform the laws that the board may better guard public health, enforce proper sanitary regulations and enlist the aid and sympathy of the people, and gather reliable mortality, health and other statistics.

ILLINOIS.

Cost of General Vaccination.—Dr. Martin W. Cushing, health commissioner of Joliet, estimates the cost of general vaccination in that city at \$4,000. The population of Joliet is more than 31,000.

Personal.—Dr. William J. Chenoweth, Decatur, recently celebrated his eighty-first birthday anniversary.—Dr. Louis J. Smith, Chester, has been succeeded as penitentiary physician by Dr. Milo H. Trovillion, Metropolis.—Dr. Edward Hasson, Peoria, has been elected physician of Peoria County.

Hospitals.—The State Board of Charities has recommended that appropriations of \$426,500 be made for the Illinois Western Hospital for the Insane, Watertown. Of this amount \$315,000 is for current expenses and \$60,000 for female infirmary and dormitory buildings.—Belleville has decided to purchase the Harrison homestead, two miles south of the city, for use as a permanent isolation hospital.

Chicago.

Resignation.—Dr. Robert H. Babeock has resigned from the faculty of the College of Physicians and Surgeons.

Rush Medical College Commencement.—At the quarterly commencement of Rush Medical College, December 19, Prof. Paul Shorey of the University of Chicago delivered an address on "Some Lessons from Greek Medicine," and 17 graduates received diplomas.

The Week's Deaths.—During the week ended December 17, 509 deaths were reported, three less than in the preceding week and 41 less than in the corresponding week of 1903. The respective annual death rates per 1,000 were 13.77, 13.84 and 16.28. Pneumonia heads the list of death causes with 95; then come consumption with 57 deaths, Bright's disease, with 45; heart diseases, with 42; nervous diseases, with 27; cancer, with 24; bronchitis, with 22, and violence, with 20.

Children's Hospital Staff.—Dr. Nicholas Senn has been appointed consulting surgeon of the Children's Memorial Hospital, Dr. Frank Billings, attending physician, and the following physicians have been appointed on the attending staff: Drs. Fernand Henrotin, William W. Quinlan, Samuel J. Walker, Malcolm L. Harris, Walter S. Christopher, Hugh T. Patrick, George F. Fiske, Alfred M. Ifall, William J. Class, Henry G. Anthony, Willis D. Storer, Julius W. Oswald, Norman Kerr, James P. Houston and George L. Chapman. The hospital realized about \$1,500 from the benefit "Travelogue," December 19.

Smallpox.—The chief medical inspector reports 16 new cases of smallpox sent to the Isolation Hospital during the week; 15 patients never had been vaccinated; one had an old, imperfect scar; 4 were unvaccinated children under the school age. One was an unvaccinated school child in school on a false certificate of vaccination, and four came from the downtown lodging-houses. Since January 1 there have been 323 cases of the disease, of which number 22 died, 251 recovered and 50 remain in the hospital under treatment. The health commissioner has asked the city council for an emergency appropriation of \$5,000 to fight the disease.

KANSAS.

Sanitarium Rebuilt.—Bonner Springs Sanitarium, which was burned in July, 1903, and is being rebuilt, will be operated as the Bonner Springs Lodge and Sanitarium Company and will be under the management of the former superintendent, Dr. Milard P. Sexton, Kansas City.

New Health Board.—The mayor of Kansas City has appointed the following board of health: Drs. Earnest J. Lutz, James W. May, Jr., Preston Sterrett, William J. Gates and C. J. Sihler. At the first meeting of the board, December 2, Dr. Lutz was elected president; Dr. Gates, vice-president, and Dr. May, secretary.

Warning.—We have received complaints that an individual calling himself Frank B. Kenneth or F. C. Burnett is calling on physicians in Kansas, offering to take subscriptions for THE JOURNAL at a discount. This man is not authorized to represent THE JOURNAL. We would again give warning not to pay money to any one on account of THE JOURNAL of the American Medical Association, unless the collector can show proper credentials.

Kansas Health Report.—During November 224 cases of diphtheria, with 42 deaths, were reported to the State Board of Health; 195 cases of scarlet fever, with 7 deaths; 318 cases of smallpox, with no deaths, and 130 cases of typhoid fever, with 15 deaths. The secretary reports that out of a total of 102 counties having county health officers only 60 have reported. From the number of cases of diphtheria and smallpox reported from these counties, should the same ratio obtain in the counties not reporting, it would show the prevalence of these two diseases to rather an alarming extent. As the season progresses, the infection of diphtheria, scarlet fever and smallpox

seems to increase in malignancy, and it is of the utmost importance that a strict quarantine be maintained in all these cases. General vaccination should be insisted on, and fresh supplies of antipneumococcal serum should be within convenient reach of every physician in the various counties.

KENTUCKY.

Lose Books and Instruments.—Fire in the offices of Drs. John P. Ferguson and John G. Clem, Louisville, December 1, destroyed instruments and books, causing a loss of \$400.

Lexington Physician Goes to Washington.—Dr. Daniel J. Healey, Lexington, has recently passed with credit the civil service examination for the position of anatomist to the Army Medical Museum and, as soon as he has received formal notice of his appointment, will move to Washington. Dr. Healey was married several years ago to Dr. Louise Bergmann, Louisville, then assistant physician to the Eastern Kentucky Lunatic Asylum, who will assist her husband in his work.

McMurtry Infirmary Nurses Graduate.—The annual commencement exercises of the Jennie Casseday Training School for Nurses connected with the private infirmary of Dr. Lewis S. McMurtry, were held December 8. After an announcement by Dr. McMurtry the address of the evening was delivered by Dr. Joseph M. Mathews with appropriate words of congratulation and advice. The address to the graduates was made by the Rev. T. M. Hawes and the pins were delivered by Dr. J. Garland Sherrill.

Smallpox.—Trigg County still has 30 or 35 cases, but the authorities have all infected houses quarantined and under guard. —In Christian County, on December 8, there were 168 cases under treatment in five localities. —In Hopkinsville during the two weeks ended December 6, 5,346 vaccinations were made. —"Dr." G. W. Waddle, Elizabethtown, was fined, December 12, for assisting a smallpox patient to escape from the health authorities. —Dr. Lee P. Trabue, health officer of Todd County, was fined \$50 on December 15 for having some smallpox patients hauled through the streets to the isolation hospital.

MARYLAND.

Bids for Hospital.—Of six bids received by the Navy Department for the new naval hospital at Annapolis the lowest bid was \$180,925.

Diphtheria Endemic.—An endemic of diphtheria is prevailing at Braddock Heights, Frederick County, and the public school there has been closed.

State Tuberculosis Society.—At a largely attended meeting for the organization of the Maryland Tuberculosis Society, held under the auspices of the Maryland Tuberculosis Commission, December 13, Dr. Henry Barton Jacobs was elected president.

Personal.—Dr. Joam S. Mathias has been appointed physician to the Carroll County jail. —Dr. Josiah S. Bowen, Mt. Washington, has been recently elected president of the medical and pharmaceutical fraternity, "Kappi Psi." —Dr. Joseph Clement Clark, Sykesville, has been elected president of the section on neurology and psychiatry of the Medical and Surgical Faculty of Maryland.

Medical Society Election.—The annual meeting of the Carroll County Medical Society was held at Springfield Hospital for the Insane, Sykesville, December 16. The following officers were elected: President, Dr. James H. Billingslea, Westminster; vice-president, Dr. George H. Brown, New Windsor; secretary-treasurer, Dr. Charles R. Foutz, Westminster; delegate to Medical and Surgical Faculty of Maryland, Dr. James H. Billingslea, Westminster; alternate, Dr. Milton D. Norris, Eldersburg, and censors, Drs. Joseph T. Hering, Westminster; Clotworthy Birnie, Taneytown, and Joseph C. Clark, Sykesville.

Baltimore.

Pneumonia Again Leads.—Pneumonia has again taken the lead in the weekly report of deaths, 25 having died from it last week.

Personal.—Dr. L. McLane Tiffany has returned from his country home. —Dr. Thomas S. Cullen has gone on a trip to the Gulf of Mexico. —Dr. Isidore Mueller, an aurist of Vienna, Austria, visited Baltimore last week. —Dr. Ernest C. Lehnert contracted blood poisoning while operating at the Northeastern Dispensary and was operated on by Dr. John T. Finney at the Union Protestant Infirmary, and is now recovering.

NEW JERSEY.

Physician Wins Suit.—A verdict in favor of the defendant by order of the court was given in the case of Seth Roberts against Dr. George W. Laws. The plaintiff claimed \$5,000 damages for alleged improper treatment of an injured arm.

Camden Health Report.—The report of the health officer for the month ended December 15 shows a decrease in contagious diseases of 12 over the preceding month. There were 20 less cases of diphtheria and an increase of 13 of scarlet fever. In all there were 66 cases of contagious disease reported, with 20 deaths. Tuberculosis has now been placed on the contagious disease list.

Library Association Entertainments.—The William Pier-son Medical Library Association of Essex County announces the following program for this winter:

December 6, Dr. Howard A. Kelly, Baltimore, "Appendicitis." January 10, Dr. James E. Newcombe, New York City, "Manifestations of Rheumatism in the Upper Air Tract."

February 7, Dr. Lewis S. Pilcher, Brooklyn, N. Y., "The Operative Treatment of the Hypertrophied Prostate."

March 7, Dr. F. LeRoy Satterlee, New York City, "The Treatment of Rheumatism."

April 4, Dr. Simon Flexner, New York City, director of the Rockefeller Institute, "Some Parasitic Conditions of the Blood with Especial Reference to Tropical Diseases."

May 1, Clinical night.

NEW YORK.

Asylum Changes.—Dr. Charles H. North, who has been assistant physician at the Danmora State Hospital since 1900, has been made superintendent of that institution. Dr. Robert B. Lamb, late superintendent of Danmora State Hospital, has been transferred to the Matteawan Hospital, vice Dr. Henry E. Allison, deceased.

Reckless Use of Fireworks.—The New York State Court of Appeals recently handed down a decision which should have a far-reaching influence in the suppression of the reckless use of fireworks in public celebrations. On the night of November 12, during a Democratic parade on Madison avenue, New York City, there was a premature explosion of bombs and rockets which injured a large number of people, in some cases fatally. A test case for damages was instituted against the city of New York, but in the lower courts the complaint was dismissed. The Court of Appeals now reverses the judgment of the lower court and orders a new trial.

Buffalo.

Insanitary Tenements.—The health commissioner has directed the district attorney to proceed against several tenement house owners for violating the tenement ordinances.

Eye and Ear Hospital Report.—The thirteenth annual report of the Charity Eye, Ear and Throat Hospital of Erie County shows the total number of new patients, 1,817; total number of old patients, 8,339; of the 1,967 new cases 1,221 were diseases of the eye, 257 diseases of the ear and 489 diseases of the nose and throat. The number of patients treated since the opening of the hospital was 22,439. The hospital received an appropriation of \$1,850 last year from the county.

Report of Health.—The monthly report of the Department of Health for November shows a death rate of 13.70 per 1,000 per annum. The principal causes of death were as follows: Consumption, 38; diphtheria, 15; measles, 9; typhoid fever, 5; debility, 43; alcoholism, 5; cancer, 19; apoplexy, 10; meningitis, 12; valvular heart disease, 21; pneumonia, 50; appendicitis, 5; gastroenteritis, 6; acute nephritis, 26, and violence, 30. Total deaths for November, 434, as compared to 438 for November, 1903.

New York City.

Large Sum for Hospital Assured.—The board of managers of the Seney Hospital, Brooklyn, has announced that the conditional \$300,000 has been raised and that it is now assured of the gift of \$125,000 offered.

Contagion Hospital Christmas.—The health commissioner has asked for funds and gifts for the patients in the hospitals for contagious diseases, namely, the Willard Parker, the Riverside, the North Brother Island and the Kingston Avenue Hospital in Brooklyn.

"Physician" or "Doctor."—The Society of Medical Jurisprudence at its last meeting took action leading toward the stricter and more exact use of words, which ought to be commended by all people interested in good English. Hereafter the society is to designate its medical members as "physicians" and not as "doctors."

Contagious Diseases.—There have been reported to the sanitary bureau for the week ending December 10, 368 cases of diphtheria and croup, with 31 deaths; 345 cases of tuberculosis, with 160 deaths; 208 cases of scarlet fever, with 14 deaths; 138 cases of measles, with 8 deaths; 87 cases of typhoid fever, with 19 deaths; 112 cases of chickenpox, and 13 deaths from cerebrospinal meningitis.

Continued Work for Pure Milk.—The Health Department inspectors who have been investigating the up-state dairies have reported that the Blooming Grove dairy in Orange County is in an unsanitary condition. As a result the permit of the Metropolitan Milk and Cream Company, which has been dispensing milk from this source, has been revoked by Health Commissioner Darlington.

Tuberculosis Dispensary.—A new dispensary for the special treatment of pulmonary tuberculosis was opened December 19 by the New York Throat, Nose and Lung Hospital. The patients will live at home and will visit the dispensary three or more times weekly for treatment, advice, medicines, etc. By this plan it is believed that each person will be made a center for disseminating information for controlling and stamping out the disease.

Health Department and the Subway.—At a meeting of the advisory board of the Health Department the condition of the subway was discussed. This body was inclined to agree with Dr. Chandler, who has continued his researches which have resulted in confirming his first statements, that there is no lack of oxygen in the tunnels. However, it was the opinion of the majority that a change in the roadbed would be advisable. This change would consist in altering the present rock ballast roadbed for one of asphalt or concrete at the stations and for 50 feet on either side, as this would insure cleanliness.

The Mosquito Must Go.—At the meeting of the National Mosquito Extermination Society, held December 14 and 15, it was decided to change the name of this association, and it will henceforth be known as the American Mosquito Extermination Society. Among those who contributed interesting papers were Dr. E. Porter Felt, New York state entomologist; Dr. Walter Wyman, surgeon general of the United States Public Health and Marine-Hospital service; Dr. M. J. Rosenau, director of the Hygienic Laboratory at Washington, D. C.; Dr. Bramley, and Dr. Quitman Kohne, president of the health board of New Orleans. It was very clearly demonstrated that the mosquito is a menace to health with which we should not temporize, and it was the conviction that the time would come when those in authority would act against the mosquito as they now do against smallpox.

PENNSYLVANIA.

Personal.—Dr. Maurice B. Oberholtzer has been appointed Burgess of Soudertown.—Dr. J. Frank Shaw, health officer of York, has resigned.

Smallpox Situation.—The report of the State Board of Health for November shows that there were 219 cases of the disease, with no deaths, as compared with 745 cases and 74 deaths in November, 1903, and 1,248 cases and more than 100 deaths last December. Of the whole number of cases reported last month 45 occurred in Harrisburg, 50 in Morris Run, Tioga County, and 50 in Dover Township, York County. Allegheny County, where the disease was prevalent last winter, reported only one case, and the only places other than those already named where more than three cases were reported were as follows: North Lebanon Township, 15 cases; York, 9 cases; Philadelphia, 8 cases; Butler County, 7 cases; Conewago Township, York County, 6 cases; Cole's Patch, Schuylkill County, 4 cases; Johnstown and Blossburg, and Covington Township, Tioga County, 3 cases each.

Philadelphia.

Desire Consumptive Camp.—At the last meeting of the County Medical Society Dr. Robert N. Willson, Jr., introduced a resolution petitioning the legislature to appropriate \$50,000 for the establishment of camps for consumptives. The resolution will be acted on at the regular meeting, December 27.

Personal.—Dr. Orem M. Deems has been appointed resident surgeon to the Wills Eye Hospital.—Dr. M. P. Sewall has been appointed resident physician in Girard College to succeed Dr. Sidney J. Repplicher, resigned.—Dr. W. J. Wanless, principal of the Miraj Medical School and superintendent of the Miraj Leper Asylum, in India, addressed the students of the University of Pennsylvania, December 15.

Typhoid Fever.—During October there were 335 cases reported to the Bureau of Health, equivalent to an average weekly rate of approximately 6.3 cases per 100,000 population. During this period not a single case of typhoid was reported from that section of the city in West Philadelphia, with a population of 46,805, which is supplied with filtered water from the Belmont plant, while the weekly average of cases in the same section which has unfiltered water, with a population of 101,566, was 7.84 per 100,000 population.

Many Unvaccinated Infants.—During a recent vaccination campaign the health authorities discovered in one section of the city about 550 unvaccinated people. Of this number the largest proportion were of infants less than six or seven months old, who were born after the last systematic vaccination canvass. This is significant from the fact that of eight patients who have been admitted to the Municipal Hospital with smallpox during November two had never been vaccinated and were less than seven months old. Efforts are being made by the Health Department to have infants vaccinated.

North Branch Society Election.—The North Branch of the Philadelphia County Medical Society, the pioneer "branch" in the new movement of organizing the medical profession of American cities, is now completing its fourth year. The officers for 1905 are: Dr. A. Birn Ilirsch, chairman; Dr. T. Turner Thomas, clerk; Drs. W. Harsey Thomas, W. Harnar Good and Anna M. Reynolds, committee on scientific business; Drs. William E. Parke, H. Brooker Mills, Clara T. Dereum, Wilbur C. Hammond, Carle L. Felt, Rose Hirschler, Samuel P. Gerbard and Wendell Reber, committee on membership.

Blockley Dinner.—The annual dinner of the Association of Ex-Residents and Resident Physicians of the Philadelphia Hospital (Blockley), was held December 3, and 72 members were present, including 17 of the present resident physicians. Dr. James B. Walker presided and the following officers were elected: President Dr. Edward L. Duer; vice-presidents, Drs. Horatio C. Wood and Dr. Roland G. Curtin; secretary, Dr. Edward R. Stone, and executive committee, Drs. Alfred Stengel, Richard C. Norris, Thomas C. Potter, J. Chalmers DaCosta, Augustus A. Eshner, George Y. MacCracken and H. B. Calhoun.

Health Report.—The total number of deaths recorded for the week numbered 519, as compared with 453 for last week and 579 for the corresponding period of last year. Pneumonia was responsible for the largest number of deaths, 70 being due to this disease, while 33 more deaths were due to acute inflammation of the respiratory tract. Seventy-two deaths were due to pulmonary tuberculosis, 26 to apoplexy, 50 to heart disease, 42 to Bright's disease, 12 to cancer and 15 to diphtheria. The contagious disease cases reported numbered 213, with 26 deaths, as compared with 260 cases and 27 deaths for the previous week. Contagious disease is present as follows: Diphtheria, 90 cases; scarlet fever, 53 cases; typhoid fever, 69 cases; and smallpox, 1 case.

FOREIGN.

Virchow Fund for Combating Infant Mortality.—The heirs of Rudolf Virchow have presented to the city of Berlin \$12,500, to serve as an endowment fund to aid in the campaign against infant mortality.

Tuberculosis Museums in Germany.—Carlsruhe is planning a still more elaborate tuberculosis museum than the one now established at Charlottenburg. Arrangements are being made by which parties of working people will be enabled to visit the museum from all parts of the country.

Proposed Memorial to Riegel.—Friends and former pupils of Prof. Franz Riegel of Giessen, who died last August, are invited to contribute toward a memorial to be erected on the scene of his labors to perpetuate the memory of the great clinician to future generations. Contributions are received by Drs. Volhard and von Tabora, privat docents at Giessen. The appeal is signed by the dean of the medical faculty and others.

Zurich Votes in Favor of Restriction on Medical Practice.—The popular vote cast in the canton of Zurich on the question whether to abolish or maintain the regulations restricting the practice of medicine to registered practitioners resulted in a victory for regular medicine. The proposal to abolish the restrictions—mentioned on a page 1882—was voted down by a vote of 51,319 against 22,881.

Nursing Consultations in Berlin.—The Berlin authorities have recently established four stations where mothers can bring their babies for advice and obtain milk or other food

for the child. Berlin now has three kinds of the Fürsorgestellen as the Germans call them, some for tuberculous, some for infants and one for cancer subjects. They aim to watch over the applicants not only on the spot, but in their homes, and to improve their environment at need. Hamburg has six salaried women whose duties are to watch over the infants in the city asylums.

Correspondence.

The Relation of the Physician to Proprietary Remedies.

St. Louis, Dec. 13, 1904.

To the Editor:—In your issue of December 3, under the heading "The Relation of the Physician to Proprietary Remedies," Dr. William J. Robinson indirectly assails the integrity of two houses with which I am connected. I feel it my duty to call your attention to a number of errors and gross misrepresentations, and in justice to these concerns, reputable manufacturers and patrons of your advertising pages for fifteen years, you should place this matter in its proper light before your readers.

I would not undertake to answer this article as a whole, because its labored efforts are apparent and its inconsistency answers itself. Nor would I take the time to correct any statement emanating from Dr. Robinson were it not given space in THE JOURNAL of the American Medical Association. I do not question the right of Dr. Robinson or of any physician to approve or to disapprove any chemical or pharmaceutical product, but I do protest against the malicious way Dr. Robinson speaks of seng and chionia as "quack nostrums," classifying them with pain-killers and cure-alls, and their manufacturers among "ignoramuses" and "saloon-keepers," "without the slightest idea of chemistry, materia medica or therapeutics." In point of fact, seng and chionia are manufactured by the Sultan Drug Company and the Peacock Chemical Company, respectively; houses whose reputation and standing have never been questioned. Their manufactory is in the hands of an experienced pharmaceutical chemist, and their exploitations are strictly ethical. Never in their entire existence have they deviated one iota from their chosen field, as manufacturers of ethical pharmaceuticals. Their advertisement has never been seen by anyone excepting in reputable medical journals. It is true that the working formulae for seng and chionia are not published, but this is done to protect those physicians who are daily employing them from the very inconvenience that Dr. Robinson has with the iron and manganese product he speaks of. If he were to prescribe our Peacock's bromids, the formula for which we plainly give, he would, no doubt, experience the same trouble. We have examined substitutes for this product, even some that were made by manufacturers whose business it is to make these substitutes for unscrupulous druggists, and who should know better, and found them to contain absolutely no bromid of lithium, and in some cases they were merely mixtures of bromids of potassium and sodium. In the case of chionia and seng, the physician, the patient and the manufacturer have some protection against this evil. Many physicians who wish to employ *Chionanthus virginica* when it is indicated, prescribe chionia, because it best represents the true therapeutic action of that drug. Its dose is well known, just as is the dose of a tincture, without knowing or caring whether it is two, four or six ounces of the drug to the pint. And again, seng, a pleasant elixir of the *Panax schinseng*, has many friends in the profession as a digestive tonic—and we feel satisfied that the practicing physician does not want its working formula any more than he would want to refer to his textbook to ascertain its exact composition each time he wished to prescribe compound tincture of cinchona.

The products of the Sultan Drug Company and of the Peacock Chemical Company have been endorsed by more than forty thousand practicing physicians in this country and England, and to these and others who may still become prescribers of their preparations, I repeat the pledge of these

concerns, to maintain the strict ethical bearing toward the physician, which they have always sustained.

FRED W. SULTAN,

President Sultan Drug Company.

Secretary-Treasurer Peacock Chemical Company.

Duplicate Twins and Double Monsters.

NORTHAMPTON, MASS., Dec. 15, 1904.

To the Editor:—As I have recently become interested in a line of investigation which requires the careful examination of all forms of double monsters, I would be extremely grateful for the gift or loan of fetal or new-born specimens exhibiting any grade of this phenomenon.

As such cases are rare, there is a natural tendency to store them up as museum specimens, in which condition the benefit to be derived from them is inconsiderable; while a thorough anatomic investigation would yield far more important results. As I am working on a definite problem, I do not care at present for other forms of monsters, such as those of microcephalous, acephalous or amorphous types, but only for those which exhibit a doubling of any axial part, ranging from single individuals with doubled median parts to two complete individuals united at a single point. Similar cases occurring among the lower mammals, or, in fact, any vertebrate, will be of nearly equal interest. For fresh material, the best preservative for my purpose is 5 per cent. formalin; i. e., the commercial article mixed with water in proportion of 1—20 or thereabouts, although material preserved by any other method will be of value. In specimens larger than four-months embryos the thoracic and abdominal cavities should be freely opened to insure complete preservation.

For a more detailed description of the types of monster I especially desire, I may refer the reader to the enumeration of the various forms, grouped under diplogai, in my article¹ in the *American Journal of Anatomy*, vol. iii., No. 4, September, 1904.

HARRIS HAWTHORNE WILDER.

Zoological Laboratory, Smith College.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

PATHOLOGIC LABORATORIES.

LINCOLN, NEB., Dec. 9, 1904.

To the Editor:—Wishing to obtain information in regard to the states in which hygienic or pathologic laboratories have been established where pathologic material can be sent for examination without charge, I would esteem it a great favor to receive answers to the following questions: 1. In what states have such laboratories been established? 2. What appropriations have been made in the several states by their legislatures for carrying on this? 3. How many men have been required in each case to do the work? 4. How much of each appropriation was used in the payment of salaries?

H. H. WAITE.

ANSWER.—1. Chapin, in "Municipal Sanitation in the United States," names the following states as equipped with bacteriologic laboratories: Colorado, Louisiana, Delaware, Maryland, Massachusetts, Minnesota, New Jersey, Ohio, Rhode Island, Tennessee and Vermont. Answers to questions 2, 3 and 4 can be best obtained by application to the secretaries of the respective boards of health. The expenditure doubtless varies from year to year as do the number of persons engaged in the work and their respective salaries. The salaries paid in municipal laboratories range all the way from \$3,000 a year to a small fixed sum (e. g., \$1) for each examination made.

OPPORTUNITIES FOR PRACTICE IN THE PHILIPPINES.

COLUMBIA, MO., Dec. 14, 1904.

To the Editor:—1. To whom must application be made for the position of contract surgeon in the United States Army in the Philippines? 2. Do you think it advisable for a young physician to go there? 3. Is it necessary for a graduate of an American College to pass an examination to practice medicine in Porto Rico?

J. M. SANTIAGO.

ANSWER.—1. Surgeon General, U. S. A., Washington, D. C. 2. Yes, if assured of a position, as the experience will be valuable. Otherwise no, as too many physicians are there already who have no work. 3. No.

1. EDITOR'S NOTE: See editorial in this issue.

Marriages.

GEORGE W. CHABOT, M.D., Otway, Ohio, to Mrs. Sadie Taner of Peebles, Ohio, December 7.

CLEMENT ANDARIESE PENROSE, M.D., to Miss Helen Stowe, both of Baltimore, December 14.

GEORGE R. TUBBS, M.D., Stearns, Ky., to Miss Beulah Alford of Alfordville, Ind., December 25.

ARTHUR F. STOTTS, M.D., Ehrenfeld, Pa., to Miss Caroline A. Greene, of Easton, Pa., December 7.

FRANK J. WAGNER, M.D., Scranton, Pa., to Miss Anna Lulu Diaz of Homestead, Pa., December 20.

JOHN EDGAR FRETZ, M.D., to Miss Frances Josephine Rodenbough, both of Easton, Pa., December 7.

Deaths.

John W. Porter, M.D. Kentucky School of Medicine, Louisville, 1833, of Pittsburg, Kan., a member of the American Medical Association, Kansas State Medical Society, one of the organizers of the Southeast Kansas Medical Society, and health officer of Crawford County, died at Mount Carmel Hospital from peritonitis following an operation for appendicitis, December 14, aged 49.

Alloysius G. Blincoe, M.D. University of Louisville, 1868, a member of the American Medical Association; state, district and county societies; one of the best-known physicians of central Kentucky, and an ophthalmologist of renown; a Confederate veteran, died at his home in Bardstown, Ky., from appendicitis, after a brief illness, December 10, aged 60.

Bickerton L. Winston, M.D. New York University, New York City, 1885, a member of the American Medical Association; twice a member of the state legislature and a member of the Democratic committee of Virginia, died at his home in Hanover Court House, Va., December 11, after a long illness, aged 42.

Cary Judson Gill, M.D. Rush Medical College, Chicago, 1866, a member of the American Medical Association, a veteran of the Civil War, and a resident of Riverside, Cal., since 1876, died suddenly from paralysis, December 6, while driving near his home, after an illness of two years, aged 67.

James M. Carden, M.D. Medical Department of the University of Tennessee, Nashville, 1887, of La Follette, Tenn., at one time representative from Anderson and Knox counties in the state senate, died one day after an operation, at the Knoxville General Hospital, December 8, aged 50.

Jesse Jackson Jacobs, M.D. Medical Department Arkansas University, Little Rock, 1898, a member of the American Medical Association and a prominent physician of Franklin County, Arkansas, died at his home in Webb City from hematuria, December 7, after a brief illness.

Levi Curtis, M.D. Jefferson Medical College, Philadelphia, 1847, a surgeon in the Army during the Civil War and a member of the Philadelphia County Medical Society and the Northern Medical Society, died at his home in Philadelphia from heart disease, December 12, aged 82.

Oliver L. Hutzel, M.D. Jefferson Medical College, Philadelphia, 1903, of King's Mills, Ohio, interne in the Williamsport (Pa.) Hospital, died at Comfort, Texas, from chronic ulcerative phthisis, December 9, after an illness of one year, aged 24.

W. S. McMurry, M.D. University of Louisville Medical Department, 1844, a veteran of the Mexican War; once state senator; for 55 years a resident of California, died at his home in Los Gatos, December 8, after a long decline, aged 86.

Howard T. Smith, M.D. Michigan, 1900, of Bridgman, Mich., who was struck by a train at Stevensville, Mich., while driving across the Pere Marquette tracks, December 2, died at Mercy Hospital, Benton Harbor, Mich., December 4, aged 36.

Arch. E. McNeal, M.D. Medical Department of the University of Iowa, Keokuk, 1868, surgeon of the Ninety-ninth Illinois Volunteer Infantry during the Civil War, died at his home in Quincy, Ill., December 14, aged 78.

Samuel S. Turner, M.D., acting assistant surgeon United States Army since 1869, died from Bright's disease, December 11, while on his way from his station at Fort Columbia, Wash., to Washington, D. C., aged 70.

W. M. Carney, M.D. Hospital College of Medicine, Louisville, 1903, was shot six times in a street fight with his former part-

ner, Dr. Edward C. Courtney, at Neave, Ky., December 9, and died half an hour later.

Robert J. Barry, M.D. College of Physicians and Surgeons in the City of New York, 1890, city health officer of Ansonia, Conn., died at his home in that city, November 15, from meningitis, aged 35.

David Kirkpatrick, M.D. Rush Medical College, Chicago, 1860, one of the oldest practitioners of Whitley County, Indiana, died at his home in Larwill, December 5, after a lingering illness, aged 68.

Lorenzo W. Whitney, M.D. Medical Department of Western Reserve University, Cleveland, 1885, of Chicago, died suddenly from heart disease, on an elevated train in Chicago, December 15, aged 56.

Richard H. Barber, M.D. Royal College of Physicians and Surgeons, Edinburgh, Scotland, 1887, of Gardiner, Douglas County, Ore., was drowned while making a professional call, December 4.

John T. Watson, M.D. Jefferson Medical College, Philadelphia, 1850, formerly a practitioner of Nash County, N. C., died at the home of his daughter in Norfolk, Va., December 6, aged 81.

William Kroeger, M.D. University of Wooster Medical Department, Cleveland, 1881, a noted priest and physician of Epiphany, S. D., died at his home in that place, December 8, aged 51.

Martin L. Yost, M.D., twice coroner of Lehigh County, Pa., one of the oldest physicians of Allentown, while driving, December 3, was struck by a trolley car and instantly killed, aged 71.

Charles F. Norton, M.D. Medical Department University of Texas, Galveston, 1899, died at his home in Asheville, N. C., from tuberculosis, December 14, after an illness of two years.

Harry J. Strack, M.D. Medical College of Ohio, Cincinnati, 1901, a district physician of Cincinnati, died suddenly at his office in Cincinnati, December 10, from heart disease, aged 24.

Joseph Albert Starr, M.D. University of Georgetown (D. C.) Medical Department, 1902, was recently found dead in his room in Washington, D. C., from gas asphyxiation, aged 30.

Solomon K. Barndt, M.D. Jefferson Medical College, Philadelphia, 1863, died at his home in Alburts, Pa., December 6, after an illness of three days, from heart disease, aged 62.

Jacob Schaefer, M.D. University of Heidelberg, Germany, 1848, once coroner of Meigs County, Ohio, died at his home in Rock Springs, December 3, after a brief illness, aged 77.

Henry S. Babbitt, M.D. Berkshire Medical College, Pittsfield, Mass., 1848, died at his home in Dorchester, Boston, Mass., December 10, after an invalidism of five years, aged 78.

Melvin Wheeler, M.D. Medical College of Ohio, Cincinnati, 1884, died at his home in Covington, Ky., from hemiplegia, November 8, after an illness of four years, aged 52.

Charles K. Law, M.D. New York University, New York City, 1893, died at his home in Jersey City, N. J., December 13, from peritonitis, after a short illness, aged 40.

James F. Kidder, M.D. Indiana, 1897, a pioneer practitioner of Jay County, Ind., died at his home in New Mount Pleasant, December 2, from chronic gastritis, aged 65.

Frank A. Thorne, M.D. College of Physicians and Surgeons of Chicago, 1891, died suddenly at his home in Seattle, Wash., November 26, from heart disease, aged 44.

Charles E. Birtwell, M.D. New York University, New York City, 1884, of Lawrence, Mass., died at the home of his sister in Providence, R. I., December 8, aged 43.

David W. Birge, M.D. Cleveland Medical College, 1848, who retired from practice in 1894, died at his home in Hector, N. Y., November 24, aged 82.

George E. Butcher, M.D. Jefferson Medical College, Philadelphia, 1864, died at his home in Mauricetown, N. J., from heart disease, December 13.

John Taylor Wells, M.D. Indiana, of Indianapolis, died at the Indiana Central Hospital for the Insane, Indianapolis, December 4, aged 65.

John Moon, M.D. University of Buffalo (N. Y.) Medical Department, 1872, died at his home in Dolgeville, N. Y., December 6, aged 79.

John F. Fisher, M.D. Jefferson Medical College, Philadelphia, 1872, died at his home in Philadelphia from apoplexy, December 9, aged 60.

Frederick Fisher, M.D. University of Leipzig, Germany, 1882, formerly of Alameda, Cal., died at Santa Cruz, Cal., December 5, aged 59.

Francis L. Foscue, M.D. Jefferson Medical College, Philadelphia, 1884, of Demopolis, Ala., was robbed and murdered, December 17.

William H. Bigler, M.D. Pennsylvania, 1871, died suddenly on the street in Philadelphia from heart disease, December 10, aged 64.

Eliphalet E. Houghton, M.D. Castleton (Vt.) Medical College, 1853, died at his home in Schuylkill, N. Y., December 2, aged 73.

Franz Simon, M.D. University of Giessen, Germany, 1848, died at his home in Manitowoc, Wis., December 13, aged 81.

R. M. Wade, M.D. University of Maryland School of Medicine, 1875, died at his home in Athens, Ga., December 7, aged 64.

John J. Garrigus, M.D. Indiana, 1897, died suddenly at his home in Tangier, Ind., from heart disease, November 27.

William E. Gallagher, M.D. Detroit Medical College, 1884, fell dead at his home in Milwaukee, November 14.

Zebina Z. Bryant, M.D. Illinois, 1881, died at his home in Hennepin County, Minn., November 28, aged 63.

John T. Austin, M.D., died at his home in Nixon, Texas, December 4, from pneumonia, after a short illness.

W. S. Barrett, M.D., of Social Circle, Ga., died at his home, December 11, aged 84.

THE PURE-FOOD BILL.

Abstract of Discussion of This Important Bill in the United States Senate.

We quote and abstract from the *Congressional Record* the following account of the daily proceedings in Congress concerning the Pure-Food Bill:

Thursday, December 8.

Senator Heyburn of Idaho asked leave to call up the bill, and Senators Cullom of Illinois and Aldrich of Rhode Island asked that the bill be read in full. To call up the bill at that time required unanimous consent. Senator Tillman of South Carolina objected, because of other business which he desired to have considered, and the request of Senator Heyburn was therefore not granted.

Monday, December 12.

The Senate took up the consideration of the bill, which was read with the amendment reported from the committee on manufactures. The bill was printed in *THE JOURNAL* April 2, 1904, page 910. The amendment is to strike out all after the enacting clause and to insert new matter which, in the opinion of that committee, covers the desired ground to better advantage. Senator Heyburn explained that the House bill proposes to establish a new bureau to execute the provisions of the bill, and that the Senate bill contemplates this work being done by the existing departments of the government. He made the general observation that every state had passed some law on the subject of pure food, and said that since no one would defend the fraudulent manufacturer in his adulteration it only remained to determine the character of the bill to be enacted.

Senator Carmack of Tennessee asked the reason for the provision prohibiting exportation of adulterated goods to foreign countries.

Senators McCumber of North Dakota, Spooner of Wisconsin and Heyburn gave the following reasons: 1. Reciprocity: that is, we should prevent our citizens from doing to other countries what we do not want their citizens to do to us. 2. Protection of industry: that is, we should protect our honest exporters from unjust competition with those who adulterate their goods. 3. Reputation of American goods: that is, our name in foreign markets should stand for purity and integrity. 4. Increase of trade: that is, a good reputation will increase our commerce.

PHYSICIANS AND MEDICAL ASSOCIATIONS HEARD FROM.

Senator Heyburn said: "The demand for this class of legislation comes from those who have most nearly at heart the health and welfare of the people. I have here something like

3,000 requests from physicians of good standing; I have hundreds of petitions from medical associations; I have on my desk here the petition of the American Medical Association asking for the enactment of this legislation. They had the bill before them when they passed those resolutions."

NEED OF PUBLICITY CONCERNING ADULTERATIONS.

Senator Stewart of Nevada expressed the fear that the bill will not pass, but agreed that something ought to be done. He suggested that the Secretary of Agriculture be given \$200,000 to make and publish analyses of adulterated foods, etc., and that the resultant awakening of the people on the subject would make it easy for the states and Congress to legislate. Continuing, he said:

"I do not think the country has any idea of the extent of the poisons that are administered in the food that is sold and eaten in this country. I think it is sapping the foundation of the constitutions of our people. If we had to raise soldiers now as we did in 1861 I do not believe that throughout the country we would find as large a percentage of young men fit for hard service as there were at that time, and I believe the degenerated condition of many of the young men results in a great measure from the poisonous food that they eat—the alum in the bread, the formaldehyd in the milk, the meats, and so on. I need not go on to enumerate them now. Those things are destroying the stomachs and injuring the health of the people."

"But in order to apply the remedy we first want to have the evil thoroughly exhibited. An individual can not publish the list; no professor, or doctor, or other man can publish it. The press will not publish it. The patronage is on the other side. They will cry him down if he attempts it. No individual can do it. But it can be done effectively by the Department of Agriculture through its Bureau of Chemistry, where they have a man at the head who understands the subject and who has done a good deal of good so far. What we want to do is to give him money enough, so that he can go forth and analyze and publish the result, and the people will find the remedy for this evil."

"I am afraid my friend from Idaho can not get his bill through, and I am afraid if he does it will not be exactly fitted to the condition of things. If we had all the facts the country would no doubt demand a remedy for such a great evil. I believe the first thing to do is to put in the agricultural appropriation bill a lump sum and tell the Secretary of Agriculture to look into the question, and he will do it in a way that will induce legislation in the states and in Congress, so far as necessary. I have no doubt of that."

REASONS FOR PASSING THE BILL.

Senator Heyburn gave the following vigorous and most pertinent answer:

"Mr. President, the demand for the passage of this legislation, or this class of legislation, comes to us from the states—from the legislatures of the various states. They demand that we shall co-operate with them in carrying out the principle they have undertaken to deal with. They have undertaken, in several states, to the extent and limit of their jurisdiction, to prevent the introduction and use of deleterious foods and drugs, and they complain that they can not enforce their laws; that their laws are not effective because of the fact that other states and countries may force on them without their present knowledge or will substances that they do not permit to be manufactured and sold within the state. That is the difficulty. They are not asking us to inaugurate the subject of legislation upon pure food. They are asking us to co-operate with them. They have already spoken through their legislatures as Congress spoke when it had the matter before it."

"It seems to me that the subject is one which should receive consideration and ultimate action, because it is impossible for the states to prevent, under the unbroken-package law, the importation within their borders of the very substances which their own people are prohibited from manufacturing or selling within their states."

"If this proposed law is found to be insufficient, if it is found to be open to objection, let us amend it here and har-

monize it with the House bill. Let us enact some law on the subject. That is the important thing to do. . . .

"We have ample time to consider the question and all the proposed objections and amendments that may be offered to the bill. Let us act. Let us heed the call of the states and the people and protect them not only against their own weakness, as exhibited by the manufacture and sale of these articles among ourselves, but let us protect them against the importation of these substances from other countries. Let us protect each state against the cupidity and greed and fraud that come into it over the borders from its neighbor or from some other state."

Senator Heyburn then closed, because the time had arrived for other business.

Senator McCumber made the following appeal:

"I sincerely hope, Mr. President, that those even who are opposed to this bill will at least co-operate with us in assisting us to secure a vote during the present session. In the last four years this bill, or substantially the same bill, has passed the House on two different occasions. By the manipulation of appropriation and other bills, especially by those who have been opposed to the enactment of this proposed law, we have been unable to secure a vote in the four years. It does seem to me that after the House has twice expressed itself strongly on this subject by an overwhelming majority we should at least have the opportunity in this body during the present session of securing an expression of the Senators on a question which affects every state in the Union and every individual in every state in the Union."

Tuesday, December 13.

On motion the House agreed to the consideration of the bill, and Senator McCumber spoke at length. After using the pointed argument which we have quoted editorially, he urged the magnitude of the evil, and stated that the value of the adulterated and misbranded goods sold annually in the United States is about \$3,000,000. He said:

NEED OF PROTECTING THE STATES.

"The fact that nearly every state in the Union has passed stringent pure-food and pure-drug laws is evidence of the existence of the necessity for that character of legislation. The fact of their inability to enforce those laws makes it evident to us that there is some reason outside of the authority of the state whereby the state is not enabled to enforce its own territorial laws.

"Now, is the state entitled to this protection? By the silence of Congress on the subject we impliedly say that the state shall be the dumping ground of all spurious, adulterated and misbranded goods, and the state itself is absolutely at the mercy of manufacturers and shippers of that character of goods; and why? Because by the construction of the interstate commerce clause of the Constitution it has been held that the failure of Congress to pass on the subject of what may be imported into a state is evidence of the desire of Congress that any goods that can be said to be marketable may be shipped into any state in unbroken packages, and in that condition may be sold. Therefore, the state itself can not reach the goods until they have become lost in the mass of the property of the state; and when they have so become lost, I submit that the state power to reach and punish the real offender is absolutely gone. The evil is rooted in soil outside of the state and over which the state has absolutely no jurisdiction."

Continuing Senator McCumber gave illustrations of the handicap on state authorities at present. He urged that the honest manufacturer is worthy of protection, and said further:

"The bill as it is drafted injures no legitimate business: it does not determine what shall be shipped into any state. It does not determine what shall be done with it in the state. It neither prohibits nor interferes with any commerce whatever. It simply says that all goods must be unmasked before they cross the state line. No legitimate dealer can object to a law of that character. It does not prevent a man from buying what he desires to eat or what he desires for a drug. It simply declares that he shall be protected in buying what he does want

either for food or in the drug line. I anticipate that no person could urge any objection to a law of that kind.

"It is not partisan in any sense. It does not in the least degree infringe state rights or interfere with them in any way. The Federal law will stop exactly where the state law begins, and it will not attempt to interfere in the slightest degree with the police power of the state. The provisions add no new machinery of government. They add no additional expense in order to carry out the law. There is a wrong impression, as I have suggested, that this is a law to fix standards of foods, and that in some man is placed the power to determine what may be sold and what may not be sold in the country. On the contrary, it is nothing of the kind. It is simply a bill to provide that all articles shall be sold for exactly what they are, and if the state itself has a power to declare, and if it is proper for it to declare, what shall not be sold within its boundaries, then the nation has the power to declare, and it is also proper for it to declare, under the power given in the interstate commerce clause of the Constitution, what shall not pass the borders of a state. That is all this bill seeks to do—to supplement the power of the state to prevent the sale of adulterated and misbranded goods in the state. . . .

"Now, as I have stated, this proposed law keeps entirely outside of the state itself. The definitions are somewhat voluminous, it may be, but they are all clear; they are all concise. They are designed simply to protect those who are innocent and to punish those who are guilty. There has been no change in the measure as it came from the House in the matter of definitions. They have been rearranged so as to conform more particularly to their headings, 'adulterated' and 'misbranded,' and nothing further than that."

THE RESPONSIBILITY OF THE DEALER.

Senator Platt of Connecticut then asked an explanation of one provision of the bill. He said:

"The object of this bill is a good one, but its terms are so involved that I am not sure I understand just what it does provide and mean, and therefore I wish to ask the Senator from North Dakota whether he understands that this bill provides that any person who orders goods from another state, and to whom they are shipped, does, by receiving them only, make himself liable to prosecution and penalty unless the goods are accompanied by a guaranty from the person of whom he buys them that they are pure? Does the bare receiving of them make him liable? To illustrate, suppose a grocery merchant, a retailer, in Connecticut orders from a wholesale grocery store in New York some packages of coffee. Now, does he, by receiving those packages of coffee, make himself liable to prosecution unless they are accompanied by the guaranty of the person from whom he buys them that they are pure?"

Then followed a long discussion as to the interpretation of the words of the clause referred to. Senator Spooner joined Senator Platt in the view that the bill would make innocent recipients liable to arrest and prosecution for even receiving adulterated or misbranded goods unless a guaranty from the manufacturer accompanied the goods. Senator McCumber admitted that the change of one word might be advisable to remedy this.

Senators Platt and Spooner further contended that the importer should be protected by the passage of the articles through the customs house, where, supposedly, the government had examined them, and, further, that since the bill makes it an offense for any one to receive impure goods, the importer may innocently receive such goods, and therefore a provision in the bill ought to be made excepting from prosecution the importer who has a guaranty from the foreign merchant.

Senator McCumber showed the fallacy of this by explaining that, if such a provision were added, the importer could be protected in selling adulterated goods by simply having a guaranty from a foreign merchant, and that the United States has no power to prosecute the foreign merchant.

It was further explained that the expression "knowingly receive adulterated goods" can not be used, because experience in the state shows that the majority of offenders can escape when such language provides a loophole.

Senator Spooner said: "Then are we not put to the alternative of not regulating on the one hand or on the other regulating in this way, to the obvious injustice of a great body of honest American citizens?"

Senator McCumber said: "I can not see where any injustice will necessarily or even probably be done them under a law of this kind. We have a great many cases of like character. It is made a criminal offense probably in every state in the Union to sell a minor liquor. A man may be absolutely innocent of the fact that he is a minor when he sells it, but nevertheless he is compelled to know what he is doing; it is considered necessary that he should know."

Attention was called to the fact that the bill puts the burden on the dealer of knowing that he is handling genuine products. This was the intention.

Senator Platt objected to the bill on the ground of its complications. He considered that it required much study to ascertain just what was intended by it. He thought a simpler way would be to define "adulterated" or "misbranded" goods, and to require all goods shipped between states to have on them a guaranty as to purity, etc. He said this was only an opinion, as he had not studied the subject deeply.

Senator McCumber declared that general views make a matter appear simple, but that to draft a law to guard the rights of citizens under those general provisions becomes often a very complex matter. So it had been in this case. He stated further that the bill covered the points laid down by Senator Platt. It defines adulterated and misbranded goods, and it requires all such goods to be correctly labeled.

Wednesday, December 14.

The bill was taken up, on motion, and the discussion resumed. Senator McCumber quoted from a statement by the food commissioner of North Dakota concerning the adulteration of ham, sausage, canned eelken, salmon, peas, mushrooms, tomatoes, etc., which showed that 80 to 90 per cent. of such goods were adulterated or had preservatives in them.

Senator Aldrich of Rhode Island brought up the protection to the innocent dealer who purchases goods supposedly genuine.

Senator McCumber showed that he is protected by the guaranty of the manufacturer in this country, but that he must himself see to the purity of the goods that he buys of a foreign merchant. He said:

"The object of requiring a guaranty in the states is that we may follow up the article to the manufacturer and may hold the manufacturer of the article responsible. Such a provision could not apply, of course, where the article is imported from a foreign country. This country has no jurisdiction, of course, over the producer in a foreign country, and for that reason it was deemed unnecessary and improper even to have the same provision in reference to the importation of foreign products. In addition to this, we now have a national law which provides for the inspection of all these imported articles, and I believe it is working very well. There is very little complaint."

Discussion by Senators Aldrich, Platt, McCumber, Spooner and Money of Mississippi was on alleged imported goods. The so-called French peas are, to a large extent, put up in this country and are highly colored by chemicals. Cottonseed oil was formerly shipped abroad and reshipped to this country as olive oil. The governments of this and of other countries have largely stopped this. The substitution and the use of foreign labels is now done in this country, and is one of the evils at which the bill is aimed.

Senator Aldrich argued that because of the uncertainty of analysis and the difficulty of the importer securing evidence that the goods he imports are not contrary to the provisions of the bill, the importer in some instances would be liable to unjust prosecution. He declared that the bill was not just, in so far as it would allow this to occur.

Senator McCumber urged that it was right to put the burden of proof on the importer, because he is the first man who handles the goods on whom the government can lay its hand. He is the responsible party.

Senator Spooner urged that since goods pass through the United States Customs Department they should there be examined, and that the certificate of entry should be a guaranty to the importer and from him to the retailer as to the innocence of any one thereafter handling the goods thus guaranteed. He said further that in passing this legislation Congress should industriously see to it that no innocent person could be punished.

The time having come for other business, the discussion ended.

Friday, December 16.

The bill was called up, but was suspended by other business on motion of Senator Lodge of Massachusetts.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Dec. 17, 1904:

Cox, Walter, and Marrow, Chas. E., asst.-surgeons, advanced to rank of captain Dec. 12, 1904.

Mearns, E. A., surgeon, sick leave of absence further extended thirty days.

Reidy, Wm. W., asst.-surgeon, relieved from duty at Louisiana Purchase Exposition, St. Louis, and ordered to Fort Myer, Va., for duty.

Buck, Carroll D., asst.-surgeon, relieved from duty with Philippine scouts, Louisiana Purchase Exposition, St. Louis, and ordered to Fort Des Moines, Iowa, for duty.

Stark, Alexander N., asst.-surgeon, granted two months' leave at expiration of present sick leave of absence.

Ives, Francis J., surgeon, granted three months' leave of absence about Dec. 20, 1904.

Banta, Wm. P., asst.-surgeon, relieved from duty at Fort Sam Houston, Texas, and ordered to duty as surgeon, transport *Sheridan*, during the voyage to Philippine Islands, relieving Asst.-surgeon De Lancy; on arrival at Manila to report for assignment to duty.

De Lancy, M. A., asst.-surgeon, relieved from duty on transport *Sheridan* and ordered to report in person to the Surgeon General of the Army at meeting of Pan-American Medical Congress, Panama, Washington, D. C.

Gorgas, Wm. C., asst.-surgeon general, and La Garde, L. A., surgeon, detailed to represent the Medical Department of the Army, at meeting of Pan-American Medical Congress, Panama, Jan. 3-6, 1905.

Ashford, E. K., asst.-surgeon, detailed to represent the Medical Department of the Army at the meeting of the American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

Ewing, Charles B., surgeon, granted twenty-one days' leave of absence about Jan. 2, 1905.

Mans, Louis M., deputy surgeon general, granted four months' sick leave of absence at expiration of present leave.

Hallwood, James B., contract surgeon, returned to duty at Fort Leavenworth, Kan., December 7 from leave of absence.

Brewer, Isaac W., contract surgeon, granted an extension of fifteen days in his leave of absence.

Hays, Melville A., contract surgeon, granted an extension of one month to his leave of absence.

Roak, S. Davis, dental surgeon, arrived at Fort Myer, Va., Dec. 11 for duty.

Foster, Douglas E., dental surgeon, left Fort Monroe, Va., December 12 for his proper station, Fort Slocum, N. Y.

Wing, Franklin F., dental surgeon, left Fort Des Moines, Iowa December 10 for duty at Fort Washakie, Wyo.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Dec. 14, 1904:

McIntosh, W. P., surgeon, granted leave of absence for one day, December 10.

Stouer, J. B., surgeon, to proceed to Delaware Breakwater Quarantine and assume temporary charge during absence, on leave, of medical officer in command.

Wertenbaker, C. P., surgeon, detailed to represent the Service at meeting of American Public Health Association at Havana, Cuba, Jan. 9-12, 1905.

Blue, Rupert, P. A. surgeon, granted leave of absence for five days from December 13.

Oakley, J. H., P. A. surgeon, granted leave of absence for one day, December 12.

Wickes, H. W., P. A. surgeon, granted leave of absence for one month from December 23.

Greene, J. B., P. A. surgeon, granted leave of absence for fourteen days from December 19.

Von Ezdorf, R. H., P. A. surgeon, granted leave of absence for six days from December 12.

Anderson, J. F., P. A. surgeon, detailed to represent the Service at meeting of the Laboratory Section of American Public Health Association at Havana, Cuba, Jan. 9-13, 1905.

Rehrenburg, L. P. H., asst.-surgeon, granted leave of absence for twenty-one days.

Burkhalter, J. F., asst.-surgeon, granted leave of absence for twelve days from December 24.

Jackson, J. M., Jr., A. A. surgeon, Department letter of Oct. 10, 1904, granting leave of absence for thirty days from October 26, amended to read thirty days from November 26.

Kestley, H. W., A. A. surgeon, granted leave of absence for eighteen days from December 10.

Primrose, R. S., A. A. surgeon, granted leave of absence for eighteen days from December 5.

Hanraff, F. R., pharmacist, relieved from temporary duty at Cleveland, Ohio.

RESIGNATION.

Harris, B. Y., A. A. surgeon, resigned, to take effect Dec. 15, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Dec. 16, 1904:

SMALLPOX—UNITED STATES.

Illinois: Dec. 3-10, Chicago, 7 cases, 1 death; Danville, 1 case.

Kentucky: Louisville, Dec. 1-8, 3 cases.

Louisiana: New Orleans, Dec. 3-10, 4 cases, 2 imported.

Maine: Nov. 1-30, Cape Elizabeth, 1 case; Eagle Lake Plantation, 1 case; New Sweden, 1 case; St. Agatha, 1 case; St. Francis Plantation, 1 case.

Michigan: At 75 places, Nov. 26-Dec. 3, present.

Missouri: St. Louis, Dec. 3-10, 15 cases, 2 deaths.

Nebraska: Omaha, Dec. 3-10, 1 case.

Ohio: Cincinnati, Dec. 2-9, 3 cases; Toledo, Nov. 26-Dec. 10, 3 cases.

Pennsylvania: Dec. 3-10, Johnstown, 3 cases; Philadelphia, 1 case.

South Carolina: Greenville, Nov. 26-Dec. 3, 2 cases.

Tennessee: Nashville, Dec. 3-10, 5 cases.

Wisconsin: Milwaukee, Dec. 3-10, 18 cases.

SMALLPOX—INSULAR.

Philippine Islands: Oct. 29, Marinduque Province, epidemic; Siguir Province, epidemic; Surigao Province, epidemic.

SMALLPOX—FOREIGN.

Austria: Vienna, Nov. 19-26, 1 death.

Brazil: Bahia, Oct. 29-Nov. 12, 36 cases, 3 deaths; Para, Nov. 15, epidemic.

Denmark: Copenhagen, Nov. 5-12, 1 case.

France: Nov. 19-26, Lyon, 1 case; Paris, 11 cases.

Germany: Munich, Nov. 19-26, 2 cases, 2 deaths.

Great Britain: Glasgow, Nov. 25-Dec. 2, 1 case; Nov. 19-26, Manchester, 1 case; Newcastle-on-Tyne, 4 cases; South Shields, 1 death.

India: Bombay, Nov. 8-15, 7 deaths.

Italy: Palermo, Nov. 12-26, 36 cases, 9 deaths.

Mexico: City of Mexico, Oct. 1-Nov. 19, 15 cases, 5 deaths.

Russia: Odessa, Nov. 19-26, 1 case; St. Petersburg, Nov. 12-26, 8 cases, 1 death; Warsaw, Oct. 22-29, 9 deaths.

Spain: Barcelona, Nov. 20-30, 7 deaths.

YELLOW FEVER.

Mexico: Nov. 20-Dec. 3, Marida, 2 cases; Textistepec, 21 cases, 2 deaths.

CHOLERA.

India: Calcutta, Oct. 29-Nov. 5, 11 deaths.

Persia: Nov. 26, Gilan Province, epidemic; Mazenderon Province, epidemic; October, Resht, 10 cases daily; Tabriz, 400 cases daily.

Russia: Nov. 4-8, Baku, 6 cases; Balachany, 5 cases; Erivan, 132 cases, 62 deaths; Samara, Oct. 17-24, 65 cases, 14 deaths; Tiflis, Nov. 7, 1 case.

Turkey in Asia: Mesopotamia, Oct. 22-29, 96 cases, 89 deaths.

PLAGUE—INSULAR.

Hawaii: Honolulu, Dec. 10, 1 death.

PLAGUE—FOREIGN.

Arabia: Aden, Nov. 4, 1 death.

Argentina: Salta, Nov. 21, epidemic.

Brazil: Bahia, Nov. 5-12, 8 deaths.

Egypt: Nov. 5-12, Achmou District 1 case, 1 death; Tukh District, 4 cases, 1 death.

India: Bombay, Nov. 8-15, 75 deaths; Calcutta, Oct. 29-Nov. 5, 9 deaths; Karachi, Oct. 31-Nov. 6, 11 cases, 9 deaths.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Western Surgical and Gynecological Association, Milwaukee, Wis., December 28-29.

Pan-American Medical Congress, Panama, Jan. 2-6, 1905.

American Public Health Association, Havana, Cuba, Jan. 9-13, 1905.

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Seventeenth Annual Meeting, Held at Birmingham, Ala., Dec. 13-15, 1904.

The Second Vice-President, Dr. J. Shelton Horsley of Richmond, Va., in the chair.

Addresses of Welcome were made by Mayor Drennan and

Dr. L. G. Woodson, and were responded to by Dr. W. P. Nicolson of Atlanta, Ga.

Officers elected: President, Dr. Lewis C. Boshier, Richmond, Va.; vice-presidents, Drs. John D. S. Davis, Birmingham, Ala., and I. S. Stone, Washington, D. C.; secretary, Dr. W. D. Haggard, Nashville, Tenn., re-elected; treasurer, Dr. Charles M. Rosser, Dallas, Texas, re-elected.

Louisville, Ky., was selected as the place for the next annual meeting, in December, 1905.

Intestinal Obstruction.

DR. DYER F. TALLEY, Birmingham, Ala., pointed out two difficulties in the way of early operation for intestinal obstruction: 1. It is hard to make a positive diagnosis in the first 24 hours. Indeed, in some cases it is impossible to do so, unless an exploratory laparotomy is made. 2. There is a tendency on the part of his patient and his friends, and also on the part of the physician, to wait until to-morrow and see what purgatives and enemata will accomplish. Dr. Talley reported 8 cases of intestinal obstruction that have come under his care during the last 15 months. One case showed that a laparotomy can be done without anesthesia, and many cases that are seen late and are too weak for an anesthetic may be operated on and relieved without a general anesthetic. The results of operation in the 8 cases were 5 recoveries and 3 deaths.

DISCUSSION.

DR. GUY LEROY HUNNER, Baltimore, said that he would rather err on the side of operating occasionally unnecessarily than to commit the error of not interfering and be too late. He cited cases in point.

DR. W. P. CARR stated that the more he sees of cases of intestinal obstruction, the more he is convinced that whenever there is a strong suspicion of it an exploratory operation should be made. There are so many cases that have little or no symptoms for quite a while, and others that have considerable fecal movements in the lower bowel after obstruction has taken place, that one is apt to be misled. He has been misled a number of times.

DR. J. GARLAND SHERRILL, Louisville, Ky., advocates early operation in these cases. Whenever a patient has intra-abdominal pain, which is not properly relieved, an exploration should be made. Whenever a patient has a severe pain in the abdomen that ceases suddenly, it is likely to be the result of gangrene of the gut, and for that reason such a case demands very prompt operation. Many of these patients can be saved by opening the abdomen at once, even in the presence of shock, and in this way inflammation of the peritoneum may be avoided.

DR. CHAS. L. BONIFIELD, Cincinnati, recommends changing to ether when patients cannot stand chloroform, particularly in children.

DR. W. O. ROBERTS, Louisville, Ky., narrated the case of a child, 9 months old, on which he had operated. The child had been treated for dysentery. When he saw the patient there was a considerable amount of distention of the abdomen, great straining on the part of the child, and bloody mucus passed by the bowel. He introduced his finger into the rectum and found an intussusception. The intussusception was within two inches of the anus. Laparotomy was performed, and he found that the intussusception began at the ileocecal opening, and extended to within two inches of the anus. It was relieved; but the child died in the course of 12 hours from shock. He thinks it important in all cases of intestinal obstruction to examine the rectum carefully.

DR. WM. E. PARKER, Hot Springs, Ark., said that the general practitioner should be impressed with the importance of early diagnosis in these cases, and if there is any question, to call in a general surgeon or some one who has had experience in this class of cases. After the diagnosis is made, one should get into and out of the abdomen as quickly as is consistent with good work.

DR. W. P. NICOLSON, Atlanta, Ga., said that we should always bear in mind that the location of pain in the abdomen

in many cases bears practically no relation to the site of the lesion.

DR. SAMUEL J. MIXTER said that a patient who has had intestinal obstruction for days, and is in a very critical condition, can be saved, if too much is not attempted. Many of these patients die because surgeons attempt too much. In a case of gangrene following intussusception, if a simple opening is made in the distended loop of bowel, a tube tied in, and the intestine drained, a later operation can be done, and the patient probably be saved, whereas if one attempts to do a resection or a serious operation at the time, the patient will almost surely die.

DR. A. PALMER DUDLEY stated that the surgeon is at a great disadvantage when he is called to a patient to whom morphin has been administered for pain, because it masks the symptoms. Peristalsis is arrested, and the obstruction goes on more rapidly. He has not given a dose of morphin in 15 years to any patient on whom he has performed an abdominal section.

A Review of One Thousand Operations for Gallstone Disease.

This joint paper by DRs. WILLIAM J. MAYO and CHARLES H. MAYO, Rochester, Minn., was read by the latter. In 1,000 operations for gallstone disease there were 50 deaths—5 per cent.—counting as a death every patient operated on who died in the hospital without regard to cause of death or length of time thereafter; 960 for benign disease, with 4.2 per cent. mortality. More than one procedure through a single incision, only the major was counted, therefore 101 cholecystostomies, and 44 cholecystectomies in connection with common duct operations were not included. Of 673 cases operated on by cholecystostomy there was a mortality of 2.4 per cent. This group included most of the acute infections. In no case did the stones re-form in the gall bladder. This is the operation of choice in the average uncomplicated case, and especially if there is or has been cholangitis.

Of cholecystectomy, there were 186 operations, with a mortality of 4.3 per cent. This operation was employed for special indications, such as cystic duct obstruction, thick-walled gall bladders suspicious of malignant disease, and cholecystitis without calculi. There were 137 operations for stone in the common duct, with a mortality of 11 per cent., 7 per cent. from the operation, and 4 per cent. from secondary complications after more than three weeks. Of the cases operated on during the quiescent period, with little jaundice and slight infection, all recovered. There were 4 cases with extreme icterus from obstruction, who had subcutaneous hemorrhages at the time of operation (purpura). All of these died; 4 cases of complete biliary obstruction in which the common and hepatic ducts were filled with clear cystic fluid and no bile; all died. Including malignant disease, 14.6 per cent. of the total were of the common duct; 40 cases of malignant disease, with 22.5 per cent. mortality; 2 cases with cancer of the gall bladder now alive and well, more than two years after operation; 2 additional favorable cases of more recent date. Of the remaining malignant cases, a few received marked palliation, but the majority were but little benefited.

Enterostomy.

DR. J. W. LONG, Greensboro, N. C., reported 8 cases of enterostomy occurring in 22 years of practice, with 5 recoveries, or 62.5 per cent. He drew the following conclusions:

1. Enterostomy is a life-saving measure and never an operation of choice.
2. It is not indicated where a more ideal surgical procedure is feasible.
3. In the hands of an experienced, carefully trained, competent surgeon, capable of dealing with grave emergencies, enterostomy need rarely be resorted to, but the better the surgeon the more quickly he will adopt any measure which will rescue his patient.
4. Every abdominal surgeon must, according to the abundance of his material, find cases in which only enterostomy can with propriety be done.
5. When an enterostomy is indicated, to hesitate is to lose the patient; to operate promptly and with delicate means to tide the patient over the imminent peril and spare him for future consideration.

DISCUSSION.

DR. JAMES A. GOGGANS, Alexander City, Ala., said that

drainage of the distended intestines is very important. He makes it a rule, if possible, when he does a laparotomy for any trouble whatever, to drain the intestine in order to let it regain its elasticity and to move the fecal current along as it should go.

DR. J. GARLAND SHERRILL believes that enterostomy has a place in surgery in those cases in which complete surgery can not be done; but whenever a surgeon sends a patient away from the operating table with an open intestine, he subjects the profession and himself to criticism from the laymen who do not understand the condition. Therefore, he would lay it down as a rule that no enterostomy should be done in any case where it is possible to do complete surgery, and instead of widening the field for enterostomy, surgeons should strive to contract it.

DR. I. S. STONE, Washington, D. C., said that Dr. Long must have got hold of a number of very difficult and delayed cases for operation. He thinks his idea is that rather than let a patient die from obstruction, he would catch up a loop of bowel and make an artificial anus. This is the old-fashioned way of doing enterostomy, and Dr. Long obtained as good a mortality as most surgeons would have gotten under the same circumstances.

DR. LONG said that he has, unfortunately, had quite a number of cases in which it seemed proper to do enterostomy. These 8 cases were spread over a period of more than 22 years' practice. He doubts if any surgeon has a better percentage of recoveries in cases of acute intestinal obstruction by any method than that which he had reported, namely, 62.5 per cent.

(To be Continued.)

CHICAGO MEDICAL SOCIETY.

Regular Meeting, held Nov. 16, 1904.

The President, Dr. John B. Murphy, in the Chair.

The Advantage of Muscle-Splitting and Muscle-Retraction Incisions in the Prevention of Ventral Hernia.

DR. MARTIN B. TINKER, Ithaca, N. Y., read a paper (by invitation) on this subject, saying that the very considerable number of ventral hernias, following clean, uncomplicated abdominal operations, should furnish ground for reflection as to the necessity for their occurrence. The number of these cases which have come to him during the past year has formed almost 4 per cent. of his total number of cases. He believes that the patients seldom return for the cure of their hernia to the surgeon who performed the original operation causing the hernia. The state of many of these patients, with their constant discomfort from wearing some form of abdominal support, with pain from adhesions about the hernial opening, and with the not infrequent occurrence of symptoms of strangulation, often makes their condition but little preferable to that for which the original operation was undertaken.

To avoid the disadvantages of the rectus incision, especially the paralyzing of the median side of the muscle, and in opening the abdomen for pelvic operations of any kind, Dr. Tinker usually employs the Pfannenstiel supra-symphysis cross incision, which gives free access to the pelvis and organs near the median line of the body, although if freer exposure is desirable, the Lennander rectus retraction incision is preferable. The Pfannenstiel incision has the possible additional advantage of placing the scar below the pubic hair line, where it is not noticeable. It will be found very satisfactory for myomectomy; operations on the tubes or ovaries; advancement of the round ligaments for backward displacement, or other operations near the median line of the lower part of the abdomen. For abdominal hysterectomy the Lennander incision is better, and also for exploration of the right iliac fossa, where involvement of the pelvic organs is suspected. Where simple appendectomy is to be performed, the McBurney muscle-splitting incision is prefer-

able, but when appendectomy is combined with work in the pelvis, the Lemander incision is the better. Operations in the upper abdomen are less likely to be followed by post-operative hernia, but the muscle-splitting incisions in the treatment of diseases of the gall passages afford far greater security against the occurrence of ventral hernia.

Healing by first intention is of great importance in the prevention of ventral hernia; the careful arrest of hemorrhage, to prevent accumulation of blood in the wound, not only lessens the danger of infection, but favors firm healing. The prevention of strain after operation, by distention, postoperative nausea and vomiting is also very important, as is also the prevention of strain on the wound by the patient exerting himself too early. The accumulation of intestinal gases can be greatly lessened, if not entirely prevented, in most cases by thoroughly emptying the intestinal tract before operation, and by careful attention to the bowels afterward.

The possibility of getting the patient out of bed at an early date following operation with a feeling of absolute security from hernia, and without the necessity for wearing a binder, is a great satisfaction and sufficient reward for the extra pains and few additional minutes of time required to open and close the abdomen by any one of these methods.

DISCUSSION.

DR. L. L. MCARTHUR stated that the lines of cleavage described by Kocher bear a relationship to three factors: to those lines in which the least tension would occur; to those in which the least destruction of muscular fiber or actual paralleling of muscular fiber will occur; and, finally, to those incisions in which the innervation of the muscles involved shall not be disturbed. He said that he was very much surprised that in any man's statistics, in uncomplicated cases, where drainage has not been necessary, that so large a per cent. as one in five, or 20 per cent. of hernias, should occur. It may be applicable on the basis that patients do not return to the surgeon who has been the cause of the hernia. He thinks a very decided improvement is an incision at the edge of the rectus, where occasionally one finds it necessary to go into the pelvis for complications in operations which are associated with appendical work, as ovarian tumor, suppurative tubes, twisted ovarian pedicle, etc.

DR. ARTHUR DEAN BEVAN agreed with Dr. Tinker as to the importance of planning incisions so as to reduce the danger of resulting postoperative hernia to a minimum. First, plan the incision so as to give free and sufficient exposure to do the operation. Second, plan the incision so as to give the least possible danger of a resulting hernia. In opening the abdomen to remove a large fibroid of the uterus, one could not employ the Pfannenstiel incision, and, in opening the abdomen to remove a large spleen, one can not employ the muscle-splitting incision. In opening the abdomen posteriorly, to remove a large tumor of the kidney, the muscle-splitting incision is out of the question. Furthermore, in opening the abdomen to operate on the common duct, the muscle-splitting incision should not be considered. An incision can be planned for the exposure of the kidney, which is parallel with the nerves of the region of the abdominal wall, yet not a muscle-splitting incision, and in which there will be very little danger of hernia. An oblique incision, parallel with the costal arch in the upper abdomen, which divides nerves, muscle fibers, or fibrous tissue transversely, is not nearly so apt to be followed by hernia as a muscle-splitting incision in the lower portion of the abdominal wall. It is rare to have a hernia following an incision parallel with the costal arch for gall-bladder work. He does not think, however, that the muscle-splitting operation should be employed where other factors are more weighty. An incision in the linea alba is a very safe and useful one, and he employs it quite extensively. He thinks that the statistics of 7 per cent., or 20 per cent., are altogether too great. Why should there be a hernia in a median incision of from three to six inches in length which heals by primary intention, and where the pa-

tient has been allowed to remain in the recumbent position until wound healing is complete? German surgeons have more hernias following their operations than American surgeons. Statistics of operations from the Heidelberg Clinic, by Czerny, which have been extensively reported in the *Beiträge zur Klinische Chirurgie* for the last four or five years, show the proportion of hernias to be from 20 to 25 per cent. in suppurative cases. This percentage would be considered large in America. The length of the incision is of comparatively small importance as compared with primary wound healing. The recumbent position should be maintained until wound healing is complete. He does not approve of a patient getting up on the second day, after a muscle-splitting incision or not.

DR. E. WYLLYS ANDREWS said he had supposed that the Pfannenstiel incision is a skin incision only. He has only used it a few times. He goes one-half or three-quarters of an inch out from the median line and secures muscular wall for the incision. He attaches a good deal of importance to the imbrication idea, even in ordinary celiotomy.

DR. A. J. OCHSNER said that whoever has witnessed the German clinics knows that several things are done which must result in bad unions. First, the incision usually is made very long; second, the tissues are handled roughly; third, the stitches are applied with the least possible amount of care and accuracy; fourth, they are tied so tightly that they tend to cause pressure necrosis. All those factors are bound to cause ventral hernia. He said that there is not .25 per cent. of ventral hernia possible provided the conditions he mentioned are carried out. He has followed many hundreds of his cases, and in those in which there was no drainage nor suppuration there was no ventral hernia. There can not be a ventral hernia if the different layers are accurately and properly approximated. He places a silkworm-gut suture down through the transversalis fascia as an emergency suture, so that if the patient should sneeze severely at the time when the catgut has become softened, there will be a safety suture on the outside to hold it. He sutures the peritoneum and transversalis fascia together; he passes a second catgut suture through the muscle, and a third catgut suture through the aponeurosis of the external and internal oblique, and ties the silkworm-gut suture sufficiently loosely to guard against pressure necrosis. Furthermore, he applies, for emergency's sake again, broad adhesive strips, so that if the patient should strain, vomit severely, or sneeze, the soft tissues will not be torn. He takes the additional precaution of always emptying the bowels thoroughly before operation, and of keeping them moved always so as not to cause a great amount of intraabdominal pressure.

DR. E. C. DUDLEY said that the probabilities are that the most practical single incision for exploration is one that is made near the median line. He makes his so-called median incision through the right rectus muscle, parallel with the fibers of the muscle, somewhere near the inner margin of the muscle. This is done in order to avoid ventral hernia or to get a more accurate closure. For many years he has abandoned the through-and-through suture and has used chromicized catgut, suturing layer by layer, first the peritoneum, the posterior fascia, the anterior fascia over the rectus muscle, and then, if there is a great deal of subcutaneous structure, sutures through that and then inserts a buried suture for the skin.

DR. WILLIAM CUTHBERTSON stated that Pfannenstiel recognizes the limitations of his own incision, which is applicable to the removal of large tumors or of appendices complicated by some pelvic difficulty where there may be a short meso-appendix or oecum. He agreed with Dr. Bevan in reference to the after-treatment. Experiments which he has made on dogs have directed his attention particularly to the fact that, after having opened the abdomen of a dog, forty-eight hours later it was quite easy to open the wound by simply pressing the finger through the line of incision. In from four to five days it was hard to open the skin incision with the finger, and it usually required the handle of a scalpel,

a Kocher dissector, or a moderately sharp instrument to re-open the skin incision. After getting through the skin, it is an easy matter, with the finger, to separate the abdominal muscles and to re-enter the abdominal cavity. In abdominal operations we should not be in such a great hurry to get patients out of bed unless they are old and feeble, but to give them a longer time to let wound healing be complete. Furthermore, to have thorough hemostasis before closing the abdominal wound, and not leave a blood clot between the surfaces of the wound to become organized.

DR. CARL BECK stated that German surgeons publish a larger number of statistics than do Americans, because they keep more exact clinical records. If patients in America have hernia they do not return to the clinics as do the patients in Germany, but they go to other surgeons. The percentage of hernia, therefore, following operations in America is much greater than would appear from what has been said. Secondary union is due in many instances to poor hemostasis in closing the abdomen. He has removed large tumors through a small transverse incision because one can stretch the incision. The muscles are not split, but simply the fascia. The disadvantage of this method is that we open large surfaces, and if exact hemostasis is not secured secondary union is invited, which can be avoided in the other incision by putting in a number of sutures of catgut or of silk. He avoids sup-puration by putting in drainage in the septic cases clear down to the surfaces that had been divided. With the addition of tubal drainage, one can employ this incision satisfactorily and can avoid hernia.

DR. ALBERT GOLDSPOHN said that his belief is that the percentage of hernia is far less than that mentioned, and he is inclined to regard it as almost a closed chapter. The cardinal principles of closure of wounds must be carried out, or there will be a hernia. He described a technic similar to that of Dr. Ochsner, except that he does not find it necessary to open the sheaths of both recti, but severs one rectus muscle and opens one sheath only, not splitting the muscle, but separating it from the linea alba, and then uniting it with a few through-and-through sutures to guard against the accumulation of serum or of blood between the layers of the wound.

DR. TINKER said that he would not have any one believe that he advocates these incisions for all kinds of surgical work. No one recognizes their limitations any more clearly than he does. It is not his custom to allow his patients to get up in less time than a week, and usually not until ten days after operation. Healing is not likely to be complete until that time; but he does feel perfect confidence in allowing a patient with one of these incisions to get up at the end of two weeks, at the latest, without the use of any binder, and he has yet to see any evil results following it.

Travel Notes.

GRANT MEDICAL COLLEGE AND THE HOSPITALS OF BOMBAY.

NICHOLAS SENN, M.D.
CHICAGO.

(Concluded from Page 1895.)

PREVALENT DISEASES.

Tropical abscesses are very common in Bombay. They affect most frequently the thighs and gluteal regions. They do not give rise to serious constitutional symptoms and the local symptoms are likewise mild. Speedy healing after incision and drainage may confidently be expected. Tetanus is most frequently met with during the two hottest months of the year, April and May. The serum treatment has not had an extensive trial, and the mortality is large, more than 50 per cent. In one case an intracerebral injection of the antitetanic serum was made. The patient died. On postmortem

the serum was found at the site of injection, no absorption having taken place. In the treatment of tetanus, hydrate of chloral and potassic bromid in very large doses are relied on. Hydrophobia is quite prevalent in India. Bombay sent last year 65 cases of suspected dog bite to the Pasteur Institute at Simla. Elephantiasis of the scrotum is much more common among the Parsees than among the Hindus. Patients thus affected now seek surgical relief before the weight of the swelling becomes a source of great inconvenience, as the former objections to the operation have been overcome by the better operative results. Many cases of hydrocele in young men develop during the hottest months of the year. About from fifty to sixty cases of stone in the bladder apply for relief every year.

Hernia in women is very rarely met with in India, and the surgeons believe that this is due to their spare bodies and the vigorous exercise incident to the hard work the common women are required to undergo. Several cases of Madura foot and ainhum find their way into the hospital every year. Actinomycosis and blastomycosis are not known here. In the coolies gonorrhoea pursues a very mild course. No local treatment is used. Under internal use of an alkaline mixture, the disease subsides in the course of ten days.

HOMELESS LEPER ASYLUM, MATUNGA, BOMBAY.

One of the most creditable and beneficial of the hundreds of charity institutions of Bombay is the Homeless Leper Asylum in the suburb Matunga. It is the largest leper asylum in India, and at present it is the home of 370 lepers. The inmates are well cared for, and instead of living the lives of outcasts in misery, beggary and much suffering, are well housed, kindly treated, and their discomforts and pains alleviated to a remarkable degree. Segregation has never been carried into effect, and there are now about 150 vagrant lepers roaming the streets of Bombay. Mr. H. A. Acworth, I.C.S., C.I.E., municipal commissioner for the city of Bombay from 1890 to 1895, is the founder of this model institution, as it was through his influence that the necessary funds were obtained. Rich merchants and native princes responded to his appeal and made liberal contributions. The many tile-roofed, one-story brick pavilions are situated in grounds embracing 11½ acres of fertile land, advantageously located, enclosed and unenclosed; municipal and leased from the government at a nominal rent. On the morning of Nov. 7, 1890, about fifty vagrant lepers were collected by the health department and the police at various centers and, after medical examination, were sent to the asylum under police escort and, after thorough cleansing and change of clothes, were entered as the first installment of patients of the leper home. The poor lepers have since learned from experience and observation the full extent of the benign and humane intentions of the asylum and now enter it voluntarily in increasing numbers, happy in the thought that by doing so their short lives will be made more endurable by the care and kind treatment which awaits them there. The grounds are beautifully laid out and ornamented with trees and flowers. The garden of roses is one of the finest in Bombay. In the grounds there is a school for children, a Roman Catholic Church, a Hindu temple and Mohammedan mosque. All the Hindus that die in the asylum are cremated by the inmates, according to the Hindu custom. After appropriate ceremony, in a place set apart at the extreme east corner of the grounds, the rites incidental to cremation are performed by the patients themselves, and one khandi (28 maunds) of firewood is allowed for each corpse, at a cost of 8¼ rupees (\$2.72). A bier and pall are provided for the Mohammedans and the corpses are removed to the cemetery at Marine Lines by bearers, who are sent from the city and are paid at the rate of about 7 rupees (\$2.24) per corpse, to defray the charges of conveyance and all incidental expenses. A Mohammedan priest, who has been the subject of the anesthetic form of leprosy for 11 years and an inmate of the asylum for 5 years, attends to the spiritual needs of those inmates of the asylum who are of the same religious belief and receives a small salary for his services. A Roman Catholic priest from Bombay visits the

asylum regularly every week. The Roman Catholic dead are removed from the asylum for burial at the expense of their fund, all arrangements being made for the purpose by the Rev. Father Peters, S.J. The Protestants have a pauper funeral at the expense of the asylum funds. The Protestant missionaries do not seem to be aware of the existence of the Homeless Leper Asylum or its contingent of protestant inmates. One of the most interesting features of the asylum is the small sewage farm connected with it, and which is fertilized with sterilized sewage. The sterilization is effected by collecting all the sewage and passing it through a series of open tanks. This method of sterilization and utilization of sewage has been found entirely satisfactory and has been a source of no inconsiderable income to the asylum. The report of the asylum shows about the following proportion of the various religious beliefs of the inmates:

	Percentage.
Hindus (Maharattas)	66.43
Mohammedans	9.32
Christians	10.61
Hindus (low caste)	13.41
Other castes23

There are about twice as many men as women, and the children constitute about 2.5 per cent. of all the inmates. One of the touching instances among the many I saw in visiting this great institution was a group of children, numbering about 15, who had just left the schoolroom and had congregated near the gate of entrance to the grounds to bid the visitors good-bye. They ranged in their ages from 6 to 12 years and were all lepers.

The anesthetic and tubercular forms of the disease are about equally represented, and the mixed form affects about 12.63 per cent. of all cases. The dispensary is well supplied with medicines, the hospital is scrupulously clean and supplied with comfortable cots. A physician visits the asylum every day, and his assistant resides in the institution, always ready to render necessary medical and surgical aid.

THE PLAGUE RESEARCH LABORATORY OF THE GOVERNMENT OF INDIA, PAREL, BOMBAY.

This institution owes its origin to Mr. W. M. Haffkine, C.I.E., a Russian scientist, who has rendered India such signal service since 1893, first by his prophylactic treatment of cholera by serum inoculations and later by his discovery of a serum against the plague. I was very anxious to meet Mr. Haffkine, but unfortunately he was absent on a visit to Europe, but I met in his place Lieut. Col. W. B. Bannerman, M.D., B.S.C., I.M.S., who temporarily filled his place as director-in-chief of the laboratory and who holds the permanent position as superintendent. The former residence of the governor of Bombay, at Parel, a beautiful suburb, has been converted into a laboratory and the former ballroom is now the place where the anti-plague serum is brewed, and halls and bedrooms where fashion reigned are now occupied by dozens of cages containing animals for experimental use.

According to a paper presented by Lieut. Col. Bannerman to the Royal Society of Edinburgh in 1902, the serum treatment, in the prevention of the bubonic plague, devised by Haffkine, is reliable and specific in its results. The immunity thus obtained remains throughout an epidemic and has been known to last two years; its exact maximum limits, however, remain undetermined. The serum is prepared on a very large scale and is sent wherever needed free of expense through government channels. Wide bottles with long, narrow necks, holding about a liter, are filled with bouillon and the culture medium is inoculated with the plague bacillus. A characteristic growth in the form of innumerable hanging stalactite-like threads form. At the end of two months the culture is sterilized by boiling and is kept ready for use in another room. The culture and serum rooms contain hundreds of these bottles, protected against contamination by a cotton plug with ends burnt off. The prophylactic treatment consists in making a single hypodermic injection of from 4 to 5 c.c. of the sterilized culture under strictest aseptic precautions. All subjects thus treated have escaped the disease, even in badly infected districts. The experience with this

serum has reached enormous dimensions and its absolute reliability can no longer be questioned. Accidents have happened, but they could always be traced not to the serum *per se*, but to its improper administration. Bannerman concludes his paper as follows: "The final conclusion, then, appears to be that in this discovery of Haffkine's we have within our reach a means of controlling an epidemic of plague and converting it into a manifestation of sporadic cases only, easily controlled and exciting little alarm."

Haffkine receives a salary of 2,000 rupees (\$640) a month, an amount not any too large for the man through whose scientific researches two of the most dreadful epidemic diseases of India are on the way to extinction.

BOMBAY BUBONIC PLAGUE HOSPITAL.

During my tour through the tropics I made frequent inquiries at the different ports for the purpose of finding an opportunity to see cases of bubonic plague. All the ports were free from this disease until I came to Bombay. For four years Bombay has been the center of an epidemic of this disease and in consequence a dreaded port for navigators and ship owners. The disease has passed its climax and is gradually being gotten under control. The plague hospital is located outside of the city limits and consists of a row of one-story brick buildings which serve as wards.

During the height of the epidemic as many as 30 patients a day were admitted from the city and nearby villages. The mortality has been very great. Many die from the general sepsis, others from pulmonary and other complications. After a period of incubation of from five to seven days, the disease is ushered in abruptly with very high temperature and other symptoms indicative of a profound constitutional disturbance. The inguinal glands are most frequently involved, next the glands of the axillary spaces. The cervical glands are very seldom affected. Enucleation of the suppurating glands has been tried, but was abandoned, as it was found that after such attempts to cut short the local infection, the general infection usually became aggravated.

The local treatment resorted to now consists in the use of poultices until fluctuation is distinct when the abscesses are incised and the antiseptic gauze dressings take the place of the poultices. The general treatment is supporting and stimulating. Large abscesses frequently develop remotely from the infected glandular regions. At the time of my visit about 25 patients remained in all stages of the disease. Some of them were in the height of the primary fever, more of them were slowly recovering from extensive glandular abscesses in the inguinal regions. I only saw two patients in which the axillary glands were also involved. In all the inguinal abscesses that had been incised the enlarged glands partially isolated from the surrounding tissues presented a grayish appearance with no indications of any attempt at repair.

Some of these survivors had been in the hospital for two or more months. One of the convalescents, who had recovered sufficient strength to walk about, had lost his speech, the result of cerebral complications which set in during the acute stage of the disease. All convalescents were emaciated to an extreme degree. Three heroic trained female nurses take care of the sick, aided by male and female helpers. One of these nurses has been on constant duty since the epidemic commenced, more than four years ago, and notwithstanding the arduous and trying duties that she has so faithfully performed her general health has not suffered; an interesting proof of woman's endurance under circumstances that would be a severe test on the strength of the strongest man.

A COBRA DEN.

My visit to the research laboratory was made late in the day. It was during the short twilight and in the absence of electric or gas lighting we had to find our way through the dark halls and rooms of the former palace of the governors of Bombay with the aid of the light of a lantern. Lieut.-Col. Bannerman led the way. We passed through halls and rooms on the first floor between rows of cages containing rabbits, guinea pigs, rats and mice, and the little creatures, scared

by the appearance of the late visitors, were roused from their dormant condition and displayed an activity begotten by fear. We finally came to the door of a large room in which darkness was complete. The moment we entered a fearful hissing from every part of the room greeted us, mingled with short raps resembling the tapping sound made by striking a wire screen with a small hammer. I was in a cobra den, in the midst of 150 of these terrible reptiles, imprisoned in cages, it is true, but wide awake and roused to anger by our untimely intrusion. They were assisted in their hissing and striking against the wire screen which guarded the open end of their cages by 50 other snakes still more venomous, Russell's viper. (*Daboia russellii*.) Through the meshes of the wire screen shot the forked tongues of 200 of the most venomous reptiles known. Add to the hissing and striking noises the 200 forked red tongues, 400 staring, deceptive and treacherous eyes, the snaky odor that pervaded the atmosphere of their dungeon and you will have a good idea of what is meant by a cobra den. The cobra (*Naja tripidians*) is about four feet in length, and when angered the flat head and neck expand into wing-like projections on each side, increasing their width to the size of the palm of the hand. The color is almost black, the tail tapering into a sharp point. The viper is of about the same size, but has circular stripes. I know of no more ugly sight than a cobra in striking attitude. Every snake in the room was in a fighting mood, hissing and striking the wire screen with a thud-like noise; at short intervals red forked tongues shot out through the meshes of the wire screen on all sides, and the situation was made more horrible by the revolting snake smell issuing from so many cages.

The snake, the most despised animal in creation, is an object of fear and horror to all who are familiar with his damnable record in the Garden of Eden and with the curses imposed on him by the Almighty. I did not know but some of these terrible beasts might be at liberty in that large imperfectly lighted room, and only breathed easy again after we had left the room and the door was shut and securely locked.

It was prearranged that I should become more familiar with the dangerous part of the anatomy of cobra and viper. We ascended the broad staircase leading to the second floor and entered the office of the superintendent of the laboratory, Lieut.-Col. Bannerman, who on this occasion extended so many courtesies to me. He sent for the "snakeman," and in a very short time three coolies made their appearance with so many snakes in their cages, one cobra and two vipers. I was to witness the "milking" of their poison sacs. I begged to be informed beforehand how this was to be done in order that I might make my own plans of conduct for safety during the ordeal. The superintendent smiled and said: "You must see for yourself." The snakes were in an offensive attitude, as they had undergone this procedure repeatedly and had learned by experience to dread it. I could see no opening in the boxes through which the snakes could be made *hors de combat*.

The "snakeman" was a very slender coolie, with very long, thin arms and legs, and fingers like the claws of a monkey.

The cobra, with its raised, expanded head in striking position came first. The man held a smooth stick the size of an ordinary cane and about two feet in length in his left hand. Suddenly, standing behind the box with the wire screen directed toward him, he threw open the opposite side with a lightning jerk and out shot the angry monster, and in undulating rapid movements advanced toward me. A quick retreat on my part behind the table increased the distance between us. Before the snake had advanced three feet the "snakeman" grasped the end of his tail with a lightning movement of the right hand, lifted it high in the air, and with the stick passed from tail to neck prevented a recoil, lowered it to the floor. With the stick, the neck was pressed against the floor, the right hand, quickly substituted for the stick, grasped the neck firmly and with the left hand made traction on the tail, thus straightening out the squirming body. A small goblet, covered drum-like with American adhesive plaster with adhesive side directed outward, was placed near enough for the snake to strike it. The fangs penetrated the plaster

and by pressure against the poison sacs about half a dram of viscid opaque fluid escaped into the sterilized goblet. The cobra was returned into the cage with the same expertness as characterized its liberation. The whole procedure did not occupy more than ten minutes. Snakes refuse all food during confinement, hence they are fed each time the poison is removed, which is done every 10 days. The long tip of a small funnel is inserted into the throat and about two ounces of a mixture of egg and milk is poured into the funnel, which enters the alimentary canal without meeting any obstruction. The vipers were then handled in a similar manner, only that in their case the poison was received direct from the fangs into an open goblet by opening the mouth widely with a pair of forceps and steadying the fangs with a thread passed around them and on which traction was made by an assistant, who at the same time held the goblet. I could see distinctly the drops of poison escape through the tiny opening at the very tip of the enormous fangs, which looked like fish hooks without a barb.

The poison is desiccated in the laboratory under aseptic precautions, and is later sent to another laboratory, where it is used in the preparation of Calmette's antivenene. There is no lack of an adequate supply of cobras and vipers for this laboratory as they are bought from the natives at from a few annas to one rupee each.

CALMETTE'S ANTIVENENE.

Calmette of Lille is the discoverer of antivenene. Captain Lamb, I.M.S.,¹ who has made a very careful study of the therapeutic value of this agent in the treatment of bites of poisonous snakes has come to the conclusion that antivenene prepared from the venom of one genus of snakes is only curative in the treatment of bites inflicted by that genus and no other, a position fully endorsed by Lieut. Col. Bannerman.² Convincing experimental research and a large clinical experience combine to prove that the antivenene prepared from the cobra venom is, if used in time, a specific for cobra bites, but useless in the treatment of bites of the viper. Reasoning from this standpoint, it seems to me that an antivenene prepared from the venom of our rattlesnake ought to prove successful in the treatment of bites inflicted by this genus of snakes.

Only one accident has so far occurred in the Parel Laboratory. A coolie in handling a cobra struck one of his thumbs against one of the fangs. Antivenene of doubtful age was used at once, but proved useless in warding off the immediate symptoms provoked by the poison. Great prostration set in, he became paralyzed in the lower limbs and unconscious. Antivenene from another source was quickly procured and administered half an hour after the accident occurred. The threatening symptoms disappeared promptly and in three hours the patient was able to walk to his house. Gangrene of the end of the thumb, however, occurred, which proved the intensity of the local action of the cobra venom.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Tapeworm.

There are two principal varieties of tapeworm in man, the *tinea solium*, the pork tapeworm, and *tinea saginata* or beef

1. Snake Venoms: Their Physiological Action and Antidote. Journal Bombay Natural History Society, p. 220, vol. xiv.

2. The Use of Calmette's Antivenene in Snakebite in India. Journal Bombay Natural History Society, vol. xv.

asylum regularly every week. The Roman Catholic dead are removed from the asylum for burial at the expense of their fund, all arrangements being made for the purpose by the Rev. Father Peters, S.J. The Protestants have a pauper funeral at the expense of the asylum funds. The Protestant missionaries do not seem to be aware of the existence of the Homeless Leper Asylum or its contingent of protestant inmates. One of the most interesting features of the asylum is the small sewage farm connected with it, and which is fertilized with sterilized sewage. The sterilization is effected by collecting all the sewage and passing it through a series of open tanks. This method of sterilization and utilization of sewage has been found entirely satisfactory and has been a source of no inconsiderable income to the asylum. The report of the asylum shows about the following proportion of the various religious beliefs of the inmates:

	Percentage.

A physician visits the asylum every day, and his assistant resides in the institution, always ready to render necessary medical and surgical aid.

THE PLAGUE RESEARCH LABORATORY OF THE GOVERNMENT OF INDIA, PAREL, BOMBAY.

This institution owes its origin to Mr. W. M. Haffkine, C.I.E., a Russian scientist, who has rendered India such signal service since 1893, first by his prophylactic treatment of cholera by serum inoculations and later by his discovery of a serum against the plague. I was very anxious to meet Mr. Haffkine, but unfortunately he was absent on a visit to Europe, but I met in his place Lieut. Col. W. B. Bannerman, M.D., B.S.C., I.M.S., who temporarily filled his place as director-in-chief of the laboratory and who holds the permanent position as superintendent. The former residence of the governor of Bombay, at Parel, a beautiful suburb, has been converted into a laboratory and the former ballroom is now the place where the anti-plague serum is brewed, and halls and bedrooms where fashion reigned are now occupied by dozens of cages containing animals for experimental use.

According to a paper presented by Lieut. Col. Bannerman to the Royal Society of Edinburgh in 1902, the serum treatment, in the prevention of the bubonic plague, devised by Haffkine, is reliable and specific in its results. The immunity thus obtained remains throughout an epidemic and has been known to last two years; its exact maximum limits, however, remain undetermined. The serum is prepared on a very large scale and is sent wherever needed free of expense through government channels. Wide bottles with long, narrow necks, holding about a liter, are filled with bouillon and the culture medium is inoculated with the plague bacillus. A characteristic growth in the form of innumerable hanging stalactite-like threads form. At the end of two months the culture is sterilized by boiling and is kept ready for use in another room. The culture and serum rooms contain hundreds of these bottles, protected against contamination by a cotton plug with ends burnt off. The prophylactic treatment consists in making a single hypodermic injection of from 4 to 5 c.c. of the sterilized culture under strictest aseptic precautions. All subjects thus treated have escaped the disease, even in badly infected districts. The experience with this

serum has reached enormous dimensions and its absolute reliability can no longer be questioned. Accidents have happened, but they could always be traced not to the serum *per se*, but to its improper administration. Bannerman concludes his paper as follows: "The final conclusion, then, appears to be that in this discovery of Haffkine's we have within our reach a means of controlling an epidemic of plague and converting it into a manifestation of sporadic cases only, easily controlled and exciting little alarm."

Haffkine receives a salary of 2,000 rupees (\$640) a month, an amount not any too large for the man through whose scientific researches two of the most dreadful epidemic diseases of India are on the way to extinction.

BOMBAY BUBONIC PLAGUE HOSPITAL.

During my tour through the tropics I made frequent inquiries at the different ports for the purpose of finding an opportunity to see cases of bubonic plague. All the ports were free from this disease until I came to Bombay. For four years Bombay has been the center of an epidemic of this disease and in consequence a dreaded port for navigators and ship owners. The disease has passed its climax and is gradually being gotten under control. The plague hospital is located outside of the city limits and consists of a row of one-story brick buildings which serve as wards.

During the height of the epidemic as many as 30 patients a day were admitted from the city and nearby villages. The mortality has been very great. Many die from the general sepsis, others from pulmonary and other complications. After a period of incubation of from five to seven days, the disease is ushered in abruptly with very high temperature and other symptoms indicative of a profound constitutional disturbance. The inguinal glands are most frequently involved, next the glands of the axillary spaces. The cervical glands are very seldom affected. Enucleation of the suppurating glands has been tried, but was abandoned, as it was found that after such attempts to cut short the local infection, the general infection usually became aggravated.

The local treatment resorted to now consists in the use of poultices until fluctuation is distinct when the abscesses are incised and the antiseptic gauze dressings take the place of the poultices. The general treatment is supporting and stimulating. Large abscesses frequently develop remotely from the infected glandular regions. At the time of my visit about 25 patients remained in all stages of the disease. Some of them were in the height of the primary fever, more of them were slowly recovering from extensive glandular abscesses in the inguinal regions. I only saw two patients in which the axillary glands were also involved. In all the inguinal abscesses that had been incised the enlarged glands partially isolated from the surrounding tissues presented a grayish appearance with no indications of any attempt at repair.

Some of these survivors had been in the hospital for two or more months. One of the convalescents, who had recovered sufficient strength to walk about, had lost his speech, the result of cerebral complications which set in during the acute stage of the disease. All convalescents were emaciated to an extreme degree. Three heroic trained female nurses take care of the sick, aided by male and female helpers. One of these nurses has been on constant duty since the epidemic commenced, more than four years ago, and notwithstanding the arduous and trying duties that she has so faithfully performed her general health has not suffered; an interesting proof of woman's endurance under circumstances that would be a severe test on the strength of the strongest man.

A COBRA DEN.

My visit to the research laboratory was made late in the day. It was during the short twilight and in the absence of electric or gas lighting we had to find our way through the dark halls and rooms of the former palace of the governors of Bombay with the aid of the light of a lantern. Lieut.-Col. Bannerman led the way. We passed through halls and rooms on the first floor between rows of cages containing rabbits, guinea pigs, rats and mice, and the little creatures, scared

by the appearance of the late visitors, were roused from their dormant condition and displayed an activity begotten by fear. We finally came to the door of a large room in which darkness was complete. The moment we entered a fearful hissing from every part of the room greeted us, mingled with short raps resembling the tapping sound made by striking a wire screen with a small hammer. I was in a cobra den, in the midst of 150 of these terrible reptiles, imprisoned in cages, it is true, but wide awake and roused to anger by our untimely intrusion. They were assisted in their hissing and striking against the wire screen which guarded the open end of their cages by 50 other snakes still more venomous, Russell's viper. (*Daboia russellii*.) Through the meshes of the wire screen shot the forked tongues of 200 of the most venomous reptiles known. Add to the hissing and striking noises the 200 forked red tongues, 400 staring, deceptive and treacherous eyes, the snaky odor that pervaded the atmosphere of their dungeon and you will have a good idea of what is meant by a cobra den. The cobra (*Naja tripidans*) is about four feet in length, and when angered the flat head and neck expand into wing-like projections on each side, increasing their width to the size of the palm of the hand. The color is almost black, the tail tapering into a sharp point. The viper is of about the same size, but has circular stripes. I know of no more ugly sight than a cobra in striking attitude. Every snake in the room was in a fighting mood, hissing and striking the wire screen with a thud-like noise; at short intervals red forked tongues shot out through the meshes of the wire screen on all sides, and the situation was made more horrible by the revolting snake smell issuing from so many cages.

The snake, the most despised animal in creation, is an object of fear and horror to all who are familiar with his damnable record in the Garden of Eden and with the curses imposed on him by the Almighty. I did not know but some of these terrible beasts might be at liberty in that large imperfectly lighted room, and only breathed easy again after we had left the room and the door was shut and securely locked.

It was prearranged that I should become more familiar with the dangerous part of the anatomy of cobra and viper. We ascended the broad staircase leading to the second floor and entered the office of the superintendent of the laboratory, Lieut.-Col. Bannerman, who on this occasion extended so many courtesies to me. He sent for the "snakeman," and in a very short time three coolies made their appearance with so many snakes in their cages, one cobra and two vipers. I was to witness the "milking" of their poison sacs. I begged to be informed beforehand how this was to be done in order that I might make my own plans of conduct for safety during the ordeal. The superintendent smiled and said: "You must see for yourself." The snakes were in an offensive attitude, as they had undergone this procedure repeatedly and had learned by experience to dread it. I could see no opening in the boxes through which the snakes could be made *hors de combat*.

The "snakeman" was a very slender coolie, with very long, thin arms and legs, and fingers like the claws of a monkey.

The cobra, with its raised, expanded head in striking position came first. The man held a smooth stick the size of an ordinary cane and about two feet in length in his left hand. Suddenly, standing behind the box with the wire screen directed toward him, he threw open the opposite side with a lightning jerk and out shot the angry monster, and in undulating rapid movements advanced toward me. A quick retreat on my part behind the table increased the distance between us. Before the snake had advanced three feet the "snakeman" grasped the end of his tail with a lightning movement of the right hand, lifted it high in the air, and with the stick passed from tail to neck prevented a recoil, lowered it to the floor. With the stick, the neck was pressed against the floor, the right hand, quickly substituted for the stick, grasped the neck firmly and with the left hand made traction on the tail, thus straightening out the squirming body. A small goblet, covered drum-like with American adhesive plaster with adhesive side directed outward, was placed near enough for the snake to strike it. The fangs penetrated the plaster

and by pressure against the poison sacs about half a dram of viscid opaque fluid escaped into the sterilized goblet. The cobra was returned into the cage with the same expertness as characterized its liberation. The whole procedure did not occupy more than ten minutes. Snakes refuse all food during confinement, hence they are fed each time the poison is removed, which is done every 10 days. The long tip of a small funnel is inserted into the throat and about two ounces of a mixture of egg and milk is poured into the funnel, which enters the alimentary canal without meeting any obstruction. The vipers were then handled in a similar manner, only that in their case the poison was received direct from the fangs into an open goblet by opening the mouth widely with a pair of forceps and steadying the fangs with a thread passed around them and on which traction was made by an assistant, who at the same time held the goblet. I could see distinctly the drops of poison escape through the tiny opening at the very tip of the enormous fangs, which looked like fish hooks without a barb.

The poison is desiccated in the laboratory under aseptic precautions, and is later sent to another laboratory, where it is used in the preparation of Calmette's antivenene. There is no lack of an adequate supply of cobras and vipers for this laboratory as they are bought from the natives at from a few annas to one rupee each.

CALMETTE'S ANTIVENENE.

Calmette of Lille is the discoverer of antivenene. Captain Lamb, I.M.S.,¹ who has made a very careful study of the therapeutic value of this agent in the treatment of bites of poisonous snakes has come to the conclusion that antivenene prepared from the venom of one genus of snakes is only curative in the treatment of bites inflicted by that genus and no other, a position fully endorsed by Lieut. Col. Bannerman.² Convincing experimental research and a large clinical experience combine to prove that the antivenene prepared from the cobra venom is, if used in time, a specific for cobra bites, but useless in the treatment of bites of the viper. Reasoning from this standpoint, it seems to me that an antivenene prepared from the venom of our rattlesnake ought to prove successful in the treatment of bites inflicted by this genus of snakes.

Only one accident has so far occurred in the Parel Laboratory. A coolie in handling a cobra struck one of his thumbs against one of the fangs. Antivenene of doubtful age was used at once, but proved useless in warding off the immediate symptoms provoked by the poison. Great prostration set in, he became paralyzed in the lower limbs and unconscious. Antivenene from another source was quickly procured and administered half an hour after the accident occurred. The threatening symptoms disappeared promptly and in three hours the patient was able to walk to his house. Gangrene of the end of the thumb, however, occurred, which proved the intensity of the local action of the cobra venom.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Tapeworm.

There are two principal varieties of tapeworm in man, the *tinea solium*, the pork tapeworm, and *tinea saginata* or beef

1. Snake Venoms: Their Physiological Action and Antidote. Journal Bombay Natural History Society, p. 220, vol. xlv.

2. The Use of Calmette's Antivenene in Snakebite in India. Journal Bombay Natural History Society, vol. xv.

tapeworm. The latter is much more common in this country, while the former is more common in the continental countries of Europe. The presence of either in the intestinal canal of man may cause no symptoms whatever, and knowledge of their presence is made manifest only when a segment or series of segments appear in the stool. In other cases they give rise to an abnormal and ravenous appetite on account of their interference with digestion and assimilation of food. In other cases still reflex nervous disturbances may arise. Before outlining a treatment of tapeworm the general condition of the patient must be considered. If heart lesions are present and the patient has reached the age when changes in the heart muscle have taken place, care must be observed not to give those preparations which tend to depress and to produce too strong irritation to the gastrointestinal mucous membrane. Where marked arteriosclerosis is present those preparations which tend to produce the least amount of vomiting should be administered. It must also be remembered that those tœniifuges which produce the greatest subjective disturbances do not, in most cases, constitute the best treatment. On the other hand, it is sometimes necessary to employ these drastic measures before the entire worm can be removed. After the patient's physical condition has been ascertained he should be put on a modified diet for two days, during which time the intestinal tract must be cleared, and on the evening previous to administering the vermifuge a good cathartic must be given and the following morning the preparation given while fasting, as the head is then in a state of least protection. This should be followed in a few hours by another laxative. The patient may then be allowed to eat food which will tend to increase intestinal peristalsis. Herring salad combined with onions and garlic is recommended by some authors, given the evening before the administration of the tœniifuge. No breakfast should be taken and the medicine should be given while the patient is still in bed and repeated as necessary. The recumbent condition is in most cases necessary in order to prevent nausea and vomiting as well as the vertigo which frequently accompanies their administration. The purgative to be used after giving the anthelmintic depends to a great extent on the physical condition of the patient. Senna, jalap, calomel, saline laxatives or castor oil, any one of these, as a rule, may serve the purpose. The infusion of senna made up as follows has been recommended:

R. Pulv. sennæ fol. ʒiiss-iii 10-12 |
 Aquæ ʒiiii 90 |

M. Fiat infusum. Sig.: The entire amount sweetened with an ounce of the syrup of bitter orange peel, to be taken at one dose one hour after the anthelmintic.

Should this fail to act within one or two hours, a purgative enema should be given. For this purpose Bérenger-Feraud recommends the following combination:

R Pulv. sennæ ʒiiss-ʒiiii 10-12 |
 Sodii sulph. ʒx 40 |
 Aquæ ʒviii 240 |

M. Sig.: To be given as an enema.

Frequently a large enema of the normal saline solution will take the place of the foregoing and will prevent the worm from attaching itself to the intestinal wall after it has reached the large intestine.

The following preparations have been found to be the most successful in getting rid of tenie: Pomegranate, male fern, kousoo, pelletierin sulphate or tannate (the alkaloid of pomegranate), kamala, turpentine, pumpkin seeds and thymol.

POMEGRANATE.

Pomegranate or granatum is a bark which contains two alkaloids possessing teniacidal properties—pelletierin and isopelletierin. The bark given in the form of a decoction is, as a rule, better than its alkaloids given alone. The decoction is prepared as follows: Macerate two ounces (60.) of the pomegranate root, chopped up fine, in water for twelve hours. Then add one and a half pints (720.) of cold water, boil and macerate for twelve hours and evaporate to one pint (480.)

and administer in divided doses within one hour. If no purgative effects are obtained in one or two hours, a dose of castor oil should be given.

Bamberger recommends the following combination:

R. Granati rad. cort. ʒiiss-ii 45-60 |
 Macerate for 24 hours, then boil in
 Aquæ dest. ʒxii 360 |
 Evaporate to 6 ounces and add
 Extracti filicis maris ether. ʒiii 8 |

M. Sig.: One-third the amount to be taken (fasting) every half-hour. Take a saline aperient the night before, and no food other than soup or tea, or a salt herring.

The following combination has been recommended by Fleischmann in *Clin. Ther.* in the treatment of tapeworm:

R. Ext. granati rad. gr. xl 2 | 65
 Ext. filicis maris. gr. xl 2 | 65
 Pulv. radicis granati. gr. viii 50 |

M. Fiat pil. No. xl. Sig.: One-half hour after giving the child a cup of milk, give ten of these pills every half-hour, keeping others in reserve in case some are vomited. A few hours afterward give a dose of castor oil.

The taste of the decoction of granatum is extremely nauseating and for this reason its active principle, pelletierin, is substituted. The dose of the latter ranges from two to five grains (.12-.30). The addition of tannic acid prevents its absorption and toxic symptoms without altering its effect on the worm. Therefore, the tannate is the best preparation of this alkaloid and it is tasteless. French speaks of giving one-half an ounce of magnesium sulphate, followed in twenty minutes by the pelletierin dissolved in lemonade, and this in turn followed in twenty minutes by another dose of magnesium sulphate.

The following is an old-time but serviceable combination:

R. Granati radicis ʒss 15 |
 Seminis péponis ʒi 30 |
 Ext. filicis maris ether. ʒi 4 |
 Pulv. ergotæ ʒss 2 |
 Pulv. acaciæ ʒiii 8 |
 Olei tigllii gtt. ii 12 |

M. The pomegranate and pumpkin seed should be thoroughly mixed in a mortar with the ergot and boiled for fifteen minutes in water and strained. The croton oil is first mixed with the acacia and male fern and then formed into an emulsion with the decoction.

The following combinations are serviceable in some instances:

R. Olei terebinthinæ ʒss 2 |
 Olei ricini ʒss 15 |
 Mucil. acaciæ q. s. |

M. Fiat emulsio. Sig.: To be taken at one dose after fasting. Or:

R. Ext. granati rad. cort. ʒiiii 90 |
 Sodii bicarb. ʒi 4 |
 Aquæ Oi 480 |

M. Macerate six hours in hot water. Sig.: Take in the morning after fasting in three equal doses, following the last with oleum ricini, ounce one (30.).

PEPO.

The use of pumpkin seeds in the removal of tapeworm is as effective as it is simple. Like too many preparations, however, their efficiency depends to a great extent on where they are purchased. They should be obtained from a reliable seed firm in order to insure their strength. About two ounces should be hulled, thoroughly crushed to a fine powder, mixed with a small amount of honey and spread on a thin piece of bread and eaten as an ordinary sandwich. This should be followed in one or two hours by one of the cathartics previously mentioned. Some authors recommend an infusion or decoction of pumpkin seed instead of the foregoing preparation. This is a mild teniacide and can be given to children in one or two ounce doses. Pumpkin seed is dependent on a resinous principle, peporesin, as supposed by some, but this has not been definitely proved. It is a harmless remedy and can be repeated without danger in case of failure on first trial.

KAMALA.

Kamala is another preparation recommended. It is a fine granular powder, inodorous and tasteless. It can be administered in one to two-dram (4-8.) doses of the powder, or in the form of the tincture. Age impairs its efficiency. It is sometimes given combined as follows:

R. Kamala	gr. xx	1	30
Pelletierini tannatis	gr. ii	12	
Confect. sennæ	ʒss	2	

M. Sig.: The entire amount at one dose after fasting. This amount may be given to a child of 8 to 10 years.

MALE FERN (ASPIDIUM).

This preparation is usually the one relied on for the removal of tapeworm. The crude drug is never used, but in its stead the oleoresin, given in doses ranging from dram one-half to two (2-8.). The ethereal extract is less frequently given. This is prepared by evaporating the oleoresin at a very moderate heat in the oven; therefore, its dose is somewhat less than the oleoresin. The latter is best given dropped in capsules and administered in divided doses fifteen minutes apart. It is very essential that a fresh preparation be used. The fresh oleoresin is greenish in color.

Male fern may be given combined with oil of turpentine as follows:

R. Oleoresin aspidij	ʒiss	6	
Olei terebinthinae (rect.)	gtt. xx	1	30
Spts. chloroformi	m. x	65	
Mucil. acaciae q. s. ad.	ʒi	30	

M. Sig.: Shake well and take one-half the amount at night after fasting, and the remainder the following morning, followed in one hour by a brisk purge. Or:

R. Oleoresina aspidij	ʒiss	6	
Olei peponis express.	ʒiv	15	
Olei terebinthinae	gtt. xx	1	30

M. Sig.: To be taken at one dose after fasting, followed by a purgative. Or:

R. Ext. filicis ether.	ʒiss	6	
Pulv. kamala	ʒiij	8	
Mucil. acaciae			
Syr. simplicis, aa q. s.			
Aq. cinnamoni q. s. ad.	ʒiij	90	

M. Sig.: To be taken at one-half the amount to be taken at bedtime and the remainder in the early morning.

CUSSO.

Cusso is recommended, given in the form of the infusion, two or three drams (8-12.) to four ounces (120.) of boiling water and allowed to cool. It may be given in the powder form combined with male fern as follows:

R. Pulv. cusso (koussou)	ʒiij	8	
Ext. filicis maris ether.	ʒi	4	

M. Fiat capsule No. xxiv. Sig.: Four to be taken every fifteen minutes.

Pregnancy is a positive contraindication to the administration of cusso.

THYMOL.

Thymol is recommended by some authors as a very efficient tennicide, given in capsules or combined as follows:

R. Thymol	ʒiss	6	
Sacchari	ʒiij	8	

M. Fiat chart. No. xii. Sig.: One powder every thirty minutes, followed by castor oil.

Medicolegal.

Validity of Notice Required for Health Insurance.—The Supreme Judicial Court of Maine says, in Whalen vs. Equitable Accident Company, that the former was insured against loss resulting from sickness caused by various diseases, among which was dysentery. The policy provided that failure to give written notice as therein provided within 10 days of the

date of the beginning of any sickness should invalidate any and all claims under it. The insured fell sick October 17, and no notice was given to the company or its agents of the sickness until December 30. Within 30 days after the insured became sick with dysentery, but not within the first 10 days of his being sick, he became insane. The court holds that the condition in the policy was a valid one, and by its terms the failure to give notice within 10 days of the date of the beginning of the insured's sickness invalidated all claims under the policy. The provisions of the Maine statute to the effect that notice of accident, injury, or death may be given to a foreign or domestic casualty or accident insurance company insuring at any time within 30 days after the happening of an accident or injury or death, and shall be valid and binding on the company, do not extend to cases of health insurance. Where a health insurance company, after the expiration of 10 days from the time a party insured became ill, but before it knew the date when he did become ill, sent blank forms for proof of claim to him to be filled out, such conduct did not constitute a waiver on its part of the provision requiring the insured to notify it within 10 days from the beginning of the sickness.

Skill and Care Required of Physician and Surgeon.—The Supreme Court of Rhode Island says, in the malpractice case of Bigney vs. Fisher, that whether the defendant used proper skill and care in setting the broken bone in the plaintiff's leg and his subsequent professional treatment of the case were necessarily questions to be determined by the testimony of experts in the science of medicine and surgery. Barker vs. Lane, 23 R. I. 224. "The implied contract of a physician or surgeon is not to cure—to restore a fractured limb to its natural perfectness" (McCandless vs. McWha, 22 Pa. 261), but to treat the case with that degree of diligence and skill which are ordinarily possessed by the average of the members of the profession in good standing, in similar localities, regard being always had to the state of the medical profession at the time. If more than this is expected, it must be expressly stipulated for. S. & R. Neg. (5th Ed.), sec. 605; Am. & Eng. Ency. Law, vol. 22 (Rev. Ed.) 799-801; Smothers vs. Hanks, 34 Iowa, 286; Almond vs. Nugent, 34 Iowa, 300; Small vs. Howard, 128 Mass. 131. In short, a physician or surgeon must apply the skill and learning which belong to his profession (Higgins vs. McCabe, 126 Mass. 13); and, if he do this, he discharges his full liability. The law relating to malpractice is well stated in the late case of Pike vs. Honsinger, 155 N. Y. 201. Under the evidence submitted in this case the court thinks it was clear that the defendant possessed all of the qualifications called for by the rule stated in that case, that he used his best judgment in the case, and that he exercised at least an ordinary, if not, indeed, a high, degree of care and skill in his professional treatment of the plaintiff, so that the verdict of the jury (apparently for the plaintiff) was clearly wrong, and must be set aside, and a new trial granted.

Right to Determine Physical Examination.—The Court of Civil Appeals of Texas says that, in International & Great Northern Railroad Co. vs. Gready, a personal injury case brought by the latter party, who had suffered injuries to his head, back, spine, kidneys, etc., that he consented to an examination by three physicians appointed by the court, which was made; the court adjourning at 11 a. m. for that purpose. The court convened at 2 p. m., and waited three hours. At that time two of the physicians appeared and testified. On cross-examination they stated that they had applied all the tests except chloroform and the electric battery, whereon the company's counsel made a motion to have these tests applied, whereon the court asked one of the physicians how long it would take, and he answered, "I don't know." On further inquiry the physician stated that it was "very difficult to say. For instance, we must get the battery in good working order, which is not always the case. The battery is not used all the time, and it has a trick of getting out of order, and there you are." Whereon counsel for the plain-

tapeworm. The latter is much more common in this country, while the former is more common in the continental countries of Europe. The presence of either in the intestinal canal of man may cause no symptoms whatever, and knowledge of their presence is made manifest only when a segment or series of segments appear in the stool. In other cases they give rise to an abnormal and ravenous appetite on account of their interference with digestion and assimilation of food. In other cases still reflex nervous disturbances may arise. Before outlining a treatment of tapeworm the general condition of the patient must be considered. If heart lesions are present and the patient has reached the age when changes in the heart muscle have taken place, care must be observed not to give those preparations which tend to depress and to produce too strong irritation to the gastrointestinal mucous membrane. Where marked arteriosclerosis is present those preparations which tend to produce the least amount of vomiting should be administered. It must also be remembered that those taeniifuges which produce the greatest subjective disturbances do not, in most cases, constitute the best treatment. On the other hand, it is sometimes necessary to employ these drastic measures before the entire worm can be removed. After the patient's physical condition has been ascertained he should be put on a modified diet for two days, during which time the intestinal tract must be cleared, and on the evening previous to administering the vermifuge a good cathartic must be given and the following morning the preparation given while fasting, as the head is then in a state of least protection. This should be followed in a few hours by another laxative. The patient may then be allowed to eat food which will tend to increase intestinal peristalsis. Herring salad combined with onions and garlic is recommended by some authors, given the evening before the administration of the taeniifuge. No breakfast should be taken and the medicine should be given while the patient is still in bed and repeated as necessary. The recumbent condition is in most cases necessary in order to prevent nausea and vomiting as well as the vertigo which frequently accompanies their administration. The purgative to be used after giving the anthelmintic depends to a great extent on the physical condition of the patient. Senna, jalap, calomel, saline laxatives or castor oil, any one of these, as a rule, may serve the purpose. The infusion of senna made up as follows has been recommended:

R. Pulv. sennæ fol. ʒiiss-iii 10-12 |
 Aquæ ʒiii 90 |

M. Fiat infusum. Sig.: The entire amount sweetened with an ounce of the syrup of bitter orange peel, to be taken at one dose one hour after the anthelmintic.

Should this fail to act within one or two hours, a purgative enema should be given. For this purpose Brénger-Peraud recommends the following combination:

R Pulv. sennæ ʒiiss-ʒiii 10-12 |
 Sodii sulph. ʒx 40 |
 Aquæ ʒviii 240 |

M. Sig.: To be given as an enema.

Frequently a large enema of the normal saline solution will take the place of the foregoing and will prevent the worm from attaching itself to the intestinal wall after it has reached the large intestine.

The following preparations have been found to be the most successful in getting rid of tenia: Pomegranate, male fern, koussou, pelletierin sulphate or tannate (the alkaloid of pomegranate), kamala, turpentine, pumpkin seeds and thymol.

POMEGRANATE.

Pomegranate or granatum is a bark which contains two alkaloids possessing teneicidal properties—pelletierin and isopelletierin. The bark given in the form of a decoction is, as a rule, better than its alkaloids given alone. The decoction is prepared as follows: Macerate two ounces (60.) of the pomegranate root, chopped up fine, in water for twelve hours. Then add one and a half pints (720.) of cold water, boil and macerate for twelve hours and evaporate to one pint (480.)

and administer in divided doses within one hour. If no purgative effects are obtained in one or two hours, a dose of castor oil should be given.

Bamberger recommends the following combination:

R. Granati rad. cort. ʒiiss-ii 45-60 |
 Macerate for 24 hours, then boil in
 Aquæ dest. ʒxii 360 |
 Evaporate to 6 ounces and add
 Extracti filicis maris ether. ʒiii 8 |

M. Sig.: One-third the amount to be taken (fasting) every half-hour. Take a saline aperient the night before, and no food other than soup or tea, or a salt herring.

The following combination has been recommended by Fleischmann in *Clin. Ther.* in the treatment of tapeworm:

R. Ext. granati rad. gr. xl 2/65
 Ext. filicis maris gr. xl 2/65
 Pulv. radicis granati. gr. viii 5/0

M. Fiat pil. No. xl. Sig.: One-half hour after giving the child a cup of milk, give ten of these pills every half-hour, keeping others in reserve in case some are vomited. A few hours afterward give a dose of castor oil.

The taste of the decoction of granatum is extremely nauseating and for this reason its active principle, pelletierin, is substituted. The dose of the latter ranges from two to five grains (.12-.30). The addition of tannic acid prevents its absorption and toxic symptoms without altering its effect on the worm. Therefore, the tannate is the best preparation of this alkaloid and it is tasteless. French speaks of giving one-half an ounce of magnesium sulphate, followed in twenty minutes by the pelletierin dissolved in lemonade, and this in turn followed in twenty minutes by another dose of magnesium sulphate.

The following is an old-time but serviceable combination:

R. Granati radicis ʒss 15 |
 Seminis peponis ʒi 30 |
 Ext. filicis maris ether. ʒi 4 |
 Pulv. ergotæ ʒss 2 |
 Pulv. acaciæ ʒiii 8 |
 Olei tiglii gtt. ii 12 |

M. The pomegranate and pumpkin seed should be thoroughly mixed in a mortar with the ergot and boiled for fifteen minutes in water and strained. The croton oil is first mixed with the acacia and male fern and then formed into an emulsion with the decoction.

The following combinations are serviceable in some instances:

R. Olei terebinthinæ ʒss 2 |
 Olei ricini ʒss 15 |
 Mucil, acaciæ q. s.

M. Fiat emulsiõ. Sig.: To be taken at one dose after fasting. Or:

R. Ext. granati rad. cort. ʒiii 90 |
 Sodii bicarb. ʒi 4 |
 Aquæ Oi 480 |

M. Macerate six hours in hot water. Sig.: Take in the morning after fasting in three equal doses, following the last with oleum ricini, ounce one (30.).

PEPO.

The use of pumpkin seeds in the removal of tapeworm is as effective as it is simple. Like too many preparations, however, their efficiency depends to a great extent on where they are purchased. They should be obtained from a reliable seed firm in order to insure their strength. About two ounces should be hulled, thoroughly crushed to a fine powder, mixed with a small amount of honey and spread on a thin piece of bread and eaten as an ordinary sandwich. This should be followed in one or two hours by one of the cathartics previously mentioned. Some authors recommend an infusion or decoction of pumpkin seed instead of the foregoing preparation. This is a mild teneicide and can be given to children in one or two ounce doses. Pumpkin seed is dependent on a resinous principle, peporesin, as supposed by some, but this has not been definitely proved. It is a harmless remedy and can be repeated without danger in case of failure on first trial.

KAMALA.

Kamala is another preparation recommended. It is a fine granular powder, inodorous and tasteless. It can be administered in one to two-dram (4-8.) doses of the powder, or in the form of the tincture. Age impairs its efficiency. It is sometimes given combined as follows:

R. Kamala	gr. xx	1	30
• Pelletierii tannatis	gr. ii	12	
• Confect. sennæ	ʒss	2	

M. Sig.: The entire amount at one dose after fasting. This amount may be given to a child of 8 to 10 years.

MALE FERN (ASPIDIUM).

This preparation is usually the one relied on for the removal of tapeworm. The crude drug is never used, but in its stead the oleoresin, given in doses ranging from dram one-half to two (2-8.). The ethereal extract is less frequently given. This is prepared by evaporating the oleoresin at a very moderate heat in the oven; therefore, its dose is somewhat less than the oleoresin. The latter is best given dropped in capsules and administered in divided doses fifteen minutes apart. It is very essential that a fresh preparation be used. The fresh oleoresin is greenish in color.

Male fern may be given combined with oil of turpentine as follows:

R. Oleoresin aspidii	ʒiiss	6	
• Olei terebinthina (rect.)	gtt. xx	1	30
Spts. chloroformi	ʒm. x	65	
Mucil. acaciae q. s. ad	ʒi	30	

M. Sig.: Shake well and take one-half the amount at night after fasting, and the remainder the following morning, followed in one hour by a brisk purge. Or:

R. Oleoresina aspidii	ʒiiss	6	
Olei peponis express	ʒiv	15	
Olei terebinthina	gtt. xx	1	30

M. Sig.: To be taken at one dose after fasting, followed by a purgative. Or:

R. Ext. filicis ether	ʒiiss	6	
Pulv. kamala	ʒiij	8	
Mucil. acaciae			
Syr. simplicis, āā q. s.	ʒiij	90	
Aq. cinnamonii q. s. ad	ʒiij	90	

M. Fiat emulso. Sig.: One-half the amount to be taken at bedtime and the remainder in the early morning.

CUSSO.

Cusso is recommended, given in the form of the infusion, two or three drams (8-12.) to four ounces (120.) of boiling water and allowed to cool. It may be given in the powder form combined with male fern as follows:

R. Pulv. cusso (koussou)	ʒiij	8	
Ext. filicis maris ether	ʒi	4	

M. Fiat capsule No. xxiv. Sig.: Four to be taken every fifteen minutes.

Pregnancy is a positive contraindication to the administration of cusso.

THYMOL.

Thymol is recommended by some authors as a very efficient teneicide, given in capsules or combined as follows:

R. Thymol	ʒiiss	6	
Sacchari	ʒiij	8	

M. Fiat chart. No. xii. Sig.: One powder every thirty minutes, followed by castor oil.

Medicolegal.

Validity of Notice Required for Health Insurance.—The Supreme Judicial Court of Maine says, in *Whalen vs. Equitable Accident Company*, that the former was insured against loss resulting from sickness caused by various diseases, among which was dysentery. The policy provided that failure to give written notice as therein provided within 10 days of the

date of the beginning of any sickness should invalidate any and all claims under it. The insured fell sick October 17, and no notice was given to the company or its agents of the sickness until December 30. Within 30 days after the insured became sick with dysentery, but not within the first 10 days of his being sick, he became insane. The court holds that the condition in the policy was a valid one, and by its terms the failure to give notice within 10 days of the date of the beginning of the insured's sickness invalidated all claims under the policy. The provisions of the Maine statute to the effect that notice of accident, injury, or death may be given to a foreign or domestic casualty or accident insurance company insuring at any time within 30 days after the happening of an accident or injury or death, and shall be valid and binding on the company, do not extend to cases of health insurance. Where a health insurance company, after the expiration of 10 days from the time a party insured became ill, but before it knew the date when he did become ill, sent blank forms for proof of claim to him to be filled out, such conduct did not constitute a waiver on its part of the provision requiring the insured to notify it within 10 days from the beginning of the sickness.

Skill and Care Required of Physician and Surgeon.—The Supreme Court of Rhode Island says, in the malpractice case of *Bigney vs. Fisher*, that whether the defendant used proper skill and care in setting the broken bone in the plaintiff's leg and his subsequent professional treatment of the case were necessarily questions to be determined by the testimony of experts in the science of medicine and surgery. *Barker vs. Lane*, 23 R. I. 224. "The implied contract of a physician or surgeon is not to cure—to restore a fractured limb to its natural perfectness" (*McCandless vs. McWha*, 22 Pa. 261), but to treat the case with that degree of diligence and skill which are ordinarily possessed by the average of the members of the profession in good standing, in similar localities, regard being always had to the state of the medical profession at the time. If more than this is expected, it must be expressly stipulated for. *S. & R. Neg.* (5th Ed.), sec. 605; *Am. & Eng. Ency. Law*, vol. 22 (Rev. Ed.) 799-801; *Smothers vs. Hanks*, 34 Iowa, 286; *Almond vs. Nugent*, 34 Iowa, 300; *Small vs. Howard*, 128 Mass. 131. In short, a physician or surgeon must apply the skill and learning which belong to his profession (*Higgins vs. McCabe*, 126 Mass. 13); and, if he do this, he discharges his full liability. The law relating to malpractice is well stated in the late case of *Pike vs. Honsinger*, 155 N. Y. 20). Under the evidence submitted in this case the court thinks it was clear that the defendant possessed all of the qualifications called for by the rule stated in that case, that he used his best judgment in the case, and that he exercised at least an ordinary, if not, indeed, a high, degree of care and skill in his professional treatment of the plaintiff, so that the verdict of the jury (apparently for the plaintiff) was clearly wrong, and must be set aside, and a new trial granted.

Right to Determine Physical Examination.—The Court of Civil Appeals of Texas says that, in *International & Great Northern Railroad Co. vs. Greedy*, a personal injury case brought by the latter party, who had suffered injuries to his head, back, spine, kidneys, etc., that he consented to an examination by three physicians appointed by the court, which was made; the court adjourning at 11 a. m. for that purpose. The court convened at 2 p. m., and waited three hours. At that time two of the physicians appeared and testified. On cross-examination they stated that they had applied all the tests except chloroform and the electric battery, whereon the company's counsel made a motion to have these tests applied, whereon the court asked one of the physicians how long it would take, and he answered, "I don't know." On further inquiry the physician stated that it was "very difficult to say. For instance, we must get the battery in good working order, which is not always the case. The battery is not used all the time, and it has a trick of getting out of order, and there you are." Whereon counsel for the plain-

tiff said, "We think there ought to be some limit to this thing, and we don't propose to submit to the pain of it," whereon the court said, "Well, we won't go any further, then." This all occurred in the presence of the jury, and was taken advantage of in argument by both sides. The Court of Civil Appeals holds that the court did not err in not ordering a second or further examination against the will of the plaintiff. It says that the court was without power to require him to submit to an examination. *Railway vs. Cluck* (Tex. Sup.), 77 S. W. Rep. 403. Such an examination being subject to the consent of the plaintiff, he could, the court thinks, have terminated an examination while same was being conducted.

Can Not Be Cross-Examined as to Opinions in Other Cases.—The Supreme Court of Illinois says, in *Chicago & Eastern Illinois Railroad Co. vs. Schmitz*, a personal injury case brought by the latter party against the railroad company and others, that a certain physician was put on the stand as a witness for the plaintiff to testify in regard to her injuries, and on the cross-examination it was attempted to discredit the witness by asking him questions in regard to the professional opinions he had given in other suits brought to recover damages for personal injuries against one or more of the defendants in this case. It was also sought by the defendants to show by direct examination of certain witnesses that the physician in question was interested as a medical man in a large number of personal injury suits against corporations. The court holds that there was no error in refusing to admit this class of testimony. It says that cross-examination on independent cases of the same character, and about the same time as the principal case, is not allowed. The rule is more strict against the use of this kind of testimony in direct examination. The acts and declarations either of strangers, or of one of the parties to the action in his dealings with strangers, are irrelevant. There is nothing in the case of *Chicago City Railway Co. vs. Carroll*, 206 Ill. 318, which is opposed to the view here expressed. In that case it was held to be proper to ask a physician on cross-examination in a personal injury case by whom he was paid, etc. But the testimony whose introduction is there justified, applies directly to the relation of the witness to the party in interest and to the particular case, and not to his relation with other parties and other cases. It was there said: "It is always competent on cross-examination to ask a witness if he is not in the employ of a party, or if, at the time he rendered the particular service, he was in the employ of such party, for the purpose of showing his relation in the case and his interest in it, as affecting his credibility and weight of his evidence."

1. **Problems in Obstetrics and Gynecology.**—Webster discusses the determination of sex, the anatomy and physiology of the ovary, the antagonism between the maternal organism and the ovum, and the functions of the placenta.
3. **Carbohydrate Metabolism.**—Rhodes made extracts from

animals killed immediately after the taking of a heavy carbohydrate diet and after they had been starved for some time. He found that all the organs contain enzymes which may be extracted and which cause the destruction of grape sugar. The pancreas showed this action more positively than any other organ. The extract which gives the best results is one made by using glycerin and alcohol. Rhodes found by experiment that this extract shows the presence of pronounced diastatic enzymes as well as the glycolytic. Clinically, good results were obtained by the administration of the glycerin-alcohol extracts of pancreas, spleen and muscle. The best results were by hypodermic injections of combined pancreas and muscle. Judging from the peculiar action at times in the different experiments, Rhodes believes that it is quite possible that there is more than one enzyme concerned in the sugar-destruction and that at times other enzymes interfere with the glycolytic action.

4. **Dangers of the Microscope in Tuberculosis.**—In consonance with a number of other writers, Clapp decries implicit reliance on the microscopic findings for a diagnosis of incipient pulmonary tuberculosis. He says a skilled auscultator (and all physicians should be skilled auscultators) can very often recognize an incipient case before tubercle bacilli appear in the sputum. Very often, not by physical examination alone, but by a thoughtful consideration of symptoms and physical signs, in connection with a close study of the personal and family history of the patient, aided, if necessary, by the tuberculin test, a satisfactory conclusion can be reached weeks and months before the bacilli appear in the sputum or even before the sputum itself appears, and thus gain time enough, perhaps, to save the patient.

7. **So-Called "Piroplasma Hominis."**—A most careful study of this subject has convinced Craig that Chowning, Wilson and Anderson, who investigated the etiology of a fever prevailing in the Bitter Root Valley for a number of years, and who concluded that it was due to a minute parasite which inhabited the red blood corpuscles, have mistaken areas devoid of hemoglobin in the red cell, which occur frequently in disease, for a protozoan parasite. He also refers to a report by Stiles, Chief of Division of Zoology, which details the results of his study of ten cases of spotted fever, in none of which Stiles succeeded in finding any structure in the blood which he could interpret as a protozoan organism.

8. **Problems in Diabetics.**—Thompson attempts to solve some of the complex problems in the matter of dieting that frequently confront us and in which regulation of the food is of special importance. On the other hand, there are a number of nutritional disorders the etiology of which is still so obscure that the formulation of proper dietetic principles becomes unusually difficult. In typhoid, he deprecates the undue prolongation of the milk diet, as it is liable to produce scurvy, it protracts convalescence and, by impoverishing nutrition, makes the patient more liable to serious complications. He makes it a rule to commence the feeding of semi-solid food, in ordinary cases, on the day when the body temperature first reaches normal. Soft cooked eggs, baked custard, junket, milk toast, mutton or chicken broth, thickened with rice or crackers, plain, delicate foods like blanc mange and wine jelly, and light farinaceous foods may then be given. On the third day, if convalescence be uninterrupted, a scraped beef sandwich is given. Thompson recommends early increase in the dietary in very mild cases in general, but not if there be much tympanites, diarrhea or recent severe hemorrhage. In asthenic cases the maintenance of better nutrition is imperative. When much tympanites exists during a milk diet, beef juice and egg albumin or broths should be substituted for

the milk for two or three days. Cases of arthritis deformans are treated very much as if they had chronic phthisis, or chronic sepsis—by forced feeding—using largely fat foods, such as butter, cream, eggs, oils, bone marrow, bacon, etc. With a little care this dietary is well tolerated. The ordinary meals should be supplemented by two or three luncheons during the day. The use of simple bitters before meals or of dilute hydrochloric acid with *nux vomica* after meals, and the promotion of elimination of waste are of value in most cases. In nephritis the problem is a very complex one, and although in acute cases the conventional diet is demanded, in chronic cases there is occasion for greater latitude. In these cases the danger of meat eating is overrated considerably, and there are some cases in which its moderate use is positively demanded. Such cases are (1) those of very long standing, in which the chief symptom is a moderate albuminuria; (2) those in which anemia and loss of strength and weight are the prominent features, and (3) those in which some associated disease makes the use of animal food desirable. In diabetes, the author is convinced that a routine dietary may beget more harm than good. Each case should be given separate dietetic study. Mild cases do well on a diet chiefly proteid. Serious cases should be given more fats, such as butter (one-quarter pound or more a day), cream diluted with water and drunk as a beverage (one pint or more a day), the fats of cod-liver oil, olive oil on salads, sardines, etc.; olives, oily nuts, eggs, bacon and ham fat, bone marrow, suet and lard; rich cheese, soups, enriched with "dripping" and fat fish, mackerel and salmon, fat meats, goose and duck and the tender fat of corned beef. Potato is given best in the form of "Saratoga chips." Lithemia requires more or less abstinence from proteid food, the copious use of water (60 or 70 ounces a day), plenty of fresh air and rest, especially before the principal meal of the day. The dietetic treatment of arteriosclerosis is somewhat similar to that of lithemia, though the quantity of water to be allowed must be judged carefully, so as not to overburden a weak heart or to encourage inadequacy in damaged kidneys. In gout, the following general principles are of prime importance: 1. To reduce the consumption of food as a whole; 2, to increase the consumption of water; 3, to eliminate entirely sugars and sweets of every kind, as well as alcohol; and 4, to reduce the consumption of red meats to a minimum. The dietetic treatment of rheumatism should, in general, resemble that of gout, a milk diet during the acute attack and restriction of meat and sweets in the interval. In closing, Thompson enters a word of protest against the common practice of basing dietetic and other treatment of stomaehic disease on the results of a single gastric analysis. At least half a dozen tests should be made before any definite conclusions are justifiable, dietetic or otherwise.

10. Treatment of Pneumonia.—Manges defines pneumonia as a general disease, the tendency of which is to recovery after the lapse of sufficient time for the body to produce its own antitoxin. When treatment is required it must be directed against the toxemia: 1, to maintain life; 2, to support the heart; 3, to control undue fever; 4, to relieve suffering; 5, to control complications. Intelligent nursing and careful dieting will meet the first indication. The drugs which best support the heart are strychnin, caffeine, alcohol, camphor and ergot. There should be no hesitancy to use them freely, and hypodermic medication should be substituted promptly for medication by mouth, if the latter fails to produce the desired result. Adrenalin, the precordial icebag, enpping, and venesection are also useful measures. Fever may be reduced by the use of large, flat icebags to the affected area, but this is not to be looked on as a specific and it is to be remembered that carelessness in their use may give rise to an intercostal neuritis. Cold baths are absolutely contraindicated. Cold sponging and cold packs are often useful, but are to be used with caution. Properly applied moist compresses enveloping the entire chest often comfort the patient, although they are not of much therapeutic use. The rational use of small doses of any of the coal tar products may add not a

little to the patient's comfort. The suffering incident to the pleuritic pain and the distressing cough is best relieved by the hypodermic injection of small doses of morphin, grain 1/10 to 1/8, or heroin hydrochlorid, grain 1/8 to 1/6. The Paquelein cauterly often acts magically in quieting pleuritic irritation. All administration of drugs, etc., should be done at stated times; during the intervals between them, rest or sleep should be procured. The complications require the treatment pursued ordinarily. Manges warns against routine or "schedule" plans of treatment.

12. Foreign Bodies in Appendix.—Mitchell gives a list of foreign bodies found in the appendix during his service as cotter's physician. One or more grape seeds were present in 5 cases; one or more shot in 3 cases, and fragments of bone in 2 cases. Other objects found were a fragment of shingle nail, a globule of solder, a piece of nut-shell, the centrum of the vertebra of a small fish with part of the vertebral arch attached, and fragments, apparently, of ash or stone. None of the appendices containing these bodies showed any signs of inflammation, either past or present.

17. Circum-Rectal Infections.—Jelks' operation consists of free incision and thorough curettage after irrigating the abscess with a formalin solution. The cavity is then packed with iodoform gauze. After the second day, gauze saturated in balsam of Peru, castor oil and ichthyol is used, the preliminary formalin irrigations being continued. Should large cavities remain unfilled after repeated curetting, they may be closed with 20-day catgut. Under this procedure the abscess cavity is converted into a clean surgical wound, thus favoring healing without attendant suppuration; nor is the integrity of the rectal sphincter diminished. Jelks throws out the surmise that the external sphincter has a distinct ganglion, and that division of the nerves about the rectum may be accountable for temporary atony and impaired function.

23. Dentition and Epilepsy.—Spratling maintains that we are never justified in looking on the convulsions of infancy and early life as harmless manifestations, because they often end in established epilepsy. The lesson physicians often fail to learn is the necessity for constantly recognizing in such children the presence of the convulsive tendency. To keep the child free from convulsions in the future this tendency must be borne in mind and always respected. For some years Spratling has been studying the age at the onset of epilepsy in several thousand cases to determine what proportion of these children acquired epilepsy coincident with the first or second dentition periods. In 1,215 cases the disease occurred between the first and twentieth years, inclusive, represent-

tiff said, "We think there ought to be some limit to this thing, and we don't propose to submit to the pain of it," whereon the court said, "Well, we won't go any further, then." This all occurred in the presence of the jury, and was taken advantage of in argument by both sides. The Court of Civil Appeals holds that the court did not err in not ordering a second or further examination against the will of the plaintiff. It says that the court was without power to require him to submit to an examination. *Railway vs. Cluck* (Tex. Sup.), 77 S. W. Rep. 403. Such an examination being subject to the consent of the plaintiff, he could, the court thinks, have terminated an examination while same was being conducted.

Can Not Be Cross-Examined as to Opinions in Other Cases.—The Supreme Court of Illinois says, in *Chicago & Eastern Illinois Railroad Co. vs. Schmitz*, a personal injury case brought by the latter party against the railroad company and others, that a certain physician was put on the stand as a witness for the plaintiff to testify in regard to her injuries, and on the cross-examination it was attempted to discredit the witness by asking him questions in regard to the professional opinions he had given in other suits brought to recover damages for personal injuries against one or more of the defendants in this case. It was also sought by the defendants to show by direct examination of certain witnesses that the physician in question was interested as a medical man in a large number of personal injury suits against corporations. The court holds that there was no error in refusing to admit this class of testimony. It says that cross-examination on independent cases of the same character, and about the same time as the principal case, is not allowed. The rule is more strict against the use of this kind of testimony in direct examination. The acts and declarations either of strangers, or of one of the parties to the action in his dealings with strangers, are irrelevant. There is nothing in the case of *Chicago City Railway Co. vs. Carroll*, 206 Ill. 318, which is opposed to the view here expressed. In that case it was held to be proper to ask a physician on cross-examination in a personal injury case by whom he was paid, etc. But the testimony whose introduction is there justified, applies directly to the relation of the witness to the party in interest and to the particular case, and not to his relation with other parties and other cases. It was there said: "It is always competent on cross-examination to ask a witness if he is not in the employ of a party, or if, at the time he rendered the particular service, he was in the employ of such party, for the purpose of showing his relation in the case and his interest in it, as affecting his credibility and weight of his evidence."
