CONTENTS AND DIGEST

ORIGINAL.

Pleural Effusion in Heart Disease. J. Dutton Steele, M.D., Philadelphia 927
Review of the literature. Statistical study of reported cases. Mechanism of the formation of fluid in cases of pleural effusion in heart disease. Report of two cases with autopsy. Great obstinacy not a characteristic of these effusions.

Prolonged Delirium in Pericarditis and Endocarditis. Report of a Case. Edgar Moore Green, A.M., M.D., Easton, Pa. 933

Prolonged delirium unusual. Heart disease and rheumatism. Course of the disease. Report of a case and final results of treatment.

The Limitation of Digitalis in Mitral and Aortic Regurgitation. Frank Jones, M.D., Memphis, Tenn. 935
Careful study of symptoms necessary before using digitalis. Digitalis the sheet anchor in mitral insufficiency when compensation has failed or is failing. Digitalis contraindicated in aortic insufficiency with secondary mitral leakage from ventricular dilatation.

Some Points in the Acoustics of Respiration. Charles E. Quimby, M.D., New York City 937
Laws governing the formation of respiratory sound and their pitch relations. The possibilities arising when considering the question of pitch in the composite sound of vesicular respiration. Manner in

which inspiratory pitch falls under varying grades of consolidation. Conclusions. Discussion on powers of Drs. Steele, Green, Jones and Quimby by Drs. Tyson, Cabot, Rochester, James, Wells, Sailer, Livingston, Webster, Anders, Coleman, Steele, Green, Jones and Quimby.

Intracranial Neurectomy for Trigeminal Neuralgia. Cases and Comments. Harry M. Sherman, M.D., San Francisco 941
Report of five cases in four patients. The order of symptoms and their predominance. Results of operation. Remarks.

Physiologic Extirpation of the Ganglion of Gasser. Further Report on Division of the Sensory Root for Tic Douloureux Based on the Observations of Four Cases. Charles H. Frazier, M.D., and Wm. G. Spiller, M.D., Philadelphia. 943
Résumé of experimental work. Advantages of this over other procedures. Technic. Difficulties attending the operation. Avoidance of ocular disturbances. Methods of Abbe and Van Gehuchten. Sympathetic fibers in the ganglion of Gasser. Résumé of four cases.

Osmic Acid Injections for Relief of Trifacial Neuralgia. John B. Murphy, A.M., M.D., Chicago 947
Résumé of cases appearing in the literature. Pathology of trifacial neuralgia. Explanation of the recurrences. Detailed report of experiments. Microscopic findings in injected nerve tissue. (To be continued.)

Blood-Pressure and Pulse Rate. As Influenced by Different Positions of the Body. O. Z. Stephens, A.M., M.D., Chicago. 955

Objections to Hales' method. Description of method employed by the author. Results. Discussion of effects on blood pressure and on pulse rate. Summary. Discussed by Drs. Brainard and Hall.

Treatment of Fractures of the Patella by Lateral Sutures. Joseph A. Blake, M.D., New York 962

The mechanical versus the operative treatment. Indications for operation. The operation for the treatment of "tear" fractures. Technic. Results.

Discussed by Drs. Gibbons, G. T. Vaughan, Thienhaus, Binnie, Elsendrath, Bullitt, Lemon, Powers and Bink.

The Etiology of Hay Fever. The Relation of the Chemistry of the Saliva and the Nasal Secretions to Diseases of the Mucous Membrane of the Mouth and Upper Respiratory Tract. D. Braden Kyle, M.D., Philadelphia. 966

The chemistry of the alkaline and acid, nasal and salivary secretions. The clinical importance of their reaction from the standpoint of treatment. Unusual salts found in the saliva and their significance. Chemistry of the staphylococci. Report of cases.

S C H E R I N G ' S

Ex- odin	Tasteless and odorless cathartic, unique in promptness, reliability, pleasantness and harmlessness.
Duo- tonol	A 100% compound of Lime and Sodium Glycero-phosphates (1:1), convenient for dispensing and administration.
Empy- roform	Well borne in all eczematous and vesicular diseases. Free from the offensive odor and color of tar.
Sub- lamine	Has the potency of the bichloride, but is non-irritant, penetrating, and instantly water-soluble.
Uro- tropin	Effects a urinary antiseptis that was wholly unattainable before its introduction by Prof. Nicolaier.
Beta- Eucaïn	A local anesthetic which never pro- duces untoward actions. Solutions are permanent and can be boiled.
Formalin Lamp	Renders infections shorter and milder, lessens danger of contagion. Invaluable in all zymotic diseases.

Literature on request.

PLEURAL EFFUSION IN HEART DISEASE.*

J. DUTTON STEELE, M.D.

Associate in Medicine, University of Pennsylvania; Bacteriologist
to the Presbyterian Hospital.

(From the Department of Clinical Medicine, University of
Pennsylvania.)
PHILADELPHIA.

In a paper entitled "The Distribution and Etiology of Cardiac Hydrothorax," which was published in 1897, I called attention to the fact that passive pleural effusion may occur in the course of failing compensation of the heart, before there is any tendency to external dropsy, and that this pleural effusion is very often unilateral, with a preference for the right side. That paper contained an analysis of the autopsies of 75 cases of hydrothorax occurring in patients with undoubted disease of the heart muscle. It was shown that in three-fourths of these cases the effusion was greater on one side than on the other, and in one-fifth the effusion was unilateral. The greater amount of fluid was on the right side in three-fourths of the unequal effusions and in 10 of the 13 cases of the unilateral effusions the fluid was found in the right pleural sac.

The material for my table was obtained from the notes of 2,427 autopsies contained in the records of the Philadelphia Hospital, and of the Middlesex Hospital in London. I also published the clinical notes of 4 cases from the wards of Dr. Stengel and Dr. Packard that showed this right-sided hydrothorax. In all of these cases the formation of the effusion preceded the edema, and I called attention to the fact that such effusions may precede external edema.

Dr. Stengel (University of Pennsylvania Medical Bulletin, 1901), took up the subject in a paper published in 1901, and gave an analysis of seventeen instances of hydrothorax which occurred in 100 consecutive cases of cardiac disease. His conclusions are probably of more value than those of my first paper, although mine were obtained from the autopsies of many more cases; because Stengel's analysis was based on clinical notes of living patients, while mine were all fatal cases; for it will be readily understood that in autopsy findings the sequence of events of the morbid state can not be accurately determined. Consequently, it was impossible to tell from autopsy notes whether in double effusion the fluid had been unilateral at the onset or not, and it was usually quite impossible to tell whether or not the pleural effusion had preceded general edema and effusions into other serum cavities.

In the 17 cases of hydrothorax that Stengel gives, the effusion was confined to the right side at some time in the course of the disease in 7 cases; 7 more were bilateral, with greater involvement of the right side, and in 3 cases the effusion was entirely left sided. In 8 of Stengel's 17 cases edema was absent or slight.

The literature of the subject has been fully considered in the papers by Dr. Stengel and myself. It is sufficient to say that several writers of text-books, including Pepper, Osler, Baccelli, and Rosenbach, state that cardiac hydrothorax is apt to occur before general edema, and is then unilateral with preference to the right side. Many observers have reported isolated cases of right-sided cardiac hydrothorax, and a group of Italians, including Piazza-Martini, Villani, Lizzato Cardenelli and Peter, have called attention to the occasional occurrence of right-sided pleural effusion of a non-inflammatory nature in atrophic cirrhosis of the liver. But so far as can be determined there has been no attempt made to consider the distribution or etiology of cardiac hydrothorax by an analysis of a series of cases before the subject was taken up by Dr. Stengel and myself.¹

In endeavoring to obtain another series of observations on the distribution and etiology of the hydrothorax of cardiac disease, I have gone over the records of the Presbyterian Hospital in Philadelphia since 1895. In this period of nine years there have been 31 cases of hydrothorax in patients with well-marked disease of the heart muscle and enlargement of that organ. Fortunately, 4 of these cases have been under my personal observation during the past winter in the wards of the Presbyterian Hospital in the service of Dr. John H. Musser, and I had the opportunity of examining two of these postmortem.

The condition required in selecting these cases and in deciding between cases of cardiac effusion and effusion from other causes was that there should be decided evidence of myocardial disease and enlargement of the heart. It was required also that the cardiac condition should be predominant, or at least a very prominent factor in the patient's condition. Aneurism, tumor or any other cause for effusions was sufficient to throw out the case in question.

With one or two exceptions the patients were free from fever, pain and cough. The exceptions were one case of acute pleurisy occurring in a case of well-marked disease of the heart, and two cases of acute endocarditis with great cardiac enlargement and with much effusion.

1. Beside Dr. Stengel's paper the following communications concerning pleural effusion of heart disease have appeared in current medical literature since 1897: Gerhardt: Pleural Effusion in heart disease. Rosenbach: Localized Congestions and Effusions in Cardiac Disease. Münchener med. Woch., No. 14, 1901. Germani: Right-sided Hydrothorax in Cardiac Disease. Gazz. degli Ospedali, No. 99, 1900. Barle: The Involvement of the Pleura in Heart Disease. Semaine Médicale, 1902, No. 4. Esser: Pleural Effusion in Heart Disease. Münchener med. Woch., No. 4, 1902.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

As has been said, every case presented distinct signs of degeneration of the myocardium with enlargement of the heart, hypertrophy and dilatation.

Most of the cases had valvular lesions, with or without arterial changes; some had arteriosclerosis and nephritis, and there were two instances of acute endocarditis and cardiac dilatation in children.

In some cases all the chambers of the heart were dilated, in some all the chambers were enlarged, but the right side was mentioned as particularly affected. In others the left side was the only part of the heart enlarged or was the part particularly affected.

In 3 cases one or the other of the pleural sacs was totally obliterated by adhesions, and these have not been included in the tables. As I have said, in one case the effusion is apparently due to acute pleurisy, and occurred entirely on the right side. This gives a total of 27 cases for analysis.

The effusion was at some time during the period of observation confined to the right side in 11 cases, or 40 per cent. The effusion was bilateral, but greater on the right side in 4 cases, or 15 per cent. It was left sided in 5 cases, or 19 per cent., and double, but greater on the left in 6, or 22 per cent. The effusion was double and equal in one case, or 3 per cent.; right sided in 60 per cent., left sided in 40 per cent.

The figures in my first paper based on autopsy findings alone are:

Right-sided hydrothorax, unilateral or greater on the right side, 41 cases, or 77 per cent.; left-sided hydrothorax, unilateral or greater on the left side, 12 cases, or 23 per cent.

Stengel's 17 cases of hydrothorax were practically all right sided, since 2 of the 3 left-sided effusions could be explained by the obliteration of the right sac by adhesions, and the other case was probably due to aneurism. Consequently the figures in the analysis of the Presbyterian Hospital cases are not so conclusive that cardiac hydrothorax in the great majority of cases is right sided as those of Stengel or of my previous article.

The Presbyterian Hospital figures, however, show that the effusion has a decided preference for the right side. The figures indicate very decidedly that the pleural effusions of cardiac origin are usually unilateral or unequal. Moreover, when the etiology of such effusions is considered, it will be seen that the larger percentage of left-sided effusion in the Presbyterian Hospital figures, when taken in connection with the side of the heart affected, is very suggestive and interesting.

The effusion was entirely left sided at some time in 5 cases, or 10 per cent., and was double but greater on the left side in 5 more cases.

That is, the effusion showed a preference for the left side in 10 cases, or 40 per cent. in round numbers, as contrasted with 15 cases, or 60 per cent. that were right sided.

The effusion was double and equal in but one instance, showing very decidedly that these pleural effusions in heart disease are unequal in a great majority of cases.

A very interesting point shown in the table is that, while right-sided effusions occur with enlargement of the right heart, left-sided effusions are usually associated with enlargement of the left heart. This phase of the subject will be considered more in detail in the section on etiology.

It was difficult to ascertain whether the formation of the effusion preceded external edema. Such cases are

usually not admitted to the hospital until the severity of the symptoms are such that external edema is present to a considerable degree. It is then usually impossible to fix the time at which the effusion commenced from the history of the patient.

In 3 of my cases edema was absent or slight on admission, while there was considerable effusion; in 3 other cases the edema disappeared before the effusion.

This small number of cases, however, together with the clinical reports in my first paper, and by the observation of Stengel, Gerhardt and others, demonstrate that such effusions may precede external edema.

Various theories have been advanced to explain the formation of this unilateral or unequal pleural effusion in heart disease.

Wintrich, in an article extensively quoted in my first paper, gave obliteration by adhesions of one of the pleural sacs as the most frequent cause for unilateral hydrothorax. He says, however, that the effusions may rarely be one sided, when both pleura are free.

Buequoy, Saint Philippe and Dequet insisted that the effusion was inflammatory and attributed it to pulmonary infarction on the right side. Their theory, however, is not supported by the researches of Gerhardt and Stengel, or by either of my lists of cases.

Esser, in a recent paper, reported 3 cases of unilateral right-sided effusion without symptoms in patients with cardiac dilatation, in which autopsies showed large bronchial glands in the root of the right lung. He attributed the effusion to the interference with the lymphatic circulation of the right pleura, which was produced by these glands. This effusion occurred in heart disease, because in such cases the general circulation is feeble, and consequently there is a greater tendency to lymphatic stasis. The improbability of this explanation is obvious. Such a condition was not noted in any of the cases cited by any of the other authorities. Unilateral enlargement of the bronchial lymph glands is not a common enough condition to explain a phenomenon of such regularity as the occurrence of these effusions.

As is shown in Stengel's paper, right-sided effusions in dilatation of the heart are not caused by obstruction to the general lymphatic circulation produced by interference with the circulation of the superior vena cava, and hence with that of the right lymphatic duct. The right lymphatic duct is protected by valves, and if general lymphatic obstruction was the cause of the effusion, unilateral swelling of the arms, neck and chest would necessarily be more frequent.

A group of clinicians, mostly Italians, have observed right-sided hydrothorax in cirrhosis of the liver. Villani reports nine such cases of atrophic cirrhosis, with right-sided pleural effusion in two, of which the diagnosis was confirmed by autopsy. He explained the effusion by assuming that in such cases inflammation of the capsule of the liver extending through the diaphragm caused a low grade of inflammation in the right pleura with effusion without symptoms. He extended this theory to right-sided hydrothorax in cardiac disease. He argued that in such cases of heart disease the liver is distended by passive congestion, and its capsule is subacutely inflamed. This inflammation spreads through the diaphragm in the same manner as he assumed it would in cirrhosis of the liver. Peter and Huchard held approximately the same view.

Piazzini-Martini reported several cases of right unilateral hydrothorax in atrophic cirrhosis, and explained the condition by assuming that the dilated veins of the esophageal plexus pressed on the vena azygos and inter-

fered with the return of blood from the right pleura.

The liver was noted as distinctly enlarged in four of the Presbyterian Hospital cases, and in six of Stengel's seventeen cases. Four of the Presbyterian Hospital and three of Stengel's cases had ascites. All of these cases, however, showed much general edema, so that the abdominal effusion may have been merely part of the general anasarca.

The responsibility of the inflammation of the liver capsule in the cases of right-sided effusion is not obvious, and this theory fails entirely to account for the effusion that is confined to the left side, or greater on that side.

The theory that appears to explain most satisfactorily the preference of these pleural effusions for the right side, supposes that enlargement of the right heart and especially of the right auricle can press on the root of the right lung and obstruct the vena azygos major.

The vena azygos major represents the common trunk of the nine or ten right lower intercostal veins. It lies on the right side of the bodies of the dorsal vertebrae extending from the diaphragm as high as the third intercostal space. From that point it arches forward and curves around the root of the right lung and then empties into the superior vena cava just before that vessel enters the pericardium. It receives as tributary the right superior intercostal vein, which is the common trunk of the three upper intercostal veins. The vena azygos major consequently drains the whole of the costal layer of the pleura from the right side. Obstruction of this vein would, therefore, result in congestion and stasis in the whole of the right pleural sac.

The vena azygos major also receives as tributary the vena azygos minor, which is the common trunk of the lower four or five intercostal veins on the left side. It crosses over the body of the eighth dorsal vertebra to join the vena azygos major. Obstruction of the vena major would consequently cause congestion in the lower third of the left pleural sac.

The vena azygos major, as it curves around and partially surrounds the root of the right lung, is in a position which renders it especially liable to compression. As has been said, such obstruction would produce stasis and congestion in the whole of the right pleura and in the lower portion of the left pleura, and consequently the resulting effusion in its early stage would be wholly right-sided, and in its later stage bilateral but greater on the right.

In my former article I advanced the theory that right-sided pleural effusions in heart disease were produced by pressure exerted on the root of the right lung by a dilated right auricle. It has been shown how such pressure would tend to compress the vena azygos major, and hence could cause a passive effusion on the right side, and in case the pressure was long continued would produce a smaller effusion in the left sac.

Dilatation of the right auricle was especially mentioned in sixteen of the thirty-five cases of right unequal hydrothorax tabulated in my first paper. The figures given by the analysis of the Presbyterian Hospital cases strongly support this theory.

In sixteen cases of right unequal hydrothorax in the Presbyterian Hospital list the right side of the heart was much dilated in fourteen. Both sides were dilated in six cases, and the left side alone in two. That is, the right side of the heart was greatly dilated in nine-tenths of the sixteen cases.

The two autopsies which I had the opportunity of making personally on two of the cases in the Presby-

terian Hospital list, showed much dilatation of the right auricle and ventricle. In both the right auricle pressed on the root of the right lung, and in both the vena azygos major was engorged and dilated. There were no adhesions or enlarged bronchial glands or great congestion of the liver which would suggest any theory for the production of the effusion other than that of pressure on the azygos vein.

The report of these two cases in detail, together with the notes on the autopsies, are as follows:

CASE 19.—J. G., male, white, aged 50 years.

Clinical Diagnosis.—Myocarditis, mitral stenosis and insufficiency. Large right-sided pleural effusion which had been tapped once. Specific gravity of fluid 1015, with 4 grams of albumin per liter.

Pathologic Diagnosis.—Double pleural effusion greater on the right side. Mitral stenosis. Thickening of the coronary arteries and myocardial degeneration. Great dilation of the right auricle. The right auricle pressed directly on the root of the right lung. The vena azygos major was dilated and engorged.

History.—The patient had always been a drinking man, but beyond this little concerning his personal or previous history could be obtained. About two years previously he began to suffer from morning vomiting and gradually became short of breath on exertion and lost his usual vigor. He had been under a physician's care for the two months previous for dyspnea and edema of the feet.

Examination.—On admission he had much general edema and some ascites. There were signs of pleural effusion on the right side below the level of the fourth rib. The left side was free. The day after admission 2,000 c.c. of clear fluid was drawn from his right pleura. The specific gravity of the fluid was 1015, and it contained 4 grams of albumin per 1,000 parts, and contained a small amount of blood. After the fluid was withdrawn the left border of the heart was found to extend to the anterior axillary line, the upper border was at the second rib, and the right border was at the right border of the sternum. There was a murmur of mitral insufficiency at the apex preceded by short, rough presystolic murmurs, apparently due to mitral stenosis. There was also a rough systolic murmur in the aortic area transmitted to the carotid. There were no other murmurs. The action of the heart was weak and irregular. The pulse was small and weak, and there was moderate thickening of the radial and temporal arteries. The liver was slightly enlarged, but did not pulsate. There was no pulsation in the veins of the neck.

Course.—The patient was slightly delirious for the next few days. His pulse grew very rapid and irregular and he died suddenly six days after admission.

Autopsy.—Both pleuræ were free from adhesions. There was 1,500 c.c. of clear, slightly blood-stained fluid in the right pleural cavity. The right lung was slightly compressed and somewhat congested, but otherwise normal. There were 200 c.c. of fluid in the left pleura. The left lung was congested.

The left border of the heart extended as far to the left as the anterior axillary line, and the right border, which was formed by the right auricle, extended 4 cm. to the right of the sternum from the third rib to the fifth interspace. All the chambers of the heart were distended. The left ventricle and left auricle were much dilated, and also much hypertrophied. The right ventricle was dilated and hypertrophied. The right auricle was tremendously dilated and as large as a boy's fist. The heart muscle was very pliable and yellow, and evidently much degenerated. The coronary arteries were hard, stiff and calcareous and their caliber was diminished. There was much thickening of the mitral leaflets, and the leaflets themselves were adherent, forming a typical funnel-shaped valve, such as is often seen in mitral stenosis. The aortic valves were thickened and rough, but were competent. The tricuspid orifice was dilated and admitted four fingers, so that there was probably some insufficiency of the tricuspid valves as well. The portion of the heart formed of the right auricle pressed directly on

SUMMARY OF CASES OF PLEURAL EFFUSION IN HEART DISEASE

Number, Age in Yrs., Sex.	Condition of Pleural Sacs.	Pleural Ad- hesion.	Diagnosis.	Cardiac Enlargement.	External Edema.	Liver.	Remarks.
1 37 M	Effusion commenced on left side. Autopsy: both pleurae half full.		Autopsy: Mitral stenosis and insufficiency; aortic regurgitation; tricuspid insufficiency.	Both sides enlarged.	Effusion preceded edema.		
2 53 M	Autopsy: Right pleura . . . 200 c.c. Left pleura . . . Free		Mitral stenosis and insufficiency.	All chambers enlarged, especially left ventricle; weight 625 grms.	None		
3 56 M	Autopsy: Right pleura . . . 270 c.c. Left pleura . . . Free		Mitral insufficiency.	All cavities much distended, especially right auricle; weight 450 grms.			
4 42 M	Right-sided effusion before fourth rib, which increased rapidly; tapped once, 1200 c.c.; left side remained free.		Mitral insufficiency; tricuspid insufficiency.	Enlarged to left and right.	Present	Enlarged and pulsating.	Clear yellow fluid; pulsation in jugular vein and liver.
5 36 M	On admission: Double effusion; the left effusion disappeared first; confirmed by puncture one week after admission; right-sided effusion to first rib; left side free.		Mitral stenosis and insufficiency.	Enlarged to left and right.	Present on admission.	Enlarged and pulsating.	Fluid clear yellow.
6 52 M	Right-sided effusion to third rib; left side free.		Mitral and tricuspid regurgitation.	Enlarged to left.	Present on admission; ascites.		
7 33 F	Left-sided effusion below fourth rib; right-sided effusion below sixth rib; confirmed by autopsy.		Autopsy: Mitral and tricuspid stenosis and insufficiency.	All cavities dilated, especially right auricle.	Present on admission.	Congested	
8 52 F	Clinically and at autopsy, large double effusion.		Mitral stenosis and insufficiency; tricuspid insufficiency.	Bulk of heart made up of greatly dilated auricles; the right auricle was especially dilated.	Present on admission	Congested	
9 52 M	Lower half of right pleura contained one quart of fluid at autopsy.	Both sides obliterated, except lower half of right pleura.	Arterio sclerosis; fatty heart.	Both sides enlarged and dilated.			Pulsation in jugular vein.
10 43 F	Autopsy: Lower half of right pleural sac contained 8 ozs. of fluid.	Both sides obliterated, except lower part of right pleura.	Fatty heart	All chambers dilated, especially right side.			
11 63 M	Clinically: Right-sided effusion; left free. Confirmed by autopsy.	None	Autopsy: Fatty heart; atheroma; mitral stenosis; aortic thickening.	All chambers enlarged, especially the right and left auricles; weight 650 grms.	Present		
12 40 F	On admission: Left side, effusion up to third rib; right side, effusion to fifth rib, three weeks later; double effusion; tapped once. Soon after patient developed fever with development of pus in left pleura and 6000 c.c. pus was removed.		Mitral insufficiency and stenosis; action weak and irregular	Enlarged to left and upward in left.			
13 74 F	Clinically on admission: Acute pleurisy on right side with effusion up to the fourth rib; no effusion in left side. The effusion persisted for some days after subsidence of fever and then disappeared.		Mitral insufficiency; aortic insufficiency and roughening; fatty heart.	Enlarged to left.			Fever on admission which lasted for six days, with pain on right and cough; fever gradually disappeared.
14 41 F	Clinically on admission: Right-sided effusion up to angle of scapula; confirmed by autopsy.	Autopsy: Left side totally obliterated by adhesion.	Autopsy: Mitral stenosis and insufficiency; fatty heart; arterial sclerosis.	Clinically: enlarged, especially toward right.	Present on admission.		History of acute articular rheumatism; 3 weeks of sharp pain in chest; leucocytes 28,900.
15 45 M	Clinically on admission: Double effusion slightly greater on right, which gradually disappeared.		Mitral stenosis and insufficiency; aortic insufficiency.	Enlarged to left and right; left border, anterior axillary line; right border, right parasternal line.	Present on admission; ascites, which gradually disappeared as improvement occurred.		Considerably jaundiced; gradually improved until an attack of cerebral apoplexy caused death.
16 52 M	On admission: Right-sided effusion to third rib; confirmed by puncture; later some left-sided effusion.		Aortic roughening and regurgitation.	Clinically: enlarged to right (right parasternal line) and to the left.	Slight on admission.	Enlarged to within 1 inch of umbilicus.	Recovered slowly and effusion disappeared.
17 40 F	Clinically: Double effusion greater on left; confirmed by puncture. Tapped left twice 500 c.c. Tapped right once 600 c.c.		Clinically and at autopsy: Mitral stenosis and insufficiency; tricuspid insufficiency; fatty heart; atheroma of coronary arteries.	Autopsy: Dilatation of all chambers, but especially of the right auricle; weight 600 grms.	Present on admission; ascites.		Fluid 1020; albumin 45 per 1000. Patient had been in hospital several times for same trouble; gradually grew worse and died; autopsy reported in full in paper.
18 . . M	Admitted twice with pleural effusion. Always on right; left side remained free; right side tapped once 1200 c.c. and filled again rapidly and then disappeared as patient recovered. Persisted longer than external edema.		Mitral insufficiency; aortic insufficiency; deeneration of myocardium.	Enlarged to left and right.	Present on each admission; ascites; edema disappeared before the effusion.		Had been admitted 4 times for cardiac disease; twice with pleural effusion; fluid 1044; albumin 1.5 per cent. by weight; death; no autopsy.

SUMMARY OF CASES OF PLEURAL EFFUSION IN HEART DISEASE.—CONCLUDED.

Number. Age in Yrs. Sex.	Condition of Pleural Sacs.	Pleural Adhesion.	Diagnosis.	Cardiac Enlargement.	External Edema.	Liver.	Remarks.
19 50 M	Clinically on admission: Right-sided effusion up to fourth rib; left side free; right side tapped, 2000 c.c. Autopsy: Right side, 1500 c.c.; left side, 300 c.c.		Autopsy: Fatty heart; atheroma of coronaries; mitral insufficiency. (relative)	Clinically: Left side enormously dilated, left anterior axillary line; right border, right edge. Autopsy: All chambers distended; right auricle enormously dilated.	Present on admission; ascites.	Congested and enlarged.	Fluid 1015; albumin 4 per 1000; autopsy reported elsewhere.
20 53 M	Autopsy: Left pleura . . . 1300 c.c. Right pleura . . . 750 c.c.		Autopsy: Acute pericarditis; chronic interstitial nephritis; arteriosclerosis; no valvular lesions.	Autopsy: Enormous involvement of left ventricle.	Considerable edema; some ascites.		
21 44 M	Left-sided effusion 750 c.c. at autopsy	Some on left side.	Chronic parenchymatous nephritis; no valvular lesions; fatty heart.	Much enlargement of left ventricle.	Present: legs and eyes.	Much congested.	
22 60 M	Left-sided effusion.	Some in right side.	Aortic thickening; fatty heart.	Dilated hypertrophy of left ventricle.	Both legs.		
23 31 F	Autopsy: Left pleura full; right pleura almost empty.	None.	Chronic interstitial nephritis; no valvular lesions.	Hypertrophy of left ventricle; heart weighed 535 grms.	Legs and eyes preceded pleural effusion ascites.	Atrophic; wt. 1420 grms.	
24 47 F	Double effusion greater upon the left.	None.	Chronic interstitial nephritis; no valvular lesion.	Much hypertrophy of left ventricle; weight 740 grms.	Legs and face preceded pleural effusion; some ascites.	Congested and enlarged.	
25 29 M	Autopsy: Right sac contained 1000 c.c.	Left sac obliterated.	Mitral stenosis and insufficiency; general atheroma.	All cavities enlarged, especially left ventricle.	Present on admission.		
26 58 F	Autopsy: Right pleura contained 400 c.c.; left pleura contained 200 c.c.		Mitral, tricuspid and aortic valves all thickened; fatty heart.	All chambers enlarged.			
27 58 F	Autopsy: Double effusion, greater on right.		Mitral stenosis and insufficiency.	Much enlarged, especially right auricle and ventricle which were greatly dilated; weight 690 grms.	Present.		
28 57 F	Autopsy: Left pleura completely filled; right pleura one-half full.		Double aortic disease.	Right side enormously dilated; left ventricle enlarged and made up bulk of heart.	Legs; some ascites.		
29 53 M	Right effusion to 2nd rib, which slowly increased; left remained free.		Aortic roughening and insufficiency; mitral insufficiency.	All chambers enlarged.	Present on admission.		
30 8 F	Double effusion, decidedly greater on right; confirmed by puncture; right to 5th dorsal vertebra; left to 6th dorsal vertebra.		Acute endocarditis of mitral and aortic valves; old mitral insufficiency and stenosis; presystolic thrill at apex.	Enlarged upward to 2nd rib and to right to right parasternal line enlarged slightly to left; probable dilation of left auricle and right side of heart.	Slight of legs; disappeared before effusion.		History of rheumatism and chorea; improved and effusion disappeared; the patient had an irregular fever for the first 2 weeks after admission.
31 12 M	Left-sided effusion up to angle of scapula; disappearing as heart grew stronger and reappearing with relapse of endocarditis.		Acute endocarditis, myocarditis and pericarditis; mitral insufficiency; tricuspid insufficiency; friction rales in pericardium on first admission.	Enormous dilation of left ventricle and left auricle; less degree of dilation in left side.	Present on both admissions, disappearing rapidly.		Sudden onset of acute endocarditis, with fever first week; leucocytosis; gradual improvement and discharge; returned in 8 days with fever and return of all symptoms; systolic pulsation in veins of neck.

the root of the right lung and must have exerted some pressure on it.

The course of the vena azygos major could not be traced around the root of the lung since all the tissues were very edematous, but the vein was dissected out as it ran up along the spine underneath the costal pleura. It was distended by dark blood and was fully one-third of an inch in diameter. The lower intercostal veins were correspondingly dilated. The left azygos, or azygos minor, was small and collapsed, and could not easily be found. The surface of the pleura showed nothing out of the ordinary.

There was some ascites. The liver was rough and hard, and there was a high grade of the cyanotic induration. There was no perihepatitis. The kidneys also showed cyanotic induration and were much congested. There was no enlargement of the esophageal veins.

CASE 17.—A. B., female, colored, aged 40 years. The patient had been admitted twice in six months for the same condition.

Clinical Diagnosis.—Much pleural effusion, greater on the left side. Myocardial degeneration and mitral disease. Tapped twice. Specific gravity of the fluid was 1020, and it contained 4.5 grams of albumin per liter.

Pathologic Diagnosis.—Double pleural effusion, greater on the left. Fatty heart. Great dilatation of all the chambers of

the heart, equally as great on the left as on the right side. The vena azygos major was dilated and engorged.

History.—She had had several attacks of acute articular rheumatism. In December, 1902, she began to suffer from dyspnea, vertigo, cough and fainting attacks. In June, 1903, her feet began to swell for the first time. She was admitted to the hospital July 27.

Examination.—On admission she had much dyspnea and could not lie flat in bed. There was no fever or cough. Examination of her lungs showed evidence of effusion in both pleural sacs, but more on the left than on the right side. The heart was enlarged to the left and to the right, the apex was in the sixth interspace one inch above the mid-clavicular line. There were blowing systolic murmurs at the apex and in the aortic area. The urine was of good specific gravity, averaging 1020. At first it contained albumin, but this disappeared as the patient improved.

Course.—She grew rapidly better under digitalis, strychnin, nitroglycerin and rest in bed and was discharged in a few weeks. At the time of her first discharge there was no evidence of fluid in her pleural cavity. The patient remained fairly well until Nov. 12, 1903, when she was again admitted with symptoms of failing compensation.

Examination.—At that time her condition was as follows:

Thorax: Evidence of effusion in both pleural sacs, greater on the left side. The effusion extended to the level of the fifth rib on the left, and on the right to the level of the seventh rib. Exploratory puncture gave clear yellow fluid on both sides. This fluid had specific gravity of 1020 and contained 4.5 per 1,000 albumin. Respiratory murmur above the effusion was clear with the exception of a few rales.

Heart: The heart was enlarged to the left, to the right and upward. There was a systolic murmur at the apex, which was also heard in the aortic area, but was not transmitted to the vessels of the neck. There was a distinct systolic murmur in the tricuspid area of a different character than that heard at the apex. This murmur apparently originated at the tricuspid valve. There was systolic pulsation in the veins of the neck.

Liver: The liver was somewhat enlarged but did not pulsate. There was some edema of the legs and ascites.

November 14, 600 c.c.m. of clear yellow fluid was drawn from the left pleura and November 17, 450 c.c.m. were drawn from the left side. November 18, the right chest was tapped and 500 c.c.m. of clear yellow fluid was obtained.

Blood: Red cells 72 per cent., hemoglobin 68 per cent., white cells 6,000. There was slight cough and no fever. The urine was scanty and albuminous and contained casts. The patient died suddenly December 3.

Autopsy.—The right pleural cavity showed some firm adhesions posteriorly, probably diminishing the capacity of the right pleural cavity to a considerable extent. The right pleural cavity contained 130 c.c.m. of clear fluid, the left pleural cavity was free and contained 400 c.c.m. of clear fluid. The layers of the pleura on both sides were thickened, but not congested. The vena azygos major could be plainly seen lying against the spinal column on the right side. It was considerably dilated and was approximately the size of a large goose-quill. The vena azygos minor was not dilated and was collapsed so that it could not be satisfactorily studied. There was dilatation of the right and left auricle, about equal in degree. The right auricle extended two inches to the right of the sternum in the fourth interspace. There was dilatation and hypertrophy of the left ventricle and dilatation of the right ventricle. The mitral valves were insufficient, due to the thickening of the valve leaflets and chordae. The tricuspid valves were insufficient, due to a dilatation of the valve orifice. There was atheroma of the aortic valves and the aorta, and great thickening and calcareous infiltration of the coronary arteries. The lumen of these vessels was considerably diminished. The wall of the left ventricle near the apex was very thin. The section of the heart muscles in these areas showed much degeneration. There was hypostatic congestion of both lungs. There was moderate fatty degeneration and fibroid changes in both kidneys. The kidneys each weighed 160 grams. The heart weighed 600 grams.

In my first paper I reported the result of the autopsy on a case of double hydrothorax greater on the right side, increasing as the heart lost strength. There was little ascites and edema, but the thoracic effusion preceded the appearance of the subcutaneous edema.

Autopsy showed chronic fibrous myocarditis and hypertrophy and dilatation of the heart, especially affecting the right auricle. The dilated right auricle pressed directly on the root of the right lung.

The right pleural sac contained 1,600 c.c. of clear blood-stained fluid. The visceral layer of the pleura was somewhat thickened, but there was no sign of acute inflammation. The left pleural sac contained 600 c.c. of clear blood-stained fluid.

The liver was slightly smaller than normal, and there were a few adhesions between it and the diaphragm, which were evidently due to an old perihepatitis, but there was no evidence of any recent inflammatory process. The bronchial glands were not enlarged nor diseased.

Wintrich has reported a case of unilateral right-sided

hydrothorax without external edema. Wintrich remarked that no cause could be found for the effusion except a dilated right auricle, the result of chronic myocarditis from alcoholism. There was no inflammatory change about the liver, nor ascites.

Stengel reports two autopsies in his list, in which there was dilatation of the right ventricles, auricles and vena cava, and marked backward pressure on the root of the right lung and azygos vein. One of these was a case of unilateral right-sided hydrothorax, and the other was one of double hydrothorax greater on the right side.

Dr. Stengel states as his opinion that such pressure on the root of the right lung, causing compression of the vena azygos major, is the cause of the right-sided effusions observed in his cases. In his article he gives a very convincing anatomic diagram prepared by Dr. G. G. Davis, which shows very plainly how dilatation of the right side of the heart may press on the root of the right lung, and compress the vena azygos major.

Dr. Stengel and myself can not claim the entire credit of originating this explanation for such right-sided effusions. Baccelli advanced this theory in a modified form as early as 1863. He assumed that a dilated right heart produced obstruction of the vena azygos major not by direct pressure on the root of the lung, but by a downward displacement of the right side of the heart due to its increased size and gravity. The superior vena cava would then be carried downward and with it the azygos major, consequently this vein from its anatomic position would be drawn tightly around the root of the lung and compressed. Baccelli's idea was supported by Lizzato, Cardinelli and Fusa.

Rosenbach has advanced the theory that such right-sided effusions are explained by the pressure exerted on the azygos vein by dilatation of the right heart. This is aided by congestion of the liver caused by weakness of the heart. The enlargement of the liver hinders the action of the diaphragm, and consequently prevents thorough emptying of the veins of the right side of the pleura, thus favoring an effusion.

Just as the dilatation of the right heart appears to bear some relation to right-sided pleural effusion, so enlargement of the left heart, with or without involvement of the right side, was observed in nearly all the cases of left-sided effusion. In the eleven cases of effusion confined to the left pleura, or greater on that side, the left heart, and especially the left ventricle, was especially mentioned as enlarged in nine cases, that is, in four-fifths of the cases of left-sided effusion. It seems fairly well established that dilatation of the right heart bears some relation to right-sided effusion. The figures just given suggest also that enlargement of the left heart may bear some relation to left-sided effusion. I can give no reason why this should be so. The pressure of a dilated left auricle on the root of the left lung would not obstruct any large venous trunk analogous to the vena azygos major. The venous drainage of the upper part of the left pleura is afforded by two small veins, the upper left azygos vein and the left superior intercostal vein. These are so placed that they are not liable to compression by an enlarged left heart.

Rosenbach explains these left-sided effusions by assuming that the enlarged left ventricle presses on the lower lobe of the left lung and produces atelectasis. Long-continued congestion produced by the collapse of the lung brings about a low-grade inflammation of the pleura, and finally an effusion forms in the pleural sac which is partly transudate and partly inflammatory.

My list of cases gives nothing to confirm or to deny this theory of Rosenbach. I can only call attention to the fact that left-sided cardiac dilatation seems to bear some relation to left-sided pleural effusion.

Signs of acute inflammation of the pleura were not found at autopsy in any of the Presbyterian Hospital cases, or in any of those analyzed in my former paper. Dr. Stengel did not find any such condition in the three autopsies held on the cases he reports. However, the fluid removed in Cases 1, 2 and 3 had too high a specific gravity and too large an amount of albumin for a pure transudate. The fluid did not contain fibrin and was certainly not the result of an acute inflammatory process, but the physical characteristics of this fluid are such that it might have been the result of transudation combined with an exudate of a low-grade inflammation of the pleura, as has been suggested by Rosenbach.

The pleura in Case 17 and in Case 4 of my previous paper were reported as thickened and whitened, although there were no signs of acute inflammation. It may well be that long-continued congestion had set up some subacute inflammation here, which was not active enough to cause fever, cough or pain, but may have aided materially in the production of the effusion.

Stengel suggests that a long-continued congestion produces some trophic change in the vessels of the pleura favoring the passage of the fluid, and also calls attention to the fact that inflammation of the pleura may be latent and without symptoms. He suggests that in some cases an inflammatory element may be present in the production of these cardiac pleural effusions.

Gerhardt mentions a class of cases in which the effusion is very obstinate and recurs with great rapidity and persistence. Some of these cases have been tapped a great number of times, and the clinical picture they present is that of a chronic pleuritis of a low grade, combined with a process of transudation, due to the congestion of the vessels of the pleura.

Certain features of two of my cases suggest that some trophic change takes place in the pleura in cardiac disease that may render the pleura membrane a point of lessened resistance to infection.

Case 13 was an instance of acute pleurisy which occurred on the right side in a case of well-marked heart disease, with cardiac dilatation and symptoms of failing compensation. The pleurisy was accompanied by pain and fever.

In Case 12 the empyema developed in a case of double cardiac hydrothorax, greater on the left side, after both pleural sacs had been emptied by aspiration. The heart was much enlarged toward the left.

These two cases suggest that long-continued congestion may have altered the tissues of the pleura and that the pleural sac had become a *locus minoris resistentiæ*. Two isolated cases of this sort are not very convincing, but they are mentioned because they seemed to have some bearing on the question as to whether the effusion in cardiac disease is purely a transudate, or whether it is partly passive and partly inflammatory.

It seems probable, then, that the mechanism of the formation of fluid in these cases of pleural effusion in heart disease is not that of a simple transudate, but that congestion of the pleura produces a chronic inflammation of low grade, and that the effusion is both a transudate and an exudate. This is supported by the following facts: First, the specific gravity of the fluid and the amount of albumin contained in it is often too high to be consistent with the pure transudate; second, the effusion

may precede, by a considerable length of time, external edema or other serous effusions; third, the two cases reported suggest that the pleural sac particularly affected may undergo some trophic change, making it a point of lesser resistance to infection; fourth, the effusion in certain cases is very obstinate, lasts a long time and returns quickly after aspiration.

Gerhardt mentions the obstinacy and persistence of this effusion as a characteristic of this class of cases. Rosenbach, Brouardel and Liebermeister have called attention to this peculiarity of such pleural effusions.

Rosenbach mentions two cases in which the effusion lasted six and fourteen months respectively.

None of my cases showed this obstinacy of the effusion in any marked degree. Several of the patients were admitted to the hospital more than once for symptoms of failing compensation and pleural effusion, but usually one or two tapplings were sufficient to relieve the dyspnea, and the fluid returned slowly, even when the case was near to a fatal termination.

There was no case in the Presbyterian Hospital list in which the fluid persisted for any great length of time, and which was not relieved by one or, at most, two tapplings. The effusion usually disappeared spontaneously as the patient grew stronger, or else increased slowly until death. Consequently, I can not say that the Presbyterian Hospital list supports the statement of Gerhardt and Rosenbach, that great obstinacy is a characteristic of these pleural effusions in heart disease.

PROLONGED DELIRIUM IN PERICARDITIS AND ENDOCARDITIS.

WITH REPORT OF A CASE.*

EDGAR MOORE GREEN, A.M., M.D.

EASTON, PA.

I have taken the liberty of bringing to your notice the subject of delirium in certain diseases of the heart, not because it was possible for me to demonstrate any new scientific theory, but rather because from my reading and my own limited personal experience it seemed to me that prolonged delirium in such cases was quite unusual. It is, of course, well known that heart disease is a frequent complication of rheumatism, and endocarditis is much more common in such cases than is pericarditis. According to Whittaker,¹ Bouillaud believed that in every case of acute articular rheumatism the heart was more or less affected. Williams states that 75 are affected in every 100 cases. Leudet fixes the ratio at 22 in 100; Sibson 20 in 100. Wunderlich 19 in 100. Duchek 16 in 100. Bamberger has claimed that 30 per cent. of cases of cardiac trouble arise from rheumatism, and Thompson has placed the figures at 16 and 20 per cent. On the other hand, Latham states that pericarditis only occurs seven times in 136 cases of rheumatism. The latter disease is certainly more apt to occur in severe cases, and is said to be more frequent when the inflammation has a tendency to wander from one joint to another in rapid succession. It is said to occur very infrequently in cases of subacute or chronic rheumatism; in fact, some authorities deny that it ever occurs as a complication of the latter.

Ordinary cases of the disease run a comparatively

1. Twentieth Century Practice.

short course, frequently not more than eight or ten days, except where the amount of effusion is great, and these terminate in from three to six weeks. It will not be necessary for me to enumerate the ordinary symptoms and complications of this disease. I may say, however, that the rarer symptoms mentioned by most authorities are aphonia and hoarseness, from pressure on the left recurrent or laryngeal nerve, syncope from anemia of the brain resulting from pressure on the large vessels of the heart or myocarditis, vomiting from pressure on the phrenic nerve. Stupor, delirium and coma are mentioned as occurring from hyperemia due to pressure on the vena cava or to the accumulation of toxins in the blood. All authorities whom I have consulted, however, have stated that the latter signs usually show themselves in the last stages of the disease. Austin Flint has reported cases marked by delirium, but in all the cases of which I have read the delirium has been of comparatively short duration.

It will not be necessary for me to give a detailed report of the symptoms of this case, but a résumé may be given as follows:

History.—Dec. 15, 1902, I was called to visit a man, age 46, whom I found to be suffering from acute rheumatism. His previous health had been good. Early in life he was said to have had an attack of brain fever, but of this I could obtain no detailed history. He had had two attacks of acute rheumatism, each lasting several weeks. In one of these attacks he had been under my care, and although the case was somewhat tedious, there were no complications and he made an uninterrupted recovery. There was no specific history. During the first week of his illness the inflammation was rather migratory in character, at one time an arm would be affected, on another day one knee would be inflamed, or one ankle or possibly both ankles, at another time an elbow or wrist. During this time the temperature ran as high as 103 to 104 degrees. At the end of about one week he was suddenly taken with pain in the left side about the level of the fifth and sixth ribs. This pain was acute in character and accompanied each inspiration, the respiration became more rapid, running up to 37 or 38 per minute, pulse 100 to 108, temperature 100 to 101 degrees.

Examination.—Auscultation at this time revealed symptoms of acute pleurisy, and also a systolic murmur over the precordium, but more intense at the apex. There was also found a to-and-fro friction sound at the fourth and fifth interspaces directly over the heart. The sounds of the heart rapidly diminished in force and loudness. Visible impulse of the heart was practically obliterated. Percussion of the chest revealed great increase in the lateral diameter of the cardiac dullness. The urine was about normal in quantity, but was quite high colored and of high specific gravity. There was no albumin nor sugar, but urates were present in considerable excess.

Symptoms.—In addition to great pain in the region of the heart there was difficulty in swallowing. The latter symptom was so marked that even the swallowing of liquids caused great discomfort and frequently he was unable to take more than one or two swallows in succession. At the same time he became extremely restless, talkative and frequently saw imaginary objects. It was exceedingly difficult to induce sleep. Morphine, $\frac{1}{4}$ gr., with atropin would partially relieve pain, but seldom caused more than one hour's continuous sleep. He was exceedingly restless, frequently trying to get out of bed and almost constantly trying to pick up imaginary objects. His most frequent delusion was that he was traveling in some distant city or foreign country, although he usually recognized those about him. After a number of days he believed he was on a sort of houseboat on a trip which his wife was conducting. His usual question when I visited him in the morning would be, "Well, how did you get here today?" It is difficult to understand how this delusion could have originated. His occupation for several years had been

that of superintendent at large iron works and during certain seasons of the year he was in the habit of traveling for the making of purchases in various parts of the West. At no time did his delirium become violent, though, as stated before, he frequently attempted to get out of bed. This mental condition continued without interruption until January 26, or about five weeks, when, after a fair night's sleep, the nurse stated that his mind wandered but little. After this time the mind was more or less confused for a few moments at a time each day for two weeks, but it may be said that the mental condition steadily improved. From the time of the onset of pericarditis his temperature did not run above 100.4 degrees. As a rule, it would fall to 99 or even 98.6 degrees in the morning and would rise to 100.2 degrees in the evening.

Dyspnea was always present, though it did not develop to the extent of orthopnea. Cyanosis was also present and its presence, of course, indicated the extent to which the brain must have been disturbed by this venous congestion. Osler states in his practice that delirium and marked cerebral symptoms are associated with the hyperpyrexia of rheumatic cases. I think, however, that you will agree with me that the degree of fever was not sufficient in this case to account for the continuance of delirium through so long a period of time.

Treatment.—December 31, Dr. William L. Estes of South Belkhelem was called to see the case in consultation. The treatment adopted at this time was large doses of citrate of lithium and potassium with iodid of potassium three times a day. Tincture of strophanthus was also given three times a day in doses of ten drops. Fortunately for the patient the bowels were rather active, frequently four to five stools per day, and these were often more or less watery in character. Under the action of the alkaline salts given with copious draughts of water, the kidneys became more active, the quantity of urine running some days as high as 102 ounces and not on any day being allowed to fall below normal. The skin was kept active and perspiration continued profuse. As soon as the patient's condition permitted general massage was given in order to tone up the general system.

Result.—Recovery, of course, was very slow, and he was not allowed to take up any work until March 31; even then the amount of physical exercise was much restricted. In October, however, he started West on a business trip and much of his time was spent at great elevations above the sea level and yet with no untoward result. On November 8 he left Durango, Colorado (elevation 6,520 feet), at 8 a. m. and went to Silverton (elevation 9,224 feet), where he walked two miles to a stamping mill and there climbed up to a height of 150 or 200 feet, afterward returning by train to Eureka. The following day he drove twenty-six miles alone, starting from Silverton (elevation 9,224 feet), and going to Ouray (7,700 feet), passing meanwhile over a height of 11,002 feet, then on nine miles further to Mount Sneffles (elevation between 11,000 and 12,000 feet), and back to Ouray at 6 p. m.

The ability to take such an amount of exercise at such an elevation would seem to me to show how thorough his recovery had been; moreover, careful physical examination of the chest made within the last few days revealed no markedly unnatural sounds. The cardiac impulse is normal in location and force, and the sounds almost natural in character, except for a slight blowing murmur heard at the apex.

How They Do It in Iowa.—A Red Oak paper of August 20 has the following: "Dr. A. A. Potter, who advertised that he would be in Red Oak last Saturday and meet all who wished to have their ills taken away and their youth renewed, was on time all right. But he met with grief a plenty. He had no more than unpacked his pill box when a local officer arrested him and took him before Mayor Reiley to answer to the charge of practicing medicine in Red Oak without having procured a license. The doctor plead guilty and was fined \$29.10. He left town."—*Iowa Health Bulletin.*

THE LIMITATION OF DIGITALIS IN MITRAL AND AORTIC REGURGITATION.*

FRANK JONES, M.D.
MEMPHIS, TENN.

While this subject has been thrashed over and ground up before various medical societies and by numerous eminent authorities, there yet remains much to be done in the crystallizing and refining process. What I have to say may seem erratic and dogmatic to some, but I shall try to show by reason of the anatomic location and the physiologic action of the mitral and aortic valves, that in mitral insufficiency when compensation has failed or is failing digitalis is the sheet anchor, the general in command, while in aortic insufficiency with the same condition, it too often plays the rôle like the soldier, Jack Falstaff, of old.

In treating any heart lesion the careful clinician must study closely the cardiac state and the condition of the blood vessels, and he must take into consideration the various organs that are complicated.

The mitral valve, located as it is, at the gateway between the great arterial reservoir, the left auricle and the great arterial pumping station, the left ventricle, can, when it fails to close with systole, throw its burdens on various organs, particularly the right heart, the lungs, liver and kidneys. When compensation has failed or is failing the pathologic picture is that of venous stasis.

The column of blood is forced back on the left auricle. This chamber of the heart can not perform its functions as a reservoir, receiving the blood from the pulmonary veins and sustain this backward flow at the same time. As a result the pulmonary veins are obstructed in their efforts in carrying the systemic blood to the auricle. The right ventricle has to contract against resistance. It has to pump the venous blood of the right side through the lung already engorged from the backward pressure through the pulmonary veins, hence the marked hypertrophy of the right ventricle which ensues. The lungs are overwhelmed, this condition giving rise to dyspnea as an evidence of edema, and to cough denoting bronchitis from irritation to the terminal branches of the bronchial tree. This edema and bronchitis will be in proportion to the degree of obstruction and stasis, and the condition of the cardiac muscle.

This backward pressure exerts its force further on the liver, giving rise to marked engorgement of this organ through the inferior vena cava; on the stomach, spleen and intestinal tract through the portal vein; on the kidneys through the renal veins. Thus it can be seen that we have hyperemia of the lungs, liver, stomach, bowels and kidneys. We have stasis everywhere, beginning at the incompetent valve and ending in a great many cases in the rectum, in the form of hemorrhoids. It is seldom that one sees a classical mitral regurgitation with failing compensation but what hemorrhoids are also found. All these organs enumerated have important functions to perform. Nutrition is profoundly disturbed as a result of this stasis and engorgement. The governing band of metabolism has run off. The constructive and the destructive forces are in a state of unstable equilibrium. We have perverted secretions, faulty excretions, bad nutrition, low blood pressure, vitiated blood and leaking

blood vessels. Dropsy, in mitral insufficiency, if properly treated, very often yields readily.

With this clinical picture before you, with all the organs stagnated and overflowed, is there any necessity for dwelling on the marked effects of digitalis in mitral insufficiency with failing compensation? The very location of the mitral valve when the muscle becomes incompetent is conducive to marked hyperemia and venous stasis. The right heart, in other words, must suffer the brunt of nearly all the evils as a consequence of failing compensation. Now let us consider the other great valvular lesion, aortic insufficiency. The aortic valve stands as a sentinel at the very gateway of life, the aorta. This great blood vessel arises from the great pumping station, the left ventricle. When this valve becomes incompetent from disease, and when the left ventricle fails to compensate and cries for help, it has not the neighbors to call on as the mitral valve has. When it does sound the alarm and cries for help it is, alas, too often too late. When the aortic valve becomes incompetent and can not close with diastole, we have a backward column of blood from the aorta thrown on an organ highly endowed with muscular structure, the left ventricle. For a long period of time the left ventricle is the only portion of the heart that comes to the rescue of the incompetent valve when it cries for help. The ventricle responds with vim and vigor. It puts forth all of its energies. Its fight and struggle is something to be applauded. In its efforts to relieve the leaking valve it becomes enormously hypertrophied. The beef heart attains to its most classic and highest degree in aortic regurgitation. In nearly all cases of aortic incompetency there is naturally a high blood tension.

There frequently exists a well-defined arteriosclerosis. There is not the hyperemia of all the organs which we find in mitral insufficiency, except in the terminal stage when death is close at hand. With this evidence before you let me ask, Has digitalis any place in aortic insufficiency? Nearly all of the eminent authorities teach us that when the left ventricle fails in its efforts to come to the rescue of the incompetent aortic valve, and becomes dilated and relaxed to such a degree as to produce leakage at the mitral valve, then digitalis is indicated.

The argument is that this secondary or relative, or more properly speaking, muscular insufficiency on the part of the mitral valve gives the mitral symptoms of engorgement and stasis added to the aortic symptoms. Therefore, digitalis must be given, just as we would in a frank case of mitral insufficiency with failing compensation. In other words, they teach that failing compensation, it matters not from what source, means digitalis as a remedial agent. I wish to oppose these views most emphatically. Digitalis in my hands has no place at all in aortic insufficiency, it matters not what may be the condition of the muscular structure of the heart. The conclusions reached have not been on theoretical grounds, as some of our authorities are so accustomed to charge, but from a careful clinical bedside study in the hospital wards and in the outdoor clinic.

As we said in the outset, in mitral insufficiency with failing compensation it is the general in command. It tones up the walls of the blood vessels by its vaso-constrictor action. It comes to the aid of the left ventricle, which does not primarily undergo that marked hypertrophy which we have in aortic insufficiency. By its actions on the ventricles, particularly the right, and the walls of the blood vessels, engorgement is relieved, blood tension is raised, stasis is overcome, absorption of serum through the blood vessels and lymphatics takes place.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

very often symptoms disappear and the patient is made fairly comfortable.

As Broadbent well says in his book on diseases of the heart: "Mitral insufficiency with dropsy is the disease that brings patients to the outdoor clinic. Dropsy can be relieved, their symptoms can be materially alleviated so that they can resume for a time their occupation."

My experience at the outdoor clinic voices the sentiment so well expressed by Broadbent. Dropsy, however, in aortic insufficiency means preparation for a funeral in a short while.

It can readily be seen why this is so. The ventricles, particularly the left, become hypertrophied and dilated, relaxed, worn out and degenerated to such a degree that the administration of digitalis is of no use.

To give digitalis in aortic insufficiency, where we have secondary mitral leakage from ventricular dilatation, calls to mind the fable of the crawfish and the worm. They became engaged in a heated argument. Harsh words followed. They challenged each other to a duel. When they met on the field of battle the worm entered a protest that the crawfish had all advantage of him because he (the worm) could not tell which end of the crawfish to attack, because, as you know, the crawfish can move as freely backward as forward.

So it is in giving digitalis in aortic insufficiency with failing compensation. You do not know which end of the circulation the digitalis is going to attack. In aortic insufficiency with failing compensation, where the mitral valve is relatively incompetent, we have leakage both at the mitral and aortic openings. The leakage at the mitral valve spins its force backward with systole on the pulmonary veins, lungs and the right heart. The backward current from the aorta through the incompetent aortic valve spends its force on the left ventricle.

Let me ask the authorities who contend that digitalis is as much indicated in aortic insufficiency with failing compensation as in mitral insufficiency: Does not the digitalis by its action drive as much blood back through the incompetent mitral valve as it does forward through the incompetent aortic valve? Does it not in this way increase the already existing stasis in the left auricle, pulmonary veins, lungs, right heart and liver? The authorities will answer by saying that digitalis will contract the ventricle, and by so doing will close the mitral valve, thus checking this backward flow, thereby relieving stasis.

Let me ask: When you close the mitral valve do you not put too much work on the left ventricle already overburdened from its continued efforts to come to the rescue of the incompetent aortic valve? Is there not danger by increasing this pressure within the ventricle of paralyzing the left ventricle already dilated to its utmost degree? Do you not put too much work on it while the coronary arteries are crying out for blood to maintain nutrition in the muscle? You are giving the heart more work to do and a stone for food, while it is crying out for rest and bread.

Dropsical symptoms in aortic insufficiency are very late manifestations. They are the expressions of a heart tired and fagged in its efforts to relieve the incompetent valve, and in the majority of cases the dropsical manifestations have their origin in the mitral and not in the aortic valve. To give digitalis in these cases is like trying to make a wick burn when there is no oil in the lamp, or like trying to make an engine pull a heavy train up grade with the brakes on, with the flues burnt out and no steam in the boiler. When compensation fails in aortic insufficiency the left ventricle goes to pieces very much

after the fashion of Dr. Holmes' masterpiece, "The Deacon's One Horse Shay."

Let me quote from our own Dr. Babcock, in his most excellent book on diseases of the heart. You may read between the lines just which way the pendulum is swinging in his analytical mind. He says: "In cases, therefore, of aortic defects manifesting dropsy, the indication is for the administration of cathartics and digitalis the same as in mitral disorders. I believe, however, that the latter should be administered with judgment. There are some physicians who advocate the employment of large doses of digitalis in all cases of aortic regurgitation with broken compensation. My experience leads me to agree with Broadbent when he says that a distinction should be made between cases of aortic insufficiency with edema and those without. When loss of compensation is shown by symptoms pointing to the left ventricle's feebleness, rather than by edema and back pressure consequent on relative mitral regurgitation, then I am emphatically of the opinion that digitalis must be given with caution." He cites the following case: "The man had aortic insufficiency with failing compensation. He says: "Edema was not present, yet the state of the heart seemed to call for heroic doses of digitalis in the forlorn hope of lessening the dilatation of the left ventricle. Instead of doing this, however, the digitalis appeared to aggravate the back pressure, and at last death came suddenly and unexpectedly."

There is no more eminent authority on heart disease than Dr. Babcock. If you will follow him closely you will note that he qualifies to a great extent, the reference to digitalis in the treatment of aortic insufficiency with failing compensation. He wants a string tied to the digitalis so that he can guide it.

In my own experience, as I said at the outset, I can see no rational reason why digitalis should be given in this great valvular lesion. Broadbent says in his book on diseases of the heart: "In the absence of mitral symptoms it is rarely that digitalis is indicated in aortic incompetence or is of service, and it may undoubtedly do harm. It may set up sickness, which is an ominous symptom in this form of disease and induces a condition of asthenia difficult to remedy."

In my opinion, this argument as set forth above can best be applied in aortic incompetence where mitral symptoms are present. There is more reason for discrimination as to the indications for digitalis in these two valvular lesions than there is for the administration of quinin in the various malarial disorders. The subject has always been of particular interest to me, and I have reached the conclusion, after a careful study from bountiful clinical material, that there is but one valvular lesion where digitalis is indicated, and that is mitral insufficiency, and not until compensation has failed.

Tuberculin in Diagnosis.—The *Beiträge zur Klinik der Tuberkulose* is a new periodical, just entering its second volume. It is issued by Professor L. Brauer of Heidelberg. No. 4 contains an article by Bandelier, of the sanatorium at Kottbus, who states that out of 500 persons to whom the tuberculin test was applied, 92.6 per cent. responded positively. All those who failed to exhibit the specific reaction have remained apparently healthy to date. Out of 114 patients tested as they left the sanatorium, 38 per cent. gave no reaction, and 22 of these patients, tested again twelve to twenty months later, were found permanently cured with but 2 exceptions. He urges the application of the tuberculin test as a current measure, not only by specialists, but in hospitals and in general practice. In order to have a uniform standard for comparison he pleads that Koch's technic should be followed.

SOME POINTS IN THE ACOUSTICS OF
RESPIRATION.*

CHARLES E. QUIMBY, M.D.

NEW YORK CITY.

The first attempt to define, even relatively, the pitch of respiratory sounds was made by the late Austin Flint in a prize essay published in 1852. The opening sentences of that essay are as follows:

Very little attention has hitherto been paid to variations in pitch of sounds heard in the practice of percussion and pulmonary auscultation. By most writers on physical exploration pitch modifications, except in rales, are not recognized, no allusion whatever being made to them.

Flint makes essentially no attempt to explain the production of respiratory sounds, or to offer physical evidence in support of his purely dogmatic affirmations. His statements as to the pitch of normal and pathic respiratory sounds, quoting verbatim, are these:

On placing the stethoscope over the trachea the respiratory sound is found to be notably high in pitch. The relative altitude of pitch is immediately perceived on comparing the tracheal sounds with the vesicular respiration, heard on listening over the chest. Two sounds are heard uniformly in this situation, viz., inspiration and expiration. The sound of expiration is higher in pitch than that of inspiration. In vesicular respiration the pitch is uniformly and notably lower than that of tracheal and bronchial respiration. The pitch of the bronchial sound is high, probably not much below that of the tracheal sound. In the more important elements the tracheal and bronchial sounds are similar; they are both high in pitch, and the expiration in each is higher than inspiration.

The foregoing statements, made over fifty years ago are identical with those found in the standard works on physical diagnosis to-day, and have evidently been accepted through the intervening years by one author after another without question or investigation.

In a former article¹ I presented a comprehensive discussion of the laws governing the formation of respiratory sounds and their pitch relations, and, as I believe, not only demonstrated the fallacy of accepted beliefs, but established, on a strictly physical basis, the truth of the exactly opposite propositions regarding the pitch and pitch relations of such sounds.

It is the purpose of this present paper, reserving the right of reversion to the former article for exactness of statement under criticism, to present anew, in brief outline, a demonstration of the following propositions:

1. The tracheal note represents the inferior pitch limit of respiratory sounds, and that limit may be defined by a letter of the musical scale, as may every other respiratory pitch.

2. In vesicular respiration the inspiratory sound represents the superior pitch limit of respiratory sounds.

3. The passage from vesicular respiration to bronchial breathing is attended, at first, by a lowering in pitch of the inspiratory note, and later by lowering of both inspiration and expiration.

4. In vesicular breathing the inspiration is of a higher pitch than expiration; in rude, bronchial and tracheal breathing the inspiration is of a higher pitch than or the same pitch as expiration. There is no respiration resulting from consolidation in which expiration is of higher pitch than inspiration.

In the proposed demonstration it is necessary to con-

sider first the formation of respiratory sounds. Whatever modifications they may undergo later, there can be no question but what they depend primarily on vibrations excited in the respiratory air column by its motion through the tubes. Any such confined column of air will be thrown into sonorous vibration when it meets or passes an obstruction whereby it is suddenly compressed. Such points are found in the respiratory track only at the larynx and bronchial bifurcations. At the larynx sonorous waves are produced by the primary compression of the air in passing the vocal chords, and the subsequent expansion as it enters the laryngotracheal tube; at the bronchial bifurcations similar waves are developed, on inspiration, by the deflection and compression of the air column, and on expiration by the impact of the two columns of air as they meet in a common tube. Now, it is an established law of acoustics that the pitch note of any vibrating column of air is determined essentially by its length, and that the greater this length the lower the resulting pitch note. In stating this law I am not unmindful of the measures employed by musicians in tuning such instruments as the clarinet and flute; they are but seeming contradictions of this law. Hence, since pitch depends on length, the only supposition under which normal or vesicular respiration could be of low pitch, and bronchial breathing of higher pitch, would be that the respiratory air column vibrates as a whole from the larynx to the ultimate tubes, which column would be at its longest, i. e., lowest pitch in health and shortest, i. e., highest pitch when its terminal was cut off by consolidation of the lung.

If this were the case, however, there could not be two notes in the same tube, and vesicular and tracheal respiration must be of the same pitch, which we know is not true. It is also made an impossibility by the physical conditions, since there is no constant tube length from the larynx to the terminal tubes, and the main air column could not vibrate in harmony with the various terminals. Moreover, we know that a sonorous air column vibrates as a unite only within the limits of uniform compression. These limits within the lung are the points of bronchial bifurcation. It is thus evident that the normal respiratory sound, as heard at any given point, is a composite sound made up of the tracheal sound and an added term from each and every tube in the line of passage to and within that part of the lung under examination, and that each and every one of these component sounds has its own fixed pitch, determined by the length of the tube in which it is developed. By reason of the manner of bronchial bifurcation the notes of the several components of this sound may fairly be represented by lines, of which one represents the trachea, progressively shorter ones the single branches, and multiple short lines the terminal tubes. Now, of these component notes, which combine in normal respiration and which represent all the possible respiratory notes, the trachea is the longest, and hence gives the lowest possible pitch note to be heard in respiratory sounds. Whereby is established the first of our propositions. For proof that the pitch note of this sound is, in the majority of persons, not far from G of the musical scale, I could quote high musical authority, but prefer to leave it to the decision of your own musical friends.

In considering the question of pitch in the composite sound of vesicular respiration it is evident that there are three possibilities:

1. These several components may be heard separately or in groups, thus making vesicular respiration not one but two or more sounds, each of distinct pitch. As it

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.
1. Medical Record, March 25, 1893.

most certainly is not thus heard by the majority of diagnosticians, we leave this contingency as not pertinent to the present discussion, merely stating that it is the case with those whose ears are acutely trained in the differentiation of pitch.

Assuming, then, that but a single sound is heard in respiration, its pitch must be determined by some one or by a combination of similar pitched components about which all the others are gathered as quality. This dominant tone or tones will be that which reaches the listening ear with the greatest intensity.

Therefore, we have for our other possibilities: 2. One of the single notes, either that of the trachea or a primary bifurcation, may dominate the multiple short tube notes, in which case vesicular respiration will be of relatively low pitch. 3. The multiple short tube notes may, by reason of their combination, be the louder, in which case vesicular respiration will be not only relatively high, but the highest pitch respiration to be heard. Which of these possibilities is the truth can be determined only clinically by the ear. But leaving that point for the moment, some conclusions can be deduced from what has already been shown.

It is obvious that, if the second assumption be true and vesicular respiration of low pitch, whether from the trachea or an early bifurcation, the short tube high pitch sounds are heard only as quality of the respiratory sound and their elimination under the processes of consolidation can only affect quality, and can not by any possibility make the resultant bronchial breathing of higher pitch than was the vesicular. On the other hand, if the third assumption is the correct one, and vesicular respiration is of high pitch, by reason of the dominance of the multiple combined short tube sounds, then their elimination by consolidation can only leave the longer tube low pitch notes to supply pitch for bronchial breathing.

Hence, under either contingency, vesicular inspiration represents the highest pitch of any form of breathing; it being under the second assumption, that of one of the single branches, and under the third relatively high from the terminal tubes, but in neither case admitting the possibility of a rise of inspiratory pitch during the consolidation of the lung.

A justification for the decision of the ear in favor of the third possibility is found in a consideration of the factors determining intensity of the inspiratory notes. As the air current is more rapid in the trachea and primary bronchi, their notes are primarily the more intense. Each of these notes, however, is single and suffers a loss of both intensity and clearness by interference as its waves pass into succeeding tubes, while the terminal tube notes not only suffer no such disturbance, but gain relative intensity by their number and production close under the listening ear. It is thus that vesicular inspiration becomes not only relatively and absolutely of high pitch, but of the highest respiratory pitch to be heard, which gives the justification for our second and third propositions.

Turning now to expiration, we see, since this must be a composite sound, formed in the same manner as inspiration, that an expiration of higher pitch than inspiration requires the development of multiple dominant notes in still shorter tubes than on inspiration.

Two things, however, render this impossible. First the manner in which sonorous vibrations are developed at any given bronchial bifurcation. On inspiration this is by impact of the air on the sharp, firm junction of the bronchial walls, conditions most favorable to the produc-

tion of such vibrations; on expiration it is by the collision of the two columns of air from the distal tubes, conditions most unfavorable to the production of such vibrations. Hence the note produced at any given point must be more intense on inspiration than expiration; and for this cause alone, other things being equal, it is evident that the distal point of sound production must be deeper in the lung, i. e., in shorter tubes, on inspiration than on expiration.

Second, the intensity of sonorous vibrations depends, other things being equal, on the pressure or rate of flow of the air column. This is greater on inspiration than expiration, so that both factors of intensity thus combine to make the point of ultimate sonorous vibrations in respiration such as will give an expiration of lower pitch than that of inspiration. What acoustics thus demonstrates to be a necessity the ear confirms clinically, and establishes the fourth and last of our propositions in so far as it relates to vesicular breathing.

It can hardly be necessary to repeat the demonstration for rude or bronchial breathing, since the same conditions governing intensity are in force after the elimination of the short tube notes, until the sound heard is purely a transmitted note from some tube without the affected lung. In such a case the inspiratory pitch may fall until it is the same as that of expiration, but it is impossible that it should fall below the expiratory pitch. Thus we have established our final proposition for all forms of respiration.

A brief word as to the manner in which inspiratory pitch falls under varying grades of consolidation. If the bronchial bifurcations, and the consequent notes which they contribute to the respiratory sound, were in geometrical ratio, i. e., two at the first, four at the second, and thus on through, say, eight, sixteen, thirty-two and sixty-four, and it was found that sixteen tubes, of any one note, were sufficient to dominate the lower notes, it would then be easy to see that normal inspiration must have the pitch of the 128 notes, and that, as consolidation advanced from the surface, the inspiratory pitch would drop successively and gradually through the pitch of the 64 and 32 to that of the 16. But our assumption as to bifurcation is not true; for, in fact, the bronchi, and hence the respiratory notes, going to any given part of the lung, show two, or at the most three, large single branches and then a multitude of very small ones, the difference between these last and the single branches being extreme from the acoustic standpoint. As a result the dominance of these high pitch tubes in the respiratory sound is not destroyed by the occlusion of a portion of the number; but when such pitch control is finally lost by more extensive occlusion the change in inspiratory pitch is not gradual, but by a sudden drop to that of one of the large single tubes, while such small tubes as may still give sonorous elements now appear in the respiratory total as quality. This explains how certain grades of rude respiration, which means retention of higher pitch notes without pitch dominance, may have a pitch nearly if not quite so low as that of pure bronchial breathing. With this change the pitch relations between inspiration and expiration remain unchanged. Indeed so convinced am I that no form of pulmonary consolidation can give a respiration with relatively high pitch expiration, that for nine years I have had a standing reward at the City Hospital for a case showing such respiration. That reward has yet to be claimed.

Twice, however, in ten years I have heard such pitch relations in what was apparently, for the individual, nor-

mar respiration. In each case it was evident that the expiratory pitch was due to a peculiarity in the second branch on the right side, whereby the inspiratory high pitch notes were weakened and the expiratory current from the lower lobes impinged on the angle of bifurcation, as is the rule in inspiration.

CONCLUSIONS.

In conclusion, I beg to answer the question so commonly asked: "Admitting all this to be true, of what good can it be to revise all our ideas, since men are making diagnoses by present methods?"

To this I reply: 1. If it is the truth, it should be known, accepted and taught. 2. It makes available for purposes of diagnosis the full value of the element pitch in respiratory sounds, which, if the position taken is correct, has never been so employed heretofore. 3. An experience of fifteen years in the teaching of physical diagnosis, making practical use of these principles with students, has shown that it enables students to acquire a far greater skill and confidence in diagnosis, within a much shorter time, than under the present methods of teaching.

DISCUSSION

ON THE PAPERS OF DRs. STEELE, GREEN, JONES AND QUIMBY.

DR. JAMES TYSON, Philadelphia.—We should bear in mind that "the proof of the pudding is the eating," and I will simply state what I am doing in cases of aortic regurgitation with loss of compensation, which means that there is also regurgitation at the mitral orifice. My first step is to place the patient in bed; I believe one-half the battle is won by securing a complete relaxation and reduced demand on the heart—taking off the breaks as has been suggested—and this can often be accomplished only by rest in bed. In bad cases I fortify this treatment with small hypodermic injections of morphin, scarcely ever exceeding one-eighth of a grain, with probably some atropin added which softens the effect of the morphin. These two measures will sometimes produce the most satisfactory and even unexpected results. Having done this we are prepared to take more active measures toward the relief of the dropsy, and this can be done by active purgation; I go even further than this sometimes and puncture the dropsical tissues to allow the fluid to drain off and relieve the tension. After this is done, and compensation remains unrelieved, I add digitalis, not in large but in small doses, say five minims every four hours, slowly increasing the dose, after waiting a reasonable time to get the primary effect. I think very often physicians want to see the effects of digitalis before they should expect it. I prefer to give moderate-sized doses and then wait two, three or even four days sometimes; after which, if there is no contraindication, I may increase the dose. In this way I think digitalis is helpful. Dr. Jones' illustration of the forward and backward movement of the erab is applicable, but I do not think the parallel is exact. Of course, if there was an equal balance between the regurgitation at the mitral orifice and that of the aortic orifice, i. e., if the blood came back as fast as it went forward, his position would be strikingly sustained; but so long as there is a chance of getting the blood to go forward more strongly than backward, I think we are justified in using digitalis. I believe the general principles announced by Dr. Jones are correct, and I agree with him, but I think we meet many cases which are successfully treated with digitalis, when there is mitral regurgitation with loss of compensation associated with aortic disease.

DR. RICHARD CABOT, Boston.—Experience seems to show that digitalis may do good in uncompensated mitral disease, stenosis or regurgitation, in the vast majority of cases, and that it does not do good in aortic regurgitation. I think a distinction should be made within the group of cases, known as aortic regurgitation; in elderly persons, with degeneration of the arteries and with high peripheral tension digitalis will

do harm; but there is another and much smaller group of cases, occurring usually after rheumatism and in young persons. In this group the disease attacks primarily both valves, mitral and aortic, the change being not merely a muscular one, but affecting chiefly the valves. Here digitalis will do good, though not so much good as in cases of primary mitral disease. I was struck with one of Dr. Jones' figures about trying to haul a train up hill with the brakes on and with very little steam in the boiler. Better let off the brakes than to try to make the engine do more work. Better lower the peripheral resistance, if it is high, than try to stimulate the heart. I have seen many cases where compensation had failed, and yet the heart seemed to be pumping strongly. In these cases good results may be obtained by using purgatives and diuretics, and, when the dropsy is reduced, digitalis. We should first deplete, reducing the load, and letting off the brakes; after that stimulation may be followed by improvement. I take issue with Dr. Quimby in all the points he has raised. Musi has interested me for many years, and particularly matters of pitch, and I wish to state that before writing my book on "Diseases of the Chest," I went through Flint and verified point by point everything that he stated regarding the pitch or respiratory sounds. Dr. Quimby is of the opinion that the pitch of bronchial breathing ought not to be higher than that of vesicular breathing, but he does not prove that to be the case. My ear tells me that bronchial breathing is higher than vesicular breathing. Also, it is my experience and that of my friends with musical ears that in bronchial breathing the expiratory sound is usually higher in pitch than the inspiratory one. Therefore, I believe that what Flint has stated in his book is correct. Anyone who is to consider this subject should have a musical ear, and should not base his remarks on the theory of the production of sound.

DR. DELANCEY ROCHESTER, Buffalo.—I am in accord with what Dr. Jones has stated regarding the use of digitalis in mitral and aortic insufficiency. I think Dr. Tyson will get better results with rest in bed than by placing his patients on digitalis in cases of aortic insufficiency. There is one thing I wish to disagree with: Dr. Jones stated that the only place for digitalis was in failing compensation in mitral insufficiency; if he had stated "mitral disease" I would have agreed with him. I think it has a great use in mitral obstruction. In mitral obstruction the heart has great difficulty in forcing the blood from the left auricle to the left ventricle; digitalis will lengthen the time of diastole and will energize systole. Therefore the auricle is given more time in which to empty itself. I think that there is a clear indication for digitalis in mitral obstruction. We do not give drugs in cardiac diseases simply because we find a murmur; the use of drugs should be controlled by the condition of the circulation and evidences whether or not it is failing. I am glad that Dr. Cabot took issue with Dr. Quimby; I also take issue with him, and I agree entirely with Dr. Cabot. Change of pitch is more easily recognized in the violin than in any other instrument known, and I must say that, clinically, Dr. Quimby is wrong in the position he takes in this matter.

DR. S. C. JAMES, Kansas City, Mo.—A very unfortunate element in the make-up of the heart is the fact that the valves are too close together; if I had the making of a heart I would like to separate the valves, five or six inches, then we western doctors would know when to use the whip, digitalis, and when not to use it. The average physician, when he comes in contact with a case of heart disease, immediately thinks of digitalis. I think that digitalis has done more harm in the world than it has done good. On the other hand, I think that digitalis is one of the grandest remedies in the hands of medical men today. The lack of the intelligent use of this drug has placed many an unfortunate, though trusting patient, in his coffin. If the cardiac condition were more carefully studied by the physician he would know better how and when to use digitalis. I think if I was to lay the whip on a horse I would not do it at the foot of the hill. I believe in the use of blarney; by its use a horse may be much encouraged and helped in pulling his load. Digitalis should be used, but with intelligence. I believe,

too, in taking off the brake, and, as Dr. Tyson says, use digitalis moderately and with a great deal of caution.

DR. EDWARD F. WELLS, Chicago—In the discussion and reading of Dr. Jones' paper it must have been clear to everyone that the keynote to the situation in failing compensation in cardiac disease, so far as the management of the condition is concerned, is that of opportunity. In the severer cases of lost compensation our opportunity for doing good is sometimes remarkable. Take, for example, a man who has been sitting in his chair for days, with no sleep, with advancing swelling of the limbs, labored breathing, etc., and the management of such a case should be something like this: Minute doses of morphin, 1/16 of a grain, administered hypodermically, will allow the patient to sleep for hours. Cathartics should be given, and watery bowel movements should be obtained by giving elaterium, 1/8 or 1/10 grain doses every three hours, until eight or ten watery movements have been produced. Then, if necessary, several punctures may be made in the feet or legs and you may allow quarts, or even gallons, of water to pass off within twenty-four, forty-eight or seventy-two hours. Now comes the opportunity for the use of digitalis, and with the greatest benefit. I am sure that if the members of the section will review their experience they will corroborate all that I have said.

DR. JOSEPH SAILER, Philadelphia—Dr. Steele's theory of the causation of hydrothorax is not capable of direct proof, and, therefore, depends on the accumulation of presumptive evidence. There are certain facts which appear to be against it. I believe that in the majority of cases of cardiac disease, hydrothorax is present when the left auricle is distended more than the right. This opinion is based on careful percussion and examination of the heart. Moreover, it is difficult to understand how sufficient pressure can be made on the vena azygos major to obstruct it without producing symptoms of pressure on some of the other important viscera of the thorax. The dilatation of the cutaneous veins on the right side, which we should expect to occur on account of their anastomosis with the branches of the azygos vein, is not present, and, as Dr. Steele has said, the theory is hardly applicable to the left-sided cardiac hydrothorax, although there is little reason to believe that the etiology in the two conditions is different. In regard to Dr. Jones' paper, it has been my experience that aortic disease is more common than mitral disease, the proportion being about three to two. When severe edema occurs in the course of aortic regurgitation and fails to clear up in three or four days after the patient has been put to bed, the prognosis is extremely grave. Dr. Cabot spoke of taking off the brakes. The older writers, commencing with Laennec, used venesection freely and apparently with great benefit. In those cases in which I have used it I have never known bad results.

DR. ALFRED T. LIVINGSTON, Jamestown, N.Y.—The heart, as a pump, is a peculiar pump, being practically two double pumps combined and connected with each other. One of the peculiar conditions which makes it differ from an ordinary pump is that it does not pump from a reservoir to a given point, but from the termination of one circuit into the beginning of the other. Now, it is generally conceded that disorders of the heart have their primary cause in disturbances of the circulation. If the two circuits are in perfect condition the pump will have easy work to perform and will not get out of order. If it does get out of order, it is because something has gone wrong in one or both the circuits. Therefore, it seems to me that the primary indication is to correct the abnormal conditions in the circuits. Digitalis has been spoken of by Dr. Jones as acting on the general circulation, but he regards it as a difficult creature to control and, therefore, to be used only with great skill. My general experience with ergot leads me to say that I find it to be the best drug for correcting the fundamental conditions on which these cardiac difficulties arise. Its action is certain, and is chiefly on the disordered tissues, unstriated muscular fiber; in using it you need not stop to consider where the circulation is disturbed. If an overdose be given it will not do harm. Its effect is to tone and contract the relaxed unstriated muscular fibers in the walls of the blood vessels from the crown to the

toe; in so doing it helps the circulation. I am quite sure that you will agree with me, when I say that if the general circulation is helped the heart will have a better chance to recover itself.

DR. GEORGE W. WEBSTER, Chicago—Dr. Jones has stated that digitalis should not be used in any case of aortic regurgitation; here I think we should discriminate and think of the condition which causes it. In aortic regurgitation, when this is the only valvular lesion present, it is, as a rule, due to syphilis and, therefore, is often accompanied by a general arteriosclerosis; here there might have been a widespread disease that started in the blood vessels and ended in the aortic valve. On the other hand, aortic regurgitation is frequently found as a complication of, or exists with, other valvular disease, an obstruction at the aortic valve, as well as a regurgitation. We should differentiate carefully between these cases of aortic regurgitation due to infection and aortic regurgitation secondary to syphilitic infection. In the latter, Dr. Jones will find that where there is a general arteriosclerosis of specific origin, there is no drug in the materia medica capable of doing more harm than digitalis. On the other hand, where there is a simple infection and involvement of the aortic valve, or an involvement of the mitral valve as well, without involvement of the heart muscle, blood vessels, or kidneys, then it is possible to show that digitalis not only may but occasionally does good. I think we should discriminate more than we do.

DR. J. M. ANDERS, Philadelphia—Hydrothorax is a form of dropsy, or venous stasis, dependent on a passive hyperemia. For its production there must be some obstruction to the venous circulation, and on the distal side of the obstruction fluid exudes from the lumen of the small veins. The reason dropsy begins in the feet is because the venous obstruction is here reinforced by another causative factor, i. e., the effects of gravitation. In hydrothorax the influence of gravitation is not manifested, and yet we have all met with cases of pleural dropsy in which general dropsy was slight, or even entirely absent. For an explanation of some of these cases, at least, it seems to me that the theory advanced by Dr. Steele is tenable, namely, that within the thorax there is an obstruction to the venous circulation produced by abnormal pressure by the enlarged heart on the azygos veins. Popoff and other clinical observers, and I myself, have observed inequalities of the radials in valvular disease of the heart, and I think this is explained by assuming that the right auricle exerts pressure on the large vessels within the thorax. It is reasonable to suppose that the azygos veins might be pressed on and produce hydrothorax, although absolute proof is still wanting. Cardiac dropsy is more common on the right than on the left side of the thorax, although it may be more marked on the left than on the right side. Recently I saw a case in which it was confined entirely to the left pleural cavity. There is a principle in the treatment of hydrothorax that should not be lost sight of. When a cure results some of the fluid is obviously absorbed through the lymphatics; but it should be borne in mind that the fluid in hydrothorax is very poor in proteins, and may, therefore, be absorbed also through small veins. As a matter of fact, there is no better way of getting rid of the dropsical fluid in hydrothorax than by systematic daily purgation by means of saline laxatives. Venesection has a similar influence and exerts its good effects in the same way. These measures rid the blood vessels of some of their serum and thus stimulate absorption from the pleural sac through veins and lymphatics to replace that which has been lost. This should be done before the administration of digitalis. The delirium which occurs in chronic heart disease is difficult to explain. I have seen a number of cases which occurred after failure of compensation and where there was a general venous stasis. I had occasion not long since to state that venous stasis should be looked on as a pathologic condition; it means, as Lazarn-Barlow has pointed out, starvation of the tissues, the retention of waste products, and finally an anatomic alteration in the various viscera in the body; in just the same way as we have disturbances of the liver, gastrointestinal tract and the kidneys, so we may have disturbance of the function of the brain, or delirium. There is

another class of cases in which a different causative factor is at work; I refer to the blood changes—the toxic materials in the circulating blood. These may produce heart lesions and general arteriosclerosis, and this sclerotic process may affect the cerebral vessels. Here, coexistent cardiac disease and delirium may be met with before rupture of compensation has occurred. In these cases I think the delirium is rather due to arterial changes within the brain than to any cardiac lesion *per se*, and that both of these organs suffer in consequence of the action of a common cause, namely, the altered blood state. I believe with Dr. Webster that we should classify our cases of aortic regurgitation into those due to endocarditis and those due to general degenerative changes before we begin to use any special method of treatment. I agree with Dr. Jones that in aortic regurgitation, with marked arteriosclerosis, it is bad practice to give digitalis, and especially unguarded; in these cases it should be used cautiously only when indicated, and be guarded by the use of the nitrites or nitroglycerin, so as to diminish the arterial resistance.

DR. X. R. COLEMAN, Columbus, Ohio.—There are conditions in which digitalis does good; this has been my experience. When we have a condition approaching a normal cardiovascular system, then we may secure good results from the cautious use of digitalis; but if there is a degenerative change in the blood vessels, such as an arteriosclerosis, or some marked change in the heart, such as a granular degeneration, then digitalis will not only do no good, but in the majority of cases it will be found to be a dangerous agent. I take issue with Dr. Quimby's theory. While I am not a musician, I believe my ear will detect matters of pitch pretty correctly. I have studied physics, and especially acoustics, with care, and I do not believe the normal vesicular murmur is higher in pitch than the bronchial or tracheal respiration. I will even go farther and say that the tracheal and bronchial expiration is higher than the tracheal and bronchial inspiration sound.

DR. J. DUTTON STEELE—I agree with both Dr. Sailer and Dr. Anders in thinking that there has been no theory thus far advanced that can be called entirely satisfactory, to account for pleural effusions in heart disease. The theory that there may be some pressure on the various venous trunks within the thorax causing congestion and consequent effusion of fluid has a wide acceptance. The vena azygos major curves around the root of the right lung and is, therefore, specially liable to be compressed. The only point of practical value that can be drawn from our present knowledge of the subject appears to me to be that long-continued congestion may cause effusion, not as a mere obstruction to venous circulation, but by reason of the long-continued congestion causing some atrophic change; therefore, the effusion may not be entirely a transudation, but an exudation, and therefore in these cases of hydrothorax I think we had better not wait and give purges, digitalis, etc., to relieve the dropsy, but do early and frequent tapping.

DR. E. M. GREEN—As has been stated in the discussion, the cause of the delirium in pericarditis may be, 1, from hyperpexia, which generally exists in these cases; 2, from venous congestion; 3, from the existence of some toxemia in the blood. The fever, however, was not exceedingly high in the case reported, and the delirium seems to have been caused by venous congestion.

DR. FRANK JONES—I was glad to hear what Dr. Sailer said regarding the frequency of mitral and aortic lesions. It has happened to me to encounter more aortic lesions than mitral. My experience has not been in keeping with the text-books in this respect. In regard to Dr. Wells' statement regarding the general types of aortic insufficiency and the conditions which bring them about, I wish to say that, according to my own observation, when it occurs in early life the prognosis is invariably good. In the endocardial form, the integrity of the heart muscle is not necessarily lessened; the coronary vessels are intact and the circulation is clear. With regard to the remarks of Dr. Tyson, I understand the position he takes in reference to the injudicious use of digitalis. Particular stress should be laid on its use in approaching dissolution, when there is sleeplessness, dyspnea, much anxiety, etc.

DR. C. E. QUIMBY—I am neither surprised nor disturbed that the gentlemen take issue with my statements. I only regret that they have been unable to meet a logical demonstration of specific propositions with anything more interesting or pertinent than dogmatic personal opinions, as it affords me no opportunity for a reply.

INTRACRANIAL NEURECTOMY FOR TRIGEMINAL NEURALGIA.

CASES AND COMMENTS.*

HARRY M. SHERMAN, M.D.

SAN FRANCISCO.

At this time and place one may not report opinions or cases which are merely conventional, and the report of the following five cases in four patients is permissible only because of the exceptions to the rules in two of them. All were cases of trigeminal neuralgia, in all the pain had been of considerable duration, and had gradually become so severe as to be unbearable. In all four patients the third branch was involved, in two the second branch as well, and in one all three branches. In two patients the results were conventional. Complete and lasting relief followed the operation. In two patients, one of whom had two operations, there were exceptional, unconventional accompaniments.

In the first case the exceptional element was a complete and permanent paralysis of the facial nerve, noticed first the morning after the operation. In this patient the pain had been limited to the third branch, but the intention at the time of the operation had been to remove the entire ganglion. However, all that I did remove was the outer half of the ganglion with the second and third branches to their foramina of exit. The wound healed aseptically, the pain was gone, but the seventh nerve was paralyzed. Studying the possible traumatism to the nerve during this operation, it is easy to exclude pressure on the pes anserinus, as the operation was done six or seven years ago, and on the lines of the original Hartley-Krause technic, so the zygoma was not cut and it stood between the nerve and any instrumental pressure by retractors; indeed, the osteoplastic flap of skin, muscle and bone was folded down over the zygoma and protected this very area. On the other hand, while it is possible to reach back, inside the skull, into the posterior fossa, it is not conceivable that I let my finger wander so far as to pick up and tear the seventh nerve before it entered the petrous bone, and I am, moreover, certain that I did not do this. Finally, the man has had no trouble with his ear, nor anything to indicate disease of nor injury to the nerve during its passage through the bone.

Excluding trauma to the nerve in its superficial location, put the case outside that class, of which Pershing wrote and to which Wyeth the other day referred, and in which pressure or pull on a superficial nerve during the period of anesthesia resulted in temporary or permanent paralysis. It is a satisfaction to do this, for the advent of the paralysis suggested this as the first and most obvious explanation and had it proved to be the true one, it would have had to be accepted as a fault in technic. The integrity of the nerve before the operation and the lack of any pathologic ear or temporal bone process make it most probable that some injury inside the skull caused

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

the condition. I am aware that a man working by touch in the dark may easily reach farther than he intends, especially if he does not keep his eye on the external wound, but in this case the work was done by sight and not by touch, so that I can be sure an errant finger did not do the damage. The case was reported in THE JOURNAL some months ago, but no explanation has been offered and for this reason I include it with the other operations and submit it for discussion.

In the other patient the pain began in the supraorbital branch and was associated with an attack of herpes facialis. Primarily it acted as a definite neuralgia and the nerve was cut finally just above the orbit, but without giving relief. Then, because of a history of plumbism some years before, which had yielded to potassium iodid, because of miscarriages by the patient's wife, and because of non-response of the pupils to light, the potassium iodid was again given in doses of 5 grm. daily, with no local relief and with a distinct loss in general health. Thus the consideration of the case took cognizance of syphilis, but as treatment for syphilis proved of no avail, and as the pain had extended to include all three branches, an exposure of the ganglion was decided on. It was also decided to cut the root of the nerve behind the ganglion and to go no further, unless some distinct pathologic process like a gumma should disclose itself. That this might be the outcome was the hope of Dr. Clark J. Burnham and Dr. L. Newmark, when they turned the patient over to me.

As I intended merely to cut the root, as has been practiced by Frazier, I prepared for the possible cutting of the sensory root only, so made my incision to circumscribe the temporal muscle. The muscle was then separated as a whole from the pericranium down to the point where the bone was to be cut. This also avoided unnecessary stripping of the pericranium from the skull in a putative syphilitic. At the proper level, about 1.5 cm. above the zygoma, the pericranium was cut and the skull bared. The zygoma was left untouched. A small trephine opening enlarged by rongeurs gave ample room, the exposure of the ganglion was uneventful and the fasciculi of the root were hooked up and cut, the cutting causing a reflex movement by the patient. It was not possible to discriminate between sensory and motor filaments, but the fact of the section of the entire root was satisfactory and the ganglion was tipped forward out of its bed to make this proof clear.

On coming to close the wound it was seen that the brain did not expand immediately to occupy its original space, and so, to avoid leaving an air space in the skull, normal salt solution was poured in and the head rolled over so as to keep it there while the suturing was done. For two days the man was free from pain and there was paralysis of the temporal and pterygoids. On the third day, however, he began to have pain, and this pain gradually increased in its old area and intensity. For two months the anesthesia, to light touches and to pin-pricks over practically the whole of the area of the fifth nerve, persisted and was verified by several examinations, while the temporal and pterygoid paralysis also persisted. In the third month sensation returned, to my surprise, and light touches and pin-pricks could be felt everywhere over the whole area excepting the supraorbital branch area which had been anesthetic from the time of the superficial section of that nerve. The sensation as it returned was not of normal intensity. It was described as being dull, but it was demonstrably present and evidenced a union of the cut nerve root beyond

any doubt. The paralysis of the pterygoids, however, persisted.

This is the supposedly exceptional point in this case. I do not know the number of cases operated on by Frazier and others in which the nerve root alone has been cut and nothing interposed between the ends, as was suggested by Abbé, but I was impressed with the simplicity of the plan when Frazier, on Spiller's suggestion, tried it and with apparent success. I report this case to call attention to the fact, which I am obliged to accept as proven, that the nerve root may unite and resume its function, and that this most simple operation is not, in itself, to be wholly trusted for the production of an anesthesia and an analgesia which will be permanent.

Because of the persistence of the pain, and also and chiefly, because of the return of sensation, I again exposed this man's gasserian ganglion, three months after the first operation. The point of interest here for me was the possibility of encountering such firm adhesions of the dura mater to the bone as to interfere with the operation. I followed, from the skin to the ganglion, the old line of operation. The incision was, therefore, wholly in scar tissue, which nowhere was it impossible to discern. The dura mater was but normally adherent to the bone and consequently separated easily, and I attributed this to the salt solution, which presumably did not absorb quickly, which diluted any escaped blood, and so resulted in a light areolar tissue bond between dura and bone. A little hook, passed under the root of the fifth nerve, behind the ganglion, demonstrated that the ends had, by some kind of a bond, anatomic or cicatricial, united. The union was broken, the ganglion tipped forward and wholly removed. Salt solution was again poured into the skull and the wound again closed and healed aseptically.

There is now a permanent anesthesia to tactile, heat, cold and pain sensations, except along the borderline between the fifth nerve distribution and areas of contiguous nerves, a line that is never a typical one and which permits, because of its anatomic irregularity, of easy explanation of physiologic anomalies. It may be added that in this last operation the zygoma was cut and pushed down, but that the addition to the field of view did not seem to me to be great.

Since this second operation the patient's subjective pain has continued unabated.

REMARKS.

The points of the case are the variations of the incision so as not to injure the fibers of the temporal muscle nor strip more than the necessary amount of pericranium from the skull. The use of physiologic salt solution to fill the space to be occupied by a slowly expanding brain and exclude air. The fact that a ganglion can be exposed a second time, three months after the first time, with no difficulty and no hemorrhage, by following the lines and planes of the first incision. Finally the fact, on the evidence of this case, that the cut root of the fifth nerve may unite and resume its physiologic function. Other cases may be added to confirm this statement, but even if they are not forthcoming the fact of union in this one case can not, to my mind, be gainsaid.

Dr. Hoffa's Tribute to American Surgery.—In Dr. Hoffa's recent visit to this country he found much to commend in American surgery. He was greatly impressed with the completeness of American hospital appointments, especially the corps of nurses found in every large hospital. He praises the nurses for their intelligence and efficiency.

PHYSIOLOGIC EXTIRPATION OF THE GANGLION OF GASSER.

FURTHER REPORT ON DIVISION OF THE SENSORY ROOT FOR
TIC DOULOUREUX, BASED ON THE OBSERVATIONS
OF FOUR CASES.*

CHARLES H. FRAZIER, M.D.

Professor of Clinical Surgery, University of Pennsylvania; Surgeon
to the University Hospital.

AND

WILLIAM G. SPILLER, M.D.

Professor of Neuropathology and Associate Professor of Neurology,
University of Pennsylvania.
PHILADELPHIA.

From the William Pepper Laboratory of Clinical Medicine (Thebe
A. Hearst Foundation).

REMARKS BY DR. FRAZIER

In June, 1901, three years ago, I reported to the Section on Surgery of the American Medical Association then in session at St. Paul, the results of a series of experiments on dogs conducted by Dr. Spiller and myself, with a view toward determining the feasibility of dividing the sensory root of the gasserian ganglion for the relief of tic douloureux.

RESUME OF EXPERIMENTAL WORK.

These experiments consisted in carrying out this operation on a number of dogs and subjecting the structures removed several months later to a rigid histologic examination to determine whether regeneration of the sensory root after simple division could occur. The results of these investigations admitted of but one interpretation, namely, that there was not the slightest evidence of regeneration within the central nervous system. More recently,¹ Dr. Spiller and myself pursued this line of investigation in a series of experiments on the sensory roots of the spinal ganglia with equally positive results.

Having established by experimentation in lower animals beyond a peradventure of doubt the inability of the sensory root to regenerate at least within the central nervous system, it only remained to obtain equally positive results in the human subject before any substantial claims for the operation as a rational, practical and "tried-out" procedure could be made. These we present to-day as a result of our experiments with four cases; all have remained free from recurrence.

ADVANTAGES OF THIS OVER OTHER PROCEDURES.

Extraction of the ganglion. Certain theoretical claims were advanced in favor of the operation, and these have been substantiated by our clinical experience.

1. *Control of Hemorrhage.*—It minimizes the amount of hemorrhage. No one can speak the truth and say that hemorrhage is not a troublesome feature. Hemorrhage from the middle meningeal artery is of little or no moment, and it can be controlled easily whether the vessel be injured as it courses along the temporal bone or at the foramen spinosum. On the contrary, hemorrhage from emissary veins is distinctly troublesome. The greater the number and firmness of dural attachments, the greater will be the hemorrhage from this source, and the nearer we approach the ganglion the firmer the adherence and the freer the bleeding. Inasmuch as the ganglion receives its greatest blood supply from below, surgeons are advised to put off elevation of the ganglion to the last. To divide the sen-

sory root the base of the ganglion is left undisturbed and this cause of free and persistent bleeding avoided.

The only other source of hemorrhage worthy of consideration is the cavernous sinus. Injury to this sinus has caused hemorrhage, if not serious and alarming, at least necessitating suspension of the operation for a day or more. This vascular channel being in intimate relation with the internal aspect of the ganglion, is exposed to danger once the operator begins to free it from the ganglion. Confining, as we do in practicing division of the sensory root, our manipulations to the root itself and to the posterior aspect of the ganglion, work at the point of greatest safety, insofar as the sinus is concerned, and need never give it a thought.

2. *Simple Technic.*—Its execution is comparatively simple. It goes without saying that the exposure of the ganglion is by far less difficult than its extraction. Once the ganglion is exposed, we have made all the preparations necessary for the division of the sensory root; thus this operation is complete before the difficulties common to the extraction of the ganglion have been approached.

3. *Avoidance of Injury to Adjacent Structures.*—The cavernous sinus is not exposed to injury. The abducens is in such intimate relation with the ophthalmic branch that division of one is almost impossible without division of the other. In the extirpation of the ganglion it is a matter of great difficulty to preserve this cranial nerve intact. The motor root is always destroyed in extraction of the ganglion; whereas, in division of the sensory root, the motor root may be preserved intact.

4. *Reduction in the Rate of Mortality.*—If the troublesome difficult features attending operation for the extraction of the ganglion are, to a great extent, eliminated, there should be an appreciable reduction in the time required to complete the operation, and it is only reasonable to predict that the operation, which is more economical as to time and attended with considerably less hemorrhage, will be attended with a lower mortality.

TECHNIC.

This phase of the subject has been treated fully in previous papers.² The approach to the ganglion by the usual Hartley-Krause method, the temporary or permanent resection of the zygomatic process, the exposure of the foramina ovale and rotundum as guides to the ganglion; an incision in the dura propria from one foramen to the other; the reflection of dura propria from the superior and posterior aspect of the ganglion revealing the sensory root; picking up of the root on blunt forceps and division of same completes the operation.³

2. University of Pennsylvania Med. Bul., December, 1901; Philadelphia Med. Jour., Oct. 25, 1902.

3. Considerable importance has been attached to what has been called the intra-arterial route and the difficulties attached to injury to the middle meningeal artery grossly exaggerated. One familiar with the great variation in the course of the middle meningeal artery and its relation to the temporal and frontal bone realizes at once the futility of attempting to establish a point below which one can operate always with the assurance that the vessel will not be injured. The danger of injuring the middle meningeal vessel in opening the skull is due to the fact that the vessel sometimes runs in a bony canal, sometimes in a deep channel. When the fragment of bone is removed the vessel is lacerated. Sometimes there is no canal at all, usually the canal begins sufficiently high to escape injury; exceptionally, however, the canal begins so far down that it would be impossible to make an opening large enough to enable one to carry out the necessary manipulations on the ganglion by the so-called intra-arterial route. Common sense prompts one to make the opening as near the base of the skull as possible, not especially to avoid the artery, but in order to reduce to a minimum the distance from the margin of the skull to the ganglion and to make the opening only as large as the manipulation may require. No other directions to the operator are necessary; he avoids injuring the artery if he can, and if he can not, it is a matter of no difficulty to control the hemorrhage.

DIFFICULTIES ATTENDING THE OPERATION.

An objection has been made to the operation we advise for the relief of tic douloureux, viz., that the sensory root can not always be exposed, and that in such a case resection of this root would be impossible. Dr. Spiller thinks it is extremely probable that resection of the posterior part of the gasserian ganglion would have the same effect as resection of the sensory root. The object we strive for is the division of the central nerve processes which arise in the cells of the gasserian ganglion. Many of the cells that send processes into the sensory root are cut off from this root by a resection of the posterior part of the ganglion, and the effect in the permanent relief from pain would probably be the same as though the sensory root were divided. If, therefore, there is any difficulty in exposing or recognizing the sensory root Spiller recommends a resection of the posterior part of the ganglion, believing that it would be as effective as a resection of the sensory root.

PHYSIOLOGIC EXTIRPATION OF THE GASSERIAN GANGLION.

Up to this time the claims which have been made for division of the sensory root have been based altogether on the results of our own experimental and clinical evidence. It might be well at this juncture to introduce the evidence of an impartial critic whose judgment and opinions in matters pertaining to the physiology, pathology and anatomy of the nervous system are held in great respect. Van Gehuchten has published recently a most instructive and interesting paper on the surgical treatment of trifacial neuralgia,⁴ and in this article he discusses somewhat at length the effects of division of the sensory root. Owing to the fact that he believes this operation to be as radical in effect as extirpation of the ganglion, he has styled the former not inappropriately the "physiologic extirpation of the ganglion," and regards it as both less dangerous and more complete than the operation of Krause.

His observations and conclusions on the question of regeneration or degeneration of the sensory root confirm absolutely our own. Every fiber of the central nervous system, he says, attacked by secondary degeneration is a fiber inevitably lost. "The nerve fibers of the central nervous system interrupted at any part never regenerate. The section of the large root of the trigeminal nerve is equivalent, then, at least as regards its effects on the bulbo-spinal root, to the destruction or extirpation of the gasserian ganglion itself. Whether the cause of the trifacial neuralgia resides in the semilunar ganglion, or in one or the other of the three peripheral nerves, at the moment we interrupt completely all communication between the ganglion and cerebrospinal axis, we destroy inevitably the route by which painful impressions are conveyed to consciousness.

"The section of the large root of the trigeminal nerve, even though it does not constitute an anatomic extirpation of the semilunar ganglion, is equivalent, then, to a true physiologic extirpation, and is the only one which is of importance in point of view of treatment of trifacial neuralgia.

"This physiologic extirpation is not only more complete and easier to accomplish than the tearing out of the ganglion recommended by surgeons, but it has an advantage over this mode of operation which is not to be despised. It leaves intact the connections of the ganglion with the peripheral organs."

That the operation on the root is much more simple than the extirpation of the ganglion might be inferred from the fact that many surgeons, among them Poirier, Horslev and Lauwers, recommend tearing out the root as a preliminary measure to extirpating the ganglion. If the exposure of the root were a matter of any great difficulty, this step of the operation naturally would have been postponed until the last when the ganglion was entirely freed from its attachments.

It has been said that the suggestion made by Dr. Spiller, in 1898, of treating tic douloureux by division of the sensory root was not original; that there was on record one instance in which, prior to 1898, the operator had deliberately torn out the root. This is quite true, but it should be borne in mind that the surgeon did not perform this as an operation of choice, but did it because he was unable to remove the ganglion. His patient died within a few hours, and he never repeated the operation nor recommended it to others. For the conception of the idea that division of the root was equivalent to physiologic extirpation of the ganglion credit is due to Spiller alone. Furthermore, those who have taken exception to the claim of originality ought to have known that there is a very distinct difference between avulsion of and division or resection of the root. Avulsion of the root is not only unnecessary, but what is still more important, may be distinctly harmful. Simple division of the root suffices to cause complete and persistent degeneration of the bulbo-spinal root of the trigeminal nerve, and the possibility of recurrence of the symptoms is therefore *nil*. Avulsion may expose even the pons to concomitant lesions (Van Gehuchten), and for this reason alone the procedure should be rejected.

AVOIDANCE OF OCULAR DISTURBANCES.

Noteworthy in our experience is the absence of any ocular disturbances. Attention has already been called to the frequency with which the structures on its inner aspect, including the third, fourth and sixth nerves, have been injured in extirpation of the ganglion, and to their escape from injury in division of the sensory root. The most serious ocular disturbances of extirpation of the ganglion is corneal ulceration. Although no especial pains have been taken to guard against it, our cases have been entirely free from this complication. Spiller says it is probable that sympathetic fibers pass to the eye after entering the trigeminal nerve through the gasserian ganglion, and as in division of the sensory root these fibers are not injured, the danger of ocular disturbance by this operation is lessened. The trophic influence of the gasserian ganglion on the eye may possibly depend on the integrity of these sympathetic fibers, but it is probable that these fibers are not so numerous in man as in the lower animals. (The literature bearing on this subject has been carefully studied by Kreuzfuchs.) Of this phase of the subject, Van Gehuchten writes: "The persistence of the anatomic connections between the peripheral organs and the gasserian ganglion, separated from the nervous axis, without doubt, prevents the grave ocular complications mentioned by Kraus and Lauwers." The experimental investigations of Van Gehuchten himself and of Lugars and Bonne have shown that while degeneration of the fibers of the central stump follows division of the sensory root, the ganglion itself does not undergo any marked modification. This is equally true of the posterior roots of the spinal cord and their ganglia as of the cranial nerves and their ganglia.

⁴ Le Noyraxe, vol. v. and University of Pennsylvania Med. Bul., April, 1904.

METHODS OF ABBE AND VAN GEHUCHTEN.

Recognizing from his wide experience the difficulties and dangers that attend extirpation of the ganglion, Abbe recommended another operative procedure, because it was very much safer and, in his opinion, equally efficacious. This consists in division of the second and third divisions at their exits to their respective foramina and the subdural interposition of tissue. Two objections to this method of treatment at once suggest themselves: The first that the operation is applicable only to those cases in which the pain is distributed only to the second and third divisions; the second that there is a possibility of the rubber tissue acting in the rôle of a foreign body setting up a reaction in the tissues, which would terminate in abscess formation and necessitate the removal of the foreign material.

Abbe says: "It is certainly past dispute that there is no need for the removal of the first branch of the fifth pair in any case of grave tic douloureux unless the origin is to be found in a tumor of the gasserian ganglion or behind it." This may apply to the majority of cases, but it certainly is not a rule without exception. In fact, in two of the four cases which constitute this series, the pain was most intense in the distribution of the first division.

It might also be said of Abbe's operation that it offers no assurance against subsequent involvement of the first division, and so far as the mortality is concerned, it should be no less than that following division of the sensory root, since both are intracranial operations, the only difference being that in one two peripheral branches are divided, while in the other the central root of the ganglion.

Van Gehuchten, in his recent contribution to the treatment of trifacial neuralgia, recommends the tearing out of the peripheral branches, a procedure which, he says, is simpler and much more easily executed than intracranial resection. This recommendation is based on the following phenomena: Simple division of a cranial nerve nearer to or further from the base of the cranium is followed by degeneration of all the cells of origin, but with complete integrity of all or almost all of the fibers of the central end. This degeneration is only temporary, however, and is soon followed by reparation of the nerve and restoration of the function. Tearing out of the nerve, on the other hand, produces reactional phenomena much more intense; the degeneration that follows soon becomes an achromatosis, and this, in turn, is followed by atrophy and disappearance of all the injured cells. These phenomena have been observed only in motor nerves, and to prove whether sensory nerves would be affected in a similar manner, experiments were conducted on rabbits; the three peripheral branches were seized with a hemostatic forceps at their exits from the supraorbital, infraorbital and mental foramina and torn away. The results were positive; not only was there atrophy of the cells of the ganglion, but Wallerian degeneration of its bulbospinal root.

As regards the technic of the operation, the nerve should be freed as far as possible from all its connections and seized as near as possible to the base of the cranium, in order to make the resulting traumatism more intense. In reviewing the literature of the subject, Van Gehuchten found that this operation had been recommended and practiced by Blum in 1881, and later by Doyen. There seems to have been some apprehension on the part of surgeons that there was

danger in employing the force necessary to tear the nerve, or inflicting some serious injury to the brain centers. In any other cranial nerve this complication might occur, but the gasserian ganglion is so firmly attached to the base of the skull that this accident could not be considered possible.

These observations of Van Gehuchten are certainly worthy of the surgeon's consideration. If avulsion of the nerve will result in such degenerative changes of the ganglionic cells and the bulbospinal root that restoration of function is impossible, this operation should be practiced as a substitute for the intracranial operations. Whether or no surgeons at large would be willing to practice in those cases in which a so-called central operation is indicated, it should at least be given a trial, when circumstances call for a peripheral operation; that is to say, instead of resecting a portion of the inferior dental or infraorbital nerve, the nerve should be forcibly torn away. If Van Gehuchten's observations are correct, it is reasonable to assume that there would be less chance of recurrence in the case of the latter than of the former operation. Not, of course, until this operative procedure has been proven successful in its application on the human subject can it claim the support of the surgical profession. Therefore, with the exception of a few isolated cases, it is supported only by the results of experimentation on rabbits.⁵ Davis, in 1898, operated on a case in which this idea of Van Gehuchten's was put into practice, but with unfavorable results. The superior maxillary nerve was exposed as it ran from the gasserian ganglion. The nerve, as it entered the bone, was grasped with a hemostatic forceps and pulled upward; with another forceps the nerve was grasped closer to the ganglion and twisted loose from it. The relief which followed the operation was only temporary, the pain gradually returned and became so severe as to require a more radical operation. In commenting on the case, Davis says the explanation of the return of pain is left to the experts. The operation was practiced in the manner prescribed by Van Gehuchten; it might be claimed that the twisting out of the nerve was not sufficiently violent or brusque, but this view is hardly acceptable.

REMARKS BY DR. SPILLER.⁶

In studies of the nervous system of dogs,⁷ in which the sensory root had been cut, I found that when only the external part of this root was divided the degeneration in the spinal root of the trigeminal nerve of the pons and medulla oblongata by the Mareh method was only in the dorsal part of the root. This is well shown by photographs in the article referred to. I believed from these investigations, published in December, 1901, that I was justified in concluding that the fibers of the lateral portion of the sensory root at its entrance into the pons, in their further course, occupy the dorsal part of the descending spinal root. From this it follows that the fibers of the inner portion of the sensory root occupy the ventral portion of the descending spinal root.

The investigations of Van Gehuchten on the changes occurring in the sensory root of the trigeminal nerve, after tearing out peripheral branches of this nerve, are important. He says, in relation to this subject: "This

6. The following observations on the relative position of the fibers belonging to the three peripheral branches of the trigeminal nerve in the gasserian ganglion and the sensory root and their continuation in the spinal root are by Dr. Spiller, including an explanation for the limited area of anesthesia of the face occurring after partial division of the sensory root.

7. Spiller and Frazier: University of Pennsylvania Med. Bul., December, 1901.

degeneration of the fibers of the bulbospinal root, after a tearing out of the peripheral nerves, is so constant that we have encouraged one of our students, Dr. Bochenek, to employ this method in determining the situations in the bulbospinal root of the fibers belonging to each of the three branches: The results of his investigations have shown that after a tearing out of the frontal nerve the degeneration is localized exclusively to the ventral portion of the bulbospinal root; after a tearing out of the mental nerve, it occupies the dorsal portion of the same root. The tearing out of the infraorbital nerve is followed by a degeneration of a certain number of fibers in the middle region.

"Our own recent investigations are in support of these findings. They show, further, that the number of fibers in degeneration of the bulbospinal root is in direct relation to the number of peripheral fibers that have been ruptured. Bochenek, in his investigations, was content to tear out only one of the branches of the ophthalmic nerve of Willis, the frontal nerve; he obtained distinct

Fig. 1.—Showing the area of anesthesia one week and thirty-two months after division of the sensory root.

degeneration involving a small number of nerve fibers at the ventral extremity of the bulbospinal root. In our own investigations we have torn out the three branches of the ophthalmic nerve, emptying completely the orbital cavity. After a survival of forty-five days we have obtained a much more extensive degeneration of the ventral portion of the bulbospinal root.

"This degeneration of the fibers of the bulbospinal root can be understood, in our opinion, only by admitting that rapid atrophy occurs in a certain number of cells in the semilunar ganglion, an atrophy following the tearing out of the peripheral branch. We desired to determine the existence of this atrophy by the examination of the gasserian ganglion, but our investigations have not been successful. After the tearing out of one or the other of the three branches of the trigeminal nerve, chromolysis of the cells in the ganglion is found after about ten days, but if the animal is allowed to live fifty or sixty or eighty days it is impossible to determine whether the

number of nerve cells has diminished in the ganglion on the operated side, even after a tearing out of all three nerves, frontal, infraorbital and mental. These results should cause no surprise; the gasserian ganglion is difficult to remove; it has, further, a very complex structure; its constituent cells, instead of being placed one close against the other, are usually situated in long bands, like islands, between the fasciculi of nerve fibers, which they accompany in a certain part of the nerve. It is, furthermore, very difficult, if not impossible, to make comparable serial sections of the two semilunar ganglia of the same animal.

"Having in mind the Wallerian degeneration of the fibers of the bulbospinal root after a tearing out of the branches of the trigeminal nerve, and the cellular phenomena which occur in the cells of origin of the peripheral nerves after the tearing out, we believe that we may conclude that the tearing out of one or the other branches of the trigeminal nerve is followed by rapid atrophy of the corresponding cells of the gasserian ganglion, an atrophy which causes in its turn Wallerian degeneration of the central fibers. It is, therefore, proper to propose the tearing out of the nerve as a rational surgical treatment of trifacial neuralgia."⁵

Comparing Van Gehuchten's results with those obtained by me, it will be seen that the fibers of the ophthalmic nerve are represented in the ventral portion of the descending spinal root of the trigeminal nerve (Bochenek, Van Gehuchten), and that the fibers of the inner portion of the extrapontile sensory root are represented in the ventral portion of the descending sensory root (Spiller); therefore, these fibers do not mix with those belonging to the other peripheral branches of the trigeminal nerve; likewise that the fibers of the third division are represented in the dorsal part of the descending spinal root (Bochenek, Van Gehuchten), and that the fibers of the external portion of the extrapontile sensory root are represented in the dorsal portion of the descending spinal root (Spiller), and, therefore, these fibers do not mix with those belonging to the other peripheral divisions of the trigeminal nerve.

This is an important conclusion, because if only the outer portion of the sensory root of the trigeminal nerve is cut loss of sensation should be expected only in the third division of the nerve, and we may conclude when loss of sensation is found also in the distribution of the second division that at least half the sensory root is cut through. This explains why sensation of the face is only partially lost when only a portion of the sensory root is cut, and in such cases it will probably be found that the anesthesia is in the third division of the trigeminal nerve, because the external fibers of the sensory root are more likely to be divided than the inner.

Recent anatomic studies in the territory innervated by the sensory root of the trigeminal nerve, show that this territory is less extensive than formerly supposed. The sensory area of the trigeminal nerve as shown by Otto Grosser does not extend to the chin.⁸ In the diagram of Frohse, the cervical nerves supply the sensation to a considerable area of the face above the chin. According to Zander, the area of the cervical nerves extends almost to the corner of the mouth, and is only about a finger-breadth from the bony orbital border. It is very important that these facts should be borne in mind when the extent of the anesthetic area caused by resection of the sensory root is tested.

SYMPATHETIC FIBERS IN THE GANGLION OF GASSER.

The effect on the sympathetic fibers of the eye from operations on the trigeminus is worthy of attention. Kreuzfuchs has collected considerable proof of the existence of sympathetic fibers in this nerve.

Budge cut the trigeminus in animals, in some cases through the trunk, in others peripherally to the ganglion, and found that after either operation contraction of the pupil occurred. After central division of the fifth nerve the pupil did not contract so greatly nor persistently as after peripheral division of the nerve. Budge assumed that the trigeminus receives in the gasserian ganglion those sympathetic fibers which innervate the dilator pupillæ, and this opinion has been held by all subsequent investigators who have studied the motor tract for the dilatation of the pupil. These fibers pass from the gasserian ganglion to the eye through the first division of the trigeminus, and therefore contraction of the pupil occurs after division of the trigeminus.

Schiff also found that dividing the trigeminus causes contraction of the pupil, and that there is a difference when the division is made behind or in front of the gasserian ganglion.

Claud Bernard found that the pupil contracts after division of the trigeminus and after a certain time dilates but never attains the same size as the pupil on the other side. These phenomena occur after central as well as after peripheral division of the fifth nerve, but these changes are much more striking and are associated with disease of the cornea when the division is peripheral.

Balogh concluded that all pupillary dilator fibers pass through the gasserian ganglion and the first division of the trigeminus.

Similar opinions were held by Oehl and Gutmann, although the latter believed that no pupillary dilator fibers arise in the medulla oblongata, as Balogh had assumed, and that the division of the trigeminus stem has no effect on the pupil. This view has been shown to be incorrect by Claud Bernard and by Kreuzfuchs.

Budge having believed that the trigeminus contains motor dilator fibers, later investigators have tried to determine whether these fibers are a part of this nerve or merely received from the sympathetic. From the investigations of Schpilow and Braunstein, it seems to be decided, at least for many animals, that the trigeminus receives the dilator fibers of the pupil through the gasserian ganglion.

Kreuzfuchs has cut the trigeminus in rabbits at the base of the brain. The pupil was smaller immediately after the operation than it was later. In these animals exposure and irritation of the cervical sympathetic on the operated side caused maximal dilatation of the pupil on the same side, so that the dilator fibers could not have been cut.

Examination of cases in which the gasserian ganglion has been removed in man seems to show that removal of this ganglion does not cause contraction of the pupil, so that Kreuzfuchs doubts whether what is true of the lower animals is true also of man, viz., that all dilator fibers of the pupils pass through the gasserian ganglion, and he is inclined to accept the view that in man the dilator fibers act through the abducens. He says, however, that after removal of the gasserian ganglion in man, the pupils are of equal size in the

light, but in shadow the pupil on the unoperated side is larger.⁹

It seems probable from these observations that even in man a certain number of sympathetic fibers enter the gasserian ganglion, but in a case of division of the sensory root reported in 1901 by Dr. Frazier and myself no difference in the size of the pupils in shadow can now (May 21, 1904) be determined. After several years a re-adjustment of the pupillary mechanism is to be expected.

RESUME OF FOUR CASES.

CASE 1.—J. L., age 68. Duration of affection, five years. Previous treatment, four peripheral operations. The first division alone was involved.

Operation.—October 12, 1901. Two years and eight months ago.

Result.—No recurrence.

CASE 2.—S. R., age 79. Duration of affection, three years. Preliminary treatment, course of hypodermic injections of strychnia with only temporary relief. Third and second divisions involved in the order named.

Operation.—October 21, 1902. One year seven and one-half months ago.

Result.—No recurrence.

CASE 3.—A. W., age 54. Duration of affection, nine years. Treatment, nil. Second and third divisions involved in the order named.

Operation.—March 31, 1903. One year and two months ago.

Result.—No recurrence.

CASE 4.—F. S., aged 54. Duration of affection, 14 months. Previous treatment, nil. First and second divisions involved.

Operation.—March 17, 1904.

Result.—No recurrence.

OSMIC ACID INJECTIONS FOR RELIEF OF TRIFACIAL NEURALGIA.*

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

The publication of Delbastaille's¹ article on the injection of osmic acid in inoperable tumors and its subsequent use in the same direction by von Winiwarter² and others, attracted much attention, but the results were unfavorable and its use was abandoned. During this experimentation Neuber reasoned that, as osmic acid has a special affinity for the medulla of peripheral nerves as a stain, it might prove beneficial in a clinical way. At this juncture a patient presented himself who had been suffering from neuralgia of the first and second branches for six years on whom, Aug. 15, 1880, a resection of the second division by Professor Albert, on the plan of Lücke, von Bruns and Lassen, had been made. The patient experienced relief for one year, then had several relapses. On Nov. 30, 1882, there was a ligation of the carotid, with no relief. From Jan. 18 to Feb. 9, 1883, daily injections of 4 to 6 drops of a 1 per cent. solution of osmic acid in water were given, inserting the fluid near the infraorbital foramen, angle of the nose and in the lower lip. The relief was only short lived and by the middle of June the pain returned. A second similarly treated case was well at the end of three months. A third case of sciatica had the injections over the sciatic nerve at the site of pain. The patient remained well up to the time of publication of this article.

2. Mittheilungen aus der Chirurgische Klinik zu Tübingen, 1883, p. 213.

The local reaction was very slight, with no necrosis of tissue and little swelling or edema; no paralysis. (It will be noted here that the injection was not made into the nerve trunk, but around it, nor was the acid injected into the foramina.)

The toxicity of osmic acid as shown by Naunyn, Guélin, Husemann and Brancell is mild, and only in doses of 2 grams or more, administered by the stomach, does it prove fatal to animals. But one fatal case in man was reported by Raymond, the dose not given. It is safe to say that administered hypodermically it is free from constitutional reaction.

Osmic acid injections for peripheral neuralgia, says Joseph Lipburger,³ were first recommended by Neuber of Kiel. Osmic acid was used by Nicoladoni in a case of trifacial neuralgia of nine years' standing, originating in the supraorbital nerve, which was resected, and the pain then appeared in the infraorbital and mandibular branches. These were each resected in succession and it then recurred in the supraorbital, six years after the first resection. Sensation had returned in the whole face, notwithstanding the resection of all the facial nerve branches and the mandibular, even up to the angle of the jaw; though it was not perfect compared with the opposite side, it was practically restored. Patient, October 16-22, received six injections of $\frac{1}{15}$ m. of a 1 per cent. solution into the supraorbital area. There was some gangrene after the second series of six injections of 2 cm. of a 1 per cent. solution. This was slow to heal and left a dark scar. The gangrene is attributed by Lipburger to the excessive quantity used so close to the skin. (In this view I concur; while I have had no such result following any of my cases, there is a deep necrosis of the area around the point of injection.) The pain in this case was absent for a year after the injection was made. There was no incision made in Neuber's or Nicoladoni's cases, and no effort was made to inject the solution into the nerve substance, as was done by Mr. Bennett. The effect was supposed to be exerted on the perinheral nerves and not on the trunks. It was cheerfully commended by Leipsiger, but dropped out of general observation until restored by Bennett.

Jacobi⁴ treated 18 cases of neuralgia with subcutaneous injections of 1 per cent. osmic acid, giving one-half to one syringe-ful; of these, 8 cases, among which were 5 sciaticæ, were cured; 2 improved, and 8 not cured. It is most efficacious in inveterate sciaticæ. Application is not without danger. Radial paralysis followed an injection into the arm.

J. Mercer⁵ reports favorable results from deep injections of 1 per cent. osmic acid in sciatica. Relief following one to four injections between the tuber ischii and the trochanter major was temporary, though in the later cases there was greater relief than after morphin injections. Twelve injections were made in one case.

B. M. Shapiro⁶ treated 8 cases of trigeminal neuralgia with subcutaneous injections of osmic acid (3 males and 5 females). Two males and 3 females were cured; 2 improved, 1 unimproved. He recommends osmic acid, 0.1, water 6.0, glycerin 4.0. About twelve injections. Bad results occurred only once in an epileptic woman. He believes the result to be due to corrosion (atzung) of

the terminal branches. Even though there are no cures and recurrences take place, the method is to be warmly recommended.

W. H. Bennett⁷ treated 12 cases of neuralgia with injections of 10 to 15 m. of 1 per cent. solution of osmic acid. Ten cases were trigeminal, several of them with very severe symptoms. (sic). One case an amputated stump in which the popliteal and peroneal nerves were injected. In one case where the median nerve was injured and thickened with paralysis of long standing, the injection was made below the point of thickening; results were favorable in all cases. Bennett laid the nerves bare by a short incision and injected 10 to 15 m. of the solution into the nerve trunk, changing the position of the needle three times. The cases were all obstinate. Symptoms were alleviated in a few hours and disappeared within a few days. There were slight recurrences in 2 cases—one in a different area, e. g., that supplied by the auriculotemporal branch when the original pain was in the infraorbital. Bennett operated on his first case in May, 1897. He believes the method ought to be applied early.

PATHOLOGY OF TRIFACIAL NEURALGIA.

The changes described by pathologists who have had opportunities to examine avulsed ganglia from operations, or to make postmortem examinations of the ganglia of trifacial neuralgia cases, are almost as varied and diverse as the number of investigators. Hence it would be fair to say that there is no definite well-defined pathologic lesion that is found with anything like uniformity. However, this does not detract from our interest in the pathologic findings reported by different investigators. There is also a great divergence of opinion as to nerve changes proximal to division of the sensitive fibers or of the posterior roots of the spinal nerves, as well as the regeneration and degeneration of the trifacial.

G. Marengli⁸ made 127 experiments on animals, using the sciatic nerve. He believes the following conclusions are established:

1. Electric inexcitability in the scar; 2. impossibility of transmitting electric excitation through the scar; 3. excitability of the central stump; 4. excitability of the peripheral stump above the scar.

The re-establishment of motor function is not indissolubly connected with regeneration of nerve fibers, but that function in a given territory may be re-established by collateral nervous paths, e. g., the crural after-division of the sciatic.

Keen and Spiller⁹ remark that in six of their seven cases the lesions were intense in degree and unquestionable. In the ganglia the medullary sheaths and axis cylinders were much swollen, the fibers atrophied, the sheaths empty, with nerve bundles in which the nerve elements had been destroyed and only connective tissue was left. The ganglion cells were atrophied and stained faintly; the blood vessels were sclerosed and even in some cases without a lumen.

Garré,¹⁰ in writing on nerve regeneration after extirpation of the gasserian ganglion, and the cause of the return of trifacial neuralgia, says the majority of trigeminal neuralgias are located in the peripheral nerves, therefore, recurrences after resection are not surprising and are due to this regeneration. In one of Garré's cases, in spite of resection of the gasserian ganglion, the

second and third branches of the trigeminus were regenerated, the former twice. He offers as explanation of the recurrences:

1. Hysteria. (I do not consider this of any value; merely another expression for an absence of definite knowledge.)
2. Seat of neuralgia in the brain center.
3. Regeneration of nerves through anastomosis or imperfect resection of the ganglia.

T. C. Renton¹² reports examination of two ganglia in which there was absolutely no abnormality.

Schäfer¹³ states Van Gehuchten and Nélis observed that sensory nerve cells of the vagus ganglion disappeared after cutting fibers. If this were true of other sensory nerves it would be difficult to see how they could ever regenerate. Restoration of function would have to be explained by ingrowth of sensory fibers from other areas of distribution. Other observers have not confirmed

Fig. 1.—Shows the supraorbital in two divisions—the infraorbital; the submaxillary or mandibular and the lingual branches. (From Toldt.)

In his cases cited above there was no question as to complete removal of the ganglia.

L. F. Barker¹⁴ examined two cases, using Nissl's method. There were scarcely any normal appearing cells; in some there was an absence of tigroid bodies. Some of the nuclei were swollen; there was no typical Marchi degeneration, no pigmentary changes in cells, no vascular changes and no interstitial hypertrophy. Concentric bodies were present.

these statements as far as the spinal root ganglia are concerned.

Sidney I. Schwab¹⁴ collected 20 cases from the literature in which ganglia were examined after removal. Few of these cases will stand criticism. He also examined two cases, in one of which the nerves had been resected ten years previously. In both cases the nerve cells must be regarded as pathologically altered.

14. Annals of Surgery, vol. xxxiii, 1901.

but in neither to such an extent as to consider them permanently affected. The definite changes usually found in acute or long-standing parenchymatous nerve cell affections are absent. The more marked changes in one of the cases lose significance from the fact that the nerves were previously resected. Neuritis and atrophy were probably present. The concentric bodies of brain sand found in one case and which have been described by Barker and Spiller are probably corpora amyloacea. Their pathologic significance is probably *nil*. He concludes that trigeminal neuralgia has no definite pathologic entity. That it is:

of the study of four cases of trigeminal neuralgia, remarks that the ganglion cells showed pigmentation, vacuolization and atrophic appearances. There were no changes in the blood vessels and no interstitial neuritis. He believes that the changes are, first, parenchymatous in nature, and, second, that the myelinated nerves are involved later.

P. L. Friedrich¹⁵ reports a case of recurrence on both sides after complete successful excision of the ganglion on one side. He explains this—according to Garré's hypothesis—that by means of nerve regeneration and collateral nerve branches the sensory trigeminal center

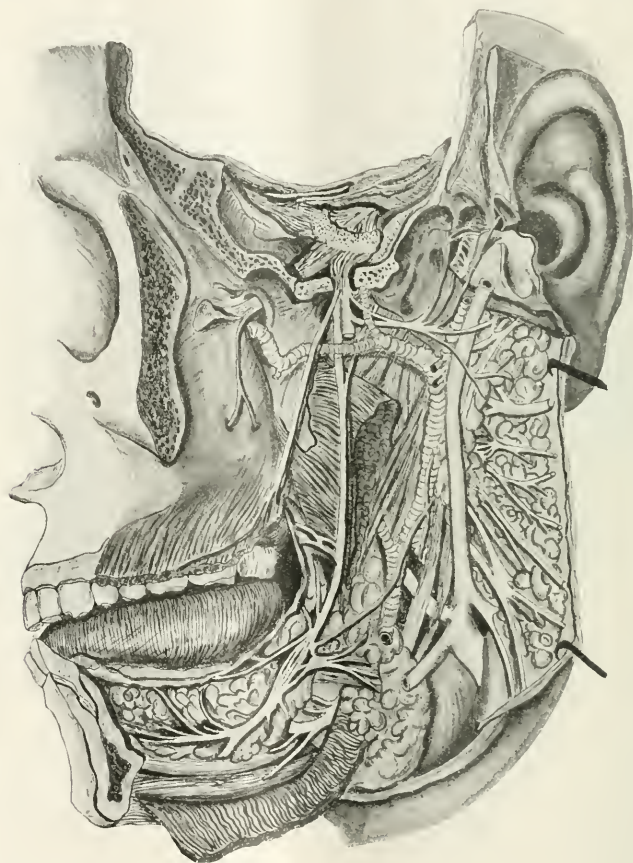

Fig. 2.—Shows the ganglia and the relations of the branches at the exit from cranium, as well as the glandular divisions. (From Toldt.)

1. A neuritis beginning in the terminal divisions of the fifth nerve, and having a tendency to ascend to the ganglia.

2. An interstitial inflammation, chronic and progressive, of the ganglion itself.

3. Central neuralgia or neuritis, affecting the sensory root as it leaves the pons.

He believes also that wherever the process is located, removal of the ganglion must be the first means of relief.

Krause in his report (*Die Neuralgie des Trigemini*),

is certainly brought into communication with the periphery. (This, we believe from our observations, comes nearer to the true explanation of the recurrences of trifacial neuralgia.)

W. G. Spiller and C. H. Frazier¹⁶ report the division of the sensory root of the trigeminal for the relief of *tic douloureux*. The sensory roots of the trigeminal were resected in dogs. Experiments were not conclusive, but

15. *Deut. Zeitschrift für Chirurgie*, vol. III, p. 360.

16. *Univ. of Penn. Medical Bulletin*, December, 1901.

rather contradicted regeneration. A canvass of the literature convinced them that regeneration had not been established in man and that no recurrence of its function was known after resection of the sensory root.

They again report¹⁷ the division of three posterior roots in dogs. The animals were killed at the end of ten months. There was absolutely no trace of regenerated nerve fibers in the cord. The intramedullary portion of the roots was completely degenerated.

Spiller and Frazier¹⁸ further report on the treatment of tic douloureux by division of the sensory root of the gasserian ganglion. The rationale of the operation depends on the inability of this root to undergo regeneration. They proved that only those nerve fibers provided with sheaths of Schwann have the possibility of regener-

ation. The division of the posterior roots in dogs do not correspond with those obtained by Y. Bikeles in the Physiologic Institute of Prof. A. Beck²⁰ in Lemberg. This author showed by experiments that after compressing the posterior roots there are slight attempts at regeneration, contrary to the theory advanced that there is no intramedullary regeneration.

No positive evidence has been obtained to show that regeneration of nerve fibers takes place within the nerve centers after artificially produced lesions. It is remarkable, however, that outside of the nerve centers or ganglia the nerves are regenerated and that the regenerated fibers find their way along the old nerve sheaths to the same structures to which they were distributed before section or degeneration occurred. Regeneration

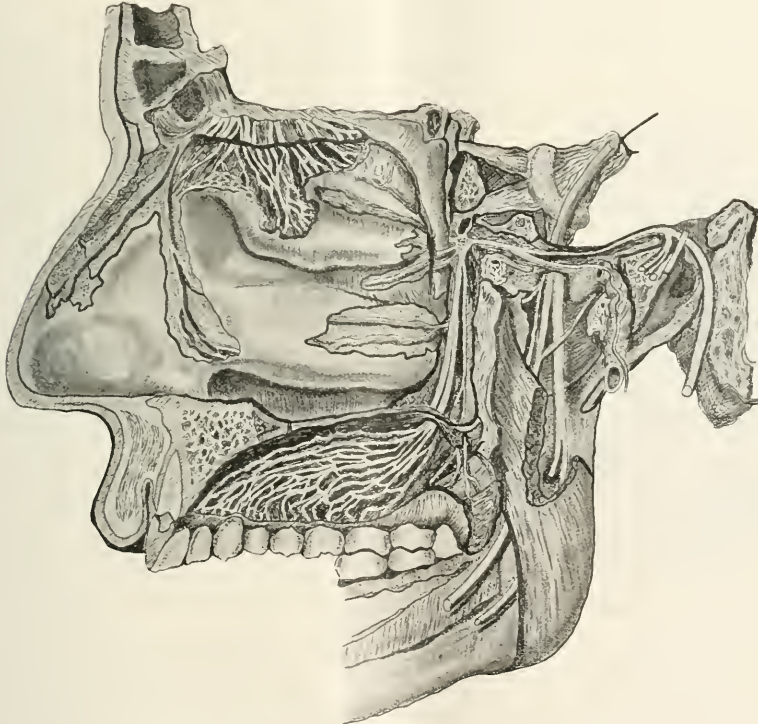

Fig. 3.—Shows the posterior palatine, the posterior palatine foramen and the mandibular branch. (From Toldt.)

ation. This was confirmed by Ballance and Stewart.¹⁹ Therefore, regeneration of peripheral nerves is common, while regeneration of the nerve fibers of the central nervous system is rare, if it occurs at all. This leads to revival of the old theory of peripheral regeneration.

After resection of the sensory root, if nerve fibers have grown out from the sheath of Schwann, they can only go as far as this sheath is present, i. e., to the point of entrance of the sensory root into the pons. They report one successful case with complete anesthesia at the end of one year.

The findings reported by Spiller and Frazier from the

on the distal side of division of a nerve cylinder is readily understood, as the cylinder is merely an extension of the cell from its nucleus, and cell portions do not long survive when they are disconnected from their nucleus. It is well recognized that distal degeneration takes place early in motor fibers after division, and that proximal degeneration advances slowly, probably from non-use, as after amputation. This may account for the absence of degeneration in specimens obtained in our first experiments, as the time was so short, but the paralysis was complete and continuous. The portion of the nerve cut off from the central cell nucleus always undergoes degeneration. Even after division ascending degeneration is limited to a small distance: after division of a sensi-

20. Neurologisches Centralblatt, 1903.

tive nerve, chromatolysis can not be attributed to loss of function or action. It has not yet been satisfactorily explained why, after complete division, some nerves are rapidly (by primary adhesion) restored to function; others by secondary regeneration are restored; while still others, either after division and after reapproximation (either immediate or remote), or after "pressure paralysis" without division, never regain function, still these facts exist clinically, and we must accept them in our empirical treatment of diseased, divided and contused nerves, as well as to hope that chemical substances may permanently interrupt conduction from the periphery to the center, and *vice versa*. It is on this clinical basis that we are justified in hoping the trunk injections may produce more lasting inability of transmission of impulse than neurotomy or neurectomy. From Goltz's experiments it is fair to assume that bodily pain can be of central nerve origin, and this is supported by irritative lesions of the thalamus (Schäfer).

Last year²¹ I made a preliminary report of a case operated on June 8, 1903, with the technic, which has been

Fig. 4.—Shows a section of the nerve trunk with osmic acid discoloration and granulation condition of axil cylinder.

followed, practically the same, in all subsequent cases, except that I am using a 2 per cent. solution of osmic acid, where formerly I used a 1½ per cent. solution. The case reported at that time has continued free from pain up to date. In that communication I have the results of Sir William Bennett's cases as published in the *London Lancet*, Nov. 4, 1899. I have now the pleasure of reporting his more extended experience with results down to Jan. 22, 1904, as given in a personal letter, for which I express my sincere appreciation. It is as follows:

Results of first 20 consecutive cases operated on.

First case treated July, 1897:

- 2 patients remained altogether well at the end of 4 years.
- 2 patients remained altogether well at the end of 3 years.
- 3 patients remained altogether well at the end of 2 years.
- 2 patients remained altogether well at the end of 1 year.

Two cases may be regarded as failures, i. e., the relief was only temporary (3 months and six months.) Two patients died without recurrence (1 in 9 months and 1 in 6 months) from causes unconnected with the condition for which the treat-

ment was adopted. Six were lost sight of within 9 months after the operation.

In the other cases operated on, the time which has elapsed since the treatment is not sufficient to justify any conclusion.

In 3 of the successful cases recurrence of pain occurred: 1 at the end of 6 months; 1 at the end of 8 months; 1 at the end of 12 months.

The symptoms subsided in one of these cases after a second injection, and no further trouble had arisen when the patient was last heard from.

EXPERIMENTS.

In order to determine, if possible, the *modus operandi* of cure, I have made the following experiments:

Dog No. 35.—Large size, male. Operated on Aug. 14, 1903. Osmic acid solution 1.5 per cent., freshly prepared, injected into trunks of both brachial plexuses; 3 nerve trunks were injected on each side and both supraorbital nerves. Incisions closed with subcutaneous catgut sutures.

August 18.—Extensor muscles of both fore-legs paralyzed. Dog walks with paws doubled under legs. Paralysis appeared on second day and was complete on the third.

August 25.—Paralysis continues as on 18th.

September 11, 1903.—Paralysis has continued. Anterior surfaces of fore feet ulcerated from pressure of the flexed paws in attempt to walk. Dog killed with chloroform, and specimens from supraorbital nerves and brachial plexuses secured for microscopic examination. No gross changes except at points of injection, where tissues were blackened.

Doc. No. 37.—Small, male. Operated on Aug. 14, 1903. Osmic acid injections in trunks of both brachial plexuses, 3 on right side and 2 on left, and in right supraorbital nerve. Incisions closed with subcutaneous and over-and-over catgut sutures.

August 18.—Right foreleg paralyzed in extensor muscles as in dog No. 35. Left not paralyzed.

August 25.—Condition same as on 18th. Right axillary wound open and granulating, but clean. Paralysis same.

Sept. 11, 1903.—Paralysis has continued. Ulcerations on anterior surface of fore feet (larger on right) from walking with paws flexed. Left cornea opaque with whitish secretion. Nutrition poor. Dog killed with chloroform. Brachial plexuses dissected and specimens taken from following situations for microscopic examination: 1, at site of injection; 2, proximal to injection; 3, anterior nerve roots and posterior roots with ganglia; 4, sections of cord at levels of these roots. Both supraorbital nerves dissected out and following specimens taken: 1, at site of injection; 2, proximal to injection; 3, gasserian ganglia; 4, sections of pons and medulla with sensory roots and nuclei. Specimens put in Mueller's fluid. No gross lesions except at points of injection, where nerves were blackened.

The microscopic findings on the slides made from the injected nerves as given by Prof. F. R. Zeit and Dr. A. A. Goldsmith of the Pathologic Department of the Northwestern University and concurred in by Professor Hill are as follows:

Stains were made both by the Weigert-Pal, and also by the usual hematoxylin and eosin method. All the tissues were fixed in Mueller-formalin. The Marchi method was not used in these specimens to show the degeneration of the nuclein sheath, but was used in the experiments conducted for me by Dr. Dunn.

Dog No. 35.—Anterior roots and posterior ganglia of roots of left side, normal. Injected trunks of right plexus. Many of the medullary sheaths of the nerve fibers stained brownish black by the osmic acid. Anterior roots and posterior ganglia of left side normal. Injected trunks of left plexus. Many of the medullary sheaths of the nerve fibers stained brownish-black with the osmic acid. Anterior root and posterior ganglion of right side, normal. Injected part of the right supraorbital nerve. Some of the medullary sheaths of the nerves are stained brownish-black by the osmic acid. Injected part of left supraorbital nerve, practically the same as right. Ophthalmic division of the 5th nerve proximal to injected supraorbital nerve of left side, normal. Gasserian ganglion and ophthalmic

division of the fifth nerve (left), normal. Gasserian ganglion and part of sensory root (right), normal.

Dog No. 37.—Right gasserian ganglion, normal. Ophthalmic division of the 5th nerve and gasserian ganglion not injected (left), normal. Pons and medulla with sensory root of 5th nerve, normal. Injected trunk of brachial plexus (right). Many of the nerve fibers show their medullary sheaths stained brownish-black with osmic acid. Trunks proximal to injection in brachial plexus (right), normal. Cord at level of brachial plexus, normal. Trunks on proximal side of injection in brachial plexus (left), normal. Anterior roots and posterior ganglia of brachial plexus (right), normal. Injected trunks of left brachial plexus. The medullary sheaths of many nerve fibers show a brownish-black stain from the osmic acid. Anterior roots and posterior ganglia of trunks of left brachial plexus, normal.

While the motor nerves were paralyzed by the injection, the microscopic report does not show that there was an ascending or descending degeneration or any change other than the local ones at the site of the injections in the nerve. This is not sufficient to account for the clinical phenomena as obtained in our cases, nor is it what should be found after a chemical destruction of a motor or combined nerve. Still the fact remains that there was complete paralysis of the motor nerve and some trophic changes as well. It shows that we are not permitted to use the osmic acid injections in neuralgias affecting the motor nerves.

Additional experimental injections were made under my direction by Dr. A. D. Dunn on four dogs to determine through a second source the pathologic changes produced by the injection of osmic acid into the nerve trunks, and to check the former experimental results.

Dog No. 1.—Injected March 3, 1904. About 15 m. of a 1½ per cent. aqueous solution of osmic acid were injected into each of the supraorbitals, and the cords of the brachial plexus. The supraorbital incisions were closed with horsehair. The axillary incision was closed with catgut and silkworm gut. The connective tissue sheath enclosing cords of brachial plexus and great vessels was reunited with catgut.

Complete paralysis of right upper extremity occurred immediately following injection and persisted until the dog was killed on the 13th day. The right supraorbital incision healed by primary intention, the left with a slight amount of suppuration. The dog gnawed the stitches of the axillary wound, which broke open and suppurated freely.

Necropsy, March 17, 1904.—Right supraorbital incision clean, an indurated lump to be felt beneath it. The supraorbital nerve is buried in a mass of blackened tissue. The nerve for about 1½ inches is blackened, smaller in caliber and more or less adherent to surrounding tissues. No suppuration. Macroscopically, no change could be observed distally or proximally to point of injection. Left supraorbital, some suppuration from wound. There is a more extensive mass of inflammatory tissue. The nerve when dissected out appeared similar to the right. Brachial, large suppurating subcutaneous pocket. Considerable inflammatory deposit. After sheath, which had been reformed by suturing fascia over nerves, was dissected off, the nerves were readily obtained. The inflammatory process seemed to have affected them little. The nerves were completely blackened for a distance of 1¼ to 1½ inches. Distally the diameter of the nerve seemed diminished. Proximally no changes were apparent. The gasserian and cervical spinal ganglia with corresponding part of cord were removed. No gross changes were noted.

Dog No. 2.—Small puppy. Injected March 12, 1904. About 15 m. of a 1½ per cent. aqueous solution of osmic acid were injected into each of the cords of the right brachial plexus and the right supraorbital. The nerves were small and the injections made with difficulty. The wounds were closed with silkworm gut and with catgut to unite fascia to form sheath over brachial plexus. Complete paralysis of right anterior extremity

followed and persisted up to necropsy. The wounds healed by primary intention.

Necropsy, March 26, 1904.—Induration present under right supraorbital, the injected nerve was dissected out of a mass of recent inflammatory tissue; no pus. The nerve was very small and blackened for about 1¼ inches. There was considerable blackening of the adjacent tissues. Distally to, and at the point of injection, the caliber of nerve seemed diminished. The left supraorbital was removed as a control. Axillary wound healed; a considerable amount of inflammatory tissue lay about sheath of great vessels and nerves, and in the paraneurotic tissues. The cords were blackened for 1½ inches with some diminution in their caliber at and distal to point of the injection. No gross changes in cervical cord and ganglia or in gasserian ganglia.

Dog No. 3.—Small puppy. Injected March 12, 1904. About 15 m. of a 1½ per cent. aqueous solution of osmic acid were injected into each of the supraorbitals, and into each of the cords of the right brachial plexus. The nerves were small and the injections were made with difficulty. Much of the osmic acid escaped into the surrounding cellular tissues. The supraorbital incisions were closed with silkworm gut. The fascia over great vessels and brachial plexus was carefully reunited with catgut; the skin incision closed with silkworm gut.

Complete paralysis of the right foreleg occurred immediately following the injection and persisted until death on the 16th day. There was a small amount of suppuration of right supraorbital wound. The other wounds appeared to have healed by primary intention.

Necropsy, March 26, 1904.—Induration present beneath both supraorbital wounds. Suppuration from right; stitches in situ. Inflammatory masses on both sides, but greater on the right. The tissues about nerves were much blackened. The nerves were dissected out with considerable difficulty. The nerve trunks were blackened for about 1¼ inches. No changes distally. The caliber of the nerve was only slightly diminished at the point of injection. Axillary wound healed. Stitches in situ. After opening wound, a small pocket of pus was discovered. Amount of inflammatory reaction greater than usual, but the nerves were easily freed. They were blackened for a distance of about 1½ inches. No diminution in the diameter of trunks. No gross changes in gasserian ganglia, in cervical ganglia, or in cervical cord.

This dog was also a small puppy. Consequently injections were made with considerable difficulty and did not prove as satisfactory as on the first dog, which was very large and whose nerves were large, so that the osmic acid was easily retained within the sheath.

Dog No. 4.—Injected March 30, 1904.—The supraorbitals and cords of the brachial plexus were each injected with about 15 m. of a 1½ per cent. solution of osmic acid in water. The nerves were laid bare and their trunks injected under aseptic precautions. The incisions were closed with silkworm gut suture. The fascia in the axilla was brought together with catgut. The wounds healed by primary intention. There was an immediate partial paralysis of the upper extremity on the injected side. This rapidly disappeared so that there was little residual paralysis at the end of two weeks.

Necropsy, April 14, 1904.—Supraorbital nerves are buried in a mass of inflammatory tissue. The nerve trunks are completely blackened for about 1½ inches. No changes are apparent proximal or distal to the point of injection. No suppuration in axillary wound. There is a considerable amount of inflammatory tissue. Some of the trunks are blackened only superficially. The osmic acid has apparently not penetrated well. A trunk was selected in which the penetration seems to have been good. There are no gross changes in the ganglia or cord.

The following pieces were taken for microscopic examination. At, distal to, and proximal to the point of injection, the gasserian ganglia, cervical ganglia, and parts of cervical cord.

This case differed from the others in not showing any of the slight changes that were present in the ganglia. There

was little or no diffusion of the Nissl bodies, and the nuclei were for the most part located centrally.

It may be noted in these experiments that about 15 m. of a 1½ per cent. aqueous solution of osmic acid were injected into each nerve trunk, under aseptic precautions. The supraorbitals and cords of the brachial plexus were selected for this purpose. The nerves were subjected to as little trauma as possible, and the injections were made slowly. The fascia was always reunited over the cords of the brachial plexus with catgut, and the skin wound closed with horsehair or silkworm gut.

The wounds usually healed by primary intention. Complete paralysis of the leg in which the brachial plexus had been injected, occurred immediately and persisted until death. The

dogs were killed about the 13th day after the injection. There was a considerable amount of inflammatory reaction in the tissue surrounding the nerve. The supraorbital nerves were embedded in a blackened inflammatory mass from which they had to be dissected with care. There was a considerable amount of inflammatory reaction about the cords of the brachial plexus, but the cords themselves lay comparatively free in the reformed connective tissue sheath. The nerve trunks were more or less blackened for a distance of 1 to 2 inches. In several instances the size was slightly diminished at, and distal to the point of injection. No gross changes were observed in the proximal portions of the nerve trunks, in the ganglia or in the cervical cord.

MICROSCOPIC FINDINGS IN INJECTED NERVE TISSUE AT DISTAL AND PROXIMAL TO THE POINT OF INJECTION, AND IN GANGLIA.

DOG NO. I. Ganglia overheated; Nissl's stain was unsatisfactory.

* Eosin affects the myelin of a few fibers, blackening the sheath uniformly. † No marked changes. ‡ No changes.

Two pieces were taken at the point of injection, proximal to, and distal to the point of injections and put in Mueller's fluid, 90 parts, formalin 10 parts. After one to two days, sections from each portion were washed in water for 24 hours, mounted in paraffin and stained with hematoxylin and eosin. The remaining pieces were left for two weeks in Mueller's fluid, which was changed several times to get rid of the formalin. They were then placed in Marchi's mixture, which consists of Mueller's fluid 2 parts, 1 per cent. osmic acid, 1 part, and left for six days. They were then washed in water for two days and afterwards remounted in paraffin. By this method any fatty degeneration occurring in the myelin sheath of the nerve fibers can be demonstrated. It has been found that myelin which has been mordanted for eight days or over in Mueller's fluid or other solutions of the bichromates, loses the power of reducing osmic acid, while fat retains this property unimpaired. The gas-serian ganglia and the cervical ganglia connected with the excised pieces of nerve were removed and placed in Zenker's fluid and stained with hematoxylin-eosin and by Nissl's method after they were mounted in paraffin. Specimens were taken from the cervical cord to be examined later if changes elsewhere should warrant it.

Microscopic Examination.—The most important changes were found at, and distal to the point of injection. The degree of pathologic alteration varied to a considerable extent dependant on the thoroughness of the injection and whether infection had resulted. For example, in one nerve that to all appearances was perfectly injected and blackened throughout, degenerative processes were found only in a limited portion. At the point of injection there was always more or less staining of the paraneurotic and interstitial fat with the osmic acid. There was quite marked derangement of the fibers. The inflammatory reaction was always less extensive than might naturally be expected. An occasional area of focal necrosis, a few foci of round cell infiltration, and here and there a leucocyte, attracted thither by the foreign substance, were all that was to be noted.

Distal to the point of injection the nerve trunk in some cases seemed atrophic, but there were no interstitial changes. Proximally, no changes were to be found except in the immediate vicinity of the injection. At and distal to the point of injection, there was more or less extensive fatty degeneration of the myelin sheath, this varied in amount from the involvement of all the fibers to an occasional fiber. Proximally the myelin was unaffected, except immediately above the limit of blackening, which was our means of defining the extent of injected area.

There were no signs of inflammation in the ganglia. Slight changes, similar to those one would be led to expect after nerve resection, were present. The nuclei of many of the cells were located at the periphery and the stainable substance of Nissl was diffused throughout the cytoplasm.

(To be continued.)

NOTE.—The conclusion of Dr. Murphy's article next week will be followed by the discussion on the papers of Drs. Sherman, Frazier and Murphy.

BLOOD PRESSURE AND PULSE RATE.

AS INFLUENCED BY DIFFERENT POSITIONS OF THE BODY.*

O. Z. STEPHENS, A.M., M.D.

Department of Physiology, Northwestern University Medical School,
CHICAGO.

HISTORY.

The blood pressure in the arteries was first measured with some degree of accuracy by Stephen Hales in 1733. He ordered a mare to be tied down on her back, into whose crural artery, about three inches from her belly, he inserted a brass pipe one-sixth inch in diameter. To this pipe, by means of another brass

pipe, he fastened a glass tube 9 feet long, and of nearly the same diameter as the pipe in the artery. He then untied the ligature on the crural artery, as a result of which the blood rose 8 feet 3 inches above the level of the ventricle of the heart.¹

While blood pressure can be measured in this way with some degree of accuracy, there are several objections to the method, chief among which are the following: 1, Through the uncomfortable position of the animal and the consequent effect on the vasomotor nerve fibers, the pressure is likely not to be the same as it would under normal conditions; 2, the inaccuracy due to the speedy coagulation of the blood; 3, the clumsiness and inconvenience of the apparatus.

Poiseuille, many years later, improved this method of Hales by substituting for the glass tube a mercurial manometer. The tube connecting this manometer with the artery was filled with a solution of sodium carbonate to prevent coagulation of the blood.²

Later, Ludwig made an improvement on Poiseuille's mercurial manometer by placing on the mercurial column a float carrying a writing style, by means of which records of the variation in pressure could be taken on revolving drums. By means of the apparatus a fair degree of accuracy can be obtained, but the oscillations of the mercurial column, due to inertia, render it objectionable. The mercurial manometer, however, has been used very extensively and with very valuable results.

Piorry, a noted French physician, was one of the first to observe the effect of the force of gravity on the circulation, i. e., the effect of the change of position on the blood pressure. His observations, however, were clinical. Having been called to a patient who had lost consciousness, and who was being supported in a sitting position by his friends, he placed him in a horizontal position, after which the patient at once regained consciousness. Hill has also found, through a trephine hole in the skull, that the intracranial pressure is negative in the sitting posture and positive when the head was bent down toward the knees.³

Many other observations of the same nature have been observed clinically on the human subject and experimentally on the lower animals.

Most of the work on the lower animals has been done by inserting a cannula connected with a mercurial manometer into the carotid or femoral artery, and then shifting the animal from one position to another, about a horizontal axis which passes through the point of insertion of the cannula. In this way, quite accurate results have been obtained. Of course the animals were invariably narcotized or anesthetized.

So far as we have been able to learn the experimental observations on blood pressure in different positions of the body have been confined to the horizontal, vertical feet-down and vertical feet-up positions. The same is true of the pulse rate. The clinical observations have been confined to the horizontal, head-up and head-down at no particular angle.

Since the advent of the sphygmomanometer, experiments have been performed on the healthy human subject in the standing, sitting and horizontal postures.

The pulse rate in the human subject in different positions of the body, so far as we have been able to learn.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

was first studied by Guy,⁴ who made observations on 100 men, averaging 27 years of age, in the standing, sitting and lying positions. He found the pulse rate to be highest in the standing, lower in the sitting and lowest in the lying positions.

We see, then, that the subjects of blood pressure and pulse rate in different positions of the body are not new ones; that some of the apparatus used in getting blood pressure was inaccurate; that experimental observations were on narcotized or anesthetized animals; that clinical observations on blood pressure in the different positions of the body are confirmatory of the experimental observations.

In our work on blood pressure we have dealt with the subject in a different manner, in some respects, from our predecessors, inasmuch as we have chosen more positions of the body and have taken the pressure on both sides of the body in each position.

Fig. 1.—Standing.

METHOD.

(a) *Subjects*—The subjects used in these experiments were twenty-two male medical students, with an average age of 24 years and an average height of 170 cm. In one of these subjects, however, the pulse rate was not obtained, hence only twenty-one are used in making computations on pulse rate. In changing from one position to another, they were allowed to remain long enough in the new position for the circulatory apparatus to become adjusted to the new conditions before observations, either on blood pressure or pulse rate, were taken. Every means was taken to keep them comfortable and to avoid anything which would tend to provoke excitement or muscular effort. The rate of respiration was also kept normal.

(b) *Apparatus*.—The instrument used in taking the blood pressure was the Riva Rocci sphygmomanometer,

as modified by H. W. Cook. The instrument is now so well known among physiologists that a description of it here is not demanded.

(c) *Technic*.—Each of the twenty-two men were taken through the following positions: 1, Standing; 2, sitting; 3, supine; 4, head down at an angle of 45 degrees; 5, right lateral; 6, left lateral.

The blood pressure was taken in both brachial arteries in each position by placing the band of the instrument around the upper arm midway between the elbow and shoulder.

The pulse rate was also taken in each position, the count being taken through a whole minute of time.

In taking the pressure in the standing position, the patient stood erect, the upper arm was abducted to the horizontal plane and the forearm flexed at right angles to the brachium and held perpendicularly, with the hand uppermost. The arm was supported in this po-

Fig. 2.—Sitting.

sition by an assistant in order to relieve the subject of any muscular effort in sustaining the arm himself. The opposite arm was allowed to hang laxly by the side.

In the sitting position, the subject sat on a stool, with the thighs parallel and flexed at right angles to the axis of the body. The legs were flexed at right angles to the thighs. The arm in which the pressure was taken was held in the same position in relation to the body, as it was in the standing posture (the assistant supporting it), while the hand of the opposite arm lay laxly on the thigh of the same side.

The subject in the supine posture lay flat on his back with legs parallel, and the arm on the opposite side to the one in which the pressure was taken lay parallel with and along side of the body. The arm in which the pressure was taken was abducted to right angles with the body axis, and the forearm at right angles to the brachium and held perpendicularly. Thus it is seen that the arm did not take the exact relation to

the body in this position that it did in the standing and sitting postures. In the latter, the brachium was so rotated that the inner aspect faced forward, while in this position the inner aspect of the brachium faced toward the feet, having rotated through an arc of 90 degrees. The variation in blood pressure, due to this slight difference in the relative position of the arm, if there be any variation at all, would certainly be too insignificant to be taken into account.

The subject in the head-down position was placed on a table on his back, around his ankles were placed comfortable straps, which were fastened to one end of the table. The end of the table was then elevated so that the subject hung with his head down, at an angle of 45 degrees. The arms assumed practically the same position, in relation to the body, as they did in the supine position, the forearm of the arm operated on being held perpendicularly, and the opposite arm lying along side of the body.

In the right lateral position our subject lay on the

Fig. 3.—Supine.

right side, the head raised to the horizontal level by a pillow, the legs parallel and straight, and the left arm parallel with and on the body. The right arm was extended anteriorly at right angles to the body axis, the forearm flexed at right angles to the upper arm and held perpendicularly when the pressure was taken in this arm. When the pressure was taken in the left arm in this posture, the right arm was allowed to assume a position most comfortable to the subject, in order to obviate any nervous influence on the circulation which might arise from the subject being uncomfortable. The left arm assumed the same relation to the body as it did in the supine when the pressure was taken in it. This, of course, put the forearm in a horizontal plane.

The left lateral position is a repetition of the right lateral in reversed order, and need not be detailed further.

RESULTS.

After the pressure in each brachial was taken in a given position, the two results were averaged to obtain a mean pressure in that position. The results of such observations, together with the pulse rate, are shown in the following table:

TABLE NO. 1.

No.	Stand- ing.	Sitting.	Supine.	Head- down.	Right Lateral.	Left Lat.

	Pulse rate ... 122	119	142	153	159	111
20	Right arm ... 119	113	127	158	98	155
	Left arm ... 76	75	59	58	63	62
	Pulse rate ... 127	124	159	162	143	96
21	Right arm ... 133	127	133	161	111	157
	Left arm ... 77	72	62	58	63	66
	Pulse rate ... 132	118	163	185	157	106
22	Right arm ... 141	129	159	189	128	165
	Left arm ... 67	65	55	59	61	60
	Pulse rate ... 67	65	55	59	61	60

In summarizing the above data, we used the Hall-Quetelet method.⁵ This method uses the median value, instead of the average or arithmetical mean. The data collected from each individual are recorded on a card. The cards from the several individuals are grouped as desired. We grouped our cards according to the pulse rate and blood pressure in each arm in the different positions of the body. For illustration, let us take the blood pressure in the right arm in the standing position; and let us take all those cards showing a blood pressure of 105-110 mm. Hg, inclusive, and place them in one group, and all those showing a pressure of 110-115 mm. Hg in another group, etc., till we have all the twenty-two cards placed in groups, the difference between the minimal values of which is 5 mm. Hg pressure. We shall then have the following table:

TABLE NO. 2.

Blood pressure	105+	110+	115+	120+	125+	130+	135+	140+	145+	150+	155+	160+
No. of observations	1	2	1	2	3	6	1	1	1	3	0	1

In adding the number of observations shown in the table, we get a total of 22, which corresponds to the number of subjects in whom the pressure was taken.

The next step is to find the median value, which Dr. Hall defines thus: "The median value is that value which is so located in the whole series of observations of a single measurement of a single group that there are as many above it as below it; i. e., that the number of values which it exceeds is equal to the number of values which exceed it." Since the number of observations is 22, the median value, therefore, will have on one side of it 11 values, which are less, and on the other side 11 values, which are greater than itself. We must, then, find the eleventh value. In counting from left to right, we find that the eleventh value lies in the group 130 mm. Hg. and is the second from the minimal value and fourth from the maximal value of this group. The median value, therefore, lies in this group, which may be called the median group. We know, then, that it must be between 130 mm. Hg. the minimal value of the group, and 135 mm. Hg. the minimal value of the next higher group. Now, according to the biologic laws, the six values in this median group will be practically evenly distributed throughout the 5 mm. Hg. pressure between its minimal value and the minimal of the next higher group. Hence the sec-

are likely to balance the giant values, in which case the arithmetical mean is an accurate though time-consuming method of evaluating data. In a small number of observations, however, one extreme is more certain to overbalance the other, and in this case the Hall-Quetelet method is the only accurate one. It is also accurate in handling large numbers and is much simpler and more easily applied than the old method.

Our data pertaining to the pulse rate and blood pressure in both brachial arteries, in the different positions enumerated above, were handled in this manner, the summary of the results of this evaluation being given in the following table:

TABLE NO. 3.

	Standing.	Sitting.	Supine.	Head down.	Ret. Lat.	Lat. Lat.
Right arm	131.6	133.3	152.5	195.2	155	110
Average	130.8	131.7	150.1	165.6	134.5	133
Left arm	130	131	148.3	165.6	111	137
Pulse rate	86	82	68.7	65.8	68.1	69.1

DISCUSSION OF EFFECTS ON BLOOD PRESSURE.

In scanning this table, it is seen that the average blood pressure in the two arms increases in the standing, sitting, supine and head-down positions, respectively, while the pulse rate decreases. It has been considered that the blood pressure varies as the heart rate times the heart strength times the resistance.

Expressed in terms of a formula, we have P varies as Hr × Hs × R, where P equals blood pressure, Hr, the heart rate, Hs the heart strength, and R the resistance.

This resistance may be due to arterial causes—arterial resistance; it may be due to the capillaries—capillary resistance; it may be due to contractions of the arterioles—peripheral resistance; it may be due to venous causes—venous resistance; or it may be due to the effect of gravity on the circulation—hydrostatic resistance.

Now, it remains to be seen whether the phenomena observed in Table 3 can be explained by means of this formula.

Standing Position.—We see that the average blood pressure in the standing position is lower and the pulse rate is higher than in any other position in the series. Here the current meets with the least arterial and hydrostatic resistance on the arterial side of the circulation, and with the greatest hydrostatic resistance on the venous side. Both of these factors tend to decrease the pressure in the upper portions of the body by tending to allow the accumulation of blood in the lower portions of the circulatory system. This is partially compensated for, however, by the abdominal muscles and contraction of the arterioles in the splanchnic area.³

Sitting Position.—The average pressure in the sitting position is nearly 1 mm. Hg. greater than in the standing position, a difference almost so slight in itself as to be ignored. But when we observe that the pulse rate in this position has decreased four beats to the minute, more importance attaches to this slight rise in pressure, and we begin to wonder why the pressure did not sink with the lowering of the heart rate.

According to the formula, P will vary with Hr where Hs and R remain constant. Therefore, if Hr decreases, P will decrease also. If P does not decrease when Hr decreases, but, on the contrary, remains constant or increases, it is evident that the variation of Hr is counterbalanced or more than counterbalanced by the varia-

FIG. 4.—Head down.

ond value from the left must be 130 mm. Hg. pressure, plus 2/6 of 5 mm. Hg. pressure, which equals 131.6 mm. Hg. the pressure for the right arm in the standing position.

Dr. Hall has also reduced this process to a mathematical formula, thus:

"Let n equal total number of observations; m equal the number of observations in the median group; l equal the sum of observations to the left of median group; r equal the sum to the right; a equal the minimum value of the median group; d equal the arithmetical difference between the minimum values of the groups, and M equal the median value to be determined."

Then

$$M = a - \frac{(d \cdot n - 2l - r) - m}{m}$$

$$M = a + \frac{d \left(\frac{n}{2} - 2l - r \right)}{m}$$

$$M = 130 + \frac{5 \left(\frac{22}{2} - 9 \right)}{6} = 131.6 \text{ mm. Hg. pressure, by substituting the values of the letters in the above cases.}$$

In taking the arithmetical mean, however, we get a pressure of 132.2 mm. Hg. In observing the table, we see that we have one observation of quite high pressure. This slight increase of the average over the median value is doubtless due to this one observation.

In a large number of observations the dwarf values

tion of either Hs or R, or both, in an opposite direction. Can we account in any way for a sufficient rise in Hs or R, or both, to produce the slight rise of P against the decrease in Hr?

It will be recalled that in the sitting position the thighs were flexed at right angles to the body axis, and the legs at right angles to the thighs; that the body was sustained erect on the pelvis, and the hand of the arm not being operated on was lying relaxed on the thigh of the same side. The blood, then, must take a somewhat different course in this position from what it took in the standing position, i. e., it must course around two right angles in each leg—one at the inguinal region and one at the knee. It also deviates slightly from a straight line at the elbow of the arm not being operated on. Thus the blood in two of the largest arteries turns two right angles in each lower extremity, and one large artery turns an angle of approximately 45 degrees at the elbow. The same is true of the veins in the same localities. This introduces an arterial and venous resistance which did not exist in the standing position.

Fig. 5.—Right lateral, lower arm.

It is possible, too, that the capillary resistance may be increased by compression of the gluteal region and upper part of the thigh by the weight of the body on them.

It has been stated that through the influence of the vasodilator nerve fibers the flow of blood to a contracting muscle is increased.⁶ If this be true, the flow of blood to the muscles of the lower extremities will be increased while the muscles are contracting to maintain the body in a standing position. This increased flow of blood to the lower portions of the circulatory system will tend to raise the pressure here and lower it in other portions of the arterial system.

The relaxation of these muscles in the sitting position, however, with practically the same tension of the abdominal muscles and the muscles of the back in maintaining the trunk erect on the pelvis, prevents the increase of flow of blood to the lower extremities, which results in higher pressure in the rest of the arterial system, i. e., the peripheral or arteriolar resistance is increased in this position.

The force of gravity also plays an important rôle. In a man 6 feet high the hydrostatic pressure of a col-

umn of blood reaching from the vertex to the sole of the foot is equal to 140 mm. Hg, and from the vertex to the middle of the abdomen about 50 mm. Hg.⁷ If this statement be true, the hydrostatic pressure in a man 5 feet 8 inches high—the average height of our 22 subjects—will be about 134 mm. Hg. Now, if the average distance from the bend of the femoral artery in the inguinal region to the bend of popliteal behind the knee be about 40 cm., the hydrostatic pressure in this position will not be 134 mm. Hg by 31.5 mm. Hg, the pressure of a column of 40 cm. There will be 40 cm. of the column of 170 cm (5 feet 8 inches), on which gravity exerts a pressure downward on only the lower wall of the vessel. This column of 40 cm. of blood, meeting resistance to its downward tendency, has no effect through its own weight in the column in the leg below it as it had in the standing position, but tends to check the flow of the column above. The latter, by its own weight or hydrostatic resistance, and the elastic force of the arteries must sweep this 40 cm. of blood through a horizontal distance of 40 cm. In overcoming this extra hydrostatic resistance, the column above must necessarily experience a rise in pressure. Thus the decrease in the hydrostatic resistance

Fig. 6.—Right lateral, upper arm.

due to the decrease in height of the column of blood, is reacted on by the increased pressure due to the hydrostatic resistance of the 40 cm. to be moved in a horizontal plane. This is true on both the arterial and venous sides of the circulatory system. Whether or not these two factors balance we do not know. However, to summarize, we see that we have an increase in the arterial, venous, capillary and peripheral resistances, and also the hydrostatic resistance due to the horizontal column of blood. We also have a decrease in the hydrostatic resistance due to a decrease in height of the blood column.

Now, since we have an increase in P and decrease in Hr, it is evident that the increasing factors of R must more than counterbalance the decreasing factor, since the respiration was kept normal and all nervous stimuli avoided which would tend to increase Hs. This increased pressure is shared by the coronary arteries, in consequence of which an increase of nutriment is carried to and increased tension placed on the heart muscle, both of which tend to increase the heart strength.⁷

7. Roy and Adams: Philosophical Trans. of the Royal Society, 1892, vol. cxxxiii, B. pp. 90, 262.

It is clear, then, that the total increase in P is not due alone to the increased resistance, but is brought about partially by the increase in the heart strength. This increase of the heart strength, however, results from the increased pressure due to the increased resistance. Just what proportion of the total increase in P is due to the increase in R , and what proportion is due to the increase in H_s , we do not know. We conclude, therefore, that the increased blood pressure in the brachials in the sitting position over that in the standing position is due to an increase in both the resistance and the heart strength.

Supine.—In referring to Table 3, the median pressure in the supine position is seen to be 150.4 mm. Hg, a distinct rise over that in the two previous positions. We see, also, that the pulse rate has decreased to 68.7 beats per minute, a distinct decrease below that in the two previous positions. Therefore, since P is higher and H_r lower than in the two other positions, it is clear that H_s or R , or both, have made a greater increase.

Hill of London has shown that, when the body of one of the lower animals takes the vertical feet-down position, the blood pressure falls in the carotids and at the same time rises in the femorals. When the body resumes the horizontal position the pressure increases in the carotids and decreases in the femorals, as compared with what it was at first. When the animal is placed in the vertical feet-up position, the pressure still further rises in the carotids and falls in the femorals. These phenomena he attributed to the hydrostatic pressure of the blood. Again, if the phrenic nerves be divided when the animal is in the vertical feet-down position, the pressure will still further fall in the carotids and rise in the femorals. Furthermore, if a crucial incision be made in the abdominal walls, the pressure falls still further in the carotids and rises in the femorals. These phenomena, he attests, point to a compensatory apparatus in the splanchnic area and the abdominal walls, since compression of the latter will cause the pressure to rise in the carotids and fall in the femorals. This compensatory apparatus, he thinks, becomes more nearly complete in animals that assume more nearly the vertical position as their natural posture; therefore, more nearly complete in man.³

The clinical experience of Piorry, cited above, and of many others, also shows the effect of gravity on the circulation in the supine position. When the subject is placed on his back the blood which previously tended to gravitate to a plane below the heart, especially into the spacious venous system of the splanchnic area, now tends to become more equally distributed throughout the circulatory system, since this system has taken a horizontal position. This tends to increase the hydrostatic resistance in the plane of the heart and above it, through an increased flow of blood to these regions and to lower it in the planes below through a correspondingly decreased flow to those regions.

At the same time, the hydrostatic resistance is further increased by the blood in the arterial system having to be moved along a horizontal plane at right angles to the force of gravity.

It is decreased, however, in the lower portions of the venous system by a force equivalent to the difference between that required to raise the return circulation to the level of the heart, and that required to move it through a horizontal plane throughout the venous system. It is increased, however, in the upper portions of this system through the general tendency of the blood

to become equally distributed throughout the circulatory system.

The increased hydrostatic resistance in the circulatory system tends to strengthen the heart beat by increasing the nutriment to and the tension on the heart muscle. This increased force of the heart "may more than counterbalance the increase in the resistance to the contractions of the left ventricle which that rise introduces, so that the ventricle may contract more completely than it did before the pressure was raised."⁴

It may be possible that the capillary resistance is slightly increased in this position by the weight of the body on the tissues of the back; this is evidently small, as the body rests largely on bony prominences, such as the sacrum, shoulder blades, etc., leaving the large muscular areas of the back practically free from pressure.

We see, then, that there is an increase in the hydrostatic resistance in the arterial system and upper portions of the venous system; that because of this increase of hydrostatic resistance the heart's action is strengthened; that there is a possible slight increase in the capillary resistance; that there is a decrease in hydrostatic resistance in the lower portions of the venous system.

Now, since P has increased, we are forced to conclude that the increase in H_s and R more than counterbalances the decrease in R in the lower venous system. Furthermore, that the ultimate factor in bringing about the increase in P in this position is the hydrostatic resistance.

Head-Down Position.—Referring again to Table 3, it is observed that the blood pressure in the head-down position has made a leap of over 15 mm. Hg above what it was in the supine, being now 165.6 mm. Hg. It will also be noticed that the heart rate has been lowered almost three beats per minute, the rate now being 65.8. Now, since the pressure is the greatest and the heart rate is the lowest in this position, it is evident that the heart strength or the resistance, or both, have experienced the greatest increase.

Since the man is on an inclined plane with the head downward, it is clear that the blood will tend to course toward the head through the influence of gravity. This produces an increased hydrostatic resistance in the upper portions of the circulatory system, which is greater than it was in the supine, since gravity acts on an angle of 45 degrees with the course of the blood, instead of 90 degrees. It is also greater than in the standing and sitting postures, since in the latter gravity acts in a straight line with the blood stream and tends to pull it to the opposite extreme of the circulatory system.

The hydrostatic resistance in this position is equivalent to that of a column of blood extending perpendicularly between the plane of the feet and that of the brachial artery, a distance of about 99 cm., with a pressure of about 78 mm. Hg.

According to Hill,³ the increased hydrostatic pressure in the carotids in the vertical head-down position is partially compensated for by a decrease in the resistance in the splanchnic area, brought about through the vasodilator mechanism; but this compensation is far from complete.

The same may be said in regard to the capillary resistance here, as was said in case of the supine; if there be an increase it must be slight.

The hydrostatic pressure, being greater in the upper portion of the circulatory system than it was in the pre-

vous postures, will necessarily be shared to a greater extent by the coronary arteries, in consequence of which there will be a greater increase of nutriment to the heart muscle. The tension on the heart will also be greater. We conclude, therefore, that the strength of the heart is greatest in this position.

Lateral Positions.—In Table 3 it will be seen that the pressure in the right lateral position is 134.5 mm. Hg, and the pulse rate is 68.1 beats per minute; in the left lateral the pressure is 133 mm. Hg, and the pulse rate 69.1 per minute. Here the same general law holds good—that the pulse rate decreases as the pressure increases. But we notice that the pulse rate approximates that in the head-down position, while the blood pressure approaches that in the standing and sitting postures, i. e., the pressure is lower compared with the pulse rate than in the other lying positions.

Now, since the pulse rate is much lower and the blood pressure slightly higher in these positions than in the standing and sitting positions, it is manifest that both the heart strength and resistance, or either one of them, must be increased to a greater extent than in the latter. For convenience we shall take the average pressure and pulse rate in these positions in comparing them with the others, and later take the two separately, in comparing them with each other. The following table will then be useful:

TABLE NO. 4.—LATERAL POSITIONS.

	Right Arm.	Left Arm.	Average.	Lower Arm.	Upper Arm.
Blood Pressure.....	134.5	133	133.8	155.5	112
Pulse Rate.....	68.1	69.1	68.6

This table shows the average blood pressure in these positions to be 133.8 mm. Hg and the average pulse rate 68.6 beats per minute. By comparing these figures with those in Table 3 we see the pulse rate is nearly the same as in the supine, and but slightly higher than in the head-down positions, while the pressure is much lower. That means that the heart strength, the resistance, or both, have decreased.

How can we account for these phenomena? In the first place, how can we account for the slight increase in the pressure over the great fall in the heart rate from what it was in the standing and sitting positions? In the latter a comparatively small amount of blood was moved along a horizontal plane by the heart force, thus overcoming the hydrostatic resistance due to gravity acting at right angles to the blood current, while in the lateral positions the blood moves nearly horizontally through the entire circulatory system.

Here, also, the blood tends to become more equally distributed throughout the circulatory system. This results in a lowered hydrostatic resistance in the lower portions of the body, with a corresponding increase in the upper portions.

In this position it will be recalled that the lower arm was extended anteriorly at right angles to the body axis. Instead of the blood passing from the subclavian artery through the brachial in a straight line to the elbow, it deviates 90° from this course and passes directly forward. This offers a greater resistance to the blood current above, and at the same time tends to lessen the pressure in the radial below it. We conclude, therefore, that because of this variation the systemic pressure is somewhat higher than is recorded in the above table. This is a greater arterial resistance than we had in the standing and less than in the sitting positions. In the

upper arm the forearm was horizontal instead of perpendicular, as it was in the other positions, while the brachium was perpendicular instead of horizontal. Hence, these two differences balance. Because of the increased resistance the heart force is also increased in the same manner as has been given above.

We see, then, that the hydrostatic resistance is greater in the planes of the heart and above it, in these positions, than in the standing and sitting positions; that the arterial resistance is slightly greater than in the standing, but less than in the sitting position; that the heart strength is increased because of the increased resistance. Now, since P is slightly higher and Hr much lower, Hs and R, one or both, must be much increased.

Now, why is the pressure lower than, and the heart rate nearly the same as, it was in the supine? In the latter the circulatory system lies practically in a horizontal plane. In the lateral positions it is "on edge," as it were, and beside, the upper portion is slightly higher than the lower, since the distance from the central axis of the body to the point of the shoulder is somewhat greater than it is from the same axis to the most distant point of the crest of the ilium or great trochanter. This gives a slightly inclined plane, down which the blood tends to gravitate toward the feet, thus raising the pressure below the heart and lessening it above, as compared with what it would be in the supine position. The resistance, therefore, being less, the heart strength will be less because of lessened nutrition to, and tension on, the heart muscle. The decrease in P, then, must be due to a decrease in Hs and R.

The same things are true in the head-down position as in the supine, but in a more marked degree. Here, however, Hs has decreased to a greater degree; hence, we conclude that P has decreased as a result of the decrease in Hr, Hs and R.

Now, Table 4 shows that the average pressure is 1.5 mm. Hg greater and the pulse rate a half beat less in the right than in the left lateral position. How may this slight rise of pressure be explained?

The aorta passes from the left ventricle upward and slightly forward and to the right. It then curves backward, upward and to the left. Therefore, in the right lateral position the heart lifts the greater portion of blood against the force of gravity to the perpendicular distance between the planes of the mouth of the ascending and the beginning of the descending aorta, respectively. It also turns this blood through a semicircle in its course through the arch. In the left lateral this resistance is absent. The force of gravity alone would be sufficient to take the blood around the arch of the aorta after it reaches the top of the ascending portion. This increased resistance in the right lateral in turn produces a greater heart strength. It is clear, then, that the increase in P is due to an increase in Hs and R.

DISCUSSION OF EFFECTS ON PULSE RATE.

"The mere fact that the centripetal fibers which call the vagus into play by reflex action come chiefly from the heart itself, shows that one part, and a very important part, of the vagus function is to reduce the work done by the heart in the interest of the heart itself. We conclude, then, that the vagus acts as a protecting nerve to the heart, reducing the work thrown on that organ when, from fatigue or other causes, such relief is required by it. The fact, however, that there exists centripetal fibers which call the vagus center into activity, in such nerves as the sciatic and splanchnic, shows that the vagus mechanism may be called on to act in the in-

terests of other parts of the body whose circulation requires to be diminished. We conclude, therefore, that the vagus may be used by other parts of the body to diminish the blood pressure and the output of the heart, and thereby reduce the circulation.

"Among the organs whose protection against over-congestion is of the greatest importance, it need hardly be said that the central nervous system takes the foremost place. It is well known that if the intracranial pressure be raised artificially powerful excitation of the vagus center is produced. Vagus action also results from rise in the blood pressure in the systemic arteries, and the excitation thus produced can be shown to be due to the high pressure within the vessels of the central nervous system and not to any direct effect of the rise of pressure on the heart. We must, therefore, look on the vagus mechanism as a means by which the central nervous system gains protection against too great congestion.

"The dependence on the blood pressure of the degree of vagus action, and the readiness with which the vagus center in the medulla is called into play by a rise of the intracranial pressure, seem to us to indicate that the mechanism in question is especially employed in the interests of the central nervous system as well as the heart itself."

Now, if it be true that the vagus acts as a protecting nerve both to the heart itself and the central nervous system, it is clear that the reduced heart rate in the various positions of the body in the order named is in response to the action of the vagus in endeavoring to protect the heart and central nervous system against the increasing pressure.

SUMMARY.

1. The blood pressure increases in the brachials from the standing to the head-down positions, inclusively, in the following order: Standing, sitting, left lateral, right lateral, supine and head-down.
2. The greater the hydrostatic resistance in the upper portions of the circulatory system the greater the increase in pressure where the nervous and respiratory systems are kept normal.
3. An increase of resistance is accompanied by an increase in heart strength; the strength of the heart, therefore, will increase in the different positions in the following order: Standing, sitting, left lateral, right lateral, supine and head-down.
4. The pulse rate decreases in the same order that the blood pressure increases.
5. The decrease in the pulse rate is a conservative act on the part of nature to protect the heart itself and the central nervous system.

DISCUSSION.

DR. H. G. BRAINERD, Los Angeles, Cal.—Are these data altogether from pressure in the arm, or are they taken in any other way? Can they be taken in the temporal region or elsewhere? The Riva-Rocci apparatus, as I have it, is not adapted to use in the temporal region. I have been very anxious to find what the temporal blood pressure is and how it compares with the pressure in the arms. Would it not be necessary to use an air pad?

DR. WINFIELD S. HALL, Chicago—The Riva-Rocci apparatus, as it is furnished to us by the medical instrument houses, is not adapted to taking any measurements except those on the arms or legs. A very easy adaptation can be made for taking the pressure in the temporal artery. One has only to put a band around the head, insert an inflatable bulb between the band and the temporal artery, and inflate the bulb sufficiently to cut off the temporal pulse. Having thus a method of determining the pressure in the temporal artery, we could, at the

same time, take the pressure in the brachial artery; and also perhaps that in the popliteal artery. With these three observations taken simultaneously one could compare not only the three different pressures, but could also get an idea of the average arterial pressure.

TREATMENT OF FRACTURES OF THE PATELLA BY LATERAL SUTURES.*

JOSEPH A. BLAKE, M.D.

NEW YORK.

The question as to the operative versus the mechanical treatment of fracture of the patella has been ably discussed in a number of papers in the last few years. Some of these have been read before this Association.

I do not intend to reopen this discussion, inasmuch as my contribution deals only with a detail in the technique of the open operation; yet it is only fair that, in order that I may not be misunderstood, I should state my position in the matter; the more so, since the principle of my technic is closely linked with the reasons for my views in regard to the treatment in general.

Fractures of the patella are divisible into two classes—those caused by direct and those caused by indirect violence. Or, as von Mikulicz¹ has very aptly put it, "blow" and "tear" fractures. To this classification he also added another which was the result of both, or a "combination" fracture.

The difference between the "blow" and the "tear" fracture is well known to all, yet the importance of its bearing on the question of treatment seems to be generally overlooked. In the fracture by direct violence, usually the bone alone suffers, and although it may be comminuted, there is little separation of the fragments. In the "tear" fracture, on the other hand, not only the bone but the lateral expansions of the quadriceps muscle on either side of the patella are likewise torn, and there is considerable separation of the fragments. In the "combination" fracture the injury to the soft parts is similar.

Great stress has been laid on the interposition of fibrous frills from the torn aponeurotic structures covering the patella by the advocates of the open operation. This interposition does not occur in the "blow" fractures, because these structures are not frilled.

The fractures by direct violence or blow fractures, then, do not offer indications for open operation, except for the reduction of otherwise irreducible displacements of the fragments, and in practice their treatment by mechanical methods will be found to yield excellent results. On the other hand, the treatment of the "tear" fractures by mechanical means is extremely unsatisfactory. These cases, unless contraindications exist, by reason of age or disease, should in my mind be operated on, particularly those to which a sound limb is a necessity.

The indications for operation consist, then, not in the extent of injury to the patella itself, but to the lateral extensions of the insertion of the quadriceps extensor muscle. The importance of these structures has been emphasized by von Mikulicz,¹ who termed them the "para patella ligaments." I have been accustomed to call them the lateral patella ligaments and for convenience shall adhere to that term. They are strong aponeurotic structures, which are directly connected

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

1. J. von Mikulicz: British Med. Jour., Dec. 13, 1902, p. 1828

with the tendon above and with the ligamentum patellae below, and, in fact, extend its insertion laterally to the tuberosities of the tibia. On their deep surfaces they are intimately blended with the capsule of the joint.

In direct fractures of the patella, the lateral patella ligaments remaining intact, considerable power of extension is present, although the patient may not exercise it on account of pain. In such cases when voluntary trials at extension are made or when the knee is passively flexed little separation of the fragments will result. The function of the ligaments is so important that when these structures are torn as in the "tear" fractures, no operation based on the suture of the patella alone is correct. The lateral patella liga-

ment should be sutured as well. In fact, I have gone so far as to rely on suture of the lateral patella ligaments alone in the treatment of "tear" fractures, only employing enough other sutures of fine catgut to coapt the remaining fibrous tissues.

The steps of the operation are as follows: A curved transverse incision, one centimeter below the line of fracture and long enough to sufficiently expose the tears in the lateral patella ligaments, is made. The fringes of the aponeurotic tissues, which are usually found closely applied to the surfaces of the fracture are separated and trimmed off with seissors, and the blood clots washed out of the joint with a stream of sterile salt solution. All these manipulations are performed with instruments; not even the gloved fingers touch the tissues. Irritation of the synovia by sponging is abstained from.

A suture of strong chromicized catgut, No. 4 preferably, or kangaroo tendon is then introduced in the lateral patella ligament on each side of the patella in the following manner: A strong, full-curved Hagedorn needle is inserted one centimeter from the line of fracture and as close to one of the fragments as is possible, and brought out in the line of the tear just in front of the synovia; again introduced at a similar point at the margin of the opposite torn surface and hugging the other fragment it emerges one centimeter from the line of fracture on the anterior aspect of the lateral liga-

Fig. 1.—Showing the method of introducing the sutures close to the sides of the fragments and in front of the synovia.

Fig. 2.—Main sutures tied with others to repair the extensions of the tears in the lateral patella ligaments and coapt the tissues in front of the patella.

ment (Fig. 1). The sutures are introduced on both sides of the patella before tying. It is very important that the sutures should be introduced as closely as possible to the fragments. The sutures are now tightened and tied simultaneously, and the coaptation of fragments will be found to be so exact (Fig. 2) that the slightest movement on one another in any direction is absolutely impossible on account of the interlocking of the slight irregularities of the surfaces.

OPERATION.

The coaptation will be good even if the fragments are comminuted, provided the sutures grasp the tissues beyond the fragments.

The reason for the accurate coaptation lies in the fact that the stress of the sutures is exerted at right angles to the centers of the surfaces of the fracture, a feature which is not accomplished by any other method of suture with the exception of the purse string.

Fig. 3.—E. W., female, age 35 years. Refracture of right patella. X ray four weeks after second operation.

One or two additional chromicized sutures of somewhat smaller size are used to repair the extensions of the rents in the lateral ligaments, and the aponeurotic tissues in front of the patella are united with a few fine catgut stitches, the point being not to introduce any more sutures that are not readily absorbable than are absolutely necessary (Fig 2).

The cutaneous wound is closed with silkworm gut without drainage.

The whole procedure should not occupy more than fifteen minutes.

The advantages of the method are its simplicity and ease, the avoidance of prolonged manipulation and traumatism, which is unavoidable when the fragments are bored for sutures; the exertion of the lines of the restraining force in the most efficient direction; the absolute coaptation; use of absorbable sutures and its rapidity.

In regard to the last point, I think that it is generally conceded that with the present perfection of aseptic technic as regards instruments and gloves, infection occurs almost in direct proportion to the length of the operation and the consequent traumatism of the tissues.

(Left knee.)

(Right knee.)

Fig. 4.—T. B., male, age 19. Fracture left patella junction lower one-third and upper two-thirds. Tear later ligaments $\frac{3}{4}$ inch on each side. X-ray 2½ years after operation. Union and function perfect.

The after-treatment is the usual one. A molded plaster splint is put on, which is removed daily for massage after the fifteenth to the twentieth day.

In regard to the time for operation, I consider it is well to operate as soon as is convenient after the injury. I do not wait for the effusion to subside. In fact, I think it a distinct disadvantage to delay operation over four or five days, since after that time the tissues begin to heal in abnormal relationship, and the difficulty in properly coapting them is thereby increased. Also by then, the fibrous fringes become attached to the surfaces of the fracture and fresh hemorrhage is provoked in separating them.

RESULTS.

I have used this method exclusively for three years, and during that time have sutured by it twenty-two fractures of the patella, two of them being refractures. Of these cases two have been done so recently that the

result as regards bony union is still undetermined. In the remaining twenty, bony union was obtained. There have been no infections, the wounds healing in all *per primam*.

In regard to the restoration of function. Some have passed from observation before the motions of the knee were absolutely free, but in all the cases that I have been able to trace, three months after operation the motions of the knee have been perfect, with one exception to be mentioned later. In the earlier cases I was not so particular in instituting early massage, and some of these cases were left in splints for six weeks; consequently, the motions of the joint were limited for longer periods than would otherwise have been the case.

Two patients refractured their patella. One of these was a laborer, 39 years of age. The original fracture was by indirect violence, and was accompanied by considerable separation and tearing of the lateral patella ligaments. The fracture was a clean transverse break. Two months after the operation, while walking, he slipped on some ice and refractured it. He immediately reapplied for operation. At the operation the surfaces of the break were found to be as rough and sharp and bleeding as freely as when first fractured, and there was not the slightest evidence of fibrous union. Furthermore, there had been a considerable formation of new bone on the sides of the patella at the ends of the original line of fracture. Union had been bony, but the time elapsed (two months) since the first fracture had probably not been sufficient for the new bone to become as dense as it would have later. The second operation resulted in good union, but there was a great deal of thickening of the soft tissues and considerable stiffness remaining when the patient passed from observation some three months afterward.

The other case was a negress, 35 years of age. The original fracture was a transverse one, with tilting of the lower fragment, so that its fractured surface was directed forward. There was considerable separation. The result of the first operation was perfect as regards union and function. Seven months later she fell and refractured it. At the operation I was at first unable to determine whether the fracture was at the site of the original one or not, the surfaces were so sharp and rough. Finally, I noticed that the fractured margin of the articular cartilage was somewhat rounded, showing that the line of the second fracture coincided with that of the first. The result of the second operation was excellent. Figure 3 is from a radiograph taken thirty-five days after operation.

In these cases there was no evidence at the second operation of there having been any interference with the circulation in the fragments as a result of the original procedure. In fact, in one of them there was considerable proliferation of new bone at the sides of the patella at the points where the greatest stress from the sutures was exerted. In some of the cases in which there was comminution of the fragments there has been a marked production of new bone during the process of repair, thus adding considerably to the size of the patella. This is evident in the accompanying radiograph (Fig. 4).

In the preparation of this paper I endeavored to get radiographs of as many of the cases as possible. Although I heard from many of the cases I could only get six to come for radiographs. In all of these both knees were taken, and the comparisons of the patella were interesting, particularly in regard to the enlargement of the bone as a result of comminution.

DISCUSSION.

Dr. JOHN H. GIBBONS, Philadelphia—The improved technique added to our knowledge of the pathology of fractures of the patella have gradually increased the indications for operation on this condition. One supposed contraindication to operation is age, but the excellent result I recently obtained in a man over 60, operated on ten weeks after fracture, convinces me that age alone is no longer a contraindication. I showed this case at the Academy of Surgery recently and demonstrated a perfect restoration of function. There is one contraindication to which we should always give consideration, and that is alcoholism. Delirium tremens is a common and serious complication in fractures. The incision is an important point. The old straight incision should be relegated to the past and Dr. Blake's curved incision extending just below the line of fracture is much to be preferred to the straight one. With the straight incision you can not satisfactorily perform the operation as it is impossible to get at the lateral ligaments. I use a horseshoe-shaped incision for all operations on the patella and its bursae. The question of sutures should be referred to and I do not believe that wire is required for the satisfactory union of this fracture. I agree with Dr. Blake that the absorbable suture is the better. We will get practically as good results by suturing only the tendon as by suturing the bone. The avoidance of rough handling of the tissue is important, as traumatism of this character is more apt to result in infection than probably any other one thing. Early massage is an essential in the after-treatment. We are apt to keep the limb quiet too long. We can make the mistake, however, of giving massage and movements too early, as I did in one of my cases. The man was out of bed at the end of two weeks. The result was only some swelling and ultimately the limb was just as useful as in other cases. I want to lay stress on the fact that massage is an essential part of the after-treatment.

Dr. G. T. VAUGHAN, Washington, D. C.—The incision depends on the case. For recent cases I believe the horseshoe or transverse incision is better, but in old cases, with a good deal of separation of the fragments, the longitudinal incision is better. The transverse incision can be reinforced if necessary, but a long longitudinal incision is the better. This method of uniting the lateral ligaments has been usually done in fractures of the patella. I always unite the lateral ligaments when they are lacerated. I have seen cases where there was very little laceration of the ligaments, as in fractures from direct violence. As to the suture, at first I thought it was almost inexcusable to put silver wire into the knee cap, but I have had good results follow the use both of kangaroo tendon and catgut. I have also seen some bad results, but they were not my cases. Sometimes the animal suture gives way too early, and recently I have been using silver wire on this account. To get patients up early the fragments should be fastened together with silver wire, though, as a surgical principle and as a rule I do not approve of the non-absorbable suture. The old cases sometimes give trouble when there is a great deal of separation. I would like to know the best way to get the fragments together. I have used two methods, one of which was to split the tendon of the quadriceps down, cutting across on opposite sides above and below, and the other was to make an oblique cut across it and slide it down. Both of these have been followed by good results, and I have had no particular weakening of the quadriceps extensor. I have had 19 cases altogether of operation for fracture of the patella. In one of the earliest I used the old Barker method and got a fibrous union. Bony union resulted in all the other cases. I had one patient with a refracture of the patella, the fracture occurring at a different site, one-third of an inch above the original fracture.

Dr. C. O. THIENHAUS, Milwaukee—In April of this year I operated on a man who fractured his patella two years ago in South Africa. After having been confined in the hospital at Rhodesia and having been treated by conservative non-operative methods for nine weeks, he left the hospital with an apparatus without union. When I saw him the distance of the fragments was about 15 cm., his leg almost useless, the condi-

tion having grown worse within the last year, and he was unable to extend his leg when it was flexed. The difficulty of getting the fragments together in such cases is very often enormous and different methods of lengthening the rectus femoris muscle have been proposed. Some years ago von Bergmann advised chiseling off the tuberosity of the tibia with a wide chisel. Thereby the inferior fragment is made movable and later heals higher up. In many cases this method alone has proven sufficient to get the fragments together, but this was not possible in my case. I, therefore, combined this method with one of the methods of lengthening the rectus femoris, that is, by a Z-shaped incision through the muscle. After this I succeeded in getting the fragments together and wired them with three silver wires, one of which was removed four weeks after operation. The result has been satisfactory; bony union was obtained. He walked without the aid of a cane eight weeks after the operation. There is still some stiffness in the joint which must naturally be overcome by bending the knee gradually to avoid a refracture.

Dr. J. F. BINNIE, Kansas City, Mo.—I do not think bony union is of very much importance. Thoroughly good fibrous union between the fragments seems to give every bit as good functional results as is possible. I have never yet wired the patella simply because by following a method similar to Dr. Blake's and getting free exposure of the lateral ligament, I have gotten just as good results. There is no use bothering with wire. I would strongly advise, 1, early operation before there has been time for marked changes to take place in the tissue, and 2, thorough operation and suturing of the lateral ligament. I use catgut, either plain or very mildly chromicized. I very much dislike strongly chromicized catgut.

Dr. D. N. EISENDRATH, Chicago—I was obliged to resort to a similar method to that described by Dr. Blake about one year ago in a case of fracture of the patella. The operation was performed twenty-four hours after the injury, and my original intention was to drill the upper and lower fragments respectively, and unite them by means of a kangaroo tendon. Unfortunately, just at the moment when most needed, the drill failed to act, and I was obliged to utilize simply the periosteum covering the anterior surface of the patella in order to get a basis of support for my sutures. I used one kangaroo tendon over the center of the patella, inserted in a mattress fashion, and was very careful to turn outward the edges of the periosteum at the line of fracture believing that this turning in of the periosteum, thus separating the bony edges, will often prevent good union. I fully indorse the point made by Dr. Blake as to the necessity of inserting sutures through the aponeurosis of the quadriceps lateral to the break in the patella, because the fracture of the patella is almost invariably accompanied by a more or less severe laceration of the aponeurosis. I agree that fractures of the patella should not be operated on unless the most aseptic conditions prevail. The early use of massage to overcome the atrophy of the quadriceps is of the greatest importance.

Dr. J. B. BULLITT, Louisville, Ky.—The phase of the subject presented by Dr. Blake has not had the wide recognition that it deserves, and it seems to me that we should change the nomenclature. Instead of sticking to "fracture of the patella" we should say "rupture of the lateral ligaments" of the patella. The attention of the surgeon has always been directed rather to the broken bone than to the ruptured ligaments. We should keep our attention confined to the latter. Dr. Binnie says that he does not give any attention to the fracture of the patella, and he is about right. It has been demonstrated that the patella is not essential and that a perfectly strong joint can be had without it. The separation of the fragments with non-union and the resulting disability has oftentimes led to the impression that it was the non-union which led to the disability, whereas it was simply the lengthening that caused the trouble. I am glad to report that success in this operation has no geographical limitations south of Mason and Dixon's line just as north of it. I have operated on three patellae in two cases and have obtained quite satisfactory results. As to the time elapsing before operation, Dr. Blake says that four or

five days is all that is necessary, and that further time is really a disadvantage; but this is not in accord with the teaching of some of our best surgeons. Some of them have told me that it is much safer to let the cases go ten or twelve days before operation. Probably the danger of infection is less by waiting and the injured tissues are in better shape to take care of themselves. The delicacy of the technic of the operator will necessarily bear some relationship to the time at which he might operate. If a man knows exactly how to manipulate tissues he might venture to operate at an earlier time than a less skilled man. For most surgeons it would be better to wait longer. As to the necessity of keeping the fingers out of these wounds, this can not be too strongly dwelt on. Our chairman advised years ago that we keep our fingers out of wounds of this nature. Most of you are familiar with his work on this subject, and I am sure we should all like to hear from him.

DR. C. H. LEMON, Milwaukee, Wis.—The increasing speed at which street railways are operated is increasing the number of these cases. The operation described by Dr. Blake requires little or no handling of the tissues, which is one of the most important features in an attempt at operation in these cases. I say "attempt" because I wish to raise my voice in warning, by calling your attention to the fact that many of the cases operated on have not had the excellent results reported by Dr. Blake. Occasionally a man riding on a car will lose his hat and jump off before the car stops. We had such a case in Milwaukee where the man fractured both patella. I do not believe the man lives who should attempt to operate on both patella at the same time. I have in mind just such a case and as both suppurated the man's condition was pitiable. The advantage of the operation in young men is that it shortens the disability. If a fracture of the patella is treated by the old plan it will take six months, but if an operation is done as described by Dr. Blake he may go back to work in eight weeks.

DR. CHARLES A. POWERS, Denver—Some years ago I made a report to the American Surgical Association on the question of operation in recent fractures of the patella. I approached the subject with a decided opinion that operation was unwise, but after thorough study I was convinced that it has a very legitimate place in surgery. Where there is no contraindication operation is not only permissible but advisable. Dr. Blake's paper adduces splendid results and I am impressed by his method of local suture. We all endorse Dr. Lemon when he says that the operation of suturing a broken patella demands perfection in aseptic technic.

DR. JOSEPH A. BLAKE—I purposely did not include the treatment of old fractures in my paper and consequently did not mention the cases I have treated. The method I have used is not new, since the treatment of these cases by suture of the lateral ligaments has been done for some time, although the chief reliance has been placed on the sutures in the capsule in front of the patella. My only possible claim for originality exists in my contention that suture of the lateral ligaments is alone sufficient, and in the method of introduction of the sutures. The sutures must be introduced very closely to the sides of the fragments in order to hold them firmly and prevent them from moving laterally on each other. The sutures should actually grasp the bone, as shown in the drawings. As to the suture material, its nature is largely a matter of preference. I have always made sure that it was sterile and then have felt safe. In most of my work on fractures in the neighborhood of joints I use a very mildly chromicized catgut. I prefer the chromicized to the plain, as the plain catgut soon becomes soft and its surface slimy. The chromicized gut does not become slimy and does not untie. In order to make a plain catgut suture knot hold we must put a large amount of foreign material into the wound by having to tie it many times. In chromicized gut this is not the case. If the gut is chromicized too much we then introduce a substance which is worse than silver wire, because we not only have a non-absorbable material, but we have in addition a chemical irritant. As to the time for operation when I have operated about a week after the injury, in many cases I have

found that attempts at repair had already taken place, and I have had to cut away granulation tissue extensively in order to oppose fresh surfaces. I now operate as soon as possible after the case comes into the hospital. I like to have twenty-four hours' preparation, and as a number of these cases do not apply until twenty-four hours after the injury, two days usually intervene between the accident and the operation. It is better to operate early than late, although I have not observed any great difference in the results except that repair is more rapid in early operations. In the suturing of an old fracture, of any bone, the repair is not nearly so rapid as it is after a fresh fracture. Union is often delayed for double the period in old fractures as compared with fresh ones.

THE ETIOLOGY OF HAY FEVER.

THE RELATION OF THE CHEMISTRY OF THE SALIVA AND THE NASAL SECRETIONS TO DISEASES OF THE MUCOUS MEMBRANE OF THE MOUTH AND UPPER RESPIRATORY TRACT.*

D. BRADEN KYLE, M.D.

PHILADELPHIA.

While this paper has special reference to the etiology of hay fever, it is necessary to go into the chemistry and pathology of the saliva and nasal secretions before taking up the special subject. In doing this, I take the liberty of quoting from my previous papers on the subject.

In the chemie study of the nasal and salivary secretions we may conveniently classify them under three varieties: First, secretions, non-irritating *per se*, which on exposure (when coming to the surface) undergo some chemie change producing an irritant; this may be noted in either an acid or alkaline secretion. As I will show later, an exceedingly alkaline secretion is decidedly more irritating and productive of a more destructive pathologic process than even a strongly acid secretion. Second, secretions which are irritating *per se* when poured out on the surface. Third, secretions which come to the surface in a non-irritating form, but on coming in contact with extraneous material are rendered irritant.

Two great principles which have been satisfactorily demonstrated are these: In highly alkaline conditions there is an exaggerated oxidation process and the chemie change takes place in the secretion after it is poured out. This is of the greatest importance in nasal, laryngeal and pharyngeal lesions, and is also of immense significance in pathologic changes in the gums and about the teeth, as highly alkaline secretions will cause external irritation more quickly than an acid secretion. In highly acid conditions the oxidation process is incomplete, hence there is a greater tendency to precipitation of material within the tissue, with the necessary pathologic alteration—an infiltration process.

Michaels¹ of Paris was the first, I believe, to call attention to this subject, not in medicine, but in relation to dentistry. Kirk of Philadelphia has also taken up the investigation.

For the chemical formulæ employed in the laboratory investigations reference may be made to Michaels' article, as they are practically the same as my own.

Naturally it was necessary to investigate the histochemistry of a normal secretion, concerning which subject the literature is very meager, before taking up its pathologic or chemie changes. The saliva is the mixed

* Read at the Fifth-fifth Annual Session of the American Medical Association, In the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barzihill.
1. International Dental Congress, Aug. 9, 1900.

secretion of the parotid, submaxillary and sublingual glands, and the small mucous glands of the mouth. Physiologically, three kinds of secretion may be distinguished—a serous, from the parotid gland; a mucous, from the mucous glands, and a mixed secretion, from the submaxillary and sublingual glands. Mixed saliva is opalescent, tasteless, generally alkaline, and has a specific gravity of 1,004 to 1,009. Saliva contains serum albumin, globulin, mucin, urea, an amylolytic ferment called ptyalin, and a proteolytic and lipolytic ferment; also salts, the most important of which are ammonium, sodium and potassium and the sulphocyanid combinations derived especially from the parotid gland. The nasal secretion is practically the same as the salivary.

The ammonium salts and sulphocyanids in healthy saliva are in equal proportion and in very small quantities; in the hypoacid condition the ammonium salt exists in greater quantities than the sulphocyanid, and tends to rapid decomposition, and changes quickly when poured out on the surface. In the hyperacid condition the sulphocyanid is in excess, although it may be present in the hypoacid conditions, and the tendency to decomposition is not so great as in the hypoacid condition until exposed to moisture or air, and the chemic action has caused alteration of the compound.

In hyperacid conditions the sulphocyanids are in greater proportion than the ammonium salts, and the secretion is less irritating, while in the hypoacid state the ammonium salts are in excess of the sulphocyanids and the secretion is decidedly irritating, and in many cases in which I have been able to examine the secretions, especially of hay fever patients, this hypoacid condition has existed.

My studies of the saliva have been very much in the same chemic line as Michaels'. First, the study of the normal healthy saliva; second, the saliva from hypoacid individuals; third, the hyperacid condition. To this I have added the neutral or irregular cases, which are neither normal, hyperacid, nor hypoacid.

From my investigations, I found that the reaction of the salivary and nasal secretions as given by the ordinary litmus test was often faulty and misleading, that owing to chemic changes which had taken place after the secretion is poured out on the surface of the membrane the reaction of the secretion changed. This was of the greatest importance from the standpoint of treatment, as the reaction might show precisely the opposite of what existed in the secretion as it came from the gland proper. This has been verified by Kirk of Philadelphia, who has shown by his investigations that the neutral sodium phosphate is frequently present. This may be the cause of much confusion in testing the chemic reaction. This is especially true in the hypoacid conditions. Kirk also agrees with Michaels that the polariscope is of the greatest value, and a direct aid in the chemic study of these secretions. He has also shown, to quote his own words, that

The neutral sodium phosphate occurring so abundantly in the hypoacid conditions has been put down in earlier works as ammonium chlorid. The appearance of the two compounds is very similar until a special study has been made of them. However, the so-called neutral sodium phosphate is really alkaline, and the alkalinity of the normal saliva may be measured in terms of sodium phosphate, with sodium carbonate and bicarbonate. Both are found in normal and hypoacid saliva, but in different amounts.

When we came to the hyperacid individual we had an entirely different aspect. Here we had an individual producing large quantities of CO₂, more rapidly than it can be eliminated,

the excess being dammed up in the plasma of the blood, existing as H₂CO₃. The normal reaction by which this over-acidity is taken care of by the renal epithelium is H₂CO₃+HNa₂PO₄=H₂NaPO₄+HNaCO₃, but when the conditions are such as to produce larger quantities of carbonic acid than the kidneys can eliminate as sodium acid phosphate, other epiblastic structures take on the same action and there is a higher acidity of the saliva as well as the urine. A curious chemic feature of this matter is that the acid sodium phosphate and the neutral sodium phosphate might exist in the same solution without neutralizing each other, giving a solution that would turn blue litmus paper red and red litmus paper blue, the so-called amphoteric reaction.

The appearance of the lactophosphate of calcium in the saliva and urine indicates certain diseases of the liver. Dr. Kirk has been led to this conclusion from reading the researches of Minkowski, who found, in a series of experiments on geese, where he had removed the liver, that they then excreted, instead of uric acid and the urates, the ammonium lactate, and he deduced from these experiments that one of the functions of the liver was to convert ammonium lactate into urates, as the appearance of lactates in excessive amounts in the excretions, especially the urine, is indicative of a disordered liver function.

The condition of neutral, hypoacid and hyperacid conditions can best be illustrated by cases. The excessively alkaline condition is observed more frequently in hay fever, although either one of the three, the hypoacid, the hyperacid or the neutral condition may exist.

STRONGLY ALKALINE CONDITIONS.

The following case illustrates this condition:

Dr. B., who had been suffering from an irritating, rasping cough since September, 1902, was referred to me in January for an examination of his throat. The symptoms presented were principally the cough, with hyperemic and irritated mucous membranes, though the congestion and swelling were not in proportion to the severity of the cough. The cough was persistently spasmodic, almost resembling paroxysms of whooping-cough, except more often repeated. There was decided hoarseness and congestion of the vocal cords. The chest examination was negative, with the exception of slight bronchial rales. Here and there on the mucous membrane were small hemorrhagic spots, which I believe had been produced by the violent irritation caused by the spasmodic cough.

Examination of Saliva.—The saliva was found to be hypoacid, the ammonium salts being in excess, and when the secretion came to the surface there was liberated free ammonia gas, which was in sufficient quantity to produce the irritation.

Treatment.—On this basis the treatment was administered, all the organs of elimination were stimulated, and the chemistry of the secretion was changed to acid or neutral reaction, following which change the cough disappeared within a few days, the irritation rapidly subsided, and in ten days all inflammation had disappeared with the exception of some slight localized areas, which probably had been brought about by the persistent coughing, and these areas rapidly yielded to local treatment.

In so many cases in which the objective symptoms were in excess of that which the local lesion would justify, I have found that the irritation was brought about by some altered chemistry of the secretion, and that the local lesion was merely a manifestation and result of this alteration.

To review the chemistry, ammonium is a hypothetical alkaline base, having the composition of NH₃; it does occur in a free state, however, in the form of ammonia gas, NH₃, the inhalation of which is very irritating to the mucous membrane and causes suffocation and edema of the glottis. As the ammonium salts usu-

ally exist in combination with other materials, is it not likely, in certain conditions in which the secretions are hypoaoid, that when the secretion comes to the surface of the mucous membrane, owing to its chemie combination with oxygen, there is liberated NH_3 , the irritating ammonia gas? Surely the symptoms, identical with those produced by ammonia gas, in many cases justify this conclusion, and the chemie study of the secretions supports this view.

Many cases of hay fever illustrate this point, although in hay fever the nasal secretions may be either hypoaoid, hyperacid or neutral, or irregular.

ETIOLOGY.

The numerous theories as to the etiologic factor in this disease prove conclusively that as yet there has not been established a definite cause. It may be that different conditions act as etiologic factors; in fact, it is my belief that not all cases which we call hay fever, or hyperesthetic rhinitis, are due to any one cause; or, if to any one factor, that factor must be the altered chemistry of the secretions of the individual. In fact, I am persuaded, after making a series of examinations of the saliva in certain individuals afflicted with hay fever and those not so afflicted, that in some cases the causes, direct or indirect, of local irritation in the nasal mucous membrane are brought about by chemie change in the constituents of the secretions of the mucus-secreting glands. Treatment based on this view is certainly most effective. Sensitive areas within the nasal cavities, or irregularities in formation of the cavities themselves, are factors in some cases, yet such areas or irregularities, instead of being etiologic, are merely auxiliary factors, which render the individual more susceptible to the irritant from within.

It is a well-known fact that in many cases of hay fever the irritation is not limited to the nasal mucous membrane; the conjunctival, buccal, pharyngeal and laryngeal mucous membrane, and even that of the stomach and bladder, may be markedly involved. This could scarcely be explained on the basis of a reflex neurosis. In such cases the mucous membrane suddenly becomes engorged, and is exceedingly sensitive, with profuse, watery, irritating discharge. This comes on suddenly, often without any apparent external irritant, and at times looks very much as though there was an effort on the part of the mucous membrane to rid the system of material which had just reached a certain point of accumulation.

The question may be asked: Why does hay fever come on at certain times of the year? That climatic and atmospheric conditions produce changes in function and secretion, that certain diseases are prevalent at certain times of the year, and that under certain climatic and atmospheric changes individuals are more susceptible to disease, has long been observed. This may be due to some condition of the individual which renders him susceptible to disease, owing to lowered cell resistance and altered chemistry, since temperature and climatic changes do affect the chemistry of the secretions. As to the effect of pollen in certain cases, is it not possible that, owing to some peculiar constituent of the secretion of the mucous gland, there is deposited in or on the nasal mucous membrane certain materials which, when brought in contact with certain extraneous materials as pollen, through some chemie action produces a material which brings about the irritation and causes an attack of what is known as hay fever; or that the extraneous material merely acts as a stimulant to the mucous glands

and causes a flow of mucus, which, owing to its altered chemistry, acts as an irritant?

This is exemplified in the cases in which the ammonium salts bring on an attack identical with that produced by the rag-weed pollen. If the administration of the tincture of rag-weed produced immunization to hay fever, it must do it through the secretory function, and the chemistry of the secretions would be such as to contain no materials which, when coming in contact with the pollen of the plant, would produce any irritating substance. I have seen cases illustrating this point.

There is no question that the irritation is caused by some product of chemie action. The question involves organic chemistry, and any one familiar with the work recognizes the time and labor necessary to work out such chemie formulæ. I have, however, done sufficient laboratory work in the past eight years to convince me that on this basis we can relieve many cases of hay fever. That the chemistry of the secretions has to do with the causal factor, I have illustrated in a number of cases by rapidly changing the reaction of the secretion either from acid to alkaline or from alkaline to acid, or rendering it neutral, and in many instances I have been able, either partially or wholly, to cure the attack.

Certain individuals will have, at any time in the year, an attack which is quite similar to hay fever. The individual may be sitting comfortably at home, subject to no draughts or exposure whatever, when he is suddenly seized with congestion of the nostril, followed rapidly by the thin watery discharge of a decidedly irritating nature, free lachrimation, with burning and itching in the nasal cavities, eyes and nasopharynx. Frequently associated with this is a slightly asthmatic tendency. It can not be cold; it is something in the nasal secretion, and when the secretion comes to the surface and in contact with the air there is liberated some material (chemie) which acts as an irritant to the vasomotor system (peripheral terminal nerve filaments) and causes sudden congestion. Such attacks are quite like inhaling ammonia fumes, and in such cases there is present an excess of ammonium salts in the saliva. Owing to some chemie change in the secretions of the individual there is accumulated material within the system, which in the point of accumulation reaches that period in which it overflows, and the secreting glands liberate on the surface this material, which when exposed to the air undergoes a chemie change. In many instances, on examination of the saliva and the nasal secretions there has been found an excess of the sulphocyanids and the ammonium salts. When this secretion is exposed to the air, free ammonia is liberated, which I believe to be in many cases the cause of the attack. The symptoms produced are identical with those of the inhalation of ammonia fumes. When the secretion is exceedingly alkaline the patient will often have symptoms identical with those of articular rheumatism.

CASES IN WHICH THE SECRETIONS ARE HYPERACID.

The following case is an illustration:

Mr. C., aged 42, consulted me in regard to what he supposed to be a catarrhal condition, associated with ozena. His breath was most offensive, but, although pronouncedly so, it was not the penetrating, clinging odor observed in atrophic rhinitis with ozena. He had observed the condition rather suddenly, and it had existed continuously for some four or five years. His history was absolutely negative as to any catarrhal condition other than an occasional cold. He had consulted specialists both in this country and abroad, not only as to the possibility of the odor coming from the nose or some of the accessory cavities, but had also consulted specialists on dis-

eases of the stomach, as well as having had a thorough inspection of all his teeth. He had been told that he had practically no catarrh, and, as his digestion was good and nothing found wrong by analysis of the contents of the stomach, it was quite puzzling as to the source of this odor. After a thorough examination, and knowing that the men under whose care he had been were most thorough and competent in their line, I reasoned that there must be some source of the disagreeable odor outside of the parts already mentioned. As this was in the winter of 1895, and as my attention had been called to the importance of the secretions by other conditions, as well as a statement made to me by the patient, I decided to investigate the saliva. The statement which he made to me, which was most significant, was this: "That, while his appetite was very good, and when his olfactory nerve was stimulated by the odor of a delicious meal, causing his mouth to water, the disagreeable odor and taste became so pronounced as to almost nauseate him." I then collected some of the saliva. The method used for its collection I learned from my experience in a dentist's chair, that while sitting with your mouth wide open for a few minutes you have a most profuse flow of saliva. This method, practiced just before meal time, enabled the collection of quite a large amount of the secretion. The offensiveness of the secretion was at once detected.

CHEMISTRY OF THE SULPHOCYANIDS.

In order to explain the chemie source of the offensive odor it is necessary to take up the chemistry of the sulphocyanids. As to the sulphocyanids which are present in the saliva, it is a chemie fact that most of the cyanids are actively poisonous and that a cyanid is formed, or is a compound, of cyanogen with a metal or radical. A sulphocyanid is a salt in which sulphur takes the place of oxygen in the acid radical. Cyanogen is a radical molecule having the structure CN , an acid compound of carbon and nitrogen. A radical is a group of atoms having unsatisfied valency, an unsatisfied molecule which goes into or out of combination without change to itself and which determines the character of compounds. A sulphocyanid is a combination, then, denoting the chemie combination of sulphur with a radical. When a sulphocyanid is eliminated the secretion in which the ammonium salts are in excess is alkaline, but when it comes in contact with the air, owing to the chemie change which takes place, it becomes an acid radical. Hence in many instances in which from our test we believe the secretion to be acid, it is really hypoaoid (alkaline). This is most important, and in many instances in which from the test reaction we are led to conclude the reaction to be acid, it is in reality in the system an alkaline reaction, and only becomes acid when, owing to chemie action due to exposure to air, certain materials are eliminated and the reaction changed. In some of the sulphocyanid combinations in which we get the bad odor, as illustrated in the above case, the chemie change causing such odor is as follows: Sulphur itself is an acid element, which unites with oxygen to form an acid radical, but in a sulphosalt the sulphur takes the place of the oxygen in the acid radical. The sulphocyanid itself would be a sulphosalt in which, in combination, the sulphur would take the place of the oxygen and give off sulphuretted hydrogen. In a sulphosalt the sulphur takes the place of the oxygen in combination to form an acid. A sulphocyanid is a sulphosalt, and when the sulphocyanid is in excess, when liberated and coming in contact with the secretion which contains moisture (H_2O), the sulphur would unite with the hydrogen, giving off free oxygen, and form hydrogen sulphid. A radical is a group of atoms having an unsatisfied valency, and is really unsatisfied molecules which go into or out of combination. It is possible, then, to have in a hyper-

acid condition many chemie combinations take place. This chemie result surely verified the olfactory diagnosis in this case.

CASES NEITHER HYPOACID NOR HYPERACID.

That cell nutrition depends on the chemistry of its supply is illustrated in disease processes associated with any form of infection or rise of temperature. This opens up an enormous field for speculation and investigation. The amount of infection, the peculiar chemie change produced by temperature, the materials absorbed into the body from infective processes, or the auto-infection from the intestinal tract, would in each condition produce its own peculiar chemie compound. Yet I believe a general basis can be reached, at least sufficiently accurate, from which to draw chemie and clinical deductions.

For example of peculiar effect on various structures in the body brought about by an altered chemistry in which the secretions may be neutral or irregular, I will quote from an article which was published in *American Medicine*, Feb. 8, 1903, in which I reported a number of cases of enlargement of the thyroid gland in which the cellular elements of the thyroid structure were increased, the enlargement not being due to distended vessels, cystic condition of the gland, or new growth.

I reasoned the matter out as follows: It is a well-known physiologic and therapeutic fact that certain drugs have a selective action on certain tissues or organs of the body, e. g., belladonna, with its selective action on the pharyngeal surface; sodium phosphate, with its selective action on the liver, etc. It is also a physiologic fact that the normal chemistry of the body controls the normal secretions from the various secretory organs, that any perversion from the normal necessarily alters the character and chemistry of the secretion, and that the products of such alteration act as irritants to certain parts of the body; the difference between this and drugs administered is that one is introduced into the body and one is manufactured within the body. I, therefore, reasoned that under certain conditions there is precipitated—due to perverted chemie reaction—a certain material which, circulating through the blood, had a selective action on certain tissues; in the cases observed such selective action occurred in the thyroid gland, acting as an irritant to that gland. While the treatment of these cases reported was somewhat theoretical, I believe, however, that the drug introduced into the body, by its chemie action, altered the chemistry of the material which was acting as an irritant, either rendering that irritating material inert or forming a compound which was non-irritating.

In regard to the pathologic chemie process producing such reactions of the secretion, it is a well-known clinical and laboratory fact that a study of the products of the secreting organs, which in their excretory functions throw off waste material, gives us by deduction a fair idea of what process is going on within the body. Yet this excretory secretion or material is altered in its chemie composition and controlled by the chemie constituents within the body proper.

There is no question that under certain conditions—for example, when the secretions are acid or alkaline—the chemie process taking place within the various secretory glands must vary, and the product of such variation in these unknown quantities must be somewhat the same as the variations we would obtain in dealing in the laboratory with known compounds. In other words, that the body is largely a chemie laboratory, having on hand

a certain amount of material and having added to it daily ingredients through the respiratory and alimentary tract. Now, any perverted condition from what is known as the normal chemistry may bring about a series of changes and produce chemie products which may be harmless or productive of disease processes. On no other basis can we explain the various diatheses and the precipitation of certain materials in the tissues of the body.

The altered chemistry of the saliva presents many possibilities from an etiologic standpoint. Many forms of lesions of the mucous membrane of the nose, nasopharynx, larynx, mouth and gums, as well as diseases of the stomach and intestines, may be brought about by the altered chemistry of the saliva. A great many morbid processes are traced to uric acid in some of its many forms, but I believe that many other substances, especially hyperacid conditions, equally important are deposited and eliminated, which substances act as irritants, producing apparent local lesions. It is a well-known clinical fact that saliva from certain individuals is exceedingly poisonous, as is indicated by the infectious wounds produced by the bite of such individuals, showing that the saliva may be the site of poisonous pathologic, as well as physiologic, compounds. This is especially true in the sulphocyanid cases.

Unquestionably the chemie reaction of the secretions of the body is an important factor in the susceptibility of individuals to disease. I think there is no doubt that the fact that at one time the individual resists disease and at another time succumbs can be largely explained on this basis. To be sure, it is a question of resistance on the part of the individual, but that resistance is largely controlled by the chemistry of the cell or secretion. It also demonstrates the fact of the accumulative phenomena of certain of the diseases, as is illustrated in uric acid diathesis, which Haig has described as the uric acid storm. There is no reason why these same phenomena could not occur as the result of the accumulation of other materials brought about by chemie changes which lessen oxidation and tend to precipitation and accumulation of various morbid products.

The administration of drugs for the relief of, for example, an infective process, probably affects such a process beneficially, owing to the fact that in its action it changes the chemistry of the secretions and blood constituents, thereby producing a chemie compound which either prevents the formation of infectious material or alters the nidus of infection to such an extent that it is not suitable for the growth of bacteria.

While my investigations are incomplete and fragmentary, I am convinced that from the study of the saliva we can determine to a great extent any variation in the chemistry of the body. As these various secreting glands receive from the blood the supply from which they elaborate certain chemie compounds, if an analysis were made of the composition of such secretions it would give a good index to the general condition of the individual, and while in many cases the deductions would have to be based on or associated with clinical observation, I have found them to be of immense value from a standpoint of diagnosis.

The fact that the reaction of the secretion may be apparently acid when there really is present an alkaline condition, explains to us many of the cases in which, from an acid basis, our treatment has failed. That such a condition may exist has been shown by Douin and Gautrelet in their studies of the blood; that the reaction of the plasma is really acid, and if waste prod-

ucts are not eliminated this acidity is increased. The secretions and excretions then also become of an acid reaction.

The irritating gases which form in the stomach and intestines and produce laryngeal and pharyngeal irritation, are the result of chemie changes in the intestinal secretion, and such chemie change in the secretion can be demonstrated by a study of the saliva. That auto-infections and chemie changes in intestinal secretions have a marked general effect on the individual is well known. Such material absorbed into the system will unquestionably alter the chemistry of all secreting glands, and the compounds formed by such alteration which affect the individual can only be determined by the study of organic chemistry. The asthmatic conditions which are not associated with any organic lesion, I believe can all be explained on this basis, and when treated accordingly can, in many instances, be relieved.

In examining the secretion and excretion of the body, we can obtain as good an index of the systemic condition of the individual by a study of the saliva as by a study of the urine; in the urine we have only an index of the waste material, while in the saliva we have products of elimination which return into the body to perform a physiologic process.

Another important factor to be worked out is the different chemie changes which take place in individuals suffering with so-called functional diseases and those suffering from organic or structural changes. In the functional we have a perverted chemistry, which may be brought about by many causes, such as faulty elimination, from the kidneys or liver, and perversion of secretion from the intestinal tract, autoinfection from the intestinal tract; also chemie changes of the secretion illustrated in mental tension from fright, worry and anger; while in the organic lesions we have to deal with a structural change in tissues, with retrograde metabolic changes, in which there is also associated inflammatory processes with their accompanying phenomena and physiologic and pathologic effect on the individual.

EFFECT OF CLIMATE AND ALTITUDE.

The effect of climate and altitude on hay-fever individuals is interesting from a number of standpoints. If the disease is distinctly a neurosis, why should the patient, as a rule, improve in a high, dry altitude, when such altitudes are decidedly irritating to a nervous individual? Why is it that an individual, after having hay fever for several years, will miss one season, or even two, having no treatment whatever? Personally, I think the answer lies in the individual, at least in a majority of cases, and that the secretions of such individuals having changed under certain conditions were non-irritating. The famous case of Mackenzie's, in which the artificial rose produced an attack of hay fever, surely is strong evidence in the line of neurotic origin. At the same time, in a nervous individual with a perverted nutrition and necessarily perverted secretion, any particle of dust or anything whatever that would stimulate the nasal mucous membrane would promote the flow of secretion, which secretion being decidedly irritating, would at once bring on an attack.

INDIVIDUAL VARIATIONS IN SUSCEPTIBILITY.

Another interesting fact is this: That in the cases which I have watched closely for the past eight years, the hay fever was no respecter of persons as to weight; that some individuals who were stout had the worst form of hay fever, while others who were very thin had equally bad attacks.

I also noticed that in a number of such individuals, when the secretions were changed and irritation ceased in some of the stout cases, they lost flesh rapidly, one patient losing as much as 40 pounds, while the thinner individuals improved in weight. This led to a comparison of the chemie examination of the various individuals. The very thin individuals in 90 per cent of cases had an excess of sulphocyanids which, of course, was acting as an autotoxic infection, while in the excessively stout individuals the reaction of the secretion varied, usually neutral or acid, which, of course, predisposes or causes lessened oxidation and increase of fatty tissues. Also that in individuals with an excess of the sulphocyanids, the individual always has the appearance of an autotoxic infection, deranged digestion and intestinal tract, and with the relief of this condition always shows rapid improvement.

Is it not possible that certain pollens coming in contact with the nasal mucosa, thereby acting as stimulants, promote the flow of secretion, and when such secretion is poured out on the surface either, as I have stated before, as an irritating secretion or when combined with the pollen, a chemie change takes place and an irritating material is produced? Dunbar's inoculation theory surely proves this statement, and agrees exactly with what I have said as to the secretions. Under this class of cases would come the rose cold, the ragweed, the horse fever, hay fever, rye fever, etc. Think of the difficulty of procuring an antitoxin for horse fever! In all such cases I think that the secretion is the predisposing and the extraneous material or pollen is an associated factor.

As is shown by Dunbar, the inoculation method is not successful in all cases, which is easily understood, as the chemistry of the secretions in the various individuals are markedly different; so that instead of an antitoxin for exciting factor, use preventive measures by altering the secretion. My own experience surely justifies this statement. Unquestionably, certain individuals, owing to the low grade of their vitality and neurotic temperament, are more likely to be subjects of this disease than persons of healthy type; nevertheless, many individuals of most perfect physical condition are the worst sufferers from this peculiar and annoying disease, and while I do not wish to be understood or quoted as saying that all cases of hay fever can be cured on this basis, my own experience does show that between 80 per cent. and 90 per cent. of the cases can be relieved and cured. When I say cured, I mean in the same sense as you would speak of curing a cold, and most certainly if the condition of the secretion changes and the irritating material returns, if the individual is exposed to the same irritants, he most certainly would have another attack.

1517 Walnut Street.

DISCUSSION.

DR. E. C. KIRK, Philadelphia—My interest in this matter originated with a paper read by Dr. Michaels in Paris in 1900; subsequently I spent some time with him in his laboratory and went over the subject in detail. I have been studying the changes in the saliva since that period, and have become convinced of the importance of the generalizations made by Michaels that the chemical composition varies quite constantly with certain pathologic states, especially in relation to faulty metabolism. My own studies have been largely confined to the pathologic conditions of the soft tissues of the oral cavity, especially of the retentive tissues of the teeth. The method of study suggested by Michaels, the use of the micro-polariscope, first made it possible to accurately know the

chemistry of the saliva; it gives a means of analysis which is extremely delicate and is as accurate in qualitative test as the gravimetric method could be. With the use of the polariscope we can detect the salts by polarized light. It is quite true that a study of this subject tends to confirm the general views entertained regarding the etiology of gout and other similar conditions. We have in the arthritic subject a condition of insufficient oxidation with large quantities of carbon dioxide dammed up in the blood plasma. It is part of the function of the kidney epithelium to return sodium bicarbonate to the blood and eliminate the acid phosphates through the urine as a result of the mass action of carbonic acid on the basic phosphates of the blood plasma. When the condition becomes excessive and chronic, it causes the loss of enormous quantities of phosphorus resulting in phosphorus starvation, and during that period other waste products, irritative in character, manifest their presence. Prominent among these is oxalic acid. Oxaluria generally means a state expressed in the terms of calcium oxalate. Enormous quantities of sodium oxalate, however, make their presence felt about the time phosphatic starvation supervenes. The patients then become neurasthenic, and in that connection also we have certain local phenomena. I have watched the development of leucoplasmia in the mouth and its subsequent degeneration into epithelioma. I am of the belief that there is a definite relation between the irritation which these waste products produce and the conditions of the nasopharynx described by Dr. Kyle. I regard them as productive of direct irritation to the mucous surfaces, and that they may even stimulate the tissues to the formation of new growths.

DR. JUDSON DALAND, Philadelphia—A proper appreciation of the chemical causes of this affection indicates a plan of treatment which has given brilliant results. It is not at all improbable that certain spasmodic bronchial affections that are usually considered under the name of asthma may have a like cause and a study of the disease from this standpoint may yield similar therapeutic results. The profession has been gradually recognizing the importance of hyperacid conditions of the upper respiratory tract and mouth, but Dr. Kyle is to be complimented on drawing attention to direct poisonous inflammation of sulpho-cyanids and of the marked local irritating effects of hyperacid conditions which are frequently in association with ammonia compounds, and, at times, free ammonia. These observations are of importance to the general practitioner because of their prejudicial influence on the general health, and there can be little doubt that certain cases of general toxemia are due to this cause. On the other hand, I am inclined to believe there are certain cases of toxemia of intestinal origin, usually fecal, that play an etiologic rôle in the production of the morbid chemical state of the nasal secretions and saliva. If we remember that within a very few minutes after the taking of lithium, it can be discovered spectroscopically in the saliva, and that normally within eight minutes after the swallowing of a solution of iodid, iodin can be detected in this same secretion, we realize how rapidly is the diffusion of these soluble substances and how promptly the salivary glands excrete these substances which here have the peculiarity of again being swallowed to again be absorbed into the circulation. I shall in the future give especial attention to the chemistry of the saliva and nasal secretions, more especially in well-marked examples of auto-intoxication, nervous asthma, hay fever and neurasthenia.

DR. E. FLETCHER INGALS, Chicago—The paper recalls to my mind the remark of the professor of medicine when I was a student, who, when asked what he would do for a certain disease, replied that it would depend entirely on what was the matter. It is encouraging to find some men searching among the living for the causation of disease. Pathologists deal with the dead, and hence become therapeutic agnostics. In the past nearly all medicinal treatment has been empirical, but the kind of experimentation outlined in this paper is destined to do much to enable us to know for what reason we are giving our remedies. It is certainly unwise to continue to give medicines, the action of which we can not satisfactorily explain. The pathologic side of disease is of great importance, but we

should bear in mind the fact that over 90 per cent. of the physician's work is therapeutic in character, and that nine out of every ten sick people get well. Our aim should be to try to cure them more quickly, and it seems to me that the greatest work before the profession in the coming years is along the line of therapeutic research. In our hospitals we find bright, energetic internes, but quickly discover that they have little knowledge of therapeutics. In the large hospitals with which I am familiar nothing whatever has been gained in the way of therapeutics for the past twenty-five years. It is difficult for the older members of the profession to do research work, and the younger men have not been encouraged to undertake it in this line.

DR. W. H. F. FITZGERALD, Hartford, Conn.—I believe the position taken is correct that these conditions are due to irritative changes, basing my opinion on the history of twenty-four cases I have worked at myself during the past two years. There can be no question about the irritative effect on the lining membrane of the nose, and it really makes little difference where this area is located. In my opinion, it is due entirely to the fact that the individual in question does not use his nose. As a class, we do not know how to breathe, and just so long as we go on breathing through the mouth we are bound to have these irritated areas.

A man may go to a certain district and the irritating pollen or organism attacks a particular irritated area of the mucous membrane of the nose and produces the condition of hay fever. Of these twenty-four cases treated, I have had but one case return; I have heard from all of them, and they have stated that they have had no recurrence. This is due largely to the fact that they are now breathing as they never did before. I see that they breathe properly at night, for I plaster their mouths up during the night and make them exercise the nose during the day. In the treatment of these cases I have employed no therapeutic measures at all after obliterating the irritable areas. One of the worse cases I ever saw was that of a minister who was prostrated two or three days out of every week, and at one time for nine months continuously. He then lived in the west, and for the past three years has been living in the east, and his trouble was as great in one locality as in the other. I found he was a very bad breather, and I have succeeded in making a good breather out of him. He recovered entirely, and even went back to his former residence looking for trouble, but failed to find it.

Another case was that of a woman who used from forty to sixty handkerchiefs a day during a period of thirteen years. The condition was complicated during the thirteenth year with attacks of asthma which kept her awake most of the night. I removed obstructions, irritable areas, etc., and discharged her over a year ago. She has since been averaging not more than one handkerchief a day, and says that she has had but one slight attack of asthma in the course of the year. She states that she often had the feeling that if she took one breath through her mouth she would have another attack, and that under these circumstances she often resorted to the plaster during the day. Since she has become a normal breather this has not been necessary.

DR. W. S. ANDERSON, Detroit—Has Dr. Kyle made any study of the secretions of the pharynx in mycosis leptothrica? It runs a very stubborn course and occurs usually in healthy persons.

DR. J. HOLINGER, Chicago—There is a series of experiments which have a bearing on this subject of the chemical composition of the saliva and all the juices of the digestive tract with reference to the food taken. In experiments with dogs, it has been found that if a certain character of food is offered to the dog the saliva has characteristic changes, going very far in the direction spoken of. How can this series of experiments be brought into connection with the paper?

DR. G. V. WOOLEN, Indianapolis—I have examined the statistics relating to the surgical treatment of these cases and have not been satisfied that they offered a definite solution of the problem. When Sajous' book came out, dealing with peculiar idiosyncrasies, external irritation, and diseased noses,

we thought we had the solution in a definite form, but the idiosyncrasy suggested did not wholly satisfy me because this condition of the system is present at all times of the year. I then began, not chemically but clinically, to gather and observe these secretions. I have carried this investigation to an extreme degree ever since and am convinced that the secretions do not offer a solution of the whole matter. I also felt that if I could control the acid condition of the system I should have the key to the whole matter, but that was a disappointment. I am disappointed to-day. There has been a great deal said with reference to the mouth and pharynx, but these do not explain the conditions in the nose. As Dr. Ingals has intimated, the discussion is in the right direction and younger men will perhaps work out the problem along the chemical line.

DR. D. B. KYLE—Many of the points which have arisen in the discussion will be found answered in the remainder of the paper, all of which was not read on account of its length. I omitted to say that the chemical reaction of the saliva is so nearly the same as that of the nasal secretion that I did not use the terms nasal and salivary each time. In some cases, if tested at the same time, one will give an acid reaction and the other alkaline, but if the chemical composition is studied they will be found not to differ, the chemical reaction having changed after exposure to moisture and air.

As to mycosis, if it is a genuine case of mycosis and not keratosis, it is a well-known fact that bacteria grow better in alkaline media than in acid. I have made a careful examination in a few cases of pharyngeal mycosis and the secretion was alkaline in reaction.

POISONING BY WOOD ALCOHOL.

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS.*

CASEY A. WOOD, M.D.

CHICAGO.

AND

FRANK BULLER, M.D.

MONTREAL.

With the kind assistance of the profession in the United States and Canada, we have been able to report the following instances of methyl alcohol intoxication, most of them hitherto unpublished.

The list of deaths and cases of blindness following the ingestion of "Columbian spirits" and other forms of wood alcohol, as well as methylated "Jamaica ginger," lemon "extract," "bay rum," "cologne water," "witch hazel," essence of peppermint, essence of lemon, etc., not to mention all sorts and kinds of other official, domestic and proprietary remedies into which alcohol enters, has lately grown to alarming proportions. This record of death and blindness has been made in recent years only, since the cheap, "deodorized" methyl alcohol [untaxed, retail price 50 cents a gallon; ethyl alcohol, taxed, retail price \$2.60 a gallon] has been put on the market.

Wood alcohol and methylated spirits made by the old processes subserved useful as well as harmless purposes. They possessed practically all the solvent and other properties required for the various arts in which they were employed, and no one thought of drinking them or employing them as adulterants in foods or drugs. Indeed, so abhorrent to the organs of taste and smell was even a small percentage of wood spirit in any mixture, that no person in his senses would drink so noxious a compound, however diluted and disguised, or however much he craved an alcoholic drink.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

With the advent of preparations like "Columbian spirits," "colonial spirits," "eagle spirits," *et hoc genus omne*, the principal safeguard against poisoning by methyl alcohol has been removed. Some of these deodorized alcohols are with much difficulty distinguished by the laity from pure ethyl alcohol. Hence it is that in spite of ordinary precautions, such as labeling bottles of these preparations "not to be taken internally," they have been and are now, through accident and design, much used as substitutes for grain alcohol.

The appended histories by no means constitute a complete list of deaths and blindness from wood alcohol poisoning. A more careful canvass will, we are sure, bring to light numerous additional instances of this intoxication that we have not been able to gather during the limited time at our disposal. The remarks of Dr. Moulton properly apply to many localities where grain alcohol beverages are difficult to procure:

Cases (of wood alcohol poisoning) are of frequent occurrence in Indian Territory, where the sale of ethyl alcohol is strictly prohibited by the United States government, so that those who crave stimulants drink anything they can get. I can safely say that in that country at least fifty deaths have occurred from this cause in the last few years.

The same remarks apply, though in a less degree, to methyl alcohol blindness. A circular letter on this subject was addressed by Dr. Wood to a large majority of the ophthalmic surgeons in the United States and Canada, and there is good reason to believe that, as a result of these inquiries, descriptions more or less complete of most of the well-defined and recent cases of wood alcohol amblyopia and amaurosis will be found in this report. At the same time, since blindness from methylated liquids was practically unknown until the recent introduction of this "purified" product, medical men may well be excused for not recognizing, for attributing to other causes or for afterward forgetting cases that several years ago came under their notice.

For purposes of subsequent reference we have divided these histories into four classes:

Class A.—Published cases of blindness or blindness followed by death, due to the drinking or inhalation of methyl alcohol. The cases comprised in Class A were collected, abstracted and tabulated by Dr. Buller.

Class B.—Cases (hitherto unpublished) of blindness or blindness followed by death from drinking methylated liquids.

Class C.—Cases (hitherto unpublished) of blindness from methyl alcohol absorbed through the lungs or skin, or both.

Class D.—Cases (hitherto unpublished) of death from methyl alcohol poisoning, without history of previous blindness.

The cases detailed under Classes B, C and D have been collected and edited by Dr. Wood. The sources of the information in the last three classes, arranged in alphabetical order, will be found at the head of each history.

SUMMARY OF PUBLISHED CASES.

The tabulated records (to appear later in this article) of 54 of the published cases show the ages of individuals to be from 21 to 65 years; mostly about middle life. Of 51 we note: Sex, males, 47; females, 4. Habits of life; 8 were, or had been, hard drinkers; 9 admitted occasional indulgence, 3 habitually temperate, 30 habits not stated, but no doubt most of them were more or less addicted to alcoholism. Six are reported

to have used tobacco in excess, as well as alcohol. Occupations: Artistic painter, 1; attendant, 1; bricklayer, 1; barber, 1; carpenter, 2; china decorator, 1; convicts, 3; dressmaker, 1; farmer, 2; housewife, 2; hotel keeper, 1; miner, 1; millhand, 1; workmen, 4; mechanic, 1; soldier, 1; sailor, 3; woodsman, 1; watchmaker, 1; upholsterer, 1; not stated, 20.

As to the mode of occurrence: In most instances the trouble occurred as a result of a spree, generally together with friends or associates; in a few instances the alcohol was taken by accident. The preparations nearly all undoubtedly contained the drug, methyl alcohol, as the sole or chief toxic ingredient. In 28 cases methyl alcohol was specified; in 12 Jamaica ginger; in 4 Columbian spirits; in 2 essence of lemon or cinnamon; in 1 cologne spirits, so-called; in 1 an unknown alcoholic mixture; in 3 methyl alcohol vapor was inhaled.

As to the quantities consumed: The methyl alcohol series varied from half an ounce to 16 ounces. The Jamaica ginger from 3 ounces to 25 ounces, the larger quantities usually in divided doses over a period of several days. Columbian spirits from 6 ounces to 8 ounces and in 2 cases quantity unknown. Essence of lemon, 3 or 6 ounces in one case, in the other quantity unknown. Cologne spirits less than 8 ounces. Of the unknown strong alcoholic liquor, 15 ounces. Of the three inhalation cases quantity inhaled conjectural.

As to general effect: Headache was mentioned in 19 cases as a conspicuous symptom; gastric pain in 11; nausea and vomiting in 26; dilated pupils in 20.

The results as to visual disturbance were 16 total blindness, 3 total blindness of one eye, 15 partial recoveries, 7 recoveries; 10 remaining cases terminated fatally; sight became dim in three hours in one case; six hours in 1 case; eight hours in 1 case; ten hours in 1 case; twelve hours in 2 cases; twenty hours in 1 case; twenty-four hours in 19 cases; forty-eight hours in 5 cases; three days in 2 cases; six days in one case; seven days in one case; eight became lost in twenty-four hours in 10 cases; in thirty hours in 2 cases; in twelve hours in 2 cases; in forty-eight hours in 3 cases; in three days in 3 cases; in four days in 3 cases; in five days in 2 cases; in six days in 2 cases; in seven days in 1 case; in eight days in 1 case; in seventeen days in 1 case. Of the remaining 21, facts in this connection are not definite.

Certainly few members of the medical profession, and practically no one of the general public, are as yet aware that methyl alcohol taken into the system in moderate or considerable quantity not infrequently causes death, after the manner of the cases just cited. More than this, the people are still less cognizant of the fact that a certain proportion of those who survive the poisonous effect of the drug are condemned ever afterward to the miseries of greatly impaired vision, and, indeed, not infrequently to absolute blindness. It is a remarkable circumstance that notwithstanding the accumulated evidence of many similar recorded facts, there still exists a widespread unbelief in the toxic action of wood alcohol. Not long ago, with the object of discovering cases of methyl alcohol poisoning known to have occurred in Canada, Dr. Buller wrote to thirty or more Canadian oculists, asking each one for his experience in this direction. One sent this reply, which is worthy of record. It runs as follows:

I have not met with any case of blindness from drinking wood alcohol nor heard of any, notwithstanding the fact that

I live quite near one of the largest distilleries of methyl alcohol in Canada. The prevalence of the habit of intoxication from wood alcohol must be greatly exaggerated.

The italics are Dr. Buller's. Two only sent records of cases they had seen; some fifteen replied that they had no experience.

Altogether, Dr. Buller knows of only five reported and three unreported cases in Canada, and has heard of four others, without so far having been able to obtain facts regarding them. Of the five reported cases three if not four actually occurred in the United States, giving, therefore, up to the present time only one reported and three unreported cases which have happened in Canada. It would thus appear that wood alcohol poisoning occurs much more frequently in the United States than in Canada, since of the 54 cases of which Dr. Buller has collected details, some 47 occurred in the United States and two in Europe.

B.—CASES (HITHERTO UNPUBLISHED) OF BLINDNESS, OR OF BLINDNESS FOLLOWED BY DEATH FROM DRINKING METHYL ALCOHOL.

CASE 1.—(From Dr. James A. Bach and Dr. Joseph Schneider, Milwaukee, Wis.)

D. McK., Ashland, Wis., on Nov. 26, 1903, was taken ill with abdominal pains and diarrhea, while engaged in "sealing" lumber in the northern woods of Redcliff, Wis. Being far from any doctor, he secured a bottle of Hinkley's bone liniment and took the same internally according to directions, a teaspoonful every hour for a few hours, then less often. This treatment he continued from November 26 to November 27 inclusive. On November 29 Mr. McK. found his sight leaving him. Within twenty-four hours he became totally blind in his left eye and partially so in the right eye. He thereon consulted a doctor in Ashland, Wis., who told him that the "liniment" had probably "done the work." The patient is now (May, 1904), a man of about 46 years old, strong and robust in appearance and apparently has no bad habits. There is nothing in his history to account for his condition but the fact that he took the quack medicine as above stated, which was followed so promptly by practical blindness. The left disc is gray-white, and the smaller papillary capillaries and vessels are absent, with the exception of the lower macular artery, which is still seen. The larger arteries and veins are reduced in size about 20 per cent. V. = no perception of light. The right disc is also whitish, with a decided diminution of capillary circulation, but not so marked as the left. V = 3/40. The visual field in the right eye shows a large, absolute scotoma, not quite central, with concentric limitation marked.¹

CASE 2.—(From Dr. Wilfrid Beaupré, Quebec, Canada. Reported by Dr. Frank Buller, Montreal.)

J. D., aged 42, machinist, was in the habit of indulging in liquor to excess every month or two. After one of these "sprees" on March 6, 1898, having no more whisky on hand, he drank about half a tumblerful of methyl alcohol from a bottle in the house. He took this one drink only and in a few hours drove to the doctor's office nearly blind. His vision in either eye was finger counting at nine inches. He had intense photophobia and pain in the head; the papillae were white, but the retina showed no particular change. He was immediately put on potassium iodid with bromids. For a time there was considerable improvement in his vision so that he returned to work. On March 20, however, he again noticed failing sight and when Dr. Beaupré saw him on March 21, V. R. = 15/40; V. L. = 15/200. The iodid was continued and he returned on the 31st, when V. R. = 15/20; V. L. = 15/40. April 18, 1898, V. R. = 15/40; V. L. = 15/100. April 25, V. R. = 15/50; V. L. = 15/100. Then citrate of iron and strychnia were prescribed. On May 9 the nerve heads were decidedly white. V. R. = 15/75, and V. L. = 15/200. The patient's eye-

sight now became so defective that he was obliged to abandon his work and engage in selling candy in a small store. Even then he found it difficult to recognize coins or to distinguish the figures on bank bills. When Dr. Beaupré last heard of him he had entirely lost useful vision.

CASE 3.—(From Dr. M. H. Bell, Vicksburg, Miss.)

M. B., man, white, aged 50; occupation, blacksmith. Now in the Mississippi State Charity Hospital under Dr. Bell's care. V., each eye, = light perception; eyes look entirely normal externally. Ophthalmoscope shows no marked changes. There is more pigment scattered over the fundi than is usually found. Nerve heads normal; vessels, both veins and arteries, are small, two-thirds usual size. Two years ago he was working in a "dry" county and, as was the habit there, used "peruna," Jamaica ginger, etc., as stimulants. The patient's usual drink was the ginger, and he told Dr. Bell that he had been taking an occasional drink of it for three or four months. While at work one day he suddenly became blind, so that he had to be led home by another man. This was followed by nausea lasting two or three hours. On the same morning he had taken two or three drinks of ginger, rather indefinite as to quantity. On the following day his sight returned, but since that time gradually failed for eighteen months, after which it has remained the same. He can not now go about without some one to guide him. Although no analysis was made of these beverages, the clinical history and the other facts in the case point directly to methyl alcohol intoxication.

CASE 4.—(From Dr. George H. Bicknell, Omaha, Neb.; Dr. George B. Simpson, Sberidan, Wyo.; Dr. Casey Wood, Chicago.)

G. W. A., ranchman, Scotch, aged 35, had always had good health. An examination by Dr. W. A. Evans of Chicago proved him to be free of syphilis, rheumatism, or any disease of his internal organs. Blood, urine, etc., normal. On July 4, 1899, in company with a number of companions, he proceeded to celebrate the day by getting gloriously drunk. It is not known exactly what sort of alcohol the party imbibed, but it was considerable in amount. For the following four days he suffered from severe and constant frontal headaches, nausea, pain in the abdomen, frequent fits of vomiting and difficulty in breathing. About forty hours after the spree began he noticed a "dazzling" sensation in front of his eyes and in two or three hours more was totally blind. Dr. Wood saw him in consultation with Dr. Bicknell on July 28, 1899, when he said that on July 25 he first noticed his returning eyesight. This improvement in vision continued for a while, but there was a relapse about the time he left for his home in Scotland, the following November. On July 28, 1899, V. R. = no p. l.; V. L. = hand movements in the lower third of the field. Pupils widely dilated. Tension normal. Light reflexes absent; doubtful as to accommodation. Lenses showed a few striae. Both fundi exhibited blurred papillary outlines with loss of the usual transparent appearance of the nerve heads. Retinal veins somewhat engorged; arteries smaller than normal. This patient was vigorously treated by Dr. Simpson with potassic iodid, electricity and, later, was ordered full doses of iron and strychnia. Improvement for a time set in, with enlargement of the small eccentric field for white in the left eye. In July, 1899, he was able to see shadows and the outlines of large objects in the upper part of the right field and to count fingers at six inches with a small area in part of his upper left retina. On Nov. 13, 1899, his vision was much worse. He, at that time, perceived hand movements in the left eye eccentrically, but there was no light perception in his right eye. The fundus pictures were then greatly changed. The nerve heads showed shallow, atrophic excavations, the discs being whitish; veins of normal size, arteries small. Tension normal in both eyes. The patient was given a letter to Dr. Argyll-Robertson, Edinburgh, and has not been heard from since.

CASE 5.—(From Dr. Emil Borjes, Seattle, Wash. Reported by Dr. Hamilton Stillson, Seattle, Wash.)

A German, aged 27, cabinetmaker by trade, drank about two ounces of wood alcohol that was used in a saloon for filling cigar lighters. Seen about an hour afterward. Was in deep stupor, snoring, stertorous breathing; could not be aroused by his companions. Features pale, body cold, bloody froth from

¹ An examination of the proprietary remedy referred to in this report was recently made for me by a competent chemist, and found to contain a large percentage of methyl alcohol.—C. A. W.

mouth, pupils dilated, no reflexes. Had him taken to city jail, where, after heroic rubbing, applying of hot packs, and hypodermic injections of strychnia, he was sufficiently aroused to answer his name. Recovery. Vision, as well as his gait, was affected for several days.

CASE 6.—(From Dr. A. H. Brundage and Dr. James W. Ingalls, Brooklyn, N. Y.)

Mrs. M., living at East Brooklyn, N. Y., aged about 35, was addicted to the excessive use of alcoholic drinks and occasionally drank grain alcohol with water and sugar. Having heard that wood alcohol was about the same thing but much cheaper, she purchased half a pint and drank most of it.

She was found partly unconscious and sweating profusely. She was nauseated, vomited severely and was delirious, with pupils dilated. Seemed chilly. Vision gradually became blurred. Died in about thirty-six hours from the time the wood alcohol is supposed to have been drunk.

Treatment.—Free syphonage of the stomach, cold effusions to head, caffeine, digitalis, pilocarpin, external heat, oxygen, rectal injections of hot coffee, and also of normal salt solution.

CASE 7.—(From Dr. Henry D. Bruns, New Orleans, La.)

A man, about 50 years of age, came to the clinic in 1902 with the following history: He had made toddy one evening with Columbian spirits, of which he took several drinks, using at least an ounce of the wood alcohol. Shortly afterward his vision completely failed him. He then regained much of his sight for a brief period, but finally became totally and permanently blind.²

CASE 8.—(From Dr. Henry D. Bruns, New Orleans, La.)

This case,³ is that of a man of middle age who ingeniously concocted a "highball" whose spirituous portion consisted of a popular "antiseptic." He promptly became blind, but when seen a week later had somewhat improved in vision. He left the clinic and it is not possible to say whether the improvement held or not. Dr. Bruns had the proprietary article employed by this patient analyzed by the chemist of the board of health. It contained a large percentage of wood alcohol.

CASE 9.—(From Dr. A. E. Bulson, Jackson, Mich.; Dr. Pray, physician to the State Prison, Michigan; Dr. J. F. Byington, Battle Creek, Mich.)

John C., convict, aged 48, appeared March 5, 1903, at morning sick call and asked to be excused from work. He walked unsteadily and the pupils were somewhat dilated. He said he had eaten no breakfast and had vomited. On accusing him of having taken some drug he admitted that he had drunk wood alcohol. This was used in the prison shirt shops for dampening collars for the purpose of turning them. The mixture was equal parts of wood alcohol and water with glycerin, 2 ounces to the pint. On March 3 patient consumed 10 ounces of this mixture, and on the next day 4 ounces. He was sent to the hospital and treatment, consisting of large doses of bismuth, given to quiet the intense, burning pain in the stomach. At 7 p. m., although the electric light at the head of his bed was turned on, he asked to have a light; in other words, he was apparently blind. Dr. Pray says the blindness came on quite suddenly. He instituted alternate hypodermics of pilocarpin and strychnia every four hours (1/16 gr. pilocarpin, 1/30 strychnia), and potassic iodid grs. 20. On March 10 the patient could distinguish the hand held close to his eyes. March 15 he could see quite plainly. March 18 again failing vision, and on March 24 very poor vision. Discharged from hospital March 27. Strychnia and potassic iodid continued in pharmacy. Vision 7/30. Dr. Bulson examined this case later and found only light perception in the right eye with blue white discs, and marked retinal changes, the former more pronounced on the temporal side. In the left eye V. = 3/20 for central vision; about the same changes in the papilla. There was a decided contraction of the peripheral field. In September, 1903, Dr. Byington again examined this man who, then a blind pedler, presented himself with the request that the physician, as a matter of charity, give him a "statement of his case" so that he could the better dispose of his small stock in trade. Dr.

Byington made only the superficial examination demanded by the patient and found V. = finger counting at 3 to 4 inches in each eye, associated with white atrophy of both nerve heads—each lamina cribrosa being distinctly visible at the bottom of a shallow, atrophic excavation.

CASE 10.—(From Dr. Homer Collins, Duluth, Minn.)

J. A., aged 46, carpenter, Cromwell, Minn., was in the habit of going on several sprints yearly, but avoided liquor between these sprints. Used tobacco, smoking or chewing about "ten cents' worth a week." On Nov. 22, 1901, with a companion, he drank about one dozen bottles of Jamaica ginger bought at Cromwell. The following day the companion vomited freely, but his eyes did not suffer. The patient vomited "everything" the next day and his eyesight began to fail at once. On the second day he could distinguish only light from darkness, and remained in this condition for two days. Then improvement of vision began and continued until about Dec. 12, 1901, when V. = 2/200 (white letters) in either eye. Right half of each field was covered by a scotoma, the most acute vision being eccentric, to the nasal side of the fixation point. In the left eye the field is very little contracted; central vision is best. There is some tenderness above and behind the eyeballs. The patient gave the history just outlined and stated that immediately after the poisoning he had considerable pain in his eyes, which were too sore to touch. He was put on pilocarpin treatment, under care of the county physician, and on December 22 thought he could see a little better, but tests showed no improvement, and there has since been little change in his condition. Bilateral post-neuritic optic atrophy.

CASE 11.—(From Dr. Coote of Quebec, and Dr. Frank Buller, Montreal, Canada.)

A man between 28 and 30 years of age, well built and healthy in appearance, without any history of a serious illness, while working in a lumbering camp, caught a slight cold. To cut the trouble short he took what he considered a big dose, about a wineglassful, of methylated Jamaica ginger. He commenced to suffer from violent headaches and retching shortly afterwards. Some twelve or fourteen hours later his sight commenced to grow dim. A second dose was then taken and his sight grew worse. He was taken home and, with the exception of his eyes, he was shortly well again. About three months later, when he appeared at the hospital, central vision in both eyes was completely lost. Toward the periphery of the field of vision in both eyes a few patches of retina remained sensitive to light and fingers could be seen at a couple of feet. The pupils reacted to light and on convergence. Both discs were pale (not white) and the margins well defined; the arteries and veins were contracted, but not equally; the media were clear. He was kept in the hospital for some weeks, but the treatment was of no avail.

CASES 12 and 13.—(From Dr. Homer Collins, Duluth, Minn.)

In the year 1900 (exact date unobtainable), an Indian from one of the Minnesota reservations, accompanied by an Indian attorney (G. H. B.), consulted Dr. Collins. The history of the case showed that at least six Indians, having procured a supply of essence of lemon, drank freely of it. Three died promptly, evidently from the direct effects of the beverage, one of them becoming blind before death. Two others suffered considerably, but recovered without apparent damage to any of their organs. The sixth Indian, the patient under discussion, survived, but became totally blind. An ophthalmoscopic examination revealed marked atrophy of both optic nerves.²

3. Through the kindness of Dr. J. W. Chamberlin of St. Paul, Mr. G. H. B. wrote me the following note, giving further information regarding this matter: "Your letter of inquiry reached me at White Earth, Minn. In reply, an Indian trader, named Malone (afterward prosecuted by the U. S.), sold to several Mille Lac Chipewya Indians a number of bottles of essence of lemon on June 28, 1897, which they drank in lieu of alcohol, when that had been exhausted. A large number of Indians drank alcohol; only six or eight drank the essence of lemon. The latter were all taken seriously ill within an hour after they began to drink the essence, and three of them died before morning. I can recall the name of only one of those who died, a chief, Mah-keh-keewis. Another Indian, Bad-dub-ay-kesheh, became blind and has not since recovered his sight. He is still living at Mille Lac, Minn. The others, although very sick, recovered without any bad effects. It was thought at the time that the death of the Indians was due to the wood alcohol in the essence of lemon." C. A. W.

2. This case, as well as the next one, is entered in the tables published by Dr. Bruns in the annual report for 1902 of the New Orleans Eye, Ear, Nose and Throat Hospital.

CASE 14.—(From Dr. W. G. Craig, Hartford, Conn.)

M. J., colored, aged 50, was given as a beverage a mixture of sugar, water and Columbian spirits, about three fluid ounces in all. This was on April 30, 1902. The dose was followed by nausea and vomiting and in twelve hours by complete loss of vision. She recovered her sight to some degree, but a month later it was only $\frac{1}{4}$ in each eye. Nerve heads chalk white.

CASE 15.—(From Dr. M. M. Cullom, Nashville, Tenn.)

While acting as interne in the Manhattan Eye and Ear Hospital, New York City, the following case came under Dr. Cullom's care:

In October, 1897, a workman was brought into the hospital with the following history: Two nights before he drank some wood alcohol in his room. It threw him into a stupor and, as he expressed it, "When he waked it was so dark that he supposed it was still night." He groped his way out into the hall and asked some one the time, and was informed that it was about 9 o'clock in the morning. The following day he was brought to the hospital. His pupils were widely dilated and did not respond to light. He had only perception of light in both eyes. The ophthalmoscope showed both nerve heads to be milk white in appearance and the entire fundus was blanched, the vessels being much smaller than normal. He was put on increasing doses of strychnia nitrate, administered hypodermically, which were carried to the physiologic limit. The vision improved for a short time until with his left eye he could count fingers, but the improvement was soon lost and he was discharged as hopelessly blind. There was no attempt made to secure a sample of the alcohol.

CASE 16.—(From Dr. I. F. Dickson, Portland, Ore.)

Two teamsters, strong, healthy men, under 30 years of age, who had been working hard all night, arrived at a friend's house in the early morning, much fatigued. The friend offered them a drink of something that, he said, "would make them feel better." He accordingly prepared a mixture of wood alcohol and water sweetened with syrup. One man died toward evening. The other took only a few mouthfuls and spat some of it out, as he did not like the taste. Shortly afterward he became unconscious and remained so till next morning. When he awoke he could only distinguish light, and within three weeks the sight was entirely lost. About this time the discs began to show signs of atrophy; otherwise the fundi were normal. He was first seen by a physician shortly after taking the drink, when it was noticed that the pupils were slightly dilated, but nothing abnormal was then seen in the background of either eye and no fundus changes appeared for about three weeks. The latest report from the patient is that he is still totally blind.

The following case is of great interest owing to its early occurrence (1898). It was one of the first examples of blindness due to bay rum made from Columbian spirits:

CASE 17.—(From Dr. J. A. Edwards, Columbia, Tenn.)

In February, 1898, he was called to Centerville, a town thirty-one miles distant, to see a young lawyer, W. A. K., aged about 26 years, who gave the following history: Living in a "dry" town and being in the habit of going on periodical sprees he called on a friendly physician who was in the habit of giving him a prescription containing alcohol and any other simple drug which would protect the druggist filling it from prosecution for violation of the liquor laws. On this occasion he was given, to supply the needed alcoholic beverage, as well as to protect the druggist against the provisions of the prohibition law, the following prescription:

R. Bay rum 2 fluid ounces.
Alcohol 4 fluid ounces.

Sig.: To be applied externally.

He drank all this in an hour or so, and was afterward seized with violent pains in the stomach, nausea and vomiting, which continued about 24 hours, when he became totally blind. Dr. Edwards found him with pupils widely dilated and some tenderness of the globe on firm pressure. Having obtained the above history of his case the diagnosis of retro-bulbar

neuritis or toxic amblyopia was made. At that time very few reports of such cases had been published, but he was given an unfavorable prognosis, and was told that his vision would probably clear up in from ten to twenty days, but that blindness, either partial or complete, might re-ur from secondary changes in the optic nerve. The patient promised to call on Dr. Edwards in a few days, but saw, instead, another very competent oculist, under whose care for three or four weeks his vision cleared almost to normal. Very soon thereafter his sight again declined to 20/60, with scotomata in parts of the visual field. He still sees only well enough to read very large print, and that with much difficulty, on account of the scotomata. He practices his profession, but is very much handicapped, his wife being obliged to assist him in his legal work. Investigation developed that the "bay rum" in this prescription with which he was poisoned, was put up by a firm in Buffalo, N. Y., and made of Columbian spirits.

CASE 18.—(From Dr. W. E. Driver, Norfolk, Va.)

J. B., male, white, age 25, U. S. sailor, brought July 12, 1898, from the U. S. Naval Hospital, by the surgeon in charge. He gave the following history: One week since the patient and two of his companions, who were in charge of a naphtha launch, indulged freely in the wood alcohol used in starting the engine. He and his companions were made desperately sick, and he became totally blind.

The pupils were widely dilated, but there was no visible pathologic change in the fundus. The diagnosis was wood alcohol amblyopia. Treatment was potassium iodid, ten grains three times a day at first; increased doses later. July 16, 1898, pupils still widely dilated. Had something more than light perception in each eye. Optic nerve, each eye, decidedly paler than at the previous visit. July 23, 1898, decided improvement in vision of each eye. Can now recognize large objects. Both pupils widely dilated. Eyes very bright. Both optic nerves show decided pathologic changes, and very much whiter than at previous visit. Dr. Driver learned from the Naval Hospital that soon after the last visit to his office, the patient was discharged from the Navy and nothing further was heard of his case. His two companions died during the debauch, from the effect of the intoxication.

CASE 19.—(From Dr. W. E. Driver, Norfolk, Va.)

A. H. S., male, white, aged 25, came Feb. 2, 1903. Referred to Dr. Driver by Dr. Holland of Holland, Va. The patient became suddenly blind ten days before. When he went to bed he could see as well as ever; on waking was totally blind. Had been drunk from cider purchased from a country store.

Right eye: Cornea very bright and glistening. Pupil widely dilated. Optic nerve pale, but no other pathologic change in fundus. No light perception. No reaction of pupil to light.

Left Eye: Cornea clear and bright. Pupil widely dilated. Nerve white. No reaction of pupil to light.

Diagnosis: Wood alcohol amblyopia.

Patient was sent to hospital and given potassium iodid, 10 grains three times daily, and twentieth of a grain of strychnin. On February 9 vision began to return in left eye. Has light perception. No improvement in right eye. February 15, counts fingers one foot from left eye. Light perception only in the right eye. Optic nerve, each eye, decidedly paler than normal. February 23 patient went home, with no improvement in the right eye, but counts fingers at three feet with left eye. Nerve, each eye, white, bluish tint. Pupils widely dilated. Corneal reflex extremely bright.

This man has consulted Dr. Driver three times since he left the hospital the first time. There has been no improvement in vision of the right eye. With left eye vision is 6/200.

CASE 20.—(From Dr. William H. Dudley, Easton, Pa.)

Ralph W., single, aged 39, an essence pedler, about June 15, 1903, took for a "cold," diluted with water, four ounces of what he says he bought for grain alcohol. Two days later his vision became very bad, and when seen three months later his optic discs were quite white; fields were narrow; vision 1/200 right and left. Seven months later his condition remained practically the same. Patient states that as soon as he had

drunk the alcohol he discovered his mistake, realizing then that he had taken wood alcohol.

CASE 21.—(From Dr. H. P. Engle, Newton, Iowa.)

G. F. of Mingo, Iowa, aged 45, drank at least half a pint of Columbian spirits diluted. He lived forty-eight hours, but before death there were present gastrointestinal irritation, blindness, delirium and collapse.

CASES 22, 23 and 24.—(From Dr. W. H. Ford, Sulphur, Ind. Ter.)

As detailed elsewhere in this report, four men, aged from 30 to 40 years, went on a spree with methylated bay rum. Two, who consumed large quantities of the poisonous perfume, died. There is no history of blindness in one case, but the other, S. B. B., age 24, who succumbed to the poison, lived about eighteen hours, and suffered the most excruciating pain in stomach and bowels. Even though heroic doses of morphia, administered hypodermically, were given him, he had to be held in bed. He was totally blind most of this time. About an hour before death his pulse became imperceptible at the wrist, his heart being very rapid all the time. The odor of methyl alcohol was very noticeable in the perspiration, which was very profuse. The two that survived, aged 29 and 37, suffered for some twelve to fourteen days with marked ocular disturbances. Vision was very indistinct; it seemed at times as if they were "looking through a moving screen." Again, in a few hours there would be a total loss of the outlines of objects. After two weeks vision appeared to return.

CASE 25.—(From Dr. P. G. Goldsmith, Belleville, Ont., and Dr. Sprague, Stirling, Ont., and from the *North Hastings Reporter*, June 15, 1904.)

William Sutherland of Montague met his death under very distressing circumstances on Monday night. He had returned from working with the chemical company near Orillia and brought a bottle of wood alcohol with him to let his neighbors see it. Not suspecting its poisonous nature he let some of them taste it. Finding it too strong, they were all satisfied with merely tasting it. But Sutherland, it is estimated, took about a wineglassful. In a short time he complained of difficulty in breathing, then of blindness, and asked for a physician, who was sent for. He soon lapsed into unconsciousness and died before medical aid could arrive. Deceased was a respectable farmer about 45 years of age, and a widower, having two sons. The sad event cast a gloom over the community.

CASE 26.—(From Dr. A. H. Gordon and Dr. Frank Buller, Montreal, Quebec.)

B. K., aged 40, female, domestic, alcoholic. On Jan. 18, 1904, had been drinking for two days. Drank one quart of whiskey, a half-pint mixture of gin and spruce gum, as well as nearly eight ounces of wood alcohol. Vomited all one morning, and in the afternoon became excited, partially delirious. Complained of severe headache, pain in arms and fell to floor unconscious. Later, general convulsion and death in half an hour after convulsion. Half an hour before falling she groped about the room calling for light, evidently completely blind. Pupils widely dilated and inactive. The cause of death was undoubtedly the wood spirit drunk within twenty-four hours of her death. The autopsy showed no brain or kidney lesion.

(To be continued.)

An Aid to the Comfort of Bedridden Patients.—*American Medicine* says that in cases of severe heart disease with orthopnea it is often extremely difficult to keep the patient in the semi-upright position as the direct pressure on the tuber osities of the ischium is not only uncomfortable, but is conducive to bedsores, and there is also a tendency to slip down in the bed. In such cases a hard bolster is placed under the mattress at the level of the thighs, forming with the pillows a double inclined plane, in the trough of which the back rests. The support and the removal of a part of the weight from the tuber ischii to the fleshy part of the thighs affords great relief to the patient.

FATAL POISONING DUE TO SKIN ABSORPTION OF LIQUID SHOE BLACKING (NITROBENZOL).

WITH AUTOPSY REPORT.

WILLARD J. STONE, B.Sc., M.D.

TOLEDO, OHIO.

A report of the clinical and autopsy findings in the following case is of interest, first, because of its rarity, it being, so far as I have been able to ascertain, the only case recorded in which the fatal result could be attributed to skin absorption of this poisonous agent; and, secondly, since it reiterates once more the danger attendant on the use of the various cheap products of coal-tar distillation as solvents for the anilin dyes in certain commercially manufactured articles.

Dr. A. W. Wheeler and Dr. Peter Donnelly have kindly furnished the clinical history of the case.

History.—W. R., aged 22, male, salesman, in excellent health so far as could be ascertained, was taken suddenly ill in a café about 12:30 a. m., March 20. He had attended a dancing party earlier in the evening in company with some friends. After the party he and four or five of his associates went to the café for a lunch. His friends were with him during the entire time after he left his room earlier in the evening. He remarked while in the café that he did not feel well, but his friends noticed nothing unusual about his appearance except that he seemed very pale. In the café each one drank four or five glasses of beer. While standing up to put on his coat, which one of the men present was holding for him, he suddenly seemed to faint, and fell to the floor. He was carried into an adjoining room, and a medical student who happened to be present dashed cold water in his face, which seemed to revive him. He complained of no pain, but felt dizzy and faint, and shortly after vomited the beer, crackers and cheese eaten but a few moments before. He was assisted to a carriage, and arrived at his room at about 2 a. m.

A physician was not called until about 3:30 a. m., since his roommate supposed him in a drunken stupor. The physician, Dr. Wheeler, was informed that he had passed into the comatose condition on arrival at his room about 2 a. m., and that he had not recovered from it.

Examination.—Dr. Wheeler found him in collapse; very pale skin, eyes glazed, cyanotic lips, ears and finger tips, corneal reflexes absent, no peculiar odor to breath, no convulsive tendencies, heart action fairly good, both sounds clear, pulse rapid, 130, skipping about one beat in 25; respiration 28. His friends were unable to throw any light on the cause of his condition, except that they thought him drunk.

Death.—After giving 1 30 strychnin and 1 10 apomorphin. Dr. Peter Donnelly was called in consultation, but shortly after his arrival (4:45), a slight convulsion occurred, and with a sudden dilatation of the left pupil the heart stopped beating (not heard by auscultation or perceptible at wrist). Slight respiratory efforts continued for about five minutes, after which the patient died; in all about four and one-half hours after the fainting attack in the café.

Autopsy.—This was made by me about six hours later, March 20. Length, 71 inches; weight about 160; good muscular build; no scars or deformities; no signs of trauma or surgical wounds; skin and all visible mucous surfaces very pale; ear lobes and finger tips cyanotic; hair black; both feet discolored black to above ankles, resembling the crook of black-colored hose; rigor mortis just beginning in jaw; no postmortem lividity of under surfaces; slight body heat present; no distention of abdomen; no edema lower extremities.

Thorax: Mediastinal tissue small in amount; lymph glands normal; no fluid in pleuræ; pericardial sac not distended; fluid normal.

Heart: Fatty covering normal; section muscle normal color; left ventricle wall hypertrophied, 20 mm. thick; mitral valve

admits two fingers; valve flaps thin, normal; aortic opening admits thumb; valves normal; coronary openings patent, traced to smaller ramifications; no thrombus or embolus; right heart normal; dark fluid blood and small mixed clot in right auricle; pulmonary artery traced to small ramifications; no embolus; thoracic aorta normal.

Lungs: Pleuritic adhesions both lungs behind and at apices; section, old scar right apex; anthracosis moderate; dark red in color, yields slight fluid on pressure, crepitant throughout; slight hypostasis lower lobes; bronchial lymph glands negative.

Abdomen: Omentum and peritoneum normal. Stomach: Ligated cardia and pylorus—removed entire. Spleen: 12 by 10 cm.; capsule normal, dark red on section; follicles, pulp and connective tissue normal. Liver: Not enlarged; brown-red on section; mottled appearance in areas; consistency normal; shows cloudy swelling; parenchymatous degeneration. Gall bladder and ducts: Normal; no calculi. Pancreas: Small, otherwise normal. Adrenals: Normal; small. Right and left kidneys: Identical in appearance; large capsules strip off readily; do not drip blood on section, though they appear congested; dark red in color; cortex paler in color; congestion (?); parenchymatous degeneration; acute nephritis (?). Ureters: Patent throughout. Bladder: Normal; 150 c.c. urine withdrawn by catheter for examination. Duodenum: Small intestine and colon normal; serosa not injected. Appendix: Long, free entire length; contains small, hard concretion.

Fig. 1.—Camera lucida. Acute desquamative nephritis from nitrobenzol. (Zelss, oc. 4. obj. A. A.) A. True epithelial cast of medium-sized tubules. B. True epithelial cast of larger tubules. C. Red and white blood cells. D. Fine granular cast.

Brain: Meningeal vessels congested. Internal capsule normal. Vessels traced to finer branches; no embolus or hemorrhage. Ventricles normal. Basal sinuses, cerebral ganglia peduncles, circle Willis, cerebellum, pons and medulla, normal.

Stomach contents: About 40 c.c. opaque, rather thick, dark red fluid. Absence of free HCl to Congo red and di-methyl-amido-azo-benzol papers. Sour odor. Microscopically, much amorphous debris, cellulose fibers en masse (crossed striation), many finer cellulose particles. Many fat globules, large and small; many small non-motile bacilli; few shreds gastric mucosa (columnar celled); no crystals of any kind seen. Negative guaiac test for blood.

Urine: Amount withdrawn by catheter, 150 c.c.; specific gravity, filtered urine, 1013; reaction, acid; heat plus HNO_3 , slightly positive; acetic acid plus potass. ferrocyanid, positive; Fehling's, negative; Nylander's, negative. Microscopic examination: Many white (see illustration), and red blood cells; many finely granular casts (medium size); many larger hyaline and leucocyte casts; few very large epithelial casts of the larger tubules (about one in every two fields with low power); bladder epithelium and spermatozoa (death phenomenon).

Microscopic examination of liver: Congestion slight, cloudy

swelling (parenchymatous degeneration) and fatty degeneration quite general throughout sections; necrosis in areas.

Microscopic examination of kidneys: Stained in eosin-hematoxylin and Van Gieson. Cloudy swelling (parenchymatous degeneration), general throughout sections. Necrosis in areas. Much debris in larger tubules. Partly exfoliated epithelial lining of tubules in many areas.

Diagnosis.—Acute desquamative nephritis and acute hepatitis (toxic?).

Etiology.—Subsequent inquiry four or five days later into the circumstances surrounding the death by the coroner, Dr. C. Storz, revealed the following facts: The young man had purchased, a few days before his death, a pair of shoes at a sale being advertised in the city. These shoes were black patent leather lowers with cloth tan tops. On the evening of the dance above mentioned he had applied a liquid shoe blacking, made in Chicago, to the tan cloth uppers of the shoes. These shoes were worn that evening. The cloth uppers absorbed enough of the blacking to entirely cover up the tan color, and, moreover, since the shoes were put on before the tops were dry, to stain his feet and ankles black.

The coroner found in the man's room part of the bottle of blacking used and also the shoes. Both the shoes and blacking emitted a strong odor, not unlike oil of bitter almonds, the shoes having this odor a week after death. A portion of the blacking and the shoes were turned over to City Chemist G. A. Kirchmaier. Through his kindness I am able to append his report.

Chemical Examination.—About three drams of liquid shoe blacking was received from the coroner. Suspecting nitrobenzol from the odor, the blacking was distilled after adding H_2SO_4 , according to the method of Jacquemin.¹ To the distillate zinc and H_2SO_4 was added to reduce to anilin, after which the liquid was treated with excess of sodium carbonate and filtered. On the addition of a drop of carboic acid and then some sodium hypochlorite a brown coloration, rapidly changing to blue, appeared, due to formation of sodium erythrophenate, and which indicated the presence of nitrobenzol. The amount of pure nitrobenzol obtained was nearly as much as the total amount of blacking received from the coroner. The shoe tops were also extracted with solvents and marked traces of nitrobenzol obtained.

Reinsch's test for poisonous metallic salts was applied to stomach contents with negative results.

Nitrobenzol (or nitrobenzol $\text{C}_6\text{H}_5\text{NO}_2$) was discovered by Mitscherlich in 1831. Casper,² cited by Blyth, first called attention to its poisonous properties. Its importance as a commercially used article lies in the fact that it is a cheap solvent for the various anilin dyes and that it is used as a flavoring or odoriferous agent, under the name "Essence de Mirbane," in cheap perfumes, soaps and confections. Nitrobenzol is an intermediate product between benzol, a constituent of coal-tar, and anilin. It is in reality formed from the action of nitric acid on benzol ($\text{C}_6\text{H}_6 + \text{HNO}_3 = \text{C}_6\text{H}_5\text{NO}_2 + \text{H}_2\text{O}$), and anilin, the next step in the process, is formed direct from nitrobenzol (Allen³ and Lloyd⁴).

Pure nitrobenzol is a pale yellow liquid, having an odor closely resembling that of the essential oil of bitter almonds. It differs, however, from that body in many respects, the oil of bitter almonds being benzoic aldehyd ($\text{C}_7\text{H}_6\text{O}$).

SYMPTOMS.

Jübbel⁵ collected, between 1848 and 1876, 42 cases of poisoning by nitrobenzol, 13 of which were fatal. R.

Bachfeld,⁶ cited by Gould,⁷ has collected 63 poisoning cases by anilins and benzols. He concludes that there is danger of poisoning if clothing soaked with anilin or nitrobenzol remains in contact with the body. Nitrobenzol is a powerful narcotic poison, whether taken in the form of vapor or as a liquid. The fatal dose for an adult is probably about 1 gram, although numerous examples exist of serious poisoning by much smaller doses. The quantity which would be fatal if breathed is not known with any accuracy. Husemann⁸ mentions several cases of poisoning associated with the symptoms stated by the various authors mentioned as common to all: 1, fainting; 2, cyanosis, and 3, coma. A case cited by Taylor⁹ is typical:

A woman tasted a liquid used for flavoring pastry (it was afterward chemically identified as pure nitrobenzol. She immediately spat it out, swallowing probably not more than a drop. In replacing the bottle about a tablespoonful was spilt. As it was a small room the vapor rapidly permeated the atmosphere in it, and caused illness in herself as well as in a fellow servant. In about three hours, when seen by a physician, she showed symptoms of prussic acid poisoning. The features were pale and ghastly, skin clammy, lips and nails cyanotic, pulse feeble but mind clear. She became suddenly unconscious a few moments later, consciousness returning in eleven hours. Recovery not complete for weeks.

This case is exceptional, since recovery in instances where coma has developed is very rare.

Blyth¹⁰ states that the symptoms are almost identical with prussic acid poisoning, except that in nitrobenzol poisoning there is a much longer interval between taking the poison and its effects. "This is, indeed, the strangest phenomena of nitrobenzol poisoning, for the person taking it may appear well for periods varying from fifteen minutes to three hours, or even longer, and then there may be the most alarming symptoms, followed by coma and sudden death." (Note similarity to the present case, also Dr. Collamore's case below.)

Cases vary but little in their main features; in a few the blue skin and deep sleep are the only symptoms noted. This, of course, is quite typical for excessive doses of any of the coal-tar products, i. e., antipyretics, naphthalene yellow, metanil yellow, orange II or picric acid combinations. These latter have been used as constituents of butter color along with anilin yellow (dimethyl-amido-azo-benzin), and from the use of which several fatal poisoning cases have been recorded.

Nicholson¹¹ reported a case of fatal poisoning by liquid nitrobenzol. He stated also that the vapor from "almond glycerin soap" had caused in a friend of his who used it while taking a warm bath symptoms of mild poisoning (fainting and illness for some time afterward). It would seem that the circumstances surrounding this last case were favorable to skin absorption of the poisonous agent, and that the symptoms of poisoning which followed could be attributed to absorption in such a way.

Dr. G. A. Collamore, Toledo, about ten years ago attended a man who, when intoxicated, touched a small bottle of nitrobenzol to his lips under the impression it was whisky. The accident happened in the home of a local soap manufacturer, who had brought the stuff to the house from the factory and deposited it on the man-

tel because it imparted a pleasant (*sic*) odor to the air of the room. Shortly after, the man became unconscious and was cyanotic. After twenty-four hours he regained consciousness and insisted on returning to his work, though still cyanotic. He died suddenly while attending to work twenty-four hours later. The skin was dark colored and the breath exhaled the odor of bitter almonds.

Letheby¹² relates the case of a man who spilt some considerable quantity on his clothes. For several hours afterward he went about breathing an atmosphere of nitrobenzol. He then became drowsy, expressionless, and, with unsteady gait, presented the symptoms of intoxication. The stupor suddenly developed into coma and the man died, the fatal course being altogether nine hours, i. e., four hours before coma and five hours of total insensibility.

The first symptoms usually are headache, drowsiness, flushing of the face (which is shortly followed by extreme pallor, with cyanosis of the ears, finger-tips and lips), dyspnea (not present in the case under consideration), dilation of pupils, loss of voluntary power, and sometimes convulsions. These symptoms are followed by coma, which usually appears suddenly and increases in intensity till death ensues in five or six hours. When the stage of coma is reached there is but little chance of preventing a fatal termination (Allen). Death is usually stated to be due to paralysis of the respiratory centers. In the present case death was evidently caused by paralysis of the circulatory centers, since the heart stopped beating about five minutes before respiratory efforts were discontinued.

POSTMORTEM FINDINGS.

It is such an insidious narcotic poison that indications pointing to severe irritative action on stomach or bowels—when swallowed—are usually absent. The kidneys and liver may show extensive parenchymatous degeneration, as in the present case, this being probably mere evidence of the attempted eliminative process on the part of these organs. The changes are, however, no different from the action of many other actively poisonous agents. When swallowed the breath may give off an odor resembling the oil of bitter almonds. Filehne¹³ states that the blood gives the spectrum of acid-hematin. A dark brown to black color of the blood has been noted in some cases—the blood not being coagulated.

Cushy¹⁴ says that the oxygen-carrying power of the hemoglobin, when combined with nitrobenzol, seems to be lost. Its carbon dioxid is also decreased. With the spectroscope methemoglobin has been found, although in two cases—not fatal—cited by Huber¹⁵ the blood was chocolate colored, but gave in both instances normal blood and spectroscopic tests. An absorption band which does not seem to correspond to any of the usual hemoglobin products, often appearing between the yellow and red, has been noted in several cases. It has been designated the nitrobenzol-hemoglobin line.

Weyl¹⁶ mentions that sugar is found in the urine in nitrobenzol poisoning, although in the present case (and in Huber's cases, mentioned above) no reducing substance was present which reacted to Fehling or Nylander's solutions.

TREATMENT.

Since death occurs from narcotic action, with subsequent paralysis of the respiratory and circulatory centers, in this as well as in poisoning with other coal-tar-anilin preparations, a prompt emetic should be given or the stomach tube used. The stomach tube should be used, since, as in the case of morphin, the possibility of the drug being excreted into the stomach and bowels should be borne in mind. An effort should be made to ward off the impending coma; constant exercise, flagellation with wet towels and rubbing being employed. Hypodermically, atropin 1/100 to 1/60 gr. and cocain 1/4 to 1/2 gr. might be used for their stimulative action on the respiratory and cardiac centers. Evidently the process of elimination is attempted by the kidneys (as in the present case) and possibly also by the bowels. Large quantities of hot normal salt solution per rectum or intravenously would undoubtedly assist in this process. The depressant action of and danger attending the use of pilocarpin to assist elimination by the skin, in cases of already depressed circulatory activity, would seem to be contraindicated because of the danger of pulmonary edema.

CONCLUSIONS.

This case reiterates the danger of the promiscuous use of nitrobenzol by manufacturers. How they are able to prevent poisoning among the workers in their factories is somewhat of a mystery. Its use should be still more strenuously prohibited as entering into the composition of liquid shoe blacking, cheap soaps, confections and similar articles of widespread usage. The conditions present in this recorded case were unfortunately such as to permit of absorption by the skin. The shoes were put on before the blacking was dry, and shortly afterward the exercise incident to the dancing party probably aided its absorption. Nitrobenzol is probably used as a solvent for the anilin dyes in many liquid shoe-blackings on the market. The reason that the small boy shoeblack is not more frequently poisoned lies in the fact that but a very small quantity of the liquid comes in contact with his fingers, brushes being used instead, while the fingers are usually used for the application of the "polish." The "polish" is probably an anilin-black in most cases and probably contains nitrobenzol as a solvent. Why fatal poisoning is comparatively so rare among shoe-blackers is not quite clear. Perhaps but extremely small quantities are absorbed and that this absorption extends over a considerable time.

SPLENECTOMY FOR SPLENIC ANEMIA.

J. H. CARSTENS, M.D.
DETROIT.

Splenic anemia is a distinct variety of anemia, and entirely different from the various conditions characterized by enlargement of the spleen and classified under various names. The distinctive features are enlargement of the spleen without enlarged lymphatics, evidence of pigmentary deposits, and if long continued, disturbance of the liver and ascites. So far as etiology is concerned, nothing definite is known.

The special features of the condition are: 1, Slight diminution in the number of red corpuscles; 2, reduction in hemoglobin, and 3, a most remarkable reduction in leucocytes. This last seems to be the pathognomonic condition.

H. C. Wood¹ first described this in 1871. He says:

"I now desire to show that there is still a third form of pseudoleukemia, a splenic variety. Under the names of tumor of the spleen, splenic cachexia, etc., medical records furnish accounts of cases which I believe represent this affection." Griesinger, in 1866, describes a case in a child and called it anemia splenica, although it has since been shown that enlargement of the spleen in children is different from that peculiar enlargement found in adults.

Sippy has given us an excellent résumé on the subject and reported in full a case which ended in death. He gives all the blood examinations and careful microscopic examination of the spleen with illustrations.

Oslér, in two papers, reports 18 cases, some of them having extended over a period of many years, the patients being in fairly good condition. Harris has also reported quite a series of cases.

My case is as follows:

History.—Mr. B., aged 38; had always been well until last winter, when his abdomen began to enlarge. He became weak and pale, digestion was poor and he was unable to work. Various remedies were tried without much benefit. The enlargement of the abdomen increased until it reached the symphysis, crowding the abdominal viscera toward the right. It

Spleen, removed by Dr. J. H. Carstens.

was diagnosed as an enlarged spleen. He was brought to me by Dr. Peterson of Ruth, and I had his blood examined by Dr. Sill of the Detroit Clinical Laboratory. The report is as follows:

Blood examination—Erythrocytes.....	3,804,000	%
Hemoglobin	75	%
Color index	0.94	%
Leucocytes	1,250	%
Polynuclears	10	%
Mononuclears	90	%
Eosinophiles	%

There was a marked reduction in the number of leucocytes and an enormous increase in the proportion of the lymphocytes. The red cells showed no degeneration.

Operation.—July 21. An incision was made along the outer edge of the left rectus, a large incision being necessary on account of the size of the growth. I found some slight adhesions of the omentum, but otherwise no complication. The spleen was very soft, almost like jelly. In trying to lift it out of the wound I turned it a little so that the apex would come out first. It broke and a severe hemorrhage occurred, which was controlled by clamping the pedicle. I removed the spleen, ligated the blood vessels separately and then the pedicle. There was one vein the size of an ordinary pencil. Several bleeding points in the omentum were ligated, the abdominal

¹ American Journal of Medical Science.

cavity washed out and the wound closed. He was given an enema of two quarts of saline solution and put to bed.

During the first few days there was a temperature varying from 99 to 101 degrees, with the pulse 120. On the 26th the temperature went higher, and a blood examination made by Dr. Edmunds showed leucocytes, 11,000. On the 29th temperature went up to 105 degrees, pulse 132, and the increase of leucocytes indicated sepsis.

REPORTS BY DR. C. W. EDMONDS.

July 26.—Reds	2,745,000
Leucocytes	11,204
Mononuclears	73 %
Polynuclears	27 %
Hemoglobin	70 %
July 29.—Reds	2,919,200
Leucocytes	4,077
Mononuclears	18 %
Polynuclears	82 %
July 30.—Leucocytes	4,771
Mononuclears	19.7 %
Polynuclears	80.3 %
July 31.—Leucocytes	4,526
Polynuclears	85 1/2 %
Mononuclears	14 %
Eosinophiles	1/2 %

August 26 I removed the dressing and examined the abdominal incision, which had been closed with sterilized catgut. I found a red spot which indicated a stitch abscess. This was opened and a small quantity of pus removed. The leucocyte count again dropped. He had been irrational for a day or two, and one night, in the temporary absence of the nurse, he got up and walked around the room. He was put to bed and a restraining sheet applied. The next morning, during a violent effort at coughing, something gave way, and on examining him I found that the edges of the abdominal wound had separated and the intestines were protruding. An anesthetic was administered, the abdomen thoroughly washed out and the incision closed with silk-worm-gut sutures.

Results.—His recovery after this was rapid and uninterrupted. He developed a voracious appetite, his mind became perfectly clear, and he returned home four weeks after the operation perfectly well. A few days after sewing the abdomen I had another count of his blood made and the report by Dr. Sill was as follows:

August 1.—Erythrocytes	4,128,000
Hemoglobin	60 %
Color index	0.75 %
Leucocytes	2,666
Polynuclears	77.77 %
Mononuclears	22.23 %
Eosinophiles

In comparison with previous examination the blood showed a marked change. The red cells had increased, but the hemoglobin had dropped in percentage. There was an increase in the number of leucocytes with a startling change in the proportion of the varieties, the polynuclears regaining their normal proportion.

The spleen weighed fourteen pounds. The pathologic examination of the growth, made by Dr. H. Gibbs, is as follows:

Examination of Tumor.—Hyperplasia of splenic tissue without increase in the capsule or trabeculae. The whole tissue is infiltrated with blood, in some places amounting to extravasation. There is no appearance of malignancy.

Further blood examinations were made occasionally by Dr. E. Edmunds as follows:

August 8.—Reds	3,325,000
Hemoglobin	65 %
Leucocytes—	
Mononuclears	26 %
Polynuclears	74 %
August 12.—Leucocytes	3,032
Polynuclears	31 1/3 %
Mononuclears	48 1/3 %
Eosinophiles	1/3 %
Hemoglobin	70 %

The peculiarity of the blood in these cases is the very small number of leucocytes. That seems to be distinctive of splenic anemia, but the most remarkable change was: 10 per cent. polymorphonuclears and 90 per cent. mononuclears before he was operated on, while ten days after the operation the proportion was nearly normal.

In order to throw more light on the subject I asked him to come for another blood examination. He came, and eight months after the operation the blood report, by Dr. Joseph Sill, is as follows:

Date received, April 5—Erythrocytes	5,448,000
Hemoglobin	100 %
Color index	1.0 %
Leucocytes	9,250
Polymorphonuclears	58 %
Mononuclears	42 %
Eosinophiles	..

This specimen of blood was practically normal.

Beside this the man's appearance was remarkably improved. I did not have him weighed when he arrived at the hospital, but when he left he weighed 97 pounds, and the day the last blood examination was made he weighed 193 pounds, was the picture of health and in every way well, except having a slight bulging at the line of incision, and hence was incapacitated for hard physical labor.

SUMMARY.

1. Splenic anemia is a distinct variety of enlargement of the spleen.
2. It can be diagnosed by blood count, which shows an abnormal and small number of leucocytes. It is, as a rule, slow in its development, and is but slightly relieved or retarded by treatment.
3. Splenectomy seems to offer the only chance for a permanent cure.

X-RAY THERAPY IN LEUKEMIA.

A PRELIMINARY REPORT. WITH SPECIAL REFERENCE TO LYMPHATIC LEUKEMIA.

JOSEPH A. CAPPS, M.D., AND JOSEPH F. SMITH, M.D., CHICAGO.

EDITOR'S NOTE: The article with the above title in THE JOURNAL, Sept. 24, 1904, page 891, was marred by the inadvertent omission of the accompanying table. The readers of the article easily recognized the fact that something was omitted, as the table was referred to in the article.

CASES OF LEUKEMIA TREATED BY THE X-RAY.

Case No.	Type.	Acute or Chronic.	EFFECT OF THE X-RAY ON			Time of Observation under X-Ray.	Present Condition.
			Spleen.	Glands.	Leucocytes.		
1*	Spleno-Myelogenic.	Chronic.	Enormous mass reduced to small size. Recurrence.	None	261,000 to 10,000. Recurrence 250,000 to 9,400	18 months.	Dead.
2	Spleno-Myelogenic.	Chronic.	Much reduced.	None	400,000 to 46,500.	12 weeks.	Improved.
3	Lymphatic.	Subacute.	Much reduced.	Reduced nearly to normal size.	70,500 to 25,000.	10 months.	Dead.
4	Lymphatic.	Subacute.	Not noticeable.	Not noticeable.	80,000 to 64,500.	6 weeks.	Dead.
5	Lymphatic.	Acute.	Not noticeable.	Not noticeable.	69,000 to 299,000.	10 days.	Dead.
6	Lymphatic.	Chronic.	Reduced.	Much reduced.	208,000 to 46,500.	16 months.	Dead.
7	Lymphatic.	Chronic.	Reduced.	Much reduced.	150,000 to 4,200.	5 months.	Improving.
8	Lymphatic.	Chronic.	Reduced nearly to normal size.	Reduced nearly to normal size.	355,000 to 6,800.	8 months.	Improving.

SATURDAY, OCTOBER 1, 1904.

THE VALUE OF CYTODIAGNOSIS IN DISEASE OF THE CENTRAL NERVOUS SYSTEM.

During the last two years a number of articles have appeared, particularly in journals devoted to neurology, dealing with the so-called cytodagnosis. This procedure, which is a natural outgrowth of the differential blood count, consists of a differential count of the cells in an inflammatory exudate, or in one of the natural secretions of the body, as the cerebrospinal fluid. The introduction of a test of this sort is almost invariably followed by a certain number of articles based on an insufficient number or an insufficient variety of cases, and as a result of this false though often very attractive conclusions are reached; and too many of us are too apt to accept the various claims set forth for new methods without the necessary saline flavoring.

In the case of cytodagnosis, the most work has been done on the central nervous system by staining centrifugized cerebrospinal fluid withdrawn by lumbar puncture. It is in diseases of the central nervous system that the procedure has been claimed to be of the greatest value. The main claims, briefly stated, of the majority of French, German and American writers, have been that an increase in the lymphocytes in the cerebrospinal fluid is pathognomonic of a meningeal irritation, and that such an increase is characteristic of the early stages of general paresis and *tabes dorsalis*, and of cerebrospinal syphilis.

In a recent article,¹ Niedner and Mamlock have drawn attention to some of the fallacies which are apparent in the technic and in the interpretation of the results of cytodagnosis as it is now done. As these observers point out, if we are to compare the results of different workers with a test of this sort it is necessary to base all observations on a common technic, and so far this has not been done. A measured quantity of the fluid should be taken; it should be centrifugized in a centrifuge having a given number of revolutions per minute, and should be left in the centrifuge for a given length of time. Further, the method of making spreads, and the method of staining should be uniform, and the technic as a whole should be as simple as possible. The present lack of uniformity of technic makes it difficult if not impossible to compare the results of different authors, and leads different observers to give different figures as normal. Thus French observers state that

three or four lymphocytes in a microscopic field with a magnification of 100 diameters represent the normal, while certain German observers, as Merzbacher, state that under similar circumstances six to eight lymphocytes in the field are normal.

Up to the present the common conditions in which an increase of the lymphocytes in the cerebrospinal fluid has been observed have been general paresis, *tabes*, and syphilis of the nervous system. Occasionally such an increase has been found in other conditions, as herpes zoster, sciatica and parotitis. On the other hand, it has generally been stated that in functional neuroses, epilepsy, senile hemiplegia, cerebral tumor and compression myelitis no increase in the lymphocytes takes place. Niedner and Mamlock studied a large series of cases from von Leyden's clinic to determine whether they could substantiate the reported findings. They conclude that an increase of lymphocytes in the cerebrospinal fluid is not necessarily associated with parasymphilitic affections (*tabes*, general paresis), but that it may be due to any cause producing sufficient irritation of the meninges which lasts a certain length of time. Thus it may be due to intoxication (*lues*, uremia, tetanus), or to mechanical irritation from tumors or other mechanical factors causing cerebral pressure.

Simple irritation of the meninges from injury or disturbances of the circulation is not in itself sufficient to cause an increase in the lymphocytes. As to the value of the test, the authors state that they feel somewhat disappointed. The frequent appearance of lymphocytosis in *lues*, and its not infrequent absence in *tabes*, make its value in the latter disease rather problematical. While the test may be of some value in general paresis, as the lymphocytosis here is quite constant, still the diagnosis in these cases is so seldom in doubt that the test is rather a superfluity than an aid. The impression received by the work of Niedner and Mamlock is that the test has been very much overrated in the articles so far written.

PSYCHOPATHIC HOSPITALS AND CLINICS.

One of the disadvantages with which American alienists have had to contend in the past has been the inability to study and treat the acute insane and milder grades of psychoneuroses under such advantageous conditions as the surgeon and physician enjoy in caring for medical and surgical cases in city hospitals. The acute insane are sent to large state asylums as soon as legal commitment is possible, and the psychoneuroses have never been properly provided for in city clinics. They are not admitted to general medical and surgical hospitals. Strangely enough, they are not often regarded by the admitting authorities as sufficiently ill to require hospital treatment. American cities have as yet provided no special hospital for the proper care of neurologic cases other than a few infirmaries in con-

1. *Zeitschrift für klin. Med.*, vol. liv, Nos. 1-2.

nection with almshouses. The usefulness, even of such provisions, has obviously been sacrificed by the nature of the associations and surroundings of such hospitals.

However, it looks more promising for the future. Ann Arbor and Albany already have their psychopathic wards. The last New York legislature appropriated several thousand dollars for a psychopathic hospital for New York City, and plans of construction are now in preparation. It is interesting to note with what singleness of purpose well-meaning reformers put in operation the state care of the insane. They seem to have entirely overlooked the various economic, therapeutic and scientific principles which were sacrificed in transporting all the insane from the towns and cities into large and only too often inaccessible country district asylums. On the continent of Europe the mistake of caring for the insane so far from their homes was recognized early and was in process of correction long before the state-care movement had become at all general in this country. Thus in the early sixties Griesinger pointed out the urgent necessity of forming small city hospitals and out-clinics for reception and treatment of the acute insane, to supplement the workings of the large district asylums for the chronic cases which were situated quite remote from the populous centers. Its general adoption soon followed. Germany preceded us, therefore, by at least two decades in establishing this type of hospital for the acute insane and psychoneuropathic.

Out-clinics or dispensaries have been in successful operation for several years in the German psychopathic hospitals; indeed, the great majority of the so-called functional neuroses, such as hysterias, epilepsies, chronic neurasthenics and the like, have been treated in this manner. Their ratio in the psychopathic hospitals at Giessen and Kiel has steadily increased. In the first year's opening of the hospital at Giessen in 1896, 6.5 per cent. of the total number treated in the dispensary and wards were of the psychoneuropathic class. In five years it increased to 23 per cent.

In this country the lack of proper facilities for diagnosis and treatment of such cases in general neurologic clinics has often been commented on. Clark and Montgomery¹ have included these essential out-clinic departments in their suggested plans for psychopathic hospitals in American cities. They have arranged ample out-clinic provisions for diagnosis and treatment by electricity, hydropathy, mechanicotherapy, massage and systematized movements. Out-clinics of this kind would be of inestimable value for selection of proper cases for in-ward treatment. They would reduce the fear with which the general public regards such hospitals. They would also result in lessening the necessity for so many private sanatoria which, for economic reasons at least, are only too often impossible for the poor.

THE PASSING OF PRIMITIVE MAN.

The disappearance of primitive man before civilization has been recently discussed in an interesting manner by Dr. F. A. Cook.¹ He says that alcohol and venereal diseases have been largely credited with the result, a conclusion which he questions, though he admits his observation has been limited to the sub-Polar races, the Fuegians, Patagonians, Eskimos and sub-Arctic Indians. He is inclined to credit as an important factor the lack of immunity of these races to the diseases of civilization, which, to civilized man, have, from long familiarity, become comparatively innocuous. The part played by such disorders as measles, mumps, whooping cough and scarlet fever in the destruction of primitive man, was to him a great surprise. Even chicken-pox is a fatal epidemic among the Eskimos, and even more severe among adults than among children. The infant mortality among the Indians is very great, and this he attributes to the introduction of new diseases by explorers, traders and missionaries. Alcohol and venereal diseases come second. Lastly, he considers the destruction of savage ambition and altered conditions of life and environment as important factors leading to physical degeneration, and making the savages ready subjects for tuberculosis.

There is undoubtedly considerable truth in these conclusions. They may certainly be accepted as the deductions of a careful and trained observer in a comparatively limited field. Many will think that he underestimates the influence of alcohol as a cause of degeneration and fatality. There would be little difficulty in exterminating many native tribes by free trade in intoxicants during their hunting season with the consequent results of improvidence and later famine. Such a condition of affairs occurred some years ago on St. Lawrence Island. There is undoubtedly a great deal of truth in his theory of lack of immunity, and this would be an interesting study could it be taken up over a wider field by competent observers. If we could exterminate tuberculosis for many generations and then admit the infection, we might have a similar experience of our own.

The influence of changed environment and of contact with a higher grade of civilization generally, unattended by a higher grade of morals, is also probably underestimated by many observers. We can imagine, perhaps, a similar demoralization occurring in our own race were the presence of a vastly superior class of beings without moral restraint suddenly thrust on us. Mr. Wells' fantasy of the "War of the Worlds," even without the active extermination he portrays, would probably soon be more than realized. There is a vast difference, however, as regards racial vitality in uncivilized man, and, in some sections, with special conditions, primitive man is capable of existing and even flourishing in spite of the demoralization and disease introduced by contact with the whites. Thus in the

1. Suggestions and Plans for Psychopathic Wards, Pavilions and Hospitals for American Cities, by L. Pierce Clark and H. P. Van Montgomery. *American Journal of Insanity*, vol. lxi, No. 1, 1904.

tropics the partial immunity toward malaria of some of the colored races is apparently an adequate defense, and among the Eskimos we might look for a similar partial immunity to evils of crowding and non-ventilation. This may account for the fact reported by Nansen, who has observed that while tuberculosis is not uncommon among the semi-civilized Greenland Eskimo, it is by no means always a rapidly fatal disease with them, but may exist in a readily recognizable form for years without seriously interfering with their ordinary activities and pursuits, and this notwithstanding the exposure that these involve.

Primitive man, however, is rapidly disappearing under all these causes and unfavorable conditions that have been mentioned, together with many others, in most parts of the world. The desirability of careful medical studies among primitive people is, therefore, the more imperative. There is a field of study here which has been too much neglected, and in many cases the opportunity is forever lost. It is to be hoped that medical explorers and even non-medical ones will give it their future attention. It may be that such a study thoroughly carried out would lead to some valuable practical deductions as regards the warding off of disease among civilized races as well.

THE GROWING NECESSITY OF COLLEGE TRAINING PREPARATORY TO MEDICAL STUDY.

For the young man who is planning to fit himself for the practice of medicine there are two possible routes: One, the longer, but admitted by all to be more nearly the ideal, involves the intervention of a greater or less length of time between the completion of the high-school course and the actual assumption of medical study, to be spent in attendance at some college or university; the other is the short cut from high school to medical school, which is recognized as practical by a large number of eminently well-conducted medical schools, although their number is steadily decreasing. There can hardly be a question as to which is the better route. The question that does arise in the minds of many is, however, does it pay to give up from two to four years to college work which, in large part, may have no direct bearing on the study or practice of medicine?

There are two things that are to be obtained in a college course: One is the acquisition of certain knowledge, and this is, perhaps, what the majority of people consider the chief function of any educational institution. The other is the social training, the habit of contact with people of rather better than average bearing and education, the broadening of prospect and the development of ideals; and it is these less material profits of college education that those most familiar with the subject will insist are really the most important. In the nature of things a medical school must be given over almost entirely to the first matter—the

imparting of information. The curriculum of every school is so crowded that there is little opportunity for anything but hard work, and the student's mind has little time for play on any but the topics of his work. The hours for social contact are few, the instruction afforded is essentially narrowing, and the desire for hospital appointments and other immediate rewards holds the attention of the student fast on the one subject. The intensity of concentration and the eagerness for new information that is so characteristic of the medical student is brought out very strongly in those institutions in which medical and undergraduate students occupy the same buildings and grounds. Therefore, the medical student seldom gets much social advantage from contact with his fellow-students, and still less from the faculty, as a rule, and the student who has entered medical work in the immature condition of the high-school boy is bound to lose altogether this benefit that is conferred so well by the college. To be sure, there are some of the most broad-minded, cultured and estimable of the members of our profession who have had never a moment of undergraduate life in their career—some who have not even had a high-school education but these are brilliant exceptions. Most of us must get our polish through contact. Furthermore, it will be generally found that these are the very men who regret the lack of a college education most of all. With the rapid increase in the number of colleges and universities throughout the country, and the great growth among them all, the proportion of college-bred men and women in every community is rapidly increasing, and already they form a very considerable proportion of the generation with which the present-day medical student will live. It is certain that these college-bred people, holding the positions of trust and influence in their several communities, will constitute that portion of the society to which the physician will naturally look for his companionship and associations, and the mere holding of a degree and a title without the necessary breadth of education and culture behind it will not of itself make him acceptable to them. Success consists of a good deal besides a large income, and a professional man who is not socially recognized is seldom happy. No one would be so foolish as to insist that a college education is the *sine qua non* of social and mental success, but we know of no other aid that is so great or so satisfying in after years.

As for the advantages of the college training in the way of the addition of knowledge, there is much that could be said bearing on the relation of a full training in literature, economics and history to breadth of character and the formation of ideals, but there are also many other things of immediately practical nature. First of all should be mentioned the study of French and German, without a reading knowledge of which no student should be at the present day. Then there are the fundamental conceptions of biologic science, and also geology and paleontology, which afford such excel-

lent foundations for the study of human biology and development which every student needs, but which he can not possibly get elsewhere than in college. But of most immediate concern to the teacher in the medical school is the training in methods of laboratory study. High-school laboratory work, when it exists at all, can give little training that is of the same type as should be demanded of every medical student, and affords little conception of the real meaning of the words science and research. Put together in the same laboratory two students, one of whom has had but a high-school preparation while the other has taken laboratory courses in the sciences in any good college, and the high-school student is of necessity handicapped from the start.

THE DIPLOMA-MILL BUSINESS.

According to the newspapers, not less than 20,000 people are labeled doctors of laws, letters, science or theology by diplomas bought from a young man named Farr who is, in his corporate capacity, half a dozen or more colleges and universities entitled to issue diplomas giving high-sounding degrees. If one individual can be all this and distribute 20,000 doctorates up to date, what is the output of the numerous competitors, the Buchanans, the Armstrongs, the Proberts, and all of that ilk who are also in the business? The prospect seems to be that every fool who can spend ten dollars, more or less, may become a doctor of some sort or other. Unearned honors coming cheaply are always in demand by a certain class. Fortunately, in most of the states now there is a legal restriction on medical degrees, and imperfect as the law often is it is far better than it has been.

WOOD ALCOHOL.

At the session of the American Medical Association held last June, the House of Delegates unanimously adopted the following preambles and resolution:

WHEREAS, The employment as beverages of wood spirit or methyl alcohol and its various preparations is known to have been responsible for numerous deaths and many cases of blindness in this country during the past few years; and

WHEREAS, Even the breathing of confined air charged with the fumes of this form of alcohol has been shown to produce blindness, it is

Resolved, That the House of Delegates of the American Medical Association, recognizing the dangerous character of wood alcohol and liquors containing it, believes that it should be placed on the list of poisons. It accordingly urges the proper federal and state authorities to take the necessary steps to protect life and eyesight from its pernicious influences.

At the time this action was taken—on the recommendation of the Section on Ophthalmology—only a preliminary statement was ready for presentation; now, however, the investigations are complete, and we publish this week the first installment of the report of Drs. Wood and Buller¹ on the subject, which confirms all that has been claimed in the preambles and resolutions. To a large extent "Columbian spirits" and other "deodorized" forms of this deadly poison, wood alcohol, are being substituted for the innocuous, or less injurious,

grain alcohol in all sorts of liquid which—legitimately or otherwise—are used by human beings. These include the medicines we use, the perfumes we smell, the condiments, sauces and flavors we employ in cooking, as well as the common intoxicating beverages. Surely, it is high time that the medical profession should voice an emphatic protest against this wholesale poisonous adulteration of food and drink—an adulteration so far confined, by the way, to the American continent—and consider whether the sale of this "deodorized," palatable and attractive poison should not be altogether prohibited.

EXPULSION PENALTY FOR EXTORTION

A German medical society, it is reported, has recently disciplined one of its members for charging extortionate fees. Being consulted by an American millionaire for appendicitis, he recommended an operation and suggested the name of a surgeon. The latter was employed and received a liberal fee. Then the physician in question who was first consulted sent in a bill for \$2,000 for his advisory services. This charge was objected to and a smaller sum offered. The physician then instituted legal proceedings, and had the American arrested and humiliated by being placed in "jail limits"—we presume a sort of unpleasant *quasi* confinement. The matter aroused public attention, and the conduct of the physician was severely condemned by press and public, and his fellow-physicians took the matter up with the result as stated. It is generally admitted by the public, as well as by the profession, that a physician's charges may vary with his professional reputation, and also according to the means of his client. There are high-priced physicians as well as high-priced lawyers, and nothing unethical is recognized in the distinction. Moreover, the scale of charges varies according to standards fixed by medical societies to fit the means of the patients. Practically, there is no limit as to contracts between physician and patient. One is at liberty to receive whatever the other is willing to pay, and one's conscience permits one to receive, and there is nothing unprofessional or unethical in large fees *per se*. When, however, as in this instance, a physician attempts to force by legal means what the public would regard as extortionate demands not corresponding to what is considered the value of his services or opinions, he is liable to receive the tacit, if not the open, condemnation of most of his professional brethren. The occurrence of such affairs and the concomitant public discussion is an unpleasant thing—a sort of scandal on the profession—and probably our German confrères followed the least regrettable course in the matter.

NIELS R. FINSEN.

In the death of Niels R. Finsen in Copenhagen, Denmark, September 24, there passed away one of the heroic figures in modern medicine. In spite of chronic and incurable disease, Finsen, with rare persistence, developed phototherapy on a strictly scientific basis so that it became definitively established as a successful means of cure in lupus vulgaris. He early recognized

1. See page 972.

that if the great forces contained in light ever could be used in the science of practical medicine it would result only from investigations of physical, chemical and biologic nature, together with practical experiments in different diseases. Apparently, his earliest publications concerning light and its action on the animal organism date from 1893. In 1896 the results of his scientific researches led to the establishment in Copenhagen, as the outcome of private and public support, of "Finsen's Medical Light Institute." Subsequently this institute, which soon became known everywhere, was greatly enlarged. In 1899 Finsen began the issue of a series of reports (Meddelelser fra Finsen's medicinske Lysinstitut) in which are published the results of the scientific and practical work of the institute. In the meantime, there appeared important monographs by Finsen in the Danish, French and German languages. Here were considered especially the rôle of the chemical rays of light in medicine and in biology and the treatment of lupus vulgaris by concentrated chemical rays. The report covering the first 800 cases of lupus vulgaris treated at Finsen's institute (November, 1895, to November, 1901) show that 407 were cured, 85 had interrupted the treatment, while 308 were still under treatment. This report may be taken as a model of thoroughness and exactness in dealing with matters of this kind: one is particularly impressed with the carefulness to avoid premature and exaggerated statements as to the value of the method. This is not the time nor the place to give any detailed account of the scientific work of Finsen and his assistants. To Finsen belongs the credit of having placed phototherapy on a firm and scientific basis. But no one must think for a moment that this was accomplished without persistent effort. In reading Finsen's writings and the publications of others working in his institute, one at once finds the keynote to be continuous extension of our knowledge of the action of light on living matter and improvements in the practical application of the chemically active rays. Finsen was ever conservative in his own estimation of the therapeutic powers of light and advanced claims which subsequently proved to be without adequate foundation. In his short but fruitful career, Finsen consistently illustrated that unselfishness and modesty which medical men love to see in their best types. He cared not for personal gain. When he was awarded the Nobel prize in medicine, in December, 1903, he generously turned the money received over to the use of the institute. From whatever side we look at Finsen and his work, there comes only the impression of a noble character.

Medical News.

CALIFORNIA.

Donation for Hospital.—The Pasadena Hospital has recently received an anonymous donation of \$15,000 to be applied to the construction of a new hospital building.

New Buildings for Sanatorium.—Work has been commenced on a two-story building and a bungalow cottage to cost \$30,000 for the Southern California Sanatorium for Nervous Diseases, Pasadena.

Angelus Hospital Association Will Build.—A permit was issued September 16 to the Angelus Hospital Association for

the construction of two fireproof hospital buildings in Los Angeles, to cost \$150,000.

One-fifth of Deaths Preventable.—In the last two years, 28,600 deaths have occurred in the state, of which 5,798, or more than one-fifth, were from preventable diseases, and especially typhoid fever. No case of plague has been reported since February.

Personal.—Dr. Frank S. Woolsey, Berkeley, has been appointed physician of Alameda County, vice Dr. Hubert N. Rowell, resigned.—Dr. Dwight H. Trowbridge, Fresno, has returned from Europe.—Dr. Rae Felt, Eureka, was injured in a wreck on the New York Central Railway at Lyons, N. Y., September 25.—Dr. James H. Todd has been re-elected president of the Oakland Board of Health.

Restrictions of State Health Board.—Dr. Newel K. Foster, Sacramento, secretary of the State Board of Health, in his report to the governor, says that while the law imposes important duties on the board, it bestows little power, as it does not oblige local boards of health to answer interrogations from the state board, does not allow enforcement of proper measures to protect life and health, gives no means for eradicating causes of diseases and epidemics or for the dissemination of information to the people save through the good will of the press.

CONNECTICUT.

Bequest.—By the will of the late Mrs. Ruth Ann Adkins of Winsted, the residue of the estate, after the payment of legacies, is devised to the Litchfield County Hospital. The value of the bequest is about \$15,000.

Infectious diseases were reported during August as follows: Measles, 15 cases in 7 localities; scarlet fever, 44 cases in 17 localities; cerebrospinal fever, one case; diphtheria, 86 cases in 22 localities; whooping cough, 6 cases in 3 localities; typhoid fever, 173 cases in 47 localities, and consumption, 18 cases in 6 localities.

Personal.—Dr. Edward S. Brackett, Hartford, has been appointed surgeon of the schoolship *Philadelphia*, which is about to take a trip round the world.—Dr. Franklin H. Mayberry, East Hartford, has been nominated for state senator.—Dr. L. Z. Skinner, Windsor, has been appointed assistant professor of anatomy in the medical department of the University of Illinois.

August Deaths.—During August 1,362 deaths were reported, 46 less than in the preceding month, 33 less than in August, 1903, and 53 less than the average of August for the five years preceding. This is equivalent to an annual mortality of 17 per 1,000. The principal causes of death were diarrhea, 361; diseases of nervous system, 136; consumption, 123; heart disease, 104; and violence, 86.

GEORGIA.

Personal.—Dr. Thomas H. Hall has been elected city physician of Dublin.

Journals Consolidated.—The editor of *Southern Medicine* announces the consolidation of that journal with *Gaillard's Medical Journal*, beginning with the October issue.

Health Department Appropriation.—Augusta has appropriated an additional sum of \$2,400 for the health department, \$1,200 of which is to be used in betterment of the isolation hospital.

National Guard Surgeons to National Meeting.—The governor has detailed the surgeon general, Col. Joseph A. Guinn, Connors; Majors Floyd W. McRae, Atlanta, Joseph G. Jarrrell, Savannah, Olin H. Weaver, Macon, Charles J. Montgomery, Augusta, and Andrew H. Hilsman, Albany, and Lieutenants James M. Kelly, Griffin, Guy Chappell, Dawson, John M. Spence, Camilla, and Sam H. Greene, Atlanta, as delegates to the Association of Military Surgeons of the United States, which meets in St. Louis, October 10 to 15.

IDAHO.

Society Meets.—The South Idaho District Medical Society met at Idaho Falls, July 2.

Hospital at Coeur d'Alene.—Plans are nearly completed for a hospital building to be erected at Coeur d'Alene lake on the water front, by Dr. W. W. Webb.

Smallpox Death.—A patient who had been ill with smallpox for two weeks at Mahon's Mill on Lake Creek, died, principally, it is said, from want of proper care and attention.

In Prison for Shooting.—Dr. James W. S. Emerson, Milner,

has been sentenced to two years' imprisonment in the state penitentiary for shooting and seriously wounding his wife last autumn.

ILLINOIS.

Hospital Incorporated.—Baptist Hospital, Woodstock, has been incorporated, with a capital stock of \$10,000.

Personal.—Dr. Howard Kelly, Baltimore, was the guest of honor at a dinner in Peoria, September 22, at which Dr. Clifford N. Collins presided.—Dr. Elijah A. Morgan, Deatur, has retired from practice on account of ill health.

Hospital Planned for Oak Park.—A hospital "built by Oak Park people, and managed by Oak Park people for Oak Park people" is planned. Dr. John W. Tope is the chairman of the incorporation committee. The projectors expect to erect a building to cost \$125,000, with separate isolated and maternity buildings.

Illinois Suitable for Consumption Cure.—The Illinois State Board of Health has issued a third revised edition of its circular on the "Cause and Prevention of Consumption," which was published in July. In this circular Illinois is commended as a suitable place for the treatment of consumption, and attention is directed to climatic conditions, elevation and soil, which is equally as good as, and in some instances superior to those found at the famed tuberculosis sanatoria of Massachusetts, New York and Pennsylvania. The sections on the care of the consumptive, prevention of consumption, and consumption in schools, contain much new information. Within the last few weeks \$10,000 has been offered to the board, to be utilized in the construction of a consumptive hospital.

Chicago.

Requests to Hospitals.—By the will of Mrs. Elizabeth G. Kelly the Home for Incurables receives \$60,000; the Presbyterian Hospital, \$25,000, and St. Luke's Hospital a liberal sum, the amount of which is not yet announced.

Personal.—Dr. George F. Butler has severed his connection with Alma Sanitarium and will resume practice in Chicago.—Dr. John L. Sweeney has returned from Europe.—Dr. and Mrs. Daniel R. Brower have returned from the west.—Dr. Norval H. Pierce has returned from a summer in Europe.

Mortality for the Week.—In the week ended September 24, 457 deaths were reported, 14 more than in the previous week, and 41 less than in the corresponding week of 1903. This is equivalent to an annual death rate of 12.36 per 1,000. Acute intestinal diseases caused 81 deaths; consumption, 63; violence, 42; heart disease and Bright's disease, each 34, and pneumonia, 32.

Antitoxin Stations Opened.—The department of health has established antitoxin stations at 7 drug stores on the north side; 14 on the south side; and 19 on the west side, at which diphtheria antitoxin can be obtained at the following prices: 1,000 units 75 cents, 2,000 units \$1.25, 3,000 units \$2.25. The department supplies culture outfits and makes a diagnosis of diphtheria free for all physicians who apply. They advise all physicians to make a culture and send it to the laboratory in every case of "sore throat," whether they suspect diphtheria or not, "because it is well known that it is practically impossible to diagnose diphtheria clinically in every case. If a child dies of diphtheria one of two parties is directly responsible—either the parents in not calling in a physician soon enough, or the physician for not making the correct diagnosis and giving antitoxin early enough in the disease."

Summary of Smallpox in Chicago.—During the last six years 1,241 cases of smallpox have been sent to the Chicago Isolation Hospital. Of these 1,114 never had been vaccinated; 127 had some sort of a scar said to have been of a vaccination in early life. None of these with the old marks had ever been re-vaccinated. Three experienced physicians examined these persons for evidence of vaccination, and the figures are absolutely reliable. These 1,114 cases came from the remnant of unvaccinated persons. It is probable that 90 per cent. of the people of Chicago are vaccinated, and from this source came only 127 cases, while from the remaining 10 per cent. 1,114 cases were sent to the hospital. Last year 389 patients with smallpox were sent to the hospital, 102 of whom were unvaccinated children under the school age of 6 years, 14 of whom died. This year, out of 161 cases, 52 are unvaccinated children under the school age. The children under school age are not required by law to be vaccinated, which accounts for these babies falling victims to this face-scarring and death-dealing disease. The unvaccinated children under 6 years of age, and the unvaccinated new

arrivals in the city who have found employment without being required to produce a certificate of vaccination, furnished nearly all the victims. The disease has changed recently to a more virulent form, four deaths having occurred in the last fifteen days. There were but three deaths in the previous eight months. Evidence that no recently vaccinated person ever contracts smallpox is the fact that during the last six years the most recently vaccinated person to be sent to the hospital with smallpox had an imperfect mark made thirteen years previous to the attack.

MARYLAND.

Baltimore.

Opening of New Surgical Building.—The new surgical building of Johns Hopkins Hospital will be dedicated with elaborate ceremonies October 5.

College Opens.—The twenty-fourth annual course of instruction at Baltimore Medical College was opened, September 20, with an address by Dr. George Reuling.

Teachers to Examine Children.—The board of commissioners has instructed the teachers to examine the arms of all children under them for vaccination marks and report to the health department.

Need Isolation Hospital.—A fatal case of diphtheria, in which a woman was without medical attendance for a week, and was dependent on her neighbors for sustenance, again emphasizes the need of a hospital for infectious diseases.

Personal.—Dr. William Lee Howard has returned from abroad.—Drs. Isaac E. Emerson and Smith Hollis McKim arrived home from Europe September 18.—Dr. and Mrs. Charles Whittier Young will sail October 25, from San Francisco, for China, where Dr. Young will be a medical missionary.

Defects in State Lunacy Laws.—Attention is drawn to numerous defects in the lunacy laws of Maryland. Dr. Preston, secretary of the lunacy commission, says the law is unconstitutional. All that is necessary to commit any one to an asylum is the signature of two physicians to a certificate of insanity. There is no identification of the signers, no affidavit is required. "It would be an easy matter for a person to procure a blank certificate and forge the signatures of two reputable physicians to it; or he need not do that, but simply inscribe 'M.D.' after any name. I know of no instance in which this has been done, but the mere fact that it is possible under the present law is sufficient warrant for an amendment to the law." Again, the law says a person so committed "shall be confined until released by due process of law," which is legally imprisonment for life, as there is no process of law in the Maryland statute books by which an insane person can be released. The commission has endeavored to get around this by "paroling" patients who have recovered, but there is no legal warrant for it, as there should be. The last legislature passed a bill by which the state, in January, 1905, will assume the care of all insane institutions, except those in private asylums. By this law all pauper lunatics will be removed from county jails and almshouses to one of the state asylums. Dr. Preston proposes that commitment shall be made only on an order from a court of record. The judge is to order an inquiry to be made into the alleged insanity by two competent physicians. If they find insanity present they shall certify so under oath, after which the finding is to be approved by the judge, who, if he thinks proper, may order a new examination by physicians or jury, or may summon the parties before him. In case of emergency a patient may be admitted to an institution for three days, during which the examination is to be made as above. The secrecy with which the incarceration of an alleged insane person is permitted under the present statute is further said to be one of the weightiest arguments against the law, as it practically legalized kidnaping.

MINNESOTA.

Ames May Go Free.—The county attorney of Hennepin County has made a motion for a nolle of the ten indictments against Dr. Albert A. Ames, formerly mayor of Minneapolis.

August Vital Statistics of Duluth.—During the month 72 deaths and 114 births were reported. Typhoid fever caused 5 deaths; tuberculosis, 6; and violence, 16. No death from contagious disease was reported.

Anti-Spitting Crusade Extended.—The health commissioner of Minneapolis, after having conducted a successful campaign against spitting on sidewalks, has now caused to be placed in

the galleries of all the theaters of the city huge placards reading, "Don't Spit on the Floor. Fine, \$5."

Hospital Notes.—The new emergency hospital at the state fair grounds, secured by the efforts of the Woman's Medical Society of Minneapolis, contains 3 wards, an operating room and several private rooms.—A thoroughly-equipped hospital was recently opened at Cass Lake.—Work on the State Sanatorium for Consumptives at Walker will be begun soon. During 1904 and 1905, \$25,000 is available for the sanatorium.

NEW YORK.

Medical Staff Changes in Utica.—At the quarterly meeting of the medical staff of Utica General Hospital, Dr. Raymond L. Baker was elected a member, vice Dr. Thomas J. Bergen, resigned.

Medical Colleges Open.—The medical department of the University of Buffalo opened for the session of 1904-05 September 26.—Albany Medical College reopened September 20. Dr. Richard M. Pearce delivered the introductory address.

For Nassau Hospital.—A charity fair was held at the home of Mr. and Mrs. Clarence Mackay at Roslyn for the benefit of Nassau Hospital. Mrs. Mackay has recently presented this hospital with a new ambulance complete in every detail and also with a home for nurses.

Faculty Changes.—The following faculty changes in Albany Medical College have occurred: Dr. Richard Mills Pearce has succeeded Dr. George Blumer as professor of bacteriology and pathology; Dr. H. Judson Lipps has been made clinical professor of obstetrics; Dr. Spencer L. Dawes, adjunct professor of materia medica; Dr. Wilfred S. Hale, demonstrator of anatomy and assistant curator of the museum; Dr. Edwin McD. Stanton, lecturer on histology; Dr. Howard E. Lomax, instructor in anatomy; Dr. Charles K. Winne, Jr., instructor in bacteriology; Dr. George G. Lempe, instructor in anatomy; Dr. Donald Boyd, demonstrator in anatomy of the nervous system; Dr. Edward F. Sibley, instructor in clinical microscopy, and Dr. Silas L. Filkins, prosector of anatomy.

Buffalo.

Mercy Hospital Opened.—The new Mercy Hospital was opened with appropriate ceremonies September 24. Bishop Cotton made an address.

Returned.—Dr. W. Harry Glemay has returned from Muskoka.—Drs. George W. York and Charles H. Stadlinger have returned from California.—Dr. James W. Putnam has returned from St. Louis.—Dr. Bernard Bartow has returned from Wanakah.

Crusade Against Insanitary Bakeries.—Health Commissioner Greene has started a crusade which has for its object the bringing of every bakery in the city into a sanitary condition. Hereafter every baker will be required to obtain a permit from the health department before securing a license from the mayor. This will bring the bakeries under direct supervision of the health department and the department will thoroughly inspect the bakeries at regular intervals.

New York City.

Dinner to Semon.—Invitations have been issued to a dinner to be given by the Section on Laryngology of the New York Academy of Medicine on November 1 to Sir Felix Semon of London.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended September 24, 305 cases of tuberculosis, with 145 deaths; 224 cases of diphtheria, with 16 deaths; 93 cases of typhoid fever, with 21 deaths; 58 cases of scarlet fever, with 4 deaths; 43 cases of measles, with 4 deaths; 2 cases of smallpox, 3 of variella, and 19 deaths from cerebrospinal meningitis.

Protest Against Carbolic Acid Ordinance.—Health Commissioner Darlington has given a hearing to a number of druggists on their protest against the new ordinance forbidding the sale of carbolic acid in other than a weak solution without prescription. The druggists claim that it would not lessen the number of suicides, as such persons would seek some other remedy, and that the five per cent. solution would be as deadly in effect if it were taken in sufficient quantity. Dr. Darlington declared that his investigations of carbolic acid suicides for the past several months showed that in 42 per cent. of the cases the acid was procured in drug stores without any difficulty.

OHIO.

Dr. Scott Stricken.—Dr. Xenophon C. Scott, Cleveland, was stricken with apoplexy while making a professional call, September 15, and is in a serious condition.

Hyndman's Successor.—Dr. Albert V. Phelps has been chosen to succeed the late Dr. James G. Hyndman as secretary of the faculty of Ohio Medical College, Cincinnati.

Memorial to Dr. Buechner.—The Mahoning County Medical Society devoted its meeting of September 20 to a consideration of the life of its late honored member, Dr. William L. Buechner, Youngstown.

Personal.—Dr. Amanda H. Miller, Cleveland, has returned from Europe.—Dr. John P. Kenny, Youngstown, is ill with diphtheria.—Dr. Frederic W. Lamb has been appointed to succeed Dr. William Muehlberg on the staff of the Cincinnati City Hospital.—Dr. Charles L. Harmer has resigned from the staff of the Massillon State Hospital, Drs. J. D. O'Brien and D. E. Harris have been promoted from internes to assistant physicians, and Dr. H. F. Vaughan has been promoted from druggist to assistant physician.

Colleges Open.—Dr. Starling Loving, Columbus, opened the fifty-eighth session of the Starling Medical College with a clinical lecture, September 14. Additions to the teaching force are: Dr. Sissons in the department of anatomy; Dr. Clement Jones in biology and embryology, and Dr. Sterling B. Taylor, demonstrator of anatomy, vice Dr. Louis Kahn.—Toledo Medical College opened for its twenty-fourth annual session, and its first session as a department of the Toledo University, September 22.

PENNSYLVANIA.

Personal.—Dr. John P. McCord, Pittsburg, has been elected surgeon general of the Union Veteran Legion.—Dr. and Mrs. James M. Anders, Philadelphia, have returned from an extended visit in Europe.

Smallpox in Pottstown.—Smallpox continues and is apparently on the increase in Pottstown, and general vaccination is to be carried out. An order has been issued preventing all pupils who have not been successfully vaccinated from entering the public schools.

Diphtheria in Chester Schools.—Since the opening of the public schools in Chester several cases of diphtheria have been discovered among the pupils. The disease is scattered throughout the city, and the authorities claim that the epidemic is due to weather conditions, and not to any sanitary defects in the buildings.

Asks Increased Powers.—The State Board of Medical Examiners has prepared a bill which will be introduced at the next session of its legislature, giving the board the power to cancel any license issued by it whenever it appears that the holder is not a fit person to be so licensed because of lack of education or unsatisfactory professional and moral character.

New Pittsburg Hospital.—St. Joseph's Hospital, Pittsburg, was opened for public inspection September 20. The first floor of the building is devoted to the administrative department, dining room, kitchen, etc.; on the second floor are the medical and surgical wards and the operating room, and the third floor is used for dormitories for the nurses and resident hospital staff. The staff consists of Drs. Otto Gaud, John P. Saling, M. L. Schoenfeld, Benjamin B. Wood, Alexander R. Hampsey, Thomas P. Cochran, Charles H. Hertzog, Christopher C. Hersman and G. Arthur Dillinger.

Philadelphia.

Public Baths.—The 16 public bath houses maintained by the municipality have been closed for the season. During the season 4,725,142 persons, including 3,525,736 boys, 1,072,941 men, 98,952 girls, and 27,513 women made use of the baths, an increase of 734,525 over the bathers of last year.

Smallpox Hospital Closed.—The smallpox building of the municipal hospital has been closed and thoroughly fumigated. This is the first time in five years that the building is without an occupant. The freedom of the city from the disease is attributed to universal vaccination, and this is to be continued by house-to-house visitations during the entire winter.

Brunton and Liebreich in Philadelphia.—Sir Lauder Brunton, F.R.S. London, formerly lecturer on therapeutics in St. Bartholomew's Hospital, London, and Prof. Dr. Oscar Liebreich, professor of pharmacology in the University of Berlin, addressed the students of Jefferson Medical College, Friday, September 30, and were entertained at dinner by Dr. Hobart A. Hare in the evening.

Health Report.—The typhoid situation is much improved. The number of new cases reported for the week was 97. This is a decrease of 37 over the preceding week. In all 186 cases of contagious disease were reported, with 23 deaths, as compared with 234 cases and 27 deaths for the previous seven days. The general death rate remains low, and the deaths from all causes for the week aggregated 401, a decrease of 7 from those of last week and a decrease of 9 from those of the corresponding period of last year; 51 deaths resulted from tuberculosis.

Medical Colleges Open.—The medical department of the University of Pennsylvania opened for its 139th session September 30. The exercises were held in the new laboratory building, and Dr. John H. Musser delivered the address.—Hon. William Potter, president of the board of trustees, delivered the address at the exercises, which marked the opening of the 80th annual session of Jefferson Medical College, which were held in the new college building, September 26.—The Medico-Chirurgical College of Philadelphia held its 23d annual opening exercises September 28. Dr. Judson Daland delivered the address of the evening.—The 55th session of the Woman's Medical College of Pennsylvania was opened September 21. Dr. Clara Marshall, the dean, delivered the opening address.

TENNESSEE.

College Opens Later.—Tennessee Medical College, Knoxville, will open for the year, November 1, a month later than usual.

Epidemic Disease.—There are three cases of smallpox in Grundy County at Coalmont. All necessary precautions have been taken.—Sumner County is reported to have an epidemic of scarlet fever. Three cases have been found at Portland, 2 at Fountain Head and 9 at Grabell, with one death. Schools have been closed.

Personal.—Dr. William A. Duncan, Nashville, has passed the examination for admission to the medical department of the Army, and is ordered to report for duty in Washington, October 1.—Dr. Z. D. Massey, Sevierville, is unopposed as candidate for state senator from the fourth district.—Dr. John P. Bates, St. Bethlehem, has been appointed a member of the sanitary staff of the Isthmian Canal Commission, and left for his post of duty, September 20.

TEXAS.

Personal.—Dr. Joseph S. Wooten, Austin, is seriously ill with typhoid fever.—Dr. Thomas M. Colley, a retired physician of Palestine, was run over by a buggy, September 15, and seriously injured.

Yellow Fever Kept Out.—The U. S. Public Health and Marine-Hospital Service and the state health authorities of Texas have succeeded in preventing the introduction of yellow fever across the American border from Mexico. Last year the disease managed to get into some of the American towns on this side of the border. New Orleans quarantined against a number of Texas points, and the state health boards of a number of southern states took the matter up. The work this year has been directed toward extermination of mosquitoes along the border, and has been quite successful. Mexicans and Americans have joined in doing all they could to prevent yellow fever getting a foothold in this country this year. So far there has not been a single case in the country.

WASHINGTON.

Tacoma's Health.—During August 54 deaths occurred, equivalent to an annual death rate of 9.96 per 1,000. Three cases of consumption, 4 of smallpox, 3 of measles, 20 of typhoid fever, and 2 of diphtheria, were reported during the month.

Medical Building for Seattle.—Local physicians and capitalists are to erect a ten-story building, to cost \$200,000, to be occupied exclusively by physicians, and to be known as the Medical Building. The lower floor will be occupied by a prescription drug store and a medical supply house.

School Children Inspected.—For the first time in the history of Everett, through inspection of school children was made, September 7, by physicians of the department of health. Two suspicious cases were found, and the children sent home.—Medical inspection of Seattle school children began September 6.

WISCONSIN.

Healthy Milwaukee.—During August 330 deaths were reported, equivalent to an annual death rate of 11.95 per 1,000.

Tuberculosis caused 30 deaths; organic heart disease, 29; violence, 17, and diarrheal diseases, 75.

Physician Enjoined.—Dr. L. W. Zochert, Hingham, has won his suit against Dr. J. H. Blekking, of that village, whose practice he recently bought out, with the condition that Dr. Blekking would not practice medicine in neighboring towns. The latter resumed practice, however, and Dr. Zochert brought suit against him. The judge granted an injunction against Dr. Blekking.

Milwaukee Colleges Open.—Milwaukee Medical College opened for the first session of its second decade September 20. Dr. William H. Earles delivered the address of welcome, and Dr. William G. Doern, formerly of Fort Madison, Iowa, the newly-elected professor of anatomy, the formal address of the evening.—The opening exercises of the Wisconsin College of Physicians and Surgeons were held September 20. Dr. Arthur J. Patek delivered the address to the matriculants.

Health Teacher Fined.—"Dr." Mak, claiming to hail from Colorado, but who also says he has been a "health teacher" in Wisconsin for many years, was fined \$50 and costs, or sixty days in jail, September 3, on the charge of practicing without a license in Ashland. The sentence was suspended twenty-four hours, to give him time to get out of town. With a view, however, of protecting the citizens of Wisconsin, notices have been sent to cities throughout the state notifying the authorities to be cautious and to see to it that "Dr." Mak does not attempt to practice medicine in their vicinity.

GENERAL.

Mississippi Valley Medical Association.—The thirtieth annual meeting of this society will be held at the Grand Hotel, Cincinnati, October 11-13.

Hospital for Manila.—The Board of Health of Manila and the Secretary of the Interior have approved plans for a building to be used as a civil hospital, on the grounds on Calle Padre Faura, known as the exposition grounds.

American Neurological Society.—At its annual meeting at St. Louis this society elected the following officers for the ensuing year: President, Dr. Z. W. Spiller, Philadelphia; vice-presidents, Drs. Philip Zenner, Cincinnati, and William Lullard, Boston; secretary, Dr. T. M. Hammond, New York City. Philadelphia was selected as the meeting place for 1905.

New Hot Springs.—The United States government is preparing to spend \$600,000 in improving the reservation and park at Sulphur Springs in the Chickasaw nation, I. T., for the purpose of making a second Hot Springs similar to the famous Arkansas resort. It is to be maintained by the government in the same manner as is Hot Springs, Ark., but will be even more beautiful and picturesque. There are three groups of springs and abundant fresh water of good quality in sufficient volume for city water supply.

Sanitary Conditions in Panama.—An interesting feature of the sanitary work of the canal zone consists of what is known as "mosquito engineering." Owing to the heavy and intermittent rains, anopheles abound. Breeding places have been found in the Ancon grounds at Colon, where the hospital is situated, and all the collections of water contain the larvæ. One of the worst localities in Culebra, where the actual work of excavation is going on and malaria is very prevalent among the laborers. In order to prevent smallpox an ordinance regarding vaccination has been promulgated by the chief medical officer.

Luncheon to World's Fair Visitors.—A luncheon was tendered the delegates of the biologic and medical sections of the International Congress of Arts and Science by the faculty and staff of teachers of the medical department of Washington University, Sept. 21, 1904. Among an attendance of 100 the following eminent men participated: Theobald Smith, Harvard University; Oskar Hertwig, Berlin; Yves Delage, member of the Institute of France; Wilhelm Waldeyer, Berlin; S. J. Meltzer, New York; Max Verworn of Göttingen; Pierre Janet, College de France, Paris; Morton Prince of Boston; William Osler of Johns Hopkins; William T. Councilman of Harvard; William T. Sedgwick, Massachusetts Institute of Technology; Ronald Ross, Liverpool; Ludvig Hektoen, Chicago University; Johannes Orth, Berlin; Sir Lauder Brunton, London; Frederiek C. Shattuck, Harvard; T. Clifford Allbutt, Cambridge; William S. Thayer, Johns Hopkins; L. F. Barker, Chicago; Shibusaburo Kitasato, University of Tokio; James J. Putnam, Harvard; Charles L. Dana, Cornell University; Edward Jackson, Denver; George M. Gould, Philadelphia; Sir Felix Semon, London;

Theodor Escherich, Vienna; Abraham Jacobi, New York; John H. Musser, Philadelphia; William B. Northrup, New York; R. A. Reeves, Toronto; William H. Welch, Johns Hopkins.

Cancel Charter of a Fake Medical College.—On two or three occasions THE JOURNAL has referred to a diploma mill that has been in active operation in Guthrie, Oklahoma, under the title of "The Twentieth Century Physio-Medical College." Last week a suit was filed in one of the district courts of Oklahoma Territory by the attorney general of the territory against this college to have the charter canceled. The petition for the revocation of the charter states that the concern was organized by H. Warner Newby, C. A. Newby and M. E. Newby, and that it was for the purpose of carrying on an educational institution for the conferring of degrees, etc.; "that instead of conducting the institution as a medical college it has been fraudulently used for illegal means of issuing diplomas, and that instead of issuing these as a result of a legitimate course of study, the diplomas were sold at wholesale." The institution was at one time sending out circulars, not only from Guthrie, but from a little town in Pennsylvania, and through the efforts of THE JOURNAL the postal department undertook to get a case against it, but those connected with the Pennsylvania end of the concern discovered that they were being investigated and stopped. Beside the Twentieth Century Physio-Medical College, the same individuals were conducting the "Twentieth Century Health Association," which, according to their circular, was incorporated under the laws of Oklahoma. Of this concern Calvin D. Gully was president, and H. Warren Newby secretary. Ostensibly, this association was organized "to advance the cause of liberal medicine and the mutual protection of members of our association, and to form a stronger combination, where all can be benefited and have legal protection wherever they wish to go." The real object, however, appears farther down in the circular, where it is stated that the shares are \$10.00 each, and each member of the association holding one share "will receive a large, handsome certificate, with a beautiful seal and ribbons, which will be a fine ornament to your office. We wish the co-operation not only of the physicians of the association, but every healer and every good citizen in the country. . . . Every one who sends \$10.00 will receive one of these handsome certificates, 19x28 inches, as fine as any diploma you ever saw." To show the connection of the Twentieth Century Health Association and the concern against which legal steps are now being taken, a footnote in the circular says: "Graduates of the Twentieth Century Physio-Medical College, Guthrie, O. T., can practice anywhere in the United States."

CANADA.

Hamilton Supports the National Sanitarium.—The Hamilton Branch of the National Sanitarium Association has recently contributed \$1,000 toward the maintenance of patients in the Hamilton and Wentworth County Pavilion of the Muskoka Free Hospital for Consumptives. This makes \$4,000 received from Hamilton altogether for the support of their consumptive poor.

Personal.—Sir Lauder Brunton was recently the guest of Professor McPhedran of the University of Toronto.—Prof. William Osier has been visiting in Montreal and Toronto.—Dr. Charles O'Reilly, medical superintendent of the Toronto General Hospital, has been elected vice-president of the Association of Hospital Superintendents.—Dr. Brefrey O'Reilly, Toronto, has been appointed surgeon on the C. P. R. steamship *Tartar*, and has gone to Vancouver to assume his new duties.—Dr. H. A. Bruce, one of Toronto's leading surgeons, and who was recently operated on for appendicitis, is rapidly recovering.

To Quarantine All Inebriates.—A meeting of those interested in the treatment of inebriates was held at Government House, Toronto, September 19, Premier G. W. Ross being in the chair. Dr. T. D. Crothers, Hartford, Conn., delivered the principal address, outlining a system for the care and treatment of inebriates. Dr. A. M. Roseburgh, Toronto, told what had been done in Toronto and the province of Ontario. Professor McPhedran of the University of Toronto introduced a resolution to the effect that the time was now ripe for the formation of a society for the reform of inebriates. This was carried and another meeting will be held soon to organize.

Vancouver Hospital.—The report of the house surgeon of the Vancouver General Hospital for August shows that there were 58 in residence at the beginning of the month, and that 37

were admitted during the month. Eighty-one were discharged as cured, three died and sixty-one remained at the end of the month. The number of hospital days was 1,810. The special committee appointed regarding the medical staff reported as follows: That the active staff be composed of 12: Drs. Johnston, S. J. Tunstall, W. D. Brydone-Jack, Weld, Langis, Poole, Drier, Monro, Boyle, R. E. McKechnie and Mills, with one to be appointed by the directors. The following will constitute the consulting staff: Drs. D. H. Wilson, Lefevre, McGuigan, Carroll and Underhill.

Montreal General Hospital.—The regular quarterly meeting of the Montreal General Hospital was held last week, when it was decided to alter the constitution so as to leave the medical board free to engage the officers of the resident medical staff from outside of the British dominions. The clause now reads: "No person shall be eligible as resident medical officer unless he is a graduate or licentiate in medicine of some university or college approved by the medical board." The following is the medical staff for the ensuing year: Drs. J. L. Robinson, J. C. Fyche, W. G. Bicker, J. A. Nutter, L. L. Reford, W. W. Kerr, H. G. Wood, R. B. Forbes, A. C. Rankin and W. E. Ainley. Dr. J. Alex. Hutchison read the medical report for the past quarter which showed that 781 patients were treated to a conclusion. There were 67 deaths, of which 26 occurred within three days of admission, making the mortality for ordinary hospital cases 5.5 per cent. In the out-door departments there were 9,072 consultations.

FOREIGN.

Sanitation in Mexico.—President Diaz, in his annual message, reports the gratifying result of the sanitary campaign against yellow fever, and states that there has been no recurrence of the disease in epidemic form during this year.

Spanish Red Cross Society.—It is reported that the Spanish Red Cross Society voted to send 25,000 pesetas (\$4,750) to aid the Japanese branch of the society. It was proposed to send an equal amount to the Russian branch, but the proposal was rejected almost unanimously.

Gen. Kuropatkin's Gifts to Medicine.—The Military-Medical Academy at St. Petersburg has recently installed a portrait of its honorary member, General Adjutant Kuropatkin, in the main hall as a token of gratitude for his gifts. The academy owes to him the remodeling and enlargement of several of its scientific departments and institutes.

Bubonic Plague.—A recent issue of the public health report of the Marine-Hospital Service records cases of plague in widely separated localities. The disease is present in several towns in Cape Colony and in other parts of Africa. An outbreak of plague is reported from Brazil; in Rio de Janeiro ten new cases were reported in one week.

Public Disinfection in Spain.—A decree has just been issued in Spain ordering undertakers to disinfect the room after a death. The *Siglo Medico* comments on the importance of the decree, especially for the homes of the poor, as the neighbors flock to the funeral, unmindful of danger even in cases of diphtheria, smallpox, tuberculosis, measles or other disease. The authorities order that the disinfection shall be undertaken as soon as the undertakers are notified. Our exchange, however, expresses the fear that the decree will be practically a dead letter, like so many of its predecessors.

The German Training School for the Disinfection Service.—The authorities in Prussia organized last year a number of training schools to fit persons for the public disinfection service. Fourteen have been in operation, each giving a course of at least nine days altogether, and restricting the students at each course to ten. Sixty courses have been given in all, with a total attendance of 601; 585 have passed all the tests and been duly qualified as "graduate disinfectors." The authorities have been so much pleased with the results accomplished that they are urging physicians to call the attention of suitable persons to these courses and advocate their attendance. It is hoped that every district will have one or more of these expert disinfectors residing in it. Special courses for nurses are also planned. It is found that the disinfection service has gained immensely in efficiency in the hands of the graduates of these schools.

To Divert the Young from the Medical Profession.—A circular has been sent by the organized medical chambers of Germany to the high schools, warning the graduates from entering on the study of medicine. A number of these circulars were thus placed in the hands of the principals of 482 academic and

131 technical high schools, with the request that they would distribute them among their pupils. The overcrowded condition of the profession is set forth and the pecuniary stress of the majority of the members, due to overcrowding, to contract practice and to the lack of legislation against the irregular practice of medicine. The circular further cites statistics to show that 31 per cent. of all the physicians in the Brandenburg-Berlin district have an income of less than \$750. In Berlin alone more than \$5,000 had to be distributed to needy physicians during 1902, and in Bavaria 23 physicians in 1902 and 20 in 1903 had to be assisted. In 1901, 138 physicians, 1,387 physicians' widows and 399 orphans were partially supported, and many others who needed assistance refrained from applying for relief. The Berlin Medical Chamber often has occasion to help needy physicians or their widows to obtain positions in libraries or the like. On the other hand are to be considered the scant consideration accorded to the physician in these days and the hardships of a doctor's life. "In addition to all this," the circular concludes, "long years must pass after entering the university before the candidate for the medical profession can even begin to support himself by his practice."

Correspondence.

The Danger of Giving Certificates of Physical Disability to Beggars.

MUSCATINE, IOWA, Sept. 26, 1904.

To the Editor:—A few days ago a man came into my office and asked that I give him a certificate as to the condition of his heart. He told me that he was on his way west to his family and that he was out of money, in a serious condition and was soliciting aid. I examined him and diagnosed aneurism of ascending aorta with mitral insufficiency. He stated that his trouble dated from last February, and that he had been before the medical class at Ann Arbor, Mich., and some other college, and had been told that he could not live long, and had certificates from a number of physicians in good standing. His case was so interesting from a medical standpoint, per auscultation, that I called in a nearby colleague, Dr. A. J. Oliver, who examined him and concurred in my diagnosis, and we signed a certificate to the effect that he had a serious circulatory lesion, but we made no recommendation for charitable assistance. He thanked us for the certificate and went out on the street, where he had a phaeton with a couple of pillows to prop him up and a boy to drive him about. He would stop in front of a business house or office, call out the proprietor, tell him his hard luck story, show his certificate and solicit cash. In this manner he worked the business district with excellent success until he was found to have forged a prominent business man's name to his subscription list for the influence it would have, and the police ordered him out of town. We, of course, were questioned as to our motive in giving him a certificate. While the man is physically a wreck his charitable motive appears questionable. He certainly would not have to solicit in many places as successfully as here until he could travel across the continent in a parlor car. Is he a charitable fraud? He gave his name as Z. V. Good and is a man about 40 years of age, with a conspicuous scar over left orbital bone.

T. F. BEVERIDGE, M.D.

[NOTE:—Newspaper accounts show that this man operated the same scheme in Cedar Rapids.—Ed.]

Life Insurance Examinations.

DES MOINES, IOWA, Sept. 20, 1904.

To the Editor:—In the issue of September 3 Dr. O. A. Rea mildly rebukes the Des Moines physicians for adopting a fee-bill providing for minor charges of \$2 for day visits while a minimum of only \$2 is charged for life insurance examinations.

Permit me to say that I believe his conclusions regarding low fees for life insurance examinations are well founded. A typographical error, however, made the item read \$2 to \$5 for day visits, instead of \$2 to \$3, as provided.

The doctor's remarks might lead one to believe that the fees for life insurance examinations have been reduced, which

is far from being true. On the other hand, the minimum fee has been advanced 100 per cent. A number of fraternal societies doing business here, and in other states, have a fixed rate of \$1 per applicant, which includes, beside a general examination, a chemical urinalysis. Some certificates of health have been issued by physicians to certain societies for even less than \$1, which all must admit is deplorable in the extreme.

While I would not compare the service of the physician to his patient in a matter which concerns the health, or even the life of the latter, to the business proposition relating to a life insurance policy, as does Dr. Rea, it is, nevertheless, true, as the doctor remarks, "heneath the dignity of the profession of medicine" to accept the paltry fees proffered by certain societies and corporations for medical examinations on which the very life of the institutions depend.

A. P. STONER, M.D.

The Medical Profession and the French Chamber of Deputies.

PARIS, Aug. 28, 1904.

My previous letter from here related chiefly to the medical profession as represented in the Senate of France. I have since had an opportunity to investigate some of the facts relative to similar representation in the Chamber of Deputies. This is the popular branch of the French Congress: its members are elected by direct and universal suffrage; each deputy must live in the arrondissement from which he is elected, and, consequently, can not represent two constituencies at the same time, and each chamber, or legislature, as it is called in France, is elected for a period of four years. The basis of representation is one for each 100,000 inhabitants, with an additional representative for each additional 100,000 or fraction thereof. In such instances an arrondissement is divided into circumscriptions like that of Dordogne, for instance, which sends six deputies. The body thus chosen consists of 561 members, of which, in the present legislature, fifty-one are representatives of the medical profession.

It is very interesting indeed to study this body of professional men, particularly when one object of that study is to compare the French with the American profession in their relation to the public life of the respective countries. The first fact, by no means a surprising one, that impresses the student of political affairs in France is the marked evidence of individualism that is displayed in the multiplicity of parties. These exist in such number and with such minor variations of title that, in many instances, their differences can be but little else than doctrinaire, if not metaphysical. No one but a student, native to the soil and an active participant, could split terms with sufficient precision to clear up the melange of definitions. Nor is it necessary for our purpose. We can see how the medical men are moving by recounting the titles they have given themselves as candidates before their respective electorates. Thus, of the one more than a half hundred medical deputies, twenty-one inscribe themselves as "Republican Radical"—which, despite the contradiction of terms, is really the conservative wing of the republican movement; thirteen are "Radical Socialist," which, I am advised, is the really radical party, standing as it does for everything that is embraced in the socialistic program. After this general classification we get into a bewildering maze, in which we find four of our professional colleagues known as "Republican Progressistes"; a similar number simply as "Republican"; two as "Republican Liberal"; and one each as "Republican Collectivist," "Radical," "Radical Democratique," "Socialiste Revisioniste," "Socialist," "Conservateur," and one as "Socialiste Blanquiste," whatever in the world that may mean. No name of a physician occurs under such classifications as "Royaliste," "Droit," "Droite Plebiscitaire," "Rallie," "Republican Catholique," or "Plebiscitaire Antisemite," groups which, in the aggregate, make up the clerical party as opposed to the government in the present controversy with the Vatican, and which stands, in one form or another, for everything in the *status quo ante* of 1870.

If this extraordinary manifestation of individualistic activity were restricted to the medical members the prospect for the

medical profession would be hopeless. But be it remembered that each of these particular classifications represents an idea or a group of ideas for which its adherents stand before the people and in the legislature. Members of the chamber are thus segregated into little groups made up of representatives of various professions and callings. It seems to be impossible, in France, in the absence of a national crisis, to get the people marshalled into two great groups for the settlement of equally great issues. Such a crisis has been presented in the movement to which I have alluded, headed by Minister Combes—a physician—in breaking off relations with the Vatican. In this crisis practical politics has prevailed to such an extent that essentially all of the groups represented by the medical men, have co-operated under the title of "*le bloc*." Aside from emergencies such as this, however, it is comforting to be assured, as I have been repeatedly, by members of the profession in and out of the French Congress that in all matters relating to public health or to medical policy, the medical members have been and are co-operative without reference to variations in state and doctrinal views.

There are other facts, however, that strike one as both interesting and important. Thus, as I noted in my study of the French Senate, it is observable that deputies have generally served an apprenticeship in minor political offices, as mayors or members of cantonal councils, while the talismanic insignia is "70," relating as it does to participation in the fatal war against Germany. But that war, which brought the doom of the empire, brought, likewise, the opportunity of the republic, and the physicians, close to the people, knowing their wants and necessities as no body can know them, were the Republicans of that day as they are of this. Their vantage ground of observation gave them in France, as it gives us in America today, the knowledge by which to speak understandingly on economic and other questions that are beyond settlement by those who are interested disputants.

Where one finds a physician serving as deputy one is very apt to find another medical man representing another circumscription of the same *arrondissement*. Dordogne sends a delegation of six to the Chamber of Deputies, four of them being physicians, while there are two out of six from Puy-de-Dôme; two out of four from the Haute-Loire; two out of five from Correze; two out of nine from Saône-et-Loire, while out of the delegation of fifty from the department of the Seine (Paris) five are physicians. There are other important constituencies, too, that are represented by medical men in the Chamber of Deputies, among them being Maçon, Grenoble, Bordeaux, Lille and Lyon. Medical representatives come, also, from the mountainous districts of the Haute-Savoie, the Hautes-Alpes and the Hautes-Pyrenees, as well as from the teeming valleys of the Marne, the Siene, the Rhone, and the Loire.

Occasionally we hear that one physician has defeated another, showing that candidacies by opposing parties have been assumed by representatives of the profession, which is thereby assured of representation without reference to the partisan results of the election—a policy which has already been urged on our own profession by the National Legislative Committee of the American Medical Association. Until this policy is acted on by the medical profession generally throughout the United States it will not be in position to protect either its own interests or the general social interests which, in the evolution of the community and the state, have become its natural and sacred charges.

However, what about these medical deputies in a personal and professional sense? Are they mere politicians of the pot-house variety or are they men of real respectability in their respective communities, and of real worth in their profession? Well, to begin with, we have Barrios, who has served as a member of his municipal council, and is to-day not only a professor of the medical faculty of Lille, but is a medical writer of force and influence; Villejean, although representing the *arrondissement* of Tonnerre, in the department of Yonne, was a former interne of the hospitals of Paris, is now professor *agrégé* to the faculty, and is a member of the staff of the Hotel Dieu; Borne, deputy from Doubs, has written effectively

on "Pleurisy and the Neuralgia"; Dron, from Nord, has contributed an important work on "Studies on Cancers of the Eye"; Amoudru, from Seine-et-Oise, was a metallist of the Paris hospitals, the distinction having been conferred in part because of the excellence of his thesis; a good half dozen or more are laureates of the academy; a number are officers and more are members of the academy; several bear the decoration of the Legion of Honor.

One of the most interesting facts, however, that is brought to the surface by a study of the bibliography of the medical deputies of France strikingly confirms the position assumed by me at Kansas City last January, and on a number of other public occasions, as well as in this correspondence, to the effect that the education, occupation and general view-point of the physician, enable him to approach sociological questions with a clearness of understanding not enjoyed by other members of society. The confirmation of this view is found in the fact that French physicians, notably those in the Senate and Chamber of Deputies, are careful students and writers on this class of subjects. Thus, Vogeli, from Isère, is one of the best known writers of this class, his contributions having appeared for the most part through the columns of the *Reveil du Dauphin*, of which he was for years the director; he has translated important works from both the English and Portuguese languages, among others those of Agassiz, and as he has had the distinction of serving his country for fourteen years on foreign missions. Vazeille, from Loiret, is extensively known because of his work entitled, "La question Sociale est une question de methode." Baudon, from Oise, has issued a critical work on the relations of church and state that has assumed decided importance in presence of the present crisis between the French government and the Vatican, a crisis which it tended more than a little to precipitate. De Lanessian, from Rhone, has written learnedly, not only on questions of natural science, but has studied and written on sociological and governmental questions connected with the colonial interests of France; particularly on those connected with Indo-China. Dubief, from Saône-et-Loire, has not only been for many years a general councillor and vice-president of the general council, but has been at different times director of two great asylums for the insane, that of the Rhone, and that of St. Pierre at Marseilles, and has also written on social and political themes, having been at one time the editor-in-chief of the important periodical known as the "Union Republicaine de Saône-et-Loire." Dubois, of the Paris delegation, is one of the trenchant writers on social questions in the *Petite Republique*, and is an officer of the academy. Meslier, also of the Paris delegation, is likewise one of the best-known authors of sociological studies. Delbet, of the department of Seine-et-Marne, is so highly esteemed as a student of sociological questions that he was sent by the Societé d'Economie Sociale as a special envoy to Syria, Asia Minor, Egypt, and the further Orient, his reports being to-day accepted as standard contributions to the literature of sociology.

One of the most gratifying features revealed by an examination of the personnel of the Chamber of Deputies is the fact that, although that body, like our House of Representatives, ranks as the lower branch of the national legislature, it embraces among its members many who have held higher rank in the political scale. This is observable among the medical as well as the lay members. The two most conspicuous examples that have been brought to my attention among the medical members are those of de Lanessian, of the department of the Rhone, and de Mahy, deputy for the colonies. The former graduated as a physician in 1872, subsequently served as governor-general of Indo-China, later as minister of marine in the cabinet of the late Waldeck-Rousseau, and now sits as the representative of a modest constituency of less than twelve thousand. The other, de Mahy, is probably a still more striking example; he was given his doctorate in medicine in 1871; served in the National Assembly; accepted the secretaryship of Agriculture consecutively in the cabinets of Freycinet, Duclere, and Fallières, and was subsequently minister of marine in the cabinet of Tirard. Yet, after all these honors, he accepted election to the relatively modest office of deputy, serving

two terms as vice-president of the chamber. He has recently been returned by his constituency at Réunion without opposition. This spirit is certainly to be commended, and is one that may well be emulated in a democracy, which always has certain claims on the wisdom of those on whom it has bestowed its choicest honors. I do not know to what extent these examples may find parallels in our own country, but I at this minute recall that John Quincy Adams did not think it beneath his dignity to serve one or more terms in our National House of Representatives after he had retired from the office of President of the Republic. There can be no valid reason why presidents, members of the cabinet, or senators, after returning to the ranks of plain citizenship should cease to exercise all the rights and duties of citizenship. Nor is there any good reason why physicians, because they are physicians, should not do the same thing.

These are facts that the medical men of America ought to take home to themselves. The time, the eve of a general election, is auspicious for both thought and action. The special food for thought may be found in a brief résumé of the facts brought out in this correspondence:

1. In the French Senate there are thirty-nine medical members; in the United States Senate there are two.

2. In the French Chamber of Deputies—the popular branch of the government—there are fifty-one medical members; in the United States House of Representatives—the corresponding branch of our government—there is not a single medical member.

The duty of the American medical profession, to itself, to society, and to the country, is obvious.

CHARLES A. L. REED.

Queries and Minor Notes.

DIFFERENTIAL DIAGNOSIS OF PARATYPHOID FEVER.

BATESBURG, S. C., Sept. 21, 1904.

To the Editor:—Can you refer me to a good treatise on paratyphoid fever? Some time ago you commented editorially on its pathology, but I want its symptomatology as well.

THEO. A. QUATTLEBAUM, M.D.

ANSWER.—There is as yet no complete treatise on the subject of paratyphoid fever in English, the nearest approach being an article by Johnston in the *American Journal of Medical Sciences*, 1902, p. 187, in which four cases are reported and the literature to that date reviewed. See also P. Clemens' "Ueber den Paratyphus," *Deutsche med. Woch.*, 1904, pp. 280 and 314. The usual clinical examination does not serve to distinguish positively between typhoid fever and paratyphoid, but it is possible to obtain some suggestive evidence. Bleeding from the nose, a cutaneous eruption, diarrhea, enlarged spleen, intestinal hemorrhages and relapses occur in both diseases. It is stated that the eruption in paratyphoid is often hemorrhagic, and that the course of the disease is usually milder than in typhoid. It is possible that the enlargement of the spleen is not so conspicuous in paratyphoid; "the enlargement can often be made out by percussion, and in a few cases is said to be palpable." The temperature curve in general resembles that of typhoid, but is of a more irregular character, and the average and maximum temperatures are lower. The pulse is that of a mild typhoid. The disease lasts from 12 to 84 days, and convalescence is sometimes remarkably long. In the few cases which have gone to autopsy, the ulcerations of Peyer's patches, so characteristic of typhoid fever, have been lacking. Superficial erosions of the mucosa and enlargement of lymphoid follicles, however, do occur. There are two important diagnostic points in the way of bacteriologic tests. Paratyphoid should give a Widal reaction which, if not absolutely negative, is so low that it makes the diagnosis of typhoid fever unlikely. It is, moreover, possible to differentiate positively by making cultures from the blood of the patient and identifying the organism bacteriologically. Certain cultural characteristics of the paratyphoid bacillus allow it to be differentiated from the bacillus of typhoid fever. Although the treatment of the two diseases is in no sense different, the above means of diagnosis should, for evident reasons, be utilized when circumstances permit.

TINCTURE OF IRONWOOD BARK FOR DIABETES.

NEW CASTLE, IND., Sept. 15, 1904.

To the Editor:—In THE JOURNAL, Sept. 10, page 766, in a résumé of an article from the *Brazil Medico*, Rio de Janeiro, from the pen

of Dr. Freitas, the tincture of *Dialium ferrug* is strongly recommended in the treatment of diabetes. I am anxious to learn more of this matter and desire that you advise me as to Dr. Freitas' address, or as to how I may inform myself in absence of the entire article as published in the Brazil periodical.

HENRY W. GREIST.

ANSWER.—We do not think the preparation can be prepared in this country. The address of the writer was given in connection with the abstract on page 766: Dr. Octavio de Freitas, Pernambuco, Brazil. His communication was presented to the Pernambuco Sociedade de Medicina, July 1, 1904. The tree to which he refers is called *caa ferro* or *quaripitanga* in Portuguese. It belongs to the *Cesalpiniaceae*, and is a pod-bearing tree of the same family which includes the tamarind. It is noted for its hard and beautiful wood. It grows in inland tropical or semitropical regions. He gives the botanical name as the *Dialium ferrug*, *Dialium africanum* (Nahl), and *Araruna guianensis* (Aubllet), but the botanists these as separate trees. The *Dialium arouna* or *Codarium guineense* is the velvet tamarind of Sierra Leone. The botany further states that the general character of this subgroup of the leguminous trees is their purgative properties. The tamarind is used in the confection and the infusion of senega, but some of the pods are edible, as that of the tamarind plum. As stated in the abstract, de Freitas used an alcoholic extract of the inner bark. The common name in Brazil is evidently *caa ferro*, which is, literally, iron wood.

MELANCHOLIA DURING PREGNANCY AND THE PUERPERIUM.

M. A. IL, of DURKING, S. C., sends us an account of a case of melancholia during the puerperium and asks advice. The patient is a ill-para; the melancholia began during pregnancy and persists four months after the birth of the child. The patient is indifferent to the child, talks very little, avoids all company, has a poor and variable appetite and has disturbed sleep. The treatment instituted, comprising good nursing, bathing, nourishing food and the administration of iron, arsenic, strychnin and cascara, is very proper. We would suggest further that the child be removed from the mother, both because she would better not try to nurse it and because there is danger that she might injure it. A total change of scene, if possible, should be recommended. Sometimes travel is beneficial if the circumstances of the patient permit. An ideal place for such a patient is a quiet home in the country where there are no children or other disturbing elements, where there is sufficient diversion and where she can have the care of an intelligent, cheerful and sympathetic companion. Considerable time and patience may be required to effect a cure. The mistake should not be made of allowing a premature return to old associations. If the importance of the case is appreciated and all circumstances and possibilities carefully considered, it will generally be found possible, even with a patient in very limited circumstances, to arrange for such a change of scene.

Marriages.

WILLIAM C. SPANGENBURG, M.D., to Miss Clara Adams, both of Chicago, September 15.

DAVID J. MATTHEWS, M.D., to Miss Louanna Hahn, both of Zanesville, Ohio, September 14.

BURCHARD H. ROARK, M.D., Milwaukee, Wis., to Miss Mabel Florence Bryce, of Indianapolis, Ind., September 21.

CHARLES WHITTIER YOUNG, M.D., Chicago, to Miss Olive Doyle, at Baltimore, September 15.

AUGUSTUS POHLMAN, M.D., Baltimore, to Miss Kathleen Black, at Cincinnati, September 13.

IRA ENGLER WHITEHILL, M.D., to Miss Sara Maynard Smith, at New Windsor, Md., September 14.

DENNIS FRANCIS FITZPATRICK, M.D., to Miss Marie Pauline Murphy, both of Iowa City, September 28.

JOHN FRANKLIN SNYDER, M.D., Monroe Center, Ill., to Miss Veruie Blanche Sheaff of Holcomb, Ill., September 21.

WILLIAM WAYLAND FRAMES, M.D., Baltimore, to Miss Jennie Louisa Whitbread, at Syracuse, N. Y., September 14.

JOHN IRVING MCKELWAY, M.D., King's Park, Long Island, N. Y., to Miss Mabel Sanger Bennett of Binghamton, N. Y., September 17.

Deaths.

James G. Hyndman, M.D., Medical College of Ohio, Cincinnati, 1874, a member of the American Medical Association; for seventeen years secretary of the Medical College of Ohio, and professor of chemistry and laryngology in the institution;

a member of the Ohio State Medical Association and the Academy of Medicine of Cincinnati, one of the most prominent physicians of Cincinnati, died at the Good Samaritan Hospital in that city, September 18, three days after an operation for appendicitis, aged 51. The faculty of the college, at a special meeting, September 20, passed resolutions eulogistic of their departed colleague and bellowed friends.

Charles E. Pease, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1882, of Middletown, Pa., surgeon for the Pennsylvania System and the American Tube and Iron Company, died at the German Hospital, Philadelphia, September 12, from catarrh of the stomach, after an illness of several months and an operation for appendicitis, aged 47.

John A. Wegg, M.D. Western Reserve University Medical Department, Cleveland, Ohio, 1865, a member of the American Medical Association, formerly a leading physician of Sandusky County, Ohio, residing at Rollersville, but who had lived in Cohreville, San Jago de la Vega, Jamaica, British West Indies, died recently at his home in Jamaica.

Francis P. Phelps, M.D. University of Maryland School of Medicine, 1853; surgeon of First Eastern Shore Volunteers from 1861 to 1863; a member of the House of Delegates of Maryland from 1893 to 1895, and a justice of the peace since 1900, died suddenly from acute gastritis at his home in Cambridge, Md., September 17, aged 74.

Henry Ridgely, M.D. Medical Department of the University of Pennsylvania, Philadelphia, 1839, and president of the Farmer's Bank of the state of Delaware, died at his home in Dover, Del., September 17, aged 87. His death occurred suddenly and indirectly was due to hicough, which began several days before.

George P. P. David, M.D. Kentucky School of Medicine, Louisville, 1891, for five years director of a large hospital in San Pedro Sula, Spanish Honduras, died at his home in New Orleans, September 18, suddenly from heart disease, aged 45.

Jacob Chambers, M.D. University of Buffalo, 1875, one of the managers, and surgeon of the City of Kingston Hospital, family physician to Judge Alton Parker, died at his home in Kingston, N. Y., September 16, aged 52.

George Jacob Hirth, M.D. University of Michigan, Department of Medicine and Surgery, 1891, of Milwaukee, died at a sanitarium in Wauwatosa, Wis., September 14, after an illness of a year, from paralysis, aged 38.

Elery G. Fuller, M.D. Starling Medical College, Columbus, Ohio, 1888, died from Bright's disease, September 5, at his home in Sterling Center, N. Y., after an illness of two weeks, aged 46.

Charles Conrad, M.D. Tulane University of Louisiana, New Orleans, 1897, committed suicide by shooting himself through the heart at his home in Cleveland, Ohio, September 19, aged 35.

James H. Benton, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1876, of Newbern, N. C., died at Black Mountain, N. C., September 14, aged 61.

William L. Whitted, M.D. Miami Medical College, Cincinnati, 1878, of Bloomington, Ind., died at Ocean-side, Cal., where he had gone a year ago for his health, September 8.

H. Von Kochring, M.D. Friedrich Wilhelm University, Berlin, Germany, 1865, died at his home in San Antonio, Texas, September 14, from cerebral hemorrhage, aged 58.

Andrew D. Finucane, M.D. Bellevue Hospital Medical College, New York City, 1884, of Chicago, died at the Illinois Northern Hospital for the Insane, Elgin, August 16.

Frederick Dorsey Mitchell, M.D. University of Maryland School of Medicine, Baltimore, 1846, died at his home near Hereford, Md., September 15, aged 80.

Victor Rounds, M.D. Rush Medical College, Chicago, 1882, died recently at his home in Brainerd, Minn., and was buried at Verdale, Minn., September 20.

Allen M. Pierce, M.D. Rush Medical College, Chicago, 1861, an Army surgeon during the Civil War, died at his home in Wyoming, Ill., June 10.

William N. Ash, M.D. Toledo (Ohio) Medical College, 1883, died suddenly at his home in Mount Eaton, Ohio, September 14, aged 45.

G. C. Dortch, M.D. of Clarksville, Tenn., died at the home of his daughter in South Ryegate, Vt., September 10, from heart disease.

William H. Wheeler, M.D. Indiana, 1897, died at his home near Hartford City, Ind., September 14, after a short illness, aged 80.

Willard T. Parsons, M.D., died at the Spencer Hospital, Meadville, Pa., September 4, from an overdose of chloral, aged 49.

Henry F. Campbell, M.D., of Melrose, Mass., died suddenly in Boston, from heart disease, September 14, aged 65.

S. A. Meecham, M.D., died recently at his home in Norden, Neb., from malignant disease of the head, aged 87.

Charles Galloway, M.D. Rush Medical College, Chicago, 1892, died at his home in Libertyville, Ill., September 15.

Julian Fajans, M.D. Jefferson Medical College, Philadelphia, 1866, died at his home in Philadelphia, August 26.

Samuel S. Strayer, M.D. Chicago Medical College, 1872, died at his home in Naperville, Ill., August 18.

William M. Henry, M.D. University of Louisville, 1885, died recently at his home in Onton, Ky., aged 66.

Frank M. Sisson, M.D. New York, 1881, died in Rochester, N. Y., August 23, aged 49.

D. M. Reagan, M.D., died at his home in Buda, Texas, from cancer, August 14, aged 72.

George Clough, M.D., died at his home in Kansas City, Mo., August 23, aged 83.

Deaths Abroad.

Niels R. Finsen, M.D., pioneer in scientific phototherapy, died, September 24, in Copenhagen, aged 43. He was a native of the Faroe Islands. He began his work while a student in the Copenhagen University, from which he was graduated in 1890. Three years later he published an article on "The Influence of Light on the Skin," which aroused general attention because of his assertion that smallpox could be cured by the red-light treatment. This was but one application of the Finsen theory that light rays contained healing powers, and to develop the positive element of his theory he began experimenting with concentrated artificial light rays. As a result of his experiments, he effected a cure for lupus vulgaris. This cure directed great attention to the young investigator, and in 1896 the Municipal Hospital of Copenhagen allowed Professor Finsen several small buildings on its grounds in which to carry on his experiments. The Danish government then became interested in the support of the institution, and this support enabled the institute to be removed to Rosenvaenget, a suburb of Copenhagen, where under the direction of Professor Finsen, with a staff of scientists of national repute, expert electricians, and trained nurses, many cures of cases previously deemed incurable were made. In December, 1903, Professor Finsen was awarded the Nobel prize. For several years he had suffered from dropsy resulting from heart disease, but so intense was his devotion to his work that he hardly spared time from his studies for sleeping and eating, much less to recuperate his health. His death is attributable to an aggravation of the diseases from which he had suffered during his entire adult life by reason of his persistent overwork.

H. Kober, M.D., one of the founders of German dermatology and one of its most prominent representatives, died at Berlin, September 3, aged 66, just a few days before the dermatologists of the world were to gather at Berlin for the fifth international congress of dermatology. Kober founded at Breslau in 1861 the first clinic for skin diseases and syphilis in Germany, and later became director of the clinic established by the university. But was soon compelled to resign on account of his health. He settled in Berlin in 1877, where his dermatologic polyclinic and postgraduate courses were very popular. Among the subjects especially connected with his name are syccosis, mycosis tonsurans, leprosy, drug exanthemata, etc., his works on these and allied subjects having been numerous and important.

State Boards of Registration.

COMING EXAMINATION.

Board of Medical Examiners of the State of California, San Francisco, October 25. Secretary, Charles L. Tisdale, M.D., Alameda.

New Rules in Kentucky.—The State Board of Health of Kentucky, in putting into effect the new law requiring all applicants for license to pass an examination, has adopted rules

and procedures which we reproduce from a circular just issued by the board.

REQUIREMENTS FOR MEDICAL COLLEGES AND STUDENTS.

On and after July 1, 1905, every medical college shall comply with the following requirements as a condition of being recognized as reputable by the State Board of Health of Kentucky:

1. It shall uniformly exact the requirements for matriculation set forth in "Requirements for admission to medical colleges," adopted by the board.
2. It shall literally observe its own published requirements for admission, tuition, time of attendance at the annual sessions and graduation, which must be definitely expressed.
3. It shall have adequate equipment and an active and competent faculty for teaching the science and art of medicine, embracing the following departments, viz.: Anatomy, physiology, chemistry, pathology, histology, bacteriology, surgery, obstetrics, gynecology, ophthalmology, otology, hygiene and state medicine, medical jurisprudence, physical diagnosis and therapeutics and practice in accordance with the system to which the college belongs.
4. It shall have clinical and hospital facilities based on a minimum municipal population at its place of location of not less than 50,000, provided, that this requirement shall not apply to institutions under state control which, by virtue of such control, receive patients gratuitously from all parts of such state.
5. It shall require actual attendance on 80 per cent. of each of four courses of instruction of not less than thirty consecutive weeks, excluding holidays, in four separate years, and shall not hold more than one graduating course in any one year. (It should be noted that no provision is made for giving advanced standing for A.B., B.S., or other degrees.)
6. It shall not accept notes in payment of fees, or offer or accept scholarships, or any reduction in fees, or any form of rebates, except as provided for or required under state laws or under the laws of endowed universities, and no student shall be given credit for attendance, or advanced, or graduated, until all fees have been paid.
7. Colleges may honor official credentials issued by medical colleges of equal requirements, as to students who have complied with the "Requirements for Admission to Medical Colleges," except in the branches of study embraced in the last year of their own curriculum.

REQUIREMENTS FOR ADMISSION TO MEDICAL COLLEGES.

All colleges shall require every medical student applying for matriculation on and after July 1, 1905, to present to it "A Medical Student's Certificate," issued to him by a certified examiner of the state board of health or state board of medical examiners of the state in which the college is located, approved by such board, and a certificate of good moral character.

- The examiner shall require as a basis for his certificate:
- (a) A degree of A.B., B.S., or equivalent, from an approved university, college or academy of arts, science or philosophy.
 - (b) A diploma or certificate of graduation from an approved high school or normal school.
 - (c) A state teacher's permanent or life certificate.
 - (d) A diploma of medical student certificate from any state board of health or examiners embracing equal requirements.
- Or, an examination in writing in the following branches:
- (a) English, submitting a composition in his own handwriting on some subject of general interest embracing not less than two hundred words, which shall be considered with reference to penmanship, spelling, pronunciation, thought and construction.
 - (b) United States history.
 - (c) Arithmetic, vulgar and decimal fractions, percentage and common numbers.
 - (d) Algebra, through equations.
 - (e) Latin, through first year of ordinary course.
 - (f) Physics, the elements of mechanics, hydrostatics, hydraulics, heat, optics and acoustics.

GRANTING OF CONDITIONS.

Applicants failing to obtain a general average of 75 per cent. in the entrance examination and falling below 55 per cent. in but two branches may be conditioned by the official examiner, on a different point of certificate. The examiner shall make a separate list of such conditioned applicants in duplicate, one copy of which shall be sent to the state board of health or examiners and the other retained in his office.

REMOVAL OF CONDITIONS.

Such conditions must be removed by the presentation of a certificate from the examiner that such applicant has passed a satisfactory examination in the branches in which he was formerly found deficient, before he receives credit received and is permitted to enter on his second year of study, and the examiner shall furnish a list of such applicants to the state board of the jurisdiction.

FEES.

Two dollars is hereby fixed as the fee to be collected by the examiner for each certificate in Kentucky. Those examined in special subjects to remove conditions will not be required to pay again but those failing and taking a second examination will pay another fee.

Kentucky Examination Announcement.—The first semi-annual examination by the State Board of Health of Kentucky, under the new medical law, which became operative June 13, 1904, will be held at the School Board Building, corner Center and Walnut streets, Louisville, beginning at 10 a. m., on Monday, Oct. 3, 1904, and continuing for three days. All applications should be sent to the board at Bowling Green at least five days prior to the date fixed for the examinations, and applicants should be present by 9 a. m. of the first day. No one can be examined who is not reputable in the school or system of practice to which he professes to belong, and who does not hold a diploma issued to him by a college located within the United States, recognized as being reputable by this board. Each applicant must present to the secretary, at

the examination, a recent photograph of himself, the reverse side of which shall contain his signature, written in the presence of the secretary, and he shall make oath before such officer that it is his true picture and signature, and that he is the legal holder of the diploma under which the application is made. The filing of an application, or taking an examination, does not authorize the applicant to practice, and no one can legally engage in practice until he has obtained his certificate and registered in the county of his residence. Non-residents and holders of foreign diplomas are not eligible for examination. The fee of ten dollars should be sent to the secretary, Dr. J. N. McCormack, Bowling Green, Ky., with the application.

The Public Service.

Army Changes.

- Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Sept. 24, 1904:
- Bovereux, J. K., asst.-surgeon, left Fort Meade, S. D., with Sixth Cavalry on road march.
- Smart, Charles, asst. surgeon general, Smart, Robert, and Metcalf, H. F., asst.-surgeons, arrived at San Francisco on the *Sherman* from Manila, P. I.
- Church, James R., asst.-surgeon, relieved from duty at Fort Brown, Texas, on expiration of sick leave and ordered to Fort Robinson, Neb.
- Stark, Alexander N., asst.-surgeon, reports on three months' sick leave from date.
- Greenleaf, Henry S., reports on ten days' leave from date on completion of duty at maneuvers.
- Appel, D. M., deputy surgeon general, leave of absence extended to include Oct. 20, 1904.
- McAndrew, P. H., asst.-surgeon, left Jefferson Barracks, Mo., with recruits to San Francisco.
- Keen, Jefferson K., and Kafferty, Ogden, surgeons, detailed to represent Medical Department of the Army at the Thirteenth Annual Meeting of the Association of Military Surgeons of the United States, to be held at St. Louis, Oct. 10-15, 1904.
- Stephenson, Wm., surgeon, granted thirty days' leave, permission to apply for twenty days' extension.
- Smart, Charles, asst.-surgeon general, ordered to proceed from San Francisco to Army and Navy General Hospital, Hot Springs, Ark., for treatment.
- Williams, H. L., asst.-surgeon, relieved from further duty as medical director, Louisiana Purchase Exposition, St. Louis, and in addition to his duties as attending surgeon, headquarters Northern Division, he will perform the duties of examiner of recruits, St. Louis.
- Buck, Carroll D., asst.-surgeon, in addition to his present duties, will perform temporarily the duties of medical director, Philippine Government Board, Louisiana Purchase Exposition, St. Louis.
- Owen, Wm. O., surgeon, discharged from observation and treatment at U. S. Army General Hospital, Presidio of San Francisco.
- Owen, Wm. O., surgeon, relieved from duty in Philippines, and to proceed from San Francisco to Fort Logan, Colo., for duty.
- Steer, Samuel L., asst.-surgeon, granted thirty days' leave of absence.
- Lyster, Wm. J. L., asst.-surgeon, leave of absence extended thirty days.
- Greenleaf, H. S., asst.-surgeon, granted thirty days' leave of absence with permission to apply for thirty days' extension.

Brooks, John D., contract surgeon, ordered to temporary duty at Fort Washakie, Wyo., not later than September 13.

McMillan, Clemens W., contract surgeon, ordered from Fort Niagara, N. Y., to temporary duty at Fort Hamilton, N. Y.

Boak, S. Davis, Lauderdale, Clarence E., Mason, George L., and Wing, Franklin F., contract dental surgeons, arrived at San Francisco September 16 on the transport *Sherman*. They have completed three years' duty in the Philippines, and have been assigned to stations as follows: Dr. Boak, Fort Hancock, N. Y.; Dr. Lauderdale to Fort Sam Houston, Texas; Dr. Mason to Fort McPherson, Ga., and Dr. Wing to Fort Riley, Kan.

Navy Changes.

- Changes in the medical corps, U. S. Navy, for the week ending Sept. 24, 1904:
- Curti, H. C., P. A. surgeon, detached from the *Boston* and ordered to duty in connection with the Isthmian Canal Commission.
- McDonnell, W. N., P. A. surgeon, detached from the Naval Recruiting Station, Baltimore, Md., and ordered home to wait orders.
- Rodman, S. S., P. A. surgeon, detached from the *Pensacola* and ordered to the *Boston*.
- Wilson, H. D., P. A. surgeon, ordered to additional duty on the *Southerly*, September 28.
- The following named asst.-surgeons are detached from the stations indicated and ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., September 30: R. G. Heiner, *Southerly*; R. B. Chayson, *Navy Yard*; E. H. Hancock, *S. J. P. Stoops, Naval Hospital, Norfolk, Va.*; F. E. Porter, *Naval Hospital, Norfolk, Va.*; H. F. Hull, *Naval Hospital, Newport, R. I.*; W. D. Owens, *Naval Hospital, Newport, R. I.*; J. L. Belknap, *Naval Hospital, Newport, R. I.*; C. E. Porter, *Naval Hospital, Newport, R. I.*; J. P. McLean, *Naval Hospital, New York*; G. L. Wickes, *Naval Hospital, Philadelphia*; W. J. Zalesky, *Naval Hospital, Philadelphia*; O. J. Mink, *Naval Hospital, Philadelphia*; H. A. May, *U. S. R. S. Franklin*; C. T. Grayson, *Naval Hospital, Washington*; D. C. W. E. Angwin, *Naval Hospital, Mare Island, Cal.*; W. G. Farwell, *Recruiting duty, Portland and Bangor, Maine*.
- Braisted, W. C., surgeon, detached from the *Pensacola* and ordered to the *Ohio*.

McNittouh, F. E., surgeon, ordered to the *Penacola* and to duty at the Naval Training Station, San Francisco.

Kennedy, R. M., surgeon, detached from the *Dacic* and ordered to the *Massart*.

Lovell, J. A., surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C., October 3.

Ferebee, N. Melt., medical director, sick leave extended three months from September 20.

Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine Hospital Service for the seven days ended Sept. 21, 1904:

Gassaway, J. M., surgeon, detailed to represent the Service at the meeting of the Association of Military Surgeons at St. Louis October 10-15.

Carmichael, D. A., surgeon, granted leave of absence for one month from October 18.

White, J. H., surgeon, granted leave of absence for six days from September 19.

McIntosh, W. P., surgeon, to proceed to Stonington, Maine, for special temporary duty.

Woodward, R. M., surgeon, Department letter of May 13, 1904, granting leave of absence for three months amended to read two months and twenty-six days from June 14.

Stoner, J. B., surgeon, to proceed to Cape Charles Quarantine Station and assume temporary charge during the absence of Asst.-surgeon J. S. Burgess; granted leave of absence for eight days from September 26.

Wertenbaker, C. P., surgeon, on being relieved from duty at New Orleans, La., by P. A. Surgeon A. C. Smith, to proceed to the Immigration Depot, Ellis Island, N. Y., and report to Surgeon G. W. Stoner for duty.

Smith, A. C., P. A. surgeon, on being relieved from duty at New York (Stapleton) by P. A. Surgeon J. A. Nydgerger, to proceed to New Orleans, La., and assume command of the Service, relieving Surgeon C. P. Wertenbaker.

Nydgerger, J. A., P. A. surgeon, relieved from duty at the Immigration Depot, Ellis Island, N. Y., effective Oct. 1, 1904, and directed to proceed to New York (Stapleton) and report to the medical officer in command for duty and assignment to quarters, relieving P. A. Surgeon A. C. Smith.

Foster, M. H., P. A. surgeon, granted extension of leave of absence on account of sickness for thirty days from September 18.

McLaughlin, A. J., asst. surgeon, granted leave of absence for twenty-four days from October 3.

Hamilton, H. J., A. A. surgeon, granted leave of absence for thirty days from October 1.

Richardson, S. W., pharmacist, relieved from special temporary duty in connection with the Louisiana Purchase Exposition at St. Louis, and from duty in the Hygienic Laboratory, Washington, D. C., and directed to proceed to Boston, Mass., and report to the medical officer in command for duty and assignment to quarters.

LaFrance, J. W., pharmacist, Department letter of Aug. 30, 1904, granting leave of absence for twenty-three days from September 15, revoked.

Keen, W. H., pharmacist, Bureau order of Aug. 26, 1904, directing him to proceed to Boston, Mass., and directed to proceed to Chicago and report to the medical officer in command for duty and assignment to quarters.

REINSTATEMENT.

Herman, C. H., New York, reinstated as pharmacist of the third class.

BOARD CONVENED.

Board convened to meet at Stapleton N. Y., Sept. 19, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon A. C. Smith, chairman; P. A. Surgeon C. H. Lavinder, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended Sept. 23, 1904:

SMALLPOX—UNITED STATES.

Illinois: Chicago, Sept. 10-17, 14 cases, 2 deaths.
Louisiana: New Orleans, Sept. 16-17, 1 case (imported).
Massachusetts: Sept. 10-17, Lawrence, 1 case; North Adams, 1 case.
Michigan: At 41 places, Sept. 3-10, present.
Minnesota: Morrison County, Sept. 6-13, 1 case
Missouri: St. Louis, Sept. 10-17, 11 cases.
New York: New York City, Sept. 10-17, 2 cases.
Pennsylvania: Philadelphia, Sept. 10-17, 1 case, 1 death.
Rhode Island: Providence, Sept. 10-17, 1 case.
Tennessee: Sept. 10-17, Memphis, 1 case; Nashville, 2 cases.
Wisconsin: Milwaukee, Aug. 27-Sept. 17, 6 cases.

SMALLPOX—FOREIGN.

Belgium: Antwerp, Aug. 27-Sept. 3, 1 case.
Borneo: Brunai, Aug. 8, epidemic.
Brazil: Pernambuco, Aug. 17-31, 28 deaths.
China: Hongkong, July 30-Aug. 6, 2 cases.
France: Paris, Aug. 27-Sept. 3, 29 cases, 1 death.
Great Britain: Bradford, July 31-Aug. 27, 9 cases; Aug. 27-Sept. 3, Bristol, 1 case; London, 2 cases; Manchester, 2 cases; Newcastle-on-Tyne, 3 cases; West Hartlepool, 2 cases; Glasgow, Sept. 2-9, 2 cases, 1 death; Leeds, Sept. 3-10, 1 case.
India: Bombay, Aug. 16-23, 1 death.
Italy: Palermo, Aug. 27-Sept. 3, 9 cases, 2 deaths.
Russia: Moscow, Aug. 16-23, 7 cases, 2 deaths; Odessa, Aug. 3-Sept. 3, 7 cases, 1 death; St. Petersburg, Aug. 20-27, 2 cases, 4 deaths.
Turkey: Beirut, Aug. 20-Sept. 3, present; Constantinople, Aug. 28-Sept. 4, 6 deaths.

YELLOW FEVER.

Mexico: Coahuila, Sept. 3-16, 7 cases, 2 deaths; Sept. 4-10, Merida, 1 case; Tehuantepec, 1 death; Vera Cruz, Aug. 27-Sept. 10, 10 cases.
Panama: Panama, Sept. 5-12, 1 case, 1 death.

CHOLERA.

Borneo: Kodat, Aug. 19, present.
India: Bombay, Aug. 16-23, 12 deaths.
Turkey: Bagdad vicinity, July 23-Aug. 6, 844 cases, 1,023 deaths.

PLAGUE.

China: Hongkong, July 31-Aug. 6, 13 cases, 12 deaths.
Egypt: Aug. 13-20, 10 cases, 7 deaths.
India: Bombay, Aug. 16-23, 59 deaths; Karachi, Aug. 11-21, 4 cases, 2 deaths.
Japan: Formosa, July 23-Aug. 6, 21 cases, 27 deaths.
Turkey: Smyrna, Sept. 5, present.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Colorado State Medical Society, Denver, October 4-6.
Idaho State Medical Society, Lewiston, October, 6-7.
Tennessee Medical Society of Alabama, Georgia and Tennessee, Chattanooga, October 12-14.
Assn. of Military Surgeons of the U. S., St. Louis, October 10-15.
Mississippi Valley Medical Association, Cincinnati, October 11-13.
Vermont State Medical Society, Rutland, October 13-14.
New York State Medical Association, New York, October 17-20.
Medical Society of Virginia, Richmond, October 18-21.
American Confederation of Reciprocity Examining and Licensing Medical Boards, St. Louis, October 25, 1904.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Seventeenth Annual Meeting, held at St. Louis, Sept. 13-16, 1904.

(Continued from page 997.)

Operative Treatment for Painful Menstruation in Young Virgins.

D. WILLIAM A. B. SELLMAN, Baltimore, pointed out the great necessity of giving relief to young unmarried women who suffered from painful menstruation. The forms of dysmenorrhea that could be relieved by operative means were expatiated on at length. These means should not be of a character to unsex the patient nor prevent her from bearing children or from fulfilling her marital relations. The operation should not be one which will endanger life or interfere with the woman's general good health. To illustrate the condition and to demonstrate the manner in which cases could be operated on without unsexing the individual and giving absolute relief for the suffering experienced, he related the following case on which he operated in the early part of June, 1904: Miss H., aged 24, a brilliant vocalist, with a register of three octaves, had been unable to use her voice with any satisfaction for a long period on account of the pain developed in the ovarian region when attacking the high notes. June 7, 1904, under ether anesthesia, the endometrium was curetted and a quantity of congested tissue removed from the cavity of the uterus. He then made an abdominal incision in the median line, and found both ovaries hyperemic and distended. Upon the left side he opened three good-sized cysts and on the right side two medium-sized cysts. He enucleated these with a sharp spoon curette and scraped the walls in order to destroy the membrane. He closed the openings with catgut sutures and used the same material to close the opening in the abdominal wall. The patient made an uninterrupted and rapid convalescence, and had not had the slightest amount of pain in the ovarian region, and no pain during two menstruations which she had passed through since the operation. He thought very many gynecologic surgeons would have removed both ovaries under these conditions, and the result would have been the unsexing of the patient and probably the loss of her voice, especially in the upper register. He had heard her sing, and was certain that her voice had not been impaired. Two physicians present during the operation expressed the opinion that no relief would follow the operation unless he removed the appendages. Resection of the ovary was followed by such successful results that one was not justified in removing the organs unless the complications present gave no opportunity to perform the conservative opera-

tion. Lastly, he spoke of that class of cases in which dysmenorrhea was due to a general systemic neuralgic condition. In these cases one at times afforded great relief by the use of the various forms of electricity. It was doubtful in many of the cases whether removal of the appendages would accomplish anything more than to bring about a premature menopause, and the patient would remain just as nervous as before operation.

DISCUSSION.

DR. H. W. LONGYEAR, Detroit, Mich., stated that in operating, if one could save an ovary or part of an ovary, he should do so. In the majority of cases, one could conserve tissues there with perfect safety and with the result of allowing the woman to menstruate as she would in a normal condition. He would enter a protest against operating on cases of dysmenorrhea that were of short duration in young persons. One should not subject any unmarried woman to an operation if it could be avoided. The minor cases of pain of short duration did not need operative measures.

DR. HERMAN E. HAYD, Buffalo, N. Y., alluded to the importance of examination in these cases, and even after an examination was made one might find that the most distressing cases were the ones that practically had no evident pathology, which could be made out by such an examination. If on examination one should find a retroverted uterus, a prolapsed ovary, a tender sensitive tube, then there was a rational basis on which to work, but simply because a woman had a small os it did not follow that she was going to be the subject of dysmenorrhea, because in all probability most of these cases were simply due to an impoverished condition of the whole system. They were simply functional troubles, and had to be met accordingly. If, however, there was an obstructive dysmenorrhea, and usually these cases were associated with an atrophic condition of the uterus, probably one could institute some operative measures, and the interference which had been most successful in his hands had been dilatation and the wearing of a stem pessary.

DR. WILLIAM H. HUMISTON, Cleveland, Ohio, stated that dysmenorrhea was a common disturbance, and yet he had not been able to find a case that was not accompanied by an inflammatory condition of the mucosa. He had seen cases of narrow, conical os, with the patients menstruating without the least sign of distress, but the moment there was an inflammatory condition of the mucosa added, that moment the patients began to have painful menstruation. In cases of this kind he thoroughly dilated the uterine cavity, curetted, and had the patients wear an Etheridge pessary, closely watching them for several months, and if there was no accompanying disease of the appendages, the cure was decided and complete. In these cases occasionally one would have a failure because of not recognizing an ovary which was smaller than normal, the cirrhotic ovary, which was hard to detect unless an examination was conducted under an anesthetic, and there was no relief afforded except by the removal of these shrivelled, corrugated, smaller than normal ovaries.

DR. D. TOD GILLIAM, Columbus, Ohio, spoke of the undeveloped condition of the uterus as a cause of dysmenorrhea. A great many men had come to the conclusion that it was not a superficial condition; it was not produced by the condition of the mucosa, as a rule; nor the result of stenosis of the internal os or of many of the other orifices of exit, but was due to the undeveloped, unripe condition of the uterine tissues. The uterine tissues were just like unripe fruit, and one of the functions of the uterus was to throw off this membrane at stated intervals, and in doing so there were certain physiologic processes that must work their way or be concerned therewith. The time for the casting off of this membrane was at the menstrual period, a time when this membrane would easily come away, but which could not be removed at any other time without more or less violence. Vessels permeated this dense structure; these vessels were undeveloped; they were unable to accommodate the amount of blood sent there during the menstrual molimen, and this induced distress. The membrane closely adhering to the uterine wall was not ready to be exfoliated, hence it was a source of distress.

DR. JOHN YOUNG BROWN, St. Louis, Mo., said that his experience in dealing with cases of painful menstruation was that unless there was a palpable pathologic condition present, it was better to leave them alone. In looking up the etiology of pelvic disease, he had found in a rather extensive operative experience that the majority of cases that came to operation were of gonorrhoeal or puerperal infection, and those cases that came as the result of infection following minor office gynecologic procedures. He did not feel that a young woman who suffered from painful menstruation should be subjected indiscriminately to operative treatment or even to a gynecologic examination.

DR. L. H. DUNNING, Indianapolis, said that one ought not to approach any case of dysmenorrhea without studying the surroundings very carefully. He should have a complete and thorough history of the case in order to be able to determine the character of the lesion which was present before undertaking the treatment of the case. He had been surprised in studying the collected histories of some two thousand cases to find that in about 15 per cent. of them there was dysmenorrhea at the beginning of menstruation. This, he thought, would go to disprove one statement made by the essayist, that nearly all of the cases were due to inflammation, or that most of them were due to gonorrhoeal infection or some other kindred infection. In the majority of cases in which dysmenorrhea began with menstruation, he thought one would find some errors in the development of the organ or errors in the development of the nervous system which would lead to painful menstruation. Every case should be studied carefully on its merits. Some would be found to be due to nervous conditions, others to hyperemia of the ovaries, and still others to venous congestion of the pelvic organs, including the uterus and ovaries. Obviously, all of these were not cases demanding operative procedures.

DR. SELLMAN stated that the object of his paper was to prevent, if possible, this suffering to women which came on about thirteen times a year. He thought that if any member of the Association had to undergo or endure the pain from which some of these patients suffered, even for only six times a year, he would seek some means of relief. He did not use instruments in all cases, but only in those cases where a truly condition existed.

Pseudo-Membranous Monocystic Tubercular Peritonitis.

DR. H. W. LONGYEAR, Detroit, said that pseudo-membranous monocystic tubercular peritonitis was that form of tubercular peritonitis which was characterized by the formation of a thick, white, fibrinous, pseudo-membrane on all of the tubercular peritoneum, covering the parietal peritoneum and cementing together and covering the intestinal coils in such a manner as to form a sac of greater or less capacity, according to the progress of the disease, which contained straw-colored fluid, with occasionally jelly-like masses and shreds floating therein. He reported three cases of this affection, and stated that the treatment consisted of abdominal section, with evacuation of fluid and the thorough washing out of all shreds and gelatinous masses, with normal salt solution; thorough drainage by glass or rubber tubes, both abdominal and vaginal. This was to be followed by after-treatment, consisting of frequent lavage, with a weak aqueous solution of iodine (tincture iodine, 1 dram; water, 1 pint), until the pseudo-membrane was disintegrated and the purulent discharge that followed had ceased. Internally, the rational treatment of tuberculosis, consisting of the use of creosote, cod-liver oil, etc., a supporting diet, and suitable hygienic surroundings. The prognosis was bad, although a few cases might recover, if not too far advanced, after months of constant drainage and careful nursing.

DISCUSSION.

DR. RUFUS B. HALL, Cincinnati, said he differed from some writers in regard to the different varieties of tubercular peritonitis. He was of the opinion that it was tubercular peritonitis in different stages of development. In dealing with the operative treatment of tubercular peritonitis, ultimate success

depended largely on the variety of the disease, the general condition of the patient, the previous history, the great prostration, etc. Very many were in such a condition that they could not withstand much trauma of any kind. The greatest relief was to be afforded to those cases in which there was an accumulation of cysts by letting out the fluid and draining. He had time and again made section when the patients were in a desperate condition, put in a drain, and in six months or a year later the patients returned, when he removed one or two infected tubes, and cured them, whereas if he had done a prolonged operation at the outset, with the patients in a feeble condition, and unable to withstand trauma, they would not have rallied.

DR. L. H. DUNNING said there were two or three questions which ought to be settled in regard to the treatment of cases of encysted tuberculosis of the peritoneum. First, as to whether one ought to remove the fallopian tubes in all instances. He believed we should. He believed that all cases of encysted dropsy, where the fluid accumulated in the pelvis, as described by Dr. Longyear, were dependent on infection of the tube, and it ought to be removed or a fistula would persist indefinitely. Another question was with reference to drainage. He was in accord with both Dr. Longyear and Dr. Hall that these cases ought to be drained through the abdominal wall. They need not be drained through the vagina if one could possibly drain them in the other direction. Should one in these cases attempt to break up the adhesions? Dr. Price had insisted on breaking up adhesions in all cases of tuberculosis of the intestines, but he believed that this pseudo-membrane, which was an adventitious membrane thrown out, was protective, was conservative, on the part of nature, and that one ought not to attempt to separate adhesions. Another point was whether we were justified in attempting to shorten convalescence in these cases by curettement. In three of his own cases he had curetted sinuses and packed with gauze to the bottom of the cavity, and had had three recoveries. In one instance there was a wide incision in the abdominal wall and pelvis, and with a great deal of timidity he used the curette, but did it carefully, and packed. This was followed by healing of the fistula within a short time.

DR. HELMAN E. HAYD, Buffalo, N. Y., said that usually those cases with simple effusion, or dropsy which was circumscribed, got well if opened, and the opening immediately closed. One did not need to disengage bowel nor disturb the adventitious membrane. Simply the entrance of air was an important factor in the cure of these cases. If there was pathology such as had been pointed out by the essayist, it was necessary to drain. However, he did not agree with Dr. Hall that all cases of tubercular peritonitis should be drained, as his own experience did not bear that out.

DR. J. HENRY CARSTENS, Detroit, thought that all that was necessary in ordinary, simple, encysted cases of this condition was to wash them out and let them alone. One should not try to break up adhesions, as serious complications might follow. In tubercular peritonitis the patients should be let alone as much as possible, and Nature given a chance. He said if he operated on a case of tubercular appendicitis and drained it, he would get trouble, because along the track of his drainage tube there would be tubercular deposits, and he would have a fistula there for a long time. On the other hand, if he took out the appendix, closed up the opening with silkworm-gut sutures *en masse*, tightly, he would have union without the formation of a fistula.

DR. D. TOD GILLIAM did not believe in too much interference in cases of tubercular peritonitis, or in such cases as had been described. He thought many of these patients would be better without operation if their cases were diagnosed accurately beforehand. In some cases of encysted tuberculosis he did not care whether the contents were merely washed out or not; by one method or another, one was likely to have bad results. There were other forms of encysted tuberculosis, however, in which one did not have these bad results, and in such cases it was necessary to open up the cysts. He did not believe in breaking up adhesions and separating viscera.

DR. LONGYEAR did not believe that a case of simple tubercular peritonitis, with a large cyst, and the abdomen full of dropsical fluid, needed to be drained, but agreed with Dr. Hayd that all that was necessary to do was to open it, wash out the cavity, sew up the wound, and the patient would get well. Many of them, however, would have a reformation of the fluid.

Chronic Adhesive Peritoneal Sclerosis.

DR. N. STONE SCOTT, Cleveland, Ohio, stated that among the rarer abnormal conditions found within the abdomen, was one peculiar, interesting, and possibly more frequent than had heretofore been suspected. This condition was progressive, yet was characterized by an absence of active symptoms, including ascites. In the early stages the peritoneum was rigid and contracted; later the connective tissue became excessively hypertrophied, with adhesions between the involved peritoneum and all viscera with which it came in contact. As soon as these adhesions interfered with the functions of any organ, symptoms referable to such interference supervened. When the involvement prevented some important organ from performing its necessary functions, death ensued.

In an illustrative case cited by him only a circumscribed portion of the peritoneum (the pelvis) was affected.

The Relative Value of the Means and Methods Employed in Accouchement Force.

DR. E. GUSTAV ZINKE, Cincinnati, Ohio, read a paper in which he drew the following conclusions: 1. The graduated steel or vulcanite dilators and the ordinary branched or bladed dilators were mainly employed for the purpose of dilating the cervix or os preparatory to digital, manual and bag dilatation. 2. The bag or hydrostatic dilators, of which the Champetier de Ribes balloon and its modifications were the most favored, should be employed only when time was not an important element in the case; when the cervix was thoroughly softened, partly or entirely effaced, and an easy introduction of the balloon possible. This was contraindicated in central placenta previa, and in eclampsia, mild or severe. If, in these cases, it was determined to empty the uterus, deep cervical incisions, vaginal or abdominal hysterectomy, promised the best results for mother and child. To prevent continuation of the cervical incision a suture might be placed in the upper angle of the wound. 3. The manual dilatation of Harris and the bimanual (digital) dilatation of Bonnaire and Edgar. A soft and partially obliterated cervix and dilatation os were absolute prerequisites for this variety of uterine dilatation. It was to be preferred when time constituted an important element. Under this method the life of the fetus was often lost and, unless great care was observed, sepsis, lacerations, hemorrhage, profound shock and sometimes even death of the mother might occur. 4. Deep cervical incisions and Dührssen's vaginal hysterotomy were destined to play a permanent and important rôle in the management of forced labors in the future. Many of the cases now subjected to manual or balloon dilatation would be treated by cervical incisions. It was the method in the presence of sepsis of the vagina, because the operation was short in duration and could be performed under a continuous flow of an antiseptic solution. An intact cervix, whether hard, elongated or not, was always an indication for cervical incision. Vaginal hysterotomy was indicated principally when the cervix was the site of malignancy or extensive cicatrization. If there were a palpable difference between passage and passage, the conservative cesarean section should be the choice of operation. 5. The indications for the conservative cesarean section had been well defined in previous papers and it was needless to repeat them. Cervical incisions and Dührssen's operation would, however, take its place in many instances, notably in cases of marked prematurity. 6. The Bossi and similar metal dilators, if they were not entirely needless, were certainly very dangerous instruments. From what had been said it was safe to predict that rapid and complete metal dilatation would never become a popular method; that sooner or later it would receive universal condemnation and thus reach its final and well-deserved destination—the lumber room of obstetric instruments.

DISCUSSION.

DR. HENRY SCHWARZ, St. Louis, was glad to hear Dr. Zinke's experience in reference to Dührssen's vaginal cesarean section, because personally he had had no experience with that method. He could conceive of exceptional cases of eclamptic convulsions or of placenta previa in which cesarean section might be justifiable in proper hands and under proper surroundings. As a rule, in eclamptic convulsions Dührssen's method should be the one of choice, and there could be very few exceptions where conservative cesarean section was indicated. No one would maintain in a case in which the placenta was eccentric, marginal or low seated, with hemorrhage, that cesarean section should be resorted to. Whenever one made a diagnosis of central placenta previa, the cervix was so far dilated that no one would think of doing anything except to deliver the child through the natural way. He thought Bossi's dilator had a limited sphere of usefulness.

DR. JAMES F. W. ROSS, Toronto, Ontario, said he had done cesarean section three times, in each case with the recovery of the mother and the loss of the child. The question between cesarean section and the Porro operation had been pretty well settled and the conclusion reached that the Porro operation, when cesarean section failed, enabled one to control hemorrhage. The last Porro operation he did was in a case reported to the society where a woman delivered herself up through the vagina into the abdominal cavity, and the fetus and placenta were forced through an enormous rent in the posterior vaginal cul-de-sac. In this case he did a Porro operation to control hemorrhage. He had operated on two cases of rupture of the uterus, with recovery, after having performed the Porro operation, by gauze packing, and he thought this operation in these cases should not be adopted unless there was hemorrhage that could not be controlled.

DR. O. J. ELBRECHT, St. Louis, spoke of Dührssen's incisions, saying that he had had three or four of these cases, in which he had resorted to Dührssen's incisions, with good results.

DR. J. HENRY CARSTENS called attention to the point that many practitioners were too anxious to dilate the cervix in the class of cases under discussion. He had seen them use rubber dilators and dilators of all kinds in working around the uterus for two or three days at intervals, and then finally had to send for someone to help them out of difficulty. Such practitioners wanted to know whether they should do this or do that. In some cases, after he had been called in consultation, he had found that the women were not in labor at all. He thought many of the members of the society had had similar experiences. It was a mistake to suppose that because a woman had a little pain at the approach of labor that she was actually in labor.

DR. EUGENE J. BROWN, Stanford, Ky., said in these days of aseptic surgery, with the results we are having with mechanical and manual dilatation, cesarean section would become more popular, and evidently in selected cases more lives to both mother and child would be saved than by other methods. He had the pleasure of witnessing the operation by Dr. Deaver, referred to in the paper. It was performed on February 23 of this year. The simplicity and ease of the operation impressed him very deeply. The mother and baby got along without any trouble.

DR. M. W. MEYER, Columbia, Mo., spoke of the use of the Bossi dilator. While he admitted there were many men who used this instrument, and recommended its use in cesarean section, those who were not radical in the matter had determined that it was not an instrument to be used in such cases. In fact, one had to go back to the old methods of delivery in cases of placenta previa, namely, to resort to the use of tampons. One could accomplish more with them than in any other way.

DR. ZINKE said that whatever he may have said or written in the past on this subject and presented to-day came from a motive simply to do good in the future, and to get rid of a certain method of practice in obstetrics, which had been the means of rendering families unhappy and because he honestly believed that there was great room for improvement in this practice in spite of all that had been said against it.

Vaginal Cesarean Section in Grave Cases of Puerperal Eclampsia.

DR. J. HENRY CARSTENS, Detroit, said that mild cases of puerperal convulsions ordinarily could be controlled by the treatment generally advocated for this class of cases, but that there was a serious, grave form of puerperal eclampsia where one convulsion followed another in quick succession, and the patient finally died in spite of ordinary, and sometimes even heroic treatment. This severe variety of eclampsia could generally be subdued by immediate delivery. This was accomplished generally by manual dilatation, the use of powerful steel instruments, like that of Bossi, but what was better still was the operation called the vaginal cesarean section, which enabled the obstetrician to deliver the woman in about five minutes with little or no danger. In conclusion he stated that: 1, in grave puerperal eclampsia, as a rule, prompt delivery will save the patients; 2, that manual effort with the fingers and the hand was too slow; 3, powerful steel dilators were not always at hand, and often caused serious injuries; 4, vaginal cesarean section enabled the obstetrician to quickly and safely deliver the woman.

An Unusual Case with Many of the Symptoms of Appendicitis.

DR. MAGNUS A. TATE, Cincinnati, narrated this case, which was of interest because: 1. It presented an unusual history. 2. The symptoms and history of the case following scarlatinal nephritis led him and others to suppose that probably they were dealing with a case having appendicitis as a complication. 3. The patient urinated regularly and at no time was there a dribbling of urine. 4. The presence of adhesions and the enlarged bladder, with its thick walls, had only problematical causes, not explained satisfactorily by the history of the case.

The patient, a boy aged 7, was attended by Dr. L. Linss of Cincinnati for an ordinary attack of scarlet fever from Feb. 25 to March 18, 1904. March 21 Dr. Linss was called to see the boy on account of a swelling of the feet and hands. On the morning of April 1 all edema had disappeared; urine highly colored, but normal in quantity, with no sugar, albumin or casts. That afternoon the patient had a chill, vomited, and was suffering with a pain in the abdomen. Temperature, 99.5; pulse, 90. April 5, the patient had two more attacks of vomiting. Pain in the abdomen was constant, and he had not slept for twenty-four hours; temperature, 102, and pulse, 130. Dr. William Johnson saw the case with Dr. Linss, and on examination of the abdomen they found an uneven swelling which extended to the umbilicus and over the right lumbar region. On palpation exquisite tenderness over the appendix was elicited. A diagnosis of appendicitis was made, but further consultation was asked for. The next day, April 6, Dr. Tate was called. When he saw the patient, six days after the initial vomiting spell and chill, the child had been crying and moaning day and night, and could not sleep; temperature, 102; pulse, 132, very irregular; abdomen swollen, especially on the right side, and such marked tenderness that the child screamed if the slightest pressure was made over the region of the appendix. Bowels constipated and the urine highly colored. The following day there was no improvement, the pulse even worse; temperature remained at 102. Before placing the child on the operating table a bed-pan was placed under him and he passed nearly a pint of urine. Chloroform was administered, and an incision was made on the right side two inches in length, over the most prominent portion of the swelling. It revealed a dark-colored sac and a number of adhesions. The incision was lengthened to three inches. Some adhesions were broken down with the finger, but a few of them were so firm that they had to be cut. The enlarged opening gave a field of about two inches to work in, and the sac in appearance was not unlike that of a gangrenous bowel. They were at a loss to say exactly what it was, and as adhesions limited the field, gauze was packed about the opening, the child turned to the right side, and a half-inch cut was made into the sac. A dark green fluid spurted out, which had a strong, heavy odor of stale urine. About two quarts of fluid was evacuated, and the finger intro-

duced into the sac, which proved to be the bladder. The opening in the bladder was sewed up, adhesions binding the bladder on to the abdominal wall and on the right side to the large and small intestines were broken up, and the enlarged thick-walled bladder dropped back into the abdominal cavity. The appendix and appendiceal region, except for the presence of some adhesions, were normal. An opening was left in the abdomen for gauze drainage, and the rest of the wound closed up. The subsequent history was that the bladder was emptied by means of a retention catheter for forty-eight hours, after that catheterization night and morning for three days. There was a gradual decrease in pulse and temperature, and in seven days both were normal. On the third day a quantity of fluid drained out through the opening, but this gradually ceased, and on April 23, sixteen days after operation, the abdominal wound had closed, and the patient is now in good health.

Gunshot Wound of the Abdomen.

DR. JOHN D. S. DAVIS, Birmingham, Ala., reported a case of gunshot wound of the abdomen, with eighteen perforations, in which he resorted to intestinal resection of five feet seven inches, with use of the metal button, followed by recovery of the patient. The patient, a woman, 23 years of age, while attempting to place a rifle in the rack on the wall, the gun was discharged with the muzzle about eight inches from the abdomen. The bullet, a 32-caliber, entered in the median line midway between the umbilicus and the symphysis pubis, ranging backward, upward and to the right, and was deposited in the muscles of the back on the right side. The ball in traversing the abdomen made eighteen perforations of the gut, and two cuts in the intestine that went to the mucous membrane. Sixteen of the perforations and the two sero-muscular wounds were in the small intestine, and two perforations in the transverse colon. The bullet cut two mesenteric arteries, which caused a large amount of blood to collect in the abdomen. Patient was shot at 4:30 p. m., Feb. 2, 1904, and was brought a distance of eighty miles on a freight train to Birmingham, by her physician, Dr. W. O. Watson, and carried to Hillman Hospital. At 9 o'clock Dr. Davis saw the patient and had her prepared for section. Temperature at this time was 102, and pulse 130. She probably had fever at the time she was shot. A seven-inch incision was made in the median line, a large quantity of blood turned out, and the bleeding vessels controlled by hemostatic forceps. The two perforations in the transverse colon were so near the mesenteric border that he stripped up the mesenteric serosa and turned the mesenteric border in as though the two openings, one on each side, had been one large opening, including mesenteric border, and closed with interrupted silk sutures. He then brought the mesenteric folds back and sutured over the wound. Four perforations and two sero-muscular cuts in the small intestine were turned in and closed with small loop silk sutures. Two perforations were situated so close together that they had to be closed by flexing, pouching or looping the mesenteric border, the bowel being bent on its convexity so that the two wounds could be closed as one large wound by interrupted longitudinal loop sutures—suture with axis of bowel. There were two other perforations that could have been closed by suture, but the openings were between two mesenteric perforations on one side and eight on the other, and he thought it better to lose one more foot of intestine than to do two resections. He resected that part of the intestine containing the ten mesenteric perforations (sixty-seven inches), including the two large perforations in the convexity of the ileum and closed with the third-sized metal button. The resected bowel and its mesentery were removed, the vessels ligated, and the gap in the mesentery closed with interrupted silk sutures. The abdomen was flushed with hot normal salt solution; plain gauze drainage was used, and the abdomen closed with through-and-through silkworm gut sutures. The operation lasted one hour and a half. Drainage was removed on the second day. Patient passed the button on the twenty-first day and left the hospital March 1, 1904. A week later she was doing housework, and was perfectly well.

(To be continued.)

Miscellany.

TRAVEL NOTES.

OUR POSSESSION IN SAMOA FROM A MEDICAL STANDPOINT.

NICHOLAS SENN, M.D.

CHICAGO.

AUCKLAND, NEW ZEALAND, July 25.

We landed at Pago Pago on Thursday, July 21, at 6:30 a. m. The natives were on hand to welcome us, and many a greeting was expressed in the euphonious word "*talofa*" (love to you). The moment the ship was anchored in the harbor a fleet of canoes surrounded it and their brown inmates in native attire—men whose only garment was a breechcloth, women in the loose, comfortable Mother Hubbard calico dress, children with no clothing incumbrances of any kind, all of them with a copious growth of jet black long curly hair freely exposed to sunlight and breeze, with upturned faces and large, gentle, imploring coal black eyes—were soliciting patronage for the products of their charming island. Gaudily painted tapa cloth made of the bark of a tree, coral beads, baskets of various designs and sizes, shells and tropical fruits were the principal articles offered for sale. The competition between the dusky vendors was not a spirited one; it made little difference who reaped the greatest profits, as in a short time the gain of the morning's sales, according to the customs of the island, would soon be shared equally by all. Our time in the harbor being limited to a few hours, I was very anxious to improve every minute in studying the resources of the island, its people and their diseases. By previous appointment I was met on board by Dr. H. E. Odell, P. A. Surgeon U. S. Navy, the medical officer of the training ship *Adams*, now in the harbor (Fig. 1). To this officer I am greatly indebted for many charming courtesies and most valuable information. He took me ashore at once in the government launch and on landing introduced me to Chief Pan Pan of the village Aua, who happened to be present, a man highly esteemed by the natives and whites for his excellent character and good judgment. His distinctive dress consisted of a long white coat, with shoulder-straps of the same color with a narrow border of blue. His whole bearing impressed one with the dignity of his office and firmness of his character. From the time we entered the harbor until we reached the shore I had looked in vain for the American flag. I saw the bare, tall pole in front of the custom-house and was wondering what had happened in international politics since I left San Francisco, that it should have been stripped of our colors. The information came without asking any questions. A few minutes after landing a motley crowd gathered around that pole and presently I had the pleasure of witnessing the hoisting of the American flag (Fig. 2). This is a ceremony that takes place every day at 8 o'clock in the morning. The moment the Stars and Stripes reached the lofty destination, fluttering in the fresh morning breeze, the native band played our national airs, "*My Country, 'Tis of Thee*" and "*Star Spangled Banner*," and the mountains re-echoed the strains of the stirring music so dear to the heart of every American. The ceremony was an impressive one. The native guard, composed of 72 picked men, magnificent specimens of physical development, wearing a red turban, white sweater and blue trousers, stands at attention with arms at rest. The crowd of people, including many children, stood motionless, not a word being spoken until the last strains of the music had died away in the soft, balmy air of the tropics, when the guard shouldered their arms and marched away to their respective posts of duty in a truly soldierly manner and the crowd dispersed as quietly and silently as it had gathered. This beautiful ceremony reminded me that I was on American soil in the midst of the vast trackless Pacific ocean, nearly 5,000 miles from the western limits of the United States.

SKETCH OF THE HISTORY OF THE ISLANDS OF SAMOA.

Not all the people of the United States are aware of the fact that the beautiful island of Tutuila of the Samoan archipelago

is one of our ocean possessions and very few know how it was acquired. In making inquiries among officers and passengers of the *Sierra* regarding this subject I became satisfied how little there is known about it. The history of Samoa, especially the recent part of it, leading up to the time Tutuila was ceded to the United States, is a very interesting one and does not reflect much credit on some of the foreign powers, especially Germany. The extent to which Germany meddled with Samoan affairs and the fact that she now owns the two largest islands, Savaii and Upolu, are matters difficult to explain. The recent history of Samoa is a tangle difficult to unravel without losing the thread owing to the rapidity of succession of events caused by contending internal political factions, complicated by outside interference. Space will permit me only to give a few outlines. The Samoan archipelago, composed of not less than fourteen volcanic islands with numerous adjacent islets, lies nearly east and west between the parallels 13° 31' S. and 14° 31' S., and longitude 172° 45' W. and 168° 9' W. The last volcanic eruption occurred in Savii in 1866. The islands were first seen by Roggeveen, but their discovery is generally accredited to Bougainville, who came there in 1768 and stocked them with domestic animals. He called them Navigator Islands. It is supposed that the islands became populated by Polynesians migrating eastward from Sumatra, via the Philippines and Hawaii, by a party of less than fifty, in seven canoes. Two hundred years later the Tongans invaded the islands and, with the aid of Fijians, drove the Samoans into the mountain retreats. The hardships endured by constant persecution served to strengthen the Samoan forces, who finally gained the upper hand and cleared the two largest islands, and later all of them, of the invaders. Cannibalism was introduced by the Tongans, but was abandoned before the arrival of the explorers. The missionaries came in 1833, and one of the first fruits of their indefatigable labor was the conversion of Malietoa, one of the most powerful chiefs, who was christened Davita. This event gave rise to a religious wave which soon reached the different islands.

Frequent strifes between the different islands and tribes induced the natives to look to the United States as early as 1872 to establish order out of chaos by requesting our government to send Colonel Steinberger of New York as adviser. Two years later President Grant granted the request. The colonel soon improved the administrative affairs of the islands and had the full confidence of the natives. His influence excited the envy of the British and in less than a year he was deported by a British warship, no protest being made by our consul, and the unwarranted action had the full sanction of King Malietoa Laupepa. Insurrection followed and the king was deposed. From now on the political events followed in rapid succession by the aggressive interference on the part of Germany. Talavoa was elected king, but died after a short tumultuous reign, and Laupepa again succeeded to the throne only to be again deposed in 1888, when he was exiled by the German fleet. Insurrection under the leadership of Malietoa Mataafa again unsettled political affairs. At one time the German, English and American warships in the harbor of Apia were ready to clear the decks and begin war between Germany on one side against the other two powers, when the great storm swept them out of existence with the exception of the English gunboat *Calliope*. Active interference on the part of the United States resulted in the Berlin conference, which declared in favor of Laupepa against the protests of the natives. With the assistance of a German and British warship Laupepa defeated the forces of Mataafa near Apia in 1893, who shortly afterward surrendered to the British and was exiled to the island of Jaluit with twenty of his chiefs, where he remains at the present time. On the return to power Laupepa abdicated in favor of Mataafa, but European diplomacy again interfered and he remained on the throne. After Laupepa's death in 1888 came the contest between the exiled Mataafa, who had the German influence, and Tana, the son of the dead king. After a number of fierce contests the matter was referred to Chief Justice Chambers, who decided in favor of the heir to the throne. Finally Admiral Kautz of the battleship

Philadelphia interfered and insisted that both contending parties should lay their claims aside. England now withdrew from the contest, leaving the Germans and Americans in the field to dispose of the islands. A satisfactory agreement was reached by which, on Nov. 8, 1899, the two largest islands, Savaii and Upolu, were ceded to Germany, and Tutuila with its magnificent harbor became the property of the United States.

OUR SAMOA ISLANDS.

Out of the internal dissensions and whirlpool of foreign interventions arose for us, phoenix-like, Tutuila, the most beautiful, and, from a strategic standpoint, the most important of the Samoan Islands. Pago Pago harbor is land-locked, with an average of thirty fathoms in depth and sufficiently large to give protection to a fleet of from six to eight of the largest men-of-war, with a strip of land belonging to it amply large for government buildings, barracks and coal sheds. The harbor is hemmed in by mountains on all sides, from 1,500 to 2,500 feet high, except the narrow gateway communicating with the ocean. These mountains form a safeguard against any hurricane, no matter how severe it might be. The entrance is so narrow that a few mines and a battery on the high hills on each side could keep the largest naval force at bay. The island is 19 miles long and 230 in circumference. A number of islets belonging to it and included in the treaty stretch along the same east and west line, the farthest about sixty miles away. The main and adjacent islands are forest-clad, without a bare spot in the dark green carpet, extending from the shores to the highest mountain peaks. The primitive forests have never been disturbed, as the natives have had no use for timber either for themselves or barter. The forests are dense, almost impenetrable, and some of the trees, especially at the very summit of the mountains, are of prodigious size and would yield hardwood timber of great commercial value. The rim of lowland at the base of the mountains, when it exists, and the valleys near the shore line, are covered with groves of cocoa palms and wherever a sufficient number of these trees are found a hut or a small hamlet of huts may confidently be looked for. The volcanic formation of the entire island is covered with a thick layer of the most fertile black soil, as shown by the size of the trees, the luxuriance of the shrubs and plants and the abundance of nutritious grass. The soil and climate are admirably adapted for the growing of coffee, cacao, taro and all kinds of tropical fruits.

CLIMATE.

The climate of Tutuila is influenced by the unbroken, dense, virgin forest. We see here a very instructive example of what such forests are capable of accomplishing in the way of securing an adequate rainfall. Drought is unknown. The rainy season in the Samoan Islands is supposed to be during the first three months of the year, but in Tutuila it rains more or less throughout the year, rendering the atmosphere damp. The rainfall last year, according to Dr. Odell, reached nearly 200 inches. Every ravine leading from the mountain heights to the sea has its rivulets or small rivers, which drain off the excessive moisture of the saturated soil, furnishing the inhabitants all over the island with a faultless water supply. The climate is uniform, the tropical heat modified by sea and land breezes. The temperature seldom rises above 85 degrees F. and is rarely less than 72 degrees F., although on rare occasions the thermometer has registered as low as 60 degrees F. (Odell). The nights are generally delightfully cool. The climate is, on the whole, very similar to that of Hawaii.

THE PEOPLE.

"They eat, they drink, and in communion sweet quaff immortality and joy."—Milton.

The Samoans are a noble race, simple, honest, affectionate, peaceable and hospitable. The men are splendid specimens of physical development, above average size, and with a courteous and noble bearing. I observed several women who were close to the six-foot mark and as erect as the poles of a bamboo thicket. I noticed that many of the women and some of the men had dark brown hair, which, I was informed, was the result of a process of bleaching with lime, done either with the

intention of ridding it of its living inhabitants or for cosmetic reasons. The women are rather fair-looking when young, but lose their attraction before they reach the age of 30 by premature old age and obesity. Tattooing among men remains as a national custom. It is done as a ceremony as soon as the boys attain virility and the field of operation corresponds with that part of the body covered by their only garment—the breechcloth—so that in the event anything goes wrong with this, the simplest and oldest dress, they should not appear entirely naked. The operation is performed by experts, whose implements consist of a little fine-toothed comb made of the tusk of the wild boar, which is fastened to a small stick in the form of a minute rake. The teeth are dipped into the staining material, and with blows of a little stick on the blunt end of the comb they are made to penetrate deep enough to drive the stain into the deeper layers of the skin. The operation is attended by great pain and lasts, according to the artistic designs employed, from five hours upward. The lines of tattooing are exceedingly fine and the patterns are often quite artistic, as I had an abundance of opportunity to observe. There is very little crime among the Samoans. For four years there has been only one murder in Tutuila with its 6,000 inhabitants. The whites never lock their doors. What we look on as petty thefts, such as taking away without per-

Fig. 1.—Tutuila, Samoa. U. S. Naval Station.

mission a loaf of bread, a fish or any kind of fruit, is not regarded in the light of crime by the childlike Samoan. The next day the neighbor so treated will even up the account in a similar manner. So far as the food supply is concerned, the Samoans constitute one great family, giving and taking as occasion may demand, and the stranger is always welcome to more than his share. Family life is ideal. The father rules supreme; old age is respected; the ties of relationship and friendship are strong. No operation can be performed on a Samoan without a previous family council. If the father is the patient the sons decide the matter; if any other member of the family is concerned the father alone has the power to object to or sanction the operation. The bedside of the sick is never deserted by the immediate members of the family, and anxious relatives and friends are never far away.

The educational advantages of Tutuila are as yet in their infancy, a defect which should soon be remedied, as the children are very fond of school work. The Catholic Sisters have been here, and, as on so many other frontier lines, they are the pioneers in placing within reach of the ignorant children the means of obtaining an education. They have opened a school in a village near Pago Pago, which is already filled to overflowing with the little dusky scholars. All of the inhabitants are nominally Christians, but religion has failed to wipe out

many traces of paganism. There are very few legal marriages consummated. The native custom still prevails. Man and wife consent to live together, and continue to do so as long as the matrimonial sky is clear, but should anything occur contrary to the expectations of the husband the tie is severed by returning the wife to her parents or relatives. The children are always provided for. Unless other arrangements are made which are satisfactory to both parties, the sons remain with their father and the daughters accompany their mother.

The kahuna, or native medicine man, remains, and has not lost his influence among his people. They continue their mysterious ceremonies and the use of herbs and roots in battling with the diseases they are called on to treat. The remarks of Father Damien concerning the native doctors of Hawaii apply to the kahunas of Samoa: "We have to fight their doctors, who are generally nothing but sorcerers. In cases of sickness idolatrous sacrifices are still in use. All diseases are attributed to mysterious causes. It is very hard to disabuse these poor people of such superstitious notions." Superstition remains unshaken by the teachings of the gospel, a strong proof of the truth that

"Nothing has more power over the multitude than superstition; in other respects powerless, ferocious, fickle, when it is once captivated by superstitious notions, it obeys its priests better than its leaders."—Quintus Curtius Rufus.

PRESENT FORM OF GOVERNMENT.

Our government has very wisely interfered as little as possible with native rule. The harbor, with a strip of land belonging to it, is exclusively under the control of the officer in command of the naval force stationed there. He is at the

Fig. 2.—Flag-raising ceremonies.

same time the commandant of the island, to whom the chiefs can appeal in all matters in which they find it necessary to obtain advice, or when they fail to adjust local difficulties in their respective communities. The naval surgeons stationed at Pago Pago have in charge the sanitation of the island and the care of the sick poor natives. They have already succeeded in securing for Pago Pago, a village of 1,500 inhabitants, a pure water supply and many other sanitary improvements. The greatest fault with the Samoans is their inborn laziness. They will not work. The government has now under way many improvements, and, although the wages for this part of the world are large, \$1 a day, it had to import laborers from other islands to do the work. Civilization has rather increased than diminished this inherent repugnance to labor.

KAVA DRINKING.

Kava is the national drink of the Samoans. They have not, like our Indians, an unquenchable desire for alcoholic stimulants. Kava is the fleshy root of *Piper methysticum*, a succulent plant about four feet in height, with large, long petioled leaves. In propagating the plant all that is necessary is to break off one of the leaves at its point of insertion, including the bulbous base of the petiole, and stick it into the moist, rich, black soil. Kava drinking is a ceremony. Dr. Odell was kind enough to

give me an opportunity to observe this ceremony in all its details and to sample the product. Whenever possible the drink is prepared by a young woman, who always regards the task as obligatory, as well as a privilege, if not of distinction. The first young lady that passed Dr. Odell's bachelor quarters was called in, and she went through the entire performance with a grace and elegance that showed that she was no novice in that part of her domestic functions. Formerly the root, fresh or dried, was chewed by young women. Now the dried root is crushed on a stone, and the coarse powder is placed into a shallow bowl of hard wood, supported on very short legs, the pride of every Samoan family; it is to them what the samovar is to the Russians. After pouring cold water on the pulverized root it is stirred vigorously with both hands for about five minutes, when the straining is commenced with a swab of bark fibers, which is continued until all coarse particles are removed from the soapy-looking liquid; the entire time required being about fifteen minutes. The liquid has a peppery, rather pleasant taste. It is served in cups of carved cocoonut shell. This drink suits the place and climate better than any other beverage. In larger quantities it produces a form of slight intoxication, in moderate quantities it is a diuretic and slight soporific.

NATIVE HOUSES.

The natives remain true to their original architecture in the construction of their houses. The houses are circular, open, the round dome-like thatched roof resting on poles. The rafters are made of the bread-fruit tree, held together and fastened to the upright poles with an intricate lacework of bark and twigs. The ground is covered with gravel. The bed consists of tapa mats, and the pillows are bamboo sticks, as large as the arm of an adult, supported by props at each end, about four inches in height. The cooking is done outside. As there is no other furniture in the house the domestic duties of the female part of the family are certainly of the simplest kind. The tapa cloth is made of the thick, soft bark of a tree; it is pounded into thin sheets, dried and painted in figures most pleasing to its future owner. It is the principal article of barter, and its abundance or scarcity constitutes the wealth or poverty of the family. These open houses and the frugal diet are most conducive to the preservation of the native's health. Indoor air, combined with the inherent inactivity of the natives, could not fail in multiplying disease and increasing the death rate.

DISEASES.

Samoa, like all islands of the South Pacific, has lost its full share of population from the effects of the infectious diseases introduced by the whites, notably measles, smallpox and tuberculosis. Vaccination is now generally practiced by the naval surgeons, and the natives subject themselves willingly to this prophylactic measure. The spread of infectious diseases among the natives is favored by their habits. Their affectionate nature and the strong ties of friendship bring relatives, friends, communities and different villages in continuous and frequent contact with the afflicted, and in this manner infection is carried in all directions, and in a remarkably short time by progression from place to place will reach the most remote parts of the island. I imagine that any efforts to cut off free communication between the sick and well would appear as an infliction of cruelty to the natives, and would meet with their displeasure, if not persistent opposition. It is this free intercourse among the people that accounts for the rapid spread of measles and other acute infectious diseases over the entire island. The natives have absolutely no comprehension of the importance, much less of the necessity, of enforcing sanitary precautions.

Tuberculosis affects most frequently the lungs, as this organ becomes most frequently predisposed by catarrhal affections, which are very common; next in frequency are the bones and joints, and lastly the lymphatic glands and intestinal canal. Leprosy is unknown in Tutuila. On the other hand, elephantiasis is very common. It is estimated that of the male population over forty years of age 50 per cent. are suffering from

this disease. It attacks in preference the lower extremities, but not infrequently the upper become involved, and scrofulous elephantiasis is by no means rare. Dr. Odell has operated on a number of cases of scrofulous elephantiasis successfully, in which the mass removed weighed twenty and more pounds. The disease is much more common in men than women, undoubtedly because they are more frequently the subject of lesions, which determine infection. The disease is occasionally met with in children less than ten years of age, and not infrequently in young men at the age of twenty. There are only about 50 whites in the island, and one of them, a German, had been a resident for thirty-two years. He married a native woman and raised a large family of children. He is now 57 years old, and contracted the disease twelve years ago. It affected the right leg, pursued a somewhat acute course, and recently a complicating affection of the knee joint made an amputation of the thigh necessary. He made a good recovery, and will leave the hospital in a short time for his island home. This case, like so many others, proves that a prolonged residence in a tropical climate renders the whites susceptible to infection. Skin affections are very prevalent in the island,

Fig. 3.—Tamasee. Fine specimen of Samoan.

more especially ulcers of the leg. The lack of clothing and footwear is undoubtedly largely responsible for this, exposing the parts to all sorts of mechanical irritation in walking through the dense bush and along the stony, pebbly shore. These ulcers yield promptly to treatment by rest, and the local use of antiseptics. Another common affection is the so-called tropical abscess, a deep-seated, somewhat subacute phlegmonous inflammation, attended by only slight constitutional disturbances. It is undoubtedly the result of infection through surface lesions which are so common, that is, the entrance into the tissues of some mild form of pus microbe through a surface infection—atrium. These abscesses heal very promptly after incision and drainage. The frequency with which hydrocele is met with is attributed by Dr. Odell to *Filaria sanguinis* infection, but he has encountered no difficulty in effecting a radical cure by the usual operative treatment. Among the skin affections yaw figures very largely. Dr. Odell showed me a little girl suffering from this disease. The lips and lower segment of the face were covered with very super-

ficial weeping ulcers. He relies on mercury and chalk incorporated in a salve in its treatment, and has never seen this treatment fail in effecting a speedy healing of the ulcerated surfaces. Venereal diseases are not nearly as common in Samoa as in Hawaii or Tahiti, as the women are more virtuous, especially in their relations with white men. The humidity of the climate, the cool nights, absence of clothing, inadequate cover during sleep, are responsible for the frequency with which diseases of the respiratory organs prevail. Pneumonia occurs in a somewhat mild form, as the mortality is not great. Epidemics of influenza sweep over the island almost every year, and affect young and old, but the disease is mild. Typhoid fever is unknown. Malaria in certain localities is quite common, but always of the mildest type, yielding readily to the internal administration of quinin. Diarrhea among infants and children, caused by improper diet and exposure, is a very common affection throughout the entire year. The question has often occurred to me whether or not appendicitis is as frequent among the people who live largely on breadfruit, bananas, and cocoanut, that is a laxative vegetable diet, as it is with us, who are more imprudent in the matter of diet. That the disease is rare in the islands of the South Pacific I am sure, that it does occur is shown by a case recently operated on at Pago Pago by the predecessor of Dr. Odell. The patient made an excellent recovery. Dr. Odell has been at his present post since December, but so far, has not seen a single case, although his clientele is very large. Dysentery as observed here, is not a common disease, and yields readily to treatment. The island has so far escaped the ravages of scarlatina and diphtheria, the scourges of childhood in most of the civilized countries. The sanitary condition of the island appears to have been improved during the last few years, in consequence of which the population is now increasing.

HOSPITALS.

The plural number of this subheading will undoubtedly astonish the readers. Pago Pago is the only place in the island that affords hospital facilities, and this is a village of not more than 1,500 inhabitants, and our naval force does not exceed 120 men. Nevertheless, it has two distinct hospitals adjoining. One is a small, one-story cottage, with four small rooms, in which all the operating is done and in which the more serious cases and the soldiers are cared for. It would be difficult to crowd into this hospital more than twelve or sixteen cases, and yet it has met, so far, the urgent needs. The second hospital is a unique one. It is nothing more nor less than a large native house, built by the natives, for which the government paid them \$100. The cots furnished by the government are the only articles of furniture. The natives can come and go as they please, as they take care of themselves. Men and women live under the same roof. In case of an emergency about twelve patients could find shelter here. Its greatest merit is the perfect ventilation. At the time of my visit I found here three patients, one woman recently operated on for extrauterine pregnancy, a man affected with elephantiasis, and another one the subject of extensive ulcers of the leg. These patients have no lack of nurses, as a crowd of relatives and friends is always in attendance. Dr. Odell attends to their medical and surgical needs.

The obstetrical work in the island is attended to by neighboring women. The patient, as well as the improvised midwife, have only one thing in view when a new Samoan is on his way into the world, and that is to shorten the ordeal as much as possible by a combination of muscular force on the part of the patient and her attendant. It speaks well for the climate that, notwithstanding even ordinary cleanliness on such occasions is ignored, to say nothing of modern aseptic precautions, and a maximum of force is brought into play, sepsis very seldom follows, and the mother resumes her customary, routine household duties the next day. These strenuous deliveries, as a matter of course, result in extensive lacerations of uterus and perineum.

One death from puerperal sepsis came recently under the care of Dr. Odell. It was a case of retained placenta, in which general sepsis had developed before he was called. In spite of

prompt extraction of the putrid mass, and thorough disinfection, the patient succumbed to acute sepsis. Dr. Odell has performed three successful laparotomies during his residence in Pago Pago: 1. Ovarian tumor. 2. Dermoid of ovary. 3. Ruptured extrauterine pregnancy. Patients take anesthetics well, and wounds heal promptly. Myofibroma of the uterus does not appear to be as common in the women of the South Seas as is generally supposed; on the other hand, lipoma in all its favorite localities is very frequently met with in both sexes. It will, in conclusion, interest the readers to know that our island in the Pacific has a newspaper in the native language, published every month at government expense and distributed gratuitously among the inhabitants. Through this medium they receive the local news and keep in touch with the outside world.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

A Substitute for Milk in Intestinal Diseases of Children.

Helprin, in the *Med. Record*, recommends the following, which may be used in place of barley water when that mixture becomes monotonous or distasteful: "Two tablespoonfuls of ordinary flour in an agate dish retained in an oven till the flour is well browned, then blend or dissolve in a little cold water; this is now gradually added to, and stirred in two pints of water while boiling. This may be given in three-ounce apportionments, and ten feedings. One-half dram, gradually increased to a dram and a half, of condensed milk, can, in the course of a day or two, be judiciously added to each feeding." Other preparations of the same class include cornstarch and granum.

He also recommends the following prescription to be used to hold a diarrhea in check:

R. Bismuthi subnitratris	5v	20
Bismuthi salicylatis	gr. xii	75
Syrupi rhei aromatici	ʒiij	12
Aque dest. q. s. ad	ʒiv	120

M. Sig.: Teaspoonful every two to four hours.

For the same condition Kerley recommends the following:

R. Bismuthi subnitratris	5v	20
Sulphuris sublimatis	gr. xxx	2

M. Ft. chart. No. xxx. Sig.: One powder in a tablespoonful of water every two hours. The effect is soon evidenced, but it is best continued for some time.

Illuminating Gas Poisoning.

Hubbard, in the *Med. Record*, reports a case of poisoning by illuminating gas, and recommends early venesection, followed by a saline infusion. The author believes that this method deserves more recognition than has been accorded it in recent years. Cases have recovered after having been exposed to the gas for from six to twelve hours. The chances of recovery decrease with every hour of delay in operating.

AMOUNT OF BLOOD TO BE TAKEN.

There is no definite rule, the amount must be determined by the condition of the pulse. More often too little is removed than too much. When the pulse becomes feeble it is time to stop. The change in the rate is of no great value as an indicator. The amount of saline to be injected is likewise dependent on the pulse character. When the radial gives a full, steady pulse beat, sufficient infusion has been used.

In regard to the advisability of a second blood-letting the author states that if four or five hours have elapsed with no marked improvement in the respiration, and no return of consciousness, a second venesection may be indicated, more

caution being required in judging the amount of blood to be withdrawn.

Hiccough.

The *Med. Times* suggests the following: Chloral is perhaps the most generally useful drug in idiopathic hiccough, given to an adult in doses of ten grains (or even twenty grains) every hour until from sixty to eighty grains have been used. If after four or five hours the spasms still continue, it will be inadvisable to go on with the chloral. Many times a sharp counter-irritation on the surface of the epigastrium will stop the attack, used with or without the chloral internally. The simple act of sneezing will sometimes promptly check hiccough.

Cerebrospinal Meningitis.

Berg, in a recent number of the *Med. Record*, discusses the clinical and other features of the recent epidemic of this disease, and gives the following outline of treatment:

LUMBAR PUNCTURE.

The lumbar puncture is made and repeated only when, after a period of improvement, the temperature again rises, and symptoms of increased intraspinal and intracranial pressure occur, such as total abolition of the patellar reflex, slowing of the pulse, Macewen's symptom, increase in the Kernig phenomenon, increase in the delirium and stupor. If the cerebrospinal fluid flows from the canula in a continuous stream under tension the withdrawal of 15 to 30 c.c. of fluid will do much good. If it escape drop by drop, or if the puncture be a dry tap, there will be no therapeutic result. Sodium iodid is given in from 5 to 10 grain doses every three hours for a child over a year old, and from 15 to 20 grains every three hours for an adult. In adults, also mercuric ointment in doses of 15 grains is rubbed into the back of the neck twice daily until the gums are red. In older children the amount used is about equal to the size of a bean, and rubbed in several times a day. In children with open fontanelles the oleate of mercury in proper doses is rubbed into the anterior fontanelle.

FEVER.

When below 102 F. no treatment is required, above 103 F. use a warm bath at 80 F. in which the patient remains five minutes, the temperature of the bath is then raised to 90 F., and the patient is allowed to remain five minutes more. The bath not only reduces the temperature, but induces quiet and rest.

GENERAL CARE.

1. Large, light, airy room with thorough ventilation.
2. Care and cleanliness to avoid the occurrence of bedsores.
3. Cleanliness of the nose to prevent deeper infection through the nasal cavities.
4. Daily examination of the ears; a timely paracentesis of the drum membrane in suppurative of the middle ear may prevent a subsequent mastoid disease.
5. Care of an incipient conjunctivitis to prevent a panophthalmitis; the eyes should be protected from the light by means of a shade and not a darkened room.

Pulmonary Tuberculosis.

Pottenger, in a recent number of *Amer. Med.*, discusses the rôle of the general practitioner in the prevention of this disease: There are three factors in the etiology of tuberculosis which must be understood in order to properly and intelligently administer prophylactic treatment.

1. SOIL.—There will be no disease even though the bacilli be present unless the soil is suitable; the body cells must lose their natural resisting power. Under normal conditions the cells are very resistant to the growth of the tubercle bacilli. This fact is proven by the great prevalence of the tubercle bacilli and the great number of healed foci found in postmortem examinations which were of no clinical significance, in fact were never recognized before death.

2. BACILLI.—It is an established fact that the tubercle bacillus is the specific cause of tuberculosis, yet it is very questionable if it is capable of producing the disease in a

healthy individual, unless it be from a very virulent culture or the inoculation be one of great numbers.

3. All influences which lower the normal protective power of the cells must be carefully guarded against. (a) By living a natural hygienic life. Sunshine, fresh air, good food, clean lines, proper regard for the functions of the various bodily organs, and good habits will do much toward preserving the natural defensive powers of the body cells. (b) Avoid those things which actually lower vitality, such as overwork, especially under bad hygienic conditions; overcrowding, in rooms badly ventilated and poorly lighted; underfeeding; excesses, especially alcoholic and venereal; disease; mental disturbances; worry over real or imaginary troubles and depression from other causes.

The author elaborates further by advocating that a maximum number of hours should be designated as a day's work, varying according to the ages of the workers and the character of work done. Workshops, offices and dwellings should have certain requirements as to floor space per occupant. The poor should be encouraged by low rents and cheap and rapid transportation to reside in the suburbs. Greater care should be taken by the physician in the after-care of those diseases which are known to be frequently followed by tuberculosis. e. g., la grippe, typhoid fever, and measles.

DESTRUCTION OF THE BACILLI.

This is largely a matter of education and honor, and its accomplishment depends almost entirely on the medical profession. Physicians should have an accurate knowledge of the method of spread of the infection, which should be combated by instruction, by the family physician in the well-to-do classes, as to the careful disinfection of the sputum and other bacillus-bearing discharges. The patient should be told of the nature of the disease in order to gain his intelligent co-operation. The great majority of cases are among the poorer classes, and the instruction of them should be placed in the hands of the proper health officers. In order for the health officer to obtain results he should assist and be assisted by the family physician:

1. Cases should be reported to the health authorities.
2. Occasional circulars should be issued by the health department and sent to the physicians.
3. Instruction of the poor should be done by the health authorities, in matters of hygiene and disinfection. Several assistants should be appointed who, with the help of a corps of trained nurses, should visit the homes of the tubercular poor and make them hygienic. This work could be materially aided by the establishment of a free dispensary for tuberculosis. Such a dispensary to provide sputum cups and disinfectants and it would be an act of mercy if such foods as milk and eggs could be given to those who were in need of them.

EARLY DIAGNOSIS.

Of the great advantage of early diagnosis the author says: "It is conservative to say that if the disease were diagnosed, as it can be, in its very incipency, at least 75 per cent. could be restored to health by intelligent treatment." Therefore, examine all suspicious cases.

Medicolegal.

Crying as Evidence of Injury.—The Supreme Court of Alabama says, in *Montgomery Street Railway Company vs. Shanks*, a personal injury case brought by the latter party, that crying is often symptomatic of pain, and, in connection with the other evidence of actual hurts received by the plaintiff, the fact that she cried all the afternoon of the accident was admissible in evidence as of the essential circumstances of the injury, as was also the fact that she complained of pain the next morning.

Entitled to Compensation for Pain from Operation.—The Supreme Court of Michigan says that, in the personal injury

case of *Beattie vs. City of Detroit*, testimony was allowed to be given as to the cost of an operation. The jury were also instructed that the plaintiff was entitled to compensation "for the pain she may suffer from an operation, if an operation is deemed necessary." The court holds that there was no error in this, it being the opinion of the physicians who testified in the case that the injury would not yield to medical treatment, but could be cured by surgical operation.

Drinking of Liquor Before Commission of Crime.—The Supreme Court of Iowa says, in the homicide case of *State vs. Busse*, that the crime charged involved the condition of the defendant's mind at the time of the killing and evidence of intoxication could be considered by the jury in determining his mental condition. But the court goes on to say that it knows of no authority holding that the mere fact that an offender drank liquor shortly before committing the crime will constitute such evidence of intoxication as to require the question of its effect on his mental condition to be submitted to the jury. It is the mental confusion produced by liquor which is receivable on the question of intent of premeditation and not the fact of liquor having been taken; for it is a matter of common observation that one man may drink a considerable quantity of liquor without being affected thereby mentally or physically while another may be seriously affected by a small drink.

Expert Evidence and Privilege.—The Supreme Court of Missouri, Division No. 2, says, in the personal injury case of *Holloway vs. Kansas City*, that it was insisted that there was error in admitting in evidence the expert opinion of the plaintiff's physicians as to the cause of her physical condition, based on the previous history of her case as they learned it from her; that the correct method is to prove cause by hypothetical question based on facts in evidence. That the opinion of an expert witness is permissible when based on his personal knowledge of the matter under investigation, or on competent evidence in the case, or on both, the court says, is well settled; but the question here was whether a physician who testifies as an expert should be allowed to express his expert opinion based on the previous history of the patient as he learned it from her personally in consultation with her in respect to her ailments. The conclusion is that it was error to allow an expert witness to give his opinion based on the history of the plaintiff as he learned it from her in diagnosing her case, or while treating her. The court says that the statements of the plaintiff with respect to her past physical condition were mere hearsay, and should not have been considered by the expert in expressing his opinion as a witness as to her physical condition at the time of the trial. The decided weight of authority and the better reason support this contention. But a conversation between a patient and physician in regard to the former's doctor bill, or in regard to a contemplated lawsuit, the court holds is not privileged, it not being "information necessary for the physician to enable him to prescribe for such patient as a physician, or to do any act for him as a surgeon," within the purview of the statute. That the plaintiff could not sever her privilege, and waive it in part and retain it in part, the court also thinks clear. And, if she waived it at all, then it ceased to exist. That she did so waive it when she testified that a physician examined her, though not very thoroughly, and asked her about it, and she told him, and he examined her womb and back, is deemed too plain for discussion. However, such waiver should be restricted to such information as the physician acquired from her while attending her in a professional character, and which information was necessary to enable him to prescribe for her as a physician, or to do some act for her as a surgeon; and it is manifest that a conversation in regard to a contemplated lawsuit, or the plaintiff's doctor bill, did not come within the provision of the statute. But the court is not to be understood by these observations as meaning or intimating that the physician was not competent to testify as a witness to what the plaintiff said to him, if anything, in regard to bringing suit against the city for damages, and that if she would go into it they would be able to fix up his bill against her. Such statements were not within the meaning of the statute under consideration. On the other hand, the court does

not agree with the contention that because the plaintiff, after testifying that her health was good, had answered, on cross-examination, that a physician had treated her for headaches, that she waived protection of the statute, and that the defendant had the right to the evidence of the physician for the purpose of contradicting her.

Vested Right of Physician to Payment as Per Contract.—The Supreme Court of Michigan says that, in the case of *Kapp vs. Board of Auditors of Washtenaw County*, the board of health of Freedom township, in said county, made a written contract to pay for the care of indigent persons affected by contagious diseases \$10 per visit and 25 cents per mile going. After the services in question were rendered, but before the bill therefor was allowed, the legislature passed an act, giving it effect March 13, 1903, which provided for a change in the law giving the boards of supervisors authority to pass on the reasonableness of claims for services in caring for indigent persons, by direction of the board of health, whereas, before the allowance by the local board was usually final and conclusive on the board of supervisors. By reason of this the board of auditors refused to allow and pay the bill contracted in this case as above. The Supreme Court says that it was unimportant whether the township board of health might properly agree in advance on the price to be paid for such services or not, for the service was rendered at the request of that board, and the bill was audited and allowed by it. Had this allowance been made before the act took effect, it is clear that the board of auditors must have paid the bill, and that the physician's right could not, in such case, have been affected by the legislature. Did the fact that the allowance was deferred until after such act took effect justify the board of auditors in its action? The court's answer is that the physician rendered services under a law which made the county liable to pay for them on allowance by the local board. The amount was agreed on in advance. He had a vested right to such payment, when lawfully allowed by the local board, and it could not be taken away or impaired by legislation, as it would be if the supervisors were authorized to question its reasonableness. To much the same effect is the second decision of the Supreme Court of Minnesota in the case of *Comstock vs. Board of Commissioners of Lesueur County*, where it overrules the decision reported on page 1590 of THE JOURNAL of June 11, 1904. In this second decision it holds that chapter 238, page 378, Laws of Minnesota of 1901, changing the liability for expenses incurred in preventing the spread of contagious diseases from towns and villages to counties, did not change or abrogate contract relations then existing between individuals and such towns or villages. A contract existing at the time of the passage of that act, and under which an indebtedness against a village arose, may be enforced against it. Again, it says that at the time the contract here involved was entered into and the indebtedness incurred—at least the greater part of it—towns and villages are solely liable for all expenses of this kind. The rights of the parties became vested and fixed at the time the contract was entered into, and it was beyond the power of the legislature to impair its obligation, as between individual creditor and the town or village, by shifting the liability from the town or village to the county. The plaintiff in this action had the right to rely on and seek relief in accordance with the contract between himself and the village.

1. **The Nervous Symptoms of Peripheral Arterial Disease.**—These symptoms may be either paroxysmal or permanent; either motor or sensory. The one constant lesion in intermittent lameness is chronic arteritis. Aneurism, especially of the iliac artery, is not very infrequent. Intermittent lameness bears some resemblance to angina pectoris. Its rarity is apparent rather than real, and due to its not being looked for or thought of. Patients do not always present a typical clinical picture. The most striking thing is the absence of the pulse in the member or members affected. Many cases are thought to be rheumatic or neuritic, or even neurasthenic. Glycosuria is a frequent complication in both slight and severe cases. Often the disease resembles paralysis agitans without tremor, without festination and without speech defect, but with the wooden face and the waxy rigidity of movement. The morbid anatomy of the disease is much disputed. Some of these cases are spinal in origin, and there is found an overgrowth of the neuroglia and minute areas of softening, due to disease of the blood vessels in the spinal cord, but at other times there is only sclerosis of the peripheral arteries, with little or no spinal disease.

8 Remarks on the General Principles of Management of Pulmonary Tuberculosis. S. G. Bonney.

9 The Gynecological Aspect of Mental Overstrain at Puberty and Its Influence on Development. Wm. Edgar Darnall.

7. **Renal Retention with Anuria.**—Watson's paper deals with those forms of renal retention only with which anuria is associated, and which originate in complete closure of the ureter or of the outlet of the renal pelvis. He presents an analysis of 200 cases published by different writers. Cases in which the diagnosis is reasonably assured, apart from the surgical treatment, subcutaneous injections of saline solution are useful with a view to delaying or mitigating uremic symptoms. In cases of calculus obstruction, hot hip baths and manipulation aid the passage of the stone. When the obstruction is due to a kink of the ureter produced by movable kidney, the patient's hips should be raised, the abdomen relaxed and an effort made to replace the organ in its normal position. As to operative treatment, a quickly performed lumbar nephrotomy is the operation which will best fulfill all the requirements. Speed in the performance of the operation is of the highest importance.

14 *Malaria. R. Cadwallader.

15 Practical Hygiene in the Public Schools. R. S. Wilcox.

10. **Malignant Disease of the Larynx.**—Delavan's paper indicates the progress recently made in the study and care of malignant disease of the larynx and calls attention to certain special points of treatment which seem of sufficient value to demand investigation and discussion, such as the use of the x-ray and other means of producing radiant energy. Laryngectomy and tracheotomy are discussed in all their phases, and the author concludes that in properly selected cases early preliminary tracheotomy is without doubt a valuable measure. Improved technic, special skill and early recognition of the disease will continue to improve the results obtained from this operation.

11. **Post-Typhoid Laryngeal Perichondritis.**—Mayer refers to a case of this kind, which was published, in part, last year, in which a complete cure was effected by means of intubation. The special points of interest in the case are: 1. The unusual nature of its origin, a gradually increasing dyspnea requiring a tracheotomy one month after the patient was discharged as cured of the typhoid fever. Three months later an O'Dwyer tube was introduced, which was worn for six weeks. 2. The length of time the tube was worn—for three months, continu-

ously. 3. The ease of deglutition after an intubation. 4. The use of the child's size O'Dwyer tube for a short time toward the last. 5. The cure by intubation. Nine months after the last extubation the patient's general condition is good; she has increased in weight and attends to her usual duties.

12. **Pulmonary Hemorrhage.**—McLaughlin's treatment of pulmonary hemorrhage is as follows: Immediately on the occurrence of the hemorrhage the patient is given a hypodermic injection of 1/100 grain nitroglycerin and 1/4 grain morphin. Adhesive straps are applied to the side of the chest from which the hemorrhage is coming and the patient is instructed to lie on that side. Six hours after, if the hemorrhage has ceased, the patient is moved to a summer house which has no sides and is practically out of doors. At the end of four days the straps are removed and the patient is given a week of rest cure in the open. Seven cases have been treated in this manner; four were of moderate severity and two very severe; one was not severe as to the amount of blood lost in a given time, but the bleeding extended constantly over a period of more than seven weeks, during which time all the coughed-up matter was stained with blood. In all cases the hemorrhage was promptly and permanently controlled, and in none of these was there any secondary rise of temperature.

13. **Trachoma.**—Parker says that the cases for operation should be selected carefully, inasmuch as much harm may be done by indiscriminate operation. Operation is not a radical cure, but merely a means to a cure and a shortening of the time of treatment. Post-operative treatment is of the greatest importance; without it there may occur relapses which are as bad or worse than the first attack. The general condition of the patient is of importance. Proper feeding and out-of-door life should be urged. Adenoids and other hindrances to development should be removed. The treatment should be continued until the patient is cured. An effort should be made to prevent the spread of the infection and to arouse the patient's interest in doing so. For this purpose Parker gives the following printed instructions to his trachoma patients: Trachoma is a contagious disease of the eyelids, which if neglected will cause suffering and injury to the sight. To avoid infecting others, those having the disease should observe the following instructions: 1. They should have their own towels, handkerchiefs, washcloths and toilet articles, and under no circumstances should they be used by others. 2. They should sleep alone. 3. Avoid rubbing or touching the eyes, as the contagion may be carried on the fingers and infect others through articles handled. 4. The hands should be cleaned often with soap and water. 5. Treatment should be attended to regularly and continued until pronounced cured by the physician. Parker's non-operative treatment consists of bichlorid rubbing, with the use of one of the organic silver solutions, night and morning: in the hard variety, he uses copper sulphate in place of the bichlorid.

14. **Malaria.**—Cadwallader gives a summary of our present knowledge of the etiology of malaria, and reports several cases, calling attention to a number of interesting clinical features. He believes that a pre-requisite to infection, or at least to symptoms, is a watery condition of the blood, and just in proportion to the total fluid in the body will be the severity of the disease.

24 *Elevation of the Hips in the Treatment of Placenta Previa. Alfred King.

25 Our Relation to One Another. John M. Kennedy.

17. **Medicolegal Postmortems.**—Polozker believes that it is absolutely necessary that this subject should be taught in medical colleges, and from the practical standpoint only. The difference between the medicolegal postmortem and the pathologic postmortem should be emphasized. The modern methods of the coroner and the police department in the conduction of a murder case are deprecated, and a remedy for the evil is pointed out.

19. **Trachoma.**—Nydegger refers to the confusion in diagnosis between trachoma and other diseases of the conjunctiva, such as papillary conjunctivitis and follicular conjunctivitis. The subject of trachoma is reviewed in full.

21. **Non-Susceptibility of New-born to Measles.**—Graham reports a case which he believes shows the non-susceptibility of the infant at full term to measles. A woman, ill with a well-developed case of measles, gave birth to a healthy child presenting no abnormal conditions or symptoms. At no time was the child isolated from its mother; it was kept in the same bed, nursed at intervals of two hours, and treated exactly the same as if it were not exposed to the contagion of the measles. Although an older child developed a typical case of measles, the infant, six weeks after birth, presented no evidences of having contracted the disease.

22. **Insufficient Motility of the Stomach.**—Fulton's treatment of this condition is hygienic, medicinal and mechanical. The diet should be one that spares the motor powers of the stomach, and, therefore, the more feeble the motility the more liquid the diet, especially when there is obstruction of the pylorus. The feedings should be small and frequent, although each case is a guide as to the number of feedings per day that should be given. The medicinal treatment comprises the administration of 1/24 grain of strychnin, three times a day; dilute hydrochloric acid, freely diluted, in 20 or 30-drop doses after meals; teaspoonful doses of burned magnesia and sodium bicarbonate one or two hours after eating when excessive acidity exists. Fulton has obtained good results in these cases by giving a pill containing from 1/2 to 1 grain of creosote, with 1 grain each of pulverized rhubarb and soap. Of the mechanical measures, he uses abdominal bandages, lavage and internal faradization of the stomach. Cases which do not improve under this treatment should be relieved by operative procedure before the strength of the patient is entirely spent.

23. **Gonorrhoea.**—Flanagan emphasizes the fact that many cases of suppurative urethritis are diagnosed as specific and subjected to treatment which may prove harmful rather than otherwise. Treating a case of urethral inflammation, the physician should know exactly the nature of the trouble and use such treatment as the exigencies of the case demand.

24. **Placenta Previa.**—King briefly discusses the value of elevation of the hips in the treatment of placenta previa. The method is also applicable in excision of the rectum and abdominal hysterectomy, gravity operating in these cases as a great blood saver. The method is not described in text-books. It consists in inclining the patient's body to an angle of 45 degrees. This is really the Trendelenburg position, with the legs of the patient in the same plane as the body.

26.—See abstract in THE JOURNAL, xlii, p. 1376.

27. **Acute Middle-Ear Disease.**—For the treatment of this condition Donovan prefers the curette, finger nail or nail

curette. He considers ether and nitrous oxid far superior to chloroform for anesthetizing infants and young children. In older children and adults he uses cocaine; in fact, a single application of 5 per cent. may be used safely even in young children. To affect a thorough cure, it is necessary to remove all hypertrophied lymph tissues, such as adenoids and enlarged lingual tonsils. The prophylactic treatment is all-important and should not be overlooked. In all diseases affecting the nasal pharynx reasonable precautions should be used to avoid tubal infection. With the first symptoms of earache he advises the use of heat and dehydrating remedies. If these do not produce beneficial results in a few hours, treat surgically. When possible, with a catheter, use a mild continuous stream of hot air early, and repeat in eight or ten hours. If these measures fail to relieve the symptoms within ten to twenty-four hours, make a free incision through the entire drum or extend into upper canal wall, if necessary. Use aseptic gauze drainage and outside pad for absorption. Patients should never be allowed to suffer for more than forty-eight hours and remain exposed to the risks of complication.

28. **Incision of the Membrana Tympani.**—Packard emphasizes the great value of early incision of the membrana tympani in the treatment of acute suppurative otitis media, and the many advantages possessed by the so-called dry treatment, and by practicing efficient gauze drainage. Douching the ear is distinctly contraindicated, except when it is done by a skilled aurist, who can properly dry the ear after such procedures.

29. **Acute Gonorrhoea.**—Weiss continues his discussion of this subject; the various silver compounds, their advantages and disadvantages, are considered at length. The treatment of the mucosa should at all times conform to the microscopic findings.

30-33. **Tuberculosis.**—These four articles are an epitome of what is known of the questions dealt with in the papers, and serve to emphasize the importance of an early diagnosis, the necessity of careful differentiation between pulmonary tuberculosis and conditions resembling it, and the value of taking complete histories of each case.

37. **Neurofibroma of the Acoustic Nerve.**—Fraenkel and Hunt are of the opinion that the symptoms of tumor of the acoustic nerve are so well defined that a diagnosis can be made with practical certainty in every case; not only with reference to its location, but also its nature and comparative size. However, other slowly growing pathologic conditions in the posterior fossa might closely simulate this condition. The slow and essentially benign nature of the growth, its non-infiltrating character and enucleability all favor surgical interference.

But its deep situation at the base of the brain, in immediate proximity to vital centers offers very serious obstacles. From personal observation the authors conclude that the surgical technic should be perfected along the following lines: 1. The avoidance of undue concussion in the removal of the bone and the enlargement of the trephine opening. 2. A method of extirpation by which the tumor could be extirpated without undue manipulation of the surrounding parts. 3. The division of the operation into stages, as recommended by Horsley, and celerity of execution.

38. **Macrocheilia.**—Eisenrath adds a second case to the literature of macrocheilia due to adenoma of the mucous glands of the lid, the diagnosis having been confirmed by a microscopic examination. The case improved remarkably after operation, and there has been no recurrence in a year.

39. **Lingual Goiter.**—Storrs reports a case of lingual goiter, the tissue involved being accessory thyroids at the base of the tongue which are embryonic remnants of the atrophied thyroglossal duct. Only 32 cases of this kind are recorded in the literature, 29 in women and 3 in men. These lingual tumors usually are situated on the dorsum of the tongue, generally just behind and below the foramen cecum, but sometimes enclosing it in their growth on the median line, as a rule, but perhaps a little to the right or left. In shape they are round or ovoid, their size ranging from that of a cherry to that of a man's fist. The tumor is encapsulated and may project about the surface of the tongue or be almost buried in the muscles of this organ. There is no inflammation or infiltration of the surrounding tissues, and at operation the tumor is enucleated easily. Its surface is covered with the mucous membrane of the tongue; it is smooth and shiny, and in color is darker than that of the surrounding mucous membrane, due to the great infiltration of blood vessels. These vessels cover the surface of the goiter and penetrate deeply into its tissue, and cause the profuse hemorrhages which occur at operation. This rich vascularization is of great value in differential diagnosis. The tumor may or may not be movable; its consistency is variable. The troubles caused by it are purely functional, and these vary with the size of the tumor. With one exception, the patients were in the best of health. It has all the characteristics of a benign tumor. The prognosis is favorable. The only rational method of treatment is removal, either by the use of the galvano-cautery loop, or by incision with enucleation. The latter operation is preferable and is performed easily. The tumor may be reached either through the buccal cavity or through an incision in the suprahyoid region, which may be simple or include the hyoid bone or inferior maxilla.

46. **Posterior Incision for Appendicitis.**—Sheldon describes a method by which the appendix is reached through Petit's triangle. The patient is placed on the left side and a large support put under the left loin, thus bringing the appendix nearer the incision by depressing the right side of the pelvis. An incision is made from a point one-half an inch behind the highest point of the crest of the ileum toward the tip of the twelfth rib. The length of the incision depends on the obesity and the body form of the patient. The anterior border of the latissimus dorsi muscle is located, freed by blunt dissecting and retracted posteriorly. This exposes the outer border of the quadratus lumborum muscle, the lumbar fascia, and the aponeurosis of the transversalis. A transverse incision, one-half to one inch above the crest of the ileum, is made, beginning at the outer border of the quadratus lumborum and extending forward parallel to the fibers of the transversalis, as far as is necessary to secure sufficient room to operate quickly. The subperitoneal fat is pushed aside with the finger, covered with a piece of gauze. The peritoneum is opened near the forward part of the incision and the peritoneal incision enlarged in a posterior direction. On opening the peritoneum the cecum presents itself in the wound. The appendix is amputated in the usual manner and when drainage is not necessary the wound is sutured in layers, with catgut and silkworm gut. Sheldon has never found it necessary to ligate a vessel during the operation, and seldom has it been necessary to check tem-

porary bleeding with hemostats. In clean cases the operation has no advantages over the method ordinarily employed, except that it is followed by less shock and abdominal distress than is a laparotomy through an anterior incision. In obese cases the operation is more rapid and is less likely to be followed by hernia. In all cases requiring drainage the operation is preferable to the old method. The abscess is opened in the most dependent part and the infected area can be treated without coming in contact with the omentum or small intestines. Retroperitoneal infection is drained much more efficiently than is possible through an anterior incision. Sheldon has operated on 58 cases by this method and has found no disadvantages.

49. **Urethral Transplantation.**—Pringle describes three cases in which defects of the urethra have been treated by grafting portions of the urethra of an ox. Two of the patients so treated had sustained a complete and extensive rupture of the urethra in the perineum; the third patient had a hypospadias, there being a deficiency of the floor of the urethra for the whole of the penile portion of the channel. The operation in each case was a success, the grafted tissue remaining alive and furnishing a patent channel. In two of the patients the procedure had to be repeated, but in each of them, at the time of the second operation, the tissue which had been grafted on the former occasion was found to be present.

- 55 Tumors. R. Lanzerehans.
- 56 Communicability of Pneumonia by Contact. L. Weber.

54. **Acute Rheumatism in Children.**—Sheffield considers rheumatism in children a grave infection, one that requires active treatment particularly, in order to prevent serious complications. Rest in bed is the most important therapeutic measure in this direction, and should be enjoined during the entire course of the disease. Dieting he considers to be nothing but a myth. During the febrile stage the diet should, of course, be limited to the ordinary "fever diet." In older children he uses the salicylates combined with small doses of pepsin or ingluvin. For younger children he prefers aspirin, or the salicylates obtained from the wintergreen plant, in doses of 5 grains, to be repeated every two hours the first day and every four hours the following days. For the relief of articular pain and swelling the joint should be wrapped in absorbent cotton wrung out of a warm saturated solution of bicarbonate of soda. The compress should be covered with oiled silk and a flannel bandage, and changed as soon as it becomes dry. After disappearance of the acute symptoms the stiffness and lameness generally yield to gentle massage with an ointment containing 1 dram each of oil of gaultheria and ichthylol in 1 ounce of lanolin. Later on it is advantageous to supplement the local treatment by gentle general massage. The iodids should not be lost sight of in protracted cases.

55. **Tumors.**—This is a translation of that portion of Langerhans' work on pathologic anatomy which describes lipoma, myxoma, chondroma, osteoma, psammoma, melanoma and glioma.

58. **Infection.**—Babler refers to an overlooked disseminator of infection—the garment that drags on the floor of the home, that collects the filth and disease of the pavement, the steps, the darkened passageway, the street, the alley, or wherever its wearer may chance to go—and asks that every practitioner consider this matter carefully and do what he can to remedy this evil.
59. **Antistreptococcc Serum in Scarlet Fever.**—Chapman reports a case of scarlet fever which yielded promptly to anti-

streptococci serum. Within ten hours after injecting 10 c.c. the temperature dropped 4 degrees. The dose was repeated every twenty-four hours, and the temperature reached normal ten hours after the fourth injection. The only other treatment was hydrogen peroxid for a throat wash and benzoate of soda internally, tonics and calomel.

 63 Vesico-vaginal Fistula Following Hysterectomy for Carcinoma Cervicis Uteri, with Special Reference to Their Origin and Closure. John A. Sampson.
 64 The Piezometer, an Instrument for Measuring Resistances. Howard A. Kelly.
 65 Dr. Richard Brooke, the First Scientific Observer in Maryland. Bernard C. Steiner.

63. Vesico-Vaginal Fistula Following Hysterectomy.—Sampson says that the anatomic relation between the cervix and bladder is such that the anterior extension of carcinoma cervicis uteri soon invades the bladder wall, as shown by vesico-vaginal fistula, which may occur in the advanced cases; accidental injuries to the bladder during hysterectomy for cancer; cystitis following these operations. The surgeon who attempts to separate a carcinomatous cervix which has become adherent to the bladder usually leaves cancer tissue behind and the disease returns; so injures the bladder wall that a vesico-vaginal fistula may form, which, if recognized and repaired at the time, is apt to fail to unite because the fistula is situated in a portion of the bladder wall whose outer coats have been torn and whose blood supply has been injured by the operation. If he does not produce a fistula the injured portion of the bladder may be unable to resist infection and a severe cystitis may result. Because of this, if the cervix is adherent to the bladder, the portion of bladder wall adherent should be excised in order that a wider excision of the primary growth may be made; that the injured bladder wall may be repaired properly, and that the bladder may be better able to resist infection. Post-operative vesico-vaginal fistula may occur from undiscovered accidental injuries to the bladder, or the failure to repair injuries recognized at the time of operation: from the intentional formation of such fistulae at the time of the operation in order to relieve intra-vesical tension and give the bladder a rest, and also the formation of fistula after the operation, in order to minimize the dangers of post-operative cystitis. Frequently post-operative vesico-vaginal fistulae close spontaneously. Apparently the early operative closure of such fistulae, unless in healthy bladder tissue, is difficult and operative measures should not be undertaken until the tissue has had a chance to regain its natural blood supply—after about two months. The radical operations for cancer of the uterus diminish the sensibility of the vagina and bladder to pain, so that post-operative vesico-vaginal fistulae may be closed without the use of a general or local anesthetic. The following principles should be employed in the closure of these and all vesico-vaginal fistulae: 1, approximation without tension; 2, a broad area of denudation exposing healthy bladder tissue; 3, accurate approximation with inversion of the bladder mucosa; 4, tying the ligatures so as not to strangulate the tissue. Very fine silver wire, fastened by means of perforated shot, forms a very satisfactory suture material, and if a small piece of rubber tubing is placed between the shot and the vaginal mucosa, a most efficient "splinting" suture is formed, which, through the elasticity of the rubber tubing, maintains accurate approximation without strangulation.

64. The Piezometer.—Kelly designed this instrument for the purpose of aiding in outlining an abdominal tumor, and to estimate the degree of rigidity in the right iliac fossa in a doubtful appendicitis by comparing the rigidity of the right and left oblique muscles. The instrument may also be used as an algometer to determine how much pressure is necessary to elicit tenderness over the appendix. It should also have a field of value in teaching physical diagnosis, since it is far more delicate than the untrained sense of touch, and varying degrees of resistance can be demonstrated by means of it. The instrument

is intended not to replace palpation, but to supplement or confirm the results obtained by it.

 79 Chronic Non-specific Laryngitis: Clinical Forms; Treatment. Albert Kuatt.
 75. "Vocal Nodules."—Knight reports the outcome of a case of epithelioma of the larynx which he reported several years ago as one of "vocal nodules." Later a thyrotomy was done, the patient succumbing a few hours after the operation. This case emphasized the following points: 1, A stimulation to activity of malignant disease by endolaryngeal manipulations. We should always be prepared for this event, and, if possible, have the full consent of the patient to resort to whatever further operative procedures may seem advisable. 2, The testimony of the microscope is not to be depended on unless the whole thickness of suspected tissue at several points can be secured. It is seldom possible to obtain a satisfactory microscopic specimen by means of forceps passed through the mouth. 3, The question of transformation of a benign growth into one of malignant character has apparently been decided in the negative by statistics, yet in the case reported the appearance and history of the lesion continued absolutely benign for more than two years. In many cases a longer period of quiescence has been observed. There was nothing whatever in the course of the disease that justified a suspicion of malignancy until after the use of the snare. It is not supposed that the latter did more than excite the virulence of the morbid process. 4, We are still in the dark as to positive signs by which to identify malignancy at its inception. At present the only way in some cases in which to determine the character of a doubtful laryngeal lesion is by its complete exposure to an external wound. The picture in the laryngeal mirror is often indecisive as to the character of the lesion and misleading as to its extent. Although the prognosis in intrinsic cancer of the larynx is more favorable than that of malignant disease in almost

any other region of the body yet our guiding principle here as elsewhere should be early operation to include by a wide margin every vestige of morbid tissue.

76. **Malignant Growths of the Tongue.**—Johnston reports a case of sarcoma of the tongue and another of epithelioma, both tumors appearing at the base of the organ.

77. **Nasal Hydrorrhea.**—Rhodes reports a case, the patient being a woman aged 44, in which the following plan of treatment was pursued: She was given a pill containing zinc phosphid, nux vomica and quinin for her constitutional condition. Locally he used at first a 5 per cent. protargol solution, then 50 per cent. argyrol, and a spray of adrenals, 1 to 5,000, and Dobell's solution to use at home. He tried in succession cocaine, adrenalin, cauterization, zinc salts, strong applications of menthol in alcohol, and internally belladonna, aconite, etc., without the slightest benefit. Finally he used a solution of argentic nitrate in small quantities, 60 gr. to the ounce, and over a portion only of the nasal cavity. This caused some pain and a little headache, but immediately following there was a cessation of the dripping for a few moments. This treatment was continued until finally the discharge ceased entirely and has not returned.

83. **Results of Induced Labor.**—Norris says that the excellent results for mother and child following the elective cesarean section for pelvic deformity have induced many operators to unnecessarily perform that operation for the lesser degree of pelvic contraction. He exploits the usefulness of inducing labor in the lesser degrees of contraction in order to give Nature the little assistance she may need to save the children that without this aid are frequently lost after version or a difficult forceps extraction at term. When the patient is first seen, too late to induce labor at the most suitable time, it is his practice never to allow such a case to go to, or beyond, null term, but to terminate the pregnancy at once and deliver the case as may seem best after the test of labor. An operative delivery, version or forceps after the induction of premature labor adds a distinct risk to the child, and, when possible, should be avoided. After true labor pains have begun and the cervix has dilated, it is an advantage to place the patient in the combined Trendelenburg-Walcher position. This is an important practical point to be remembered not only for induced labors, but for minor degrees of pelvic contraction when first encountered at term. The method of dilation used by Norris is the proper introduction of a bougie, followed by partial dilation of the cervix, if required, and then by the insertion of the largest size Vorhees' bag, on the stem of which

more or less continuous traction is made by means of a cord and weight, if necessary, to awaken pains and aid in the dilation of the cervix. The time required to obtain sufficient dilation to accomplish spontaneous or artificial delivery varies from six and a half to fifty-three hours, the average being twenty-nine and one-quarter hours. In 30 cases of induced labor for the lesser degrees of pelvic contraction there was neither maternal mortality nor morbidity. Seven infants died; 2 were still-born, 1 from craniotomy after eversion and occiput rotating backward with the chin impacted above the symphysis. The other still-born infant was the result of a prolapsed cord, pulseless when the accident was discovered, and after delivery disclosed a large spina bifida incompatible with life. Two infants died from prematurity, the result of too early interruption of pregnancy. One infant died on the fifteenth day from infection of the navel; one on the third day from a sudden and rapidly fatal intraperitoneal hemorrhage, and one on the fifth day from aspiration pneumonia.

87.—See abstract in THE JOURNAL, xlii, p. 1511.

88. **Post-Operative Intestinal Paresis.**—Several months ago Craig published an article on the use of eserin salicylate in preventing intestinal paresis by inhibiting the inhibitory impulses ordinarily sent to the intestinal musculature by way of the splanchnics as a reflex result of peripheral irritation. Also that, through its powerful stimulant action, either directly on the muscular fibers of the intestine or the nerve terminations therein, the intestinal nerve plexuses are saved a vast amount of work, reaching in cases of actual paresis complete exhaustion. Further observation has shown Craig that under the use of eserin the post-operative conduct of the intestines is the same as though the abdomen had not been opened. In emergency operations following the use of eserin any marked accumulation of fecal matter not removed previous to operation is promptly expelled after operation. In many cases the bowels move freely and easily in from twelve to forty-eight hours after the return of the patient to her bed. When the bowels have been adequately prepared, an absence of movement during the same period is abundant testimony to the thoroughness of the preparation. During this interval both nurses and surgeon should be eternally vigilant and watch for signs and symptoms of intestinal paresis or adynamic ileus, because eserin may occasionally fail to manifest the expected therapeutic action, or sepsis may supervene and no method of treatment can wholly overcome the results of accidental infection nor of unclean, careless or slovenly technic; or obstruction may supervene, which is mechanical and not merely parietic. Eserin salicylate should never be kept in solution because of its deterioration. On the evening of the day succeeding operation Craig administers a tablet containing aloin, gr. 1/5; extract belladonna, gr. 1/4; strychnin sulphate, gr. 1/60; eserin salicylate, gr. 1/100, the same dose to be given each night. He emphasizes the importance of becoming thoroughly familiar with the physiologic action of eserin and its source so as to avoid untoward effects.

10. Cases of Appendicitis with Perforating Duodenal and Gastric Ulcer. H. A. Ledlard.
11. The Evolution of Man's Diet. Harry Campbell.

2. Human Piroplasmosis.—Donovan gives a full description of the maladies as observed by him, the causative animal parasite and the postmortem findings. He is convinced of the identity of this disease and kala-azar, the exciting cause in both being the same.

3. Epibulbar Melanotic Sarcoma.—Clegg and Hall add two cases of pigmented epibulbar tumors situated at the limbus to the literature on this subject. Of 520,523 out-patients who have attended at the Manchester Royal Eye Hospital during the last thirty-three years, only 3 were cases of pure melanotic sarcoma of the limbus, although general "orbital melanosis" has been noted more frequently. One case disappeared after operation; the other 2 recovered completely. In 1 case the eye was removed, in the other 2 the tumor was excised. Of the latter the one patient remaining under observation regained perfect vision, and is in robust health.

5. Pseudoleukemia in a Child.—Redfern reports a case of pseudoleukemia occurring in a child two years and nine months old, with no history of previous illness. The case terminated fatally by syncope after about eight weeks' illness. Only the cervical glands were enlarged, but they were not painful or tender on pressure. The axillary and anterior mediastinal glands became enlarged later. Dyspnea was marked. There was unilateral perspiration on the left side of the body, face and limbs. The left pupil was more dilated than the right. The general nutrition was maintained until death. There was no family history of syphilis or tuberculosis. The blood condition was as follows: Red corpuscles, 4,080,000; leucocytes, 8,000; lymphocytes, 30 per cent; hyalin leucocytes, 10 per cent; polymorphonuclear cells, 68 per cent; eosinophile cells, 2 per cent.

9. Injection of Paraffin in Rectal Prolapse.—Burgess has treated 18 cases of rectal prolapse by the submucous injection of paraffin having a melting point of 111. Of the 18 cases the ages ranged from 3 to 48 years, and the size of the prolapse from 1½ to 5 inches in length. In all of them the prolapse descended with almost every bowel movement, and remained down until replaced. Two were associated with excoriation and ulceration of the mucous membrane; 2 had been previously treated by linear cauterization without success, and 2 had recurred after the excision of the lower part of the rectum. The injection treatment has been extremely satisfactory in all the cases, not a single instance of recurrence having occurred. Paraffin masses can readily be distinguished after two months, feeling like nodules of cartilage. The technic of the operation is as follows: The paraffin is kept melted by placing the container in water at a temperature of about 120. The syringe has its barrel covered with rubber to retain the heat longer. The instrument is placed in the hot water bath for a few minutes, is then filled with melted paraffin, and replaced in the bath until the moment it is required to be used. The patient is anesthetized and placed in a lithotomy position; the prolapse is drawn out to the fullest possible extent. The apex of the prolapse is seized with artery forceps, at three points equi-distant along its circumference, so selected that two forceps will be placed anteriorly and the third in the posterior median line. By gentle traction the mucous membrane is raised into three ridges forming an equilateral triangle. The needle of the syringe is inserted in turn into the middle of each side of this triangle, from 2 to 3 c.c. of paraffin being introduced on each occasion. As this solidifies, the mucous membrane bulges inward, converting the lumen of the

bowel into a more or less tri-radiate slit. The forceps are removed, the apex of the prolapse is reduced, and the mucous membrane is again seized with forceps about $1\frac{1}{2}$ in. from the original apex, as before, except that at this time, two are placed posteriorly, and one anteriorly. The paraffin is injected as before, with the result that the lumen of the bowel is again converted into a tri-radiate slit, the radii, however, corresponding to the intervals between the radii of the tier above. This portion of the prolapse is now reduced and the forceps re-applied, as at the first time, and the process is repeated until the anus is reached. As a rule, three tiers are sufficient, but in a very long prolapse four may be introduced safely. In order that straining may not cause the prolapse to re-descend before the paraffin has firmly set, Burgess inserts a stout silkworm-gut suture through the buttocks on either side, tying it firmly over a pad of gauze placed over the anal orifice. This suture is removed at the end of twenty-four hours. No special after-treatment is required. The patient is kept in bed for four or five days. The bowels have usually been allowed to act spontaneously. Autopsy shows that the paraffin remains strictly localized to the area of its introduction and undergoes no change. However, the masses become encapsulated by fibrous tissue. The rectum is fixed firmly in its normal situation, and can not be drawn down to constitute a prolapse, even after considerable pressure.

15 *Antityphoid or Anti enteric Inoculation. F. Smith.

14. **Onyalia.**—Under this name Massey describes a disease found among the blacks of Portuguese West Africa. It is rarely ever fatal. The only clinical evidence is the appearance on the hard palate and buccal mucous membranes of vesicles distended with blood, ranging from one-quarter to half an inch in diameter. Sometimes these vessels are uniloculated; they can not be emptied easily; they have a tendency to appear in clots. There is no fever, the patient complaining only of discomfort in the mouth and a general feeling of lassitude. The duration of the disease is about ten days. Treatment consisted of the administration of 60 grains of bicarbonate of soda and half an ounce of unpurified codliver oil internally each day. Calcium chlorid was not given a trial.

15. **Antityphoid Inoculation.**—Smith has made a careful study of this question and summarizes his paper as follows:

1. Antityphoid inoculation has a distinct value in protecting the human organism from attacks of typhoid fever.
2. To obtain the fullest measure of protection the operation should be done, by the best methods before exposure to infection.
3. Even when inoculation is performed shortly before exposure to infection it is a beneficial procedure on the whole.
4. The protective influence is exerted for some years, long enough probably to tide over the most vulnerable age of youth and earlier manhood.
5. The protection afforded is in the proportion of 3 to 1.
6. The proportion of protection is much less than that of efficient vaccination for smallpox.
7. Vaccination against smallpox is about ten times as effective as antityphoid inoculation.
8. Typhoid under normal conditions at home and in some foreign stations is not a very common disease, such as smallpox used to be.
9. Typhoid among soldiers—in active service in most places, and when on peace service abroad, especially in India, South Africa, Egypt, Bermuda, Mauritius and Malta—is a very common and fatal disorder.
10. Typhoid is a danger to which nurses and hospital subordinates generally are specially exposed.

The final conclusions reached as regards the practical value of antityphoid inoculation are:

1. It is not at present of sufficient practical value to warrant its general adoption by the nation at large.
2. It is of distinct practical value to any community in which typhoid breaks out in an epidemic form.
3. It is of practical value to those who have much to do with typhoid patients.
4. It is of utility for general adoption among newcomers in certain special endemic areas abroad, such as some Indian stations and Malta.
5. It is of great practical value at all times to soldiers serving in India, South Africa and Malta; also, but in a less marked degree, in Gibraltar and other places.

6. It is certainly of the greatest practical value to soldiers about to take the field in any tropical or subtropical country where typhoid is known to prevail.

- 14 *Preventive Treatment of Scarlet Fever by Isolation (Aggregation) Hospitals. H. E. J. Biss.
17 Hospital Isolation and Scarlet Fever: the Statistical Aspect. C. K. Millard.

16. **Preventive Treatment of Scarlet Fever.**—Biss calls attention to the fact that isolation of the patient, except in the case of smallpox, has proven ineffectual so far as stamping out scarlet fever is concerned. If scarlet fever is to stand a chance of eradication by isolation, a prodigious number of cases of slight sore throat, of anomalous blishes of the skin, of ill-defined shagginess of the fingers, must be isolated, or a large proportion of real sources of infection will be left unrestrained. This would entail imprisonment and serious loss to many not suffering from scarlet fever, but whose illness could not be diagnosed with certainty. Any system that seeks to eliminate the personal element in scarlet fever infection must rest for its success on the separation of all cases, or of such a large percentage that a very sensible reduction in the total number of infections would be apparent. Such can never be the case until the diagnosis has improved to such a point that practically all cases, however mild, are recognized and dealt with in hospital or at home. It is doubtful whether individual elimination is likely ever to be of much service as a prophylactic measure.

21 *Burning Foot, or Erythromelalgia Tropica. P. N. Gerrard.

21. **Erythromelalgia Tropica.**—Gerrard reports six cases of burning foot, or erythromelalgia, a disease of the plantar nervous or arterial supply, which occurs in the natives of the Malay peninsula who are accustomed to work barefooted on roads and plantations. It commences, usually, with a "pins and needles" sensation, affecting the soles of the feet. It then progresses to an acute burning sensation, which in the majority of cases is so severe as to prevent the patient walking, and frequently necessitates the administration of narcotics to produce sleep. In some cases the patient is enabled to walk on the heels with the aid of a stick, while in others no progress nor attempt can be made. Although a previous history of malaria can usually be obtained, no history of malaria occurring during the progress of the disease has been found in any case. It is possible, therefore, that the disease may be a neuritis of malarial origin in which the blood supply to the nerves implicated may have become cut off by means of a deposit of malarial pigment. Another etiologic factor to be considered is "arteriole fatigue." The treatment was varied. Some relief was obtained in two cases by immersing the feet in hot water containing a quantity of salt. Various liniments and ointments were unsuccessfully tried, and general tonics, with or without strychnin, also failed to give permanent relief. Narcotics and sedatives of all kinds only relieved the disease for the period of their action.

22. **Organic Phosphorus in Therapeutics.**—Phosphorus is needed by the organism, not only for its nutritive but also for its dynamic properties, Gilbert remarks. Recent research has shown the constant absence of mineral phosphates from human milk, and has also shown the remarkable abundance of phospho-

organic compounds in the soft parts of the organism. Aside from the skeleton—in which they serve a purely mechanical purpose—the mineral phosphates are found in the organism only in the excreta, where they mainly represent the detritus left from the destruction of the organic compounds of phosphorus. The use of mineral phosphates in therapeutics is irrational. The organic phosphates, on the other hand, offer a promising field for therapeutics. Among these organic phosphates, the phospho-organic reserve found by Posternals in all chlorophyll plants seems best adapted for the purpose. It is found in all the vegetables and cereals, and contains a large percentage of organic phosphorus. He called it anhydro-oxymethylene-diphosphoric acid, and has isolated it and combined it to form a neutral sodium salt and an acid calcium salt. The acid is extracted from grains and contains nearly 22 per cent. of phosphorus in an organic combination. In the clinic it is proving the most rapid, the most effectual and the most constant in its action of any phosphorus medication known by the writers to date.

24. **Chlorosis and Tuberculosis.**—Labbé regards chlorosis as merely a symptom of some other affection, usually tuberculosis, nephritis, syphilis or some gastric lesion. When no other cause can be determined, it is almost invariably the first manifestation of latent tuberculosis, as he shows by a number of typical examples. He regards the existence of chlorosis at puberty as testimony in favor of tuberculosis later, as much so as a history of pleurisy. The chlorosis can be cured the same as the pleurisy, and the tuberculosis may be averted, but its tuberculous nature is not contradicted by the patient's recovery. The recovery depends on the cure with which the chlorosis or pleurisy is treated. If the subjects can have the benefit of country air and hygienic surroundings, the chances are in favor of a return to health. These chlorotic subjects with a suspicion of tuberculosis are the ones that will be benefited most by sanatorium treatment. They should remain in the sanatorium until the blood is completely restored to normal.

25. **Congenital Diaphragmatic Hernia.**—Planchu describes 2 cases, and mentions that 258 have been published. In his cases the necropsy showed that the hernia was absolutely incompatible with life.

29. **Enuresis in Children.**—Rey has been studying 52 cases of enuresis in children. He found that chemical analysis almost invariably demonstrated that the urine of such children was abnormally irritating or that there was some lesion in the urinary apparatus. In 19 of the 52 cases examined he found the urine turbid from enormous quantities of colon bacilli present. They were in bunches like granules floating in the opalescent urine. Such urine has generally an acid reaction and smells stale. Prolonged treatment of the entire uropoietic system was required to cure these cases of bacteriuria. Long continued use of salol, with a strict milk diet and regularity of meals, proves more successful than irrigation of the bladder. In 2 cases of recurring hydronephrosis with high fever, in girls aged 16 and 3, the palpable tumor vanished as a large amount of turbid urine was evacuated, and the fever subsided. These conditions kept recurring until the bacteriuria was conquered or checked by long salol and urotropin medication. Internal treatment is alone able to reach and cure such cases. Latent cholecystitis is particularly frequent in girls, and is not seldom the cause of the pale, depressed and irritable condition of the children who suffer from enuresis. As such cholecystitis rarely induces marked bladder symptoms, it is generally overlooked. Twenty-four of his series of 52 bed-wetters belonged to the category of simple mucous cystitis due to general acid intoxication.

The strongly ammoniacal urine irritates the bladder lining and induces a condition similar to that of "irritable bladder." Infants in this condition are liable to scream every time they urinate, and hold back all the urine they can. Frequently the trouble is ascribed to phimosis, but salol and dieting will in many instances cure it without an operation. In case a phimosis operation is undertaken, the irritating urine is liable to prevent healing or cause such complications that surgical intervention should be strictly contraindicated. In 3 other children there was pronounced phosphaturia, in another excessive uric acid output. The first were treated with milk diet and avoidance of vegetables, the latter by being put on a vegetable diet, all promptly recovering. In 3 other cases the enuresis was conquered by blunt detaching of the prepuce and removal of clumps of smegma in the corona glandis. The remaining 2 children in his series were affected with oxyuria. Some writers attribute the enuresis at night to fright in bad dreams, but Rey thinks that the bad dreams are probably the result of the impulse to urinate, or of emission of irritating urine. He thinks it is possible that the enuresis of early infancy, due to irritation of the bladder, may possibly survive its cause. These are the cases of sudden cure after faradization, epidural injection, etc. When the bladder irritation still persists, all such measures will be futile. Chemical and bacteriologic examinations should be made in every puzzling case of enuresis, and more attention should be paid to the catarrh of the bladder in infants, with cystoscopy of girl infants and older boys.

30. **The Filtering Paper in Practical Hematology.**—Tallqvist reviews the various points to be learned from his method of examining the blood taken up on filtering paper, comparing it with a standard scale. In case of leukemia, the aspect of the blood spot differs from all those in the scale. In sharp contrast, we see that the drop of blood is very slowly absorbed by the paper. Some time is required before it spreads enough for examination. The color of the spot is irregular. Nothing but an intense increase in the white corpuscles affects the behavior of the drop of blood in this way, evidently altering its physical characteristics.

31. **Cosmetic Massage.**—Two or three years ago the University of Berlin established a massage institute, in charge of Prof. J. Zabloudski. He is a frequent contributor to medical literature, as readers of these columns are aware. In this communication he discusses the subject of "beauty doctoring," as well as cosmetic massage in general. In the first place, he emphasizes the fact that rational cosmetics is synonymous to a large extent with individual hygiene. Also that cosmetic massage is far from meaning massage of the exposed parts of the body alone. Its sphere is restricted to restoring what is partially lost or warding off impending loss. Over-fat faces can be reduced, angular faces can be rounded, and recent morbid products or recently morbidly altered tissues will be found more responsive to massage than the normal elements of the organism or long-established morbid elements. But the massage should seldom be restricted to local manipulations alone, but should be extended over large areas. Nothing would be accomplished in case of a double chin, for example, if the massage were restricted to the chin. It is worked on both directly and indirectly by toning up the general system with massage and therapeutic active and passive movements. In the same way, the tendency to wrinkles is opposed by measures to improve the general nutrition, supplemented by kneading and stroking massage of the part. An emaciated part of a muscle in the brow, for instance, contracts readily when the inhibiting action of the missing subcutaneous fat tissue is lost. As soon as the nutrition of the muscle is improved by local and general massage, the muscle becomes thicker and does not contract so readily. The nerves in the part become more resistant and do not respond so easily to minimal irritations. The skin above becomes smooth and does not wrinkle so readily. Massage treatment, in his experience, has frequently abolished nervous twitchings and ties in the face. Another class of cases benefited is the climacteric congestions in the face. The circulation can be regulated by massage of large surfaces of the body. Still another class of patients benefited are those following

a special diet with irritating restrictions. At times massage may be effectually substituted for the dietetic restrictions. Zabłudowski describes his mode of massaging, using sometimes a vibrator or a vacuum pump, with a cup 3 to 5 cm. in diameter, applied for a minute or two. Both pump and vibrator are run by a motor like a dentist's drill. Digital self-massage is impracticable, as it is impossible for it to go deep enough, the hands tire soon, and so many parts are inaccessible. He recommends, however, a small apparatus for vibration massage which is worked by electricity or by turning a crank. Steaming the face is injurious, as it renders the skin sensitive to weather influences. If a salve or paste is not decidedly slippery it merely irritates the skin when massaged into it. Unless the skin is very dry or the hands very rough, the massage is best done without any medium, but if one is needed, the best lubricant is natural white vaselin (Virginia vaselina alba), made without evaporating all the water in it. It becomes unsuitable if left exposed to the air for a day or two, as the needed water dries out. He never massages more than 15 minutes at a time for the face, and 30 minutes for general massage. He aims to make it rapid, thorough and not disagreeable. The work is done with the hand and arm rather than with the fingers.

33. Subcutaneous Osteotomy.—Heine applies the principles of subcutaneous tenotomy to osteotomy. There are two or three ways of doing this, but the best is to pull the skin along so that the part normally over the bone is drawn away to a distance, and the incision is made through a part which subsides afterward to its proper place remote from the point of the cut into the bone. Such a technic is particularly advantageous for children, especially in operations on a rachitic leg. The part of the skin incised is that which lies normally over the tibialis anticus and the extensor tendons. The operation is much shorter; the incision need not be longer than the breadth of the chisel; air is excluded; the result of the operation resembles the conditions in an uncomplicated fracture, and the skin wound and the cut into the bone are far apart.

35. Improved Technic of Thiersch Grafting.—Lauenstein does not freshen the surface to be transplanted, but merely rubs it with a gauze pad until it becomes slightly bloody. He uses one pad to each area the size of the palm. The Thiersch flaps are then applied, and they heal in place much more rapidly than by the old method of freshening with the curette. The first case on which he tried this technic was an extensive defect on the arm, extending over the shoulder, the patient very much debilitated. The wound was dressed with Credé's silver gauze, and when the dressings were changed a week later the entire grafted material had healed faultlessly in place.

37. Microscopic Diagnosis of Abortion.—Hirschmann describes a case in which the young ovum was found intact while the glands showed no evidence of the changes which some have asserted are characteristic of an abortion. In another case he found the characteristic glands, but there had been no pregnancy. He is inclined to regard these changes in the glands as liable to be induced by menstruation alone. He also believes that a membranous dysmenorrhea may cause changes in the connective tissue which simulate decidua cells. He cites a suggestive case in which a typical dysmenorrhæic membrane was examined in a large series of sections, with finally the discovery of a minute ovum, not projecting above the surface, and surrounded by decidua cells only in its immediate vicinity.

38. Tubal Menstruation.—Thorn describes two cases of pathologic tubes in one of which hemorrhage from the tubes accompanied normal menstruation; in the other it substituted the latter.

40. Infection in Teaching Maternities.—Ahlfeld states that there have been 7,000 deliveries in the Marburg maternity in his charge, and that fully fifty thousand times have the students made examinations of the women before and during delivery, and yet only a single death has occurred from infection after a normal, spontaneous birth. In this one instance the examination had been done after thirty minutes' disinfection of the hands under skilled supervision. The circumstances suggested that the woman had infected herself with her own fingers, a possibility to which not enough attention has been paid hitherto. In his clinical experience of twenty-three years, with 7,000 deliveries and the training of 1,000 medical graduates and 2,000 midwives or obstetric nurses, he thinks he has not had a single case of fatal septic infection traceable to the use of the clinical material for teaching purposes. Self infection in puerperio, with fatal outcome, is extremely rare in well-conducted institutions, but self infection in partu, especially in case of a tedious, long-protracted birth, is of much more frequent occurrence and can scarcely be avoided.

49. **Etiologic Diagnosis of Typhoid Fever.**—Jürgens comments on the facts that healthy persons can shelter the typhoid bacillus, and that typhoid bacilli are liable to be found in the stools of convalescents even long afterward. These facts discredit the value of bacteriologic examination. The serum reaction is, further, not absolutely reliable evidence in regard to the etiology of a given affection supposed to be typhoid, as its findings vary so inexplicably. He remarks that "the confusion that can be induced by inadequate clinical observation and uncritical etiologic diagnosis is well shown by the literature published during the last few years on paratyphoid affections. Most of these paratyphoid cases are not typhoids with a special etiology, but merely affections interesting on account of the peculiar reaction on the part of the blood serum. Some were probably ordinary typhoid, others had nothing whatever to do with typhoid. Other cases have been observed which did not differ from typhoid in any respect, although they were caused by the Schottmüller instead of the Eberth bacillus. Typhoid fever is thus apparently not an etiologic unit, and it is merely splitting hairs whether we call the cases of typhoid not caused by the Eberth bacilli, paratyphoid, or whether we include them in the term typhoid with merely some additional term to express their etiologic peculiarity. We can speak of a typhoid with a special etiology only when the symptoms of typhoid are present and Eberth's bacillus as the cause of the disease can be definitely excluded. This is the only means to bring order out of the present confusion, the result of insufficient clinical observation and over-hasty deductions, and show whether typhoid fever should be separated into several distinct diseases."

50. **Relief of the Kidneys by Sweating.**—Strauss has been studying this subject on a large amount of material, comparing the findings by groups of patients with various affections. He obtained the sweat for the purpose by the use of dry heat, a rubber sleeve fitting over the arm, a faucet in the sleeve bag allowing all the accumulated fluid to be drawn out into a vessel below. Out of 200 tests he was able to obtain enough sweat for comparative research only in 80. In 25 of these 80 subjects some serious renal trouble existed; the others were patients for whom sweating procedures had been ordered generally on account of some neuralgic or rheumatic trouble. The findings showed that the molecular concentration of the blood was frequently higher in the nephritic than in the non-nephritic subjects, especially in the uræmic nephritics. The retention of water in cases of purely nephrogenic edema fulfills a compensatory purpose, as it serves to dilute the retained salts and other debris of metabolism. The end products of nitrogen metabolism are not so important for the origin of the edema as the salts, yet the poisonous substances which cause the uræmia must be sought among them, although we are not yet able to define them. The pathologic importance of the retention of salts is demonstrated in another direction from that of the retention of the end products of nitrogen metabolism. There is scarcely any department of internal medicine in which such opposite views prevail as in this question of the efficacy of sweating procedures for the elimination of nitrogenous molecules. In the tests here described these molecules were in proportions in half the cases of nephritis far beyond that attained in three-quarters of the non-nephritic cases. The amount of total nitrogen was generally somewhat larger than in the subjects with sound kidneys. The practical conclusions of the research reported are to the effect that sweating procedures are liable to be beneficial in nephritis, and that uræmic accidents need not be specially feared. It is advisable, however, to supplement the sweating by copious ingestion of water to prevent evil consequences from the diaphoresis in uræmic subjects. If the edema increases, this is a minor ill, and the superfluous fluid can be easily tapped. Strauss' experience has not shown that sweating had any influence in favoring the outbreak of uræmic accidents. On the contrary, his impression is that uræmic subjects are improved by it, his empiric observation confirming the results of his research here presented.

53. **Carbonic Oxid Poisoning.**—In the first of the 2 cases reported the man had worked in an imperfectly ventilated room in which coke stoves were burning. He suddenly presented symptoms suggesting a focus of softening or hemorrhage in the left hemisphere. The permanent motor aphasia justifies the assumption that this focus involved the region of the foot of the anterior central convolution. A history of mild syphilis a few years before suggests that the part may have been predisposed. In the second case, the symptoms were about the same but rapidly retrogressed. An accident to the woman's skull a year or so before may have afforded a predisposition. She exhibited likewise cyanosis and edema of both hands, knee and forearms, with pemphigus-like blisters, subsiding by the tenth day, all but two rows of blisters on the right forearm, which terminated in necrosis, healing finally after several weeks. They were evidently due to a neuritic process. The poisoning occurred in consequence of shutting the damper in the stove pipe. She and her husband were taking coffee together, when she lost consciousness and was not found until after twenty-six hours. The husband was dead.

57. **Removal of Urates and Capsule from Gouty Toe.**—In 1882 Riedel was summoned to operate on a great toe which had suddenly become swollen and intensely painful after a day's hunting, the subject a previously entirely healthy man of 45. The aspect of the toe suggested hallux valgus and suppurative in a bursa. Under narcosis Riedel incised, searching for the assumed bursa, but nothing of the kind was found, merely a typical gouty deposit of urates, the capsule congested and set with pointed urate crystals. He was horrified to find that he had operated on a gouty toe, but, having it open before him, proceeded to remove all the urates and extirpated also the capsule. The patient was relieved at one stroke from his excruciating pain, and during the twenty-two years since has had no further trouble of the kind. He was so grateful that he went about advising other subjects with podagra to submit to an operation, but none heeded him and twelve years passed before Riedel had an opportunity to operate on another case of the kind. The diagnosis in this second case had been similarly mistaken, bursitis with secondary suppurative having been assumed. The results were as perfect as in the first case. Of course this operative treatment should be restricted to isolated podagra, involving only a single toe. But the results were so encouraging in his 2 cases that he can not refrain from advocating such a procedure in case of rebellious, excruciatingly painful gout, isolated at a single point. The great toe is easily accessible, and at the same time very resistant. Extensive detachment of the capsule does not impair its nutrition if the wound is left open. In a gouty joint the inflammation is aseptic, the exudate merely serous. If a recurrence should develop, the simple operation could be readily repeated. In any event, the patient can count on years of peace in the interim.

59. **Spontaneous Healing of Cancer.**—Borrmann has examined histologically 265 cutaneous carcinomata, with over 2,000 microscopic sections, and has frequently found the so-called foreign body giant-cells. But he does not admit that these giant-cells are an indication of healing of the lesion. They do not take up living cells, but merely form around dead detritus. They were seldom or never found among the living cells of the cancer. In 80 cases the lesion was an ulcer rodens, and giant-cells were numerous, yet these lesions are inevitably slowly progressive. In his experience the giant-cells were more numerous in the rapidly growing cancers. Deported cancer cells undergo horny transformation, and when killed by this process are then taken up by the giant-cells. The latter respect them so long as they are alive.

62. **Menstruatio Precox.**—Stein was called to a babe of 6 months, as genital hemorrhage was noted. It recurred regularly month after month under the aspect of menstruatio precox. He gives an illustration of the child at fourteen months, the menstruation having recurred eight times, and, curiously, always coinciding with that of the mother.

64. **For Mosquito Bites.**—Schill recommends to apply a little sodium bicarbonate, moistened to a paste, to take the sting out

of a mosquito bite. It may be used in a concentrated solution. To drive the insects away, he swabs the exposed parts with a 2 per cent. solution of thymol. He has found these measures very effective against mosquitoes and gnats.

65. **Madeira as a Health Resort.**—The Madeira Islands offer a combination of sea air, hill and mountain climate, freedom from dust and climatic vicissitudes, remarkably beautiful scenery and luxuriant vegetation, which make it a most promising health resort. As has been mentioned in the news columns, a company has been formed to exploit Madeira for this purpose. It will be possible there to have a tuberculous subject try different climates and altitudes under the supervision of a single physician, to determine which is best suited for him. No research of this kind has yet been undertaken. It is planned to make the sanitation of the island chosen ideal, to have three sanatorium hotels at different elevations, with possibly a floating sanatorium, and to spare no pains to make it a perfect health resort, according to the most advanced ideas. The names of Pannwitz and Wölff guarantee the high scientific character of the undertaking.

68. **Kehr's Operation on Waldeck-Rousseau.**—(See page 823.) The patient was a man of 58, always healthy until icterus developed suddenly last fall after a violent emotion. There was no pain, but the icterus continued with varying intensity until the spring, when there was gradual loss of appetite and strength. An operation was undertaken, the abdomen opened, and through a small incision at the outer margin of the right rectus the surgeons (Poirier and Terrier) palpated a small, hard lump in the head of the pancreas. Without further exposure of the cystic and bile duct or of the pancreas, they made an anastomosis between the gall bladder and the jejunum. The gall bladder was large and adherent and its contents were thick and gelatinous. A week later there were three cholemic hemorrhages from the wound, but the icterus, pruritis and lack of appetite persisted. Two months after the operation the icterus was still the same as before, the only change being that the patient was weaker and more miserable. When Kehr was summoned he found an emaciated, extremely icteric patient, drowsy and already standing under the sign of cholemic intoxication. No pain could be elicited by palpation, the liver was enlarged but smooth and nowhere hard; there was no ascites and no tumor. The pulse was regular and strong. 84. The urine contained a large proportion of bile pigment, but no sugar nor albumin; the feces were completely decolored. The family physicians said that the heart and lungs were sound. Kehr diagnosed chronic occlusion of the common bile duct, but whether from a stone or tumor, pancreatitis or adhesions it was impossible to say. His experience with 947 gall-stone operations had been that a cancer had been found in 70 per cent., a stone in 10 per cent. and chronic pancreatitis in 20 per cent. The findings in the case showed that the anastomosis of the previous operation had not accomplished its purpose. The cystic duct may have been compressed by adhesions, which would explain the non-functioning of the anastomosis. Kehr's practice is always to aspirate the contents of the gall bladder before opening it. It is then incised and its contents evacuated. Only when bile flows from the cystic duct is anastomosis permissible. If the cystic duct be impermeable, then cystostomy, or, better still, choledochoduodenostomy should be considered. Eventually cholecystectomy may be done, supplemented by an anastomosis between the common duct and the duodenum. In any event, a long incision should be made to enable the conditions in the ducts to be ascertained correctly. In the case in question the cystic duct may have been impermeable at the time of the first incision or may have become so later. The patient had not lost his icterus, and an operation was the only resource left, as he and his friends appreciated. The age and sex spoke in favor of carcinoma, also the almost painless course of the trouble (possible likewise in case of stones), the severe icterus (possible in case of stone in the papilla), and the cachexia (possible also in case of occlusion from stone). Evidence against cancer was the sudden appearance of the icterus, its fluctuations and the comparatively long course of the affection. Cases of scirrhus of the pancreas

are known which have run a two-year course. The patient was doomed without an operation, and if the trouble was of a non-malignant nature it might cure, and, if malignant, it might prove palliative. The chances were 30 per cent. in favor of the former. The patient was too weak to be taken to a hospital. The abdomen was opened and a rather hard tumor was found in the pancreas behind the duodenum, studded with nodules, in all probability a carcinoma. But, as chronic pancreatitis can induce a similar tumor formation, there was a possibility of this, especially as the glands were not enlarged and there was no trace of ascites. On the strength of this possibility Kehr regarded it as his duty to provide for the evacuation of the stagnating bile. A lobe of the liver presented and was taken for the gall bladder and incised, the 1 cm. incision lengthening the operation by five minutes. The gall bladder was found lax and almost empty, containing merely a little secretion and an undigested scrap of melon. The cystic duct was completely occluded. It had taken an hour to reach this point, and the patient showed signs of collapse. A tube was inserted in the gall bladder and an incision made in the common duct above the duodenum, the bile spurting in a stream. At this sudden evacuation of the liver the signs of collapse increased, and the intended choledochoduodenostomy or anastomosis between the gall bladder and common duct had to be abandoned. Kehr had to content himself with draining the hepatic duct, tamponing and closing the abdomen, concluding the intervention in seventy-five minutes. On account of the extensive adhesions it was one of the most difficult operations he has ever done. The patient was placed in bed, the pulse grew a little stronger, but after an hour disappeared, and death ensued before the second hour. One of the lessons learned from this instructive case, he adds, is the value of a hospital environment. Everything had presumably been prepared, but the surgeon felt the lack of light from above; he missed his adjustable operating table and the oxygen-chloroform apparatus to which he was accustomed, although he had brought his own anæsthetic with him.

70. **Beck's Method of Operating on Hypospadias.**—Bötticher reviews 10 cases in which Beck's method was followed, the results compelling him to urgently corroborate König's assertion that the Beck technic has superseded all other methods of treating hypospadias. The results are just as brilliant in very young children, but on account of the soiling of the parts during infancy the Giessen clinic has adopted the rule not to operate in cases of hypospadias until after the child is in its third year.

71. **Rupture of Bladder During Bottini Electrolysis of Prostate.**—Rosenstein describes a case of prostatic retention treated at Israel's clinic by Bottini electrolysis according to the usual technic. During the process the bladder ruptured with the sound of an explosion. Experimental research since suggests that the steam generated by the heat of the cautery was responsible for the explosion of the bladder. He reproduced similar conditions in glass vessels and in rabbits' bladders, and found that an explosion followed the "Leidenfrost" phenomenon (the dancing of the drops of moisture on the white-hot knife, isolated by their steam), and the sudden evaporation into steam as soon as the knife is cooled to a certain point by contact with the tissues. He sees no way to obviate this disaster in performing the Bottini operation, and thinks that the danger from it should turn the scale in favor of prostatectomy.

78. **Increase in Sugar-Forming Property of Blood.**—Vigliani does not attempt to explain this phenomenon, but states that it occurred constantly in his experiments. By modifying the metabolism, either with phloridzin or phosphorus, the sugar-forming property of the blood serum was much augmented.

80. **Symptomatology of Gastric Cancer.**—Several puzzling cases are described. In one there was no absence of HCl, while no tumor nor specific formed elements could be discovered. The diagnosis was based on the lack of appetite, repugnance for meat, absence of the signs of perforation and of vomiting after eating, the dry, straw-colored skin, the cachexia and progressive character of the symptoms which suggested gastric ulcer. In a second case the symptoms indicated stenosis of the pylorus, but there was no vomiting and no HCl. In a third case the symptoms were those of pernicious anemia, but the progressive cachexia, the difficulty in ingesting solid foods and the pains in the intrascapular region suggested a cancer in the lesser curvature. The cancer in his fourth patient induced intermittent fever, probably from absorption of toxic products. A psychosis was the first signal of trouble in this case, soon followed by the discovery of a tumor in the stomach.

81. **Unusual Onset of Certain Infections.**—Several cases of typhoid, pneumonia and erysipelas are described, in all of which the first manifestations were identical, all of a gastro-nervous type. They included vomiting, diarrhea, colic, unconsciousness, pupil inertia, clonic convulsions, etc. Notwithstanding the severity of the onset, the after-course was unusually mild in some of the cases.

85. **Simple Stain for Tubercle Bacilli.**—Among the causes of failure to show up tubercle bacilli, Tarchetti mentions defective preparation of the material, imperfect staining and the unfounded notion that a contrast stain is necessary. He uses a simple technic, which includes spreading the material in a thin, even layer on cover-glasses, fixation with heat, staining with phenic fuchsln or Ziehl's (fuchsln, 1 part; alcohol, 10; phenic acid, 5, and water, 100), applied hot for ten to fifteen minutes, rinsing, decoloring for one or two minutes in a concentrated alcoholic solution of picric acid, changing the liquid once. The process concludes with brief rinsing, drying and mounting in balsam. The advantages of this technic are its simplicity and the mild action of the picric acid, while the persistence of the yellow stain gives the impression of contrast-staining.

87. **Technic of Subcutaneous and Intravenous Injections.**—Oliva described, two years ago, an instrument for this purpose, and his experience has impressed him more and more with its advantages. The needle is enclosed in a canula, which protects against its penetrating too far. The tube connecting it with the fluid to be injected is enclosed in a larger tube through which there is a constant flow of hot water. The simple apparatus is illustrated in detail.

90. **Hyperglobulia in Tuberculosis.**—This article has been noticed editorially, page 742. Mircoli noticed that a certain patient with incipient tuberculosis had six million red corpuscles. The aspect suggested anemia rather than hyperglobulia. These findings were repeated in a number of other cases of slight sclerosis of the apices. Pondering on this remarkable hyperglobulia in apparently anemic subjects, he came to the conclusion that it was due to the action of small amounts of

tuberculin, such as are produced by a small, circumscribed, inactive tuberculous focus. Arsenic in small amounts promotes the regeneration of the blood, and he queried whether tuberculin might not have a similar action. Experimental research on animals treated with small doses of tuberculin have confirmed the correctness of this assumption. He refers to Swan's report of hyperglobulia observed in 8 out of 26 tuberculous subjects examined (THE JOURNAL, xlii, March 12), and explains the scarcity of such findings by the general impression that the pallor of consumptives is evidence against hyperglobulia. In reality, the color of the skin depends on the pigmentation and the activity of the capillary circulation. It has nothing to do with the number of the red corpuscles. Another reason is that the blood is seldom examined in the incipient phases of tuberculosis. When the patients come to the clinics this phase is long past. Many influences are known that reduce the number of reds, and there is nothing strange in the fact that other influences may increase them. Among such influences must be reckoned the action of the tuberculin generated in some small, torpid process in the spleen or lungs. In a recent case a patient with sclerosis of the apices had hemoptysis of a pint of blood twice, with ten days' interval. The day after the second hemorrhage the reds numbered 5,600,000. Hyperglobulia in incipient tuberculosis is a means of differentiating an active from a torpid process. The hyperglobulia that follows hemoptysis is an argument in favor of venesection as an effectual measure against certain of the symptoms of tuberculosis.

91. **Tuberculin as Stimulus to Production of Red Corpuscles.**—This article relates the particulars of the research referred to in the preceding abstract. The writers found that large doses of tuberculin injected into guinea-pigs had a very destructive action on the reds. Moderate doses had no apparent effect on the reds, but repeated, small doses induce pronounced hyperglobulia. The hemoglobin increased parallel with the number of the reds. This effect was apparent in a few days, and persisted for some time. It was so marked that the writers suggest that it might be utilized in the therapeutics of non-tuberculous affections. Subcutaneous injection of minute "refractory" doses of tuberculin might prove an effective measure in combating non-tuberculous anemia and chlorosis. In such small doses tuberculin is perfectly harmless, and it is being tested now in the clinic.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE PATHOGENESIS OF UREMIA AND ECLAMPSIA.*

ROBERT N. WILLSON, M.D.
PHILADELPHIA.

Under a rather hackneyed title, it is my purpose to discuss very briefly a subject that will always be of interest until the mystery which surrounds the direct causal influences of uremia and eclampsia is entirely and finally dispelled.

None of the theories offered up to the present time has been thoroughly satisfactory in explaining either the uremic state, which seems to be associated always with renal insufficiency, or that of eclampsia, which may or may not be preceded by signs of renal disability, but presents an almost identical clinical picture. I think it fair to state that I have never seen a case of eclampsia in which the urine, drawn by catheter during the coma or the convulsive period, failed to give abundant evidence of a serious renal involvement. I have seen this statement borne out in cases in which there was neither a trace of albumin nor a single form of renal sediment distinguishable by the microscope prior to the onset of the convulsive seizure.

Often the renal insufficiency proved to be temporary, out the regularity with which it has occurred has led me to believe more strongly with each new case that uremia and eclampsia are identical states, brought about in similar ways, though under many widely variant conditions. This does not mean (and I would emphasize the point) that they are necessarily the result of kidney disease. It may be that even constipation, or an abnormal condition of the thyroid gland or of the placenta, may in certain instances influence the particular case more forcibly than the impairment or integrity of the renal function.

It is not my object, however, to discuss the similarity of uremia and eclampsia, but to suggest a coincidence of two causes for both conditions which have been brought forward separately by more than one writer and studied by very many.

The first of these is the action of a toxin or of toxins on what Landois calls the psychomotor centers of the brain, while the second is a mechanical pressure on the same cortical centers, acting either in combination with the toxin, or occasionally alone, but not in the manner held by Traube, viz., an effusion into the ventricles and consequent anemia of the brain.

That toxins, and even certain substances which can

hardly be placed in this category, may produce by their local action the complete symptom-complex of uremia, including coma or convulsions, followed by death or recovery, has been shown beyond a peradventure by the exhaustive research of Landois.¹ Weisenberg's² recent report of extensive chromatolysis of the Betz cells of the paracentral lobule, especially on the side opposite the paralysis, in two cases of uremic hemiplegia, is another indication of the presence and action of a poison destructive to the central nervous system. The cells in the anterior horns of the cord, also in the medulla, and in the cerebellum, were found to show positive alteration, as well as the fibers of one motor tract. The extensive lesion in the posterior portion of the left hemisphere of Case 3 of the series cited in this paper was more than possibly a gross destructive process of the same nature. Among many clinical evidences is the form of amaurosis which can occur in both uremia and eclampsia in the absence of any evident antemortem or postmortem lesion of the nerve. It has been shown that even the injection of large quantities of common salt solution into the blood may produce the symptoms of uremia.

I have found it equally true that many of the symptoms noted in both uremia and eclampsia resemble pressure symptoms, and can be controlled at once by relieving pressure on the central nervous system. I am led to believe, therefore, that while the toxin theory may provide a partial explanation of the uremic state, there is at times, or perhaps always, another important influence at work in the form of intracranial and probably localized pressure on the psychomotor centers. Among the symptoms that may be ascribed to intracranial pressure are the following, all familiar to the student of uremia and eclampsia alike: Headache (sometimes unilateral), sleepiness, dizziness, nausea and vomiting, neuralgias, tinnitus aurium, coma, convulsions, cyanosis, paresis, paralysis (sometimes hemiplegia), aphasia, loss of control of bladder and intestines, and, most sudden and startling of all, amaurosis.

The following three cases, briefly cited, illustrate partially the "pressure theory" and the results of therapeutics based on the same:

CASE 1.—M. R., a woman of 50 years, was admitted to the Philadelphia Hospital in March, 1904.

Symptoms.—Her feet and legs were edematous, her breath was urinous, control of the sphincters was lost and the patient was semicomatose. The temperature was 97 F. The urine contained 3.2 grams of albumin per liter, and many hyaline and hyalogramular casts. Two days later the temperature rose to 103, the breathing became very labored, and death seemed imminent.

Treatment.—Lumbar puncture was performed, and nearly 12 c.c. of colorless, clear fluid withdrawn from the spinal canal.

1. Uremia, 1891, second edition.

2. Proceedings Path. Soc. Philadelphia, February, 1904

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

The respirations at once became easy, the pulse fell from 110 to 84, and, although the patient was past all help when the puncture was performed, the cerebral relief was evident during the last two hours of her life.

Examination of Fluid.—The spinal fluid was examined by Dr. Rosenberger and was found sterile. Small quantities were injected into guinea-pigs, intraperitoneally, but with no untoward result.

CASE 2.—R. B., a man, about 40 years of age. His mother died of nephritis. The patient had syphilis fifteen years before. Seemed fairly well until two weeks before admission to the Philadelphia Hospital in April last.

Symptoms.—He was then dyspneic and had extensive edema of the feet and legs, and to a lesser degree of the entire body. Just after entering the ward he developed a pulmonary congestion, expectorated traces of blood, etc., and became very dyspneic. This condition decidedly improved during the following two days, in spite of a double valvular cardiac lesion (mitral and aortic). He began to complain of severe headaches, and then gradually developed a uremic condition. At times he was comatose, and again so delirious as to require restraint in bed. The breath was urinous, the feces were at times involuntary, the reflexes almost disappeared, the pupils contracted, and Cheyne-Stokes breathing made its appearance. The urine contained large quantities of albumin and numerous pale granular and hyalogramular casts.

Treatment.—Lumbar puncture was performed. Prior to performing the operation the pulse was 90 and the respiratory rate 33. Fifteen cubic centimeters of clear fluid were drawn, and three hours later the pulse was 50 and the respirations 23.

Result.—Immediately following the puncture the patient began to breathe quietly and more regularly, and a peaceful sleep ensued. The opening into the spinal canal, though covered with compresses, continued to drain and at such a rate as to wet the bedclothes for more than two days. During this time there was a decided general improvement, the patient being conscious and fairly comfortable. He then went into delirium and died during the ensuing night.

Autopsy.—The autopsy in this case showed aortic and mitral insufficiency, atelectasis of the lower left lobe, subacute parenchymatous nephritis and red atrophy of the liver.

The spinal fluid was cultured, and, like that of Case 1, proved sterile. Injections were also made into guinea-pigs, but proved innocuous.

CASE 3.—B. P., a colored clergyman, aged 50. His father died of a malignant tumor. His own early history was negative until two years ago, when he had a "slight stroke of paralysis" (probably a uremic seizure) in the right arm and leg. He was in the hospital three weeks, and then was discharged with the free use of his right side. He had recently had headaches for two months, especially severe during the last week. Eighteen hours prior to admission there was severe vomiting, followed by unconsciousness, from which he could not be aroused.

Symptoms.—On admission he was unconscious, his breathing stertorous, the pupils slightly dilated (later contracted); the pulse rapid and of high tension, his temporal arteries resembling fibrous cords both as the result of sclerotic change and of the tension. The second cardiac sound was loud and metallic, the legs slightly edematous, the breath urinous. He was restless and swallowed fluids with difficulty. The catheter obtained six ounces of pale urine which contained large quantities of albumin, no sugar, many hyalin and hyalogramular casts. There was also incontinence of urine. The respirations assumed the Cheyne-Stokes rhythm soon after admission, to the ward.

Treatment.—The patient on admission received two hot packs, following which all his symptoms were more pronounced. He was thoroughly purged from the start, was bled twice, and received one high enema of magnesium sulphate solution. During his last thirty-six hours his skin was bathed in a profuse perspiration. Nitroglycerin was administered hypodermically during the last twenty-four hours. In short, every reasonable treatment was resorted to except the use of acetone, which I would certainly employ in another similar

case. Lumbar puncture was performed the following morning. The spinal fluid at first spurted out, instead of dropping, as is usually the case. It was clear and soon began to drop, continuing to do so for over an hour. About 25 cubic centimeters were withdrawn. Before the fluid had ceased to flow the Cheyne-Stokes respirations had been replaced by slow, full breathing; the patient was quiet, and on replacing him on his back his attention could easily be attracted by the voice or by the finger moving before his eyes.

The wound in the tissues was allowed to bleed profusely in the hope of further reducing the vascular and systemic tension, and a pint of blood, approximately, was withdrawn in this way.

On the following morning his condition was fairly good, though coma had again set in. Lumbar puncture was again performed, and on this occasion only 10 c.c. dropped slowly into the tube. The same result was noted, however, and following the procedure the patient was partially out of his coma, and the pulse, temperature and respirations soon began to fall. Prior to the puncture he lay stupid, with the left eyelid ptosed, evidently parietic, and with the right eye wide open, but unresponsive to the finger touching the cornea. Following the withdrawal of the fluid both eyelids opened wide and the eyeballs followed the finger. On the third morning the coma was as deep as at any time. Even less fluid was obtained by the third puncture (less than 10 c.c.); it contained blood and dropped with great slowness. There was an even more decided fall of temperature and of the respiratory rate, but the pulse rapidly rose, and the patient died at 9 p. m. on the same evening.

Autopsy.—The autopsy showed a most interesting state of affairs. The heart was of the *cor bovis* type, the wall of the left ventricle measuring 4 cm. in diameter and that of the right ventricle 2 cm. The coronary arteries were sclerosed and lined with yellow patches of atheromatous change. The kidneys showed an extensive chronic diffuse inflammation, the cortex being greatly reduced, and the parenchyma showing many small cicatrices due to fibrous change. The brain was of normal size and presented a large degenerative cyst, mainly of the parietal lobe, but also including a portion both of the temporosphenoidal and occipital lobes, entirely posterior to the fissure of Rolando. The cyst contained a considerable quantity of serous fluid, together with a small clot of dark red blood. The cyst cavity communicated with the posterior horn of the left lateral ventricle, though whether as the result of trauma to the friable and degenerated tissues, sustained in removing the brain, or whether it existed *in vitro*, can not accurately be determined. The right lateral ventricle was also greatly dilated, especially the posterior horn, which contained, when opened, considerable serous fluid. The arteries of the base were brittle and remained gaping and open when incised. This was also a feature of the renal arteries, including the smaller branches within the organ.

From my experience in the foregoing cases, I am, already stated, compelled to pause before accepting Landois' well-known statement that "uremia is the result of the toxic influence of certain substances on the brain," as a complete and satisfactory explanation for the uremic and eclamptic states. This reluctance extends equally to the theories under favorable consideration at the present time, as, for instance, that of Novi dependent on concentration of the blood and cerebral anemia, and that based on the experiments of Weighard with syncytiolysins, and the still more recent and fascinating idea that impairment of the thyroid functions is at the bottom of the eclamptic condition. Any one or all of these conditions may have something to do with the complete and typical picture presented in the uremic state. In fact, I suspect that in certain instances more than one may play a part. Certainly, however, we must reckon with another factor, namely, intracranial pressure, and it may be that further study will show that

this is the most potent of all. In favor of this view we have first, the immediate, although temporary, alleviation of symptoms in each of the three cases reported in this paper, and a less prompt but similar (and permanent) betterment in cases reported by other observers."

In Cases 1 and 2 the improvement could be ascribed to relief from some form of fluid pressure only. Case 3, while more interesting because of the complicating cyst, presents a doubt as to whether the relief was one from local pressure on the psychomotor centers only, or from that pressure exerted by the fluid contained in the cyst cavity. If the cyst did indeed communicate with the left lateral ventricle, as was probably true, the effect of spinal drainage was a double one, and lowered the general and local intracranial pressure at the same time. The previous hemiplegia, so evidently uremic, renders the nature of the second attack more plain than it would otherwise be, even in a subject with so evident a renal disability.

Among the symptoms from which relief was afforded, presumably by the flow of cerebrospinal fluid, were in Case 1 the rapid pulse, the labored respirations and the restlessness; the delirium, coma and dyspnea in Case 2; the coma, ptosis of the eyelid, temperature, pulse, respiratory rate and character (Cheyne-Stokes-type) in Case 3.

So far back as 1850 R. B. Todd⁴ cited a case showing a low delirium, then a paralysis of the arm and leg, coma, and death. At the postmortem examination there was found an effusion of lymph in the "arachnoid sac of the left side, covering the upper and inner surface of the hemisphere to the level of the base, but ceasing there abruptly so that not the smallest particle of lymph was found on the arachnoid of the base. An accumulation of fluid had taken place in a cavity, circumscribed by lymph, on the outer side of the left ventricle, near the position of the fissure of Sylvius. The fluid which had accumulated there compressed the brain on the left side, and formed a complete depression on its surface."

The autopsy findings in Case 3 differed from the foregoing only in the location of the fluid and the surrounding degeneration of the brain substance. There was in both cases the same form of intracranial pressure from fluid, the presence of which was most easily and naturally referable to the cause of the general condition. The only wonder must be that this pressure in Case 3 could be exerted so close to the motor centers, and yet spare the functions of the extremities and the musculature in general. Such cases prove, in any event, that serous fluid may be in excess, either locally or generally, in the cranial cavity, and by its presence may at least assist in causing the uremic picture. No reference is made in this statement, of course, to the serum frequently found between the convolutions in the brains of senile subjects. We know, further, that the uremic state occasionally presents complete paralysis of one portion, or even of the entire half of the body. Case 3 had already exhibited the hemiplegia, and during his last attack there was present a probable paresis of the oculomotor nerve.

In studying these suggestive series of facts, it would appear certain that in drawing the cerebrospinal fluid, with either prompt or delayed, but positive, relief from symptoms which we know may be caused by localized intracranial pressure, we relieve these symptoms by depleting the excess of fluid, whether contained in the

ventricular cavities or in the brain tissue itself, or in spaces made by the fluid for its own accommodation. Gowers⁵ has called attention to the fact that a dog becomes unconscious "when there is a pressure on the surface of the brain equal to a column of mercury 130 mm. high." Moreover, the autopsy frequently shows in cases of uremia and eclampsia an edema of the cerebral tissues. It is easily conceivable from a study of these cases that sometimes the edema may involve the cortex more seriously than other portions of the brain, or even one psychomotor center more positively than another, and thus produce aphasia, paresis or paralysis of the extremities, headache, coma or convulsions. A decrease in the intracranial fluid pressure resulting from the withdrawal of from 20 to 30 c.c. of cerebrospinal fluid, may relieve just such a localized edema and alleviate strictly local symptoms. The evacuation of the normal quantity of cerebrospinal fluid may have the same beneficial effect, when an abnormal quantity or some other cause of intracranial pressure is in evidence. We have seen an effusion form and reform after tapping, and can thus understand the early recurrence of pressure signs in hopeless cases of this nature.

The word hopeless leads me directly to the remark that we must again agree that intracranial pressure is not only the influence at work in the production of the uremic and eclamptic states. Otherwise a case that has been freely purged and still more freely bled, and from which all the obtainable cerebrospinal fluid has been withdrawn, should secure a permanent rather than a temporary relief from serious symptoms and death. The effect of toxic substances could not, of course, be gone away with, even for a time, by lumbar puncture; none the less, symptoms due to pressure only should be more easily and lastingly amenable to treatment. In short, there are too many indications of a toxic influence on and in the system, such as the dry skin, the itching, the hypertension of the vessels, etc., and above all, the results of local applications of chemical substances to the psychomotor centers, as already quoted, for us to ignore the likelihood of a systemic and local intoxication. Thomson claims that at least one particular poison present resembles adrenalin in its action, constricting and increasing the tension in the vessels, and the result of clinical study would seem to bear out his belief. Landois has produced the complete picture of uremia, including coma and convulsions, by applying to the cerebral cortex creatin, creatinin, acid ammonium urate, leucin, sodium chlorid, etc. With the absorption of the substance the attacks grew slighter and slighter, and perfect recovery at times ensued.

Weighard also claims to have produced similar results by the injection of artificially prepared syncytiolysins in blood serum, and in his subjects he found post-mortem typical lesions of uremia and eclampsia, anemic and hemorrhagic liver necroses, thromboses of the small vessels, and cloudy swelling of the renal epithelium. Novi has accomplished almost as much by the injection of a 10 per cent. solution of sodium chlorid, until the blood attained a concentration twice that of the normal.

It is interesting to note that in spite of these facts the injection of the cerebrospinal fluid from uremic subjects into small animals seems to have no deleterious effect.

CONCLUSIONS.

In conclusion, it may be said that we consider:

1. That it is probable there are at work in the

3. McVall: Brit. Med. Jour., 1903, et al.

4. Linnlein lecture, p. 42.

5. 1893, vol. II, p. 102.

cerebrum, as well as throughout the system of uremic subjects, at least one, and probably several toxic substances which exert their influence more or less locally on the cortex.

2. That it is equally certain that other portions of the brain than the cortex are also acted on, as in the production of coma, etc.

3. That no small part in the production of the uremic and eclamptic condition is played by intracranial pressure, due to a temporary excess of fluid, whether acting independently of or in conjunction with the toxic substances already mentioned.

4. That lumbar puncture will at least temporarily relieve certain of the symptoms most readily ascribed to localized intracranial pressure, and that in cases in which the pressure is the main factor, drainage of the spinal canal may save life. The procedure, together with free bleeding, purging and diuresis, should be added to our routine treatment of the condition.

5. That transfusion of normal salt solution by intravenous injection or hypodermoclysis, except in cases presenting anuria, or a greatly diminished urinary secretion, is contra-indicated as tending to increase the liability to saturation of the tissues.

6. That the results of lumbar puncture in the three cases cited in this paper will not warrant the assumption that relief of intraspinal or intracranial pressure can alone be depended on to cure the uremic or eclamptic condition, provided the toxic influence is the prominent one in the particular case.

DISCUSSION.

DR. JAMES TYSON, Philadelphia.—Dr. Willson's paper has given a fair presentation of this long-disputed subject. Pressure has long been held by some authorities to have an influence in the production of eclampsia, chiefly, however, on theoretical grounds. Dr. Willson has adduced some experimental evidence, of the value of which I am not prepared to judge without further study. I am not ready, however, to concede that there is not a toxic agent which plays a certain rôle in producing the phenomena of eclampsia. It has been a great many years since I prepared a paper to prove that puerperal eclampsia is due to a nephritis, the toxic products of which are responsible for the eclamptic symptoms. I think the same reasoning still holds at the present day. We must admit, too, that puerperal eclampsia, in very rare cases, may be a reflex phenomenon, just as convulsions in children may be a reflex event due to such irritation as teething, and the like. Convulsions thus caused usually occur in primipara after long and painful labors.

DR. ALEXANDER LAMBERT, New York City.—Has any fatty degeneration of the liver been noted in these cases? In eclampsia the lesions are identical with those of acute yellow atrophy of the liver. In my experience and also the experience of the staff of the hospital, we have been struck with the fact of the apparent identity of the condition of the liver in uremia and in acute yellow atrophy. Even in the hyperemesis of pregnancy changes will appear in the urine with the development of leucin and tyrosin. There is no doubt that Dr. Willson clearly and carefully drew attention to the fact that the convulsive seizures were due to tension; but what is the cause of this intracranial tension? That is a question probably far behind that of toxemia. It is the same toxemia that kills in acute yellow atrophy. In eclampsia there are two types; that type with high tension, convulsive seizures predominating; the other type with a flat compressible pulse, and these patients die in spite of anything we may do for them. It is not uremic, but something back of the uremia. I have had experiences in which I have found acute yellow atrophy of the liver, and I think perhaps we have failed to recognize the frequency of the occurrence of that disease.

DR. ROBERT N. WILLSON.—The subject is an interesting one.

especially from the fact that many may hold that these patients would have had a better chance of recovery if the procedure had not been carried out. In each of my cases in which lumbar puncture was done the patient died; in each, however, there was an immediate and positive improvement for a time. Vail has reported three cases, all of which recovered, the only treatment being lumbar puncture and rest in bed. Seiffert has also reported successful cases. It therefore seems to me certain that in some cases the dominant influence is pressure due to toxic or other causes. Dr. Lambert has referred to the resemblance between the pathologic findings in eclamptic cases and in acute yellow atrophy. I think there is no question as to the accuracy of his statement. In short, there are cases overwhelmingly toxic, while others appear to be overwhelmingly due to pressure. In the latter lumbar puncture may be a means of saving life.

I will refer to another matter that is rather interesting. Dr. Riesman has called my attention to the fact that all of his fatal cases gave a bloody cerebrospinal fluid. It would appear that when the fluid is clear, the case is much more apt to recover. In one of my own cases the fluid was clear after the first two punctures, but bloody after the third. All of these patients died. Vail mentions the fact that the fluid from his favorable cases was clear. Whenever failure has been experienced in getting into the canal it was due to the use of too short a needle. I now use a four-inch small trochar and cannula, applied through an incision in the skin and subcutaneous tissues. I have never failed to get within the canal if I kept close to the spinous process with the needle point.

AMEBIC DYSENTERY.

ITS LOCAL LESIONS AND TREATMENT.*

JAMES P. TUTTLE, M.D.

Professor of Rectal Surgery, New York Polytechnic.
NEW YORK CITY.

Our views of dysentery have greatly altered since the days when we considered it "inflammation of the bowels" without knowing exactly what we meant by the term inflammation. These changes of views are the result of pathologic studies and are in line with the great changes made in our views of surgical etiology and pathology.

With regard to dysentery they began in the discovery by Losch of the ameba coli, and the association of this germ with the disease by Councilman and Laffeur; for a while after this the profession accepted that ameba coli, afterward called "*Amaba dysenterica*," as the established cause of the disease. In 1894 and 1895 the reports of Shiga, Flexner, Harris and others, seemed to establish the fact that at least in the epidemics of Japan and the Philippines the ameba was not always present, but there was a bacillus of a peculiar type universally present and to this they gave the name *Bacillus dysenteria* and established its etiologic relations to that form of the disease.

After this various efforts were made to establish the unity of dysenteries and to prove that this bacillus was the only cause; that the presence of amebæ in dysentery was accidental. Clinical observations, however, have failed to justify such sweeping conclusions. The best authorities have finally concluded that not only are there cases of pure bacillary dysentery and cases of pure amebic dysentery, but there are also cases at least with the typical symptoms of dysentery in which neither the bacillus nor the ameba can be found. We therefore recognize these three types: simple catarrhal dysentery, bacillie dysentery and amebic dysentery.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

It is to this last form of the disease that I wish to direct attention. What I have to say is based on personal experiences of seventy-four cases of amebic dysentery, together with what knowledge I may have gained from reading. In every case observed, with the exception of one, the diagnosis has been made on the finding of living motile *Amœba dysenteria* in the stools or scrapings. To some it has seemed a presumption to look on the amœbæ as the cause of ulcers and dysentery, but the fact that they are present with other pathogenic agents in all cases, and the fact that the dysenteric symptoms and local lesions disappear only when the amœbæ have been eradicated and recur when the amœbæ reappear is positive proof, it seems to me, of their etiologic influence in this disease. I, therefore, assume that amebic dysentery has been proved and we may proceed to consider its cause, its symptoms, its local lesions and its treatment.

ETIOLOGY.

The cause of the disease is the infection or invasion of the colon by *Amœba dysenteria*. These amœbæ consist of irregular oval masses of plasmodium, gelatinous in their appearance, scarcely visible when not moving, containing in their beds certain granular masses or vacuoles and appearing to be more or less refractile. They may be found in the mucus which is discharged in the stools, as well as in the scrapings from the ulcers in the rectum and sigmoid. Their source is unknown, nor is there any accepted theory with regard to it. The behavior of amœbæ found in dysentery differs greatly from that of those found in fresh water, when exposed to heat or cold; it is this point alone that positively distinguishes the two. The latter remain motile at high and low degrees while the former are viable only at temperatures near that of the human body. Some have claimed that there was a difference in size, but my observation does not justify such an opinion, as the size of the amœbæ varies greatly in different cases and even in the same case.

METHOD OF REPRODUCTION.

As to the method of production: It was formerly supposed that amœbæ multiplied by binary division, after the manner of leucocytes in the blood. According to Craig of the United States Army, Dofflein and others, it is now claimed this reproduction occurs through ovulation and sporulation; the spots in the amœbæ which stain deep blue with Wright's solution represent spores, and those which stain very faintly the vacuoles from which spores have been discharged. There is one point in Craig's experiments in which an assumption is necessary, viz., that the bodies observed stained are the same as those observed in the living state before the staining, for it is impossible to stain and preserve the amœbæ motile. In fact, one can hardly positively distinguish non-motile amœbæ from other substances in the stools. If, however, this assumption is admitted, the method of reproduction by sporulation would seem fairly well established, and it is confirmed by the clinical experience of recurrences long after the motile amœbæ have entirely disappeared from the stools.

TEMPERATURE AND OTHER CONDITIONS AFFECTING THE AMEBÆ.

The fact that we have been unable to isolate or obtain a pure culture of this amœba renders its study more difficult than that of ordinary pathogenic agents. Its behavior, however, under certain circumstances has been observed clinically, and from this we may formulate some of its characteristics. At the temperature of the body, or slightly higher, the life of the amœba is indefin-

ite; if, however, the temperature of the vessel in which it is obtained gets below that of 70 degrees F., the motility and life of the amœba become extinct and no amount of heat will restore the same.

Bichlorid of mercury 1-10,000, at the temperature of the body, checks the motility but does not destroy it except after very prolonged contact. Rogers states that a solution of quinin 1-1,000, at the temperature of the body, failed to destroy the amœbæ after several hours' contact, but that a 1-500 solution stopped all movements in from five to fifteen minutes; when the amœbæ were in the tissues, however, they were only destroyed by prolonged soaking in 1-500 or 1-100 solution of quinin. Saline solutions at the temperature of the body will not destroy the motility. According to Harris of Atlanta, peroxid of hydrogen is fatal to the germ. He does not state, however, whether this fluid was used cold or warm. Five per cent. of the 15 volume peroxid of hydrogen in water, however, does not seem to destroy the amœbæ at a temperature of the body. Nitrate of silver in 1 per cent. solution checks the motility but does not seem to destroy the germ. All these solutions, however, when used at a temperature below 70 degrees, are fatal to the motility and life of the amœbæ. In at least twelve of the cases which have been under my care the stools had been examined in vain for amœbæ before they came to me. In every instance the failure to find the bodies has been due to the fact that the stools were examined after they had cooled off. In order to recognize the amœbæ with any certainty the examination must be made while the stools are still warm and on warm slides. In my office these examinations are made from scrapings obtained from ulcers in the rectum and from the mucus collected on the rectal wall. These are placed at once on warm slides, put under a microscope and slightly heated now and then in order to maintain the temperature at about 98 degrees F. In the hospital or laboratory the stools are collected in warm pans, transferred immediately to the oven of the laboratory and kept there until an examination can be made at the temperature of the human body. These precautions are absolutely necessary to make an accurate diagnosis.

CHARACTERISTICS OF THE DISEASE.

Amebic dysentery is characterized by an insidious onset, variable but usually mild constitutional symptoms, frequent recurrences, extreme chronicity and latent existence. It may begin as an acute diarrhea, with blood and mucus in the stools and burning in the rectum, or it may come on as a simple looseness of the bowels, some of the stools being practically normal while others are thin and contain much mucus, with or without blood, and causing little or no pain. The acute cases are associated with burning in the rectum and frequent desire to defecate, loss of appetite, and slight elevation of temperature. The stools may be very frequent; the demand to defecate is imperative, but they are not associated with tormina nor excessive burning in the rectum. In most instances castor oil or salines, followed by moderate doses of opium and bismuth, control the disease for the time being. In two instances in the series of cases observed periods of quiescence lasting for six months in one and four months in the other have been observed. We must make some allowances with regard to the statements of these patients regarding these periods of absolute quiescence, for they are only periods of comparative activity of the amœbæ. In a few instances the patients have actually become constipated during these periods, but such cases are exceptionally rare. In al-

most every instance the patients have reported periods of feeling greatly improved at times, but when we have carefully pinned them down to the facts these patients have considered themselves practically well when they were having two to four mucous stools a day without any pain.

LATENT DYSENTERY.

By latent dysentery we refer to the condition in which *Amoeba dysenteria* are present in the intestine, without the diarrheal symptoms or the local manifestations in the form of rectal and sigmoidal ulcers. Rogers has established this fact, and I have myself observed four cases in which there was no diarrhea and yet there was amebic colitis with malaise, loss of flesh and strength and moderate temperature at night. One of these cases suffered from abscess of the liver, which recurred from time to time and which was operated on twice in five years. He could not recall ever having had a diarrhea. He was referred to me with the view of discovering some cause for these recurring abscesses of the liver in possible ulcers in the rectum and infection from these through the portal circulation. No ulcers were found in the rectum, but certain small cicatrices and some fetid mucus suggested a careful examination of the stools; these we found swarming with *Amoeba dysenteria*. Two other cases with tenderness over the caecum coli, loss of appetite and gradual decline in weight, mucous colitis but no diarrhea, have been observed, in each of which the stools contained *Amoeba dysenteria* in abundance. In one of these cases amebic ulcers were found in the rectum, and in the other two small ulcers were observed in the sigmoid. The fact, therefore, that the patient does not have frequent, bloody, mucous stools does not prove that he is absolutely free from *Amoeba dysenteria*. From cases recently observed, I am inclined to believe that no inconsiderable number of the sufferers from mucous colitis are the victims of amebic infection notwithstanding the absence of diarrhea.

GEOGRAPHICAL DISTRIBUTION OF THE DISEASE.

The locations in which amebic dysentery is likely to be found are worthy of consideration. Formerly the disease was called "tropical dysentery" under the false impression that it was only found in the tropical zones. While it is a fact that it is more frequently found in warm climates, yet it is well known that it may also occur in almost any climate. I have seen three cases of acute amebic dysentery in patients who have never been more than fifty miles south of New York and fifteen cases in which the patients have always resided above the thirty-seventh degree of latitude. The majority of the seventy-four cases observed, however, have contracted the disease in the Philippines, the West Indies and the extreme southern portions of the United States. The possibility of amebic dysentery can not, therefore, be eliminated on account of the patient's residence. The disease is nearly always sporadic even in the tropical zones, and may thus be distinguished clinically from bacillary dysentery, which is generally epidemic.

LOCAL LESIONS OF AMEBIC DYSENTERY.

The local lesions occurring in amebic dysentery differ in the acute and chronic forms. The disease is practically confined to the colon, although there are instances in which the small intestine has been involved for a short distance above the ileocecal valve. In some cases the disease begins in the rectum and travels upward, while in others it follows the reverse course. Rogers

and Fletcher state that the typical cases of infection begin in the caecum coli and travel down. At all events the rectum and sigmoid flexure become involved sooner or later in almost every case. In the three acute cases observed the mucous membrane at the anus was pouting, bright red and swollen, the radial folds were edematous and painful; the walls of the rectum were in close apposition with each other, hot and tender to the touch, bright red in appearance and in one case there were several patches of pseudo-membrane. At this stage of the disease no actual ulcerations were observed, but later on these developed. These ulcers were irregularly oval in shape with gelatinous, yellowish, elevated centers, surrounded by bright red or purplish zones. They are usually superficial and heal rapidly under local treatment.

In the chronic form the ulcers begin as small red papules on the mucous membrane, rapidly becoming more and more prominent until a yellow spot develops in the center, due to the loss of epithelium, and this constitutes the center of the ulcer. I have frequently seen these in chronic cases of amebic dysentery, but did not observe them in either of the acute cases examined. The ulcers are usually situated on the summits of the mucous folds; a favorite site is on the folds of Houston. The size and shape of the ulcers vary greatly; some are small and irregularly oval, while others occupy almost the entire circumference of the gut. The long axis of the ulcer is usually at right angles with the long axis of the gut.

In very chronic cases the ulcers sometimes assume the form of little troughs cut out of mucous membrane with overhanging edges which resemble very much worm-holes in wood. These trough-like ulcers sometimes cross one another, forming stellate ulcers. In this type of ulcer the base is hard and quite red and may extend through the muscular layer to the peritoneal layer, causing adhesions. The yellow gelatinous mass which forms the center of the ulcers is composed of submucosa infiltrated with *Amoeba dysenteria*. Strange as it may seem, the amebae are more abundantly found in the smaller ulcerations than in the large. In some cases large sloughs composed of detached shreds of mucous membrane are seen at the site of the ulcer or in the stools. Rogers has pointed out that these cases are generally associated with abscess of the liver which contain streptococci in addition to amebae, thus showing a mixed infection. As pointed out by him, the odor in these cases is gangrenous and fetid, which is entirely unlike that found in amebic dysentery. One might here call attention to the peculiar odor of the stools in amebic dysentery, which is entirely different from that observed in other types of colitis. As the ulcers heal the yellow centers melt away, assume a grayish tint and gradually disappear, leaving a clean granular base more or less indurated; the small ulcers heal rapidly and all evidence of their having been present is lost; the larger ones, however, and the trough-shaped variety leave cicatrices which have been known to result in strictures of the gut.

DISTRIBUTION OF THE LESIONS.

While all writers agree with the general statement that amebic dysentery is practically confined to the colon, there is considerable difference between them in regard to the portion of this organ most frequently affected. Fletcher and Rogers state that the caecum, appendix, hepatic flexure and ascending colon are the chief sites of the lesions. In 116 cases Fletcher rarely, if ever, found the lesions in the rectum and sigmoid. These

statements are entirely at variance with my experience, as well as that of Strong, Leonard, Craig and others. In the seventy-four cases of amebic dysentery observed by me, typical ulcers of the rectum and sigmoid were found in seventy instances. In every case except one the character of the lesions was proved by the demonstration of living motile amebæ in the stools and scrapings from the ulcers. Fitcher himself, although he claims that the chief seat of the disease is in the cecum, bases his diagnosis on the finding of *Amaba dysenteria* in scrapings from the rectal wall.

Why these experiences should differ it is impossible to say unless it be due to the fact that my observations have all been made, with one exception, on living subjects, while those of the authors quoted were made postmortem. The one patient who died while under my care from acute miliary tuberculosis showed dysenteric ulcers in the caput coli and in the ileum just above the ileocecal valve. It is possible, of course, that the other cases had ulcers so high up in the intestinal canal that it was impossible to observe them through the sigmoidoscope. In the majority of instances, however, the ulcers appeared to decrease in size and number from the rectum upward until they disappeared entirely in the upper portion of the sigmoid flexure, and as the patients entirely recovered under local treatment, it is reasonable to suppose that all the ulcers were reached. There is no doubt, therefore, in my mind that the rectum and sigmoid flexure are involved in a large percentage of chronic cases.

DIAGNOSIS.

The diagnosis of amebic dysentery rests on finding in the stools or in the scrapings, living motile *Amaba dysenteria*. Sometimes it requires several examinations before their presence can be established, but when once seen, in any considerable numbers along with the typical ulcers, the character of the disease is beyond doubt. This diagnosis will be more positive if the amebæ are observed in the scrapings from the ulcers, rather than in the stools, for it is known that *Amaba coli* may be present in the intestinal canals of perfectly healthy individuals. The simple presence, therefore, of one or two amebæ is not sufficient, without the ulcers and typical symptoms, to justify the diagnosis of true amebic dysentery.

COMPLICATIONS.

The complications of amebic dysentery are physical exhaustion, anemia, autointoxication, peritoneal adhesions and abscess of the liver. The first two are not uniformly present; patients may suffer from the disease for a long time without emaciation or any great loss of strength. Some cases, however, become rapidly emaciated; the hemoglobin is greatly reduced and they are practically bedridden early in the disease. In all instances the patients have a feeling of lassitude and are just a little below par in strength. The color is usually sodden rather than pale, and there is often the hectic flush on the cheeks which suggests the possibility of tuberculosis.

These conditions are due to the autointoxication and drain on the system brought about by the presence of amebic ulcers in the intestine. When the ulcers have healed and the intestine is restored to its normal conditions, these symptoms rapidly disappear.

Abscess of the liver is the one complication which commands our highest respect and demands the most rapid eradication of the amebæ. It is not my purpose to discuss here how these organisms reach the liver, whether

through the portal circulation or across the peritoneal cavity; the fact remains that the large majority of cases of abscess of the liver are due to infection by *Amaba dysenteria*, and these have their habitat in the colon.

As Rogers states, no case of amebic abscess of the liver has ever been observed in which there were not present amebic ulcers in the colon. This fact justifies the statement that wherever the patient has symptoms of abscess of the liver or has suffered from it, he should be treated for amebic dysentery whether amebæ are found in the stools or not. The fact that they are not found at the time of examination does not prove that the spores are not buried in the submucosa, lying dormant and ready to reproduce the disease at any time.

TREATMENT.

The treatment of amebic dysentery is based on two facts which have already been mentioned, viz.: The disease is due to an infection of the colon by *Amaba dysenteria*, and the seat of the infection is in the crypts of the mucous membrane or in the submucosa. Whether the original infection is due to the burying of the amebæ themselves in these tissues or to the deposit of the spores it is impossible to state. From recent observations I am of the impression that the latter is more probable, but this is not important from a practical point of view. Our efforts should be directed toward getting rid of them and preventing their reproduction. In the beginning we may observe that there are usually no serious constitutional manifestations in this disease except when these are due to complications such as have been mentioned.

There is, therefore, no indication for serum therapy, as the disease is not in the blood and can not be reached through that channel. The whole treatment should be directed toward the local lesions, the destruction of the amebæ and the prevention of their development from the spores, and as these are buried in the tissues, it is evident that it will be impossible to destroy them by superficial washing or flushing of the intestinal canal, although this treatment is important and should be made use of to get rid of all the germs floating about in the colon. It is clear, however, that something should be employed by which the tissues may be penetrated and the germs or spores destroyed in order to completely eradicate the disease. While the remedies mentioned, bichlorid of mercury, nitrate of silver, saline solution, solutions of quinin, peroxid of hydrogen, etc., may be germicidal to the ameba when brought in direct contact with it, it is perfectly clear that none of these remedies will penetrate the submucosa.

This fact explains why so many cases treated by these remedies recur. The ideal treatment must, therefore, consist of some method by which these buried organisms can be reached and destroyed *in situ*. Early in our studies of *Amaba dysenteria* it was discovered that when the specimen stools on the slides on which they were being examined cooled off below a temperature of about 70 degrees F. the motility of the amebæ was lost and could not be restored; this fact suggested that if the temperature of the parts containing these organisms could be reduced considerably below this degree the amebæ could be destroyed and their infecting and reproductive powers would be eliminated. The application of cold to the intestinal mucous membrane through prolonged douches seemed to offer a solution of the question. At first such remedies as krameria, ichthyol, bichlorid of mercury and nitrate of silver were introduced into the cold douches, but one after another

was discarded, as it was found that simple cold water served every purpose in destroying the amebæ.

When the bowel is tolerant of hydrogen peroxid 5 to 10 per cent. of this remedy is introduced into the water on account of its beneficial effect to the ulcers and to combat any mixed infections that may happen to be present.

In some patients it is necessary to use a long rectal tube in order to get the fluid high up in the colon, but in the majority of cases the simple rectal tip of a fountain syringe is sufficient. The patient is placed in the knee-chest posture, the bag or fountain being elevated not more than three feet above the level of the hips and the fluid is allowed to run in slowly. The amount of water used is limited only by the tolerance of the patient. Some take only a small quantity at first, but they soon learn to take even two or three quarts. Some can retain the water for only a few minutes, while others retain it for three-quarters of an hour. In the former class it is necessary to repeat the injections two or three times at each sitting in order to obtain the desired effect. The treatment is always begun by the administration of a large dose of sulphate of magnesium, and this is repeated once or twice every week, according to the necessity of the case. The time consumed in ridding the bowel of the amebæ depends entirely on the tolerance of the intestine to cold water. In those cases in which large amounts of very cold water can be retained the organisms disappear in a very short time, while in those who can only retain small quantities for short periods several weeks are required.

In the chronic cases, where there is tenderness over the cecum and hepatic flexures, an icebag is applied over this region for two hours twice a day.

A metal or glass reservoir is better than a fountain syringe for the injections because those vessels can be filled with cracked ice and the water kept very cold. The best results have been obtained in these cases in which the temperature of the water used was below 45 degrees F.

Local ulcers of the rectum and sigmoid are treated by applications of antiosin, argyrol and other astringent and antiseptic substances. This local treatment is of the utmost importance and should never be neglected, as many of these ulcers are complicated by a mixed infection.

Internal medication is indicated where the digestion is impaired or where the patient needs stimulation on account of exhaustion. In three instances the disease has been seated so high up in the colon and the patients have been so intolerant of cold water that it was impossible to reach the affected region in this manner and it became necessary to resort to surgical means in order to eradicate the amebæ. In one instance the Gibson method of valvular colostomy was employed; in the other two the appendix was drawn up into the abdominal opening and sutured to the skin, after the method of Weir, until the peritoneal cavity had closed off; it was then amputated close to its base and there was thus left an opening through which a catheter could be introduced for irrigating the colon. In two of these cases the improvement was rapid and recovery complete. In the third case the patient developed miliary tuberculosis and died at the end of three weeks, the regular treatment having never been instituted. This case showed typical amebic ulcers above the ileocecal valve, thus indicating the possible advisability of making the opening in the ileum instead of the colon in such cases. At the same

time recognizing the fact that the appendix may be the seat of amebic infection, it would be wise to remove this organ in all operative cases.

In seventy-three cases treated by these methods the results have been seventy cures, one death, one abscess of the liver, which eventually recovered, and one case improved but not cured, the patient being necessarily called to Europe after two weeks' treatment. In five cases there were at times marked tenderness over the hepatic region and considerable rise in temperature, but these symptoms rapidly subsided with more frequent douching and the application of icebags over the caput coli and the hepatic region.

42 West Fiftieth Street.

DISCUSSION.

DR. FENTON B. TURCK, Chicago—Dr. Tuttle called attention to the futile efforts to destroy the plasmodium; it is very interesting to see the efforts made to destroy them in some other way. It has been my experience that solutions have but little effect, and those that did had an effect on the circulation through the hyperemia that was produced by the drugs used. I have had a large experience in treating such infected cases while in the Army. In the treatment I have tried oil, but the oil method has not been successful. It has shown some effect in that it produced a better physiologic activity in the colon. Oil may become a powerful irritant and so excite a hyperemia of the mucosa and thus produce some effect on the plasmodium. The method I now use is hot water. At the Pan-American Congress in 1895-96 I presented a contribution on the good effects of ice water, using hot water first. I found that if I used cold water first there was danger of collapse in weak patients. Therefore I have found more benefit from using a high temperature. A temperature of 115 F. is not sufficient to produce any effect on the microorganisms; one should use a temperature of from 122 to 131 F. This can be done by gradually raising the temperature, starting with a temperature of 105 F. This heat has a very beneficial effect, seems to destroy the plasmodium, and after every treatment the amebæ disappear. Then followed the use of ice water, and the effects produced are much better than if ice water be used alone. In very weak patients the effect of the heat followed by the ice is very beneficial.

In regard to this operation I have never experienced any difficulty in reaching the caput coli. The patient should be placed on an inclined plane and the tube should be introduced into the sigmoid and water run into the colon, let out again, reintroduced, and so on can done the entire colon. When bismuth is used the x-ray will demonstrate the bismuth as high up as the transverse colon. There is no difficulty in the return of the water. Introduce a little air with the water; this increases the peristalsis and the fluid goes on. The vital condition of the patient should not be overlooked.

DR. A. W. WARREN, Weehawken, N. J.—The most successful experience I formerly had in the treatment of these cases of dysentery was by the use of ipecac or quinin, but recently I have used a remedy that I consider better. This drug is *Chaparro amargoso*, which to adults may be given in doses of from 2 to 4 grains of the extract or of 30 to 60 minims of the fluid extract every two hours during the day. In dysentery *Chaparro amargoso* seems to have a specific action by altering the secretions of the bowel in destroying the protozoa and in nullifying their power. It is also tonic, antiperiodic and astringent. *Chaparro amargoso* is also of value in the treatment of enterocolitis or summer diarrhæa of children, used in solution either alone or combined with opium.

DR. PHILIP MARVEL, Atlantic City—One year ago in conversation with Dr. Tuttle about such a case he advised me to use ice water. I had been using different remedies, such as quinin, carbolic acid, nitrate of silver, argyrol, peroxid of hydrogen, and others, with little or no effect in controlling the ulcerations. At Dr. Tuttle's suggestion, I tried ice water,

and much to my satisfaction, the patient grew steadily better. It was my privilege to see her one week ago, and she was in very good condition. I should like to ask Dr. Tuttle if he has observed contractures or strictures after the water treatment. I do not know whether the stricture in my case is due to the disease or to the topical applications made by me prior to the time of beginning the ice water treatment. The patient I refer to is now perfectly well except for a contracture in the rectum. Previously, Tuttle's proctoscope could be used, i. e. passed without pain, but now this is impossible; the stricture will only admit a medium large size old style Kelly's cystoscope.

Dr. SAMUEL S. GANT, New York—Was not Dr. Weir the first to suggest this opening of the appendix and using it for irrigating the colon?

Dr. WILLIAM KRAUSS, Memphis, Tenn.—In reference to the diagnosis of amebic dysentery, I think I am right in stating that I never made a diagnosis unless my microscope and the patient were in the room together. I have never been able to revive a motionless ameba. The mucus from the discharge or swabbing should be transferred quickly to a warm slide. I have tried Dr. Tuttle's suggestion of cold water and with success. Water can not be used hot enough to injure the parasite.

Dr. TUTTLE—As stated in the paper it was Dr. Weir who first suggested making use of the appendix for this purpose. I modified Dr. Weir's operation by drawing out the appendix and absolutely getting rid of it, at the same time obtaining access to the seat of the amebic infection. I omitted to speak of the mixed infections associated with dysentery of this type. I also wished to speak of the importance of the local treatment of ulcerations down in the rectum and in the sigmoid, when using cold water irrigations; and of hot water for improving the circulation. There are certain cases in which the ulcers become infected with a secondary infection, and they must be treated individually by local applications of tincture of iodine, etc. With regard to ipecac and quinin, how can they affect the buried amebæ? The amebæ are not in the blood, but in the submucosa. The only way to reach them in this position is by the use of low temperatures. Dr. Morton of New York has recently reported a case in which the diagnosis of amebic dysentery was made and the case was treated by him by radiized quinin, and he claims the patient is well. Operation is to be resorted to only when all other methods of cure have failed. I do not believe it is a dangerous operation; it is certainly not more dangerous than leaving the amebæ to progress to a chronic state, with its dangerous complications. There is little danger in pulling up the appendix and holding it there until adhesions form and shut off the peritoneal cavity, and then amputating it.

THE PATHOLOGY AND ETIOLOGY OF ARTHRITIS DEFORMANS.*

THOMAS MCCRAE, M.D.
BALTIMORE.

In discussing this subject there are two courses open; one is to go over the various theories and ideas that have been put forth, the other is to dispense with tradition so far as we can and state as closely as possible the condition of our knowledge in regard to this subject to-day. It is perhaps well to state frankly that we are more likely to outline our ignorance than to state our knowledge, but we can at any rate determine the lines in which investigation is most likely to be profitable, because I take it that no one would be likely to say to-day that we had

anything very firmly established in regard to the subject of this paper.

Through bacteriologic work we have been able to limit certain forms of arthritis definitely. It would seem best to restrict the term "infective arthritis" to those forms in which we have a distinct causal agent proved. The form associated with the tubercle bacillus, gonococcus, pneumococcus, etc., belong to this group. Recent work suggests that acute articular rheumatism will before long be added to these. In regard to arthritis deformans, the evidence is as yet not positive, but very suggestive.

GENERAL CONSIDERATIONS.

Almost every point that one can raise in regard to this disease is a disputed one. The more important ones seem to me as follows:

1. Have we under this term one disease with many different manifestations, or have we included two, perhaps more, totally distinct diseases?

The decision in regard to this point is, of course, essential before one can get to any satisfactory conclusion as to the etiology or pathology, and I trust the discussion may clear up some of the points in regard to it. As has been frequently pointed out, there are certainly varying types of the disease. Some observers have distinguished these as the rheumatoid or atrophic type, and the osteoarthritic or hypertrophic type. In the former the disease may occur at any age from 2 to 70 years; the arthritis is usually polyarticular, may come on with great suddenness and recur perhaps at long intervals, or it may be a slow, progressive process. In this type the changes are more especially atrophic and often especially periarticular. As has been shown by Goldthwait, there is much increased excretion of calcium salts. In the second or osteoarthritic group there is in some ways a rather different picture; the classical description of the older writers, which laid special stress on the production of osteophytic growth, applies especially to these. These groups will be considered more in detail later.

2. The question of relationship of arthritis deformans to acute rheumatism. Of course, it is quite possible that a patient may have acute articular rheumatism and years afterward arthritis deformans, but I believe this is the only association between the two diseases, and that arthritis deformans has nothing whatever to do with acute articular rheumatism. Much of the confusion has been due to the mistake of considering attacks of arthritis deformans as acute articular rheumatism. Of course, this opinion is contrary to that of many of the authorities on the disease.

3. The question as to the essential etiologic factor, which we have to discuss under three heads: (a) A neural cause; (b) infection, with a definite specific organism; (c) infection, with various organisms.

One point has to be strongly kept in mind, that although the early and late conditions are quite different both clinically and pathologically, nearly all the older descriptions of the disease are based on the late changes, and no account is taken of the early ones. This has resulted in the process being commonly regarded as a degenerative one only. It would be as reasonable to base all our views as to the pathology of chronic nephritis on the conditions found in a much contracted kidney, ignoring the early stages.

Arthritis deformans appears under very different conditions and in varying forms; coming on in the first decade of life, it differs very much from the form seen in adult life. In one it may be very acute, advancing rapidly to extreme deformity and destruction of the joints.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

or it may be exceedingly chronic and remain quiescent for a long period of time. Does this necessarily imply the existence of distinct diseases? A comparison with tuberculosis should suggest caution in passing any such judgment. Consider the varying manifestations of tuberculosis at different ages. Our knowledge of tuberculosis not so long ago was about as chaotic as of arthritis deformans to-day, and before the discovery of the tubercle bacillus it probably seemed about as hopeless to satisfactorily explain all the conditions as it is to-day in regard to arthritis deformans.

There are some points of the clinical aspect of the disease that may be noted here. One is that the more carefully the histories of the cases are studied the stronger is the impression that in the great majority there have been acute features at some time or other. It may have been many years before. This is true of both types of the disease. The man with bony deposits in the spine may have acute recurring attacks exactly as in the polyarticular form, which may begin with symptoms suggesting acute articular rheumatism. Changes in the early stages we have had comparatively little chance to study pathologically. It is to be hoped that no opportunities for autopsies on early cases will be lost. These are most likely to occur in persons who have died of accident or of some other disease.

There is one point to which I should like to draw special attention, namely, that the changes in arthritis deformans are not necessarily progressive. We have been too apt to regard the condition as going on to marked degeneration and destruction, but I believe the more carefully the disease is studied the more instances we will find of patients in whom it is to all intents and purposes cured. There is a certain amount of damage left in the joints, but this is comparatively slight and gives no great disability. This, of course, corresponds in general to our ideas of infectious disease. We have types from the very mild to the very severe. Take, for example, the varying types of virulence of gonorrhoeal arthritis—in one case slight and of no very great severity, and another going on to almost complete destruction of the joint, but the average case with a tendency to chronicity and the establishment of more or less change. Have we not practically a parallel condition in arthritis deformans?

PATHOLOGIC ANATOMY.

It is convenient in some ways in discussing this to take up the features of the two main types of the disease separately. An important matter to settle is the association of these two conditions. That they occur together in the same patient I think there can be no doubt, and this is evident both from clinical evidence and from the radiographs. It is, however, more convenient to consider them separately, and the terms atrophic and hypertrophic are convenient to use. This is convenient for description, whether they be considered as varying types or distinct diseases.

The Atrophic Type.—This, which is often termed "rheumatoid," corresponds in the majority of cases to the polyarticular type. The pathologic changes seem to follow a fairly definite course. The first structure to show a change is apparently the synovial membrane. If the joint be opened in an early case the capsule is usually found to be redder than normal; the surface may have a velvet appearance, or perhaps be covered by dark red material, much like granulation tissue. This granulation-like material in certain situations apparently replaces the synovial membrane and creeps over the sur-

face of the cartilage; in the carpus this process may advance to great destruction of interosseous structures. As the process continues the synovial membrane usually becomes thickened; various changes may occur, especially in the line of proliferation, the fringes becoming larger and at times showing the so-called villous arthritis. These fringes may become detached and form foreign bodies in the joint. These in some instances may even become calcified.

That there is any definite histologic picture which is characteristic of the changes in the synovial membrane in this disease does not seem likely. The condition seems to be much alike in the various more or less chronic inflammations of the joints. In the earlier acute stages the membrane shows infiltration of a very large number of mononuclear cells, often collected irregularly, and these sometimes, when on the surface of the membrane, may lead to the naked-eye diagnosis of tubercle. In the later more chronic stages these cells become less numerous, there is considerably more fibrous tissue, and the small arteries show obliterating endarteritis. The same condition can, however, be seen in other joint inflammations and is not peculiar to arthritis deformans. It is quite probable that in certain cases there may be no further change than that mentioned in the capsule and a fair degree of recovery take place.

In many instances, however, after the changes in the synovial membrane, the cartilage is attacked. The first change in the cartilage is usually erosion, and this, as in the case reported by Dr. Hale White,¹ seemed to be determined by the condition of the synovial membrane near it. Pressure of the synovial fringes seems to determine the perforation of the cartilage. The amount of destruction of the cartilage varies greatly. It may be comparatively slight, and is often very irregular in extent. With this there may be very little damage to the bone, although the skiagraphs in some cases suggest that there is very frequently atrophy of the bone in the neighborhood of the joint. The bone may, however, show foci of inflammation, and in these areas there is comparative absence of fat cells.

The fluid found in the joints is usually somewhat turbid; the cells found do not seem to have any special significance. With these changes in the joint itself the structures about it are also involved. There is inflammation and infiltration of the periarticular structures. These become adherent to the synovial membrane, and there may be considerable swelling. Ankylosis proper of the joint rarely results. The subsequent course varies very greatly. The process may cease to advance, absorption gradually occur, and the joint left little damaged, but more susceptible to injury on subsequent attacks. Or, on the contrary, it may go on to almost complete destruction and be useless for further function. With this, of course, other conditions are associated—muscular atrophy, contractures and luxation of the joint. In some instances the joint cavity may become practically obliterated.

What explanation can be given for such conditions? When we consider the many changes found in infective joint disease, such varying results seem perfectly possible as the effect of a specific bacterial infection. The action of toxins may be suggested, but as to this we know little. That they may influence the production of an arthritis is suggested by the cases following the injection of diptheria antitoxin.

It is possible that various septic conditions may be

1. Guy's Hospital Reports, vol. livi.

causal; at any rate, the influence of intercurrent septic infections in this disease is well known. Thus in a recent case, an acute outbreak with lighting up of fresh joints seemed definitely associated with an obstinate ulcer of the arm which involved the elbow joint. Attacks of cystitis and dysentery or an influenza may cause the recurrence of the previous disease. We see in the osteoarthropathy associated with bronchiectasis a condition which may have some bearing on this matter.

A difficult question to answer is as to the possibility of overgrowth of bone following on the changes which we have mentioned. Can hypertrophic bone changes, as we see shown in the so-called "osteoarthritic" type, occur with, or secondary to, these changes of the atrophic type? If this occurs, the identity of the two types is proved. The majority of the descriptions of the disease consider this to be the ordinary course, but recently some doubt has been cast on this opinion. I know of no definite pathologic reports which will settle the matter.

The Hypertrophic Type.—Here one of the prominent features is the bony outgrowth. The majority of the classical descriptions of the disease refer to this condition. The cartilage as a rule shows very marked involvement, with erosion and atrophy of the joint surface, while proliferation is occurring around the edges. This outgrowth of cartilage may become converted into bone, often very irregularly. Bannatyne states that as a rule these outgrowths have a covering of cartilage. We are all familiar with the appearance of the bones from this type of disease, although characteristic instances probably are seen clinically very much less frequently than those of the other type. In the joints of the limbs there may be changes in the bones, but in the spine the bone may be little affected. Some cases of this type may be very acute.

There are certain manifestations of the disease which deserve special mention. These are: 1. The conditions in the spine; 2. the monarticular type; 3. the so-called Still's disease.

Arthritis Deformans in the Spine.—We may have either type of the disease occurring in the vertebrae. Some involvement of the cervical region is very common in the atrophic type. This, however, rarely results in very marked permanent change. The frequency of the atrophic type in the lower spine is difficult to determine. Where we have definite bony outgrowth and ankylosis the process would seem to be of the hypertrophic type. The pathologic changes consist especially in the deposit of new bone. This occurs in very different positions. The intervertebral discs may be converted into bone, so that we have really a solid bony column, or the deposit may be largely in the ligaments, or, more uncommonly, there may be associated bony ankylosis of some of the smaller joints. These are very variable in position and extent; the bony deposit is very rarely symmetrical on the two sides. It may be on one side alone, or slight on one side and very marked on the other. The anterior ligaments may be ossified for a considerable distance and perhaps only one intervertebral articulation.

This irregularity of bony deposit is very striking when one examines a number of specimens, and is comparable to the irregular conditions found in the peripheral joints. The usual description given is that the condition begins in the articulations and extends to the ligaments, but signs of involvement of the joints do not seem to be nearly so common in museum specimens as the deposits in the ligaments.

These changes in the spine may occur alone, but are

frequently found associated with changes in the peripheral joints, and these of both types. This seems a strong argument for the unity of the disease. Two distinct diseases may coexist, but is such frequent coexistence probable? The cases showing definite bony outgrowths in the spine and the atrophic type of change in the peripheral joints are by no means rare. One association of special interest is that of the spinal type, with the so-called monarticular form as seen in the shoulder or hip joint. These latter, especially in the shoulder joint, are often very definitely atrophic.

There is much confusion regarding these spinal forms. We have the terms "Die chronische Steifigkeit der Wirbelsäule" (Bechterew), "Die chronische ankylosierende Entzündung der Wirbelsäule" (Strümpell) and "Spondylose rhizomélitique" (Marie), which probably are all designations for the same condition. This seems to be arthritis deformans of the spine. The varying types described depend on the condition and especially on the amount of involvement of the large peripheral joints. Bechterew, laying special stress on the associated conditions beginning with pain, sensory changes, muscular wasting, contractures, etc., regards the process as arising primarily in the nervous system. Marie, in the description of his type, insists on the condition of ankylosis of the vertebrae with ankylosis of the hips. Many variations have been described, but it seems quite possible that these may be all with one underlying condition. Cases are seen under observation at first with involvement only of the spine, and later one or both hips or shoulders concerned. I have had cases of spinal ankylosis with one, two, three or four of these large joints involved. These various degrees of involvement are against there being distinct diseases.

Certain secondary changes are common; the nerve roots are frequently involved, whether by communicated inflammation or direct pressure. This is seen especially in the cases regarded as sciatica, which are often due to arthritis deformans of the spine.

The most reasonable view at present seems to consider these various spinal forms as differing manifestations of arthritis deformans.

The Monarticular Group.—This has certain rather characteristic features. It occurs usually in advanced life. The joint involvement is in one of the shoulders or one of the hips. The malady known as *morbus coxae senilis* belongs here. The disability and the severe neuritis associated with it are important points. There are at times marked vasomotor phenomena seen in the affected limb. Pathologically, it would seem that these cases may belong to either type. In the shoulder joint the atrophic condition seems to predominate, while in the hip joint we have marked osteophytic growth. This, too, may be present in one part of the joint with very marked atrophy of other parts. The term monarticular is convenient to use as a description of a clinical type but perhaps unfortunate if it suggests anything distinctive from other forms of the disease.

The identity of this type is emphasized by the fact that if careful examination be made slight involvement of other joints can often be found. This may be nothing more than the presence of Heberden's nodes or a slight involvement of possibly one knee joint or a finger or two, but the association is always suggestive.

In a recent very typical case there was involvement of one shoulder, with marked wasting of the shoulder girdle and very severe pain. The case was regarded as a typical instance of the monarticular form. The acute features gradually subsided, and the patient was nearly

well, when suddenly the same process began very acutely in the other shoulder. Such instances speak against any special peculiarity of this type. The cases may become polyarticular.

The So-Called Still's Disease.—There is some question as to what condition is meant by this term. The most remarkable view seems to be that the cases are examples of the polyarticular type of arthritis deformans occurring in children. They show certain characteristics—polyarthritis, general glandular enlargement and an enlarged spleen. In many of the cases the course is progressively downward.

Some writers would make a separate class of these cases, but where is one to draw the line?

When one sees a series of such cases at ages varying from two to twenty years, with the characteristic features present, but as the patient grows older glandular enlargement and the splenic enlargement less marked, although present, the inference seems justified that they are all examples of the same condition somewhat modified by age. I have no hesitation in saying that patients at fifteen with this condition have arthritis deformans; why not the same at the age of five? The occurrence of adherent pericardium in a large number of younger patients is of interest. It is difficult to explain, and probably has to be left as one of the points to be solved.

The evidence at present seems to point to the unity of the various processes described. There is no group which can be constantly separated. Combinations of various features are common. Thus at present I have under observation a case in a young man with pronounced hypertrophic features, with marked general glandular enlargement and enlargement of the spleen. Trophic and hypertrophic changes may occur in the same joint, or one joint may show one type and another joint the other. In one case the atrophic changes are most marked, in another the hypertrophic. Why one process should predominate in a given case we do not know.

Certain writers would make another type which they term "infective." In the present condition of our knowledge it seems better to restrict this term to conditions associated with a definite organism.

ETIOLOGY.

Regarding this, one can only discuss the theories advanced without stating any definite conclusion. As already noted, there are probably three main theories to be considered: 1, That the disease is of neural origin; 2 that it is a definite infection; 3, that it may be the result of various infections.

Neural Origin.—This dates back for a considerable period and has received very strong support in various quarters. The principal points brought forward in support of this view are as follows: Firstly, the symmetry of the lesions and their progression from the peripheral joints to those nearer the body; secondly, the similarity of the joint conditions to those which occur in association with certain disorders of the central nervous system, such as locomotor ataxia or syringomyelia; thirdly, the very marked associated muscular atrophy, the sensory disturbances, whether as regards pain or anesthesia, various trophic disturbances, such as glossy skin, the condition resembling scleroderma, etc.; fourthly, the occurrence of neuritis.

Symmetry of Lesions.—In looking into these conditions strong exception may be taken as to the value of certain of them. Thus we find, on carefully studying a series of cases, that the lesions are by no means necessarily symmetrical; in fact, in many instances, quite the

contrary. While in many they do begin in the peripheral joints, very often the larger joints are attacked first.

Similarity of Joint Changes.—In regard to the matter of similarity to the joint changes in locomotor ataxia is this not true only of the latter stages of the lesions of arthritis deformans? Again, is the course of the disease as studied in a large series of cases in agreement with this view? It appears to me not. The cases of arthritis deformans proceeding to absolute destruction of the joints are, after all, comparatively few, and a great many proceed to almost complete recovery. Such a difference does not seem to me to at all support the analogy between the two conditions.

Muscular and Sensory Disturbances.—The question of the muscular atrophy is a difficult one to explain. It does apparently occur with greater rapidity than is usual in other forms of arthritis. As to a satisfactory explanation, I do not know that we are able to supply one. The various trophic disturbances may depend on the frequently associated condition of neuritis. This, in many of the cases, is very well marked. Undoubtedly in some it is due to a communicated inflammation. In others it is probably the result of direct pressure, as is seen sometimes in the spinal funus.

Neuritis.—The very marked neuritis sometimes found in association with the monoarticular types is at times very acute. The explanation is probably that it is often due to direct extension. In certain cases we may suggest the possibility of its being toxic.

When we turn to evidence to be obtained from the examination of the central nervous system there is very little to support this view. In a small number of cases atrophic conditions have been found in the cells of the anterior horns. They are usually in the motor ganglion cells, but have not been extensive enough to support the idea that they are important factors in the disease. In the peripheral nerves in certain instances neuritis is found, but as this is not constant we can not consider it an etiologic factor. It is more probably secondary.

The view that reflex conditions may be the cause does not seem to me sufficiently supported by any evidence we have at present. There is no evidence that any reflex action could cause the joint conditions we find.

There are some associated conditions of great interest which have been especially emphasized by Jones. Thus the occurrence with Raynaud's disease, exophthalmic goiter, etc., is interesting. In some cases one sees a condition of the skin much like scleroderma.

Specific Infection.—At present this seems to be the most reasonable view as to the etiologic factor. The character of the attack in many cases suggests an acute infection. The onset is frequently sudden, the symptoms may subside, to recur as suddenly, or may gradually progress. The subsequent course may be to complete recovery from that attack or may be to total loss of function of the affected joints; this, however, it is important to remember, being often due to secondary changes. With the acute symptoms are usually swelling, heat, redness and pain in the joints, some fever and often leucocytosis.

Visceral complications are rare, and yet in two recent cases with the joint symptoms the patients had acute pleurisy ushered in by a severe shaking chill. In one case a subsequent absence of reaction to tuberculin may be considered to rule out tuberculosis. With the acute features, marked enlargement of the glands in relation to the affected joints is almost invariably found. In the younger patients enlargement of the spleen may occur

and this in cases not considered as examples of Still's disease. Do these not suggest an infection very strongly?

It may be noted that the glandular and splenic enlargement may occur with both types of the disease. The conditions in the nervous system may be explained by the action of toxins. When we turn to examine the results of cultural work, there is little as yet to show. Various observers have reported organisms (Schüller-Bannatyne, Wohlmann and Blaxall, Chauffard and Raymond, Van Dungen and Schilde, etc.), but the most important findings seem to be those of Paynton and Paine.² From the knee joint of a man showing osteoarthritic changes they obtained a diplococcus which caused arthritis in a rabbit, with ulceration of the cartilage, flattening of the articular surfaces and the production of osteophytes with lipping of the joint. Such a result is certainly most suggestive. The results of cultures in the Johns Hopkins Hospital have thus far been negative.

Various Infections.—This view is a tempting one in many ways. As one organism may set up very different changes, so various organisms may cause the same changes. The association of arthritis deformans with various processes, such as pyorrhea, cystitis, dysentery, is suggestive. Tonsillitis and pyorrhea have by some been suggested as important sources of infection. In this series tonsillitis has been infrequent, while pyorrhea is so common that one hesitates to attach great importance to it as a causal factor. In rare cases the treatment of such local conditions has resulted in marked improvement in the general condition.

Whether these may be causal can not be proved, but they certainly at times seem to be definitely associated with exacerbations. This is not invariably the case. Some patients go through intercurrent infections without any change in the arthritis, or may even seem to be better for a time. This is true not only of septic processes, but also of infections such as influenza, measles, mumps, etc. Some would make an association between acute articular rheumatism and arthritis deformans in this way. Gonorrhea has by many observers been held to have a special relationship. In our cases, however, this has not been the case.

STATISTICS OF ONE HUNDRED AND SEVENTY CASES.

In a series of 170 cases, among the acute infections in the previous history, measles was the most common, viz., in 93 instances. Following this came whooping cough in 43, mumps in 31, scarlet fever in 27, malaria in 26, typhoid fever in 20, chicken-pox in 18, influenza in 15, pneumonia in 16, diphtheria in 11, erysipelas in 3 and smallpox in 2. Recurring attacks of tonsillitis were infrequent, being noted in 7 cases. Various conditions such as otitis media, pleurisy, carbuncles, dysentery, cystitis, etc., were noted in one or two instances. There was a previous history of gonorrhoea in 23 cases, or 13 per cent. There was a history of syphilis in 5, and chaneroid in 1. It does not seem possible to speak with any certainty at present regarding the exact relationship of these many infections to arthritis deformans.

Regarding the various factors of incidence, the figures are as follows:

Family History.—There was a definite family history of arthritis in 62 cases. Of these, 15 were undoubtedly arthritis deformans, 35 were termed "rheumatism," and undoubtedly many of these were arthritis deformans; 1 was given as gout, and in 11 the nature was unknown. In some the family history of arthritis deformans was

remarkable. One patient's father had the disease in a severe form, three brothers and three sisters suffered with it, all having chronic changes; only one sister had escaped. The patient's mother had escaped, but in her family the disease was common, all her brothers and sisters having it. Her mother also suffered with it. The combination of two such arthritic stocks would seem to portend disaster for the offspring. In another case there was a family history of the disease for four generations. In patients with a definite family history the disease does not seem to appear at an earlier age than in the others. There was a family history of tuberculosis in 39 cases.

Sex.—The males were in the majority—89 males and 81 females. This is unusual in a large series, the females usually being in the majority. Many series give as high as 80 per cent. of females.

Race.—The white numbered 161, the colored 9. The colored show a marked relative less susceptibility to the disease. The proportion of white to colored in the hospital is 7 to 1, while the proportion of cases of arthritis deformans is 16 to 1. The negro is specially prone to gonorrhoea, tuberculosis and acute articular rheumatism, a point of interest in regard to their association with arthritis deformans.

Occupation.—The largest number were engaged in housework, namely, 64; in other indoor occupations there were 46. At outdoor work there were 33. There was a surprisingly small number engaged in occupations involving special exposure. Neither exposure nor trauma seemed to play an important part as etiologic factors in this series.

Age.—On admission this was:

1 to 10	3	31 to 60	32
11 to 20	11	61 to 70	11
21 to 30	31	71 to 80	4
31 to 40	47	81 to 90	1
41 to 50	20		

It is to be noted that 92 were below 40 years of age and 45 below 30.

The age at onset, in 165 cases, shows a rather different distribution:

1 to 10	15	41 to 50	23
11 to 20	30	51 to 60	18
21 to 30	33	61 to 70	6
31 to 40	38	71 to 80	2

Practically in 70 per cent the onset was before the age of 40, while in nearly one-half it was before the age of 30 years. This seems important, as so often the disease is considered to usually occur in late adult life.

Alcohol.—Fifty-one had used alcohol, the majority in moderation. About 10 might be described as heavy drinkers.

Pregnancy and Miscarriage.—While in some series these seem to have an important relationship to the onset of the disease, such was not the case in this clinic. Frequent repeated childbearing had occurred in some, but these are not numerous enough to be important. In only three of the women had the disease appeared soon after confinement. Uterine conditions were infrequent. Mental worry or anxiety did not seem to have played any part as an etiologic factor.

CONCLUSIONS.

The conclusions which may be made are as follows:

1. That there are two great types of cases, the atrophic and hypertrophic, which are probably varying manifestations of the same disease.

2. That there are many variations, such as the spinal forms, the so-called monarticular form, the form occurring in children, etc., which are probably all arthritis deformans

2. Trans. of the Path. Soc of London, vol. III, 1902, p. 221.

3. That the etiologic factor is not determined, but our present knowledge points to its being an infection of some nature.

4. That no opportunity of pathologic and bacteriologic examination should be neglected.

ARTHRITIS DEFORMANS.*

JAMES J. WALSH, Ph.D., M.D.

NEW YORK CITY.

At last light seems to be finding its way in among the obscurities of the rheumatism problem. Acute articular rheumatism is a microbic disease, one of whose principal features is its tendency to get well entirely except for the mark it may leave on the heart. Uric acid has nothing to do with rheumatic conditions, and is only a fetish that was set up to be worshipped by those who wanted to find scientific explanations for disease long before physiologic chemistry was ready to furnish any such explanation. Rheumatic gout now disappears, there is no middle term between gout and rheumatism, and the two diseases are not closely related at any point. Chronic rheumatism is a vanishing ailment, seen more and more rarely as greater care is used in diagnosis, and in the recognition of various painful nervous conditions with which it was formerly confounded.

This preliminary clearing of the field leaves us, however, with a group of diseases, with regard to which as yet only abortive attempts have been made to get at a definite classification. Under this group of diseases are found all those in which there is a deformity of joints usually progressive and not due to traumatism or known infection. The name selected for this group of diseases, arthritis deformans, is sufficiently non-committal to be acceptable. The affections are certainly deforming. The underlying pathologic condition can be regarded, as a rule, as of inflammatory origin, though the processes of the inflammation run from acute, almost fulminant, to the extremely chronic type, which may take years before serious deformity results.

It may be said that it is only in recent years that attention has been especially called to this group of diseases. Physicians now see them frequently, and while a few years ago they were considered to be examples of a rather rare disease, this is due to the fact that in most cases the deformities when seen were attributed either to chronic rheumatism or to gout. The differential diagnosis has come for the most part within the last twenty-five years.

Arthritis deformans itself, however, in some form can be traced in history at nearly all times. The bones from the bodies of persons probably 5,500 years ago show in certain cases the signs of changes due to arthritis deformans. Bland Sutton described the same lesions as occurring in a mummy, taken from an Egyptian tomb, and which had been buried about 2,000 years before Christ. Virchow, excavating the bones from the cemetery of a medieval monastery, found similar conditions. It has even been said that the distinguished Italian painter of the Renaissance, Botticelli, always painted ugly hands. As a matter of fact, however, careful examination of his pictures will show that his favorite model seems to have suffered from arthritis deformans, since the hands show signs of this disease, and

the reason for the ugly hands in his pictures is that, just as for her hollow chest, he followed this model too closely.

Arthritis deformans is, then, a very old disease. It has existed continuously and it occurs much more frequently than has been thought. The affection of the spine, which is due to this disease and which is often spoken of as very rare, has been traced by Dr. Rubrah¹ down the centuries from the earliest times in Egypt, and any one who sees many cases in a city dispensary and hospital is sure to see one or more examples of the disease every year.

TYPES OF THE DISEASE.

Such distinguished English authorities as Dr. Hale White, Dr. Garrod and Dr. Bannatyne divide the group of diseases commonly described under the name arthritis deformans into three types. These types may be briefly described as follows: There is, first, the disease commonly known as osteoarthritis, often confined to the hip joint, and most common in old men. It consists of a bending of the neck of the femur and some other bony deformities connected with the hip joint. Secondly, there is the disease in its milder forms, often not recognized as a special affection, but considered as the result of certain kinds of work or as of traumatic origin, which is most common in women in middle life, and is represented by deformities occurring in the terminal joints of the thumb, though in this the terminal joint is not necessarily always first affected. Dr. Hale White says that the deformity becomes considerable in these cases, and is ultimately largely due to bony outgrowth. "In a large number of cases the trouble gradually spreads until many joints are implicated and the woman may become a helpless cripple, and although in one sense she is very severely ill, yet the disease is very slow, the symptoms are not acute, and there is no pyrexia."

Whether the affection thus described is different from what is ordinarily called Heberden's nodes is hard to say. There seem to be cases in which a small amount of bony outgrowth on the terminal phalanges of two or three fingers does not progress beyond a certain point of disfigurement, and gives scarcely any discomfort except when there is some trauma; this, however, is not infrequent, because of the awkwardness induced by the deformity. According to a long-established English medical tradition, Heberden's nodes occur especially in long-lived people. Whether there may be several groups of these nodular affections of the terminal joints of the fingers remains to be seen. Some of the cases certainly belong to an abortive type, and do not progress beyond a certain degree of awkwardness and unsightliness without further discomfort.

The third form of arthritis deformans is the one of most interest, since it attacks young people, simulates ordinary acute rheumatism, produces lasting changes in joints, has a definite tendency to recurrence, and ultimately makes its victim a helpless and pitiable cripple. The disease is more common in women than in men, occurring usually in young women, as Hale White says, about the age of 20.

This affection is distinctly progressive. While it is markedly symmetrical in the two hands, it is likely to invade the wrists and then other joints, and the same thing may happen in the legs.

This is the form of arthritis deformans which be-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

cause of its simulation of ordinary acute rheumatic arthritis, is especially interesting.

DIAGNOSIS.

The differential diagnosis, however, if once suspicion is aroused, does not seem very difficult even in the early stages. Certain joints are characteristically affected in true arthritis deformans. Instead of the large joints as in rheumatism, it is mainly the joints of the fingers and particularly those of the terminal phalanges which are swollen and tender. In most of the cases there is also some swelling and tenderness over the joints of the lower jaw. As the temporo-maxillary joints are practically never affected in ordinary acute rheumatic arthritis, it may be set down as probable at once when the patient complains of tenderness and disability in the jaw, with some pain on movement and swelling, that the affection is arthritis deformans. In many cases the spine does not escape. There is almost certain to be some stiffness of the neck traceable not to any spasm of the muscles, but to the tenderness of the joints. This may be so slight as to escape at first, and may disappear after a time, but its presence is always an added factor of suspicion as regards the relationship of the affection under treatment to arthritis deformans, rather than to ordinary acute rheumatic arthritis.

At the beginning of a case of arthritis deformans, there may be some hesitation as to the differential diagnosis, especially if, besides the fingers, one or more of the large joints are affected. In these cases, however, certain features, if looked for, are sure to arouse suspicion. The patient has considerably more discomfort and complains of more pain and tenderness than the amount of fever and involvement of the joints quite justifies. Of course, the question of bearing pain is very individual, and nervous patients are likely to complain much more than others. Arthritis deformans, as a rule, however, attacks people who are not especially of nervous organization. Young servant girls and hard-working men under 35 are especially its victims. The fever from which they suffer is usually not so high as it would be from ordinary acute arthritis. It rarely rises much above 102 degrees, and may remain constantly below this. It is more continuous, too, than that of true rheumatic fever; that is, it has less daily variations.

Perhaps the most characteristic of the differential diagnostic symptoms is that the salicylates fail to reduce the fever very materially, and fail almost completely to lessen the pain and discomfort. Very often the restlessness induced by this will have to be relieved by some form of opium, and even of this the patient will need more than would be anticipated.

A marked difference between ordinary acute rheumatism and arthritis deformans is found in certain slow running cases of the deforming affection. Patients will sometimes give a history of having had swelling and some tenderness around the joints of the fingers and toes which was not, however, of sufficient intensity to make them give up their work. Gradually other joints become involved. The wrist, the ankles and the knees may become affected. Not infrequently the temporo-maxillary joint shows signs of the presence of the affection. If the patient has put off the inevitable coming to the hospital for a considerable period, usually there is a notable reduction in weight and the general health is much disturbed. Usually in these cases it will be found that while there have been intervals during which the affection has not been so severe as at

other times, *quasi* intermissions in the course of the disease, there has seldom been an absence of tired feelings with chilly feelings on first exposure to air that would seem to indicate the more or less constant pressure of a low-grade fever. In these cases the fever usually runs between 100 and 101 degrees.

PREDISPOSING FACTORS.

Perhaps the most important predisposing cause of the affection is overwork. Hence the tendency for it to occur, especially in people who are deeply interested in their work, who have devoted themselves to it, who have no vices, who do not drink and who have no special care for the pleasures of the table. Not infrequently the disease occurs at a moment when patients are run down in weight because of their tendency to neglect their meals in their interest in their work. It is not unusual, then, to have patients ask rather complainingly why they should suffer from such a disease, which is usually attributed to some abuse in the matter of eating or drinking, or to some special exposure.

With regard to exposure as a prominent factor in the causation of the disease, it seems hard to get at a definite conclusion. The disease occurs not uncommonly in those who are living a rather sedentary indoor life, though quite commonly there is a story of their having been exposed to a severe wetting or some special inclemency of the weather not long before they noticed the first symptoms of their attack. Whether this is a coincidence, and is recalled mainly because the patient feels that there must be some such connection between what is commonly called rheumatism and dampness or exposure is hard to determine. In one case where there seemed no doubt from the affirmation of the patient, a very intelligent man, that a preceding exposure had been one of the causes of his illness, careful inquiry showed that the wetting had taken place some twenty-six days before he felt uncomfortable sensations which represented the preliminary stage of the disease, and over a month before there were any special localized swellings of the tendons. It would be very hard to persuade most physicians that an exposure a month away had anything to do with an attack of a disease so acute as arthritis deformans.

PROGNOSIS.

The prognosis of typical cases of acute arthritis deformans is not always so unfavorable as seems usually to be thought. The case of a physician that has recently been under observation exemplifies this. Toward the end of January he suffered with a series of red, swollen, tender joints, affecting the fingers to a marked degree and the toes to some degree. Notwithstanding the presence of the affection, he was able to go on with his work to some extent, and in fact the general course of the case was so mild that there might be some hesitation as to the diagnosis, except for the tendency to distinct ulnar deformity, and the fact that the jaws were affected as well as the joints of the fingers. This involvement of the jaw is considered by everyone who has seen many cases as the most pathognomonic symptom of arthritis deformans. In this case now at the end of four months nearly all the deformity has disappeared. The index finger of the right hand is still slightly misshapen, and there are also nodules at the joints of other fingers, but these are not very marked, and the patient is able to close his fists very well. Over the deformed parts there is still slight tenderness.

One of the most important features of the affection is the tendency to recurrence. Not infrequently pa-

tients seem practically to get completely over the first attack. Some few signs of the affection are left, however. Usually within a year or two there is a second attack, which leaves distinctly more deformity, and makes it clear that the patient is not going to escape so easily as was first thought. Subsequent attacks are apt to occur at briefer intervals. In each there is a redness, swelling and exquisite tenderness. After each attack there is more disorganization of joints than before, though there is always a distinct remission with considerable improvement, and the raising of the hopes of the patients, sometimes also of the physician.

THE TREATMENT OF ARTHRITIS DEFORMANS.*

CLARENCE EDWARD SKINNER, M.D., LL.D.

Physician in Charge of the Newhope Private Sanitarium,
NEW HAVEN, CONN.

It is only within a very few years that systematic efforts to evolve an effective management for arthritis deformans have been attempted, largely because it has been only a few years since the affection has been susceptible of anything like a sharp diagnostic differentiation. For this reason text-book literature on its therapeutics is meager and very unsatisfactory when subjected to the test of clinical application. About all that can be gleaned from it is a recommendation to give the patient cod liver oil, iron, or potassium iodid for long periods, to maintain his health in as good condition as possible, and to send him to some hot springs or other health resort. Although its present-day treatment is disappointing on the whole, yet evidence is accumulating which indicates that modern therapy is capable of producing curative results in many cases, and marked amelioration of the symptomatology in a large majority of them; that arthritis deformans will soon be resented from the category of hopeless-ly incurable diseases.

IMPORTANCE OF EARLY DIAGNOSIS.

The first and a most important step in the management of this disease is to make an early diagnosis. This is important from a therapeutic point of view because, first, when these cases are brought under an appropriate line of management at a moderately early stage, the great majority of them can be restored to useful and comfortable lives, and a large proportion can be restored to apparently perfect health, whereas, if the disease is unrecognized, hence improperly treated for months or years, organic changes will take place in the structures involved of such a nature and degree as will render utterly impossible the restoration of normal function; and, second, the treatments appropriate to the diseases which most closely resemble it clinically are not only entirely inefficacious for the relief of arthritis deformans, but in some respects are positively harmful. This is especially true with reference to rheumatism and neuritis, the affections with which arthritis deformans is most frequently confounded.

DIET.

Another important factor in its management is the prescription of a proper diet. The widespread impression that gout and rheumatism were largely concerned in the etiology of the disease is responsible for the com-

mon practice of denying these patients red meats, and sometimes all meats. I believe that this restriction is not only unnecessary usually, but that it frequently inflicts positive harm on the patient. Malnutrition is an almost constant characteristic of this disease, and the more nourishing and generous the diet, within proper limits, the more will the progress toward recovery be facilitated. These dietary limits are represented by the capacity of the individual patient for digesting and assimilating his food, and must be defined, as regards both quantity and variety, by this capacity as ascertained in each individual case. It has been my experience that, as a rule, meat of all kinds except pork are well digested by these patients and beneficial, and that restriction is much more frequently required with reference to the starches and sugars. Intestinal indigestion requires attention in these cases with a moderate degree of frequency.

CLOTHING.

In any disease exhibiting more or less constant pain as a symptom a good quality of woolen underclothing, of light weight in the summer and moderately heavy in the winter, is a source of comfort to the patient in protecting the skin from sudden changes of temperature, which are liable to increase the pain. Arthritis deformans is no exception to the rule. Protection of the skin by woolen underwear renders another service by maintaining the function of this emunctory, which is so important a factor in the general bodily metabolism. Impairment of general metabolism is usually a prominent feature of this disorder.

PHYSIOLOGIC REST.

During the acute stages the joints involved should be kept at rest. I do not mean such complete rest as would necessitate enclosing the member in a splint, but the patient should be directed not to use the joint to such a degree as to produce pain. Patients are sometimes urged to force the joints to functionate, no matter how exquisite the anguish induced, and the effect is usually to increase the local pathology already present, to say nothing of the evil influence on the general nervous system. Nothing is more depressing than severe and long-continued pain. These remarks also apply to passive movements.

ACTIVE AND PASSIVE MOVEMENTS.

After the acute process has subsided, judiciously regulated, gradually increased movements of the stiffened joints, both active and passive, are beneficial, and frequently partial ankylosis can be entirely removed thereby, but the sudden forcible breaking down of the ankylosis of arthritis deformans, when it exists to any great degree, is a procedure which I have never seen followed by anything but evil results in the way of increased and usually entirely hopeless ankylosis, and in mentioning the procedure I desire to express my conviction that it should be expunged from the therapeutic category of this disease.

MEDICINAL TREATMENT.

The drug treatment of uncomplicated arthritis deformans is unsatisfactory in the extreme so far as the obtaining of curative results is concerned. Only a very few elements of the materia medica have succeeded in gaining a lasting reputation in this connection, and all of those that have, except the salicylates, are of the "tonic" and "alterative" classes, hence exert their beneficial influence through their power to improve the general metabolic functions. Prominent among these may be mentioned the iodid of iron, cod liver oil, the hypophosphites.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

arsenic in its various combinations, strychnia, the chlorid of gold and sodium and potassium iodid. The first mentioned has given me the best results, improvement usually manifesting itself, when it obtains at all, in about three weeks after the commencement of its administration. It should be given for periods of six weeks, with an intermission of two or three weeks. Cod liver oil does good service in those cases characterized by emaciation, if well borne by the stomach. Arsenic and strychnia are fairly useful in many instances as general tonics. The chlorid of gold and sodium and potassium iodid or hydriodic acid sometimes seem to render considerable service, but they fail to influence the disease in such a large proportion of cases that their importance is not nearly so great as is generally supposed.

The relation of the salicylates to this disease deserves special mention, as they sometimes render excellent service in relieving pain and swelling. Although it is improbable that rheumatism is an etiologic factor in any considerable number of cases, yet it is not so very uncommon to see an attack of rheumatism engrafted on an already existent arthritis deformans, and, as the salicylates fail absolutely in so many manifestly uncomplicated cases, it seems reasonable to consider that many of those in which they are useful are instances of such a complication. The fact that beneficial influence is obtainable by their use only up to a certain point would favor this view. The difficulty of making a positive diagnosis of rheumatic invasion under such circumstances is in many cases, of course, insuperable. Whatever the explanation, the fact remains that the salicylates, especially aspirin, are sometimes very helpful in relieving painful joint conditions occurring during the course of arthritis deformans.

Constipation is sometimes present in a degree to demand attention, and the various mineral waters, magnesium sulphate, the aloin, strychnia and belladonna mixture, or compound licorice powder, will be found helpful. What particular one should be used must be determined by the tolerance of the individual patient.

Digestive disorders can generally be controlled by regulating the diet, but the digestive ferments, carminatives, charcoal, bismuth subnitrate and strychnia will sometimes have to be called on to assist in this work.

The constant harassing pain is one of the most troublesome symptoms of the disease so far as management is concerned. Most of these patients have become so habituated to the pain that they bear a moderate amount without much complaint, but sometimes severe exacerbations, lasting for several hours, days or weeks, will occur which demand attention. Opium, or any of its derivatives, is inadvisable because of the chronic character of the trouble, because it loses its influence in a few days unless given in increasing doses, and because of its evil effects on the system at large. I have occasionally given coal tar derivatives when the paroxysms were very severe, but they also produce undesirable results on the metabolic and circulatory functions when continuously administered in effective doses for any length of time. None of the ordinary pain-relieving drugs are of much service in controlling this symptom, with the exception of the salicylates, as hereinbefore mentioned, but much relief can usually be obtained by the use of external applications and the hot water bag; baume analgesique (Bengue), the tincture of iodine externally, and the various anodyne lotions have given me better results than anything else.

A few months ago, in a paper read before the New

aven County Medical Society, the belief was expressed that a new era was dawning in therapeutics which would be characterized by the prominent position which the natural physical and psychical forces would occupy in the management of disease processes, as opposed to a therapy constituted exclusively by the administration of drugs and ablative surgical procedures. In the treatment of the disease under consideration this new era has already established itself, and it is to the so-called physiologic therapeutics that we must look to-day for the attainment of anything approaching satisfactory results in any large number of cases.

DRY HOT AIR.

Dry hot air, electricity and mechanical vibratory stimulation are the most useful of these measures, and hydrotherapy will probably join their ranks in the near future.

In my opinion, the body dry hot air application is to-day the sheet anchor of hope in the management of arthritis deformans. Its physiologic action may be summarized as follows: First, it produces an immediate and powerful stimulation of the vital physical signs; second a reflex stimulation of the functions of all the organs and tissues of the body, resulting in, first, a degree of elimination of urea and other excreta which I believe to be unequalled by that producible with any other measure now known, and, second, an amount of reconstructive activity which I believe at the present time to be also in excess of that derivable from the use of other agents. Ample logical indication for its employment is found when we consider these influences in connection with the symptomatology and what is known of the pathology of the disease.

There is usually present, first, a notable depression of the vital physical phenomena; second, impairment of function of many of the organs concerned in the digestive, elaborative and assimilative processes of the body; and, third, a marked deficiency in the reconstructive activities. The inferences suggested above have been fairly well borne out by practical results accruing in my own personal clinical experience, and I have come to look on this measure as the most efficient single element in the treatment of the disease.

Before leaving the subject of the body dry hot air application, I wish to specify just what I mean thereby. Many who have used dry hot air for the purpose of relieving the victims of this affliction will not bear me out in the statement which I have just made regarding its efficacy, and I believe that the unsatisfactory results are largely due, other conditions being equal, to differences in the method of employment rather than to weakness inherent in the remedy itself. First, it is not a cabinet bath, heated by an alcohol lamp to 150 or 160 F., and in which the patient is treated sitting on a stool; second, it is not a Turkish bath, with a temperature of 180 or 200 F., and, third, it is not an incandescent or arc light bath. The first and second mentioned procedures are almost always debilitating and pernicious when applied with a moderate degree of frequency to cases of this disease, and in the third the light effects are so prominent as to render it impossible to produce anything approaching a proper degree of purely thermal influence. The body dry hot air application to which I refer is given by means of a metallic asbestos-lined cylinder, long enough to include the body up to the armpits, and heated by gas, gasoline or electricity. The treatment intensity should be from 350 to 400 F., and the immediate clinical effects are profound enough to render it necessary for the patient to assume the recumbent position, not only during the immediate

application, but for some time afterward. The heat should be run up rapidly, so as to secure the necessary degree of physiologic influence as quickly as possible. As a rule, an increase in the pulse rate to 120 beats per minute or an increase in the month temperature of 2 F. over what it was before treatment indicates that a proper degree of influence has been secured, and from twenty to thirty-five minutes' exposure will suffice under ordinary conditions. By this method we secure a profound stimulation of physiologic function, whereas if the patient is treated for long periods with the lower degrees of heat the ultimate result is relaxing, depressing and pernicious.

The local dry hot air application is rarely of any use in the treatment of this disease except for the relief of pain, and even for this purpose it fails more often than it succeeds, and sometimes marked aggravation is the result.

ELECTRICITY.

The next most useful of the physiologic agents is electricity, and the several forms of current have distinct and different spheres of influence. The one of greatest general utility is that derived from the static machine, and the wave current and the spark are the most frequently serviceable modalities.

Some authors claim to have cured cases with the static current alone, but such an instance has never come within my personal experience, and it is usually difficult enough to benefit them materially when all the resources at our command are brought into action.

During the acute stage the static wave current may be applied to the affected joints twice daily by means of sheet tin electrodes molded to the parts, and is frequently very effective in relieving the pain. The influence of every static application is general as well as local, no matter how the treatment is localized, and the effect on the organism at large is often happy to a degree.

Sparks may be applied over the spine and the general muscular areas of the body for their tonic effect, at any stage of the disease, but as a rule they had better not be applied to joints wherein acute symptoms are manifest. When the acute process has subsided, however, and the local phenomena have become confined to soreness and fibrous enlargement, I know of no one measure which will so frequently prove effective in removing both as judiciously-applied static sparks. The various neuralgias which accompany the disease are also amenable as a rule to the static spark.

The brush discharge from the wooden or carbon electrode, applied to the affected part for fifteen or twenty minutes, is effective in relieving the neuralgias as well as the aching pains of the acute conditions, in a certain number of cases.

The general application of the high-frequency current, applied by means of the spiral wire cage of D'Arsonval or the auto-condensation cushion, seems to promise much because of its strong tonic influence on the nervous system and general metabolism, but enough has not yet been done with it in this disease to render possible the formation of reliable conclusions. It has seemed to have exercised a beneficial influence on some cases in the treatment of which I have used it, enough to encourage me to continue observations on it in the future.

The continuous current in the form of central galvanization is very helpful in improving the patient's general condition and as a sedative to the nervous system, but I have never been able to secure any local effects with it in this disease that I could not have secured just as well, and usually better, with something else, except in muscu-

lar spasm due to nerve irritation; in the torticollis of arthritis deformans the continuous current in doses of from 5 to 20 milliampères for fifteen minutes will sometimes give more satisfaction than anything else.

The rapidly interrupted magnetic-induced current from 1,500 yards of No. 36 wire is very useful for the relief of pain wherever or whenever it may be encountered. The strength of the current should be regulated according to the sensation of the individual patient and should never exceed the limit of absolute comfort. It may be applied as often as pain demands it without any injury to the patient.

Mechanical vibratory stimulation has not yet been used extensively enough to justify the formation of an opinion as to its curative powers in the treatment of this affection. It is undoubtedly, however, a powerful general tonic; it will relieve the pain of muscular spasm and relax the spasm more effectively than any other measure with which I am acquainted, except anesthesia, and it is powerfully and harmlessly sedative to the irritable nervous system. In all of these capacities it enters into the management of arthritis deformans, and I should very much dislike to dispense with it as a part of my armamentarium.

MASSAGE.

Massage, either general or local, will very rarely have to be considered in the treatment of this affection when the agencies already mentioned are available. When they are not, however, it will be found useful in relieving pain, locally, and in improving the patient's condition generally.

GENERAL ROUTINE TREATMENT.

As I have already said, it is sufficiently difficult to benefit these patients materially, even when we use all the resources at our command; this implies the desirability of giving them the benefit of everything that is known to exhibit helpful properties and brings up the question "What are the most advantageous therapeutic combinations?" That which has given me the most satisfaction as a routine treatment, to be modified according to the conditions surrounding the individual cases, is as follows:

1. A diet as generous as can be digested and assimilated by the individual case, and consisting largely of red meats.
2. Rest in bed for at least ten hours out of the twenty-four.
3. A pill consisting of 1/40 of a grain of strychnia sulphate and 1½ grains of ferrous iodid three times daily half an hour before meals, and in the emaciated cases 1 to 4 drams of cod-liver oil three times daily, after meals.
4. A dose of some one of the mineral waters before breakfast every two or three days, if constipation is present.
5. A body dry hot air treatment two or three times weekly.
6. Central galvanization once or twice weekly.
7. A general application of mechanical vibratory stimulation two or three times weekly.
8. A static electrical application at least once every day, consisting, in acute cases, of the Morton wave current localized over the affected joints or spine, and, in the chronic cases, of long, thick sparks to the affected joints one day and the Morton wave current localized over these joints the next. In some cases some one of the high-frequency currents, applied either locally or generally, may advantageously replace some of these static applications or be added to them.
9. With ankylosed joints, wherein the acute condition

has subsided and the functional impairment is not due to osteophyte formation (and in my experience it has not frequently been due to this condition), passive movements every day, in the form of alternate forced flexion and extension, the attempt being made to increase the excursion of the manipulated member each time, are of considerable use. The movements should not be violent enough to produce sudden breaking down of the offending tissue or to cause the patient much pain; otherwise the original pathologic process is very likely to be reawakened and the last condition of the victim will be worse than the first. The effects of these movements should be carefully watched, as this same evil result will follow if they are commenced too early.

STATISTICS.

"The proof of the pudding is in the eating," and the statistics of the following 51 cases which I have had under treatment in private practice during the past four years illustrate what it is possible to accomplish by the application of the above-outlined management. For the sake of convenience in describing the gross results attained, I have divided them into five groups, the first consisting of those who have been entirely free from all active symptoms of the disease for periods ranging from 1 to 2½ years; the second, of those who have been "greatly benefited," and, third, of those who have been "considerably benefited"; the fourth, "slightly benefited," and the fifth of those who have "not been benefited at all."

The first group consists of 9 cases, 3 men and 6 women, ranging in age from 35 to 62 years. They had suffered from the disease before coming under treatment for periods ranging from three months to fifteen years. The general condition as regards nourishment, food, digestion and assimilation and sleeping ability when treatment was commenced was bad in 5, fair in 2, and good in 2. It is now perfectly normal in all. Five of them were totally incapacitated for the performance of their ordinary duties, and 4 were partially incapacitated. Complete ankylosis of one or more joints was present in 1 case, partial ankylosis in 5, and in 3 cases no ankylosis was present. Five suffered severely from more or less constant pain, 2 suffered only slight pain when the joint was at rest, but were very sensitive to manipulation, and 2 suffered only when the joint was manipulated or functioning. In 1 of these cases the disease process was confined to the joints of the fingers and toes; in every other case in the whole series of 51 one or more of the larger joints were involved, either in addition to the fingers and toes, or without the fingers and toes being involved at all. The shortest time required for the complete disappearance of the symptoms in any of these cases was two months, the longest thirteen months.

Two of these suffered recurrences of the disease, one eighteen months after treatment had been suspended and the other two years after. In the first mentioned the relapse was so slight that the patient did not return for treatment, all evidences of the disease disappearing after two months' treatment with iron, strychnia and the chlorid of gold and sodium. In the other the relapse was quite severe, it being necessary to treat the patient very thoroughly for three months before all evidences of the disease again completely disappeared.

The second group, or those who have been "greatly benefited," is composed of 16 cases, 8 men and 8 women, ranging in age from 21 to 60 years, and who had suffered from the disease before coming under treatment for peri-

ods ranging from six months to twenty years. There are included in this group 5 cases which have been entirely free from all active evidences of the disease for periods ranging from six weeks to ten months, and who give every promise of being properly classifiable in the first group during the coming year and making a total of 14 cases in which all active evidences of the disease have been absent for periods ranging from six weeks to two and a half years; 4 who are still under treatment which has already continued intermittently for periods varying from ten to eighteen months, and who are steadily improving; 7 whose treatment was prematurely discontinued for various reasons after the benefit was secured. Seven were totally incapacitated for the performance of their ordinary duties; 9 were partially so. The general condition when treatment was commenced was bad in 9, fair only in 4, in all of which it is now either normal or greatly improved, and good in 3. Complete ankylosis of one or more joints that was completely relieved was present in 1 case, that has been partially relieved in 4, and not relieved at all in 5. Partial ankylosis of one or more joints that has been completely relieved was present in 6 cases, that has been relieved to some extent in 3, and that has not been relieved at all in 3. In 7 cases no ankylosis was present. Severe pain that was constantly in evidence was present in 11 cases; in 3 of these it was removed completely, and in 8 it was completely removed in some joints and in others to such an extent as to be in evidence only when the affected part was manipulated or functioning. In 5 cases pain was present only on manipulation or functioning of the joints when treatment was commenced; in 4 of these it was removed entirely; in 1 it still persists to a slight extent after seven months of treatment.

The third group, or those who were "considerably benefited," consists of 11 cases, 3 men and 8 women, ranging in age from 30 to 75 years, and who had been ill with the disease before coming under treatment for periods ranging from six months to ten years. One is still under treatment and improving, and 10 discontinued treatment prematurely for various reasons while still improving. The general condition when treatment was commenced was bad in 6, fair only in 5; all were noticeably improved in this respect when treatment was discontinued. Complete ankylosis of one or more joints was present in 4, which was not influenced at all by treatment; partial ankylosis of one or more joints in 7, which was completely removed in 1, partially removed in 3, not influenced in 5. In 5 no ankylosis was present. Pain of various degrees was constantly present in 6, in all of which cases its severity was much lessened; was present on manipulation or functioning only in 5, in 3 of which its severity was much lessened, and in 2 it was not influenced. Seven were totally incapacitated for the performance of their ordinary duties, 4 partially so.

The fourth group, or those who were "slightly benefited," consists of 10 cases, 1 man and 9 women, ranging in age from 23 to 73 years, who had been ill before coming under treatment for periods ranging from two months to five years. Three are still under treatment and improving, 6 discontinued treatment prematurely, and 1 refused to improve in any respect except as to her general condition in spite of all that I could do, although she continued treatment conscientiously for six months; she did not grow any worse, however, and during the two years that have elapsed since treatment was discontinued she has been more comfortable at times than previously, and, as she was steadily growing worse when she came under observation, it is possible that she was somewhat bene-

fited. The general condition when treatment was commenced was bad in 5 and fair in 5; in 7 it was slightly improved, in 3 unimproved. Complete ankylosis was present in 1 case, and unimproved by the treatment received; partial ankylosis only in 2, which was slightly improved; ankylosis was not present in 7 cases. Pain of various degrees was constantly present in 9, and was slightly relieved in all but one; present only on manipulation or functionation in 1, and was slightly relieved in this case while she was under treatment. Five were totally incapacitated for the performance of their ordinary duties. 5 partially so.

The last group, or those who were "not benefited," consists of 5 cases, 1 man and 4 women, ranging in age from 21 to 60 years, who had been ill for from three months to four years before applying for treatment, and none of whom remained under treatment for more than three weeks, a totally inadequate period for the production of any permanent benefit. The general condition was bad in 1, fair in 3 and good in 1. Complete ankylosis was not present in any of them; partial ankylosis was present in 1. More or less pain was constantly present in 3, present on manipulation or functionation only in 2. All were partially incapacitated for the performance of their ordinary duties.

SUMMARY.

A practical, easily comprehensible summary of the results obtained in these 51 cases, then, would be as follows:

Out of 24 patients who were totally incapacitated for the performance of their daily duties, 6 were restored to a condition of unimpaired usefulness, 3 to a condition of but slightly impaired usefulness, and 8 of the remainder discontinued treatment prematurely. Out of the 27 who were partially incapacitated, 7 were restored to unimpaired usefulness, 4 to but slightly impaired usefulness, and of the remainder 14 discontinued treatment prematurely. Out of 36 patients who were suffering constantly from pain, 10 were relieved entirely; in 12 pain was relieved to such an extent as to be troublesome only occasionally, the patients' lives being thereby rendered comparatively comfortable, and 11 of the remainder discontinued treatment prematurely. Of 15 cases in which pain was present only on movement, 5 were relieved entirely, 3 were greatly relieved, and of the remainder 6 discontinued treatment prematurely. Of 11 cases in which complete ankylosis of one or more joints was present, complete relief of such ankylosis was obtained in one or more joints in 2, partial relief in 4, and 5 discontinued treatment prematurely; of 25 cases in which partial ankylosis of one or more joints was present, such ankylosis was completely relieved in one or more joints in 13, partially relieved in 12, and of these 11 discontinued treatment prematurely. Of 27 cases wherein the general condition was bad when treatment was commenced, 10 were restored to normal health, 12 were greatly improved; of 19 cases wherein the general condition was fair only, 5 were restored to normal, and 8 were greatly benefited.

CONCLUSIONS.

In conclusion, although there is nothing particularly brilliant about the above-described results, yet they indicate that the prognosis of arthritis deformans is rendered much less gloomy by the advent of the later therapeutic methods, more especially when the large proportion of patients who discontinued treatment prematurely, viz. 28, is taken into consideration, and that the unfortunate

victims of this distressing malady need no longer "leave all hope behind," even after they have entered far within the portals of its influence.

DISCUSSION

ON PAPERS BY DRs. M'CRÆ, WALSH AND SKINNER.

DR. JOEL GOLDTHWAIT, Boston.—All who have kept in touch with this subject in the past must be conscious that much progress is being made in this class of disease. There are already too many, but the nomenclature used is unimportant provided we understand what we mean by the terms. Under arthritis deformans there are not only the two types Dr. McCrae spoke of, the atrophic and the hypertrophic, but also the infectious type. This type may be due to many different organisms, but the essential pathologic features are the same and differ widely from the pathologic lesions seen in the atrophic or the hypertrophic types. At times it is practically impossible at first glance clinically to differentiate this type from the others. With the radiograph or by incision it can be readily differentiated and it belongs to a type which must be considered when arthritis deformans is mentioned. Still's disease is distinctly the infectious type and may be met with in childhood and in adults. As to heredity, I believe there is a predisposition in much the same way that there is an hereditary predisposition to tuberculosis. If the resisting power of the pulmonary tract is weakened then the patient is more susceptible to pulmonary tuberculosis; and much the same condition exists in the joints. It should be remembered that two types of the disease may be present in the same individual and also that they develop at different times. I have never seen the atrophic superimposed on the hypertrophic. I have seen in two instances the atrophic develop years after the hypertrophic had been present. The patient appreciated the difference. We have different degrees of severity of these diseases the same as we have a pneumonia. As to the terms monarticular and polyarticular arthritis deformans, I wish they could be given up. Either type may be monarticular or polyarticular.

DR. FERD. C. VALENTINE, New York City.—Dr. McCrae mentioned the gonococcus as an etiologic factor in arthritis deformans. Dr. Walsh said that arthritis deformans was more frequent in women than in men. This emphasizes, it seems to me, the fact that the gonococcus will invade the female more rapidly and be more destructive to her organs and, via the circulation, produce metastatic results more readily than in men. It appears not unlikely that some of these cases of arthritis deformans may be gonorrheal in origin and greater attention should be given to this etiologic element than has been hitherto.

DR. ALLEN A. JONES, Buffalo, N. Y.—Dr. McCrae took up beautifully the classification of these joint affections, but the tendency to throw out wholly and absolutely the term chronic rheumatism should be considered for a moment. I do not think we are in a position to throw out the term chronic rheumatism until we have demonstrated positively either a specific cause of acute rheumatism of the articular form, or a specific cause for both acute articular rheumatism and arthritis deformans. We see many instances of disease which may be either acute or chronic. Tuberculous manifestations may be acute or chronic, as may be malaria, etc. How are we to differentiate between the joint affections that may be so-called rheumatic, i. e., distinctly associated with causes undiscovered, or the possible manifestations of the disease which is a clinical entity known as arthritis deformans?

DR. DELANCEY ROCHESTER, Buffalo, N. Y.—The treatment of chronic cases by the electrical apparatus described is unquestionably valuable in cases where it can be used, but the vast majority of physicians have no such apparatus at hand and no facilities for using it; still, I think we can get as good results by carefully watching and handling these patients. The functions of the skin should be stimulated and I believe as good results can be obtained by the hot air, not with so high a temperature as described, but as used in the cabinet; we should be careful in the use of this procedure and follow it with

friction to the skin. Furthermore, good results can be obtained by carefully administered massage and movements of the joints in the older cases. The local applications of hot air by means of the Kelly heater is particularly beneficial in relieving local pains. With regard to the diet, we have been told that cases require forced feeding and that they should be kept in bed. A great many cases occur in stout people and any considerable amount of nutrition is not wanted. One should get rid of the excess of fat, particularly about the abdomen in women; here sweats and massage are of value. Keep the bowels open by saline waters. Sweets should be excluded and a minimum amount of starch should be permitted. Fresh green vegetables containing iron should be freely allowed, and fresh fruit and fresh meats in moderation.

DR. THOMAS McCRAE, Baltimore—I do not think that the gonococcus is an etiologic factor, but it may influence the condition as any intercurrent infection. If a patient has arthritis deformans and then contracts gonorrhoea it may light up the joint symptoms. I think the use of the term "chronic rheumatism" is unfortunate because there are no set conditions associated with it. I believe the only condition with which this term should be associated is that in which the "rheumatic manifestations" persist for a long time. For instance, a child may have an arthritis with endocarditis and pericarditis, skin lesions, fibroid nodules, etc., perhaps lasting for years, and this may be called a chronic rheumatism. All chronic manifestations in joints should not be termed chronic rheumatism. With regard to the organisms described, they can not as yet be regarded as proved causal factors. That described by Poynton and Paine as causing arthritis in a rabbit was a diplococcus. Dr. Goldthwait has divided the disease into three groups—atrophic, hypertrophic and infective. I feel that they are probably all infective in type, and so I do not make a separate group under the heading "infective." A matter that should be strongly emphasized is that this disease has nothing to do with uric acid. Many patients are told that the disease is due to uric acid and are put on restricted diet with most unfortunate results. I think we should do our best to get rid of this foolish idea in the minds of many of the profession. There is a hopeful side in treatment that has been impressed on me by the number of cases in which the disease occurred years before and the patients had practically regained good health and function.

DR. JAMES J. WALSH, New York City—Uric acid has long been a shibboleth. It was supposed to have solved many problems, and at last it is about to be abandoned. I have seen recently the wife and daughter of a physician, each suffering from the painful condition at the base of the big toe so often noted in connection with flatfoot, who had been carefully dieting themselves for gout for more than a year. One result of the mixing of rheumatism and arthritis deformans is the free use of the salicylates, which always do more harm than good since they destroy red blood corpuscles, make the patient more anemic and do not relieve pain. It has been objected that until the microbic cause of rheumatism and arthritis deformans is known, there is no justification in entirely separating the diseases. At the beginning of the nineteenth century there was in the measles and scarlet fever group of diseases, as yet undifferentiated from one another, what have now come to be recognized as four distinct diseases. Of none of these is the microbic cause known. Surely no one would say that there is no justification for their clinical separation.

DR. CLARENCE E. SKINNER, New Haven, Conn.—The local dry hot-air treatment was used in nearly all the series of fifty-one cases that I have reported, and in only one did any marked benefit follow the application, and in this we were obliged to apply the body dry hot-air application, in addition to the local, before we succeeded in getting our final curative results. This poor showing for the local application has led us to abandon it almost entirely as a measure of treatment in this disease. We sometimes use it as a palliative measure for the temporary relief of pain, and it is very rarely that we have been able to obtain even this. We have never seen any benefit follow the use of low degrees of heat, and, on the

contrary, have not infrequently seen positive harm in the way of increased debility result therefrom. In our experience it has been the stimulating influence of the body dry hot-air treatment on the central nervous system and the trophic functions that has been useful, and to obtain this it has been necessary to use the higher degrees of heat. As a possible explanation of the different results of Dr. Rochester and myself as regards the use of the local dry hot-air application, and the low degree of heat, I will say that all of my cases were chronic and very severe, which necessitated their being treated in the sanitarium. Dr. Rochester's cases may have been milder in character. I do not believe that moderately severe and well-established cases of arthritis deformans can be well treated at home. It is necessary for them to be cared for in sanitarium or other properly equipped institutions where their habits can be thoroughly regulated and where they can receive proper administration of all the physical therapeutics which to-day constitute almost our only reliance for the combating of this disease.

AUTOPLASTIC SUTURES IN HERNIA AND OTHER DIASTASES.

FINAL REPORT.*

LEWIS L. McARTHUR, M.D.
CHICAGO.

Three years ago it was my privilege to present to this Section a preliminary report of a new procedure in suturing hernia. Since that time I have been continuously using the method then described, until the cases

Fig. 1.—Cross section ($\times 25$) auto-tendon suture. Dog, 5 days after operation. A A. Auto-tendon suture. B B. Sections of fiber of silk thread inserted with tendon for identification. operated on have become sufficient in number and the time elapsed long enough to form conclusions as to its value. The results of these three years' work I now ask the opportunity of presenting.

Before doing this, however, let me epitomize the main

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

features of the former communication and describe in brief the only differences necessary in the technic of hernia work when done with living sutures. As demonstrated at that time (1) that it was an easy matter to split the tendinous aponeurosis of the external oblique from the external ring to the commencement of its

adapted to any of the recognized procedures for the radical cure of hernia. (4) That unlike any of the other numerous plastic operations advanced, the material lies directly in the wound itself instead of requiring extensive dissections or abnormal displacement of important structures.

Operators have, in the past ten years, by a process of gradual evolution arrived at certain definite conclusions regarding the cure of hernia. Most surgeons agree that in the typical operation certain structures are to be sutured to the inner shelving edge of Poupart's ligament, with variations in the order of attachment of these structures and their relations to the cord. I wish to be understood as championing no new hernia method, but I do advocate the utilization of strips of living tendon as the suture material in whatever operative technic the surgeon prefers, since it is equally adaptable to a Bassini, an Andrews-Girard, a McEwen or a Halstead operation.

TECHNIC.

The skin and fat having been cut by the usual incision exposing the external ring, the latter is prolonged

Fig. 2.—Cross section similar to Figure 1, but magnified 70 diameters. A A A. Cross section auto-tendon suture. B B. Silk thread fiber.

muscle belly, by simply lengthening the usual splitting of this structure. (2) From the cut edges of this, by carefully paralleling its fibers, that one could secure two strips of living tendon averaging 4 to 5 inches in length with which the structures to be apposed can be sutured. (3) That the use of such sutures can be

Fig. 4.—Oblique section auto-tendon suture 23 days after operation on dog ($\times 35$). A A. Tendon suture. B. Silk-thread fibers. C. upward in the usual manner, but to its commencing muscular insertion. Special care is taken to parallel the tendinous fibers. This divides the aponeurosis into an external and internal flap, each of which can be readily separated from its contact with the internal oblique. The sac having been treated as the operator deems best, a bundle of those white fibers which enter into the formation of the internal pillar of the ring is then split off, from below upward, from the edge of the internal flap of the aponeurosis of the external oblique, quite up to its termination in the muscle belly. Above it is cut loose, but left attached to the pubic spine below. This strip should vary from one-eighth to three-sixteenths of an inch, according to the develop-

ment of the tendon. An identically similar strip, beginning in the external pillar of the ring, is taken from the outer flap of the external oblique. At this stage the suturing is to be done. The operation is completed, according to the choice of the operator, by the Bassini, an Andrews imbrication or Girard method using these strips as suture material for a running stitch. As a convenient means of handling, and for the purpose of avoiding infecting the graft suture, a needle threaded with No. 3 silk is tied by a single knot to its free end, and by it the tendon graft is drawn through the tissues to be united. Using the graft ending in the internal pillar for the first or deep suture, the surgeon draws the internal oblique and transversalis down to the inner aspect of Poupart's ligament as shown in the drawing, suiting his convictions as to raising or not the cord. If raising the cord (Andrews), then no opening is left below for an external ring; if not raising the cord (Ferguson, Bassini), then the first stitch determines the fit of the external ring around it. The edges of the external oblique are then sutured with a running stitch, using the graft made from an external pillar of the

idea as to what can be done with the procedure. These cases have been largely done at St. Luke's and Michael Reese hospitals, and include both private and ward patients. Among the total number of cases, two were

Fig. 5.—Same as Figure 4 but magnified 70 diameters.

Fig. 6.—Cross section silk thread after 23 days. Dog. Note marked infiltration about and within thread. B B. Cross section thread.

Fig. 7.—Human specimen year after operation. (Patient dying of subsequent appendicitis.) A A. Cross section auto-tendon suture.

ring when a Bassini is being done; to the surface of the external oblique when an Andrews or Girard is done. The ends of the suture strips can be fixed by a simple knot in it, or by one or two stitches through and back as a tailor fixes his thread, or as shown in the specimen by a fine catgut stitch with the graft end caught in its knot. The deep suture penetrates the external oblique for final fixation, after the new internal ring has been made. The skin and fat are then closed as the surgeon prefers.

Since making my preliminary report of 12 cases on this subject, I have had two or three herniæ a month, until the number I have operated on has reached a total of 93 consecutive cases; on 85 patients, of whom 82 were males and 3 females, the youngest 6 months, the oldest 78 years. Eight cases were bilateral. While this number is small compared with the statistics of many other operators, it still furnishes something of an

associated with suppuration. One, an old man 60 years of age, with immense scrotal hernia, on whom I made a splitting of the sac into four strips after the proposal of Duplay Cazin, tying opposite strips over one another

instead of excising the sac, and used the resulting mass as a pad behind the internal ring. The operation was then completed by the Bassini method, using the graft sutures. A primary union was secured and patient discharged at the end of sixteen days. Ten days later he returned to hospital with an indurated mass just below the middle of Poupart's ligament, which was incised, pus escaping. This healed within a week without disturbance to the hernia, and patient reports himself a year afterward well and without recurrence. I am inclined to believe a mistake was made in treatment

tion was observed. In the class of cases operated on in a charity hospital it is difficult to trace them for three consecutive years, but insofar as I have been able I have done so, by mail or messenger, or personal examination, and have not yet found among them a recurrence sutured by this method. I have, through the kindness of Dr. Groenfelder, secured the scar of a hernia case operated on more than a year previously, the patient having died with a general peritonitis from a gangrenous appendix. Sections of this I believe show segments of the grafts passing in a curved manner through it, as a

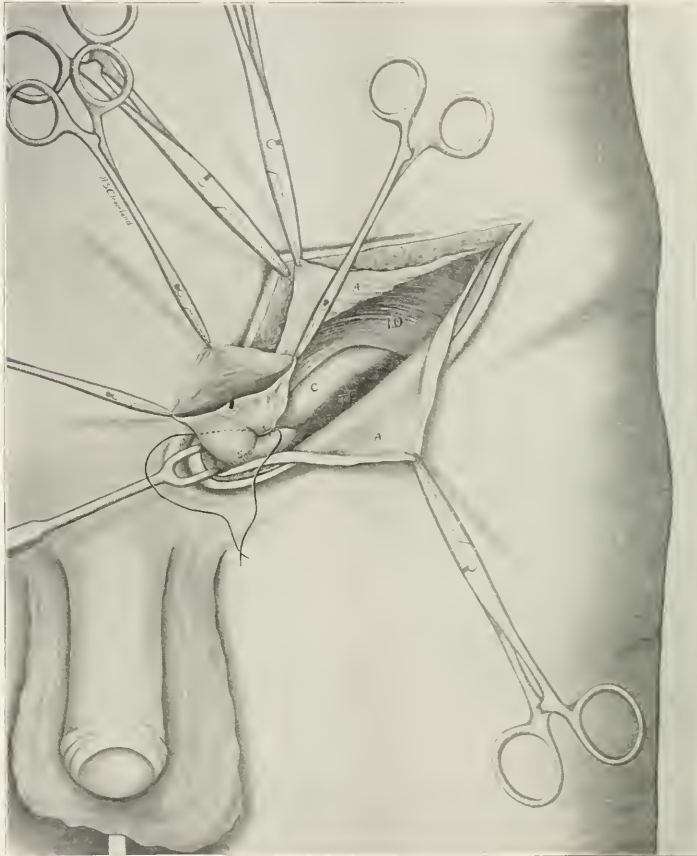

Fig. 8.—Aponeurosis of external oblique. I. O. Internal oblique. C. Cord. T. F. Transversalis fascia.

of the sac. The second case was an evident stitch abscess, seen and cared for by my colleague during my absence from the city. Removal of silkworm-gut suture and separation of skin edge at one point was all that was necessary. Patient made a good recovery, and has no recurrence of hernia. Twice there has occurred a hematoma—once in the scrotal pouch, once directly beneath the incision—requiring the letting out of blood clots by removal of one or two stitches. In these cases, too, no interference with the ultimate success of the opera-

living fibrous tissue (See the accompanying microphotographs.)

Caution should be used, I have found, to cut the strips from below upward, as the fibers often curve outward around the external ring, and if followed from above downward would occasionally end in the upper segment of the ring. The inner surface of the aponeurosis shows distinctly the tendinous fibers, so by everting the edge one can parallel them best.

In this group of cases I have naturally included op-

erations done by all the usual methods, because desirous of trying its applicability to them, but the majority have been after the Andrews-Girard or Bassini.

When the hernial aperture is particularly large, the bringing down of the inner flap of the external oblique to Poupart's without raising the cord, permits the using of an unusually strong strip of aponeurosis, as the subsequent imbrication does not require the creation of a new canal between the flaps.

Whatever the method of operation, its success is dependent on the formation of a cicatricial connective tis-

foreign material does, while if they live (as experiment seems to prove), they remain to offer permanent resistance to future stretching.

I wish to acknowledge the good work done by Dr. E. L. Dagg in making the pathologic sections and of Mr. H. D. Skelton in preparing the microphotographs.

DISCUSSION

ON PAPERS BY DRs. D. N. EISENDRATH* AND L. L. M'ARTHUR.

DR. W. B. COLEY, New York City—I have been interested in Dr. McArthur's method of autoplasmic suture in hernia

Fig. 9.—A. Aponeurosis of external oblique. T. S. Tendon suture. C. Cord. I. O. Internal oblique. C. T. Conjoined tendon. T. F. Transversalis fascia.

sue between the apposed surfaces, retaining them where placed. Could we, in addition, incorporate in such a cicatrix such white inelastic tissue as these tendons present, especially interwoven as a running suture is, then we can certainly feel more confident of its permanency and unyielding character. My former paper concluded as does this: "It is logical that if the identical technic is followed, using these living strips as aseptic animal sutures are used, and a primary union result, that if they die and be absorbed they accomplish all that the

ever since it was brought out, a few years ago, although I have never made use of it. A few years ago the indications for the employment of such a method were much greater than they are at the present day, when we have abundant proof of our ability to perfectly sterilize ordinary absorbable sutures, e. g., catgut or kangaroo tendon. Of the disadvantages of non-absorbable sutures in hernia, in showing a tendency to late sinus formation, I have given numerous examples. I have

* The paper by Dr. Eisenrath appeared in THE JOURNAL, Sept. 10, 1904.

found that the absorbable suture of chromicized kangaroo tendon remains sufficiently long in the tissues to effect a permanent cure; and this suture will cause no trouble unless it has been chromicized too long. Since I began using rubber gloves as a routine measure, in 1897, I have had less than 1 per cent. of suppurations, and the percentage of relapses following operation has been so extremely small that I think in the Bassini method, with buried absorbable sutures, we have practically an ideal method, without the more complicated suture of McArthur. At the same time, Dr. McArthur has shown that it is possible to use the autoplasmic suture with excellent results. My chief objections to it are: (1) that equally good results can

ways, behind or in front of the cord. I am fond of doing this same lapping operation in closing the rectus sheath after celiotomy, and I used it long ago in closing the ring in ventral and umbilical hernia. This step was referred to as mine by Dr. Mayo in his original paper on closing umbilical hernia for radical cure. He has, however, added a more valuable feature by overlapping from above downward, making a transverse line. It was one of the most agreeable surprises I ever had after Dr. McArthur had worked on his method to look through the microscope and see in these specimens, which he had cut, the beautifully demonstrated circular line of fibrous tissue evidently still living, and to observe that there was a true tis-

Fig. 10.—A. Aponeurosis of external oblique. I. O. Internal oblique. C. T. Conjoined tendon. T. S. Teudon suture.

be obtained by a simpler technic; (2) that in certain cases where the aponeurosis is more or less defective, its application will be unsatisfactory.

DR. E. W. ANDREWS, Chicago—I call this operation the imbrication or lap-joint method. It was first performed about eleven years ago. The theory of the operation is the doubling of the thickness of the layers of the abdominal wall by shingling or overlapping so that they lie like the scales of a fish. In a paper published in 1895 I showed a sagittal section of the aponeurotic layers of the abdominal wall illustrating how it was possible to do the operation in four or five different

sue growth in this autoplasmic stitch. We have here a new principle. If we could take strips of tissue for stitches and have them live it would be a strong help in strengthening weak points in various operations. I am sure it will interest every one here to examine the specimen as shown under the microscope, showing clearly what he claims, namely, a new living connective tissue band formed by the suture. My operation has been done over 2,000 times in Chicago and the west. Some of the cases are of over ten years' standing. The method in one of its forms is given as "Girard's operation" in v. Mikuliez and Bruns' last edition. This is an oversight, as Girard did

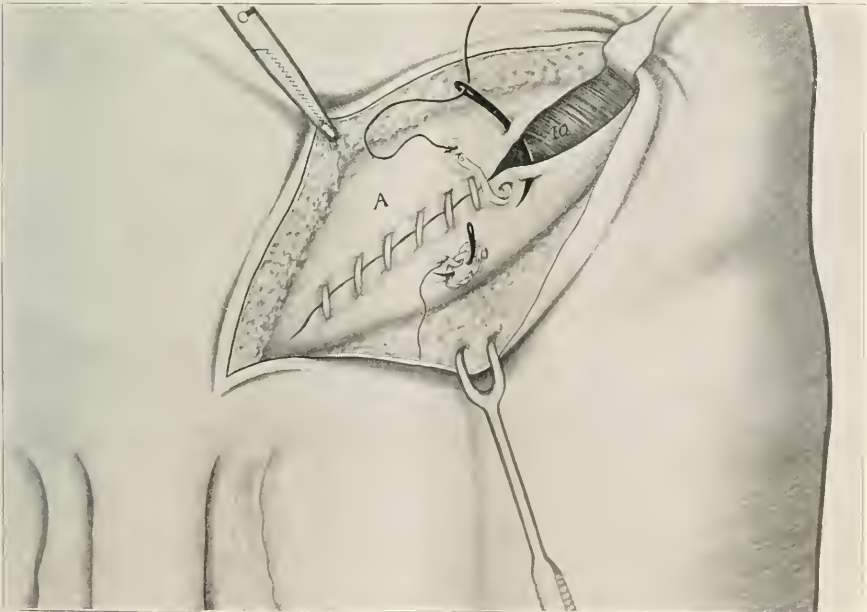

Fig. 12.—A. Aponeurosis of external oblique. I. O. Internal oblique. T. S. Tendon suture.

not publish it until seven years after I had done so. I believe it is to be corrected in the forthcoming edition of this great work.

DR. C. F. STOKES, U. S. Navy, Washington, D. C.—For many years I have been interested in the question of herniotomy in the Navy and was instrumental in establishing the operation for the radical cure as a routine practice in the hospitals of

Having only recently completed a cruise at sea, I have had no opportunity to make use of the newer methods, but after what I have heard this morning I shall give them a trial in suitable cases.

DR. J. C. BLOODGOOD, Baltimore—It must be very satisfactory to Dr. Andrews to know that many surgeons have recently adopted his method of the imbricated suture. These surgeons

Fig. 2.—Case 1. Woman, 76 years old. Impacted fracture of right femoral neck, as outlined. Angle of neck to shaft, 131 degrees; normal angle (left leg) neck to shaft, 135 degrees. Perfect result. Woman walks well. (Illustrating paper of Dr. Wills, see page 1048.)

Fig. 3.—Case 2. Impacted or "pegged" fracture of neck of right femur—"Intracapsular" of older writers. Leg one-half inch short. Excellent result. (Illustrating paper of Dr. Wills, see page 1048.)

the service. I have always taken the stand that the predisposition to hernia is congenital, exists prior to enlistment, and that the exciting cause, so-called, is secondary, and therefore, patients who refuse operative treatment and are discharged from the naval service should not be entitled to a pension. The Bassini operation, as modified by Drs. Bull and Coley, has been my choice, and the results have been very satisfactory.

started with, perhaps, different ideas and certainly with different methods, and in their endeavor to perfect their results, have, in the great majority of cases, in one way or another, both with and without the knowledge of Dr. Andrews' previous publications, gradually come to overlapping the different layers of the abdominal wall exposed for the dissection and removal of the hernial sac. It seems to me that it is a greater

compliment to the originator of a method to know that others have adopted his method not by imitation, but by a natural process in the development of the operative technic. Dr. Eisen-drath has given us a splendid demonstration of what can be accomplished with dry goods to demonstrate the operation for hernia. Dr. McArthur undoubtedly holds a peculiar position in the field of the operative treatment of hernia. We might designate him as an international peace commissioner, because McArthur with his human suture apparently accomplishes a cure with any method. The test of an operation for hernia is the test of time. Since my extensive study of the ultimate results after operations for hernia in the Johns Hopkins Hospital in 1899, recent experience has confirmed the conclusions then made. Suppuration in the past has been one of the chief factors of a recurrence. Improved technic has practically excluded this factor. It is unnecessary to transplant the cord. When the accompanying larger bundle of veins is varicose they should be excised, but only in adults; in children the veins should never be excised. In excising the sac the *vas deferens* and its accompanying vessels should be handled with the greatest care and not separated from the posterior wall of the inguinal canal. The most important factor is the separation and the suture of the internal oblique muscle to Poupart's ligament, strengthened by the suture of the divided aponeurosis of the external oblique. There are a few instances in which it will be necessary to expose, transplant and suture the belly of the rectus muscle. In one group this is indicated because the conjoined tendon is narrow, weak or obliterated (about 5 per cent. of the cases). In such cases it seems impossible to utilize the internal oblique muscle in as satisfactory a way as the rectus, to cover the lower third of Hesselbach's triangle, which in the majority of cases is occupied by the wide and strong conjoined tendon. In a second group the internal oblique muscle is situated so high or has undergone such an amount of atrophy that it is not of sufficient value for suture purposes; here again the rectus should be used. Imbrication is not essential when the internal oblique muscle is strong and the conjoined tendon wide and firm. Imbrication undoubtedly, more than any other factor, accomplishes a cure when the muscle and aponeuroses are attenuated. Imbrication in all cases allows the use of finer suturing material.

DR. H. O. MARCY, Boston, Mass.—I am reminded of the statement of Dr. Oliver Wendell Holmes, who said that the finer dissections were like splitting wood, the more sticks you split the more you will have to split. This is true of the less important factors in inguinal hernia. We all agree on some points. First as to the sac which has been referred to; we agree that it should be removed in large, old hernias. There was a time when we argued that it could be utilized for a purpose, but we now agree that it should be eliminated. The cause of oblique inguinal hernia is usually found in congenital conditions, resulting in imperfect development of the structures which form the posterior wall of the canal and internal ring. Cloquet, who based his opinions on the results of his dissections of 500 subjects where hernia did not exist, found these structures so often defective that he described his so-called infundibular process of the peritoneum as normal anatomy. That no such process or pocket of peritoneum may remain in which intraabdominal contents can find lodgment, is the most important reason for the removal of the sac. Undue intraabdominal pressure on the internal ring necessarily deflects the opening downward, shortening and distending the canal until it may become a direct opening, or hole, in the abdominal wall. This is the more usual condition in cases which come to operation. Admitting the above undeniable conditions, the general problem is easily reduced to a single factor—restore the parts to normal conditions. Although generally anatomically described, these conditions have failed to receive due surgical emphasis as amply illustrated in the papers and present discussion. The inguinal canal traverses the abdominal wall so obliquely that the intraabdominal pressure is exerted at or about a right angle to its axis, compressing laterally to its walls. This is a well-known principle of mechanics. The only other important instance of which Nature makes physiologic use is the penetration of the ureter through

the wall of the bladder, to prevent reflux of urine toward the kidney. How to restore the inguinal canal to its normal obliquity and thus deflect from it the intraabdominal pressure? This effected, it appeared to me that the "thousand year-old problem of surgery" would admit of easy solution. The parts must be reconstructed in a way made possible only by the use of buried absorbable sutures. Mr. Lister had taught me to ligate arteries cut short and buried in the structures—why not freely reconstruct the tissues by continuous sewing as the seamstress shapes clothing? This was seemingly so unwarrantable that I found it difficult to secure medical men to witness my early operations. My first published cases were in 1870, followed during the decade by a number of papers read before this Section. In 1881, in London, again in 1884, in Copenhagen, I presented elaborate papers on this subject before the International Medical Congress. These papers were prior to any reference to this method by any European or American writer. This was the first use of the buried absorbable suture, my best contribution to surgery. Little by little I broadened their use to every aseptic wound regardless of size, closing and sealing the wound without drainage. Thus reconstructed hernia is easily and permanently cured without danger to healthy individuals in all periods of life.

DR. ARTHUR D. BEVAN, Chicago—The operation for hernia has been very slowly evolved, but the majority of operators are now pretty well agreed. I have no operation. I am in a judicial position. I make an incision over the canal and open it from the internal to the external ring. I remove the entire sac if it is small, but if it is large simply that portion which is in the canal. No harm can come from the balance. I leave the cord in its normal position because there is more danger of injuring the cord if one elevates it. Three per cent. of injuries have occurred in my own work. I have never come to the imbrication method. It is called in literature the Girard operation. If there is a large opening, or if there is absence of the internal oblique and transversalis, the suggestion of using the sheath of the rectus and drawing it down through Poupart's ligament is an excellent scheme. We should more extensively use the method of local anesthesia. I use it in one-quarter of my cases and the results are most satisfactory. The suture material I am quite convinced is absorbable. There is no excuse to-day for using a non-absorbable suture. I have taken out so many silver wires that the evidence is so strong against the permanent suture acting as a permanent suture that the absorbable kind should be used.

DR. W. B. DE GARBO, New York City—I believe Dr. Eisen-drath's method of teaching anatomy is a valuable advance. Dr. Andrews' operation in the treatment of hernia I look on also with favor. In all probability I shall not adopt the method as a routine practice because I have only had eight failures out of over 1,000 inguinal cases by the Bassini operation. We are all working in the same field with the same object. The vital points are to remove all foreign substances from the canal and close it thoroughly, at the same time restoring its obliquity.

DR. JOHN B. WALKER, New York City—The Bassini operation is the one which will give the largest number of successes.

DR. CHARLES LESTER LEONARD, Philadelphia—I wish to report a case of direct inguinal and oblique inguinal hernia on the same side in which the deep epigastric was just beneath the skin. After ligating the sacs separately I found that I had a ring to close which extended from the position of the external abdominal ring to the symphysis pubis. It involved the entire inguinal canal. In closing, the cord was displaced according to the Massini method, but instead of employing interrupted sutures to close the canal, two Macewen stitches were introduced. These held the free edge of the oblique and transversalis fascia beneath Poupart's ligament. The patient, a ship machinist, has been at his trade over a year and shows no signs of a recurrence of the hernia. The case is noteworthy because of the rare pathologic condition and the combination of the Bassini and Macewen methods.

DR. E. W. HOLMES, Philadelphia—There is no subject in anatomy more difficult for students than that of hernia, because of the diversity of names used for the same structures.

Our studies of comparative anatomy show us that muscular structures may later become fascial. Thus the levator ani muscle, now arising from "the white line," originally came in muscle from the iliac crest. Not pursuing the analogy too far, I have always found it of advantage in teaching to consider all the layers of the abdominal parietes as continuous with Poupard's ligament in its whole continuity; then the testes coming down carry each layer with them in turn; and so the hernias. Thus once learning the anterior abdominal wall, we have learned likewise the coverings of the hernias, direct and oblique, and the coats of the testes. In discussing the methods of radical cure not only at this meeting, but in our journals and in the text-books, with all due regard to the eminent men here and elsewhere who have given names to particular operations, it seems to me we are entirely too partisan. I approved of the remarks made by Dr. Marey, because he talked to us like a philosopher, giving us the fundamental truths, anatomic and scientific, underlying his procedures. Some day I hope this Association will cease to debate any man's name, but, taking the best from each, we will come to agree on the principles underlying the best method for the operative cure of hernia.

I have concluded that the profession have the causes of hernia upside down, in declaring that "the congenital conditions are the predisposing," and "hard work and heavy lifting are the direct or exciting." It should be the other way; the congenital is the essential, the trauma the accidental. Now that we open up the canal and can see, we know that the "congenital hernias" and the congenital weaknesses are much more frequent than they were supposed to be. The force is a mere accident, the congenital weakness the actual cause. One can not tell the strength of the abdominal fibers by measuring a man's biceps cruris. I have seen athletic young men with the fibers of the internal oblique and transversalis as thin as paper. In a recent patient of this kind, a young man said to me, "Doctor, I am strong everywhere else; why should I have a rupture?" "Because," I replied, "you are congenitally weak in the hernial regions." The valvular condition of the peritoneum, the obliquity of the canal, the counter-pressure of the viscera and of the aponeurosis, these and other elements being present or absent, are more properly the essentials rather than strain or violence.

DR. D. N. EISENDRATH—If the sac is far down in the scrotum all we should do is to resect that portion of the sac which is in the inguinal canal. As to the sac in children, we know that it is very anatomically adherent to the cord. I have been using a method brought out at the German Hospital. I use kangaroo tendon for deep sutures and catgut for superficial sutures. In two recent cases I did not transplant the cord. I believe that leaving it in its normal position is especially advocated in non-descent of the testes. The more space we gain the better. Sometimes you will gain half an inch in the length of the cord if you do not transplant it. For the average small hernia the Bassini operation answers nearly every purpose and it is especially efficacious in cases with large internal rings.

DR. L. L. McARTHUR (closing)—The success of present methods is dependent on the broad surfaces that are brought in contact with one another. Former failures were due to bringing edge to edge. If the obliquity of the canal is restored the force compresses the canal. One wants plastic union between broad surfaces to prevent future failure.

IMPACTED FRACTURES OF THE NECK OF THE FEMUR.

REPORTS OF TWO INTERESTING CASES.*

LE MOYNE WILLS, M.D.
LOS ANGELES, CAL.

During the past year I have treated two cases of impacted fracture of the neck of the femur; one I took charge of within the first twenty-four hours after injury; the second, after four months had gone by. They differed as much in age, manner of production of injury and treatment as in the results obtained.

CASE 1. *History*.—Mrs. K. C., Sherman, Cal., aged 76, widow, born in Virginia, of large frame and good health, except for rheumatism of knees. June 22, 1903, while walking on a board-walk in her garden, she slipped and fell heavily on right hip and thigh, producing a severe contusion and pain, and was unable to get up or stand. She was put to bed and a physician summoned from Hollywood. He carefully examined her, and, diagnosing fracture, put on Burk's extension with a 10-pound weight and made her as comfortable as possible. The following day I was called in consultation; found leg in good position, a tendency to external rotation, some slight crepitus, but little if any shortening. Being satisfied that we had a fracture of the neck of femur to deal with, and the parts being in good position, very gentle manipulation was made and the dressing, which was excellently applied, was left undisturbed. We decided to send the patient to California Hospital the next morning, where she could have better attention than at home. Patient stood the journey on electric car well, and was put on a fracture bed; weight and sandbags were continued for thirty days. By great care external rotation was prevented; no harm came to her back and sacrum from the pressure. The patient stood the confinement to bed well. It seemed important, however, to get her up as soon as possible. Therefore, a well padded plaster spica bandage of pelvis and thighs, including condyles of femur, which seemed to me the dressing best adapted for maintaining fixation of the fragments, there being a tendency to shortening, was applied July 22, 1903. (Fig. 1.)

On account of her rheumatic knees, great difficulty was experienced in her attempts to use crutches and but little progress was made in walking. By degrees, however, with the assistance of the nurse, she acquired sufficient confidence to walk a little each day. She left the hospital August 9 and returned to her home.

On October 6 two inches were cut off the lower end of cast to give the knee more movement. On October 16 the cast was split up the front in the median line. On October 27 the entire cast was removed. The cast was on thirteen weeks.

November 7 the first skiagraph of the right hip and femur was taken by Dr. Soiland. November 19 the second skiagraph of both sides on one plate was taken. November 29 the third of the normal hip was taken for the sake of comparison.

December 2 the patient walked with crutches and could bear some weight on the injured leg, and, were it not for her knees and stiffness from rheumatism, would have walked fairly well. With increasing confidence she walked more and more each day. May 1, 1904, she walked with crutch or cane, did housework and worked in her garden, almost as well as before injury. (Fig. 2.)

CASE 2.—W. A. M., aged 56, married, three children; weight, 139 pounds; height, 5 feet 6½ inches; slender; no serious illness nor injuries; always good health; house painter. While painting house from hanging ladder, Sept. 5, 1903, was knocked off; fell 35 feet; received severe contusions on left side of head, shoulder and thigh, and cheek cut, while on right side no marks except bruised spot on top of right foot, an inch in diameter, and an abrasion over right biceps; no contusion or marks on right leg, yet as he fell he struck something on way down or

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. F. Moore.

Ancient Medical Advice.—The following advice, which is being printed in various lay newspapers, is said to have been given by Rhazes, an Arabian physician, to his patients more than 1,000 years ago: "Study carefully the antecedents of the man to whose care you propose to confide all you have most dear in the world, that is, your life and the lives of your wife and children. If the man is dissipated, is given to frivolous pleasures, cultivates with too much zeal the arts foreign to his profession, still more so if he be addicted to wine and debauchery, refrain from committing into such hands lives so precious."

after striking ground with sufficient violence to cause fracture of neck of right femur. Patient was examined at once by a physician at Redondo, recovered consciousness in a short time and was removed to his home and put to bed with a pillow under right knee. He lay in bed without any treatment, without splint, sandbags or weight, and never had a cast nor appliance of any kind until October 25, seven weeks after the injury, when he began to sit up, and on November 15 began to use crutches. This patient was sent to me for an opinion by Dr. G. W. Frink of San Francisco, the employer of son, Dec. 24, 1903.

Examination Findings.—Patient used crutches, walked badly, afraid to walk without them, and afraid to use leg much. A large amount of callus was found about right hip joint, giving firm union, but greatly restricting the normal range of motion. On measurement leg was one-half inch short, though femur was intact; foot slightly rolled inward; thigh and buttock somewhat atrophied.

The shortening and other findings narrowed the diagnosis down to dislocation upward and backward, or to fracture of neck of femur, and since there was firm union, if it were a fracture of neck, which seemed the more probable, it was important to know which of the two conditions existed for guidance of future treatment. Hence a skiagraph was taken, which showed positively the injury and variety. (Fig. 3.)

another, the outer and lower compact portion of neck driven like a spike into the inner fragment, consisting of small part of neck and head, and fortunately this "pegged" condition of neck was not disturbed and abundant callus was thrown out, which made good union.

The point of fracture differs a little in these two cases. Case 1 is a true "mixed" fracture, the line of fracture being partly within and partly without attachment of capsular ligament. Case 2 is entirely within attachment of capsule, and would have been called "intra-capsular" by older writers, and were it not for the immobilization due to "pegging" no such outpouring of callus would have been made, nor would the result be as it is, good.

Case 1: By careful measurement of skiagraph, considering the angle of light, contrasting the normal with fractured side, there is one-fourth inch of shortening of neck of right femur, and there is but 4° of change from normal 135° on left side to 131° on the right or fractured side. This proves the statement that there is absolutely no appreciable shortening of right leg. To be accurate, I had an architect measure the skiagraphs for angles and shortening. May 1, 1904, both legs measured $34\frac{1}{2}$ inches.

Case 2: Measurement of the two legs showed just one-half inch shortening of right or fractured leg, and since four months had passed since reception of injury, patient was advised to bear some weight on leg, and gradually give up use of crutches and thus gain a greater range of motion. Man now walks well; slight limp only, due to shortening.

The literature on this subject is very meager and rather unsatisfactory, most treatises on surgery passing over this very important and interesting variety of injury to the femur near the hip joint in a paragraph or two, as if it were a rare and unimportant condition. By far the best description of this condition I have been able to find is in Bloodgood's fifth edition of Helferich,² and I have adopted his classification of "lateral" and "median" and "mixed" in the description of these cases.

RESUME.

My reason for presenting these cases to this Section was to show the great contrasts in manner of application of force, differences in distance of fall, and method of production of fracture, especially in Case 2, where all evidences of injury were on left side, with no internal damage, while neck of right femur was fractured; contrast in treatment, one having immediate and exceptional care and attention, the other absolutely none. I wrote attending physician, asking history of case, but could obtain no reply, and simply have to depend on patient and friends and resultant condition for the history of injury given.

The results obtained are certainly beyond all expectation, Case 1 being 76 years old, with as nearly a perfect result as a younger person could expect. Case 2 walks very well, one-half inch shortening being of little moment. Two such extreme contrasts rarely come to a surgeon within a few months, hence this paper.

DISCUSSION.

DR. HARRY M. SHERMAN, San Francisco.—It seems to me that the x-ray has weakened our diagnostic acumen in fractures in general. It is so easy, when we are in doubt, to have a radiograph taken that we do not practice clinical diagnosis as carefully as we should do. In fractures of the neck of the femur this may be different. You can not take such a case always to the hospital, and some of the patients can not

Figure 1.

CONTRASTS OF TWO CASES.

The histories of these two cases have been briefly given, and the skiagraph showed them each to have been "lateral" compression fractures, due to direct violence, varying greatly in degree, one fall being three feet, while the other was thirty-five feet, both of which were severe enough to bruise and damage the soft parts and fracture neck at or near the intertrochanteric line. Case 1 when examined was diagnosed as fracture of neck with impaction, since there was little tendency to shortening, and every precaution was taken to prevent disturbance of the apposition of the fragments. Case 2, when seen four months after the injury, was diagnosed as either dislocation upward and backward, since there was no shortening of femur, or fracture of the neck with a change of angle of neck to shaft, with a large deposition of callus, making firm union and restricting range of motion of hip joint. The skiagraphs showed impaction in each case, more marked in second case than in first, where fragments were firmly compressed by blow into one another, without much change of angle or form. In Case 2 the picture showed the fragments driven into one

afford to have the portable apparatus brought to the home, and under these circumstances, ultimately, we must make our clinical diagnosis practically accurate. We must exhaust all the means at our disposal. Now, shortening of the limb is one of the classical symptoms, and yet I had two cases this past winter in which there was an absence of shortening. There was in each some disability, some pain and some discomfort. In both I happened to be deprived of the assistance of the x-ray. One case, after many examinations and after having had fractions on, was finally treated as a contusion. The only persistent symptom was the inability to lie in bed and lift the foot from the bed with the knee extended. And yet this man had no pain and could sit up in bed, and could, in general, move the hip as if it was sound. After a time in bed he got up, and we found then a separation of fragments and an obvious fracture. It was a very clear case, and the fragments of the femur had been impacted. The second case was put to bed after receiving a very slight injury. I supposed it was a fracture of the femoral neck, although there was no shortening and the man could lift his leg perfectly well. The case got well enough to be about, and could go to be radiographed, when he showed a very definite fracture of the neck of the femur, the under part of the neck having been driven in. In this latter case without the x-ray one would say there had never been anything more than a contusion. In the first case a diagnosis should have been made. The negative treatment resulted in the separation of the fragments, and then the diagnosis was clear. The second case had been treated for a fracture without definite symptomatic ground, and the result proved the wisdom of the plan. In general, in these cases, we must be careful lest we forget the art of clinical diagnosis.

DR. C. E. THOMSON, Scranton, Pa.—I do not know how the second case mentioned could be brought to a half-inch shortening if the legs were the same length originally. The x-ray shows more shortening than half an inch. At the Saratoga session I reported a series of cases of fracture of the neck of the femur. At that time I took one of my patients there with me to demonstrate bony union by the nailing operation, and I want to make a further report on that case. He walked well with the aid of a cane and had no pain. There was almost normal motion, and I considered him equal to the first case that I had reported, and presented the specimen to the Section, which proved that the union was bony. After the Saratoga session my patient developed a cancer of the stomach and died, and I had an opportunity of holding a postmortem, when I was surprised to find that there was no bony union. When the patient was presented to the Section he walked well and could bear all his weight on his leg.

DR. WILLIAM L. RODMAN, Philadelphia.—The only good results that I have ever had in fractures of the femur high up in old people were in the few impacted fractures that I have seen. I think we should remember that in the impacted fractures of the femur in this situation the best results will be secured by letting them alone, while in closed fracture this is not true. In these cases "disimpaction" should be practiced, and the kind of splint you use will be of very little importance. In the case mentioned it is very easy to understand why the shortening was not greater than it was. The fracture was evidently very high up and was intra-capsular. The old nomenclature of intra-capsular and extra-capsular fracture will not do. The vast majority of these cases are partly within and partly without, as the capsule does not extend equally low. The x-ray shows them to be both anterior and posterior. I am very glad Dr. Sherman has objected to our depending so much on the x-ray. If we are not careful the diagnosis of fracture will soon be a lost art. We are teaching students who are going to parts where the x-ray can not be gotten, and we are not giving them the amount of practical knowledge that we should. I never refer to the x-rays to students. They can not take an x-ray apparatus with them.

DR. M. K. CRANE, Rutland, Vt.—Three years ago my wife fell on the sidewalk and sustained an injury of the left hip. On examination one-half inch shortening was found, but there

was no eversion. I thought she had an impacted fracture and I kept up extension for seven weeks. She could rest better with the weight on than off. She was confined to her room for five months, and had about half an inch of shortening on getting up. I never saw a case suffer so much pain. She now walks with a cane and has about three inches shortening. I have a good skiagraph of the case. Some state that the leg should have been nailed, but I do not know that that would have been any improvement.

DR. DANIEL N. EISENBERG, Chicago—I had a very interesting experience recently, which I believe shows that occasionally the callus in a fracture of the neck of the femur either becomes absorbed to a great extent or osteoporosis occurs, permitting the fragments to move on each other so that shortening of the limb can occur many months after the period of the original fracture. During the past spring a man appeared at my clinic who stated that two years ago he had sustained a fracture of the neck of the femur. At that time measurement of the limbs showed a very slight difference. He states that the fracture had healed, but that during the past six months the leg had become gradually shorter until at the time of my examination there was a difference of two and a half inches. The x-ray examination made by my assistants showed a typical fracture of the neck of the femur, and there was free mobility at the point of fracture. We must teach our students not to depend too much on the x-ray examinations in the diagnosis of fractures. They should be taught not to overlook the many cardinal signs of fracture which enabled us to make fairly accurate diagnoses even before the advent of the x-ray. In this class of fractures (neck of the femur) one of the most typical signs has always seemed to be the eversion of the leg.

DR. JAMES B. BULLITT, Louisville, Ky.—I recently obtained a postmortem specimen which showed plainly the possibilities in cases of hip joint injury. The patient was an old lady who fell on the pavement, and while no definite signs of fracture could be elicited, she was treated as if she had one. Later she died of heart disease and the postmortem specimen showed no fracture of the hip joint at all. She had suffered a simple bruise, but the bone head and neck were infiltrated with blood. This condition sometimes afterward leads to the condition which Dr. Crane has spoken of. It seemed to me it might have been called the first degree of fracture. The woman might possibly have had later a breaking down of the head of this bone due to the failure of the vital processes. We are familiar in Louisville with a case in which two competent surgeons failed to agree. One said fracture and the other said not. One saw the case early and one saw it late. These opinions were absolutely irreconcilable, but it seems to me the above case offers a possible explanation.

DR. E. D. FENNER, New Orleans, La.—I am surprised there has been no mention made of the Hodgen splint. Those who have used it have all been struck by its tremendous influence for good on the comfort and health of the patient, and in old people its use will do much to prevent just such a fatal termination as has been mentioned by Dr. Bullitt. I call attention to this splint because it will preserve the health and life of old patients suffering with fracture of the femur.

DR. LE MOYNE WILLS—I have presented these two cases because they afford the greatest contrasts. Case 1, as shown by skiagraph, was very slightly impacted, and thanks to the gentleness of manipulation of the physician who first saw the patient, the impaction was not disturbed. The case was so interesting that I went to the trouble of taking a portable x-ray machine three times to the patient's house, sixteen miles from Los Angeles, so as to establish and confirm my diagnosis beyond a doubt. In the second case the x-ray was taken to differentiate between impacted fracture and dislocation, so as to advise the patient as to proper treatment regarding the use of the leg. In the first case I do not think any splint would have held the leg in as good position as the spica plaster dressing, extending down to and taking in the condyles of femur. It was well padded and made large enough to be comfortable, and held the leg immovably in the proper position. There was no tendency to shortening and I desired to get the patient up

as quickly as possible, and thus avoid the dangers of a long time in the horizontal position, which often causes hypostatic pneumonia in the aged. My patient was a very vigorous woman and has made a perfect recovery. The callus in each case was large and securely held the fragments in proper apposition and subsequently made good bone.

OSMIC ACID INJECTIONS FOR RELIEF OF TRIFACIAL NEURALGIA.

JOHN B. MURPHY, A.M., M.D.
CHICAGO.

(Concluded from page 955.)

CLINICAL CASES.

CASE 1.—Mr. A. L. C., age 76 years, retired farmer. Admitted to Mercy Hospital June 8, 1903.

Present Illness.—For thirteen years has suffered from neuralgic pains in right side of face, but they were not very severe or constant until four years ago. At that time he had a severe attack which he thought was caused by a diseased right upper cuspid. The tooth was removed about two months after the onset, and for six weeks following he was relieved. Pain then recurred and was severe and persistent. Two years ago he had an operation performed on the right superior maxilla, the exact nature of which he does not know. He was free from pain for four months after the operation, but at the end of that time it returned and has been present, at intervals, ever since. The pain is of a severe shooting character, beginning at right ala nasi and radiating toward cheek. He also has some pain in the forehead, just above the right eyebrow, radiating toward temple. General health has been fair for a man of his years.

Previous History.—"Ague," "bilious fever," etc., years ago. Used to smoke and drink moderately. Family history negative. Examination shows a man of rather poor nourishment; lungs and heart negative; arteries sclerotic. Urinalysis negative. Slight tenderness over supra- and infraorbital divisions of fifth nerve at their foramina of exit. No areas of hyperesthesia or anesthesia and no evidences of tumor or inflammatory processes along the course of either nerve.

Operation.—June 11, 1903. Supraorbital, infraorbital and mental branches injected with 1½ per cent. solution of osmic acid. In the afternoon his temperature was 99.8 F., and pulse 64. His pain had entirely disappeared. June 12, p. m., temperature 100, pulse 70; June 13, p. m., temperature 99.8, pulse 62; June 14, temperature and pulse normal; sat up in chair. After this temperature remained normal, he was up and around every day and the sutures were removed June 17. Wounds healed by primary union. Patient discharged from hospital, with pain entirely gone, June 20. In a report received from this patient July 21, he states that there has been no recurrence of the pain and that he feels perfectly well.

In a later report received April 14, 1904, he says he has had no pain since operation and that his general health is excellent. Appetite good, and he sleeps well.

CASE 2.—Mr. H. H. C. Age 55 years. Farmer. Admitted to Mercy Hospital Sept. 25, 1903. Family history negative.

Previous History.—"Typhoid fever" at 35. "Measles" 12 years ago. "Catarrh" for the past 30 years. Had recurring attacks of "malaria" 25 years ago. Attacks were always cured by quinin. Never used alcohol to excess, but has chewed tobacco.

Present Illness.—Twelve years ago while working in the cold suddenly felt sharp pain in right lower jaw and a little later in right upper jaw also. This attack was of short duration, but in the year following he had a second similar one. Since then they have recurred at gradually shortening intervals, and have become more severe and the area involved more extensive. For some time past the entire right side of the face and nose have been affected and the pain has been almost constantly present. It is always aggravated by eating and talking. He has had frequent acute exacerbations of the pain during

which it is sharp and shooting in character and radiates from the malar prominence to the lower jaw, above the right eye and over the right side of the nose and temporal region.

Examination.—Shows a well-nourished man of medium stature. The foramina of exit of the three branches of the fifth nerve on the right side are tender to pressure. Urinalysis negative.

Operation.—Sept. 27, 1903. Supraorbital, infraorbital and mental bran. has injected with 1½ per cent. solution of osmic acid. Convalescence was uninterrupted and the wounds healed by primary union. (Sutures removed October 3.) On September 28 patient complained of slight twitching pain in the two upper wounds when he was eating breakfast. October 1, examination showed no sensitiveness to the prick of a pin over the area supplied by the supraorbital. Analgesia also present in area anterior to mental foramen. Has had no pain in the upper lip. There is sensitiveness, however, posterior to the outer canthus of the right eye and this area extends down on the side of the face. On the night of October 3 he had an attack of pain in the right side of the face above. This was similar to, but not so severe as the pain from which he suffered before the operation. October 6, patient stated that the pain was rapidly diminishing in intensity and that he had had no pain in the lower jaw. Left hospital Oct. 8, 1903.

Patient readmitted to hospital April 7, 1904. For three months after going home he had very little pain, but in January, 1904, the pain returned in the right lower jaw behind the molar teeth and extending backward and upward to a point in front of the auditory meatus. It was not so severe as formerly, but came on every day until two weeks ago, when it subsided. About March 1 he began to have pain in the right upper jaw, extending along the gum and roof of the mouth. This was very severe and has continued almost constantly until the present time. He had no pain around the eye nor on the forehead, but slight in the right ala nasi.

Examination of the patient shows: 1. A zone of diminished sensibility 1 inch in width by 3 inches in length, extending above the right eyebrow. 2. Diminished sensibility of right side of nose. 3. Area of diminished sensibility on chin extending from symphysis to right angle of mouth and from lip to edge of jaw. There are no areas of complete anesthesia.

Second Operation.—April 9, 1904. The infraorbital nerve was exposed by incision through the mouth and injected thoroughly with a 1½ per cent. solution osmic acid. The mental branch was then similarly treated. The inferior dental branch was next exposed as it entered the mandibular canal and also injected. The lingual nerve was isolated just posterior to the last molar tooth and injected. Lastly, the posterior palatine nerve was injected, and the posterior palatine foramen. In the nerves which had been previously injected was found the staining of the tissue by the osmic acid, but there was no destruction of the nerve substance. Convalescence uninterrupted and the patient left the hospital April 16, 1904. At the time of his discharge he had absolutely no pain and had had none since operation. The right half of the tongue, right half of lower lip and of face, external to nose, were anesthetic and analgesic. Letter received from this patient since his return home states that he has remained entirely free from pain.

CASE 3.—Mrs. W. B. Age 28 years. Admitted to Mercy Hospital Oct. 6, 1903.

Family History.—Brother and sister died of pulmonary tuberculosis.

Previous History.—No serious illness. Had two miscarriages, but no children at term.

Present Illness.—Fourteen years ago began to have severe neuralgic pain around the right eye. Since then the attacks of pain have become more frequent and severe and for the last eight years she has been confined to bed every two weeks with the very severe pain about the right eye. The attacks usually last 24 to 36 hours. No pain in any other part of the head or face. Examination shows no tenderness over the supra- or infraorbital nerves. Urinalysis negative, except for the presence of a few pus cells.

Operation.—Oct. 7, 1903. The supraorbital and infraorbital

nerves exposed by external incision over the foramina of exit and injected with a 2 per cent. solution of osmic acid. The mental nerve exposed by incision from within the mouth and injected. Convalescence uninterrupted.

Examination of the patient October 9 showed numbness of the skin over the right side of the face and scalp backward to the occipital protuberance. An area just in front of the right ear was not completely analgesic, but still sensitive to the tests.

Second examination, October 13, showed numbness over right side of face and scalp except in front of the right ear. Patient left the hospital Oct. 13, 1903.

In a report received April 14, 1904, she states there has been a return of pain just above the right eye. A few attacks have been nearly as severe as before operation, but most of them have been slight and have not lasted so long. She also states there is no numbness now present in the face. General health good. The attacks of pain always come on when she is tired out or nervous.

CASE 4.—Dr. E. R. M. Age 40 (?) years. Admitted to Mercy Hospital Sept. 11, 1903.

Present Illness.—Seven years ago patient sustained a crushing injury of left hand necessitating amputation through forearm about one inch above the wrist. Immediately after operation patient complained of severe pain in the amputated hand and this persisted until March, 1897, when a second amputation was done a short distance above the first. This gave him no relief, so a month later, a third amputation, with resection of the ulnar and median nerves, 2 inches above the elbow, was performed. As the pain continued severe after this, a fourth operation was performed in November, 1898, wedge-shaped piece being removed from the ends of the nerves and the edges of the resulting defect, with the sheath, sutured together. The "pain in the hand" still persisted and in August, 1901, the radial, ulnar and musculospiral nerves were again resected, but with no benefit to the patient.

Operation.—Sept. 12, 1903. Incision in left axilla, along border of pectoralis major. Brachial plexus exposed and its inner, outer and posterior cords thoroughly injected with a fresh 1 per cent. solution of osmic acid. Wound healed by primary union. Immediately after this operation, the pain was somewhat less severe than before, but the improvement did not last long. He left the hospital September 25. From then until October 9 the pain was about the same as before the injection. He was readmitted October 9 and again operated on October 10. This time the pectoralis major was divided square across and the brachial plexus exposed at its upper part. The 3 trunks were again isolated separately, and each injected for $\frac{3}{4}$ inch with a 2 per cent. solution of osmic acid. The infiltration of the nerve substance was very thorough and 20 to 30 m. of the solution were used in each trunk. The ends of the pectoralis were then approximated with heavy catgut sutures and the skin brought together by means of silkworm gut and horsehair. Convalescence uninterrupted. On October 15 the sharp pain which had been present in the fingers had disappeared, but he occasionally had very severe pain in the hand. On October 17, pain in fingers had returned, but there was no "transmission of pain upward along the nerves" when he moved or exerted pressure on them as there was before operation. There was complete anesthesia and motor paralysis of parts supplied by the injected nerves. He could not flex and extend elbow, but was able to rotate a shoulder. He left hospital Oct. 23, 1903.

In a report received April 14, 1904, patient states that the pain in hand and fingers is just as severe as before operation. Transmission of pain on pressure or friction upward along nerves in arm is returning. The numbness which was present immediately after operation is gradually disappearing, though it is still present on outer surface of arm and over entire forearm. Motion is gradually returning in muscles of shoulder and upper arm.

CASE 5.—Dr. S. W. L. Age 62 years. Admitted to Mercy Hospital Oct. 31, 1903. Family and previous history negative.

Present Illness.—For past eight or nine years patient has suffered at irregular intervals from attacks of severe pain in right side of face. Pain begins at ala of nose and radiates to

right side of nose and upper lip, infra- and supraorbital regions, passing upward $1\frac{1}{2}$ inches above right eye and backward to a point $1\frac{1}{2}$ to 2 inches anterior to right ear. The pain is at times most intense and often accompanied by twitching of right facial muscles. Examination shows extreme tenderness on pressure over right supraorbital foramen and along the right side of nose, especially at lower part. Urinalysis, negative.

Operation.—November 2. The supraorbital and infraorbital branches were exposed by external incisions, and the mental by incision through mouth at junction between lower lip and outer surface of lower jaw. Each branch was thoroughly injected with a 2 per cent. solution of osmic acid. Convalescence uneventful.

Examination November 3 showed anesthesia of right side of face extending upward 1 inch above supraorbital ridge, backward to a vertical line drawn $\frac{3}{4}$ inch anterior to right external auditory meatus and inward nearly to median line. The pain had entirely disappeared. He left hospital November 5.

In a report received April 14, 1904, he states there had been no return of the pain. After returning home the infraorbital wound became inflamed and discharged a small quantity of pus for two months. It then healed permanently. The numbness of right side of face was still present.

CASE 6.—Mrs. A. B., age 63 years. Admitted to Mercy Hospital Dec. 1, 1903. Family history, negative.

Previous History.—Has been constipated since childhood. Has had three children, all living and well. Had infectious diseases of childhood and "typhoid fever" twenty-nine years ago.

Present Illness.—Began eight years ago during the cold weather with marked hypersensitiveness over the right malar prominence, followed in a short time by aching pain in the right upper jaw. The dentist extracted two teeth which were supposed to be the cause of the pain. Then she had some relief for a few days. Pain then returned and was continuous with severe acute exacerbations, usually coming on at night for the two years following. It then gradually gave place to frequent attacks of very severe sharp shooting pain in the right upper jaw. In January, 1900, the lancinating pain began to radiate into the right lower jaw and has persisted in two lower divisions of the fifth nerve since that time. For the last two and a half years she has rarely slept longer than a half hour at a time, because of the intensity of the pain and the frequently recurring attacks. Supraorbital nerve has not been affected; some dull occipital headache since 2 $\frac{1}{2}$ years ago. Examination: Marked tenderness over the foramina of exit of the infraorbital and mental nerves. Urinalysis, negative.

Operation.—Dec. 12, 1893. Infraorbital nerve was exposed by incision through the mouth at junction between the cheek and the upper jaw, above the cuspid tooth. The mental branch was exposed by incision within the mouth at the junction between the lower lip and the lower jaw. Both were thoroughly injected with a $1\frac{1}{2}$ per cent. solution of osmic acid. Convalescence uneventful, except that slight purulent discharge persisted from the upper wound. Patient left the hospital December 12 with pain entirely relieved.

In report received from this patient April 14, 1904, she states there has been absolutely no return of the pain. Slight discharge persisted from the upper wound for a month after going home and for a shorter time from the lower wound. Numbness of the parts supplied by the injected nerve persists. Her health, she says, is better than it has been for many years.

CASE 7.—Mr. M. M. J. Age 54 years. Admitted to Mercy Hospital Dec. 8, 1903.

Family History.—Father has been a sufferer from trifacial neuralgia for a number of years.

Previous History.—Eight years ago patient had renal colic and passed some small calculi and blood in his urine. Last spring complained of painful urination and pain in lumbar region and, at times, along the sciatic nerve.

Present Illness.—Began six years ago with hypersensitiveness in left supraorbital region. At that time pressure above the left eye would cause shooting pains through the head. A few months later he suffered an attack of "erysipelas" on the left side of the face and following this had severe shooting and

burning pain, coming on in paroxysms, in left side of face. The pain was most severe in the left side of upper lip, cheek, supra-orbital region, roof of mouth, and in an area just posterior to and in front of the external meatus. The paroxysms have persisted since onset, but have come on at irregular intervals. At one time he was free from pain for a year, but since about nine months ago the attacks have come on every day.

Examination.—Shows tenderness on pressure over foramina of exit of the three branches of the fifth nerve on the left side. Urinalysis, negative.

Operation.—December 9. Supraorbital nerve exposed through incision over supraorbital foramen. Infraorbital and mental nerves reached through incisions from within the mouth. All three branches thoroughly injected with a 1½ per cent. solution of osmic acid. On December 16 some offensive purulent material was discharged from infraorbital incision. Also slight discharge from the incision over the mental foramen. Primary union of supraorbital wound. Patient left hospital December 22, with pain entirely gone, but some discharge from two lower wounds persisting.

In report received from this patient April 14, 1904, he states there has been no return of pain. Discharge from infraorbital and mental wounds continued for one month after going home. Before the lower wound healed a small piece of necrotic bone in the lower jaw was discharged. The numbness of face, supplied by the injected nerves, continues. His general health is excellent and he has gained 20 pounds in weight since the operation.

CASE 8.—Mrs. W. J. C. Age 40 years. Admitted to Mercy Hospital Feb. 10, 1904. Family and previous history negative.

Present Illness.—Began 1½ years ago with dull pain in the right side of the lower jaw. After a short time pain began to radiate into the right cheek and upward toward the right eye. When the pain became more general over the right side of the face it came on in paroxysms, lasting for a few minutes at a time and occurring every day for several months at a time. Last October she was free from paroxysms for three weeks. Four months ago pain became less severe in the jaw and concentrated in the right eye and right supraorbital region. At the same time it developed in the inner side of the right upper jaw and right half of hard palate, where it has persisted until the present time. At times she has had shooting pains in the back of the neck, in front of the right ear, and in the right half of the tongue.

Examination shows tenderness over the supraorbital, infraorbital and mental foramina. Urinalysis: Albumin present; no sugar, no casts. This albuminuria was transient and disappeared after a few days.

Operation.—Feb. 11, 1904. Supraorbital nerve injected through incision over supraorbital foramen. Infraorbital and mental nerves exposed through incision within the mouth. All three nerves injected with 2 per cent. solution of osmic acid. The posterior palatine nerve was exposed through incision in hard palate over posterior palatine canal. It also was injected with 2 per cent. osmic acid solution. On February 13 examination showed numbness of skin on the right side of the face and in mucous membrane of right half of hard and soft palate. Pain did not entirely disappear from the eye until February 20, after which date she had absolutely no more pain. She left the hospital Feb. 26, 1904.

Later reports from this patient show she has had no return of the pain since February 20. Slight discharge persisted from infraorbital wound for several weeks after she went home. The sinus, however, completely closed and she had no further trouble from it. July 18, the sinus reopened and caused some pain for a few days preceding the discharge.

CASE 9.—Mr. A. G. D. Age 63 years. Occupation, merchant. Admitted to Mercy Hospital April 11, 1904.

Family History.—One sister has suffered from neuralgia.

Previous History.—"Intermittent fever" while in army in 1862. Ten years ago he was told that he had "kidney trouble."

Present Illness.—Ten years ago he began to have pain in

the right side of the upper lip and soon afterward in the right cheek. The pain next affected the mental division of the fifth on the right side, and lastly the right supraorbital division. For the first two or three years the pain was not very severe, but the paroxysms gradually increased in frequency and intensity until of late they have been almost unbearable. At this time he had a resection of the infraorbital branch through the foramen into the orbital cavity. It gave relief for a few months only. At the present time all three divisions are about equally affected and there is constant and characteristic radiation. The right side of the face is always tender to pressure, and eating is so painful that frequently he takes no nourishment for a day or two at a time. During a paroxysm of pain the tears flow down over the cheek, the right side of the face is flushed and there is twitching of the facial muscles under the eye. The attacks last a quarter to one minute and occur many times a day and often during the night. When he eats, drinks or swallows he has severe pain in the right side of the hard palate and in the right half of the tongue. Examination shows tenderness over entire right side of face, especially over three foramina of exit. Urinalysis negative.

Operation.—April 13. Supraorbital nerve exposed through external incision, infraorbital and mental branches through incision from within the mouth. All three divisions injected with a 1½ per cent. solution of osmic acid. The lingual and posterior palatine nerves were then exposed by incisions through the mucous membrane and injected with the same solution. External wound closed with horsehair suture and mucous membrane wounds with catgut. On April 18 it is noted that the patient had no pains since the operation. On April 20 there was considerable swelling of the right side of the face and he had an afternoon temperature of 100.6 degrees. Sutures removed. Temperature went down to normal the next day and remained so during the remainder of his stay in the hospital. On April 25 the following areas of analgesia were found on examination: 1. Right supraorbital region almost to hair line. 2. Right side of nose. 3. Right side of face, adjacent to nose. 4. Right upper lip. 5. Right lower lip and chin. 6. Right side of tongue and roof of mouth. Taste not affected.

Patient left the hospital entirely relieved of pain on April 27.

In a letter received from this patient, May 24, 1904, he states there has been absolutely no return of the pain. The lower wound is still discharging purulent matter and has been incised several times to secure better drainage. There is some swelling over the lower jaw. This is probably due to a necrosis of the mandible around the foramen menti, the result of the injection. While this case was not a typical one for the osmic acid treatment because the infraorbital nerve had been previously resected, the relief is complete up to date. The infraorbital nerve had redeveloped to about its normal size. It seems to me that the redevelopment of the nerve bears a close relation to return of the neuralgia.

CASE 10.—Mr. C. J. Age 81 years. Admitted to Mercy Hospital April 15, 1904.

Family History.—Patient's son was operated on for trifacial neuralgia Dec. 9, 1903. (See Case 7.)

Previous History.—Several years ago the superior maxillary was resected at the foramen of exit from the skull, with temporary relief to patient.

Present Illness.—For several years past has suffered from severe paroxysms of pain in right side of face. The pain radiates through all of the branches of the fifth, but is particularly severe in the infraorbital and the anterior auricular branches and in the right side of the lower lip. The fact that the superior maxillary root had been resected so deep made it questionable whether the osmic acid would relieve the patient, but it was deemed advisable to try it. On exposure of the infraorbital foramen the nerve was found to have regenerated to about its normal size, although sensation to pain over that area was perverted, but not absent.

Operation.—April 16. Supraorbital nerve exposed by external incision and infraorbital, mental and posterior palatine by incisions from within the mouth. All four branches were injected with a 1½ per cent. solution of osmic acid.

Convalescence uneventful and patient left hospital April 23. On date of discharge from hospital examination showed analgesia to be present in right supra- and infraorbital regions, right side of nose and right halves of upper and lower lip. The patient has had no pain since operation.

Two months after the operation there began to be pronounced pain in the superior maxillary area and in the anterior auricular branch. This increased rapidly in severity until patient presented himself, July 15, when he was suffering severe paroxysms of pain in the upper jaw and in the neighborhood of the ear. It was decided to remove the ganglion.

Operation.—Through the Cushing incision the mandibular and superior maxillary branches were readily exposed. They were divided at the foramen and avulsed with the ganglion. There was considerable hemorrhage, but the patient, notwithstanding his age (81 years), withstood the operation very well. Iodoform gauze drain remained for forty-eight hours, after which it was removed. There was an escape of some cerebrospinal fluid.

This was my twelfth gasserian ganglion operation, but I must confess that familiarity with the technic has not made it any more inviting.

The second and third days following the operation the patient was in excellent condition, save a gradually increasing intestinal tympany; the paralytic condition of the bowel continued for many days, and the marasmus increased. There was primary healing of the wound. On the eleventh day his senile marasmus increased and he died August 4, fourteen days after operation. This case shows what a grave matter it is, notwithstanding the fact that the wound made a primary healing, to operate on a patient of his advanced years.

CASE 11.—Miss E. Y. S. Age 50. Admitted to Mercy Hospital June 2, 1904.

Family History.—Mother and father died along in their eighties. Sisters and brothers all living.

Personal History.—Has always lived at home.

Menstrual History.—Began at 14. Regular every four weeks. Usually painful for a day or two preceding flow. Flowed about four days. No intermenstrual flows. Menopause four years ago.

Previous Illness.—Measles when young. Some mild attacks of rheumatism.

Present Illness.—In May, 1902, patient first felt a sharp, cutting pain in her left cheek along the outer canthus of the eye. She thought it was from her teeth and had most of her upper teeth extracted. Following this she had relief for a day or two. She then called a physician and he gave her medicine which relieved the pain for a short time. She went away to the seashore and the pain grew worse and covered a larger area. Pain traveled up over the eye and involved the lower angle of the jaw. Returned home; pain gradually grew worse and patient was forced to go to bed and remained there for five months, during which time she could not take any solid food, nothing but warm liquid diet, as the pain was so intense when she moved her jaws. She went to California and remained there for many months, but received little or no relief. The pain was almost constant with the exception of a few hours, each day.

Present area of pain: Over region of masseter muscle; over and to the side of the left eye; along the angle of the lower jaw; nose has never been involved; gums have never been involved; lower portion of left chin and lip. Bowels usually regular. Appetite fair, but the taking of food was so painful that she is much emaciated.

Operation.—June 4, 1904. Exposure of supraorbital, infraorbital, mandibular and posterior palatine branches of trifacial nerve. From 7 to 10 minims of a 2 per cent. solution of osmic acid were injected into each of the nerve trunks, and a few drops into each foramen. There was only slight irritation and very little edema. The second day following the operation all of the neuralgic pains had disappeared; on the third day anesthesia of the left side of the forehead, left cheek, nose and upper side of lip, also on the left lower lip and chin, ex-

tending back to the angle of the mouth. The face was swollen and continued so for about three weeks, but gradually subsided. In a letter dated July 2 the patient states that she is entirely free from pain and has had a month of comfort and ease which she never expected to experience again. In a letter, August 8, patient states that her condition is just as satisfactory as it was on July 2.

In a third letter, dated September 9, the patient states she is still free from pain. The upper and lower incisions are still suppurating, the latter quite freely. The inferior maxillary nerve protruded, and about one inch in length, very much blackened, was pulled out.

CASE 12.—Mrs. D. H. K. Age 62 years. Admitted to Mercy Hospital June 20, 1904. Discharged July 6. Family history negative.

Personal History.—Married at 30; has four children living; no miscarriages; no evidence of specific infection. Menstrual history began at 15; regular; duration three days; painless; menopause at 45.

Present Illness.—Nine years ago patient began to notice sharp, cutting pain along the angle of the left lower jaw. It remained confined to that locality for a few weeks, then extended to the outer angle of and above the left eye. Eight years ago the infraorbital branch was resected. Following the operation she was free from pain for six months. Then it returned with more intensity and in a larger area; always on the left side. She has had the "rest cure" in New York, but received no relief. Three years ago she was again operated on and portions of the supramaxillary resected, back into the orbit. This gave her relief for eight months. Since that time pain has been constant on the inner side of the cheek, in the gum, left lower jaw, above and below the left eye. The pain was intense if she was exposed to draughts, taking cold drinks, eating, talking, or on contact of any material with the face. She has been compelled to live on liquid foods and to take them through a tube or drop them into her mouth. She has emaciated considerably. This case, having had a division of the nerve on two occasions, was not a favorable one for the injection.

Operation.—June 23. The supra- and infraorbital nerves were found freely developed and about their normal size, notwithstanding they had been resected. The mental branch had also regenerated and was larger than normal. The foramina as well as the nerve trunks were injected with the usual quantity of 2 per cent. solution. There was slight suppurating around the mental foramen. These wounds are subject to infection from the mouth and as the osmic acid produces necrosis of the tissue *in loco*, they are, therefore, very liable to infection.

In a letter received from this patient July 21, 1904, she states there has been no return of the pain. There is still some slight discharge from the incision at the mental foramen. In a letter received August 20 the patient says that her case is progressing favorably. There is some discharge at the foramen mental and some slight induration at the infraorbital foramen.

CASE 13.—Mr. J. E. V. Age 60 years. Admitted to Mercy Hospital July 10, 1904. Discharged July 18. Family history negative.

Personal History.—Married twenty-eight years; has been a heavy smoker; very moderate drinker, and has always been well and strong. No specific disease.

Present Illness.—July 16, 1901, was sitting at his desk talking to his secretary when he suddenly lost his power of articulation. He did not fall out of his chair; just leaned over on his desk. He was not able to speak, but was sufficiently conscious to understand what his secretary was saying. This attack of inability to speak lasted a couple of minutes only. Immediately thereafter patient stood up, but felt very weak in his legs. Half an hour later he was able to walk to his carriage and go home. For ten days following this his mental condition was not exactly clear and he did not have entire control of his words, that is, he would endeavor to say one thing and would say something entirely different. The patient says

he was told at a Michigan sanitarium that he had softening of the brain. He was treated for five weeks at Detroit and regained control of his power of articulation and expression.

In September, 1902, patient began to have very severe head aches; they were "all over his head," but were especially bad in the frontal region. They continued all fall with only slight intermissions. In January, 1903, patient began to have severe pain just under the angle of the upper lip on the left side of the face, over the left cheek, the outer canthus of the eye and the left eyebrow. There was some pain in the lower lip and roof of the mouth. This came on in spasms whenever he partook of food or drink, touched his face, or was subject to a draught. The pain was intense, totally incapacitating him. He was under strychnia treatment by a celebrated neurologist with apparently no effect. The pain was present during all of his waking hours and frequently roused him from his sleep. He became emaciated and finally resorted to large doses of opiates.

Examination.—The patient will not permit one to touch any part of the left side of his face. He is fed by lying flat on his back and having the food dropped from the end of a spoon into his mouth. He does not permit it to touch his hard palate, his teeth or the anterior portion of his tongue. When it does there is severe spasm of pain. The posterior palatine, supraorbital, infraorbital, anterior palatine, mandibular and anterior auricular branches are all disturbed. He has never had an operation.

Operation.—July 10. The supraorbital branch was exposed by external incision; the infraorbital and mental branches through the mouth. The posterior palatine was a little difficult of exposure, but was finally hooked up. All of these branches were injected with from 7 to 15 minims of a 2 per cent. solution of osmic acid and the wounds closed. There was some suppuration from the infraorbital area. The second day after the operation there was a very slight twinge of pain. From that time up to date he has been entirely free. The pain in this case was located on the left, the same side on which he had his central cerebral lesion, which affected his speech, about two years previous, and would suggest that this central lesion was the cause of the pain.

He discontinued his morphin at once. The suppuration in this case extended along up the line of injection, in the foramen to the orbit, necessitating a small incision in the lower lip for drainage.

His report on August 25 states there has not been the slightest recurrence of the neuralgic pain.

CASE 14.—Mrs. C. W. S. Age 47 years. Admitted to Mercy Hospital July 1, 1904.

Family History.—Father and mother living.

Personal History.—Has been married twenty-seven years; two children; no miscarriages; no evidence of specific infection. Menstrual history began at 12 years; regular every twenty-eight days; menopause three years ago. Menstruation was never painful; gave her no discomfort.

Previous Illness.—Had rheumatism some years ago.

Present Illness.—In the fall of 1896 patient noticed a small tumor on the right side of the lower lip. It was present for four months. Her family doctor pronounced it carcinoma and had it removed by paste. Seven years ago last April patient had a severe attack of bronchitis; during this attack she sat up in bed to cough when she was suddenly taken with a severe cutting pain on and along the right side of the nasal cavity. This pain gradually extended over the right side of the face into the right upper gums and into the lower jaw. The pain lasted but a short time, but returned every time the patient partook of food, hot or cold drinks, or whenever her mouth was open to draughts, or if a draught passed over her face. This condition lasted about six weeks. During the summer of that year it entirely disappeared. In November of the same year she was attacked with the same type of pain, but over a larger area, and it was particularly severe in the right eye; always aggravated by exposure to cold, the taking of food or liquids, or the moving of her lips, washing the face, etc. The following summer there was slight relief.

In March, 1899, patient was operated on and the infraorbital nerve resected. Patient was entirely free from discomfort for one year.

In March, 1900, patient began to again have pain below the right eye and in the right upper jaw. This time patient had all of her teeth extracted. This relieved her of all pain up to October of the same year. Again the pain returned in the same positions. In July, 1900, patient was again operated on, resecting the stump of the infraorbital and the supraorbital nerve. Following this patient had no pain up to June, 1903, when it returned in the former locations. In July, 1903, she had a third operation on the same nerves. After this she was free from pain until March, 1904. Since that time the pain has been intense all over the right side of the face and right side of the mouth and gums; it has been constant, with occasional relief for a week or two. During most of this time patient has had occasional attacks of dysuria. These have no special relation to the neuralgic attacks. The sensation to touch, heat and pain have returned all over the face, notwithstanding the resection of the nerves, but it is somewhat perverted. She states that after each resection there was anesthesia over the area supplied by the nerves resected, but that after some months this anesthesia disappeared and the face assumed practically its normal sensibility.

Operation.—July 20, 1904. Supraorbital and infraorbital branches had redeveloped to about their normal size. The mental branch was represented by a small threadlike nerve escaping through an opening one-third of an inch above the original mental orifice, which had filled by new bone after the last operation. The supraorbital, infraorbital, mental and posterior palatine branches were all injected, as well as the foramina, with the usual quantity of 2 per cent. solution. The day following the operation she had some pain; on the second day after there was entire absence of neuralgic pain. In a letter August 20 the patient states the relief has continued up to date.

RESULTS.

The results obtained by operations may be divided into: First, the resections of the nerve trunks, extracranial; second intracranial divisions; third, ganglion removal; fourth, sensory root division or avulsion. From the standpoint of danger to the life of the patient, the extracranial may be said to be free from danger except in senile patients, when any operation has in it elements of danger. The relief from this type of operation has in a small percentage been permanent. In a very large percentage it has lasted from nine months to three and a half years. In all of the intracranial operations there are about the equal elements of danger, as the exposure of the nerve branches, ganglion and motor root is the most difficult and dangerous part of the procedure. The seriousness of this procedure has been impressed on me by four deaths in my 12 cases, a mortality of 33 1/3 per cent. Two of these deaths occurred in patients over 80 years of age. The analysis of 108 cases collected by Tiffany, as shown in the following table, shows the great mortality of these operations—great, since the disease, *per se*, does not threaten life.

TYPE OF OPERATION.

Nearly two-thirds Hartley-Krause, nearly one-fourth Rose's, 7 Horsley's, 4 Doyen's, 4 Quenu's, 1 Novaro's, 1 no method mentioned.

Nerves affected: Right side twice as often as left; third division alone 10 times, second division alone 6 times, first division alone none; involvement usually reflex. All divisions 22 times, second and third divisions 68 times.

Mortality of 108 cases, 23 died—22 per cent.

Cause of death: Shock, 8; sepsis, 8; brain trauma, 2; brain abscess (trauma ?), 1; brain trauma and edema of lung, 1; apoplexy on tenth day, 1; cause unknown, fourth day, 1; cause unknown, sixth day, 1.

"Recurrence of pain after removal of gasserian ganglion is

not recorded." The author says "it can not occur." But the clinical fact is that it *does* recur in quite a percentage of cases in which the ganglion has been supposedly removed, and recent experiments support the clinical phenomena that it can and should recur. The immediate result of intracranial operation, whether section or removal of ganglia, is relief of pain. Recurrence in cases of excision are not uncommon.

Ordinary sensation in the territory supplied by the nerve operated on is abolished over a small area and exists irregularly over a large area. Ordinary sensation will be found where pain sense is absent. Sensations of heat and cold are frequently forfeited. Tiffany gives the following indications for operation: 1. If more than one branch is affected. 2. If painful area receives filaments from branches near exit from head (cranial cavity), *e. g.*, tongue, temporal region. 3. If pain is not an expression of constitutional disease. 4. If cause central to ganglion does not exist. 5. If other measures have failed to relieve.

Operation: Removal of lower two-thirds of ganglion, together with second and third branches as far as their foramina of exit from skull all in one piece, so as to be certain of amount of tissue taken.

Upper one-third of ganglia and first branch should not, for the present at least, be excised for neuralgia.

CONCLUSIONS.

From clinical reports, my experiments and personal clinical experience I conclude as follows:

1. That trifacial neuralgia, tic douloureux, is not the result of a pathologic entity which has so far been definitely determined.

2. The tendency after all types of operation, with the possible exception of removal of the sensory root behind the ganglion, is to recurrence of the disease.

3. This is probably due to the regeneration of certain nerve elements following the deep operation, and anastomosis and retention following the superficial.

4. Sudden shocks and irritation to the terminal filaments of the trifacial not infrequently cause an immediate and occasionally a permanent cessation of the neuralgic pain.

5. The mortality from the superficial excisions is practically *nil*; the mortality from the intracranial operations is great. The hazard is greater than should be taken in a disease which does not in itself jeopardize life.

6. Injections of osmic acid in 1 to 2 per cent. solution into the nerve trunks relieve the pain immediately and in a large percentage of cases for a long period of time.

7. The injections into the superficial tissue for peripheral neuralgia should be abandoned, as the nerve trunks are easily located, and there is no danger of superficial necrosis following such operation.

8. It should never be injected into a motor nerve or a motor nerve area and, therefore, never into the spinal nerves except in amputation stumps.

9. It produces a local necrosis of the tissue into which it is injected and even of the wall of the foramen. This necrosis does not suppurate unless the area is exposed to mouth infection. In that case the suppuration often continues for weeks, draining into the mouth, giving no special inconvenience, and in no way interfering with the final result.

10. The best results are obtained with a 1½ to 2 per cent. solution; this should be injected in many places into the nerve trunk and also into the foramen.

11. All of the nerve branches should be injected—the palatine, lingual, mandibular, superior maxillary (infra-orbital), and supraorbital. They can all be exposed through mouth incisions, except the supraorbital. Many times there are three or four divisions of the supraorbital

and they should be searched for carefully and each injected. Occasionally it is necessary to inject the auricular branch. The posterior palatine is not so difficult to inject as one would at first imagine.

12. The foramina can and may be injected without anesthesia or incision. The procedure is quite painful, however, and is not certain in its results.

13. The injections can be made with local or general anesthesia. I prefer the general.

14. The injection is free from danger.

15. Judging theoretically from the experience with incisions, resections and ganglion operations, the relief *should not be permanent after the injection of the osmic acid*. From clinical experience up to date, however, and particularly from Mr. Bennett's showing, the fact is that many cases are permanently cured. Time alone must determine the final result of this treatment. Its ease of application, its *nil* mortality, and its immediate results forcefully commend its use.

100 State Street.

DISCUSSION

ON PAPERS BY DR. SHERMAN, FRAZIER AND MURPHY.

DR. CHARLES K. MILLS, Philadelphia—For many years I have had an opportunity of observing many cases of tic douloureux. With the exception of the osmic acid treatment, I have had my cases treated by all forms of surgical procedure. In order that you may have pain in the fifth nerve or anywhere else three things are necessary: 1, Peripheral sensory irritation; 2, channel of communication, and, 3, cerebral centers for the conscious recognition of pain. It does not matter what the pathology of this disease is. The essential thing in its surgical treatment is the complete separation of the cerebral centers concerned with sensations from the periphery. I believe that the best method of treatment is either extirpation of the gasserian ganglion or section of the sensory root, but I am somewhat unsettled which should receive the preference. However, it matters little which is done if the operation is performed successfully. In some cases, perhaps, the sensory root operation is better on account of the effect on the eye from the gasserian operation. My reason for not favoring the osmic acid treatment is that I am usually not inclined toward any peripheral treatment. Experience shows that when one branch of the fifth nerve is involved, sooner or later others, and perhaps all, will be implicated.

DR. WILLIAM G. SPILLER, Philadelphia—As to the pathology of tic douloureux, I have had an opportunity of examining many gasserian ganglia, probably about 15, removed at operation, and have always found degeneration. It matters little whether the disease begins in the peripheral nerve fibers or in the ganglion, because it can not exist long in the former without affecting the nerve cells of the gasserian ganglion. The alteration sooner or later involves the whole nerve structure, including ganglion and peripheral nerve fibers. The relief of pain after resection of a peripheral branch does not prove that the lesion is primarily in the peripheral branch. The cells of the ganglion are altered by the resection and their function is partially impaired, and until they recover pain is not likely to return. I was surprised to hear Dr. Murphy say that there was no ascending or descending degeneration in his experimental cases. I do not understand how axis cylinders can be destroyed without causing secondary degeneration. The method recommended by Dr. Murphy is most valuable if the relief is permanent. The action of the osmic acid is to cause destruction and hardening of the tissue into which it is injected. Osmic acid is one of the best hardening agents, and when injected into a nerve it probably makes regeneration more difficult. Dr. Sherman's case is important, but it is not at all a typical one. He states that pain returned on the third day, and I can not understand how the sensory root could have been entirely divided if pain returned within so short a time. Very few gasserian ganglia have been entirely removed without relief of

pain; indeed, I know of only two cases, and I am skeptical concerning these. Sensation sometimes returns in peripheral nerves before motion, but if there were a regeneration of the fibers of the sensory root it is probable the fibers of the motor root would also regenerate, and there would be some return of motion in the muscles of mastication, which I have not heard was present in Dr. Sherman's case. It would be well to resect a piece of the sensory root to make sure that division is complete. The operation on the sensory root is difficult and very bloody, and one may easily be deceived regarding complete division of the root. In the dogs examined by Dr. Frazier and myself I found that the external part of the sensory root was more frequently degenerated than the internal part, and that the fibers of the external part of the root were represented in the posterior part of the descending spinal root. Combining the results of my studies with those of Van Gehuchten, I believe we may say that the fibers of the third division of the trigeminal are represented in the external part of the sensory root and in the posterior part of the spinal root, and that when the anesthesia is of very limited area after an operation on the sensory root, it will be found in the distribution of the third division, and that this indicates that only the outer part of the sensory root has been injured at the operation.

DR. ROBERT F. WEIR, New York City.—The osmic acid treatment failed in my hands many years ago, and I do not see how it is any better than the resection of a certain portion of the nerve. The nerve is destroyed by the acid, as would be the case with a resection. The intervention of gutta-percha tissue between the nerve ends, or under the dura, to prevent adhesions has been tried by myself with failure as a permanent result. I have also employed gold leaf with the same intent. In one case of trephining I had put in a small gutta-percha sheet; the wound healed, but headache resulted and persisted. On cutting into the scar several months later I found that this gutta-percha tissue was still there, and that it was finely perforated, allowing in many places adhesions to pass through it. This condition was also observed in another case. I am, as others have been, driven to the conclusion that for the permanent relief of these trigeminal neuralgias we are bound to resort to an intracranial operation, which has a very serious risk, for we are resorting to an operation that brings with it a risk of death for a disease that has no such risk. I yet believe it well to try the lighter operations first.

DR. J. SHELTON HORSLEY, Richmond, Va.—Ten years ago it was held by many surgeons that the spinal cord after being injured, particularly in its upper portion, never regenerated, but Harte and Stewart reported a case where this view was shown to be incorrect, as the patient recovered quite satisfactorily after complete section of the cord at the level of the seventh dorsal vertebra. We must consider the idiosyncrasy of the patient. In some individuals regeneration of nervous structures takes place, whereas in others there will be no attempt at repair, though the lesion may be identical in both instances. There seems no way of telling whether a nerve in a given individual will repair until an actual trial is made. I have done two operations on the gasserian ganglion, and both resulted satisfactorily. In one case the whole ganglion was removed intact. The external carotid was ligated, which lessens hemorrhage and adds to the confidence of the operator. The Cushing operation gives a very satisfactory exposure if carried farther under the base of the skull, somewhat after the method of Doyen. I have tried to mitigate the shock by the hypodermic injection of cocaine into the ganglion before division of the nerves, but the patient suffered shock to some extent, the blood pressure dropping to 80. I do not know how much good the cocaine did. In the second case the Abbé operation was performed. Only the second and third divisions were involved here. There must be a legitimate field for extirpation of the gasserian ganglion, as Spiller and others have demonstrated that in nearly every instance after persistent tic this ganglion shows pathologic lesions. Milder operations may sometimes succeed, but they can not supplant the more radical procedure.

DR. JOHN B. MURPHY—I have had many cases of tic, and I know the "real thing" when I see it. I am not a novice in the

work. I lost three cases out of eleven following the operation of ganglion removal. Dr. Spiller's experience in pathologic findings has not been supported by others. I had one case from California in which every branch was involved, and so severe was it that a doctor had to accompany her to Chicago for the operation. I did the injection method and completely relieved the patient by the end of the third day. As to what Dr. Weir says about nerve regeneration, there are some things that we do not understand. At times, in contusions or pressure on a nerve without division, some change occurs to interfere with the re-establishment of communication between the periphery and the centers and prevents the return of function. I hope to get the same result from the injection method and we are justified in this hope by Mr. Bennett's experience, extending over a period of six years. It is my opinion that the results should not be permanent, but the clinical test is the final test, and so long as I am able to relieve these cases for even a year or two by this simple and safe procedure I will not again resort to the ganglion removal. The ganglion removal is ideal, but the hazard is too great except as a *dernier ressort*. The injection may be renewed with benefit, as shown by Bennett's and my cases.

DR. H. M. SHERMAN, San Francisco—As to the question of the return of pain referred to by Dr. Spiller, its return and persistence suggests strongly the idea that the disease and the cause of the pain is central. The persistence of the paralysis shows that I had surely cut all the sensory fibers, but the return of sensation led me to think that there was some error in the proposed technic of the operation. After the second operation we have permanent anesthesia, but still a persistence of the pain. In this second operation the ganglion was removed.

DR. C. H. FRAZIER—With reference to the occurrence of facial paralysis as a complication in the operation on the gasserian ganglion, I have explained it in one of two ways; it may be due either to the forcible retraction of the musculocutaneous flap with a metal curved retractor, the tip of which may easily exert enough pressure on the facial nerve to cause at least temporary disturbance of function, or it may be due to too forcible and prolonged elevation of the temporal lobe. The time has come when we should discard the percentages which have been estimated from the series of cases operated on before the adoption of the more perfect methods of modern technic. The operation on the ganglion itself, the central or peripheral roots, is no longer a "kill or cure" measure. I am not prepared to accept the report which Dr. Sherman has made as conclusive evidence against the rationale of the operation which I have advocated. I still believe regeneration of the sensory root will not occur after its division, and, therefore, that there can be no recurrence such as Dr. Sherman has reported. It is more than probable in this case that the root was not entirely divided. It is a source of disappointment to me that such a report should have been made, inasmuch as it will throw some doubt on the accuracy of our observations. The operation was based on the results of very careful and painstaking experimental investigation by Dr. Spiller and myself, and not until we obtained encouraging results in these experiments was the operation applied to the human subject. I believe the operation to be established on a sound and scientific basis, and the results of our clinical experience would seem to bear me out.

A New Cure for Drunkenness.—The Norwegian authorities, who do not make light of the subject of alcoholism, are using an original method of curing drunkards of their vice, according to *Le Bulletin Médical*. The patient is placed in a room under lock and key, and all outside communication is cut off. His nourishment consists in great part of bread soaked in port wine. The first day the drunkard eats his food with pleasure, and even on the second day he enjoys it. On the third day he finds that it is always the same, on the fourth day he becomes impatient, and at the end of eight days he receives the wine with horror. It seems that the disgust persists and that this homeopathic cure gives unexpected results.

POISONING BY WOOD ALCOHOL.

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS.

FRANK BULLER, M.D.

MONTREAL.

AND

CASEY A. WOOD, M.D.

CHICAGO.

(Continued from page 977.)

CASES 27 and 28.—(From Dr. Frank A. Grawn, Munising, Mich.; Dr. T. W. Scholtes, Munising, Mich.)

J. B., aged 37, nationality French, occupation wood-man, date of death, Nov. 14, 1898. L. B., aged 40, nationality French, occupation wood-man, date of death, Nov. 14, 1898. Symptoms, in both cases, great suffering from pain in abdomen, especially in region of stomach, vomiting, severe headache, total blindness and severe prostration. The post-mortem findings consisted principally of a marked congestion of the gastric mucosa, also of liver, kidneys and vessels of brain. The conclusions arrived at were that while the local changes produced by this alcohol were quite prominent, death was undoubtedly due to the systemic effect of the poison. These two men who died from the poisoning were brothers. They came to Munising, went to a saloon and, as they stated, called for "good" alcohol. The saloonkeeper says he understood them to say "wood" alcohol. He not having alcohol in stock, went to a drug store and bought two quarts of wood alcohol for each. He delivered it to them and they left town in the evening and walked to camp. The alcohol was not labeled "poison." They both reached camp and were soon taken sick and Dr. G. M. Gould, formerly of Munising, was called to attend them. He found they had drunk a little less than two quarts between them. One of the men died about fourteen hours after they bought the alcohol and the other about seventeen hours after.

CASE 29.—(From Dr. Herbert Harlan, Baltimore.)

Storekeeper in Dorchester County, Maryland, went on a spree with Jamaica ginger. He became entirely blind, but is so ashamed of his performance and, believing his case to be hopeless, declines to see an oculist or to discuss his case with one. Dr. Harlan obtained the report from his family physician, whom he knows to be a competent and reliable observer.

CASE 30.—(From Dr. Herbert Harlan, Baltimore; Dr. P. B. Barringer, Charlottesville, Va., and Dr. Francis Lee Thurman, Keswick, Va.)

W. H. J., aged 38, a respectable and well-to-do merchant of Keswick, Va. Some five years ago, on a certain Sunday (July 15, 1899), not feeling well, took a drink of Gilbert's Jamaica ginger. After taking one dose he felt no better and took a second, later in the day taking several others. On the following day he took one more dose, drinking in all two or three ounces of the "ginger." On Monday he complained of nausea, weakness, vomiting, intense headache, giddiness and, later in the day, became blind. The blindness increased so much that in three days he could not perceive light from darkness. Then his vision gradually improved so that in another ten days it reached the acuity it at present exhibits. There has been no change in the fundus conditions during the past four years. He was then treated by Dr. Thurman and saw an oculist in Richmond, Va., whose name he did not recall. Two years afterward, when examined by Dr. Harlan, he had marked optic nerve atrophy, with some vision in the periphery of each field sufficient to allow him to get about in familiar localities.

Analysis of the Jamaica ginger taken by this patient showed that it was 70 per cent. wood alcohol.

CASE 31.—(From Drs. Alvin A. Hubbell and Lucien Howe, Buffalo, N. Y.)

Dr. B. W. S., Stockton, Chautauqua County, N. Y., consulted Dr. Hubbell in April, 1961. In March, 1899, he accidentally drank about an ounce and a half of wood alcohol. This dose was repeated the next two days—three doses in all—after which his vision became dim in both eyes. He could see well enough to get about, but was unable to read print. V. R.

==5/30, and no Jaeger; V. L.==perception of light. As Dr. Hubbell saw him once only and as he failed to keep his promise to return, the visual fields were not measured. The fundi showed well marked atrophy of both discs. Dr. Howe saw him before this, on June 12, 1899, and adds that, at that time, the patient thought his sight in the right eye had gradually improved. The right pupil was torpid, arteries small, discs pale; V.=20.50 and Sn. three, field slightly contracted. In the left eye the same condition, only more exaggerated. Disc decidedly atrophic, V.=fingers at six feet; Sn. 20 at twelve inches; field regular, about two-thirds normal limit. In a letter to Dr. Howe from the patient six months later he reported his condition to be about the same.

CASE 32.—(From Dr. M. A. Hughes, Salt Lake City, Utah.)

J. A., aged 40, stone mason, consulted Dr. Hughes in January, 1902, for a sudden attack of almost complete blindness. The history showed that he, with several companions, had drunk freely of wood alcohol on a certain Sunday. When he awoke next morning he found that he could scarcely see. On examination his vision was reduced to 10/60 in the right eye and 10/40 in the left. Under increasing doses of strychnia, given hypodermically, his sight improved slightly. A year after the poisoning he was, however, unable to resume his trade and the damage to sight seemed permanent.

CASES 33 and 34.—(From Dr. Edwin E. Jack, Boston, Mass.)

"I have seen two cases of atrophy following the ingestion of methyl alcohol in the crude form. One, J. P., aged 71, old soldier, bought a pint and drank part of it. Both had a long period of insensibility and both were blind on regaining their senses; a neuritis followed by rapid atrophy."

Although Dr. Jack was not able to find in his hospital records, the detailed case histories of these patients, there is every reason to believe that they have not been published before and that they have not been duplicated in this report.

CASE 35.—(From Dr. Edward Jackson, Denver, Colo.)

A woman, addicted to alcoholism, resorted to a jug of wood alcohol that her employer kept for a lamp. The quantity taken is uncertain. She suffered from severe gastrointestinal irritation, vomiting and impairment of vision. Next morning all "looked black," but she could see a light brought into the room. In three days vision began to improve rapidly. On the eighteenth day V.=4/60, R. and L. The optic discs were red, hazy and slightly swollen, their outlines hidden. The retinal vessels not much altered. She and her daughter said that before taking the wood alcohol she could thread the finest needle. She was not seen after the twentieth day.

CASE 36.—(From Dr. J. H. Janar, Elkton, Md.)

A drunken male tramp, aged 37, having procured a quantity of wood alcohol, ostensibly for a different purpose, proceeded with a companion (whose case is elsewhere recorded), to go on a spree by the wayside. His female companion promptly died, but he survived, was placed in jail, there being no hospital in the city, and came under Dr. Janar's care. The patient was found to be in a highly excited, delirious condition; face purple; decided odor of alcohol about him. Emetics followed by calmatives were prescribed and the patient began to improve. His eyesight was greatly affected for the first day or so, but improved in a few days, when he was discharged. The final outcome of the case as regards vision is not known.

CASE 37.—(From Dr. Dryden H. Lamb, Owosso, Mich.)

J. E., male, aged about 25, one of three men who together went on a spree. After having absorbed all the ordinary alcoholic beverages they secured some Columbian spirits and drank a considerable quantity of it; exact quantity is not known. One died shortly afterward and the others were very ill, both of the survivors suffering from amaurosis. One case was treated by Dr. Lamb, the other elsewhere. There was marked contraction of the fields in both eyes and vision was permanently reduced to 20/100 and 20/80, right and left eye respectively. Previous history good.

CASE 38.—(From Dr. Dryden H. Lamb, Owosso, Mich.)

J. B., aged 30, inhaled an unknown quantity of Columbian spirits and in a short time was totally disabled from loss of eyesight. R. E. V. was 20/200; L. E. V. was 10/200, with

narrowing of fields. Condition at present but slightly improved. Optic atrophy.

CASES 39, 40 and 41.—(From Dr. Dryden H. Lamb, Owosso, Mich.)

Owing to destruction of complete records of these three cases (during two and one-half years' absence on military duty) Dr. Lamb is unable to give details of the visual fields, fundus changes, etc., but has a distinct recollection of the main facts, which point conclusively to methyl alcohol blindness. So far as Dr. Lamb knows, the cases are here published for the first time. About four years ago three Swedes, addicted to alcoholic debauches, purchased deodorized wood alcohol because it was cheap, reduced it with water and drank "not a large quantity" of it. The eyesight was affected in each instance and it was on account of this failure of vision that Dr. Lamb saw them. Central vision was greatly reduced, the visual fields were much contracted and the fundus pictures were those of optic atrophy. Under treatment vision improved somewhat in all the three instances, and when they could readily get about the men left town and have not been seen in Owosso since.

CASE 42.—(From Dr. Eugene Richards Lewis, Dubuque, Iowa.)

J. C., aged 38, chronic drunkard and loafer about saloons; also heavy smoker, with a "specific" history. At noon one day, while prowling about the house of a woman he had recently married, he discovered a large bottle of wood alcohol, of which he drank an unknown quantity. Toward evening Dr. J. S. Lewis of Dubuque was summoned and found the man totally blind. The patient died during the night, so that a fundus examination, which was arranged for the following morning, could not be made.

CASE 43.—(From Dr. F. Park Lewis, Buffalo, N. Y.)

M. F., aged 49 years, had used alcohol for thirty years and was in the habit of taking it to excess whenever opportunity offered. She was an inmate of the Erie County Hospital in the year 1900. One afternoon, finding a large cup half filled with what she supposed to be alcohol, and which was in fact methyl alcohol, used for cleaning purposes, she drank the whole of it in two draughts with an interval of about half an hour, the total amount consumed being about four ounces. After a short period of excitement she passed into a stupor which lasted until late the next morning when, on being aroused, she found herself absolutely blind, and from that period until the present time, about four years, she has had no perception of light whatever.

She did not come under the observation of Dr. Lewis until the beginning of his service, some six months after this event. Then both optic nerves were found to be atrophic and the retinal vessels reduced in size. The woman is still an inmate of the County Hospital. She has a catarrhal conjunctivitis, but otherwise is apparently in good health. No consequences seem to have followed the toxiemia except the almost immediate complete and permanent blindness.

CASE 44.—(From Dr. J. A. Lippincott, Pittsburg, Pa.)

F. C., aged 47, laborer, drank a large quantity of wood alcohol and within twenty-four hours sight began gradually to fail and was never regained. No light perception. Pupils slightly dilated and rigid. The ophthalmoscope shows clear media. Discs a grayish silvery white, with sharply defined margins. Upper and lower temporal veins of normal caliber. All other vessels almost obliterated or reduced to mere threads.

CASE 45.—(From Dr. J. A. Lippincott, Pittsburg, Pa.)

J. R., aged 31, oil well driller, drank 24 ounces of Jamaica ginger between 2 and 3 o'clock in the afternoon. At midnight he awoke with severe browache and sight much impaired. In a few minutes he became stone-blind, in which condition he has remained ever since. External appearances are normal except that the pupils are dilated (5½ mm.) and not responsive. Tension slightly elevated, especially on right side. Eyeballs tender to touch, especially above. No light perception.

Ophthalmoscope examination: R. E., media clear; outer margin of disc perfectly sharp; upper margin very much blurred, the blurring extending upward, with radiations over the retina

for fully a disc diameter, but more pronounced, and extends downward 1½ disc diameters. In this area the retina is edematous and the vessels are interrupted in places. Inner side of retina slightly hazy. Macular region normal in appearance. L. E., disc slightly hazy and surrounded by a hazy zone about 1½ disc diameters wide. Retinal vessels slightly tortuous. Knee reflex absent.

Treatment: Iodid of potassium in large doses; leeches to temples; pilocarpin sweats daily; rest in bed; strychnin to be given a little later.

Feb. 25, 1901. V. R. E. = light perception. V. L. E. = fingers close to eye. Pupils still dilated, but responsive, though sluggish. R. E. disc bluish-white, with boundaries pretty sharply defined. Retinal vessels about two-thirds of normal size. L. E., swelling of nerve head much reduced, leaving central physiologic excavation white; rest of disc is of a grayish-white color. Pilocarpin stopped. Iodid and strychnin continued.

April 23, 1901. He states that about five weeks ago could see well enough to walk about, but about what time the sight began to fail, until he became entirely blind. Dec. 10, 1901, pronounced atrophy of optic discs.

CASE 46.—(From Dr. R. S. Magee, Topeka, Kan.)

Mrs. S. P., aged 33, Topeka, consulted Dr. Magee on July 8, 1901. The patient had always had good vision until four weeks previous to this date. She suffered from painful menstruation, for which she was in the habit of taking whisky. A month before consulting the physician she discovered she had no whisky in the house, so drank instead a medicine glassful of wood alcohol diluted with the same quantity of water. This dose was taken in the evening just before retiring. The next morning she noticed decided dimness of vision, unaccompanied by pain in either eye. Dr. Magee found vision in the right eye to be 16/100; left eye 4/200. The mirror showed "woolly" discs and the remains of small hemorrhages in both fundi. He had an opportunity of seeing her once more, at a later date, and found central vision worse and gradually failing.

CASE 47.—(From Dr. J. G. McKioney, Barry, Ill.)

James Riffe, jeweler, drunkard, in the absence of whisky drank extract of lemon, which produced blindness, followed by death in less than two days. The extract of lemon was examined by an expert chemist and found to be composed almost entirely of wood alcohol.

CASE 48.—(From Dr. J. E. Minney, Topeka, Kan.)

As reported in another column, a farm hand, one of nine Poles, living in this vicinity, who indulged in a debauch and drank nearly two gallons of methyl alcohol before the termination of the spree, became blind. This was during the year 1889. The loss of vision in this instance was unequal, the one eye being much more affected than the other, although they both exhibited the fundus signs of optic nerve atrophy.

Dr. Minney saw the case first about ten weeks after the intoxication. The man was then able to go about the farm and do work not requiring good vision. The last report from him was that there was no improvement.

CASE 49.—(From Dr. T. W. Moore, Huntingdon, W. Va.)

G. S., aged 36, baker, was first seen Jan. 23, 1904. Drank an unknown quantity of wood alcohol Sept. 15, 1902, and was totally blind thereafter for nearly three weeks. Both discs are now pale, right one decidedly so. Vision: R. E., fingers at 12 inches; L. E., with lenses, 20/40.

CASE 50.—(From Dr. T. W. Moore, Huntingdon, W. Va.)

S. T., aged 45, white, house painter, married. Uses tobacco and alcohol, the latter to excess. Had been working in a frame factory and using wood alcohol in mixing his paints. On Oct. 6, 1900, he drank one-half pint of the methylated spirits. This was followed the next day by other alcoholics. Vomited excessively all that night, and on the following morning was totally blind. Had flashes of light before his eyes quite frequently; no pain at any time in eyes, although slight frontal headache. On October 18 Dr. Moore saw him for the first time. He had perception of light and said he could see moving objects, although he subsequently failed to do so in the physician's of-

lice. Pupils dilated and did not respond to light. Both discs were slightly blurred on the nasal side; arteries normal, veins engorged and tortuous. One year later the patient was still totally blind, and both discs were white.

CASE 51.—(From Dr. H. Moulton, Fort Smith, Ark.)

In addition to the cases reported by him in the *Ophthalmic Record* for July, 1899, and November, 1901, Dr. Moulton submits the following case history: S. W. McK., age 52, of San Bois, Ind. Ter., drank, April 22, 1902, four bottles of essence of lemon. Next day he began to lose his eyesight, and on the third day he was totally blind. After three or four days he began to see again. He reported that, as treatment, "his doctor made him sweat." On May 23, 1904, one month after the poisoning, Dr. Moulton found vision in his right eye to be 10/100; in the left, finger-counting at three feet. The ophthalmoscope showed temporal pallor of the nerve heads. The pupils were abnormally dilated. Unfortunately, the patient did not return, as arranged, to have his visual fields measured.

Dr. Moulton remarks that cases of poisoning from adulterated drinks are very common in Indian Territory.

He believes that at least 50 deaths have occurred in that country from this cause.

The sale of ordinary alcoholic beverages is strictly prohibited there by the United States Government, and thirsty souls are perforce obliged to drink anything containing alcohol, Jamaica ginger, witch hazel, or even "perina."

CASE 52.—(From Dr. F. G. Murray, Cedar Rapids, Iowa.)

The patient was a cook (male) in a lumber camp in the summer of 1902, in northern Michigan. Previous to taking this job he had been indulging heavily in liquor, but had not had access to it for a number of days previous to his arrival at the camp. There was no liquor accessible nearer than the railroad station, 30 miles away. He seemed to have normal vision and command of his muscles at this time, for he did a little hunting and brought down game with a rifle at a moderately long range. This was the first of the week, in June, 1902. To satisfy his craving for alcohol, he commenced drinking a proprietary "liniment for both internal and external use" kept in the "van," or camp store. In the space of three or four days he drank at least 72 ounces of this remedy. He became weak and somewhat incoordinate in gait, and his eyesight began to fail, so that by the end of the week he could barely distinguish hand movements before his eyes. The pupils were widely dilated; the skin cool and moist. No ophthalmoscopic examination was made, and Dr. Murray does not remember whether there was or was not ptosis. The subsequent history of the case is not known. The patient went to Marquette, Mich., presumably to the hospital there. It was reported that he was seen some time after on the streets, with improved eyesight. There were, in addition to the "liniment," some common extracts used in cooking about the camp kitchen, but there is no evidence that he drank any of them. If he did, it was only a small amount.

The liniment referred to is largely used in the camps of that region (near Sault Ste. Marie) to "sober up" on, and it is a common belief among the woodsmen that free indulgence in it will cause blindness.

CASES 53, 54, 55.—(From Dr. Charles A. Oliver, Philadelphia, Pa.)

"I have had three indisputable cases: two at Wills Hospital and one in private consultation. Of the two public cases, one had his central vision reduced to 1/8 of normal; the other to 1/15, both by reason of large positive scotomata. Both patients, men of 30 and 35 years of age, were rendered practically useless for continuance of their daily work as skilled laborers. The private case, an important man in a not far distant community, was compelled to discontinue a remunerative employment for an extremely precarious and uncertain agency.

"The cases I saw were primarily mine, were never published, and will not interfere with Dr. Buller's statistics (of published cases). The histories of the public ones are buried in my special Wills Hospital case books. I used them alone for class demonstration. One case, I remember, was wood alcohol in coffee. I do not remember the amounts ingested."

CASE 56.—(From Dr. S. A. Oren, Lewiston, Ill.)

Frank H., aged 48, laborer, a habitual drinker, had been on a spree, and after drinking freely of "lemon essence" was found, Nov. 4, 1903, in a barn unconscious. Dr. Oren saw him shortly afterward and endeavored to restore him, but without avail. He recovered sufficiently to articulate, but became delirious before he died, within 24 hours after finding him. He was quite blind before death. His pulse was very weak and did not respond to stimulants.

CASE 57.—(From Dr. C. E. Patterson, Grand Rapids, Mich.)

Mr. H., aged 17, a habitual drinker of spirits, consulted Dr. Patterson several years ago on account of the nervous symptoms engendered by this habit. He used to buy the pure alcohol, dilute it with water and drink it to complete intoxication. On one occasion a mistake was made, and he was given wood alcohol (probably deodorized), and, as usual, proceeded to imbibe it to full drunkenness. This was on a certain Friday night. He awoke next morning totally blind. He recovered from the other effects of his spree, but has never regained his eyesight, there being complete destruction of both optic nerves.

CASE 58.—(From Dr. J. A. Patton, Stillwell, Ind. Ter. Dr. T. S. Williams, Stillwell, Ind. Ter.)

P. F., aged 24, single. Dr. Patton saw him first Feb. 28, 1904, 9 a. m. He had vomited since 10 o'clock the night before, after drinking six or seven bottles of lemon extract. It was afterward learned that he had been drinking lemon extract for three or four days. Pulse, 80; temperature normal; respiration, 25; capillary circulation not good. Complained of some burning pain in stomach. Could see and recognize persons within a few feet of him, but at a distance of 10 or 12 feet, as he expressed it, "everything looked white." At 1 p. m. he was totally blind. Respiration very rapid; partly unconscious. Pulse, 65 or 70, but full. At 3 p. m., unconscious; pulse slow but strong; great dyspnea; skin cold and clammy. 5 p. m.—Had several severe convulsions. Died at 5:40 p. m., Feb. 28, 1904.

Dr. Patton had the lemon extract drunk by this man and by the patients whose cases are subsequently detailed by him in this report analyzed. It was found to consist largely of wood alcohol.

CASE 59.—(From Dr. J. A. Patton and Dr. T. S. Williams, Stillwell, Ind. Ter.)

W. H. H., aged 60, married, merchant. He had drunk lemon extract, with others, for three or four days. Complained to friends on the afternoon of February 29 that "everything looked white" and that he couldn't see well. Had vomiting and other gastrointestinal symptoms, such as severe cramps. He went home to his wife, who cared for him until 4 a. m., March 1, when physicians were called. At that time he was totally blind, unconscious and had a slow pulse; respirations labored. Died after convulsions, 8 a. m., March 1, 1904.

CASE 60.—(From Dr. J. A. Patton, Stillwell, Ind. Ter., and Dr. J. T. Clegg, Siloam Springs, Ark.)

S. T., aged 34, married. Had drunk lemon extract for three or four days. On the morning of Feb. 28, 1904, he went to Siloam Springs. He was apparently in good health and sober during the day. About 7 or 8 o'clock p. m. he went to the hotel and complained of blindness, dyspnea and pain in the stomach. Dr. J. T. Clegg of Siloam was called, who gave the following history: Respiration very labored, with a prolonged expiratory effort; pulse slow (48 to 50). Other symptoms closely resembled the foregoing case, with the exception of the muscular spasm; he had no convulsions. Died at 1:15 a. m., Feb. 29, 1904.

The lemon extract drunk by this patient was analyzed and found to contain wood alcohol.

CASE 61.—(From Dr. W. T. Salmon, Oklabama City, Okla.)

H., aged 46, December, 1898. Drank alcohol, and in 12 hours was very dizzy, vomited a great deal, headache, eyeballs sensitive to touch, blind in three days, optic neuritis followed by atrophy.

CASE 62.—(From Dr. W. T. Salmon, Oklabama City, Okla.)

Miss F., aged 19, lived in Indian Territory, February, 1899. Had been drinking cologne spirits. Suffered much with headache, eyes tender, gastric disturbances; blind in five days from time when she first noticed dimness of vision. Papillomacular atrophy.

CASE 63.—(From Dr. W. T. Salmon, Oklabama City, Okla.)

H., aged 63, April, 1899. Drank "alcohol." Violent headaches and vomiting. Improved under pilocarpin and potassium iodid. Relapsed and vision was reduced to counting fingers in the left eye at three feet. R. E.=20/200. Central scotoma; optic atrophy.

CASE 64.—(From Dr. W. T. Salmon, Oklabama City, Okla.)

W., Indian Territory, aged 54, May, 1900. This man was one of a party that drank Columbian spirits on Sunday morning. Two stopped at a friend's house for dinner, ate heartily of wild turkey and never noticed any bad symptoms. Williams, however, continued his journey on horseback, riding nearly all day, taking three more small drinks (half a pint), and next morning had headache, dimness of vision, vomiting and was entirely blind in 48 hours. He improved slightly under pilocarpin and strychnia.

CASE 65.—(From Dr. W. T. Salmon, Oklahoma City, Okla.) K., aged 43, October, 1900, Indian Territory. Protracted spree with Jamaica ginger, lemon extract and "peruna." Noticed one morning that a cloud was before his eyes. He became blind in six hours afterward, had headache, vomiting and other gastrointestinal symptoms. The final outcome was optic atrophy, with narrowing of the retinal vessels.

CASE 66.—(From Dr. W. T. Salmon, Oklahoma City, Okla.) S., aged 56, October, 1899. Had been dyeing and cleaning clothes in alcoholic preparations. No evidence that he had drunk the methylated mixture. Headache and vomiting. Vision reduced to perception of light in ten days from first symptoms. Under pilocarpin he recovered most of his sight in 61 days.

CASE 67.—(From Dr. W. T. Salmon, Oklahoma City, Okla.) E., aged 24, January, 1901, Indian Territory. Drank one-half pint of "bitters." Next morning had headache, dimness of vision, vomiting, etc. In 48 hours V. R. E., counting fingers at three feet; L. E. = 20/200. Treatment consisted of pilocarpin, followed by strychnia. When last seen patient's sight was almost normal.

CASE 68.—(From Dr. W. T. Salmon, Oklahoma City, Okla.) M., aged 29, June, 1902, Indian Territory. Drank one pint of Columbian spirits. This was followed by vomiting and headache. Eyes tender on pressure. Result, much diminished vision, central scotoma and contracted fields.

CASE 69.—(From Dr. W. T. Salmon, Oklahoma City, Okla.) S., aged 34, August, 1902. This man drank four bottles of Jamaica ginger, and was found in a semi-comatose condition and totally blind. At first improvement occurred, but in a few days there was a relapse, followed by optic atrophy.

CASE 70.—(From Dr. Norman B. Saunders, Schenectady, N. Y.)

McA., aged 38, single, steamfitter, admitted to New York City Hospital, Aug. 5, 1902, in a condition of delirium due to alcohol. Under the use of large doses of strychnin and high intestinal irrigation he recovered and was subsequently employed as ward attendant. On the morning of Sept. 17, 1902, he was sent to the superintendent's office on account of intoxication the previous evening. He left the ward, but was soon brought back in a state of collapse by two patients. Pupils moderately dilated. Breathing labored and deep. Face flushed. Skin bathed in sweat. Was very restless. He complained of pain in stomach, was nauseated, and said he felt as if he was going to die. He then told the nurse that he had been drinking wood alcohol. Pulse quick and feeble; heart sounds very feeble. Patient said everything looked black; he was actually blind. Asked for water and stretched out his hand, grasping for water. Continued to moan and was restless. Soon had a spasm of muscles of clonic character, the forearm being flexed and drawn tight to the body; cyanotic during spasm; in a few minutes relaxed. In absolute coma. In five minutes another spasm; entire body stiffened; no opisthotonos. Death. The autopsy revealed nothing of importance.

CASE 71.—(From Dr. J. W. Scales, Pine Bluff, Ark.)

H. E., male, aged 46, a hard drinker. Complained of poor vision for a year previous to May, 1903. One evening in the course of one hour drank six ounces of wood alcohol and two of brand. Felt "soggy," but ate supper, got up next morning and ate his breakfast and later his dinner, but about 3 p. m. (22 hours after drinking the alcohol) vomited severely, and at 5 p. m. he went to bed. He slept 24 hours, and on awakening found that he was entirely blind, and remained so for 36 hours. He then saw dim shadows with the left eye. In a month the right eye recognized hand movements. Vision continued to improve slowly for six months, but remained unaltered afterward. At the present time, R. F. = 1/20, L. F. = 1/10. No lens improves vision. Fields greatly contracted, irregularly concentric; all color perception lost. Optic discs very white, with sharp edges. Pupils, very sluggish reaction to light. Nine months later vision was unchanged, despite treatment, and the retinal vessels were narrow, as if there was some endovasculitis.

CASE 72.—(From Dr. J. W. Scales, Pine Bluff, Ark.)

M. O. C., aged 45, railroad section "boss," in December, 1900, drank three bottles of Jamaica ginger, followed by a smaller quantity of bay rum and Hostetter's bitters. During the night he was seized with violent headache and intestinal irritation. In the morning he was blind in both eyes, and, although the other symptoms shortly disappeared, he never recovered his eyesight, the blindness persisting until his death from pulmonary disease, two years later.

CASE 73.—(From Dr. K. W. Sneed, Wortham, Texas, and Dr. J. O. McReynolds, Dallas, Texas.)

A negro, barber, a chronic alcoholic, had been in the habit of

drinking "almost everything," including "bitters" and other patent medicines, as stimulants. He bought some bay rum made with wood alcohol for use in his business. The druggist warned him of the poisonous character of the mixture, but he seems to have disregarded the warning and imbibed an unknown quantity of it on the night of July 30, 1904. At 5 o'clock next afternoon he complained of vertigo and almost total blindness. The following day at noon, when Dr. Sneed saw him, he was suffering from dyspnea, with respirations 10 a minute and very labored; pupils dilated and irresponsive to light; pulse, 104.

Examination showed no organic disease of heart, kidneys or lungs. On Sept. 3, 1904, his general condition had much improved, but his vision was no better. He could barely recognize the outlines of his room door.

CASE 74.—(From Dr. Eugene Smith, Detroit, Mich.)

April 19, 1903, Dr. Smith was consulted by Mr. A. L. B., aged 20, who stated that Feb. 8, 1903, he drank four or five tumblers of wood alcohol. On February 10 was "unable to see to get around." Dr. Smith found his vision to be only perception of light in the right eye; nerve white; all vessels attenuated. Left eye, V. = 10/200. Nerve waxy-white; vessels attenuated. Did not see patient again.

CASES 75, 76.—(Courtesy of the Surgeon General of the Army.)

A. and B. were admitted soon after noon on July 25, 1898, with symptoms of acute poisoning. Both men were able to walk into the ward, and admitted, when confronted with the query, that they had, in lieu of whisky, drank wood alcohol diluted with water and sweetened. They were but two of a number of privates in this regiment who drank this concoction, but having indulged in it to much greater degree than almost any of the others they were more seriously affected. One of their companions died, however, die in his regimental hospital. The symptoms which these two men presented were gastric pain of an acute character, relieved at times by cessation of the pain; almost persistent vomiting, dryness of the mouth and throat, though the tongue and buccal cavity seemed moist. An inordinate and insatiable desire for water which is characteristic of poisoning cases of this class was noticeable in both men, who drank eagerly the water that was given them, only to vomit it a few moments after its reception into the stomach. Temperature of both men about normal when admitted, and did not rise above 99 at any time. The speech quite coherent, but the eyes dilated pupils, incapable of recognizing either persons or things only a few feet distant. A., after an awful struggle in which he tossed about incessantly, crying all the while for water, gradually sank into unconsciousness, in which state he died at 7:30 p. m. the same day. For an hour before death he was almost pulseless, heart dirotic, and toward the last, Cheyne-Stokes' breathing.

B. died at 2 a. m. on the morning of July 26, after evidencing practically the same effects of the poisoning as did A. His temperature at 9 p. m., five hours before death, registered 93.4, but after the application of hot-water bags rose to 95.3. It is believed that both men died from an acute nephritis, although no necropsy was permitted. Both men, it was learned, had been drinking the wood alcohol for two days before admission, but no alarming symptoms made their appearance until the conclusion of 36 hours' time. A. died six hours after admission, and B. 13 hours after.

Treatment: Before admission strychnin hypodermatically for stimulation, and bismuth and egg albumin as a sedative and an emetic. At First Div. Hosp., strychnin, hot-water bags, friction and emulents.

CASE 77.—(Courtesy of the Surgeon General and of the surgeon in charge of the post at Fort Terry, N. Y.)

Private T. H., aged 29. On the same night, Feb. 26, 1904, that four other soldiers had drunk methylated bay rum, he was found drunk and put in the guard house. He denied that he had taken any wood alcohol. Two days later he was reported to be in bad condition, and as having drunk some bay rum and Florida water while in confinement. When he was brought to the hospital he was in a state of partial collapse; temperature, 96; pulse, 80, weak; respiration about 12. Was given strychn. sulph. gr. 1/20 and whisky 8 c.c. hypodermatically; M. of oil. tiglii in oil per os; no applications to body. Bowels not responding in three hours, were emptied by enema, and later freed themselves of oil. Temperature rose to normal in one hour, pulse and respiration becoming stronger. Whisky and strychnin continued till next morning, when man complained of blindness in both eyes; otherwise much improved. As this man had a specific history, he was put on large and increasing

doses of potassium iodid and strychnin. At that time patient could not count fingers at all; light perception remained, but only in lower part of retina, the man having to cast his eyes strongly upward in order to see even light. Under treatment this condition improved for about a week, when it remained the same, though at this time he could count fingers at about 18 inches and could tell time on large-faced clock by putting face about 1 inch from face of clock and hunting each hand separately. April 15, as he showed no further signs of improvement, application was made to have him discharged from service. His retina at this time were congested and edematous, but the visual field was not tested, as he could not see sufficiently well for the purpose. Except for the amblyopia, the man returned to a normal condition, but was discharged April 26, for amblyopia caused by wood alcohol poisoning.

The Columbian spirits taken by this man was bought as such by the common barber in a regular barbers' supply house and was intended for use in preparing his face preparations. He and four other soldiers (whose histories are elsewhere given) went into the barber shop and helped themselves to the stuff either through ignorance of its nature or through an uncontrollable desire to "taper off" from their spree, as most of them had been drinking heavily for a day or two previously. None of them took any wood alcohol after February 28; Nos. 1, 2, 3 and 5 only taking one or two drinks (mixing about 60 c.c. of the poison and an equal part of water). No. 4 took about a pint, the five drinking about a quart in all. Beside this, they drank "Florida water" and bay rum of cheap grades, which doubtless contained methyl alcohol in large proportions.

All of these men were what is known as "booze-hoisters," and Nos. 1, 2, 3 and 5 had been drinking for several days before they took the wood alcohol, and had been on the sick report a number of times for acute alcoholism, yet they strenuously denied, all but No. 4, that they had taken any of the poison, and it was only found out positively at the court martial which followed. Only the Columbian spirits was tested; this was found to be nearly pure methyl alcohol; but the other preparations, being of inferior grade, it is supposed that the alcohol used in their manufacture was impure wood alcohol.

CASE 78.—(From Dr. Frank C. Todd, Minneapolis, Minn.)

H. T. J., aged 45, consulted Dr. Todd on the morning of Sept. 28, 1900. Occupation, painter for 33 years. Referred by Dr. L. B. Wilson. Patient denies syphilis; does not drink more than one glass of liquor in six months. Eyes and sight were normal on Monday, though the patient had suffered from a very bad cold in the head for two weeks. Has worked with wood alcohol frequently, but vision has never been affected, although he has many times been dizzy, and last summer had trouble in accurately determining colors when mixing paint, due probably to the absorption of evaporating alcohol or turpentine while working. Saturday being a rainy day, he did some varnishing with shellac in a small room, and inhaled the alcohol evaporating from the shellac; on Sunday this same work was continued. Patient had purchased what he supposed was pure alcohol, but which proved to be, on investigation, Columbian spirits. This was used in mixing his shellac. Not feeling well, he mixed some of the Columbian spirits with water and sugar, from which he sipped, drinking altogether a glassful or more (only a small portion of this glassful of water, sugar and alcohol was alcohol.) Tuesday, on awakening, he first noticed dimness of vision, and although it was morning he thought daylight had not yet come. He now could read signs, but not ordinary print. Sight was worse Tuesday night, and on Wednesday he could not see the firelight. He then consulted Dr. Wilson, who prescribed strychnin and referred him in consultation to Dr. Todd.

Examination Friday morning showed total blindness in both eyes; careful examination in dark room proved that he had no perception of light. Pupils, medium dilatation, no response. The following treatment was advised and carried out by Dr. Wilson: Catharsis, diaphoresis by the administration of pilocarpin, hypodermic injections of strychnin in increasing doses. After nine days of treatment patient first saw daylight; then his vision rapidly improved. Dr. Todd did not see him again until Nov. 5, 1900, when his sight, with glasses, became normal in every way.

CASE 79.—(From Dr. S. W. S. Toms, Nyack-on-Hudson, N. Y.)

A. B., servant, aged 45, addicted to alcoholism, in March, 1903, deliberately drank, during the absence of her mistress, nearly half a pint of wood alcohol from a bottle so labeled. Early the next morning Dr. Toms was called to see her, on account of what seemed a transitory blindness. This soon deepened, however, and was followed by excitation, which later

lapsed into coma, pulmonary edema and death. As the pupils became widely dilated an ophthalmoscopic examination was comparatively easy, but nothing abnormal was noticed in the fundus.

CASE 80.—(From Dr. J. F. Van Kirk, Whatcom, Wash.)

On Feb. 24, 1902, T. P. presented himself at Dr. Van Kirk's office with the following history: He was 38 years of age, a laborer, of not very good habits, but no history of syphilis. Had always enjoyed good health and exceptionally good vision. On Oct. 4, 1901, while employed as a watchman in a warehouse at St. Michaels, Alaska, he discovered a barrel labeled "Wood Alcohol." On this date, Oct. 4, 1901, he drank about one-half ounce, as he said, to "cure a cold." On Oct. 6, 1901, at 9 a. m., he drank about three-fourths ounce more, and again took a third drink of three-fourths ounce on the afternoon of the same day; in all, 2½ ounces in two days. On the night of October 6 he had occasion to rise, when it was discovered that he could not see a ray of light from the lighted candle in the room. At daybreak his vision had so returned that he was able to walk one-half mile to breakfast. He went about his work until noon, when he felt an oppression in the region of his stomach which prevented him from eating dinner. He continued at work for an hour after dinner, when objects began to look cloudy. This obscuration of his vision increased rapidly until 4 p. m., when he was obliged to stop work, and at 9 p. m. he again became totally blind, being unable to see light from a candle burning in the room. He remained blind from this date, October 7, until October 15, when he began to see a faint ray of light. On Oct. 18, 1901, he took the steamer for Seattle, Wash., where he arrived on October 30. During the voyage his vision so improved that he could walk around unaided. He began to work on the railroad section, but found his vision again slowly failing, more rapidly in the left eye. On Feb. 24, 1902, he came to Dr. Van Kirk for treatment. On examination he found R. E., V. = 20/30; L. E. V. = fingers at 5 feet. Entire lower field in each eye was obscured, with a small central scotoma in both. Color sense uncertain; eyes not tender nor sensitive to light. Right pupil somewhat contracted (or left dilated); both pupils reacted feebly to light, both directly and consensually. Media clear, fundus nearly normal, showing only a suspicious pallor, with arteries somewhat contracted. The discs were clearly atrophic and exhibited an ashy paleness. The treatment consisted of 1.30 gr. doses of strychnin sulph., which was later changed to increasing doses of potassium iodid, without appreciable change in the condition. This case was characterized by frequent transient changes. The vision would be markedly improved for a few hours, and then it would suddenly fail. Often the morning vision would be good, while exercise seemed to increase the amblyopia. The patient continued under Dr. Van Kirk's care until May, 1902, when, at Dr. Van Kirk's suggestion, he secured work on an ocean fishing boat. The marked improvement noticed while on his previous sea voyage was less noticeable now, but some transient benefit was apparent. The last report from him was dated late in the summer of 1902. Vision in the left eye was light perception only. Vision in the right eye was quite useful. The patient was unsteady, and apparently much worse when on land. At this time Dr. Van Kirk lost track of the patient, and has not heard from him since.

(To be continued.)

Clinical Report.

A CASE OF TRAUMATIC ANEURISM.

C. M. TINSMAN, M.D.
ADIN, CAL.

Patient.—Saloonkeeper, aged 45. American, in good health. Aneurism involves all the arteries on the right side of the neck. (Fig. 1.)

History.—At the age of 12, while trimming a tree, it rolled over, one of the limbs striking him under the chin, just in front of the angle of the jaw, cutting a gash from one bone to the other, the scar of which still remains. Three hours after the accident the tongue was swollen to such an extent that he was unable to speak or take nourishment. Four days after the accident the aneurism was as large as to-day and very painful. The swelling of the tongue subsided on appearance of the aneurism. Two weeks after the accident he resumed his work as a farm hand, although suffering continually. About four years later

he was thrown from a horse. This caused what he terms a "forked pain"—that is, pain in front and behind the ear. This pain was so severe and continuous for two months that he contemplated suicide. On the appearance of the jugular vein on the surface of the aneurism (as seen in the photograph) this pain ceased (Fig. 2), and he has only suffered an occasional twinge of pain since. He experiences difficult breathing when in a stooped position, working at hard manual labor, at something above his head, or on getting angry. For the last ten years he has been running a saloon and drinking more or less whisky, and can see no change in it for the last fifteen years except the slight enlargement of vessels along the left clavicle, which may be seen in the photograph. On palpating the aneurism, I find the walls hard, as if calcified, in about one-fourth of the external surface of the sac. This hardened area is in a triangular form, from $1\frac{1}{2}$ inches below the ear to within $1\frac{3}{4}$ inches of the median line of the neck just above the clavicle, therefore covering about one-fourth of the external surface.

I submit to you this brief description of the case, with the photographs, and would like to have an opinion through THE

Now suppose that the blood followed the courses of the vessels and fascias of the neck to their junction with the sheath of the great cervical vessels, and that here, the tissues being loose and yielding, a rapid ballooning occurred, with relief of pressure in the tongue and appearance of tumor of the neck. The time necessary for such a process tallies well with the facts in the history. Such a condition could persist for years. The walls of the new-formed space would become covered with lymph, organization of which would result in the formation of a sac, constituting so-called false aneurism. Great thickening of the sac wall, with ultimate calcareous deposition, is not unusual in these structures. They progress in size but slowly after their original development, and the tension of the blood within them being slight, pain and pressure symptoms are less prominent than in true aneurism. The second injury probably so shifted the sac that it caused pressure or traction on a nerve, possibly the facial, and at the same time altered its relation to the jugular vein. Rupture of the sac into the vein would now explain the sudden prominence of that vessel from over-filling, and, with lowering of the pressure in the sac, we could

Figure 1.

Figure 2.

JOURNAL as to how and why such an injury would produce so large an aneurism in so short a time, and why it does not cause more disturbance than the mere difficulty in breathing only when angry, stooping over, lifting heavy weights, or working with the hands extended above the head?

[The mass in question has the appearance of a vascular structure. Its history of rapid development after receipt of an injury leaves little doubt that such is the case. We hesitate to classify it as a true aneurism because of its too rapid development and subsequent failure to enlarge, and because we lack definite knowledge of its physical signs. It is important to know whether it shows uniform, forcible, expansile pulsation, systolic in time, and whether pressure low down on the carotid alters its size or behavior. We offer the following hypothesis as a possible explanation for many of the features described: Suppose the original trauma to have lacerated an artery of the region now marked by the scar, such, for example, as the lingual where it lies between the geniohyoid and the geniohyoglossus muscles. Blood pouring into the confined spaces between the muscles would then cause swelling of the tongue.

assume relief of the pressure on the nerve. This constitutes varicose aneurism. Somewhat similar cases are reported by Roux, in which the rupture into the vein was delayed for four years, and by Rokitan-sky, in which it was delayed for thirty years. They pulsate feebly, present interesting aus-cultatory signs, show little tendency to grow or cause pain. Pain might be caused, however, by any act capable of raising the pressure of the contained blood. More light might be thrown on the case by careful inquiry into the events which occurred immediately after the injury, such as the extent of external bleeding and the treatment of the wound, and, above all, by a thorough examination of the mass itself.—EDITOR.]

Medical Organization.—Dr. Leartus Connor says: "A real organization of the medical profession must be far more than meetings for the discussion of medical science, as its individual members are far more than mere intellectual machines. As much as possible it must keep in active co-operation all the faculties we have in common under sociological laws."

SATURDAY, OCTOBER 8, 1904.

THE INTERNATIONAL CONGRESS OF ARTS AND SCIENCE.

At an early stage in the preparations for the World's Fair in St. Louis, it was decided to hold an "International Congress of Arts and Science." The special purpose of this congress was to emphasize the relationships between the various branches of knowledge, and thus to encourage harmony and unification in the intellectual world. The authorities of the fair set aside a large sum of money for the expenses of the congress, including the publication of its transactions. And so it came about that during the week between September 19 and 25 there gathered in St. Louis men of science and scholars from practically all European countries, from Japan, from Canada and from the United States. Altogether there were present about 100 delegates from foreign countries, and certainly it must be emphasized that these were all leaders in their respective fields of work. Probably so notable a group of scholars representing so diversified interests has never before been assembled.

According to the program of the organizing committee of the congress, the whole field of knowledge had been so subdivided that the methods, the progress, the relations and problems of each department and its various special branches were made the subject of special addresses. Probably the total number of addresses delivered exceeds 250, and when published these addresses will constitute an authoritative review of contemporary science and scholarship. Naturally, the audiences that assembled to listen to the various addresses varied very much in size and composition; it has been estimated that the audiences averaged about a hundred. In some of the medical sections there was probably a much larger attendance, and, again, in a few the audience numbered scarcely a dozen. While the total attendance fell far short of the anticipatory calculations of the committee, the feeling seemed to prevail in St. Louis, and has been reflected from other points since the meeting, that the congress was a distinct success in spite of the many distractions and disadvantages connected with the holding of an elaborate series of meetings of this kind within the grounds, amid the bustle and confusion, of a universal exposition. The exposition made the congress possible, however, and the congress certainly lends a feature of unique distinction to the exposition. Of course, the full influ-

ence of the congress depends to the largest extent on the publication of the addresses.

In this congress medicine was treated as a department of the utilitarian sciences, and divided into twelve sections,¹ which included the more important clinical specialties, pathology, public health and preventive medicine. Bacteriology, anatomy and physiology were placed in the department of biology. Of course, this arrangement was criticized. Why should not pathology be treated as a pure biologic science? Why two sections for public health and preventive medicine. Like all efforts at classification, even this did not escape shortcomings of this palpable sort; let it be remembered that its chief purpose was to secure the greatest possible degree of order and sequence in the proceedings, and that it does not permanently fix the position of any branch of science. Far from it. The addresses in the medical and biologic sections will make interesting reading for the serious student of medical science, as well as for the non-medical scientist and the scholar in general.

Some of the addresses contain important contributions to science, especially the theoretic side, but the larger number dealt with the general relations and problems of the special branches. Disclaiming all tendency to Chauvinism, it must be said that the American medical speakers acquitted themselves very creditably indeed, which is no small compliment when it is recalled that the foreign delegates numbered among others J. Clifford Allbutt, Wilhelm Waldeyer, Johannes-Orth, Sir Felix Semon, Theodore Escherich, Max Verworn.

If we, in conclusion, ask ourselves the question, How and in what way does this congress contribute to medical progress? then the simplest, most direct answer must be, first, by showing, from a study of the progress as well as of the problems of medicine, the enormous extent to which progress in medicine is dependent on progress in other sciences, especially, of course, in the natural sciences; second, by emphasizing that the exponents of the practical, clinical branches are dealing by means of the same methods with the same problems in different fields of medicine. Surely these lessons in the real unity of knowledge can not but broaden the scientific basis of medicine and thus favor its progress.

THE LONG LIFE OF GERMS IN CLEAN WATER.

It is almost universally acknowledged that water is a carrier of infection, and that the micro-organisms of disease may be contained in what is apparently pure, uncontaminated spring water. It is, however, not generally known that those organisms may live for long periods in such water and retain their full virulence. Indeed, the opinion generally held and borne out by the literature on this subject is that pathogenic bacteria, though they may live for a time in clean water.

¹ Reported briefly on page 1077 of this issue.

can multiply little if at all, and tend to die out rapidly. To this fact is attributed the frequent failures encountered by bacteriologists who have attempted to isolate such bacteria from drinking water. The short life of pathogenic bacteria in water is supposed to be due to the unfavorable environment, to the action of sunlight, extremes of temperature, currents in the water, but above all to the competition of the hardier water bacteria and the absence of proper nutriment. Thus Bolton states that the typhoid bacillus requires at least 67 mg. of nitrogenous matter to the liter of water, the cholera vibrio at least 400 mg. He found that the typhoid bacillus lived only seven days in ordinary tap water. Karlinsky found that the anthrax bacillus and the cholera vibrio sown in water died in seventy-two hours or less, and Kraus, who obtained similar results, states that in this respect there is no difference between pure spring water and very foul well water; under all circumstances water is an "antipathetic medium." These conclusions have been verified many times by other investigators, some of whom lay most stress on the lack of nutriment as a cause of the rapid death of pathogenic bacteria in water, others on the presence of the water bacteria which multiply at the expense of the less hardy pathogenic bacteria. Konradi¹ challenges these statements, and as a result of his experiments asserts that water is an excellent medium for many pathogenic micro-organisms and that, in the long run, it is they which survive and the water bacteria which succumb. He proceeds from the statement made by Mez,² namely, that these organisms live longer in pure than in dirty water, and that, therefore, pure drinking water, once infected, is more dangerous than is foul water.

The bacteria chosen by Konradi for experimentation were the anthrax bacillus and its spores, the *Staphylococcus pyogenes aureus* and the typhoid bacillus. In all these experiments it was found that ordinary bacteria present in the tap water multiplied greatly for a time, but then began to die out, and that, after varying periods, the water kept at room temperature was found to contain a pure culture of the pathogenic organism which, up to complete evaporation, retained its full virulence. Thus the anthrax bacillus and its spores lived for periods varying from 264 to 816 days, having completely conquered the water bacteria after three or four weeks. The staphylococcus aureus was found in pure culture after two months, and lived and retained its virulence for 508 days.

The competition of the water bacteria was greater in the case of the typhoid bacillus; only after more than four months was the latter found in pure culture. It lived in ordinary tap water at room temperature for 499 days. Sterilized water was also found to be a good culture medium for the anthrax bacillus and for the

typhoid bacillus, but the staphylococcus aureus died in a short time in such water.

These results are not only of scientific interest, but of great practical significance. We are accustomed to regard the danger of infection from contaminated water as comparatively short lived, provided the source of contamination be removed. A city which has suffered from an epidemic of typhoid fever, due to infection of the water supply, and which has instituted measures to do away with the source of infection, will consider itself free from danger the following summer, yet, according to the researches of Konradi, typhoid bacilli, living and virulent, may persist for over a year in clean water and proceed to multiply under favorable conditions. This may be one explanation for the recurrence of epidemics of typhoid fever after supposedly rigid sanitary reform of water supply, recurrences which are so discouraging and apparently inexplicable.

THE SANITARY PROBLEM IN PANAMA

One of the first fruits of national medical organization has been an awakened interest and sense of responsibility on the part of the medical profession concerning all matters of national sanitation and hygiene. The reports in the public press of friction between the governor of the canal strip and the chief of sanitation have, therefore, attracted much attention, and THE JOURNAL has accordingly obtained from an authoritative source the facts in the case.

While everything at Panama is not the color of roses, there has been no personal friction whatever between Colonel Gorgas and the administrative chiefs, and the former's sanitary scheme has been adopted by the commission in all its essential features, although with some pruning down of personnel and expenditures. This scheme in general terms contemplates an effective quarantine at Colon and Panama to keep out infectious diseases, including yellow fever, which exist on both coasts, and plague, which is present on the west coast. Also a system of hospitals is being organized for the isolation and treatment of such cases of infectious diseases as appear not only among the canal employes, but also in the civil population of the canal zone. Thirdly, health officers are appointed to carry out all works of sanitary precaution such as the destruction of mosquitoes, disposal of excreta and wastes, and to insure the observance of sanitary regulations in the terminal cities and the villages included in the zone. The Panama government, at whose head fortunately is a physician, has co-operated cordially in this plan of issuing the necessary decrees and by appointing as its quarantine and health officers the assistants of Dr. Gorgas which he has selected for these responsible positions. The quarantine system is already in effective operation in the experienced hands of two officers of the United States Public Health and Marine-Hospital Service. The cleaning up of Colon and Panama is making good progress under health offi-

1. Centralblatt für Bakteriologie, May 28, 1904, vol. xxxvi, No. 2, p. 203.

2. Mez: Mikroskopische Wasser-Analyse, 1898.

cers trained in tropical sanitation by service in the Army. The command of the mosquito brigades along the canal and the sanitary control of the fifteen or more villages distributed along it have been given to one of Colonel Gorgas' most valued assistants in his brilliant work in Havana. About 400 men are now being employed in sanitary work, exclusive of sewers and water supply.

The hospital system as authorized includes the old French hospital on the Hill of Ancon, overlooking Panama, and which has at present about 150 patients, a new hospital for 100 beds now being constructed at Colon, and a number of dispensaries along the line of the canal.

The crux of the sanitary question is involved in the purpose of these dispensaries which requires some explanation. The two diseases which were chiefly instrumental in bringing ruin on the French company were yellow fever and malaria, both infectious fevers spread by the agency of mosquitoes. There is, however, this important practical difference between them, that the yellow fever patient can not spread the disease after the third day of his illness, whereas the infection of malaria persists for months and can be disseminated by persons who are not apparently ill and are engaged in their ordinary pursuits. In fact, in the canal strip it has been found that the population, which is mainly black, and enjoys the well-known tolerance to this disease which is characteristic of the negro race, is universally infected with malaria. This population, exclusive of the terminal cities, numbers about 10,000. The vastness and complexity of the problem of bringing under control this infection which is there so universal, so deadly to the white race and so injurious to the physical energy of all races, becomes apparent. In comparison with it the yellow-fever problem is simple and can probably be readily handled by the present organization along the lines already so successful in Cuba. The antimalarial campaign outlined by Colonel Gorgas is startling alike in its simplicity and its boldness. He proposes first an unrelenting war on the anopheles by means of mosquito brigades, drainage, etc., and second, antimalarial treatment of the entire infected population. For this purpose he asked for twenty dispensaries and twenty physicians, but the commission, deterred probably by reasons of economy and a failure to realize the vital importance of the measure, has so far authorized six dispensaries and three physicians.

This unwillingness on the part of the commission to embark in so large an undertaking, new of its kind and based on a fact of etiology which they perhaps view with skepticism, is not surprising. In view of the fact that the commission contains no medical member this situation was expected, and was predicted by the representatives of the American Medical Association who interviewed the President with a view to obtaining the appointment of a medical commissioner. This defect is a

radical one which will necessarily continue to gravely handicap the administration of sanitary affairs. The problems before the commission are of three kinds—engineering, sanitary and administrative. The failure of the French company was not in engineering, but in the last two. Yet the Americans entrust the work to a commission composed of four engineers, three administrators and no sanitarian. These in their organization naturally repeat this disregard of the relative importance of sanitation. The chief engineer is given a salary of \$25,000, the administrative chief on the ground is a commissioner with a salary of \$12,000, while the chief of sanitation is a subordinate of both and lags far in the rear with a salary of \$7,500. The chief of sanitation has been likewise subjected to a sanitary board composed of his own subordinates. This arrangement, as long as the members of the board are harmonious, is only futile and productive of delays, but if disagreements occur, it will paralyze all vigor of administration. It would seem that the public interest as well as the dignity of the medical profession require that Dr. Gorgas be given a higher status, a freer hand and more authority until the occurrence of a vacancy in the commission will permit his appointment thereto.

BACILLUS DYSENTERIE IN THE SUMMER DIARRHEAS OF INFANTS.

In searching in the intestinal contents or dejecta for bacteria which might be the cause of an infectious disease, investigators have often mistaken the organism present in largest number for the one sought, and have overlooked the specific one which was present in much smaller number. This had been the case in the study of dysentery until Shiga, in 1898, made use of the agglutinating property of the blood of the infected person on the specific organism, to separate it from the other intestinal bacteria. The work of subsequent investigators in various parts of the world seems to have determined that typical dysentery, aside from the amebic form, is always due to the bacilli which are closely related to the one originally described by Shiga. Some of these bacilli have been shown to cause typical dysenteric lesions in experimental animals.

These fruitful investigations in connection with dysentery led to the conduct of studies in similar lines on the intestinal diseases of infants by Duval and Bassett during the summer of 1902. Plate cultures were prepared from the stools of 53 infants suffering from summer diarrheas of various degrees of severity, and from 42 organisms were isolated which corresponded culturally to those previously cultivated from cases of dysentery in adults. These cultures were agglutinated by the blood serum of the patients from whom they were obtained, by the serum of adult patients with acute dysentery, and by anti-dysenteric serum from horses. The specific bacillus was not found in the stools of 25 healthy children. The cases from which dysentery bacilli were

isolated included examples of dyspeptic diarrhea, of enterocolitis, and of malnutrition and marasmus with superimposed infection. Duval and Bassett concluded that their findings justified them in the conclusion that the summer diarrheas of infants are caused by intestinal infection with *Bacillus dysenteriae* (Shiga), and therefore are etiologically identical with the acute bacillary dysentery of adults.

During the summer of 1903, the Rockefeller Institute for Medical Research, under the direction of Dr. Simon Flexner, undertook the further bacteriologic investigation of children affected with various forms of diarrhea. The investigation was carried out directly by some twelve bacteriologists in the cities of New York, Philadelphia, Boston and Baltimore. The results of this collective study are presented, together with a clinical study of cases, in the second volume of the studies from the institute which has just appeared.¹

In general the results of the collective study agree with the earlier ones of Duval and Bassett. Four hundred and twelve cases of diarrheal disease among children were studied with reference to the bacillus of dysentery. Of these 279, or 63.2 per cent., yielded positive results. The cases were mostly unselected, and represented all varieties and degrees of summer diarrhea. The bacteria, cultivated and recognized as dysentery bacilli, represent several varieties or forms which have been included within a group of dysentery bacilli, because of similarities in cultural peculiarities and in the way they are affected by immune sera. It is of interest to note that Duval was able to cultivate the Flexner-Harris bacillus from the stools of two infants who were in perfect health.

In speaking of the results of treatment with anti-dysenteric serum, Holt says that on the whole they were disappointing, but that no unfavorable symptoms followed its use in any case. Out of 83 cases treated with the serum, 38 were fatal, but many were desperate cases. He believes that the profound disturbances of digestion and impaired nutrition would usually prevent any such pronounced effects as follow the injection of diphtheria antitoxin. Acute attacks in which the child's resistance is still good are most favorable.

In the same volume Ford reports the results of a study of intestinal bacteria from 50 autopsies. In 10 cases he found the *Bacillus pseudodysentericus*, which corresponds to the *Bacillus dysenteriae* in cultural reactions, but fails to be agglutinated by the serum from cases of dysentery. The frequent presence of such bacilli in the intestine and the occasional presence of dysentery bacilli in normal stools are most important and emphasize the great caution required in drawing conclusions.

Recent investigations have revealed the fact that not only the bacterium causing an infection may be agglu-

tinated by the serum of the infected animal, but that other and quite different bacteria may be almost as readily and powerfully agglutinated by the same serum. This must make us very careful in accepting the agglutination of an organism by a serum as sufficient proof of infection by the organism.

Altogether these studies have added much to our knowledge of this particular group of intestinal bacteria, but much additional, carefully controlled work is required before it can be generally accepted that the dysentery bacillus is the cause of most cases of summer diarrhea in infants.

MUNICIPAL CONTRACT PRACTICE.

Under the head of "The Socialization of Medicine" a French contemporary¹ discusses a recent decision which, it states, has been adopted by the Federal council of the city of Zurich. This is in effect to levy a medical tax of 4 francs and 35 centimes per head of the population. With the sum thus raised forty physicians are to be selected by the municipality to give free treatment to the citizens. Each physician is to have a salary of \$2,500 per annum as compensation for his work, and presumably, is to receive no further compensation. It may be that forty physicians are a sufficient number for the city of Zurich, but the beauty of the system is not altogether demonstrated by this fact. Our contemporary points out a few of the objections, such as the probability that the more unpopular of the appointees will have a comparatively easy time in earning their salaries while the more popular ones will be worked like dogs. Like every other socialistic plan, moreover, it involves a general leveling down, which will be unprofitable in the end for both the profession and its patrons. The authority of the physician would also suffer in his capacity as a paid public servant subject to every one's call and whim, and it will be fortunate if there is not serious degradation of professional standing and spirit under such conditions. There is apparently no arrangement made for specialists and some developments are to be expected on this account. Will the experiment work satisfactorily even in Switzerland?

SEX DETERMINATION.

There is nothing new in the fact that the determination of sex in some of the lower forms of animal life can be brought about by certain modifications of nutrition. It was discovered by the bee savants many years ago, and they and their relatives and descendants have made practical application of the discovery ever since. There would be nothing extraordinary or excessively startling if we should find out that we could experimentally produce similar results in other forms of animal life not more highly organized than the bees. The statement alleged to be made by the distinguished California biologist, Professor Loeb, that "science is now able to control the sexes, saying whether or not the newly generated body shall be male or female," can hardly refer alone to such matters of ancient history

1. Studies from the Rockefeller Institute for Medical Research, vol. II, 1904. See report in New York News, this issue of THE JOURNAL.

1. Journal de Médecine de Paris, August 28.

as the determination of sex in the lower organisms. The natural assumption is that his statement covered all forms of animal life. There is a vast difference between the hymenopterous insect and the higher mammals, and what may be possible with a simpler organism may be impossible with a higher and more complicated machine. If Professor Loeb's discovery is genuine, its practical importance as applied to mankind is tremendous. How it would simplify certain problems in political economy and what a boon it would be to advanced socialists if we could simplify the complicated mechanism of human society by removing the embarrassing problems connected with the proportion of the sexes and create such a harmonious state of affairs as exists in the communities of the bees and ants. It is a question, however, whether many of our reformers of the present day would like to be put in the class of neutral workers, and yet that is one of the many possibilities that may be imagined should Professor Loeb's alleged discovery be verified. In the meantime, however, it seems to us that a little judicious skepticism is the appropriate thing; the fate of Professor Schenk is still an unpleasant memory.

THE POSTOFFICE DEPARTMENT SUPPRESSES ANOTHER FRAUD.

The postoffice department has issued a fraud order against the Thomas A. Edison, Jr., Chemical Company, of New York, declaring the operations of this company to be fraudulent attempts to make money from the gullible public through the influence of the famous name of Edison. We have previously referred to the so-called magneto-electric vitalizer, which this company puts out. It seems that two attempts were made to patent this device, which is said to consist of two plates of copper with interposed acidulated blotting paper, and the patent office refused both applications, pronouncing the apparatus inoperable and therefore not patentable. The advertisements of the company have proclaimed the marvelous invention of the young Edison, and detailed at length the remarkable effects on disease said to be secured by the use of this instrument. The senior Edison declares that his son has never shown any ability as an inventor or an electrical expert, and that the chemical company has simply given him a salary for the use of his name. The company has issued a paper called *The Magnet*, said to be edited by Thomas A. Edison, Jr. In one issue an editorial headed "Father and Son" dilates on the wonderful ability of both the Edisons and the fame which will be attached to their names in future histories. The famous inventor comes tardily, it seems to us, to the rescue of his reputation. It has been charged that he was not wholly disinterested in his son's enterprise. We trust that there is no truth in such a statement. We prefer to believe that his endorsement of the appropriate action taken by the post-office department has been preceded by serious attempts to correct his wayward son and to restrain the company from linking his name with this notorious fraud. Incidentally, it is of interest to remark that this post-office regulation ought to be an effective bar to such concerns as the one under discussion. The postoffice seems

to be ready to do its part; it is left for the public and the profession to bring to the notice of the authorities the many frauds which are fattening on the public through the medium of the mails.

PROGRESS AND POVERTY

The Chicago newspapers have been deriving some amusement by commenting on the fact that a physician pleaded the good health of the city as a sufficient excuse for not meeting a financial obligation. The subject lends itself readily to the humorist, but, after all, the situation is full of pathos. Since the first of this year, as shown by statistics as well as by the personal observations of physicians in general practice, Chicago has been remarkably healthy. There have been no epidemics among children and adults, save that pneumonia for a time last winter nearly approached the proportions of an epidemic. Preventive medicine has greatly improved the general healthfulness, and the medical profession rejoices at the measure of success that has followed the earnest efforts made to banish communicable diseases. The individual physician who has seen his income dwindle during a healthy year gets no reward, either substantial or honorary, for his small share of the credit earned by the profession as a whole for its beneficent and self-effacing effort. For in Chicago, and in other larger cities, and, for that matter, in smaller towns and villages, many physicians are in dire distress for a living for their families and themselves. Pride makes them hide their plight, and their suffering is not easily imagined. To these the levity of the journalist is bitter irony. Steadily we see ourselves contributing to the health and longevity of the community, and steadily we see our numbers increase. The total sum paid by the community for the care of the sick year by year grows less, and this lessened amount is divided among a number steadily increasing by the annual output of our medical colleges. The process, however tragic for the individual physician, will continue, must continue; for certainly there must not be any let up in preventive medicine; and it would be too utopian and idealistic to expect any of our medical colleges to go out of business, or to stop urging young men and women to enter on the study of medicine.

REPORT OF THE MARYLAND TUBERCULOSIS COMMISSION.

The report of the Tuberculosis Commission of the State of Maryland has just been received. The commission found that the death rate from tuberculosis in Maryland is somewhat greater than for the United States in general and ascribe this in part to the large colored population of the state and the predisposition of the negro to tuberculosis. The report states that the death rate from tuberculosis in Baltimore exceeds that of the state at large and that in comparing Baltimore with the leading cities of the world, it was found that the death rate from this cause has shown a slight rise in the last five years and at the end of 1902 had risen above all other cities except New York. The statistics compiled by the commission show that tuberculosis of

the respiratory organs is the most prevalent form of the disease and that tuberculosis among infants in Maryland forms a much greater factor in the tubercular mortality than is generally supposed. This is particularly the case among colored infants in whom the mortality under two years exceeds the general colored tubercular death rate to a considerable degree. General and meningeal tuberculosis are the most prominent factors in the infant tubercular mortality. In summing up the economic effects of tuberculosis the life history of a consumptive has been divided into three periods: 1. A period of unimpaired earning capacity preceding the onset of the disease and extending into its earliest stages. 2. A period in which the patient is capable of irregular work at reduced wages. 3. A period during which there is an entire loss of earning capacity, with or without a condition of dependency. In this period the patient and his family become, in a considerable proportion of cases, a source of direct loss to the community. The report goes on to state that indirectly the death from tuberculosis of the main supporter of the family entails the removal of children from school before the proper time and starting them out in life with an education so imperfect as to permanently impair their earning capacity. This, of course, tends to lower the general educational standard of the community. The commission considers general prophylactic measures in force in Maryland and elsewhere throughout the country and states that tuberculosis is in many instances a curable disease. The method of treatment outlined in the report includes general hygiene, food and fresh air. Sanatorium treatment is advocated because it insures the proper medical supervision of the patient and a freedom from care and temptation to work, which can rarely be obtained in the home. The establishment of special dispensaries for tuberculosis in the out-patient departments of hospitals is also advised and it is urged that a state sanatorium for the care and treatment of consumptives is greatly to be desired, as even from a purely material standpoint it would prove to be an economic measure. The report concludes with a very full and interesting account of the Tuberculosis Exposition held last January at Baltimore.

Medical News.

CALIFORNIA.

Sanatorium Enlarged.—The Pottenger Sanatorium for Diseases of Lungs and Throat, Monrovia, is being enlarged. The new addition will be ready to receive patients Jan. 1, 1905.

New Hospitals.—The new Redlands Hospital will be completed and turned over to the stockholders early this month. —The St. Frances Hospital Company, San Francisco, have secured a permit and will build a four-story hospital to cost \$50,000, on Julian avenue, between Fourteenth and Fifteenth streets.

Medical Sir Knights Banqueted.—Dr. Curtis G. Kenyon, chief of staff of the medical department of the twenty-ninth triennial conclave of Knights Templar at San Francisco, gave a banquet to those who assisted him, September 18, at the Hotel Pleasanton. —Dr. A. Miles Taylor entertained at dinner at the San Francisco Club, the medical Knights Templar who rendered service during the conclave. Dr. Curtis G. Kenyon, the guest of honor, was presented with a silver tantalus, and Dr. A. Miles Taylor with a cut-glass decanter and set of glasses.

Expert Witness Deserves Expert Fee.—Dr. William A. Whitlock, Merced, was victorious in a contest with the district attorney, September 30. He was a witness in a suit on

trial, and was asked to give expert testimony, but declined to do so until a fee of \$50 had been guaranteed by the district attorney. The circuit judge ordered Dr. Whitlock to testify; he refused, and was committed to jail for contempt of court. After an imprisonment of three hours, the attorney came to the jail, agreed to guarantee the payment of the fee, and Dr. Whitlock went back to court and testified.

DISTRICT OF COLUMBIA.

Much Typhoid.—For the week ended September 24, typhoid fever cases in Washington increased from 278 to 291; 52 new cases were reported, and 39 patients were discharged.

Mortality.—The report of the District of Columbia Health Department for the week ended September 24, shows a total mortality of 104; 55 white and 49 colored. Diarrheal diseases caused 15 deaths; consumption, 14; typhoid fever, 9; apoplexy and heart disease, each 8; kidney diseases, 7, and violence, 5.

Contract Treatment of District Patients.—Dr. William A. Warfield, surgeon-in-chief of Freedmen's Hospital, Washington, in his annual report recommends "that the whole maintenance of Freedmen's Hospital be borne by the United States, and that the district commissioners be authorized to enter into a contract with the Secretary of the Interior for the care, at such rate per capita as may be determined on, of all persons from the District admitted to the hospital for treatment."

ILLINOIS.

Waukegan Hospital Open.—The Jane McAlister Hospital, Waukegan, is now completed and entirely fitted out, and was ready to receive patients October 1.

Memorial Operating Room.—In memory of his son, Louis F. Swift will equip the operating room of the hospital at the Methodist Episcopal Orphanage at Lake Bluff.

The Belleville Epidemic.—At a mass meeting held in Belleville, September 28, a committee was appointed to secure a site for an isolation hospital. At present about 90 cases have been reported to the health authorities.

Condemns Camps.—Dr. Martin W. Cushing, Joliet, has found camps on the drainage canal extension south of Lockport insanitary, and has ordered the buildings put in good condition, and a better quality of food furnished the workmen.

Moves to Chicago.—Dr. Mary M. Mars, Evanston, who resigned in July from the medical staff of the Cook County Hospital for the Insane, Dunning, has moved to Chicago. Her former associates at Dunning a few days ago, presented her with a valuable electrical machine.

CHICAGO.

Bequest.—By the will of the late Mrs. Elizabeth Kelly, the Chicago Baptist Hospital receives a legacy of \$2,000.

Dermatologists Return.—Drs. Joseph Zeiler and James Nevins Hyde, who have been in attendance on the International Dermatological Congress in Berlin, have returned.

College News.—The College of Physicians and Surgeons held its opening exercises, September 27. Dr. Charles C. O'Byrne, made the address. —Illinois Medical College graduated a class of 14, September 29. Judge Holdom delivered the doctorate address.

The Week's Mortality.—During the week ended October 1, 477 deaths were reported, equivalent to an annual death rate of 12.61 per 1,000. There were 20 more deaths than in the previous week and 10 more than in the corresponding week of 1903. Acute intestinal diseases caused 82 deaths; consumption, 44; violence, 42; pneumonia, 40; heart diseases, 35, and Bright's disease, 20.

Professor Northrup Speaks.—At a special joint meeting of the Chicago Medical Society and Chicago Pediatric Society, September 28, Dr. William P. Northrup, professor of diseases of children in the University and Bellevue Hospital Medical College of New York City, presented an interesting and valuable paper on "The Diagnosis and Treatment of Pneumonia in Infants and Young Children."

The Unvaccinated Suffer.—Three cases of smallpox were sent to the Isolation Hospital during the week. Two of these were unvaccinated children, and the third case was an adult who had an imperfect vaccination mark made in childhood. Two deaths occurred during the week—a colored adult and a 4-year-old white child, neither of whom had been vaccinated. These make seven smallpox deaths in one month, while there were only three deaths out of 147 cases during the previous eight months. The present type of the disease is much more severe than at any time during the last six years.

The Healthiest September.—The Health Department announces that September, 1904, takes its place in the vital statistics of the city as that of the lowest September mortality on record. Its total of 1,935 deaths represents an annual rate of 12.33 per 1,000. The lowest previous rate for the month was that of September, 1903, when the rate was 13.42 per 1,000, or 8 per cent. higher, while the average September rate for the previous decade was 15.40 per thousand, or 19.9 per cent. higher. Compared with the corresponding month of last year there were 41 more deaths from the acute intestinal diseases, but 46 fewer from typhoid fever; deaths from consumption, 223, were exactly the same in each month, while there were four more deaths from pneumonia. Among other important causes of death there were fewer from Bright's disease, 11; bronchitis and cancer, 8 each; diphtheria, 26; nervous diseases, 20; scarlet fever, 3; suicide, 7; measles and whooping cough, 2 each. There were 7 deaths from smallpox this September and only 1 in September last year and 26 more deaths from violence other than suicide.

MARYLAND.

Doctors Pay License.—By a new city license law, a special tax of \$10 is levied on every physician in Frederick City, commencing October 1. It is said the physicians will resist its payment, on the ground that the legislature has granted them the privilege of practicing where they please in Maryland, and no municipality has the right to tax them.

Baltimore.

Colleges Open.—The session at the Maryland Medical College was opened with a lecture by Dr. A. D. Macdonachie. At the University and Johns Hopkins there were no formal addresses.

September Deaths.—During September there were 810 deaths reported, of which 268, or one-third, were under 5 years. The chief causes of death were: Consumption, cholera infantum, heart disease, Bright's disease, cancer and apoplexy.

Surgical Building to Open.—There will be addresses at the opening exercises of the new surgical building, at Johns Hopkins Hospital, by Drs. T. Clifford Allbutt of Cambridge University, and Lewis A. Stimson of New York City. Dr. James J. Carroll, U. S. A., the only survivor of the Cuba Yellow Fever Commission, will deliver the address at the unveiling of the Lazear tablet.

Dairymen Seeks to Consult Birth Register.—The health commissioner refused permission to a dairyman to examine the register of births and deaths for the purpose of using the information to extend his business. The dairyman has in consequence brought suit to compel the city to yield to his demand, but the city solicitor says that if the suit is decided against the commissioner an ordinance will be passed by the council prohibiting such use.

Personal.—Dr. Elliot C. Prentiss of Washington sailed from this city for Germany, September 28.—Among Maryland doctors recently at the St. Louis Fair are Drs. Frank J. Flannery, E. T. Duke, E. J. Dirickson, S. K. Waters, J. J. McCurdy, Frederick Carruthers, L. W. Morris, J. E. Myers.—The following have arrived from Europe: Drs. Ross G. Harrison, Samuel Amberg, C. B. Farrar, Karl Osterhaus and W. G. Brown.—Nothing has been heard of Dr. Champe S. Bradfute, who disappeared suddenly several months ago.

Distinguished Foreigners in Baltimore.—A number of distinguished foreign physicians were in Baltimore during the week. Dr. Johannes Orth of Berlin, the pathologist and successor to Virchow's chair and to the editorship of *Virchow's Archiv*, was the guest of Dr. Thomas S. Cullen, and was given a dinner by Drs. Cullen and Welch. Dr. Osler had as his guests Drs. T. Clifford Allbutt, regius professor of physics, Cambridge University, and the author of the "System of Medicine," and Major Donald M. M. Ross of Liverpool, who has acquired fame in the mosquito-prophylaxis of malaria. The latter has gone to Panama. Dr. Allbutt remains to take part in the exercises connected with the dedication of the new surgical building at Johns Hopkins Hospital.—Dr. Desnos of Necker Hospital, Paris, was entertained by Dr. Hugh H. Young and Dr. Osler.—Dr. Theodore Escherich of Vienna, the authority on diseases of children and advocate of the serum treatment of scarlet fever, was the guest of Dr. J. C. Hemmeter.—Dr. Otto Cohnheim of Heidelberg also stopped here.—Dr. Wilhelm Ostwald of Leipzig was the guest of Dr. Harry C. Jones.

MASSACHUSETTS.

Counterfeiter Insane.—Dr. Frank Sauff, Roxbury, indicted for counterfeiting, has been adjudged insane and committed to an asylum.

Nurses' Training School for Harvard.—In connection with Harvard Medical School, a new nurses' training school is to be established. Dr. Alfred Worcester, now at the head of the Waltham Training School for Nurses, is to have charge, and has spent the past few months in Europe studying the hospitals and nurses' training schools there.

Serum in Smallpox. The recent epidemic of smallpox in North Adams, of more than 35 cases, is noteworthy from the successful employment of antistreptococcus serum in at least one case, with the apparent result of shortening the disease and decrease in the severity of signs and symptoms. The patient was a young priest who had not been vaccinated since childhood.

MISSOURI.

Poorhouse Appointments.—Drs. C. C. Drace and A. T. Hayman have been appointed assistant physicians at the St. Louis City Poorhouse, vice Drs. R. E. Kearney and J. B. Childs, removed.

Sentenced for Fifty Years.—Dr. Clarence D. Heflin, St. Joseph, was convicted of criminal assault on his office girl, aged 14, and was sentenced to imprisonment for fifty years in the penitentiary.

Kelly in St. Louis.—Dr. Howard Kelly, chairman of the section on gynecology in the Congress of Arts and Sciences at the World's Fair, held a clinic at Mullanphy Hospital, St. Louis, September 27.

The N. S. Davis District Medical Association.—The Northeast Missouri Medical Association has been reorganized and the name changed to the N. S. Davis District Medical Association. This association is composed of Lee, Van Buren, Davis, Appanoose and Wayne counties in Iowa, and Clark, Scotland, Schuyler, Putnam and Mercer counties in Missouri. One of the requirements for membership is that the applicant be a member in good standing of his county society. Dr. F. B. Miller, Kahoka, Mo., is president, and Dr. E. E. Parri-h, Memphis, Mo., is secretary. The next meeting will be held next Tuesday, October 11, at Memphis.

NEW JERSEY.

Hospital Incorporated.—Articles of incorporation of the Essex Private Hospital Association were filed in Newark, September 20. The incorporators named were Drs. Carl W. Lippe, Maurice J. Klein and Theodore Teimer. The capital stock is \$6,000.

Diphtheria in Newark.—Diphtheria is widely spread throughout the city, and seems to be rapidly increasing. During the week ended September 3 there were 27 cases reported, and in the following week 53 cases. During the week ended September 17 51 cases were recorded.

Camden's Public Bath.—The total number of bathers at the public bath-houses during the year numbered 41,239. During the year 1903 there were 46,944, a decrease this year of 5,705. There has been a greater attendance of white than colored females, the respective figures being 6,026 and 5,888.

NEW YORK.

Buffalo College Opens.—The Medical Department of the University of Buffalo opened for the session of 1904-1905, September 26. Dr. Thomas McKee delivered the opening address.

Summer Charities Close.—Cradle Beach and the Fresh Air Mission Hospital at Ahol Springs have closed for the season. There is a deficit of \$3,053.39. An appeal has been made to all interested in this particular charity for contributions.

Increase in Typhoid in Buffalo.—There is the usual increase in the number of typhoid cases, a census of all hospitals showing 50 cases, and there are probably as many cases in private practice. The health commissioner again urges the boiling of all drinking water.

Pollution of Lake Champlain to End.—Owners of country seats along the shores of Lake Champlain have been conducting a vigorous campaign both in this state and in Vermont, against pollution of the water by refuse from pulp mills. At last a process has been invented and successfully put into operation for the evaporation of the waste liquor thrown out. The water is not only freed from all foreign substances, but the

fiber and other materials taken from it have become a valuable product for sizing paper.

New York City.

Personal.—Dr. Iral B. Brownell arrived on the *Aronland* September 27.—Dr. William S. Ely arrived on the *Potsdam* September 27.

Bellevue Valets Must Go.—The house staff at Bellevue Hospital have lost the day in their battle to retain their male attendants. Chanbernaids will hereafter attend to the rooms and clothing of the house staff.

Benefits for Hospitals.—The military band of the Garde Republicaine will give a concert October 16 for the benefit of the French Hospital, now in course of erection.—The Alliance of Mt. Sinai Hospital will hold the first of a series of subscription dances at Hotel Astor.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended September 24, 307 cases of tuberculosis, with 107 deaths; 234 cases of diphtheria, with 28 deaths; 84 cases of typhoid fever, with 19 deaths; 68 cases of scarlet fever, with 1 death; 42 cases of measles, with 3 deaths; 11 cases of variella, 4 cases of smallpox, and 13 deaths from cerebrospinal meningitis.

Plan to Check Pneumonia.—The special commission which will make a study of pneumonia for the Department of Health and endeavor to formulate measures to curtail the alarming spread of this disease will hold its first session this month in this city. This commission is composed of Drs. William H. Welch, William Osler, Edward G. Janeway, L. Emmett Holt, T. Mitchell Prudden, Theobald Smith, John H. Musser and Frank Billings.

Deaths from Typhoid Increase.—The figures for the first three weeks in September show the total number of cases reported to be 441, with a death rate of about 20 per cent. The highest death rate last year was 13.4 per cent., and the largest number of cases reported, 324, was for the first four weeks in October. To a certain extent the increased number of cases is due to the activity of the Health Department, which is on a never-ending hunt for typhoid.

Asylum Officials Accused.—H. J. Bebro, known as the "Charles Reade of America," was heard in the Supreme Court in behalf of James P. Haughey, who is seeking release from the State Asylum at Matteawan. Mr. Bebro claimed that there are a number of sane persons detained in the asylum and subjected to cruel and inhumane treatment. The court ordered Haughey back to the asylum and appointed Dr. Edward C. Spitzka and Charles L. Dana to examine him.

Medical Colleges Open.—The College of Physicians and Surgeons of Columbia University was opened by a brief address by President Butler, after which Dr. John G. Curtis, acting dean, addressed the students on "Our Medical Training in the Light of Ancient Error." The enrollment of freshmen numbered 87, as against 100 on the opening day of 1903. The opening exercises of the New York University Medical College were presided over by Dr. Henry M. McCracken. Here the entering class showed a gain of 20 per cent. over last year, the new class numbering 150.

Complications Arise for Spratling.—Further complications now tend to postpone indefinitely the appointment of a superintendent to Bellevue Hospital. The municipal service, which refused to accede to Dr. William P. Spratling's transfer to this position unless he should successfully pass a competitive examination, is now under charges made by the Civil Service Reform Association, which has not sufficient members at the present time to constitute a working quorum. Should a quorum set the date and hold the examination, and should Dr. Spratling compete and obtain the highest marking, the fact that Civil War veterans are on the eligible list might prevent his obtaining the appointment.

Report of Rockefeller Institute.—The second annual report of this institution has just been published. It deals largely with bacteriological investigations of different forms of diarrhea in children. Twelve bacteriologists have had charge of the present investigation. Of 372 cases studied 73 proved fatal. The antidyenteric serum used was made from horses by the injection first of dead cultures and later of living cultures of dysenteric bacillus. Dr. L. Emmett Holt, in summing up the results of the work, states that the dysenteric dejection seems to be contagious, but how and to what degree is not yet proved. The spreading takes place most likely through the discharges, and this calls attention to the necessity for disinfection and the close attention to prevent contamination of

food or water. In all there were 85 cases in which the antidyenteric serum was employed; 38 of these were fatal. On the whole, the results were disappointing. Several factors worked against success. In a large proportion of the cases the serum was used late in the disease as a rule, was employed only in the most severe cases, and finally, at the beginning of the season, no rules had been formulated as to the size and frequency of dosage; hence it was evident that many of the doses were too small. Dr. Holt does not think from his personal observation that an adequate trial of the antidyenteric serum has yet been made. As a result of the investigations it is recommended that central distributing milk stations be established under city control, at least from May 15 to September 15, and that closer inspection of small milk dealers be instituted.

PENNSYLVANIA.

Combining Editor and Secretary.—Dr. Cyrus Lee Stevens, Athens, who has been for so long the efficient secretary of the Medical Society of the State of Pennsylvania, had added to his duties at the recent meeting those of editor and publisher of the *Pennsylvania Medical Journal*.

Typhoid in West Chester.—The typhoid fever situation in West Chester remains unchanged, and, indeed, the epidemic is more serious than at any time since the outbreak. Secretary Woodward of the board of health estimates the number of the cases as 30, and attributes the prevalence of the disease to sewage conditions. It has been observed that more cases have appeared along the milk route of William G. Embree, a dairyman. Of the 50 cases reported since March, more than 20 have occurred in families supplied with milk by this individual. He has been asked to withdraw from the business by the local board of health.

Meeting of State Medical Society.—The Medical Society of the State of Pennsylvania held its fifty-fourth annual convention in Pittsburg, September 27, 28 and 29. Dr. William B. Ulrich, president, Chester, called the meeting to order. Dr. Adolph Koenig, Pittsburg was elected president. The other officers elected were Drs. Erasmus V. Swing, Coatesville; Walter S. Stewart, Wilkesbarre; Joseph M. Corson, Chatham Run, and James B. Ewing, Uniontown, vice-presidents; Dr. Cyrus Lee Stevens, Athens, secretary; Dr. Theodore B. Appel, Lancaster, assistant secretary, and Dr. George W. Wagoner, Johnstown, treasurer. Scranton was selected as the place for the 1905 meeting.

Philadelphia.

Tropical Medicine at Jefferson.—Major Walter D. McCaw, surgeon, U. S. Army, will give the course in tropical medicine in Jefferson Medical College in place of Major Charles S. Kieffer.

Home from Abroad.—Dr. J. William White returned home after spending the summer in Europe. Most of his time abroad was spent in the Apennines.—Dr. and Mrs. John Marshall returned home after a lengthy tour of Europe.

Resignations.—Dr. Conlin C. Stewart, assistant professor of psychology; Dr. R. Max Goepf, instructor in physical diagnosis, and Dr. Charles E. Ruffell, assistant demonstrator of histology, in the Medical Department of the University, have resigned.

Donald Ross to Lecture.—Major Donald M. Ross, the famous English authority on malaria, will deliver a series of lectures in the Medical Department of the University of Pennsylvania some time during the year, on "Causes and Cure of Malarial Fever."

New Ambulance for German Hospital.—A modern ambulance was presented to the Jewish Hospital by the residents of Olney and vicinity. The presentation was made by Rev. William H. Wells, and it was accepted for the Hospital Association by Judge Mayer Sulzberger.

New Hospital for Chestnut Hill.—The new hospital erected in Chestnut Hill was opened for the reception of patients October 3. The hospital has been erected and will be maintained by the residents of the vicinity. Its purpose is to provide medical attention for the poor and needy of the neighborhood. Accommodations, however, have been provided for pay patients.

Honor Distinguished Visitors.—A reception in honor of Prof. Dr. Oscar Liebreich of Berlin was given by John V. Shoemaker at his residence October 1.—A special reception was given in honor of Sir Lauder Brunton, F.R.S., and Prof. T. Clifford Allbutt by the Medical Club, October 3, at which

Dr. Edward E. Montgomery presided. —Dr. Charles H. Frazier gave a dinner at the Bellevue-Stratford, September 28, in honor of Prof. Johannes Orth, Sir Clifford Allbutt, Sir Lauder Brunton, and Prof. Theodore Escherich.

Health Report.—The deaths for the week numbered 399, as compared with 401 during last week and 400 during the corresponding week of last year. Diphtheria was more prevalent than for several months past, 73 cases of the malady with 9 deaths being reported, as compared with 53 cases and 7 deaths during the preceding week. Typhoid fever is still on the increase, 80 cases with 7 deaths being recorded. Last week there were 97 cases and 7 deaths. The new cases this week, therefore, were 16 less than last week. A case of smallpox has appeared, and this necessitated the reopening of the smallpox hospital. In all, there were 200 cases of contagious disease reported, an increase of 14 over the previous seven days.

Exercises at Opening of University.—The University of Pennsylvania opened September 30, as stated in THE JOURNAL, October 1. After an address by Prof. Horatio C. Wood, Sir Clifford Allbutt, regius professor of physics, at Cambridge University, England, was introduced and made a brief address. Dr. John H. Musser made the formal address of the evening. He said that not as practical men following the profession as a business would they attain that success which means the fullness of life. As idealists alone they would fail to attain that happiness which comes to a completed life. Only as men of science ever seeking the truth, would the fullness of life, the rounding out of a career, come to them in medicine. Other distinguished men present were Dr. Johannes Orth, the distinguished pathologist and successor of Virchow, of Berlin, Prof. Dr. Theodore Escherich of Vienna, the authority on diseases of children, Prof. Dr. Oscar Liebreich of Berlin, founder and editor of the *Therapeutische Monatschrift*, and Sir Lauder Brunton of London, the English authority in pharmacology and materia medica.

GENERAL.

Naval Medical School Opens.—The Naval Medical School, Washington, opened October 1 with 20 student officers in attendance. The only faculty change is that caused by the absence of Medical Director John W. Ross, who is on duty with the Panama Canal Commission, whose place on the faculty is filled by Medical Director Phillips A. Lovering.

Reciprocity Convention.—A meeting of the American Confederation of Reciprocoating Examining and Licensing Boards will be held at the Hamilton Hotel, St. Louis, October 25. Reports are to be received and acted on as follows: Uniformity as to scope and character of examinations by state medical boards; uniformity of entrance and graduation requirements to be demanded of medical colleges; advanced standing and uniformity of forms.

Army Health Better.—The annual report of Surgeon-General Robert M. O'Reilly states that the health of the soldiers of the U. S. Army has improved during the past year. There were sent home on sick orders a number equal to 56.44 men per thousand troops. A provisionally favorable report on the treatment of leprosy is given, in view of the marked improvement said to have followed in the case of a soldier, a leper, now isolated at one of the southern army posts.

Tuberculosis Congress.—The so-called International Congress on Tuberculosis, at its session at St. Louis, adopted resolutions calling on all civilized governments to appoint commissioners of public health, with seats in the cabinets or governing bodies of their respective countries, in order to aid in checking the spread of tuberculosis. The question of municipal sanitaria was discussed, and a resolution passed urging government authorities to establish and maintain institutions where tuberculous patients may be isolated and where they may receive suitable treatment for their condition.

CANADA.

Foreign Visitors.—Sir Felix Semon, one of England's throat specialists, has been visiting Dr. H. T. Birkett of Montreal. He is a famous deer stalker in Scotland and has gone on a hunting trip into New Brunswick. —Dr. Thompson, a member of the British House of Commons, who is visiting medical institutions of America, is in Montreal inspecting the hospitals and medical colleges. —Dr. Squire Sprigge, London, England, is visiting in Toronto.

Strathcona's Gift to McGill.—At the opening of the winter session of the Faculty of Medicine of McGill University Dean

Roddick announced that Lord Strathcona had contributed an additional \$50,000 for the general purposes of the medical faculty. Lord Strathcona and Sir William Macdonald have each also contributed \$25,000 toward the proposed new gymnasium. The opening lecture of the session was delivered by Professor Abbott of the University of Pennsylvania, the subject of whose address was "The Study of Medicine and Recent Advances in Medical Science."

Personal.—Dr. Simon J. Tunstall, Vancouver, B. C., president of the Canadian Medical Association, has been visiting in New York, Boston, Montreal and Toronto. —Mr. Irving H. Cameron, professor of surgery in the University of Toronto, has returned from England. Mr. Cameron headed a deputation consisting of Prof. J. J. McKenzie, Dr. G. H. Burnham and himself, which invited the British Medical Association to convene in Toronto in 1906. The council of that association recommended that the invitation be accepted. This will be the second occasion that the British Medical Association has convened in Canada. —Dr. J. A. Leduc, formerly a house surgeon at Notre Dame Hospital, Montreal, has gone to Boston to spend one year in the Civic Hospital, preparatory to taking up work in the new civic hospital to be attached to the new Notre Dame Hospital.

FOREIGN.

Beri-beri Among Japanese.—It is reported that beri-beri is causing considerable suffering among the Japanese troops at the seat of war.

Cholera in Russia.—It is reported that cholera has appeared at Nijni Novgorod and Saratov, towns of about 100,000 population, both situated on the Volga.

Fine for Misuse of von Noorden's Name.—The proprietor of a patent medicine in Germany was recently fined \$125 for the statement that Professor von Noorden was peculiarly interested in the manufacture of a certain pancreas extract.

Visit of French Medical Men to London.—A party has been organized at Paris to visit the medical institutions of London this month. Nearly 150 French physicians and surgeons have handed in their names to the committee, including about 20 professors in the medical faculty. Extensive preparations have been made in London for the reception of the visitors, including a banquet at the Hotel Cecil.

Number of Physicians in Russia.—The number of registered physicians in the Russian empire is now 21,827, of whom 737 are women. All but 2,659 reside in European Russia. Siberia has 788, the Caucasus district 1,224 and the Central Asia possessions 459. The last restrictions have been removed from the medical career for women, and the graduates of the woman's medical college at St. Petersburg now rank in every respect with the graduates of the other medical schools of the empire.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

TREATMENT OF UNETHICAL MEMBERS OF COUNTY SOCIETIES.

A president of a county society in Kansas writes: "I have had some trouble in knowing just what to require of members. Nearly all of the members of our society are doing an ethical business, but a few constantly advertise through locals in the daily papers, by announcing births, operations, illness, etc.; also writing them selves up in the paper and letting it appear as though a reporter had done it. Some advertise themselves as medical institutes. Now, for the sake of the society we took these all in who were regularly licensed to practice, and hoped to be able to straighten them out in the society. What course should we pursue so as not to disrupt the society? Some of our members advocate leaving them alone, and others desire stringency. Should this be governed by special enactment by our local society or is it covered by state or national rules? I have the 'Principles of Ethics,' but it is hardly explicit enough for this case."

ANSWER.—There are county medical societies whose members are of broad caliber and liberal spirit that during reorganization received into membership every regularly licensed physician in the county. The original members, actuated by the true and kindly spirit of professional brotherhood, hoped thus to be able to reform the sinners. In some instances their efforts have met with failure, and some of the new members persist in advertising through locals

in the daily papers by announcing births, operations, illnesses and adding their own names. This is petty business, but decidedly reprehensible. If the public was yet sufficiently well posted to realize that those physicians who feel the need of doing this have not much else to commend their services, the matter could be left to natural evolution for its cure, which would, of course, be accomplished by elimination. Unfortunately the public is not prepared to care for itself in this respect, so that the organized profession must act, no matter how unpleasant may be the performance of duty. Such members first should be confidentially interviewed by a tactful committee and urged to do better, and intimation should be made that unless this is done they must forego the real benefits of organization. In case of members who sell themselves to quack advertising institutions the society's duty is clear. These should be told that they must make choice between the society and the institution. In case of refusal to cease advertising by alias they should be expelled. These offenders who are openly regular, but who secretly have their cases more or less fully "written up" for the newspapers, are usually hard to get at, because of the difficulty of obtaining evidence of their secret peccadillo, and frequently because their professional prominence is such that few, if any, desire to talk directly to them as should be done. Tactful older members should be entrusted with this task whenever possible. Such offenders will very seldom require expulsion. In all cases of ethical shortcoming the county society ought always to approach the judgment seat in a spirit of largest charity toward the erring brother. Few of us are without sin. The temptations of competition for existence in an overcrowded profession are great. But the chronic sinner who, after repeated warning and forgiveness, fails to live a professionally decent life has no place in the organization. As to special rules to govern particular misdemeanors, each county society is fully authorized to legislate for itself. The "Principles of Ethics," by resolution of the American Medical Association, was declared to be a "suggestive and advisory" document. As such, and it is a pure and altruistic guide. It should suggest the spirit of the ethical legislation of each county society. The "Principles of Ethics" provides no penalties, this being left entirely to the judgment of the county society. Legislation may thus be varied to suit local needs, and the way is open for interesting simultaneous experiments to determine the most effective methods of maintaining an approximation to the highest ideals of professional deportment. Most of us do not yet realize the many possibilities for professional growth that have been opened up by the reorganization.

AGGLUTINATION TEST FOR TYPHOID.

To the Editor:—Will you give in THE JOURNAL the method for the improved test for typhoid, as mentioned in your editorial some weeks ago; also Ruediger's improvement on it, and where published?

J. WHALEY.

ANSWER—Ruediger's "Improved Technic of Agglutination in Typhoid Fever" appeared in *The Journal of Infectious Diseases*, 1904, vol. 1, p. 236. The method may be briefly summed up as follows: Inoculate a large quantity of plain bouillon (100 to 500 c.c.) with a recently isolated typhoid bacillus, incubate at 36 C. for 24 hours, and then add 1 c.c. formalin for every 100 c.c. of culture. This kills the organisms, and the mixture may be kept for future use, but it must be shaken before using. To make a test proceed as follows: From the lobe of the ear collect 4 drops of blood in a test tube, or a small vial, containing 2 c.c. of a 1/500 solution of formalin in distilled water. This takes the blood, making a clear solution of a dilution of 1/10. To 1 c.c. of this solution add 1 c.c. of the formalized culture, making a dilution of about 1/50, and set it aside where it will not be shaken. If there is agglutination, the organisms collect in clumps, and within an hour or two are seen as a flocculent precipitate slowly settling toward the bottom. It is always best to make a control tube with normal blood, or by simply adding 1 c.c. of distilled water to 4 c.c. of formalized culture. The control tube should remain uniformly turbid. The mixture of blood and formalized culture may also be studied under the microscope in the form of a hanging drop, when agglutination will be observed in the usual way. When dried blood must be used, collect 4 drops on a glass slide, spread it a little by tilting the slide, and allow it to dry. This may later be dissolved in 2 c.c. of distilled water, making a dilution of 1/10, which is used as directed for the solution of fresh blood.

PHYSICIANS' CARDS.

CHICAGO, Sept. 24, 1904.

To the Editor:—Will you inform me if the following card is proper, or would it be better form to omit the word "oculist"?

DR. JOHN JONES.

OCULIST.

Hours: 9 to 1.

Bay State Building, Chicago.

ANSWER.—If unwritten laws, which are the most binding of all regulations, were uniform throughout the country, it would be an easy matter to reply to this question. It is to be regretted that invariable rules governing such matters do not exist in the United States. Thus, the appearance of the word "oculist" on the professional card of a physician would be resented as a deadly offense in some sections of the country, but would be regarded with equanimity and probably with approval in other localities. On the whole, it is not considered good form, and we think there is reason for this. In the first place, the good old word oculist has been made

much use of, by charlatans and by others who would divorce ophthalmology from medicine, so that its employment to designate one who limits his practice to diseases of the eye has somewhat fallen into disrepute. We would, therefore, suggest to our correspondent, if he feels called on to place any qualifying phrase on his card, that he use the words, "Practice limited to diseases of the eye."

REQUIREMENTS FOR PRACTICE IN MEXICO AND SOUTH AMERICA.

— — —, MANTOBA, Sept. 27, 1904.

To the Editor:—What are requirements to practice medicine in South America and in Mexico? Which part of either country would be suitable so far as climate and practice is concerned?

C. W. M.

ANSWER.—We understand that, in order to be a legally qualified practitioner of medicine in Mexico, it is necessary to pass an examination. The examinations vary in the different states, but all are conducted in Spanish and are very severe. In South America a knowledge of Spanish is required, and all examinations, which are principally oral, are conducted in Spanish. The climate varies according to locality, of course.

GRATUITOUS SERVICES TO DENTISTS.

OKLAHOMA CITY, OKLA., Oct. 2, 1904.

To the Editor:—Are physicians bound by any law or code of ethics to furnish gratuitous services to the family of a dentist who is not a physician? A case is now pending in our court, in which a physician is trying to recover a fee from a dentist for services rendered to his child, and the dentist claims that he is entitled to exemption from the payment of physicians' fees, on ethical grounds; and he claims that certain physicians will corroborate his statement in court. Please enlighten the readers of THE JOURNAL on this subject, so they may be enabled to testify intelligently.

S.

ANSWER.—Physicians are not "bound" to give gratuitous services to anyone.

Marriages.

FRANK A. METCALF, M.D., to Miss Rebecca L. Day, both of Chicago, September 21.

SHEPHERD A. WARE, M.D., to Miss Clarice Duncan, both of Springfield, Ill., August 15.

FRANK C. PARKER, M.D., to Miss Grace Croft, both of Norristown, Pa., September 22.

CHARLES A. HENRY, JR., M.D., Fostoria, Ohio, to Miss Mae Weatherston of Chicago, October 4.

ALFORD J. FARNHAM, M.D., Reinbeck, Iowa, to Miss Lillian Burns, in Waterloo, Iowa, September 14.

JAMES HOLLINGSWORTH, M.D., Avon, S.D., to Miss Grace Burgess of Vermillion, S.D., September 28.

VINCENT ALLAN FARRELL, M.D., to Miss Marie Delight Gregory, both of Mason City, Iowa, October 5.

J. W. BOWDIN, M.D., Accomac County, Va., to Mrs. N. D. Pimau, at Newport News, Va., September 22.

HORACE C. DODGE, M.D., Steamboat Springs, Colo., to Miss Nelle A. Dyche of Sabetha, Kan., September 28.

FRANK SCOTT, M.D., to Miss Elizabeth Williams, both of West Virginia, at Roanoke, Va., September 19.

ALBERT B. REKERSON, M.D., Mount Vernon, N. Y., to Miss Mary E. Breck of New York City, September 20.

THOMAS ALLEN GROVER, M.D., Washington, D. C., to Miss Ida Holden Rhodes, at Cartersville, Va., September 21.

MORRISON LE ROY HAVLAND, M.D., Glens Falls, N. Y., to Miss Mabel E. West, at Lake George, N. Y., September 8.

HENRY MARVIN HOGSON, M.D., Lonaconing, Md., to Miss Lulalie Shepherd Wilson, Allegany County, Md., September 15.

Deaths.

Phineas J. Horwitz, M.D., University of Maryland School of Medicine, Baltimore, 1845, of Philadelphia, died at Bar Harbor, Maine, September 28, aged 82. Dr. Horwitz entered the United States Navy as assistant surgeon in 1847. During the Mexican War he had charge of the naval hospital at Fontera De Tobasco. Later he was made assistant chief of the Bureau of Medicine and Surgery in the Navy Department, and subsequently Surgeon-General during the latter part of the Civil War. In 1871 he

was made medical inspector, and later medical director. From 1877 until 1883 he had charge of the Naval Asylum in Philadelphia, and was made president of the Examining Board the following year. He retired from the Navy in 1889.

Israel P. Klingensmith, M. D. Jefferson Medical College, Philadelphia, 1875, a member of the American Medical Association, British Medical Association, ex-vice president of the Medical Society of the State of Pennsylvania, fellow of the American Electro-Therapeutic Association, president of the Indiana County Medical Society, ex-president Westmoreland County Medical Society, local surgeon for the Pennsylvania railroad since 1876, medical director of the Blairsville Infirmary, died at his home in Blairsville, Pa., September 27, after an illness of more than four months, which began with pneumonia and ended in paresis, aged 54.

Thomas H. Williams, M.D. University of Maryland School of Medicine, Baltimore, 1848; assistant surgeon and medical director U. S. Army from 1849 to 1858; resigned at outbreak of Civil War, and became successively surgeon, medical director, inspector of hospitals and assistant surgeon-general in the Confederate service, died suddenly at his home in Cambridge, Md., September 17, from apoplexy, aged 75.

Joseph Bion Scott, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1881, a physician of marked ability, a keen diagnostician and a successful practitioner of Gettysburg, Pa., who had been under treatment for nervous disease due to persistent overwork, hung himself at the Friend's Asylum for the Insane, Frankford, Pa., September 24, aged 48.

Edward P. Catlin, M.D. Rush Medical College, Chicago, 1865, assistant surgeon of the 152d Illinois Volunteer Infantry in the Civil War; for many years a member of the Winnebago County Medical Society, which gave a banquet in his honor on Feb. 10, 1903, died from Bright's disease at his home in Rockford, Ill., September 26, aged 67.

George R. Reynolds, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1867, for four years post-master of Plymouth, Ind., while driving across the Pennsylvania Railway tracks at Jacoby's Crossing, near his home in Plymouth, September 25, was struck by a train and instantly killed, aged 63.

John Jackson Selman, M.D. Medical College of Ohio, Cincinnati, 1838, said to have been the oldest physician in Iowa; a member of the committee that framed the constitution of the state, state senator and president of the senate, died at his home in Bloomfield, Iowa, September 25, aged 86.

J. Lively Johnson, M.D. University of Louisville Medical Department, 1884, died at his home in Louisville, October 4, from typhoid fever. He was a member of the Jefferson County Medical Society, Kentucky State Medical Society and the Mississippi Valley Medical Association.

Arthur G. Watson, M. D. University of Maryland School of Medicine, Baltimore, 1872, a member of the Baltimore City Council, died at the Church Home and Infirmary, Baltimore, September 29, after an unsuccessful operation for malignant disease of the bowel, aged 53.

Charles Burr, M.D. Berkshire Medical College, Pittsfield, Mass., 1839, for 50 years a practitioner of Carbondale, Pa.; some-time president of the Luzerne County, Lackawanna and Carbondale medical associations, died at his home in Carbondale, September 19, aged 89.

Juan N. Navarro, M.D. School of Medicine in the City of Mexico, surgeon-general of the Mexican Army throughout the war with Maximilian, consul-general for Mexico to the United States, died at his home in New York City, September 24, 1904, from apoplexy, aged 81.

Henry C. Wheeler, M.D. Jefferson Medical College, Philadelphia, 1877, died at his home in Carbondale, Pa., from paralysis, after an illness of several weeks, aged 54. He was one of the founders of the Carbondale Board of Health, and established a hospital there in 1899.

Thomas Devereux, M.D. Minneapolis College of Physicians and Surgeons, 1901, Army Medical School, 1903, first lieutenant and assistant surgeon, U. S. Army; a native of Minnesota, died at Manila, P. I., from acute tuberculosis, September 24.

William Conrad, M.D. Tulane University of Louisiana, New Orleans, 1897, not Charles Conrad, as erroneously announced last week, committed suicide by shooting himself through the heart, at his home in Cleveland, September 19, aged 35.

Silas Updegrove, M.D. Department of Medicine, University of Pennsylvania, Philadelphia, 1854, a member of the American Medical Association, and at one time coroner's physician, died at his home in Philadelphia, October 1, aged 75.

Alexander Crawford, M.D. Kentucky School of Medicine, Louisville, 1854, for many years a practitioner of Bardstown, Ky., was killed in a wreck on the Southern Railway at Newmarket, Tenn., September 24, aged 68.

Albion Westley Johnson, M.D. University of Vermont, Burlington, 1861, an old practitioner of Kittery, Maine, died at the Cottage Hospital, Portsmouth, N. H., September 19, after a long illness, aged 76.

James W. Carter, M.D. Kentucky School of Medicine, Louisville, 1881, of Emma, Texas, was shot and killed while playing a practical joke on a friend at Estacado, Texas, September 22.

George H. Williams, M.D. St. Louis Medical College, 1882, for eight years physician to the Missouri State Penitentiary, died at Jefferson City, Mo., September 27, after a lingering illness.

John Lowe Free, M.D. University of Maryland School of Medicine, Baltimore, 1848, died at his home in Stewartstown, Pa., where he had practiced since 1850, September 27, aged 83.

P. Paul Boulanger, M. D. Laval University, Quebec, 1892, founder and manager of *La Revue Médicale du Canada*, died at his home in Montreal, September 29, after a short illness.

George S. Conant, M.D. Bellevue Hospital Medical College, New York City, 1877, died at his home in New York City, September 23, from diabetes, after a long illness, aged 51.

John Purcell, M.D. Apothecaries' Hall, Dublin, Ireland, 1841, for 30 years a physician of New York City, died at his summer home in Larchmont, N. Y., September 26, aged 86.

William D. Vaughan, M.D. Rush Medical College, Chicago, 1897, died September 23, at his home in Norwood, Cincinnati, from tuberculosis, after a long illness, aged 29.

Carl F. W. Kordenat, M.D. College of Physicians and Surgeons of Chicago, 1887, died at his home in Reedsburg, Wis., September 21, from consumption, aged 50.

Wallace M. Purcell, M.D. Jefferson Medical College, Philadelphia, 1862, of Cummings, Ind., died at the home of his daughter in Parke County, September 24.

John J. Mackey, M.D. Bellevue Hospital Medical College, New York City, 1882, of Brooklyn, N. Y., died at Bergen Beach, September 24, aged 50.

Johr M. Steck, M.D. Jefferson Medical College, Philadelphia, 1882, died at his home in Smithsburg, Md., September 23, from cerebral meningitis, aged 51.

Reinhard Wernigk, M.D. Rush Medical College, Chicago, 1882, died at his home in Alhambra, Cal., September 16, after a lingering illness, aged 73.

Albert G. Rogers, M.D., for 30 years a practitioner of Carrollton, Mo., and once mayor of that city, died in Buckhorn, Cal., September 7, aged 72.

Neemias B. Cole, M.D. Long Island College Hospital, Brooklyn, N. Y., 1890, died at his home in Phoenix, Ariz., September 11, aged 67.

Samuel Martin Hileman, M.D. Medical College of Virginia, Richmond, 1862, died at his home in Kerr's Creek, Va., September 21.

Joseph W. Gibson, M.D. Northwestern Medical College, St. Joseph, Mo., 1892, died at his home in Utica, Mo., August 24, aged 47.

W. W. Wickham, M.D. McGill University, Montreal, of Charlottetown, P. E. I., died at Ste. Agathe, Quebec, September 24.

Michael W. Gray, M.D. Philadelphia College of Medicine and Surgery, 1854, died at his home in Cave Spring, Ga., recently.

David Hardie, Jr., M.D. Philadelphia, 1901, died at his home in Wilmington, Del., from Bright's disease, September 21.

R. M. Mitchell, M.D. died at his home in Dry Grove, Miss., September 15, after a long illness, aged 75.

L. G. Murphy, M.D., died at the home of his son in Kansas City, Mo., September 23, aged 75.

Columbus H. Felts, M.D. Illinois, 1883, died at his home in Clark Center, Ill., in August.

Francis Moro, M.D. Ohio, 1844, died at his home in Warsaw, Ind., September 11, aged 80.

M. K. Church, M.D. Merri-ville, Ont., died on September 14, aged 76.

State Boards of Registration.

COMING EXAMINATIONS.

Regular Board of Medical Examiners of Georgia, Capitol, Atlanta, October 11. Secretary, I. H. Goss, M.D., Athens.
State Medical Board of the Arkansas Medical Society, Little Rock, October 11. Secretary, J. P. Runyan, M.D., Little Rock.
Kansas Medical Board, State House, Topeka, October 11-14. Secretary, G. F. Johnston, M.D., Lakin.
Michigan State Board of Registration in Medicine, Lansing, October 11-14. Secretary, B. D. Harrison, M.D., Sault Ste. Marie.
Illinois State Board of Health, Great Northern Hotel, Chicago, October 12-13. Secretary, J. A. Egan, M.D., Springfield.
Board of Medical Supervisors of the District of Columbia, Washington, D. C., October 13. Secretary, Wm. C. Woodward, M.D., Washington, D. C.
Board of Medical Examiners for the State of Texas (Regular), Dallas, October 18. Secretary, M. M. Smith, M.D., Austin.
State Board of Medical Examiners of New Jersey, Trenton, Tuesday, Tuesday evening and Wednesday, October 18-19. Secretary, E. L. B. Godfrey, M.D., Camden.
Louisiana State Board of Medical Examiners, New Orleans, October 21-22. Secretary, Felix A. Larue, M.D., New Orleans.
Board of Medical Examiners of the State of California, San Francisco, October 25. Secretary, Charles L. Tisdale, M.D., Alameda.

Virginia June Report.—Dr. R. S. Martin, secretary of the Medical Examining Board of Virginia, reports the written examination held at Richmond, June 21-24, 1904. The number of subjects examined in was 9 and the percentage required to pass 75. The total number examined was 114, of which 88 passed and 26 failed. The following colleges were represented:

Table with columns: College, PASSED, Year, Per Grad., Cent. Lists various medical colleges and their exam results for 1904.

Table with columns: College, FAILED, Year, Per Grad., Cent. Lists various medical colleges and their exam results for 1904.

The general average for all representatives of the Medical College of Virginia who passed was 79.3; of the University College of Medicine, 81.3; of the University of Virginia, 80.3.

Tennessee April Report.—Dr. T. J. Happel, secretary of the State Board of Medical Examiners, reports the written examinations held at Memphis, Nashville and Knoxville, April 5 and 6, 1904. The number of subjects examined in was 8; total questions asked, 64; percentage required to pass, 75. The total number examined was 278, of whom 166 passed and 112 failed. The following colleges were represented:

Table with columns: College, PASSED, Year, Per Grad., Cent. Lists various medical colleges and their exam results for 1904.

Table with columns: College, PASSED, Year, Per Grad., Cent. Lists various medical colleges and their exam results for 1904.

Table with columns: College, FAILED, Year, Per Grad., Cent. Lists various medical colleges and their exam results for 1904.

The general average of all representatives of the University of Tennessee who passed was 78.5; for all representatives of the University of Nashville who passed, 80.4; for all representatives of Vanderbilt University who passed, 81.4; for all representatives of Meharry Medical College who passed, 78.1; for all representatives of Memphis Hospital Medical College who passed, 81; for all non-graduates who passed, 80.9.

The Public Service.

Army Changes.

Fisher, Henry C., surgeon, granted twenty days' leave of absence.
 Vedder, Edward B., asst.-surgeon, granted one month and fourteen days' sick leave.

Usher, F. M. C., asst.-surgeon, granted thirty days' leave of absence.

Chambers, William H., Sorber, Ord. M., Tignor, Edwin P., and Voorhies, Hugh C., contract dental surgeons, relieved from duty in the Departments of the Gulf, Texas, the Missouri and the East, respectively, and ordered to San Francisco for Philippine service.

Bell, Leonard P., Aide, Walter H., Gultard, Alvin M., and Hinson, Morris J., contract surgeons, arrived from the Philippines at San Francisco on the transport *Sherman*, to avail themselves of leave of absence granted at Manila.

Merrick, John X., contract surgeon, ordered to return to station at Fort Missoula, Mont., at the close of the tourist season in the Yellowstone National Park.

Wythe, Stephen, contract surgeon, granted leave of absence for two months from the transport *Buford*, with permission to apply for an extension of one month.

Mason, George L., contract dental surgeon, granted leave of absence for five days before reporting at Fort McPherson, Ga.

Kellogg, William V., contract surgeon, granted an extension of one month to his sick leave of absence.

Whitney, Walter, contract surgeon, relieved from further duty in the Philippine Division, and assigned to duty at Columbus Barracks, Ohio, at the expiration of his present leave of absence.

Vancouver, Alden, contract dental surgeon, returned to duty at Vancouver Barracks, Washington, September 24, from leave of absence.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Oct. 1, 1904:

Lovering, P. A., medical inspector, commissioned medical inspector, with rank of commander, from June 9, 1903.

Barcus, J. W., asst.-surgeon, ordered to the *Southery*.

Shiffer, H. G., asst.-surgeon, ordered to the *Franklin*.

McDonnell, W. N., asst.-surgeon, commissioned asst.-surgeon, with rank of lieutenant (junior grade) from Sept. 10, 1904.

Hierndon, C. G., medical inspector, detached from the Naval Hospital, Yokohama, Japan, and ordered home to wait orders.

Percy, H. T., surgeon, detached from the *Iowa* and ordered to duty in charge of the Naval Hospital, Yokohama, Japan.

Dennis, J. B., surgeon, commissioned surgeon, with rank of lieutenant commander, from March 3, 1903.

Guest, M. S., surgeon, commissioned surgeon, with rank of lieutenant commander, from Jan. 31, 1903.

Peck, A. E., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from March 27, 1903.

Judd, H. W., A. A. surgeon, detached from duty with the Marine detachment, Dry Tortugas, Fla., and ordered to the Naval Hospital, Washington, D. C., for treatment.

Bucher, W. H., surgeon, detached from the Naval Hospital, Yokohama, Japan, and ordered to the Naval Station, Olongapo, P. I., Benton, F. L., P. A. surgeon, detached from the Naval Station, Olongapo, P. I., and to Naval Station, Cavite, P. I.

Bachmann, R. A., asst.-surgeon, detached from the *Supply* and ordered to the Naval Station, Cavite, P. I.

Wheeler, L. H., asst.-surgeon, detached from duty as recorder of the Naval and Medical Examining Boards, Washington, D. C., and ordered to duty at the Naval Museum of Hygiene and Medical School, Washington, D. C.

Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the week ending Sept. 28, 1904:

Vaughan, G. T., asst.-surgeon general, granted leave of absence for fourteen days from October 18.

Bailhache, Freaton H., surgeon, detailed as a member of a Revenue-Cutter Service retiring board to be convened in New York City.

Stoner, G. W., surgeon, leave of absence for eight days from Sept. 19, 1904, under Paragraph 189 of the Regulations.

von Ezdorf, R. H., P. A. surgeon, detailed to represent the Service at the meeting of the Association of Military Surgeons at St. Louis, October 10-15.

Kerr, J. W., P. A. surgeon, detailed as a member of a Revenue-Cutter Service retiring board to be convened in New York City.

Berry, T. D., asst.-surgeon, relieved from duty at Laredo, Texas, and directed to proceed to Stapleton, N. Y., and report to the commanding officer in command for duty and assignment to quarters.

Rucker, W. C., asst.-surgeon, granted three days' extension of leave of absence from September 28.

Collins, G. L., asst.-surgeon, granted leave of absence for four days from Sept. 20, 1904, under Paragraph 191 of the Regulations.

Smith, F. C., asst.-surgeon, granted leave of absence for seven days from Sept. 24, 1904, under Paragraph 191 of the Regulations.

Ferguson, Bismarck, A. A. surgeon, granted leave of absence for twenty-one days from September 27.

Frary, T. C., A. A. surgeon, granted leave of absence for thirty days from October 1.

Goldsborough, B. W., A. A. surgeon, granted leave of absence for one day, September 29.

Gray, R. H., A. A. surgeon, granted leave of absence for seven days from October 3.

Hallett, E. B., A. A. surgeon, granted leave of absence for three days from September 24.

Light, S. D., W. A. A. surgeon, granted leave of absence for five days from October 9.

McMahon, R. L., A. A. surgeon, granted leave of absence for thirty days from November 5.

Marsh, W. H., A. A. surgeon, granted leave of absence for thirty days from October 7.

Goodman, F. S., pharmacist, granted leave of absence for sixteen days from October 5.

Hall, L. P., pharmacist, to proceed to Norfolk, Va., for temporary duty.

Bierman, C. H., pharmacist, to proceed to Tampa Bay Quarantine, Florida, and report to medical officer in command for duty and assignment to quarters.

BOARD CONVENED.

Board convened to meet at Washington, D. C., Sept. 29, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon-General G. T. Vaughan, chairman; Asst.-Surgeon A. J. McLaughlin, recorder.

RESIGNATION.

Sladenburg, Frank, pharmacist of the third class, resigned, to take effect Sept. 20, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ending Sept. 30, 1904:

SMALLPOX—UNITED STATES.

- Louisiana: New Orleans, Sept. 17-24, 5 cases (Imported).
- Massachusetts: Lawrence, Sept. 17-24, 1 case; Lowell, Sept. 10-24, 2 cases; North Adams, Sept. 20-27, 4 cases.
- Michigan: At 42 localities, Sept. 10-17, present.
- Minnesota: Sept. 12-19, Morrison Co., 1 case; Washington Co., 1 case.
- Missouri: St. Louis, Sept. 17-24, 6 cases, 1 death.
- New York: New York City, Sept. 17-24, 4 cases.
- Pennsylvania: Titusville, Sept. 17-24, 1 case.
- South Carolina: Camden, Sept. 17-24, 1 case.
- Tennessee: Sept. 17-24, Memphis, 1 case; Nashville, 2 cases.
- Wisconsin: Milwaukee, Sept. 17-24, 2 cases.

SMALLPOX—FOREIGN.

- Austria: Prague, Sept. 3-10, 1 case.
- Brazil: Rio de Janeiro, Aug. 7-28, 917 cases, 408 deaths.
- China: Shanghai, Aug. 6-20, 4 deaths.
- Great Britain: Sept. 3-17, Bristol, 2 cases; London, 3 cases; Nottingham, Sept. 3-10, 1 case.
- India: Bombay, Aug. 23-30, 3 deaths; Calcutta, Aug. 20-27, 1 death.
- Italy: Palermo, Sept. 3-10, 8 cases, 5 deaths.
- Mexico: City of Mexico, Aug. 28 Sept. 4, 1 case.
- Russia: Moscow, Aug. 27-Sept. 3, 5 cases, 2 deaths; St. Petersburg, Sept. 3-10, 2 cases.
- Turkey: Alexandretta, Aug. 27-Sept. 3, 1 death; Beirut, Sept. 3-10, present; Constantinople, Sept. 4-11, 9 deaths.

YELLOW FEVER.

- Brazil: Rio de Janeiro, Aug. 14-28, 2 cases, 1 death.
- Ecuador: Guayaquil, Aug. 24-Sept. 1, 5 deaths.
- Mexico: Coatzacoacoas, Sept. 11-18, 8 cases, 2 deaths; Sept. 11-17, Merida, 1 case; Tehuantepec, 2 cases, 1 death; Vera Cruz, Sept. 10-17, 1 case.

CHOLERA.

- India: Bombay, Aug. 23-30, 39 deaths; Calcutta, Aug. 20-27, 4 deaths.
- Turkey: Aug. 22, Bagdad, 127 cases, 105 deaths; Basra, 3 cases, 3 deaths; Bazian, 53 cases, 41 deaths; Ilhit, 61 cases, 28 deaths; Mendelli, 27 cases, 10 deaths; Nasrli, 13 cases, 13 deaths.

PLAGUE—INSULAR.

Philippine Islands: Manila, July 23-30, 6 cases, 6 deaths

PLAGUE—FOREIGN.

- Africa: Cape Colony, Aug. 13-20, 1 case, 1 death.
- Australia: Perth, July 29, 1 case; Sydney, July 31-Aug. 6, 1 case, 1 death.
- Brazil: Bahia, Aug. 13-27, 10 deaths; Rio de Janeiro, Aug. 7-28, 21 cases, 8 deaths.
- China: Fuchau, Aug. 8, epidemic.
- Egypt: Aug. 20-27, Achmou (district), 2 cases; Alexandria, 3 cases.
- India: Bombay, Aug. 23-30, 59 deaths; Calcutta, Aug. 20-27, 5 deaths; Karachi, Aug. 21-28, 3 cases, 3 deaths.
- Japan: Formosa, Aug. 13-20, 12 cases, 8 deaths.

Society Proceedings.

COMING MEETINGS.

- AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.
- Tri-State Medical Society of Alabama, Georgia and Tennessee, Chattanooga, October 12-14.
- Assn. of Military Surgeons of the U. S., St. Louis, October 10-15.
- Mississippi Valley Medical Association, Cincinnati, October 11-13.
- Vermont State Medical Society, Rutland, October 13-14.
- New York State Medical Association, New York, October 17-20.
- Medical Society of Virginia, Richmond, October 18-21.
- American Confederation of Reciprocal Examining and Licensing Medical Boards, St. Louis, October 25.

CONGRESS OF ARTS AND SCIENCE.

Proceedings of the Medical Department, held at the Louisiana Purchase Exposition, St. Louis, Sept. 20-24, 1904.

The meetings of the medical department of the International Congress of Arts and Science, held at St. Louis, were well attended by representative medical men of all nations. The meetings were addressed by eminent authorities of international reputation, and the papers were listened to with great interest.

General Medicine.

The section of general medicine was presided over by Dr. William Osler of Johns Hopkins University, and the speakers announced were Dr. William T. Councilman of Harvard and Dr. Frank Billings of Rush Medical College, Chicago. Dr. Billings was unable to be present, but his paper will appear later in THE JOURNAL.

The Modern Conception and Methods of Medical Science.

Dr. WILLIAM T. COUNCILMAN said that medicine progresses by two methods, namely, speculation and observation. He reviewed the progress of medical science and proved that the modern advancement in medicine has been due to observation of clinical material. He attributes its progress largely to the aid of other sciences and inventions. He said that the laboratory formed the basis for research work by offering methods of staining, culture media, chemical analysis, blood counts and x-ray examinations. He also said that surgery has been a distinct aid in the recognition of disease, and refers to animal and plant experimentation in the same capacity. Dr. Councilman made a plea for more comparative study of plant and animal disease to aid in diagnosis. He said also that the knowledge of infectious disease had advanced by the aid of the science of therapeutics, and that the obligation rests on the profession to co-operate with boards of health and aid in the medical education of the public.

Public Health.

The section of public health was presided over by Dr. Walter Wyman, surgeon-general of the United States Marine-Hospital Service. The speakers were Professor W. T. Sedgewick of the Massachusetts Institute of Technology, Dr. E. J. Lederle, New York City, and Dr. A. J. Reynolds of Chicago.

THE RELATION OF PUBLIC HEALTH SCIENCE TO OTHER SCIENCE.

PROFESSOR SEDGEWICK said that public health science was an outgrowth of the eighteenth century. Epidemiology by Sir George Baker, state sanitation and hygiene by an act of parliament, and personal hygiene by Jenner were the origin of the most important divisions of public health science. In 1854 an important advance was made by the discovery that water may be the ready vehicle of disease; then followed a study and investigation as to the cause and prevention of disease. Professor Sedgewick said that to Pettenkofer and his disciples in Germany and to Angus Smith in England is due the important advances in sanitary chemistry. The environment and its control is to-day one of the most inviting fields for work and education. The science of architecture, including the heating and ventilation of buildings, has been a great feature in public health science. Modern engineering has rendered to public health science a greater service than any other science except medicine. Most institutions of learning neglect the training of their pupils in public health science. The community looks to the medical profession for adequate legislation and administration of public health laws.

PUBLIC HEALTH—ITS PRESENT PROBLEMS.

Dr. LEDERLE'S paper was read by proxy. It stated that one of the most important problems which confronts us is the relation of legislation and administration to public health science. We have no national public health officers. Our boards must be co-ordinated and made a part of a national board of health. Public opinion will be responsible for this progress, still the appointment of public health officers must not be controlled by politicians. Scientific men are needed at the head of our health departments. Scientific men, however, can not work for the small fees now paid. We must not depend on the medical profession alone, but must have a class of educated sanitarians. The prevention of the spread of infection will always belong to public health problems, hence we must have provision for public laboratories. These laboratories should be put under national authority so that serum can be obtained at a lower cost and well distributed, and research work be carried on for the good of the community. Better isolation hospitals should be established. It is also a fact that hospitals for tuberculosis can be maintained much cheaper than allowing the spread of

disease in the community. Laws governing spitting, public noises, and offensive trades should be more vigorously carried out. A national sanitary body would control the water and milk supply, prevent the adulteration of food, control the sale of patent medicines and restrict the sale of drugs to graduate pharmacists.

REDUCTION OF TIME BETWEEN THE PRODUCTION OF MILK AND ITS CONSUMPTION.

Dr. ARTHUR R. REYNOLDS, Chicago, said that while state laws and city ordinances prescribe all manner of requirements for dairies, cows and the constituents of milk and cream offered for sale, nothing is said of the age of the milk. He laid stress on the fact that milk 12 hours old is worth very much more from a dietetic standpoint than milk 24 hours old, while milk 36 hours old is not only of little food value, but is positively harmful to infants. Dr. Reynolds went on to say that old milk not only starves young children, but is an inducing cause of diarrhea and "summer complaint," and causes the excessive infant mortality during the hot weather.

Pediatrics.

This department was presided over by Dr. T. M. Rotch of Harvard University. The first speaker was Professor V. Escherich of the University of Vienna.

RELATION OF PEDIATRICS TO OTHER SCIENCES.

Dr. A. JACOBI, Columbia University, New York, spoke on this subject. The first part of his paper dealt with the history of pediatrics. Dr. Jacobi emphasized the importance of hereditary influence, and the care of the mother to the termination of intranterine life. He said that the mortality of infants is greatest in the first year because the functions which exist for the protection of life are not fully developed, and that the solution of the problem of lowering the mortality is intimately connected with the regulation of labor laws, marriage licenses, factories, etc. Dr. Jacobi made a plea to keep working, and said that a life spent in the service of mankind is well spent.

Ten-minute addresses were made by each of the following-named physicians: Drs. W. P. Northrup, New York City, E. W. Saunders, St. Louis, and John L. Morse, Boston.

Therapeutics and Pharmacology.

This section was presided over by Dr. Hobart A. Hare of Jefferson Medical College.

RELATION OF THERAPEUTICS TO OTHER SCIENCES.

Prof. OSCAR LIEBEICHS of the University of Berlin said that the evolution of therapeutics has been influenced by the scientific advances of the last century, that various drugs and their physiologic action in specific cases have been proven, and chemical changes within the body depend on individual cells. He also said that the difference of chemical action within and without the body affords a fertile field of observation and that the numerous discoveries in the nineteenth century prove that we are making as rapid advances in therapeutics as in other sciences.

THE PROBLEMS OF THERAPEUTICS.

SIR LAUDER BRUNTON, F.R.S. of London, said that the object of therapeutics is first to relieve pain, and second to be able to restore health, and that therapeutics might be called an art. He said that our success with drugs depends on the practical power of recognizing symptoms and the art or skill of administering a remedy. It has been the custom to continue to use certain drugs simply because they have been used with success in the past; now we use drugs for a specific purpose. One of the aims of therapeutics is to defend the body from microbes and to apply drugs that will kill them. The art of therapeutics consists in the discovery and administration of drugs that will not only destroy organisms but produce the least destruction to body cells. Serums which will render the are demanded. He also said that the highest aim of therapeutics is to relieve pain and restore health without altering the natural conditions or environments of individual cells.

Ten-minute addresses were made by the following-named physicians: Dr. G. P. Coromilis, Athens; Dr. Henry Laguer, Berlin; Dr. Hunt, Baltimore; Dr. G. A. Matthews, Chicago.

PREVENTIVE MEDICINE.

This section was presided over by Dr. J. M. Mathews, Louisville, Ky. The chief speaker was Prof. Donald Ross, F.R.S., Liverpool School of Tropical Medicine, whose paper entitled "A Logical Basis of a Sanitary Policy for the Prevention of Mosquitoes," was illustrated by means of blackboard diagrams.

Short addresses were made by Drs. W. H. Welch, Baltimore; George Dock, Ann Arbor, and Frank Jones, Memphis, Tenn.

Neurology.

This section was presided over by Dr. L. F. Barker of the University of Chicago.

The first speaker was Professor Kitasato of the University of Tokio, whose paper covered the subject of leprosy.

The second speaker was Prof. J. J. Putman of Harvard, who read a paper on hysteria, epilepsy, and other nervous diseases.

Psychiatry.

This section was presided over by Dr. William A. White of the Government Hospital for the Insane, Washington, D. C.

Dr. C. L. DANA, Cornell University, read a paper on the "Relation of Psychiatry to Other Sciences."

Dr. E. COWLES, Boston, discussed the importance of mental pathology and physiology and defined the terms neurosis and psychosis.

Pathology.

This section was presided over by Prof. Simon Flexner, director of the Rockefeller Institute for Medical Research.

The first speaker was Prof. Ludvig Hektoen of the University of Chicago. He stated that during the period since 1850 and with the perfection of the microscope, pathology had made greater advance than in all preceding time, and that all the sciences were shedding more light and aiding pathology in its modern advances.

Prof. JOHANNES ORTH of the University of Berlin, read a paper entitled "Pathology and Its Relation to Other Sciences." Professor Kitasato of the University of Tokio also made a short address.

Dr. RONALD ROSS, F.R.S., of Liverpool, gave an interesting talk on the life cycle of the malaria parasite in the stomach of the mosquito illustrated by stereopticon views.

Surgery.

This section was presided over by Dr. Carl Beck of the Post-Graduate Medical School, New York. The first speaker was Dr. F. S. Dennis, F.R.C.S., of Cornell Medical School, whose paper was a review of the surgery of the past 100 years. Dr. Beck discussed the advance of surgery in this country with special reference to anesthesia, which has made the extensive practice of surgery possible.

Internal Medicine.

This section was presided over by Dr. F. C. Shattuck of Harvard.

RELATION OF MEDICINE TO SURGERY.

Prof. T. C. ALLBUTT, F.R.S., of the University of Cambridge, gave a history of medicine and surgery from the earliest days to the present time, and showed how medicine and surgery had made progress hand in hand. He believed that the sciences were interdependent and that advance in one would open new fields in the other.

DEVELOPMENT OF MEDICAL SCIENCE DURING THE LAST CENTURY.

Dr. W. S. THAYER of Johns Hopkins University said that to recognize, to prevent, to heal, are the objects of medical science. After the clouds of tradition had cleared away the advance of medical science became possible. Science swept aside the dogmatism of the older schools. Methods now form the basis of diagnosis. The training of the modern physician requires years of work by the bedside and a broader and better knowledge of all methods for the recognition of disease. The hearty co-operation of hospitals and clinics will enable the stu-

dent to gain proper knowledge. It is the duty of the profession to see that their clinical methods keep pace with scientific research.

Ten-minute papers were read by the following: Prof. Paul Courmont, Lyons, France; Prof. F. G. Novy, University of Michigan, and Dr. Henry Sewall, Denver.

Gynecology.

This section was presided over by Dr. Howard Kelly of Johns Hopkins University. The first speaker was Dr. J. C. Webster of Rush Medical College.

IMPORTANCE OF AN EARLY DIAGNOSIS IN CANCER OF THE UTERUS.

Dr. J. N. SAMPSON, Baltimore, said that cancer of the uterus can be cured if operated on in its incipency. To lessen the list of fatal cases, we demand early diagnosis and an increase in the percentage of operative cases. Hysterectomy does not suffice because of perimetrial metastasis to the lymph nodes or lymph spaces in many cases. He said that a careful study of the condition of the patient as to operative interference is necessary, and that it is necessary to impress the profession, and through them the laity, with the fact that cancer of the uterus, if observed in time, can be cured and that bleeding in some form is usually the earliest symptom.

This paper was discussed by Dr. George Gellhorn, St. Louis, Mo.; Dr. H. Ehrenfest, Dr. F. T. Taussig and Dr. C. H. Powell of St. Louis.

It was moved and seconded that a committee be appointed to investigate carcinoma of the uterus for the purpose of helping the profession and enlightenment of the people at large, and their report be presented at the next national medical meeting.

Dr. Sampson, Baltimore; Dr. F. T. Taussig, St. Louis, and Dr. Clark, Philadelphia, were appointed on this committee.

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS.

Seventeenth Annual Meeting, held at St. Louis, Sept. 13-16, 1904.

(Concluded from page 1000.)

Some Clinical Reasons for Advising Early Operations in Cases of Fibroid Tumor of the Uterus.

Dr. RUFUS B. HALL, Cincinnati, discussed this subject under three heads: 1. Which cases should we advise not to be operated? 2. In which cases should we advise later operation? 3. In which cases should we advise early operation? He discussed at some length the clinical history of patients in order to form a correct conclusion. 1. If a patient between 35 and 38 years of age, suffering from a fibroid tumor of the uterus, the tumor and uterus combined making a mass not larger than a cocoonut, had no symptoms other than profuse metrorrhagia, the whole period not extending over five or six days, and she was free from pain except at her menstrual periods, it would be wise and judicious not to interfere surgically. But this patient, during her entire menstrual life, should be considered an invalid by her physician and should report to him at once if her symptoms became aggravated. 2. If she suffered pain in one or both iliac regions at other times than at her menstrual periods, the cause of the pain should be discovered at once and corrected. On the contrary, if her menstrual period was prolonged to ten or twelve days, the loss of blood amounting almost to a hemorrhage, and this hemorrhage could not be controlled or mitigated by the usual internal medication and rest during the period, the advisability of an operation should be considered. 3. Prolonged and severe uterine hemorrhage had not been considered a sufficient reason for advising an operation. A patient suffering from a tumor as large or larger than a cocoonut, who had profuse bleeding at each menstrual period and the period was prolonged for eight, ten or fifteen days, as frequently happened, was in considerable danger. It was his experience that a large majority of those patients in whom the hemorrhage could not be controlled by medicinal remedies in two weeks, came to operation sooner or later. They could frequently stand off the operation two or three weeks, or in some

instances longer, but the anemia was profound, and if some complication arose in the tumor, ovaries or tubes, making an immediate operation necessary, they were in the worst possible condition for it. The chances for a successful operation were greatly diminished. Therefore, when the hemorrhage could not be controlled within a few months, these patients should be advised to have the operation made before the anemia was pronounced. These symptoms, however, were not of so much importance as others, but if permitted to continue for many months they caused profound anemia and lowered vitality, and a high mortality followed the operation.

He regarded hematomata, complicating these tumors, as the gravest complication the surgeon had to deal with in the management of the late cases. His records showed that only one patient in seven operated on for fibroid tumors, where pus tubes were present, developed peritonitis after the operation; while five in every six of those operated on in which hematoma of the ovary existed, suffered from peritonitis following the operation for removal of the tumor. His experience in removing these malignant fibroid tumors had been that within a year or two after the operation for removal of the tumor the patient had a recurrence of malignant disease in the pelvis and abdomen and succumbed within a few months.

Shall We Remove All Fibromata of the Uterus on Diagnosis?

DR. THOMAS B. EASTMAN, Indianapolis, stated that in the 117 cases on which he had operated for fibroid tumor of the uterus, complications which bade fair to result eventually in death were encountered in 43 cases. Hydrosalpinx, either unilateral or bilateral, five times; suppurating dermoid cyst, three times; sarcoma, once; parovarian cyst, once; necrosis of tumor, eight times; cystic degeneration of ovaries, three times; ovarian cyst, four times; intraligamentous development of fibroid, three times; pyosalpinx or salpingitis, seven times; hematosalpinx, once; cystic degeneration of the tumor, once; myxomatous degeneration, three times; adenocarcinoma of the body of the uterus, twice. Among the more prominent complications, appendicitis was encountered once. In addition to the complications inherent in the uterus and its adnexa proper, there were those arising from the pressure of the mass on the bladder, rectum, ureters, and the persistent anemia resulting from prolonged hemorrhages.

In his forty-three complicated cases it was a significant fact that those complications which were inherent in the tumor and which presaged the most certainly fatal results, were those of such character as to preclude a positive knowledge or oftentimes even a suspicion of their existence prior to operation or even a microscopic examination. So far as the danger was concerned, the removal of a fibroma was attended with as little danger as the average abdominal section. The results obtained by various operators warranted one in classing it among the safe operations, the mortality in the hands of skilled men being scarcely more than 5 per cent., a mortality certainly much less than would result from the policy of procrastination, which advocated delay until the forces of death plus those of the operation outweighed those of surgical interference. When one considered the dangerous conditions into which an innocent fibroid might quickly change itself, and the ease and safety to the patient with which it might be removed, he believed that the deduction was evident that all fibroid tumors of the uterus should be removed on diagnosis.

Removal of Skeleton of Ectopic Fetus Ulcerating into Bladder, by Vaginal Cystotomy.

DR. WILLIAM D. HAGGARD, Nashville, Tenn., reported the case of a white woman, aged 31, the mother of two children, who presumed herself to be normally pregnant and expected to be confined August 30, 1900. There was a continuous flow from the uterus for the first three months, and she had pain in the bladder and straining on micturition from the beginning of conception; but there was no history of rupture of the ectopic gestation. On June 20, at six and a half months, while lying down she felt motion for the last time. Previously it had been unusually vigorous, more so than with her two other children. She was confined to her bed for three or four weeks with pain.

She had more or less pain for about a year, and she was a semi-invalid from weakness, pain and tenderness in lower abdomen. The enlargement of the abdomen had gradually, but appreciably, diminished. At the end of a year pus first made its appearance in the urine, and the first day after getting up, a bone, which was a fetal vertebra, made its exit through the urethra. During the second year she had been able to attend to all household duties, but occasionally would have several days of unusual bladder irritation, and pass a bone through the urethra. In the last four months she had passed all the long bones. Sometimes one would catch in the urethra. She would get hold of the free end and gradually pull it out. Commonly several days of comparative comfort would elapse before another one would set up irritation, and finally escape. In this way she passed eighty-five bones. Six weeks before admission to the infirmary she felt the discomfort of another bone and had not been free from it since nor had any bone passed. She had been in bed two weeks with pain in the lower abdomen, which was very intense on motion. Upon examination the bladder was exquisitely tender. She described a small lump to the right of the median line and low down the remains of the once six and a half months' enlargement, but this could not be made out on account of tenderness. The urine was loaded with pus and phosphates, and exceedingly offensive. Curiously enough, the woman did not void it oftener than every six or eight hours. Micturition was very painful, and after the urine was voided free pus was often expressed. Under ether, Oct. 31, 1902, the index finger was made to enter the urethra without much effort, and detected numerous bones, and communicating with the bladder, an opening into a lesser chamber on its right upper surface. There was a mass on the right to be made out bimanually about the size of a small orange, and communicating with the bladder much as a bow window with partially drawn curtains did with a room. The uterus was retroverted and not much enlarged. The bones were much too large to be removed through the urethra, and an incision was made into the vesico-vaginal septum. The finger in the bladder, through the urethra, located the bone, and it was withdrawn with a forceps introduced through the incision. In this way fifty-two bones were removed. Some were embedded in granulation tissue in the remains of the ectopic sac, and were with difficulty removed. The sac and bladder were freely irrigated, and an artificial vesico-vaginal fistula established for drainage, after Emmet's method of sewing the vaginal mucosa to that of the bladder by silver wire sutures. The operation, while tedious, was not attended with shock. The bladder was irrigated twice daily afterward with boric acid solution, and the urine soon became normal. At the end of six weeks the artificial vesico-vaginal fistula was closed successfully by silver wire sutures. A cystoscopic examination with the Bransford Lewis ureter-cystoscope revealed a healthy mucosa, and at the site of the former communication only a slight reddish depression was seen. The urethral catheter failed to disclose any depth to this aperture, and the patient was discharged cured eight weeks after the operation.

President's Address.

DR. WALTER B. DORSETT, St. Louis, president of the association, considered the various operations for the relief of retrodeviation of the uterus. He spoke of the excellent operative work which had been accomplished within the past few years, so that what he had to say was more of a résumé of what had been done surgically. He discussed the methods of operation, saying that the different plans of accomplishing the reposition of the uterus might be classified according to the route selected by the advocates of each. They might be divided into extraperitoneal, vaginal and intra-abdominal. After considering and discussing exhaustively the different methods in vogue and indulging in some criticism of them, he stated that some of the methods did not merit the prominence they had obtained in the estimation of the profession at large, and for the reason that no one could arrive at a proper conclusion as to the best method of relieving the suffering woman without a careful study of the different methods. If one operation was

in accord with the accepted idea of proper surgical technic, the other certainly was not. When one considered the great diversity of opinion as to which was right and which was not, without a proper appreciation of them all, one was certainly at a loss as to the choice of operations. In his opinion one should not consider any operation that did not contemplate the possibility of a thorough inspection of the adnexa from above the pubic bone. He would discard the entire class of operations that contemplated vaginal incision, either anteriorly or posteriorly, on account of the greater liability of sepsis as well as from the impossibility of anchorage to firm structures. While ventrosuspensions and ventrofixations had been condemned as unjustifiable, it was because only the fixation or suspension accomplished by anteverting the uterus and stitching the fundus, or the posterior uterine wall to the abdominal wall, had been considered. It was reasonable to assume that this unnatural suspension or fixation was a causative factor in the production of lengthened adhesion bands for the entanglement of bowel as well as a barrier to the proper development of the pregnant uterus. If, however, a lower segment of the anterior uterine wall was attached lower down on the abdominal wall, and omentum was allowed to drop to or behind the uterine fundus, the bugbears of necessary cesarean sections in labor cases and entangled bowel would be less feared. His own work in obstetrics and with this operation justified him in this statement.

Gunshot Wound of the Hip Joint.

DR. L. H. LAIDLEY, St. Louis, reported a case of gunshot wound of the hip joint, but before doing so referred to the literature of the subject. The patient, aged 18, a visitor of remarkably vigorous constitution and unexceptional health, was shot in a brawl on "The Pike" at the Exposition on the 18th of June. He was admitted to the Emergency Hospital and within one hour an abdominal section was made. On examination it was found that the ball had passed through the abdominal wall near McBurney's point, passing inward and slightly downward. On examining the viscera it was found that the ball had penetrated the cecum, making two openings, passing down into the soft parts and into the pelvis. These were closed by Lembert sutures, the abdomen cleansed of large quantities of blood and escaping contents of the bowel, and closed with through-and-through sutures. The patient left the table within an hour under very favorable circumstances, the pulse being 72, temperature normal. The next morning he complained of great pain in the hip joint, and was unable to move that limb. For ten days his condition was favorable, when he gave evidence of disturbance, especially about the joint. Chills and fever and increased pain suggested an examination with the x-ray, which would have been used earlier were it not for the fact that they had not been provided with such an appliance up to that time. On July 11, after the bullet was removed, an incision was made over the joint, disclosing the presence of pus outside of the joint, which was opened, showing that all of the head of the bone within the capsule was entirely destroyed and fractured; the acetabulum was fractured and necrosed; following up the course of the cavity made by the bullet, the missile was removed. It was lodged in the upper and outer margin of the cavity of the socket. The necrosed portions of the bone were chiseled out and the dead portion of the head of the femur removed, the cavity was curetted, packed with gauze and thoroughly drained. The patient afterward showed evidences of sepsis, which prompted him on July 22 to reopen the wound, wash out the cavity and introduce further drains. Later the patient manifested evidence of acute nephritis, and on examination it was found that he had a large quantity of albumin, with casts, evidently due to toxemia. Since that time, by repeated cleansing of the cavity and thorough drainage, these evidences were disappearing, leaving the patient in a fair condition for recovery. The subsequent treatment would be to free the cavity and its surrounding structures of all suppuration, and by this means he hoped to restore his patient to normal health, probably leaving him with a shortening of the limb and perchance a degree of ankylosis. The patient was exhibited.

Strangulated Umbilical Hernia.

DR. JOHN YOUNG BROWN, St. Louis, reported an interesting case of complicated strangulated umbilical hernia, and presented the patient.

Sterility Due to Retrodeviation of the Uterus and Its Treatment.

DR. HERMAN E. HAYD, Buffalo, N. Y., reported twelve pregnancies following the simple Alexander operation. Among other things, he stated that posterior displacements of the uterus were a very frequent cause of sterility. Pregnancy had frequently followed when such a uterus was placed in position, either by pessary or operative measures. He made an eloquent plea for the simple Alexander operation for a large class of suffering women who had simple uncomplicated retroposed uteri. In reporting the twelve cases in which pregnancy followed the simple Alexander operation, it was pointed out that the ligaments had stood the test of pregnancy and parturition. The canal was never opened *per se*; the internal ring and peritoneal cavity under no circumstances whatsoever. He made a plea that the simple Alexander operation be always employed for this special class of sufferers in whom a pessary was not worn with comfort nor willingly tolerated.

Circumscribed Infection of the Placenta.

DR. ALBERT GOLDSFOHN, Chicago, reported this case. There was a first pregnancy of from three to four months' duration, with severe nausea, and much vomiting almost from the beginning, with the gradual additional development of fever, and finally severe chills and a scanty, foul discharge. There was no alteration in the shape and consistency of the cervix, or of the body of the pregnant uterus. The patient had a rapid pulse, and irregular, high temperature, and chills. The uterus was emptied. The membranes and ovum were intact. The edge of the placenta bore a circumscribed area of broken-down gelatinous tissue, with a very offensive odor.

He gave a brief review of the current views of the pathology of hyperemesis gravidarum and considered the rare etiologic bearing of the above case.

Conservation of the Natural Resistance of the Patient in Surgical Work.

DR. ROBERT T. MORRIS, New York City, in discussing this subject said that the late Lawson Tait was the first great exponent for conservation of the natural resisting force of the patient. Tait operated very quickly. He did as little as possible. He avoided handling viscera; he avoided disturbing the patient's mind with details of what he was about to do. He treated the most difficult cases lightly and patients looked at it in the same light. The repair of surgical injury depended primarily, secondarily and finally on a proper hyperleucocytosis. He used this term in a generic way to avoid elaboration of detail in statement. This was a manufacturing process carried on under the control and guidance of the sympathetic ganglia. The more the surgeon shocked a patient the more he lessened the production of the leucocytes. The common ways of lessening the natural resistance of the patient were prolonged anesthesia and an unnecessary amount of anesthetic. All surgeons had seen patients who had been literally drenched with ether; they had seen patients carried to the danger line with chloroform. On the other hand, surgeons had watched the beautiful work of men who were expert in giving anesthetics, who began with nitrous oxid and a little oxygen, then changing to ether, who did it skillfully, quickly, nicely, and avoided shock, which took away one element of resistance from the patient. Quick work was a point in which Tait excelled. Expeditionary work conserved the natural resistance of the patient. Undoubtedly the resistance of patients was lessened in abdominal surgery with gauze packing. He said that if ten healthy policemen were taken from the street and a yard of gauze was introduced into the peritoneal cavity those policemen the next day would not be in good condition. This being so, how could one expect a patient with septic appendicitis to be in good condition if a yard of gauze was packed into his abdomen. If one drained quickly, got out of the abdomen quickly, disturbed the bowels as little as

possible, made short incisions—in other words, leaving the patient alone as nearly as possible, he would make such a wonderful recovery that one might be accused of taking out a normal appendix. The tendency was to do much.

If a surgeon pricked his finger in operating on a septic case, the surgeon died, while the patient recovered. Why was this? The patient was loaded with bacteria and toxins. The patient had called out all of his resistance factors; his hyperleucocytosis was under way ready to meet infection and bacteria. The surgeon had not called out his resisting factors, hence the bacteria proliferated rapidly and gained ascendancy. Was it necessary for the surgeon to get all of the septic culture media out of the patient's abdomen? No. All he needed to do was to turn the scale; there was a conflict between the bacteria and the leucocytes in that patient's case; the bacteria were winning; the leucocytes were losing. What did the surgeon do? By taking out most of the toxins and bacteria quickly, he turned the scale, turned the balance in favor of the leucocytes, and they went on and won. He took unfair advantage of them, but if he had labored conscientiously in accordance with text-books, and the best authorities, he would have put the patient out of commission where he could not have done it.

Travel Notes.

XI.

NEW ZEALAND.

THE OCEAN VOYAGE—CLIMATE—NATIVES—AUCKLAND—
AUCKLAND HOSPITAL—MEDICAL PROFESSION.

NICHOLAS SENN, M.D.
CHICAGO.

SYDNEY, AUSTRALIA, July 30, 1904.

The American has become during the last twenty-five years an enthusiastic traveler, and the increasing prosperity in our country will only tend to increase his desire to see the outside world and familiarize himself with the greatest of all subjects—man—his customs and habits in various parts of the globe, as well as the conditions, climatic and otherwise, which influence his physical and mental characteristics. The observing traveler will have become aware that

"Men's characters and habits are not influenced so much by the peculiarities of family and race as by the physical features of their native land and their mode of life—things by which we are supported and by which we live."—Cicero.

The people of the United States spend annually \$160,000,000 in touring the old world; very few, indeed, direct their steps westward, and we as a nation know very little of New Zealand, the land of geysers, mountains, glaciers, fjörds, and the Maoris, of the great continent of Australia, its strange animals, trees and flowers, its vast plains, impenetrable forests, and the home of one of the most primitive of all races. The American globe trotter usually selects the Japanese route. For a summer trip the Australian route is decidedly the best.

VOYAGE FROM SAN FRANCISCO TO NEW ZEALAND.

The southwestern part of the world, New Zealand and Australia, are now readily accessible to the traveler by the establishment of a regular steamer service. The three sister ships of the Oceanic Steamship Company, the *Sierra*, *Sonoma* and *Ventura*, modern 6,000-horse power steamers, make the trip regularly every three weeks. The table is excellent and the service faultless. The distance from San Francisco to Auckland is nearly 6,000 miles, and the time to cover it 17 days. The monotony of the voyage is broken by making stops at Honolulu and Pago Pago long enough for the passengers to get a good glimpse of the tropics, their inhabitants, animal life and products of the soil. Between these places is the desert ocean, and the passenger who does not know how to improve his time profitably might be tempted to complain of

"The burden of the desert of the sea."—Isaiah xxi, 1.

We never saw a sail or puff of smoke on the whole voyage,

except in the harbors. The interested traveler has, however, enough to see and observe. The endless, trackless waste of the ocean in itself is something wonderful to contemplate, in its various moods of peace and rest, anger and storms. The glorious sunsets paint picturesque sky, sea and clouds that delight the eye of the most unappreciative of the wonders of Nature. The starlit sky and the silvery moon enlighten the evenings and shorten the long nights in the tropics. One day out from Honolulu the sun crossed our ship, and two days before we reached Auckland the full moon, from its lofty position, smiled directly down on the very tips of its masts. The great crest-covered furrows ploughed by the ship on each side reminded one of the speed with which we move on, and at night hypnotize and delight the sense of sight by their phosphorescent illumination in the form of myriads of diamonds, which come and disappear in the twinkle of the eye. The animals encountered in the South Pacific are few, hence more eagerly looked for. That daring, tireless mariner, the sea-gull, followed the wake of the ship nearly the entire distance. Brown and white, large and small, these graceful flyers circled in the air, with little effort on their part, coming and going by simply spreading their wings, their sharp eyes fixed on the turbulent water whipped into a diminutive storm by the revolving screw, patiently waiting for their time to feed on the refuse of kitchen and table, and the moment it appeared in the agitated waters, with unerring aim would dash from their height with the speed of an arrow, grasp and greedily devour the cherished morsel. The flying fish, single, in pairs, or in schools of many, when the sea is quiet, frightened by the approach of the ship would dash from their briny element into the air and make their short flights in gentle curves, striking the water at a distance of about thirty yards, rebound and make one or two other flights, finally to disappear with a splash from whence they came. With these things around and about you and useful books to read, the longest sea voyage is stripped of its monotony. From Honolulu to Samoa the average temperature in the cabins on the port side of the ship was 80 to 82 F. At one time my thermometer registered 100 F. in the sun. The southwest wind was constant. In less than four hours after leaving Samoa a cold breeze set in which forced the passengers to lay aside the white suits and rummage their trunks for clothing of a more somber color and heavy underwear. That evening blankets were in demand, and next day those not used to a colder climate paced the deck in fur and overcoat. This sudden change in the temperature reminded us that we were approaching a part of the world where the seasons are the reverse of ours.

From now on the sea became rough, which, combined with a heavy wind and drizzling rain, soon cleared the decks. At noon, July 26, we passed several barren islands, and soon the rugged, hilly, almost treeless coast of New Zealand was sighted, and at 2 o'clock we reached the wharf of Auckland. The harbor of Auckland is one of the finest in the world. All the navies of the world would find here ample room, not only as a place of safety, but enough space in which to maneuver.

CLIMATE.

We found New Zealand in the grasp of midwinter, however not with ice or snow, not even frost. The grass had lost its emerald green, and trees with deciduous leaves were about the only reminders of the New Zealand winter. Many of the garden flowers, roses and violets, were in full bloom, and the grassy slopes of Mt. Eden were checkered with a little white flower that peeped through the low grass, anxious to inform the visitor that it had survived the rigors of the sub-tropic winter.

The snowclad mountains and the extent of the island in a line from south to north, give to the New Zealander a wide range of choice climate. On the whole, the climate is mild, equable and agreeable, extremes of cold and heat are unknown. The perpetual snow line is 7,500 feet above the lever of the sea. The great forests in the southern part of the islands secure an adequate rainfall throughout the year. During the summer months, from October or November to April or May, the weather is as nearly perfect as can be

found anywhere—days of light sunshine, with pleasant breezes and cool nights. Mt. Cook, 13,349 feet, is the highest of the many mountain peaks.

NATIVES.

The natives of New Zealand are the Maori, a chivalrous, proud, noble race. They are Polynesians of the same origin as the inhabitants of all the islands of the South Sea. Their physical and mental characteristics have, however, undergone marked changes since they made their first appearance in New Zealand. Tasman, who discovered the islands in 1642, but did not land, and Captain Cook, who visited them several times between 1769 and 1777, found them densely populated at that time, and until subdued by the British they were hardy, war-loving people.

War was a passion with them, but their greatest national characteristic was their love of the land. "Let us die for the land" was their war cry that resounded through all the ages of their possession. Civilization has made them law-abiding citizens of the colonial government and loyal to the king, as was shown during the South African war, when many of them expressed a strong desire to join the British forces. The men are tall, powerful, square, with a brown skin, jet-black eyes, scanty beard, straight or slightly curly hair, with an open, frank countenance. The women are well built, with copious hair, worn in flowing tresses or pompadours, and many of them with handsome features when young. There are about 20 per cent. more males than females. The climate of New Zealand has made its impression on this race. They had to protect themselves against cold by clothing and closed habitations.

The New Zealand flax or hemp (*Phormium tenax*), a liliaceous plant, from the leaves of which the fibers are obtained, are from 3 to 9 feet long and from 2 to 3 inches broad, furnished them with material for the texture of their garments, as well as the feathers of birds and the skin of fur-bearing animals. The scarcity of tropical fruits and starch-yielding tubers made the struggle for life more difficult than in the more favored islands of the South Pacific, something which could not fail in improving their physical condition, and in developing their mentality. The Maoris have a taste for art, as is amply shown by their rude wood carvings and the architecture of their houses. Tattooing was formerly extensively practiced, but the operation is performed in an entirely different manner than in Samoa and Tahiti. As the natives have always worn clothes of some kind they select the face, the most exposed part of the body, for the tattooing. The chiefs undergo the most elaborate process of the tattooer's art. With a sharp shell lines and scrolls are cut in the superficial parts of the skin, always radiating from the nose, and into these scratches the pigment is rubbed and permanently deposited. The women only tattoo the lower lip and chin in straight lines. Christianity has taken the place of Paganism, but is not held with much fervor by the people. Pagan customs and superstition remain. Some Maoris have taken to farming and the professions, but the bulk of the race is living in dull idleness, depending on the liberal government for their support. The young people realize the advantages of an education, and are profiting by the schools located in all of the settlements, as in it they see the only means that will prevent complete extinction of their race. Like all Polynesians, the Maoris have brought their tribute to the altar of civilization. The acute infectious diseases, syphilis and tuberculosis, brought to their islands by the whites, have reduced the population numbering hundreds of thousands, to something like 40,000. In 1891 the native population numbered 43,642, of whom 2,119 were half-castes. In 1896 the total population of New Zealand was 743,214, of whom 39,854 were Maoris and half-castes. Improved sanitary measures and a better appreciation of hygiene by the natives have contributed much in diminishing the mortality among the natives, and will, it is to be hoped, prevent the extinction of this noble race.

THE CITY OF AUCKLAND.

From the harbor the city of Auckland, with its over 60,000 inhabitants, presents a charming sight. It is spread out over a large surface encircling the capacious harbor and perched on

many hills. The two-story houses and cottages are built of brick or wood, and many of the business houses in Queen Street, the main thoroughfare, are solid structures of stone or brick and cement. Most of the streets have asphalt pavements, and are kept scrupulously clean. The electric lighting and tramway conveniences compare well with any of our modern lively western cities. The many churches, excellent schools, capacious hospital, museum and public library speak well for the intellectual life of the island city. The drive to Mt. Eden, with its bowl-shaped extinct crater, within the limits of the city, is one of great scenic beauty. I made this tour in company with Dr. Lewis in his automobile. I noticed when we made a short stop at the foot of the mountain that Dr. Lewis and his coachman held a short consultation, the significance of which I did not understand at the time. Dr. Lewis steered the French machine. The ascent was slow, and when we came to a few yards of steep grade the coachman lent aid to the quivering vehicle by a vigorous *vis-a-tergo* until this obstacle was overcome, when the rest of the ascent was made without any further difficulty. When we reached the summit the doctor and coachman shook hands, and the former said in a triumphant tone, "I told you so." It seems that there had been some misgivings concerning the possibility of accomplishing this feat, as the doctor had never attempted it before. His faith in the power of his machine had been vindicated. The view from the summit of the mountain is inspiring. The dizzy depth of the crater and the panorama all around leave deep and permanent impressions on the memory of the astonished tourist; the sight of the first is awe inspiring, the contempla-

Auckland Hospital.

tion of the surrounding scenery pleasing and full of surprises. From the summit twenty other extinct craters can be seen, and the wide expanse of the Pacific on both sides. The well-painted wooden houses and the pale red brick houses, with their silvery roofs of corrugated iron, and the harbor, with its vessels, looked like a toy city made for the amusement and instruction of children. Eucalyptus and pine trees, the lovely gardens attached to nearly all the houses, and the straight, clean streets added much to the beauty of this fairy scene. The city is supplied with pure water from the mountains, and a system of sewerage is now under completion. On an average 100 cases of typhoid fever occur annually. Malaria is almost unknown.

THE AUCKLAND HOSPITAL.

Auckland has only one public hospital, the Auckland Hospital. It is supported by appropriations made by the general government and the city. The main building was built about fifty years ago. It is built on the summit of a high hill, from which a splendid view of the harbor and city can be obtained. Seen from the harbor it is one of the most conspicuous landmarks of the city. The city has set aside for it a large tract of land, and the part around the buildings is well laid out in drives and walks, and ornamented by trees, flowering shrubs and flowers. The main building, of brick and cement, is three stories high, with large wards, well lighted and ventilated. A few years ago a Mr. Coatley donated to the hospital the munificent sum of \$160,000, out of which four brick pavilions for women and children have been built, and \$15,000 is now being spent in the construction of a modern

Therapeutics.

operating room, and equipments for the same. This operating room, now nearing completion, will be flushed daily from above, and the skylight of a double glass roof is constructed in such a manner that the light will be concentrated at a place corresponding with the location of the operating table. Dr. John C. Collins, the medical superintendent, took great pains to describe this feature of the operating room, as well as its ventilation. By the use of an electric apparatus the air of the room can be exhausted at any time it becomes contaminated. The operating room used at the present time is on the first floor, but is inadequate for modern requirements. The medical staff is comprised of three physicians, three surgeons, one oculist and aurist, no gynecologists and no obstetricians. The hospital proper and pavilions can accommodate 210 patients. Patients with means are required to pay, the amount depending entirely on their means. A charming feature in the wards of this hospital is an abundance of fresh-cut flowers on high, narrow, long tables at the foot of the beds, in constant sight of the patient when awake. The hospital has its own training school for female nurses, with an attendance of 64 at the present time. They are in training for three years, but receive a small compensation after three months. Among the interesting surgical cases shown by Dr. Collins were the following: A Maori who, by the accidental discharge of a shotgun he was handling, shot away the larger part of the body of the left side of the lower jaw. Edema of the larynx was threatened, and a tracheotomy was made. At the end of twenty-four hours the tube was removed, and although the left side of the face remained greatly swollen, he is improving rapidly. Several cases of compound fracture; resection of cecum for tuberculosis, gastro-enterostomy for stricture of the pylorus; extensive fracture of the skull in a boy, for which trephining was performed. On an average about 100 laparotomies are performed in the hospital every year by the different attending surgeons. This comparatively small number of abdominal operations, however, does not represent the bulk of this kind of work done in the city, as only the attending staff is permitted to operate in this institution, and many of these, and all other physicians perform their operations on private patients at their homes, or in one of a number of little private hospitals conducted by nurses. There seems to be no unanimity among the surgeons in the use of anesthetics and suturing material. Chloroform, ether and A. C. E. mixture are used as anesthetics, and silk, silkworm gut, catgut and kangaroo tendon as suture material according to the preference of the different operators.

THE MEDICAL PROFESSION.

I had abundant opportunity to experience that the medical profession of Auckland is cordial and hospitable. Dr. Edward W. S. Sharman, the quarantine physician of the port, after completing his inspection of the steamer, took me ashore in his steam launch, and from there directly to Dr. T. Hope Lewis, the most prominent surgeon of the city. To these two gentlemen, who gave me their whole time during the entire afternoon, I am greatly indebted for what I saw and learned in their city. There are 40 practitioners in Auckland. There is only one specialist for the eye and ear. All of the physicians do their own operating, including all kinds of gynecologic work. Dr. Lewis is the only one who is gradually leaving general practice, and will soon devote himself exclusively to surgery. The fees in Auckland are not high. Visits are charged for according to the patient's means from 75c to \$2.50. The maximum figure is very seldom reached. For any capital operation \$250 is regarded, even by the wealthy, as a very large fee, and most of the difficult operations are paid for at the rate of \$100. Most of the physicians are graduates of English and Scotch universities, and consequently their practice of medicine and surgery represents the teachings of British authorities. They are all members of the British Medical Society, and depend for the current medical literature largely on its official organ, the *Journal of the British Medical Association*. The New Zealand branch meets once a year, and the city, or local branch, monthly. These meetings are well attended, and the transactions represent the clinical and scientific work of its members.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Tabes Dorsalis.

Faure, in the *Lancet*, gives it as his opinion that the iodids and mercury are not responsible for the relaxations and diminutions in the symptoms which sometimes occur during the course of the disease, for such ameliorations are the rule. He further states that the disease is progressive in a third of the cases; it is arrested, improved, or gets well in about one-fourth of the cases; in the remainder it proceeds slowly, with periods of quiescence, and at times affecting the life of the patient seriously.

PROGNOSIS.

1. Early diagnosis means earlier treatment and better results.
2. The very general employment of mercurials and iodids in syphilis is probably a reason for the diminution in the evolution of tabes.
3. The tabetic is cared for in a hygienic manner as the tuberculous cases are, and he is not allowed to sit and fold his hands and resign himself to the fatal sentence which used to be pronounced against him as soon as the diagnosis was made.

GENERAL DIRECTIONS.

1. He must not allow the patient to think that there will be a complete and radical cure within a few months, or that there is any specific remedy for the disease.
2. He must not allow his patient to abandon himself to his lot as one without hope or to think that his disease is inevitably tending toward death, for such is not the case.
3. The patient should be told that the disease will probably not improve, that it will diminish his capacity for work, and he will have some suffering.
4. Watchful care on the part of the medical attendant and willing co-operation on the part of the patient will often avoid complications.
5. The patient may be told that tabetic patients have been known to recover.

SPECIAL DIRECTIONS.

1. Keep the bladder and bowels clean. 2. Avoid underfeeding and insomnia. 3. Live as much as possible in the open air. 4. Avoid overwork, either mental or physical. 5. Watch with care the condition of the circulatory system. 6. An annual "cure" of one or more months' duration should be taken, when the patient should have special treatment and training to repair the damage already done by the disease and put himself in a condition to resist complications. a. By special exercises he should increase the respiratory activity. b. He should also train his excretory system as regards urination and defecation. He may regain control of the lost voluntary motion. c. He may also submit himself to a special hygienic course of thermal hydrotherapy, and finally employ all methods which experience has already shown to be useful in cases of tabes.

Neurasthenia.

Merck's Archives recommends the following combinations:

B.	Tr. nucis vomice		
	Tr. conii. ʒā.....	5i	4
	Tr. calumbæ		
	Tr. galbaniæ. ʒā.....	ʒiiss	6
	Essentiæ anisi	mx	165
M.	Sig.: Twenty drops in water before meals.		

During the meal or following it a combination similar to the following is recommended to be taken in wine:

R. Strych. arsenatisgr. i	60	001
Cal'ii glycerphos.gr. v		32
Syrupi aurantii5i		4

M. Sig.: Take at one dose in a wineglassful of wine after each meal.

Acute Otitis Media and Prophylactic Measures.

Parsons, in the *Northwestern Lancet*, gives the following advice as to the treatment of this condition:

1. Remove all hypertrophic and degenerated conditions of the pharyngeal lymphoid structures.
2. Treat the catarrhal conditions of the nose and nasopharynx and keep the mucous surfaces clean with alkaline antiseptic douches to aid in preventing the infectious material from entering the eustachian tube.
3. Douching should be done carefully and blowing the nose should be done with caution.
4. Prohibit digging away in the external auditory canal to remove cerumen.

ACTIVE TREATMENT.

1. A free movement of the bowels is desirable.
2. In the earliest stages the congestion and secretion may be lessened by the administration of the following:

R. Atropingr. i	00013
Aconitini, āāgr. 1	500

M. Sig.: Give as a single dose every hour until their physiologic effect has been produced.

3. For the pain chloroform may be ponred into the ear, or the application of a 10 per cent. solution of cocain and adrenalin solution may be made to the drum head, and is often efficacious; or dry heat from a hot salt bag.

Inflation of the tympanum with the vapor of menthol and camphor will often relieve the pain by the action of the drugs and the equalization of the air pressure.

R. Mentholigr. i	06
Camphorægr. x	65
Liquid alboline5i	30

M. Sig.: Use locally to inflate the tympanum.

4. When all other efforts to relieve pain have failed, a thorough inspection of the drum head should be made, and if there is an accumulation of secretions behind it, a free incision of the membrane is demanded. This should be done under strict aseptic precautions as to instruments and field of operation. If pus is present the ear is to be packed loosely with sterile gauze, and a sterile dressing put on the outside.

There is difference of opinion as to whether these cases should be treated by the so-called dry method, which consists in packing the external auditory canal with dry sterile gauze after first cleaning out the canal, dry swab, or by the irrigation method. The author believes there are advantages in both methods, but if there is much pus present he prefers free irrigation with a 1 to 1,000 formalin or bichlorid solution, used until the return flow is clean, and followed by the instillation of a 10 to 20 per cent. argyrol solution. The argyrol is allowed to run into the tympanum through the perforation by inclining the head, and the external canal is then packed, inserting a small wick through the opening if possible. If the secretions gum up the canal they are easily removed by the application of peroxid of hydrogen. The discharge must be attended to carefully until it has ceased.

Chronic Otorrhœa.

Nouvelaux Remedes quotes Meniere as stating that carbolic acid is the best remedy for this disease. Hot water is injected into the affected ear, which is then painted with:

R. Acidi carbolicj (crystals)gr. xv-lxxv	1-5
Glycerini purismxxxv-cl	1.30-8 20

M. Sig.: Use locally.
Later, when the flow has diminished, use:

R. Glycerini puriscl	8 20
Hydrarg. chlor.	cor.gr. 3/40-3 8	.005-0'025

M. Sig.: For local use.

Carbolated glycerin, besides acting as a cure, has a distinct analgesic action in otorrhœa.

Chapped Hands.

Blake of London, "Eczema and Its Congeners," states that the following application made at night is an excellent method of preventing eczema of the hands in cold weather:

R. Phenol	5 parts.
Cade oil	10 parts.
Nutritive cream	500 parts.

M. Sig.: This should be vigorously rubbed in to promote free circulation. It is a good plan to wear a pair of loose leather gloves at night.

Ptyalism.

The *Medical Press* recommends the following:

R. Tinct. myrrhræ5iii	12
Potass. chloratis5ss	2
Sodij chloridi5ii	8
Aque dest. q. s. ad.5viii	240

M. Sig.: Use as a mouth wash. Repeat every two hours.

Hysteria.

Goodell recommends the following combination:

R. Ext. sumbulgr. xx	130
Ferri sulphatis æssiæ, āāgr. xl	260
Acidj arsenosigr. ss	103

M. Pt. pil. No. xx. Sig.: One or two pills three times a day.

To Remove Warts.

The *Med. Review of Reviews* recommends the following:

R. Ext. cannabis ind. fl.5i	4
Acidj salicylicjgr. x	160
Collodion q. s. ad.5ss	15

M. Sig.: Paint freely with a camel's hair brush twice daily.

For Falling Hair.

Walsh recommends the following combination to prevent the falling out of the hair:

R. Acidj salicylicj5iii	12
Acidj carbolicj5i	4
Olei ricini3iii	12
Spiritus vini rect. q. s. ad.5vi	180

M. Apply freely to the scalp once or twice daily.

Medicolegal.

Death from Cut in Trimming Corn.—The United States Circuit Court, in Pennsylvania, holds, in the case of *Nax vs. Travelers' Insurance Company*, that where there was a self-inflicted knife cut of the insured's toe while he was trimming a corn, and later, blood poisoning ensued, and resulted in his death, the injury was an "accidental, external, and violent" one within the meaning of an accident policy.

Hospital Not Liable for Negligence of Surgeon.—The Second Appellate Division of the Supreme Court of New York holds, in the case of *Wilson vs. the Brooklyn Homeopathic Hospital*, that a corporation existing as a public charitable institution, operating as a hospital is not liable, in conducting its hospital, for negligence in operating on a patient who pays only for board and attendance, and not for the surgeon's services, in the absence of proof that it failed to exercise reasonable care and diligence in the selection and employment of the surgeon. Nor was such a hospital rendered liable by testimony that the superintendent said that surgical treatment was included in the expense of room and board where it was clearly shown that the superintendent had no authority whatever to make any contract in behalf of the hospital to receive compensation for the services of surgeons or physicians in its employ.

No Authority to Employ Physician.—The Supreme Court of Minnesota says, in the case of *Legault vs. Minneapolis Fire Department Relief Association*, that the association was organized "to afford relief to such active members as may become sick, disabled, or injured," etc. The articles of association further provided that "any active member of the association who shall become sick or disabled or so unable to attend to his duty as a fireman, shall receive from the association while such sickness or disability continues such sum per week for sick benefits as may be designated by the by-laws." "In case

of an accident to any active member and his condition demands his immediate removal to a hospital the attending surgeon or any officer of the association may have such removal made at the expense of the association, and the president shall, as soon as practicable, call a meeting of the board of trustees," seven in number, to take such action as they shall deem proper. The by-laws provided for the duties of a surgeon, who should, "on notification from the president or vice-president of injury or sickness to an active member, visit and examine him and make a report," and also provided for "visits of such surgeon to the sick person," and for compensation at a specified rate for consultations by him, and other duties to be thus performed by that officer. The Supreme court holds that these articles and by-laws did not authorize or justify the employment by one of the officers (vice-president) of the association of a physician, not the regular surgeon of the association, to render medical services for a member injured at a fire, for an indefinite length of time, without the authority of the board of trustees. It says that while the general statement of the purpose of the association was to care for sick and disabled members, this was limited to the manner provided for in the articles and by-laws, and a contract for treatment not contemplated or prescribed therein could not be reasonably implied; and all persons dealing with the association must be held to do so with full knowledge of the limitations contained therein. Nowhere in the articles was there a provision which extended the general statement of the purposes to care for disabled members by the employment of a physician other than the regular physician of the company to render services without the authority of the board of trustees after proper notification. It was not definitely set forth and could not be implied.

Monomania, Immorality, Insanity and Insane Delusions.—The Supreme Court of Georgia says, in the case of Bohler vs. Hicks, that monomania is partial insanity, as contradistinguished from general insanity; the monomaniac is sane generally, but is insane on a particular subject or class of subjects. The party afflicted with monomania is conscious of his ability to manage his affairs, and is utterly unconscious that, with respect to any particular subject-matter, he is irrational or of unsound mind. The very name "monomania" implies partial insanity, and excludes the idea of any sort of ratiocination as to the particular subject to which the partial insanity relates. Monomania cannot be implied because a person takes a narrow or prejudiced or utterly illogical view of a particular subject. It is not the result of any conclusion; the person does not arrive at his conviction because of any attempt either at reasoning or investigation; the partial insanity is the offspring of a disordered intellect. A man may be utterly abandoned to every form of lust, and, though he has departed entirely from the paths of virtue, such depravity alone does not evince insanity. His conduct may be the result of a depraved nature, a conscious departure from the path of rectitude because of a depraved, but deliberate, choice; a preference for a sinful and immoral life over one of right doing and correct living. A sane man may have improper relations with women, and may persist in his wrongdoing despite the interference of others. Such perverse conduct does not amount to insanity. The conclusion that a testator was a monomaniac is not warranted by the bare circumstance that, actuated by a spirit of resentment against his wife, he disinherited her in his will for the sole reason that she had interfered with him in carrying out his deliberate choice to lead an immoral and dissolute life. An insane delusion was said by Sir John Nicol, in the celebrated case of Dew vs. Clark, 3 Add. Ecc. 79, to exist wherever a person conceives something extravagant to exist, which has no existence whatever, and he is incapable of being permanently reasoned out of that conception. The correctness of this definition of an insane delusion has been recognized in the great majority of the English and American cases. The delusion must spring spontaneously in the mind of the person, and not be the result of evidence of any kind. An "insane delusion" does not mean a mistaken conclusion from a given state of facts, nor a mistaken belief

as to the existence of facts. An erroneous conclusion of a sane person may arise from incorrect reasoning, or from a deduction from information which he supposed to be correct. The true test between a delusion, used in the sense of a mistake of fact, and a delusion which is the offspring of a deranged mind, is that the latter springs spontaneously from disordered intellect, while the former is the result of an erroneous conclusion based on either a mistake of fact, or an illogical deduction drawn from such facts as they really exist. The subject-matter of an insane delusion must have no foundation in fact, and must spring from a diseased condition of the intellect. If the testator undertakes to make an investigation, and arrives at the conclusion that a certain state of facts exist which in point of fact does not exist, such conclusion may be attributable either to a mistake in judgment or a mistake of fact, and will not be evidence of insanity.

1. **Tuberculosis of the Abdominal Lymph Glands.**—The purpose of Painter and Erving is to show that tuberculosis of the abdominal lymph glands may give rise to spinal symptoms; to distinguish symptoms produced in this way from similar symptoms produced by other diseases, and to suggest that in some cases vertebral tuberculosis is caused by a direct extension from tuberculous abdominal lymph glands. There are three sources of infection: 1. Direct extension from adjoining diseased tissues, which is uncommon and of minor importance. 2. Infection from the blood stream, which is not infrequent. 3. Infection through the lymphatics, which is almost invariably the mode of infection in the more or less chronic and isolated gland lesions. Often the glandular involvement is more or less localized, and a fatal termination is due to intestinal obstruction, peritonitis and formation of abscesses progressing outward. Among cases with spinal symptoms, mesenteric tuberculosis must be differentiated from Pott's disease, aneurism of the abdominal aorta, malignant disease, especially cancer, osteoarthritis, osteomyelitis and other inflammatory diseases in or about the spine. The treatment of inflammations of the abdominal lymph glands is divided into (a) general, perhaps the most important; (b) mechanical—fixation of the spine in order to give relief from pain; (c) operative—the same rules holding good for the treatment of abscesses derived from broken-down lymph glands as obtain in the treatment of abscesses in tuberculous bone lesions. The prognosis is good as compared with that of vertebral tuberculosis in the same class of patients. The most serious features of the disease are extension to, and involvement of the vertebral column, rupture into the peritoneal cavity and intestinal obstruction in consequence of the pressure on coils of intestine or the matting up of such coils in the products of inflammation. Much can be done to favor the prognosis, according to the extent to which it is possible to provide efficient treatment and the intelligent co-operation of the patient. The paper concludes with a report of nine cases.

2. **Syndrome of Conus Medullaris.**—Gordon attempts to prove that the lower portion of the spinal cord, the conus medullaris,

contains special and independent centers for micturition, defecation, erection, ejaculation, and for the anal reflex, and cites a case in confirmation of his belief.

4. **Nerve Blocking to Prevent Amputation Shock.**—Gessner reports two cases in which he made use of the method advocated by Cushing with very satisfactory results. He recommends the procedure as one well worthy of further trial, promising much that is good, and so far, appearing to be attended by no disadvantages.

6. **Garlic in Tuberculosis.**—Knott reviews the therapeutics of garlic and calls attention to (a) the favorable reports that have been issued in connection with its administration in serious bronchial affections, and (b) the experiments of Carazani, who attempted to show that a sufficiently generous use of garlic in tuberculosis will produce immunity to its infection. Of a group of guinea-pigs kept in an atmosphere charged with tubercle bacilli, those whose daily diet had contained 1 gram of garlic were found at the end of three months to be free from tuberculosis, while the others were all badly infected. The efficiency of garlic in pathologic conditions of the respiratory mucous membrane is due to its essential oil, which is almost wholly composed of allyl sulphid, which is eliminated very largely through the respiratory tract.

7. **Insomnia of the Aged.**—According to Aldrich this condition is due to starvation of the brain cells, the result of narrowed capillaries and an impoverished blood supply. The condition can be relieved by diffusible stimulants and some hot and easily digestible and agreeable food taken at bedtime, and repeated during the night if necessary.

9. **Strychnin in Shock.**—A careful investigation has been made by Crile as to the action of strychnin in shock and collapse. In the majority of instances, in the normal animal, when sufficient strychnin is given to cause an increased excitability of the spinal cord, as indicated by heightened reflexes and an increased muscular tone, a rise in blood pressure was noted. In smaller doses occasionally a slight intermediate fall, a slight immediate rise, or later irregularities were noted, but no noteworthy change occurred. Following the administration of physiologic doses of curare and convulsive doses of strychnin, the blood pressure rose as high as in the experiments in which convulsions did occur. When both vagi and accelerantes were severed, curare and strychnin given, the general effect on the blood pressure did not differ materially from the effects of corresponding doses on the normal animal. Small doses of strychnin on the whole seemed to improve respiration. Larger doses were frequently followed by respiratory failure. After the blood pressure had reached the stage of terminal helplessness, the administration of saline solution caused a rise which continued for some time during the flow. The administration of adrenalin was followed by a rise in proportion to the amount given. Bandaging and other means of external pressure produced a rise of blood pressure. Digitalis administered in the terminal breakdown in most instances produced no effect. The details of the experiments are given in full as observed in six dogs.

10. **Acute Myelitis.**—Sachs discusses the acute myelitis which is not due to trauma, specific infection or infectious diseases, and reports a case in which the symptoms pointed to an acute transverse myelitis, yet the autopsy failed to reveal the first sign of any inflammatory process. The case admits of no other interpretation than that of being an ischemic necrosis due to a general arterial sclerosis. The author also reports a case of streptococcal myelitis. Both these cases are recorded for the purpose of insisting that the spinal cord does at times become the seat of morbid processes which befall the brain

much more frequently, and that it will not do to restrict the term myelitis to the morbid process that can be distinctly traced to trauma, syphilis and the ordinary acute infectious diseases.

14. **Immunity.**—Stuart believes in the possibility of destroying the power of the blood to develop immunity by a lack of use; that the typhoid, pneumonia and consumptive patient will stand a better chance of developing his own antitoxin if we conserve his strength and stop irritating his tissues with foreign substances. In our eagerness to destroy the germ, says Stuart, we are forgetting to build up the immunity of the patient against the germ.

- 22 The Correction of Abnormal Conditions of the Blood Relative to Surgical Operations. S. C. Emley.
- 23 *Addison's Disease, With and Without Renal Tuberculosis. Charles F. Wittington.

18. **Bone and Cartilage in Tonsil.**—Newcomb speaks of the presence of true osseous and cartilaginous tissue in the tonsil and reports the case of a woman, aged 30, who had an abnormally long styloid process projecting into the tonsil, the tip of which was removed accidentally during a tonsillectomy. Other cases that have appeared in the literature are cited.

19. **Distinction Between Fractures.**—The object of Whitman's paper is to call attention to two forms of fracture of the neck of the femur, of which an accurate diagnosis may have an important influence on treatment. Simple fracture should be treated by fixation at the limit of normal abduction, an attitude which implies restoration of the depressed neck to its normal position. Partial epiphyseal separation should be treated by direct operative reposition of the head. Excision should be an operation of necessity rather than of choice. One should never be content with mechanical support, however efficient it may be in relieving the immediate symptoms. Recognizing the fact that normal function is dependent on normal form, the aim should be to remedy deformity whenever it is practicable.

20. **Rectal Administration of Hypnotics.**—The value of the rectal administration of some of the newer hypnotics, such as sulphonal, trional and veronal, is emphasized by Manges. Although the first two are almost insoluble, clinical experience proves that they are absorbed by the rectal mucous membrane, and that the speed of absorption is about the same as when the drugs are taken by mouth. Hedonal, chloralose, and chlorotone are so slightly soluble as to be practically worthless in this connection; on the other hand, sulphonal acts more powerfully than trional. Heroin, chloralamide and phenacetin are also readily absorbed. Veronal is freely soluble and may be administered in suppository form or in solution, either in warm milk or preferably in diluted sherry to which a little salt or sugar has been added to increase the speed of absorption. No irritation of the rectum following the administration of any of these hypnotics has been observed.

21. **Medical Treatment of Appendicitis.**—Hall is a firm believer in the medical treatment of appendicitis because, he says, the tendency of the disease is toward recovery. He ad-

vices, however, that in recurrent cases an operation should be performed during the interval after recovery from the second attack. The medical treatment as carried out by him is as follows: Absolute rest in bed; relaxation of the abdominal muscles by flexing the thighs and supporting the knees by pillows. A liquid diet, chiefly composed of milk, four to six enemas a day, and copious enemas of soapy water or sweet oil every four hours. A hot flaxseed poultice over the whole abdomen, replacing it every two or three hours, night and day, until the temperature is normal. The only counter-indication for the use of enemas, or at least one calling for great care in their use, is the involvement of the lower bowel in the inflammatory process. The larger the amount of liquids consumed the better, as they not only nourish the patient, but by means of the diuresis produced render material aid in the elimination of toxic material. Creosote, minim 1, in two drams of lime water, may be administered every two or three hours, and arsenite of copper, grain 1/100, every three hours. The arsenite of copper is employed as an intestinal antiseptic and prevents or diminishes tympanites and the tendency to vomiting, and has a marked anodyne effect. If the vomiting does not subside, and should it become stercoraceous, occlusion or paralysis of the bowel is indicated, and operation is the only hope of relief. Opiates and cathartics should never be given.

 30 Polymiazin Among Enlisted Men of the Marine Corps. R. O. Marceur.

24. The Eyeball in Infective Conjunctivitis.—Bull summarizes his paper as follows:

1. A careful microscopic and bacteriologic examination should be made of the contents of the conjunctival sac in every suspected case, carrying the examination as far as the cultivation of the bacteria in a proper medium, and the subsequent inoculation of the germs.

2. If toxic germs are found in great numbers, no matter what their varieties, no operation on the eyeball should be undertaken until the germs have disappeared, and the conjunctival sac has been rendered as sterile as we can hope to make it.

3. If there be suppurative disease of the lachrymal passages, whether of canaliculi, sac or nasal duct, all operations on the eyeball are positively contraindicated. The lachrymal sac must be excised, and the lachrymal puncta must be obliterated by the galvanocautery, before any operation on the eyeball is undertaken. In the case of conjunctival dacryocystitis, or of a mucocle of the sac, both canaliculi should be incised, and the sac injected daily with an antiseptic astringent solution, and free irrigation through the nasal duct carried out until all secretion has ceased. Even in cases of great urgency, as, for example, acute inflammatory glaucoma, the writer would not feel himself justified in modifying the above statement.

4. If the secretion of the conjunctival sac on examination is found to be purulent, but the bacteria are few in number and of slight toxic variety, operations may be done on the eyeball when necessary, but these eyes should be opened and examined twice in the twenty-four hours, and the conjunctival sac gently irrigated with warm normal salt solution, or warm sterilized boracic acid solution, and then the eye should be immediately rebandaged.

5. In operating on the eyeball in the presence of an apparently normal, sterile conjunctival sac, the following steps should be taken: First, The forehead, eyebrows, temple, cheek, bridge of the nose, and external surface of the lid should be carefully cleansed with hot water and soap and dried with aseptic cotton pads.

Second, The margins of the lids should be carefully but gently rubbed with sterilized moist cotton pads, and simultaneously irrigated with a warm sterilized physiologic salt solution.

Third, Careful irrigation of the conjunctival sac with the same sterilized normal salt solution and then closing the lids with a moist sterilized cotton pad.

6. In all cases the bandage should be removed and the eye examined under the strictest aseptic precautions, as strict as those employed at the time of operation.

7. On the first sign of infection of the wound, the edges of the lids are to be thoroughly cleansed in the same manner as at the time of operation; the conjunctival sac is to be thoroughly irrigated with the sterilized normal salt solution; the wound is to be re-opened and exteriorized through its entire length with the galvanocautery; and the anterior chamber is to be gently but carefully irrigated with a sublimate solution (1:5000); and then the conjunctival sac must be again irrigated, and the lids must be closed simply under a moist sterilized pad.

25. Use and Abuse of Athletics.—Coughlin considers physical over-exertion and its effects on the general health as well as on the individual functions, and the benefits to be derived from

a moderate indulgence in athletic exercise. The prime object of athletics is improvement of the general health, but to obtain good health muscle building is not a necessity. There is no evidence to show that athletics and muscle building improve the constitution; in fact, to obtain health one must not be in a perfectly trained condition, owing to the effects of severe training on the nervous system. It is necessary to keep in mind the fact that hypertrophied muscle always has a tendency to degenerate. This is especially true of the heart muscle. Athletics are beneficial when properly and judiciously applied, and are very injurious when indulged in indiscriminately.

26. Pericarditis.—According to Lewis, pathologic conditions of the pericardium are by no means as uncommon as may be inferred from their infrequent ante-mortem recognition. Pericarditis, if looked for, will be found to occur much more frequently than is commonly supposed. The symptoms of the condition may be obscure or they may be overshadowed by those of some other disease, such as Bright's disease, and therefore go unrecognized. Many factors contribute to the production of this condition, and one case is reported by the author in which a burn on the chest was followed by pericarditis. The treatment is but little understood. Lewis says that the pain can be relieved promptly by dry cupping or counter-irritation over the painful region. Absolute rest in the prone position is important. Anti-rheumatics are useless and nothing approaches the value of opium salts in large and often repeated doses, always administered in saturated solution. Heart tonics and stimulants are contraindicated unless there is evidence of cardiac failure. When effusion occurs and the conditions are not alarming, it is always safe to wait. When the effusion becomes alarming, paracentesis is the only thing to do.

St. Louis Medical Review.

September 17.

- 31 *Observations on the Cause and Treatment of Hay Fever. W. P. Dunbar.
 32 *The Practical Value of the Immunity Theory. A. P. Wasserman.

31. Hay Fever.—Dunbar's paper is a review of present-day knowledge of the etiology of hay fever, with a brief reference to the author's serum treatment. Attention is called to the fact that the results accruing from the use of the antitoxin are far superior when the serum is used strictly as a prophylactic. It is very difficult to stop a severe attack of hay fever by using the antitoxin as a curative agent. The average success, according to statistics of several hundred cases, seems to amount to about 65 per cent. Efforts to make a preparation that can be used hypodermically are still being carried on, and since it has been proven that the antitoxin part of the serum is resident entirely in the globulin, Dunbar is now experimenting with an antitoxin from which the albumin has been eliminated, in order to find out whether it can be used without causing any irritation. Dunbar is also engaged in the manufacture of an antitoxin to be used in the prevention and treatment of the autumnal catarrh prevalent in this country and due to the pollen of goldenrod and ragweed.

32. Immunity.—This paper by Wasserman is a very brief review of the subject of immunity and serves to convey the information that the author has succeeded in isolating a toxin which is bacterioid to the diphtheria bacillus. This new sera is dried *in vacuo*, and pulverized or made into pastilles. The patient merely sucks the pastilles or snuffs up the powder. This serum is to be used in conjunction with diphtheria antitoxin, because a patient treated and cured by antitoxin may still have in its throat diphtheria bacilli possessing the power of infecting other children.

- 43 *The Present Status of Cervical Sympathectomy for Glaucoma-Simplex. Robert G. Loring.

36. **Bacteriology of Trachoma.**—During the past two years Knapp has made bacteriologic examinations of 120 cases of trachoma. An influenza-like bacillus, identical with the Mueller "trachoma bacillus" was found present in 8 of the cases. It was found in great numbers in a case of clinically "acute" trachoma. This organism could not be differentiated from the true or pseudo-influenza bacillus either morphologically, culturally or by animal experimentations. Knapp is inclined to believe that its presence in these cases of trachoma was accidental, inasmuch as there is a form of influenzal conjunctivitis which constitutes the only manifestation of influenza. The organism found was of small size, rounded ends and stained with difficulty—best with diluted carbol-fuchsin. It grows only on hemoglobin media as small, dewdrop-like colonies scarcely visible to the naked eye. The culture can be continued indefinitely on proper media. The bacilli were found to be non-pathogenic for rabbits.

43. **Cervical Sympathectomy.**—The present status of this operation in the treatment of glaucoma simplex is discussed by Loring, who says that while in acute and chronic inflammatory glaucoma the removal of the superior cervical ganglion has failed to establish its claim as a rival to iridectomy, and that little of a more favorable nature is to be expected from it in the future, the matter is entirely different in glaucoma-simplex. Here iridectomy is admitted to be of much less value, in some cases seeming even to diminish rapidly what little vision remains. Loring has collected from the literature 60 cases of glaucoma-simplex treated by sympathectomy, counting each eye as one case. In a great majority of the cases there is a more or less striking improvement following sympathectomy. But when those cases are ruled out that were reported without subsequent observation of some weeks or months, at least, the verdict is not so favorable. Many cases soon suffer a relapse, the vision becoming the same as before operation or even worse, or a glaucoma-simplex develops rapidly into an acute glaucoma. This happened in 4 of the 60 cases. Of the 60 cases, the number that was observed for three months or more is 41. Of these 29, or 70 per cent., were improved for three months or more with no record or relapse. Few of the cases were observed longer than one year. The remaining 12 cases are reported as relapsing within various periods from nine weeks to one year, 4 of these becoming acute glaucoma. Serious after-results from sympathectomy are not reported either from the single or double operation. Loring believes that sympathectomy is a distinctly justifiable operation that ought to be more often tried as a final resort in glaucoma-simplex when, notwithstanding myotics, iridectomy and sclerotomy, the disease progresses steadily toward eventual blindness.

50. **Autoplastic Suspension of the Uterus.**—Autoplastic surgery, says Martin, is a simple, quick, safe and efficient suspension of the uterus attended with a minimum of risk of fixation, and does away with any form of permanent buried suture material, by substituting living peritoneum which is utilized in such a way that its vitality and integrity are maintained. A strip of peritoneum, one-third of an inch wide, is severed with scissors from one side of the wound; the upper end of this strip is severed from its peritoneal attachment, thus leaving a ribbon of peritoneum attached at its lower end beneath the lower angle of the wound to the parietal peritoneum above the bladder. The uterus is brought forward, a ligature carrier is passed from behind forward just back of the crest of the uterus, beneath its peritoneal covering for a distance of half an inch, and as it emerges at the crest of the uterus it is made to grasp the end of the ribbon of peritoneum and drawn back through the original opening, so that the uterus is suspended by the peritoneal strip. The uterus is slid well down on it until the fundus lies forward beneath the lower angle of the wound. A supporting catgut ligature is passed through the peritoneal coat of the uterus just behind the peritoneal ligament, and the uterus is temporarily suspended by this by passing the two free ends through the peritoneum and deep fascia on either side of the wound and tying it. The upper free end of the peritoneal strip is secured by including it in the running catgut suture which closes the peritoneum, thus re-uniting it to the peritoneum from which it was severed. Martin has examined the uterus bimannually after suspension by this method in over 300 cases, at periods varying from two weeks to eight years, and has always found the results to be an excellent one. Six pregnancies occurred in this series, and in none of them did the woman suffer any unpleasant symptoms during gestation or labor. There was no appreciable pull on the uterus or abdominal wall; the cervix was normal in location. The paper is closed with the following summary:

1. A very small percentage of uncomplicated retroversions may be cured by correcting an anterior position of the cervix by lengthening the anterior vaginal wall and shortening antero posteriorly the mucous membrane of the posterior vaginal vault after the Schickling method.
2. The Alexander operation of shortening the round ligaments is a safe, rational and permanently satisfactory procedure in persistent retroversion in which no pelvic complications exist demanding a peritoneal opening and should be pursued as a routine operation in such cases.
3. In slight adhesions of the fundus of the uterus with little other pathology to be palpated, a posterior vaginal incision may be made by one accustomed to deep vaginal operation, the adhesions separated and the sacrotuberine ligaments shortened.
4. With slight adhesions present and little pathology to be demonstrated, an anterior vaginal incision is justified in the hands of an experienced operator, provided that he adopts a vaginal round ligament operation for correcting the displacement and never a fixation.
5. When an Alexander operation is contraindicated in a persistent retroversion, because of doubt as to pelvic adhesions or diseased adnexa, it should become a routine procedure to open the peritoneum by a short exploratory incision through the abdominal wall above the symphysis for the purpose of managing the adhesions and diseased adnexa.
6. Some form of simple superficial ventral suspension should be followed as a routine method of retaining the uterus forward in cases where sterility is rendered imperative from the nature of the accompanying procedure, or when the patient has passed the menopause.
7. When the repair of complicating conditions in retrodisplacements requires a uterotomy, the operative procedure leaves the woman with child-bearing possibilities, a superficial ventral suspension or intraperitoneal shortening of the round ligaments should be employed to retain the uterus forward.
8. In a small but definite percentage of cases of complicated retroversions where accompanying pathology is such as to cause extensive denudations of the peritoneal covering of the uterus, or where the repair work on the appendages is such as to be liable to lead to dystocia, the surgeon should at once render the patient sterile by amputating the tubes into the horns of the uterus, obliterating them by inversion sutures, and then suspend the uterus.
9. In performing a suspension or an Alexander, one important element of danger can be eliminated by substituting for dead permanent suture material my autoplastic methods of securing the suspensory ligaments.

51. **Hemiphilia with Postpartum Hemorrhage.**—Gay reports a case of postpartum hemorrhage in a hemiphilic complicated by intrapartum sepsis. Following the birth of the placenta, and in the absence of cervical laceration, there continued a considerable amount of oozing which, in spite of ergot, packs, and massage, continued until the pulse ran up to 175 twenty-four hours after delivery. The temperature rose steadily until it reached 105.3 on the fourth day. On the eleventh day it took

on a distinctly septic character; on the twenty-fifth day metastatic abscesses were opened, and from thence onward the pyrexia rapidly disappeared. The highest temperature record was 106.8, the lowest 97.6. Pure cultures of streptococcus were isolated on the ninth day from the cervix and also from the pus of abscesses on the arms and legs. The treatment consisted of hot intra-uterine douches, saline infusions, calcium chlorid, grain 10, every four hours. The uterine oozing ceased at the end of the fourth day. When the patient seemed in extremis, irrigations of the colon were begun. Tepid salt solution was allowed to filter in without intermission, except for a daily cleansing soap and glycerin enema, for five days. After this only two quarts were allowed to run into the colon every six hours, and at the twentieth day of the disease colonic irrigation was discontinued. Gay emphasizes the value of these irrigations, and is convinced that they were instrumental, to a very large extent, in saving the life of this patient.

57 Medical Organization. George W. Baker.
58 *Disseminated Miliary Tuberculous Peritonitis, with Lesions of Primary Intestinal Tuberculosis Involving the Appendix and Cecum. Andrew J. Hosmer.

56.—See abstract in THE JOURNAL of July 2, p. 70.

58. **Tuberculosis.**—A case of disseminated, miliary, tuberculous peritonitis with ileus, and one of primary intestinal tuberculosis involving the appendix and cecum are reported by Hosmer. The first patient, a male, aged 20, family history negative, was perfectly well until six months before seeking medical aid. At that time there began a pain in the abdomen, principally toward the right side. He lost in weight and his abdomen became a little more prominent. When the obstruction occurred the abdomen was greatly distended, the pulse very rapid, temperature only slightly elevated, and the patient in a very critical condition. On opening the abdomen it was found that the obstruction was one of so-called paralysis of the bowel due to extensive tuberculous disease. An enterostomy was performed, and later six inches of the intestine was removed, and anastomosis being affected with a Murphy button, reinforced by the Halsted stitch. The patient recovered from the operation and apparently from the disease. The history of the second case is somewhat similar to that of the first, except that the pain was of three years' duration. There was no loss in weight. The pulse was about 100; temperature normal; abdomen retracted, very sensitive and hard. On palpation a sensitive, moveable mass, the size of a child's fist, was felt in the cecal region. At the laparotomy it was found that the mesenteric glands were slightly enlarged. The appendix, about four inches of the cecum and a portion of the ileum were greatly thickened and apparently agglutinated together. The intestinal wall was nearly destroyed, and an early perforation appeared imminent. The appendix, a portion of the ileum and the ascending colon above the ulcerated area were resected, and an anastomosis made between the ileum and the ascending colon by means of a large Murphy button without cutting the walls of the gut or using ligatures. The anastomosis was reinforced by means of a Halsted stitch. In the first case the button was passed on the tenth day, and in the second case on the seventh day. The patient was discharged after three weeks and has been in excellent condition ever since.

64 Should a Physician Dispense? F. G. Scott.

60. **Chronic Synovitis.**—The treatment followed by Smith consists of the use of an appliance which secures extension and counterextension, together with mild mechanical stimulation over the affected part. In one case cited, a chronic synovitis at the ankle joint, the appliance was made of steel, with a sandal, two bars and two bands, with joint at the ankle. There were six buckles on the sandal, three on each side, which fas-

tended to a plaster bandage around the ankle, and two buckles at the top of the bars, fastened to plasters on the limb. The appliance was also provided with a set screw at the ankle which prevented motion. By this means the foot was held rigidly, as in a plaster cast, and the disadvantages of the latter were done away with. The foot was brought into an extended position by means of an elastic toe strap. The result in this case was an excellent one. In a second case cited, one of chronic synovitis of the knee joint, the patient was fitted with an appliance made of steel, a sandal, two bars, four bands and a sent-piece. In this case joints were made at the knee and at the ankle, with two buckles, one on each side of the sandal, which were fastened with plaster on the limb, thus giving extension. The sent-piece was fastened to the appliance with a ratchet, thus giving counter-extension. A ratchet was also provided beneath the knee by which the limb was straightened slowly, and with practically no pain to the patient. In both cases the parts were stimulated by vibratory massage.

69 *The Manner of Stripping the Seminal Vesicles. Joseph Titus Eastman.

69. **Stripping the Seminal Vesicles.**—Stripping of the seminal vesicles, says Eastman, not only empties these organs of pathologic contents, but stimulates as does a sound in the urethra and promotes re-absorption of inflammatory infiltrations and exudation. It is essential that a distinct plan for the expression of the contents of the vesicles be followed. A long forefinger offers some advantage in the manipulation of these organs; still, if the operator possess the requisite skill and if he patiently overcomes the resistance of the perineal muscles, the shortness of the index finger becomes a matter of less importance. Eastman employs the right index finger in stripping the left vesicle (the patient being in the standing position), and the left index finger in stripping the right vesicle. In this way each vesicle may be compressed between the finger and the corresponding side of the bony pelvis. Instead of simply pushing against the vesicle with the finger tip, the tip of the finger may be passed to the inner side of the vesicle and from above downward along the inner posterior aspect of the vesicle as the organ is drawn and compressed laterally against the firm resisting pelvic musculature.

74 Congenital Hypertrophic Stenosis of the Pylorus in an Infant, with Report of a Case. John Dornbig.

70. **Lobar Pneumonia in Infancy.**—Morse's findings may be summarized as follows:

Lobar pneumonia is more common and occurs relatively more frequently in comparison with bronchopneumonia in infancy than is generally supposed. The analysis of these cases shows the following points: The onset was less stormy than is generally thought. It usually began with fever and cough, which were often accompanied by apathy or drowsiness. Movement of the abdomen was not a constant symptom. A whole lobe was more often involved than a part. The left lower lobe was the one most commonly involved. The right upper lobe and right lower lobe came next in frequency. The portion of the lungs involved was relatively the same in the fatal cases as in those which recovered. As a general rule, the area involved was larger in the fatal cases. The average duration of the fever in the cases that recovered was about eight days, being nearly the same in both years. The course was more often short in the first year, however, than in the second. As a rule, the average duration of the fever in the uncomplicated fatal cases was 12.5 days; that is, the duration of the fever was longer in the fatal cases than in those that recovered. The highest temperature was usually between 103 F. and 106 F., the number of crises being the same for each degree. The temperature fell by crisis in 68.8 per cent. Crises were less common in the first than in the second year. Collapse during the crisis was very unusual. Pseudo-crises were not very common, but irregularities and remissions in the temperature

were not at all unusual. The mortality was lowest when the temperature did not rise above 103 F., and highest in those cases in which it went over 106 F. The degree of fever between 103 F. and 106 F. had no apparent effect on the mortality. A high temperature was no more fatal in the second year than in the first year. The usual pulse rate was between 150 and 170. No case died in which the pulse was not over 140. The rate of the pulse, when it was above 140, had little or no apparent influence on the mortality. The usual respiratory rate was between 55 and 80. No case died in which the respiration was below 55. The rate of the respiration, when above 55, had no apparent effect on the mortality. The mortality, excluding the cases in which death was due to empyema, was nearly 23 per cent. It was almost twice as great in the first as in the second year, being 32 per cent. and 18 per cent. respectively. Otitis media was the most common complication, occurring in 18 per cent. Empyema was the next most frequent, occurring in about 8 per cent.

The prognosis of lobar pneumonia in infancy varies decidedly with the age of the infant, and to a certain extent with the amount of lung involved. The prognosis is good when the temperature is not over 103 F. It is serious when it is above 106 F. Variations between these points make little or no difference in the prognosis. The prognosis is good when the pulse is not over 140 or the respiration over 55. The amount of the increase above these limits is of little importance.

71. **Acute Myocardial Insufficiency.**—Forchheimer points out the large number of the acute myocardial insufficiencies developing in connection with the infections in childhood—scarlatina, diphtheria, rheumatic fever, septicemia, typhoid fever and pneumonia. For uncomplicated myocardial insufficiency the first principle in the treatment is absolute rest. The digitalis group of drugs may be used; their efficiency depends largely on the amount of myocardium affected. Predisposing causes should be controlled. Stimulants will be required in most of the cases, from alcohol to camphor or ether, according to the severity of the case. The convalescence must be especially guarded, and for the purpose of strengthening the myocardium mechanical means are invaluable—Swedish movements, massage, vibratory methods. The diet is the same as in all myocardial affections. Laxatives that act violently should be avoided. Strychnia may be used for its general tonic effects. Nitroglycerin should never be used unless there be anginous attacks. Care must be taken to exclude the existence of vasomotor paralysis, when nitroglycerin does harm. For the treatment of vasomotor paralysis, Forchheimer advises hypodermic injection of adrenalin. Inasmuch as its effects are transitory, the injections have to be repeated every two hours. Saline transfusions are used in the beginning in order to keep up the heart's contractions. Ice-bags are put on the abdomen to stimulate the splanchnic reflex. After the most violent symptoms have passed over, caffeine soda salicylate is given every two to four hours, alternating with adrenalin, which is gradually dropped.

73. **Percussion of the Skull.**—After careful investigation, Koplik advises that the MacEwen sign must be accepted with great caution in the case of infants below 2 years of age. It is one of the most useful signs of fluid in the lateral ventricles of the brain in various forms of meningitis, especially of the tuberculous type, and in tumors at the base of the brain. He emphasizes that in seeking this sign the patient must assume the sitting posture, as otherwise error is inevitable.

2.—See abstract in THE JOURNAL of September 3, p. 690.

4. **A New Trematode.**—The amphistoma Watsoni, isolated from the small intestine of a negro who had died of starvation and diarrhea, is described by Conyngham as being pear-shaped, flattened ventrally and slightly indented posteriorly, at the margin of the posterior sucker, and of a dark slate color. The anterior sucker is retracted and lies at the bottom of a sulcus, which is terminal and ventral; the posterior sucker being sub-terminal and ventral. The genital pore lies about a quarter of the length of the parasite from the anterior end, and is rather prominent. The cuticle of the body is marked with transverse ridges, these being coarser and better defined on the ventral surface; the latter is flattened, surrounded by an elevated ridge and bulges posteriorly. The worms measure 8 mm. long, 5 mm. at the point of greatest breadth, this tapering gently anteriorly to 2.5 mm.; their greatest thickness is about 4 mm.

8. **Leprosy.**—Tonkin supports the proposition that leprosy is a disease not only markedly amenable in any of its grades to intelligent direction, but one from which, both with and without treatment, recovery may take place. He believes that leprosy is a disease that often yields to the influence of improved circumstances, whether that improvement be the result of wise supervision in an institution or a fortunate course of events outside. He urges the importance of the recognition by the profession as well as by the laity of the curability of the disease, as in this way only can the authorities be made to adopt such measures as will tend toward a cure of the disease.

12. **Intestinal Obstruction.**—Barker calls attention to the fact that too much stress has been hitherto laid on the mere removal of the mechanical stoppage and not enough on the evacuation of the putrid material which is killing the patient. The older method of emptying the bowel by colotomy is unsatisfactory as the bowel is in a state of paresis or complete paralysis and expels its contents very slowly, so that until it is cleaned out the cause of the paralysis remains in great part. The best course in many of these cases, probably in all, that are still within the reach of any operative procedure, is to resect the tract of paralyzed and distended bowel at once. This does not apply to recent cases where the bowel is not seriously damaged by the retained feces and is manifestly sound at and above the seat of obstruction. Barker does not establish drainage in most cases, but closes the abdomen at once unless there be general peritonitis, having a great belief in the power of the peritonium to take care of itself. The after-treatment is of extreme importance. Patients should in all instances sit up in bed from the first as much as possible, and only lie down for sleep, so as to overcome the tendency to hypostatic pneumonia. They should begin at once to take a mixture of 10 grains of

carbonate of bismuth three times daily, which he believes to be the best intestinal antiseptic. Albumin water, with 1 dram of brandy, should be given from the first, by mouth, in small quantities, and nutrient enemata and instillation under the skin of normal saline solution or 5 per cent. solution of glucose is recommended as a routine procedure. Half a liter morning and evening may be given, if necessary. It is not well to check a diarrhea, as this material must be evacuated before the patient is safe. Bismuth cleanses the gut and so arrests the diarrhea. Cold sponging and warm drinks will take care of the possible temperature. If the fever is due to pulmonary emboli or pyelitis, the general strength should be sustained by the use of the usual stimulants.

19. **Bullet Wound of the Brain.**—In the case related by Sheen the bullet was located by the x-ray, without which, says the author, surgery is helpless. The skiagrams in this case were taken laterally and antero-posteriorly, and localization was performed by the double impression on the single plate and the MacKenzie-Davidson cross-thread localizer. In the diagnosis, stereoscopic views are of great help, giving in the matter of relations and direction confirmation of other methods of localization. Stereoscopic views of foreign bodies lying deep in the cranial cavity do not, however, give a very clear idea of the exact depth, owing to the absence of intervening landmarks. From the stereoscopic plates a "plastographic" view was made, one print in green being superimposed on the other in crimson, to be viewed through green and crimson glasses. This is the first time the method has been applied to x-ray work, and the author suggests that there may be a future for it as a means of illustrating stereoscopically x-ray photographs in medical journals.

22. **Anaerobic Plate Cultures.**—To carry out the process required for the establishment of anaerobic conditions in plates, Frenlin's method of procedure is as follows:

The rim of the chamber is well vaselined, the plates are placed in the stand, and a small test-tube of ordinary sugar bouillon or other reducing fluid colored with a drop of saturated alcoholic solution of methylene blue, is placed in the support provided for it. Eight grams of pyrogallic acid are first introduced into the chamber, followed by 80 c.c. of a 10 per cent. solution of caustic potash. The stand carrying the plates and tube is now lowered into the chamber by the handles and the lid is carefully put on. The whole apparatus can then be incubated. The process of the absorption of oxygen from the chamber and its contents by means of the alkaline pyrogallic solution can be noted by observing the change in color of the methylene blue indicator; as anaerobiosis is established the color entirely disappears. If the color does not disappear it is evident that there is a fault either in the apparatus or technique, and this must be found and remedied. It must be remembered that the absorption of oxygen within the chamber causes a considerable tendency to leakage of air inwards which must be prevented by careful attention to the seal. Bacteriologically the results obtained in this large chamber are quite satisfactory and bacillus tetani can be readily grown in it.

August.

- 23 *Case of Malignant Dermoid Cyst of the Neck. D. M. Moir.
- 24 *Carbolic Acid Treatment of Plague. Mir Hidayatullah.

23. **Malignant Dermoid Cyst.**—Moir gives the history of a patient with a large tumor covering the whole of the right side and front of the neck, and overlapping the chest to the level of the second rib. The tumor resembled an inoperable sarcoma, but on palpation a distinct thrill was felt. The tumor mass was removed by excision, and on microscopic examination of the tissue the tumor was found to be a tubulodermoid with cystic degeneration, taking its origin in a persistent branchial cleft the epithelium of which had undergone carcinomatous change. All the evidence in the case showed that the cyst was not the result of the softening of a metastatic deposit in the cervical glands, secondary tube, and epithelomatous growth in the mouth or nasopharynx, but was due to the distension of a tubulodermoid resulting from the imperfect closure of one of the branchial clefts, probably the third, epithelium of which had undergone the carcinomatous change.

24. **Carbolic Acid Treatment of Plague.**—The author has had considerable experience with carbolic acid in the treatment of plague, and when given in large doses in the commencement of the disease it has proved very useful. The acid was given in 12-grain doses every second hour to adults and in smaller doses

to children. It was given dissolved in water and sweetened with syrup and sandalwood, colored with a little tincture of cardamon. He gave it well diluted and advised his patients to drink large amounts of diuretic, cooling drinks, especially the water of watermelon and ordinary melon seeds ground in a mortar and mixed with water. Cardiac tonics such as digitalis, strychnin and rum were given, when necessary, as in the old or weak. In favorable cases the temperature fell several degrees within forty-eight hours, and within five days of the commencement of the treatment, the temperature was normal. Of 18 cases treated in this way, 12 were cured, and 6 died; 17 were bubonic cases and 1 was septicemic. Of those who died 5 were bubonic and 1 septicemic. In only 2 of the 18 cases was carbolic acid poisoning discovered, but this promptly disappeared on reducing the dose. The author concludes that septicemic cases are not influenced much by the use of carbolic acid.

25 President's Address. Urban Pritchard.

26 *Some Observations on the Mode of Origin of Nasal Polypi. Eugene S. Yonge.

26. Origin of Nasal Polypi.—A careful microscopic study was made by Yonge of the nasal mucous membrane with a view to determining the changes that take place during polypus formation, from the inception of the process to its completion. He submits the results obtained, from which he draws the following conclusions: 1. In the majority of instances, mucous polypi are probably consequent on and certainly coincident with inflammation of the mucous membrane of the nasal cavity. (2) The primary mechanical process is a localized edema of the inflamed mucous membrane, which edema, on account of certain structural peculiarities of the lining membrane, does not, in the great majority of cases, develop in any intranasal area, but that of a portion of the middle turbinal and of the middle meatal region. Analogous structural peculiarities are present in the mucous membrane of some of the accessory sinuses. (3) The determining cause of the edema in the regions specified is the degeneration and cystic dilatation of the mucous glands. (4) The particular shape which polypi usually assume, their number, probably the appearances of recurrences in some instances, and other special peculiarities of these growths are due to the edematous mucous membrane being thrown into folds and to the normal folds becoming edematous. Certain of the folds quickly increase in size by the absorption of serous fluid and favored by gravity, and finally present the appearance of ordinary mucous polypi. (5) The "polypoid" outgrowths which take origin on the inferior turbinal and more rarely on the septum, generally differ markedly in microscopic structure from mucous polypi, and although they claim a common inflammatory origin, these conditions are distinct, principally on account of the dissimilar structure of the nasal regions from which they respectively take origin. Yonge is arranging to conduct some experiments with a view of producing mucous polypi artificially in animals, on the basis of the causative influence of glandular changes.

30. Talalgia and Its Surgical Treatment.—Vincent remarks that the talalgia may be caused by a hygroma of the serous bursa or by an ossifying process with hyperostosis most marked at the points of attachment of the muscles and tendons, but the most common form is that not accompanied by any deform-

ing process. Whatever the lesion, it is always accompanied by a neuritis of either central or peripheral origin, as the primal disturbance is always due to the action of some toxin. Generally the toxin is secreted by the gonococcus, but other agents can sometimes be incriminated. The action of the toxin in question is restricted to the region of the heel. In one case it induces the formation of a hygroma, in another an ossifying process, in another the bone and tendon tissue is affected, but the nerves of the region suffer in every contingency, with the neuritis as the result. Treatment to be effectual must remove the cause, that is, clear out the toxins, when order will be restored at once. Medical treatment should be given a trial first, rest, revulsion along the spine, hydrotherapy, local massage and dry hot air. If this fails or gives but transient relief, an incision about 6 cm. long down to the bone, under local anesthesia, will allow all the proliferating tissue to be scraped out and the serous bursa ablated, no matter whether it appears diseased or not. The fibrous tissue should be scraped and abraded. This procedure facilitates the absorption of the toxins and may possibly destroy the nerve filaments which are suffering from the neuritis. The result has always been a complete cure in his experience, even of the most rebellious, long-established cases.

37. Rectal Feeding.—From his review of 128 articles on the subject of feeding by the rectum, Reach thinks we can safely count on the carbohydrates being absorbed by the rectum in considerable amounts and utilized by the organism, although the absorption is not complete. Fats are not taken up well in nutrient enemata, but their absorption can be promoted by addition of pancreas, which has also a favoring action on absorption of albumin. The opinions of various authors in regard to absorption of albumin vary widely. Individual conditions have much to do with it. The use of predigested albumin does not seem to offer any advantage, especially as such substances easily irritate the intestine. Casein and milk are not adapted for rectal feeding; Reach's personal experience has corroborated the general views in this respect. In regard to absorption of egg albumin, experiences have differed. It is certain that it is not absorbed in many cases, and defibrinated blood not much better. There is no reason for preferring the albumins to the carbohydrates; the arguments are all on the other side. In cases in which the nutrient enemas are merely supplementary to ordinary feeding, the carbohydrates are much superior. Dextrin deserves particular attention in this respect. The slight stimulating action exerted by the carbohydrates can be increased by the mode of using them and by addition of opium. At best, however, rectal feeding is unable even approximately to supply the requisite amount of energy even for debilitated bedridden patients. Reach concludes with the indications for rectal feeding and the technic. He remarks that the physician very often deceives himself when he thinks that he is making a "high" injection.

38. Appendicitis and Female Genitalia.—Pollak concludes from his study of 300 recent articles by writers of various nationalities, that the German operators are becoming converted to the principles of the American and French surgeons in regard to the advisability of prompt operating in appendicitis. The various views in regard to the connection between the genitalia and appendicitis and the modes of treatment are discussed in detail.

39. **Revulsion and Acupuncture in Japan.**—Okada's communication was presented at the Austrian Congress of Neurology last May. It was accompanied by specimens and views of the measures described. The "kju" is a kind of fibrous vegetable substance which is sold in the shape of small cylinders about 5 mm. long and 1.5 to 4 mm. thick. One is placed on the skin, slightly moistened to make it adhere, and it is then lighted. It burns or, rather, glimmers slowly, and exerts a mild thermal irritation on the skin. When it is desired to have the irritation stronger the cylinder is applied several times to one spot and an irritating salve is rubbed in. It is sometimes applied with pressure. The fibrous substance is compressed into a sausage-like roll about 18 cm. long, very compact and hard. A few layers of paper are placed on the skin and the "kju" is lighted and applied, pressing it down into the paper. As it can not get air, it burns very slowly and merely scorches without burning the paper, causing an agreeable sensation of warmth and pressure at the spot. The "kju" was known and used fully 1,350 years ago, but was then forgotten for a thousand years. It is a favorite remedy for neuralgias, headache, etc., and although practiced now only by charlatans or by physicians of the old Chinese school, yet to this day it is in use in families from the lowest to the highest. The instrument used for acupuncture is a long, fine gold or silver needle, scarcely thicker than a hair, 4 to 6.5 cm. in length, mounted in a metal handle, and with a protecting guide outside. It is inserted up to the hilt, and the procedure is scarcely at all painful. The points where this acupuncture is allowable are carefully defined. Okada thinks that the points have been empirically determined by the track of an aching nerve, as they follow the nerve in some instances and in others not. The extremities are the favorite points, and it is assumed that acupuncture of certain fingers or toes has a distant action in curing certain affections such as eye troubles, toothache, etc. Okada has had the "kju" applied to his own person several times. Once or twice it was done as a tonic measure, and a few times as a punishment for some boyish prank. He does not attempt to estimate the therapeutic value of these procedures, as he has had so little experience with them. He regards them as harmless and beneficial to a certain extent. He has witnessed violent colic subside under the influence of a few applications of the acupuncture, but does not venture to say how large a share suggestion may have had in the result.

40. **Heart Defects and Pregnancy.**—Pollak draws no special conclusions from the 245 articles which he summarily reviews, but his article presents a good picture of the views and practices of the leading clinicians of the day on this subject.

41. **Leucocytosis in Intra-Abdominal Suppurations.**—Turkel discusses the question as to the diagnostic import of leucocytosis in these cases, citing the views of nearly seventy authors on the subject, with their clinical experience in regard to the blood findings. In conclusion he emphasizes the four points which must never be forgotten in diagnosing by this measure: 1, exclusion of concurrent causes for the leucocytosis; 2, repeated determination of the number of leucocytes; 3, large numbers of leucocytes (20,000 to 25,000), with indications of involvement of the peritoneum, and finally, that negative findings should never be cited as evidence.

42. **Irritable Bladder.**—Hirsch draws the clinical picture of irritable bladder from his own clinical experience and study of 124 articles. He regards it as a well-defined symptom-complex whose clinical basis is an objectively evident hyperesthesia of the bladder mucosa. It may occur with or without pathologic findings. The latter is the nervous variety, the other is accompanied by simple, non-inflammatory hyperemia. They differ slightly in their manifestations and materially in their etiology and therapeutic indications. Irritable bladder entails in time a number of consequences which usually render the affection irreparable. Even without these, it is a very obstinate trouble, owing to the vicious circle which becomes established between the urinary impulses and the hyperemia of the mucosa. Treatment is generally very slightly effectual, as is evident from the large number of measures proposed for

the affection. It has been called by various names, but that of irritable bladder or hyperesthesia vesicæ is by far the most suitable.

43. **Mal Perforans.**—Not much has been written on the subject of mal perforans that has escaped Adrian's vigilant search, as is shown by his bibliography of 445 titles. He reviews the various articles cited and discusses the always grave prognosis and the treatment. The latter should be mainly prophylactic in persons predisposed by tabes, diabetes, etc. Their footwear should be carefully adapted to avoid pressure on the site elected by mal perforans. Cleanliness and rest in bed are the chief factors in treatment and the lesion may heal in time. Instances are on record in which a complete cure followed absolute rest in bed for a month. Caustics should generally be avoided. The outcome of treatment generally depends on the underlying affection. Cures have been reported from the constant and induced electric current, and from galvanism and faradism, or their combination. Thyroid substance has been tried without avail, as also elastic compression. Mercurial treatment has been successful in certain cases, but not in others. Surgical treatment fails when an affection of the spinal cord is the fundamental trouble. Cases due to arteriosclerosis usually indicate amputation, as gangrene is almost sure to develop sooner or later. Treatment is most promising in the cases due to peripheral paralysis following traumatism. The longer the interval since the injury and the larger the space between the stumps of the severed nerve, the less certain the results, although in one case on record the severed nerve was sutured a year after mal perforans had developed. The ulcer healed soon after the nerve had been reunited. Chipault's method of treating mal perforans by stretching the tibialis or its branches after excision of the ulcer has been tried in 79 cases, with immediate success in all but 10. Of the few cases followed for more than a year 3 are known to have been completely cured for two years, 6 for three, 4 for four, 2 for five, and 1 for six years. This permanence of the result of this "elongation trophique," as Chipault calls it, certainly warrants further trials. Delagenière prefers to expose the nerve for a considerable extent and dissociate its fibers, separating the nerve into its elements and destroying all the vessels which accompany the nerve, in order to thoroughly modify the previous conditions. He cured by this means a bilateral mal perforans in a man of 27. He calls it "hèravage," that is, the harrowing of the nerve, borrowing an agricultural term.

45. **The Urine in Health, in Rheumatic Affections and After Salicylic Medication.**—The research reported from Frankfurt shows that normal persons exhibit traces of albumin in the urine to a proportion of fully 58 per cent. of all normal subjects. The normal urine is also liable to contain particles cast off by the kidneys, the same findings as are encountered in afebrile rheumatic affections. In the febrile cases the find-

ings are the same only in more pronounced degree. The febrile rheumatic affections induce a toxic "nephritis" which manifests itself clinically by an increase in the formed elements, especially of the granulated tube casts. This "nephritis" heals under the salicylates. The latter also are liable to induce a characteristic "nephritis," which, however, heals under their continued administration. The findings in 10 out of 93 normal subjects examined are tabulated, as also 5 out of 13 cases of afebrile rheumatic affections, and 5 out of 53 febrile rheumatic cases. The most interesting tables are those of 3 typical examples out of 66 cases under salicylate treatment. Fully 1,200 separate examinations were made, with an average of 17 to 19 or more in each case.

46. Cutaneous Temperature in Health.—Among the points learned in the research reported by Oehler is the fact that the temperature of the skin grows less when food is withheld. When food is being taken the skin and rectal temperature run a parallel course, although the external temperature has more influence naturally on the former.

47. Cold-Water Bed in Treatment of Typhoid.—This article reviews the experiences at Kiel with 513 cases of typhoid. It is the practice at Quincke's clinic, whenever it is deemed inadvisable to move the patient for the Brand baths, to spread an empty rubber water-bed between the mattress and the sheet. It is then pumped full of water, using about 50 quarts for adults and 33 for a child, at a temperature of 50 to 64 F. It is refilled once to three times a day. The patient's temperature is not so abruptly lowered by this water-bed as when a cold bath or pack is used, but the reduction is much more permanent. It is particularly useful in case of intestinal hemorrhage, heart weakness, peritonitis, thrombosis or whenever muscular exertion from any cause is to be avoided. It also tends to prevent bedsores. Its place is to supplement, not substitute, other hydratic measures. In case of somnolence or when it is necessary to stimulate the circulation the cold bath is preferable. The water-bed is especially useful when the nursing personnel is limited. It is a rubber bag about a yard long by three quarters of a yard wide or a trifle larger. It is filled by siphon action from a vessel standing about four feet from the floor. Out of the total 513 cases discussed, 360 were treated with cold water and 157 by the water-bed, but only 72 by the latter alone. In 85 cases baths and packs were used in combination with it. A rectal temperature of 39.5 C. (103 F.), is the signal for cold water in some form.

48. Pseudo-Ascites as Consequence of Chronic Enteritis.—See editorial, page 116.

53. Urotropin to Prevent Nephritis in Scarlet Fever.—Buttersack's indorsement of the prophylactic use of urotropin has attracted much attention (see THE JOURNAL, xli, page 1309). In the dosage he advocates .05 to .5 gm. three times a day—there need be no fear of disturbances, even in case of recent nephritis. When it is not given as a preventive during the entire course of the disease it should be administered at the first trace of albumin in the urine. He explains its action as due to the liberation of nascent formaldehyd in the glomeruli and tubules, neutralizing the scarlatinal toxins or destroying the bacteria exactly at the points where the morbid process starts. His experience was limited to 10 cases, but he relates the details of 3 in which the typical scarlet fever followed soon after diphtheria or rheumatic endocarditis, with an evident predisposition to trouble on the part of the kidneys. There was not a trace of nephritis in a single one of the 10 children treated with the urotropin or some similar preparation.

56. Effective Internal Disinfection of the Biliary Passages.—Kuhn has been applying in the clinic the results of his experimental research in this line. As he has previously reported, thymol, menthol and the salicylates are the only drugs out of a long list tested which displayed any efficacy in this respect without serious by-effects. Salicylic acid passes into the bile in large amounts and even in a comparatively weak concentration checks the fermentation of the bile. All the numerous tests resulted positively, and justify the assumption that the salicylates can be used for effectual disinfection of the biliary passages. Exhibition of the salicylates, therefore, in cases of cholangitis and cholecystitis is to be commended to the general practitioner. Further tests of a combination of two or more of the above mentioned drugs seemed to demonstrate a still more effectual action. He found that the gas-producing power of the bile derived from a biliary fistula was very much reduced when the subject was under the influence of the salicylates alone or combined with menthol or thymol. Bile from a biliary fistula exhibits progressive fermentation, but when the subject has been taking the above drugs the fermentation is much less intense and subsides much earlier. The effect of the drugs is not perceptible until after they have been duly absorbed and it lasts for some time after they have been suspended. The best internal medication in case of inflammation in the biliary passages is, consequently, salicylic acid and its salts. Kuhn lauds his method of determining the gaseous products as an accurate test of the decomposition of a fluid. He regards it as a physiologic-chemical test, more delicate than chemical analysis. It would be difficult by the latter alone to recover the salicylic acid in the bile, while its fermentation-inhibiting action is unmistakably apparent even with minimal amounts present. He adds a trifle of sugar, infects with a little intestinal content, and sets the vessel in the incubator at 37 C., examining it at four-hour intervals to note the production of gas. The results of the various experimental and clinical tests are tabulated, the findings all emphasizing that in salicylic medication we have a powerful weapon on our command for controlling inflammatory processes in the biliary passages. Among the subjects with biliary fistulæ treated with the salicylates was one whose bile displayed a gas-forming power as follows: After addition of 1 per cent. sugar and infection with a little fecal material and incubation at 37 C., the amounts of gas in the fermentation tubes at the fourth, twelfth, twenty-fourth, thirty-sixth and forty-eighth hours were respectively 1, 3, 5, 8 and 10 cm. These same figures were found at every repetition of the test. On the other hand, after sodium salicylate had been given the patient in 1 gm. doses every four hours, the amount of gas that formed was only .2, .3, .8, 1 and 2.5 cm. at the corresponding hours. Aspirin displayed nearly as much efficacy in the same dosage, the amount of gas being .8, 1.5, 2, 3, and 3.5 cm. at the corresponding hours.

57. Success of Serum Treatment of Articular Rheumatism.—THE JOURNAL has previously described Menzer's successful application of an antistreptococcus serum in the treatment of articular rheumatism. Two years of experience have confirmed its efficiency for both acute and chronic articular rheumatism. It transforms the latter into a curable form, it seems to provide much better chances for recovery from endocarditis, and further seems to protect against recurrences better than any other means known to date. He groups his results in tabulated form. They include 29 acute and 22 chronic cases, with 3 in which the treatment was first applied in a recurrence, and 2 of chorea. He found that the appetite was always good under the serum treatment, and the general health did not suffer as under drug medication.

62. **Pathogenesis of Polyneuritis.**—In the case reported the multiple neuritis observed was ascribed to the subject's occupation, with an alcoholic predisposition. He had been a busy waiter in large hotels or restaurants for years, and the neuritis affected his legs and the muscles used in carrying and balancing his load of dishes.

 72 New Remedies and Measures for Idiary Lithiasis. G. Klempfner.—Ueber neue Mittel gegen die Gallensteinkrankheit.

67. **Humidity of the Air as a Factor in Heat.**—Frankenhäuser thinks that in order to apply Dalton's law to the human body we must modify it to read that the rapidity of evaporation from the surface of the body is proportional to the difference between the molecular pressure of the vapor escaping from its surface and the molecular pressure of the moisture already in the air. He has been studying the question at the Hydrotherapeutic Institute of the University of Berlin, and emphasizes the importance of this law for practical hydrotherapeutics. He estimates the pressure of the vapor from the lungs as approximately 43 mm.; of the naked, wet body at 48 mm., and of the lightly clothed body as 9.5 mm. at 15 C.; 14.7 mm. at 20 C., and 23.6 mm. at 25 C. The results obtained from various hyriatic measures vary as the humidity of the air of the room allows free evaporation from the surface of the body or not. When the evaporation is too rapid the subject is liable to be chilly, the vitality depressed, and he "catches cold" on coming out. When the temperature of the bathroom is 22.3 C. and the humidity 69, the pressure of the moisture in the air is equivalent to 13.6 mm. The actual heat in such a room, according to Dalton's formula, would be 22.2 plus twice 13.6. This is equal to 49.4 C. (121 F.). With a temperature of 20 C. and pressure of 27 mm. the actual heat of the room is 28 plus twice 27, equal to 82 C. (180 F.). In the steam room of a "Russian" bath, with a temperature of 46 C. and pressure of 75.16 mm., no evaporation from the body can take place; there is actual condensation on its surface and thus heat is added to it. The actual heat of such a room is equal to 196.4 C. On the other hand, a "Roman" bathroom with a temperature of 80 C. and 3 mm. pressure, has an actual heat of only 80 plus twice 3, equal to 86 C.

68. **Reduction of Obesity.**—Bornstein's principles of treatment of obesity include an abundant supply of albumin, as this imparts vigor to the cells. It is not necessary to give it in the form of meat. He allows a certain amount of fats, too, as they tend to reduce the appetite for other foods. He also allows soups and beverages, regarding the former as pre-eminently adapted to satisfy hunger by filling the stomach while supplying very little nutrient material. The patients should under-eat, but not go thirsty. They should satisfy their hunger with vegetables, soups, etc., and build up on albumin and exercise. They come out of the course with considerably more albumin in their tissues, although their obesity is reduced and they have not been hampered by the annoying restrictions of the usual anti-fat diet.

69. **Influence of Curare in Tetanus.**—After much experimental research, which is described in detail, as carried on at von Leyden's clinic, curare was used in the treatment of 3 clinical cases of tetanus. The results are a confirmation of the favorable experiences of Vella and Hoffmann in an early day. Modern scientific methods have enabled these experiences to be repeated on a large scale, avoiding the risks on which the early experimenters were shipwrecked. Claude Bernard first proclaimed the importance of curare in tetanus, and the present research has confirmed his view that it is the most important and most valuable symptomatic means at our disposal for the treatment of tetanus. The curare was used in the form of curaril, a preparation made in Berlin, which is durable, cen-

stant and pure, capable of very exact dosage and free from cumulative action. The tetanic convulsions of animals can be temporarily arrested, or at least allayed, and the course of the disease rendered much milder under the influence of curaril. In the clinic the curaril arrested the severe tetanic convulsions in one case for two hours, without displaying the slightest by-effect. In another, milder case, the convulsions were permanently controlled with the drug and the patient recovered. The curaril does not cure the tetanus, but it seems to effectually control and arrest the tetanic spasms, and is thus able to tide the patient past the stage of danger from suffocation by spasm of the muscles of respiration. It does not combat the fever nor heart weakness. Serum treatment is still indicated as before. The antitoxin binds the poison circulating in the blood, while the curaril controls the threatening symptoms caused by the poison that has already entered into combination with the cells. Morphin and chloral are still indicated also as sedative and narcotic, but the abolition of the spasms is the most important indication and this apparently can be accomplished with the curaril.

70. **Action of Radium Emanations on Malignant Tumors.**—Braunstein announces that he has benefited a number of cases of cancer by injection of a radioactive water or ingestion of radioactive bismuth. He produces the radioactive water by dissolving .1 to .2 gm. radium chlorid in water, distilling it in a Würzburg jar with a Liebig apparatus. The distillate is a radioactive fluid which he calls aqua beta, and uses for local injection into accessible tumors. For treatment of cancer in the stomach or esophagus he produces a radioactive powder by placing radium bromid, in substance or in solution, in a jar with some bismuth and leaving them in contact three to five days. The radioactive powder thus obtained he calls bismuth beta. It is applied topically or by ingestion. In these two forms the radium emanations have a marked and direct therapeutic action on the malignant growth, while they do not entail ulcerations. As the radium is capable of giving off these emanations indefinitely, it can be used over and over again. The radioactive bismuth lodges at the narrow part of the esophagus in case of a cancerous growth, and exerts its specific action exactly at the point where it is needed. Injection of the radioactive water into the tumor is followed by the destruction of the cancer cells without injury to the skin or surrounding tissues or ulceration of the surface of the cancer. The action of the emanations seems to be that the cancer cells are primarily and directly devitalized and are then absorbed. None of his patients is cured, as he instituted the treatment only last January, but the results in many of them are so encouraging that he considers it a duty to urge others to try this simple method of treatment. One of his patients was a man of 54 with carcinoma of the cardia. He had become rapidly emaciated and was unable to take any solid food. He drank 3 gm. of the bismuth beta in water, six times in seven-teen days, with the result that he was able to swallow better and his weight remained stationary. In the other cases of cancer of the esophagus the ability to swallow solid food was partially restored and the patients felt much better in every instance.

73. **Hematuria.**—Hirt reviews the various causes of hematuria and describes a number of cases to illustrate the difficulty of differential diagnosis in many instances. When the patient is seen during the course of a renal hemorrhage it can readily be traced to the kidney in most cases, but some may require exploratory incision of the kidney. Hematuria

proceeding from the bladder or prostate can generally be diagnosed with ease. The discovery of the bacilli is the only decisive evidence of tuberculosis. In one case the bladder was ruptured during extirpation of an ovarian cyst, but the rupture was not discovered at the time. A few drops of bloody urine were noticed soon after, although the general condition was excellent. The bladder was filled with a warm solution of boric acid as a diagnostic measure. The patient collapsed in a few minutes and died in less than half an hour. In another case an elderly man suffered from hematuria, with nothing to account for it except considerable arteriosclerosis. Before the patient could be examined with the cystoscope he died suddenly. The necropsy revealed cerebral apoplexy and numerous small arteriosclerotic aneurisms in both kidneys, the other organs comparatively sound. Another patient suddenly presented hematuria, without pain and with no other symptoms, no history of gout. Two weeks later dull pains were noted in the left side, and the left kidney was found enlarged, the urine from this kidney blood-stained. A small protuberance was seen at the mouth of the left ureter, suggesting tuberculosis, but no bacilli were found in the urine. The diagnosis wavered between tumor and tuberculosis, when a small concretum was evacuated with intense pains, and the hematuria ceased at once.

76. Atrophy of One Hemisphere.—Two cases are described and illustrated to show the difference between atrophy of a hemisphere due to disease, and caput obstipum due to intra-uterine pressure on the skull. Persons in the first category are generally victims of epilepsy, or are mentally deficient, while persons in the second category are comparatively normal.

78. Case of Juvenile Tabes.—The lad of 10 was the son of a tabetic father and healthy mother. At the age of 6 he developed incontinence of urine, and at 9 gastric crises. Kaufmann thinks that a hereditary tendency to tabes must frequently occur, but is overlooked when the patients are not seen until adult age. He concludes with the remark that we know certain important predisposing causes for tabes, but that the direct cause for it is as much a mystery as ever.

79. Inhalation Treatment of Catarrh of the Air Passages.—Saenger has been using for three years an apparatus which allows the vaporization of substances too insoluble to be used as a spray. He gives views of the simple apparatus and describes its workings, affirming that medication by means of fumes or gases deserves much more attention than it has yet received. The scantiness of the results obtained by this form of therapeutics to date has been due to the imperfectness of the apparatus used. With improved technic the results in his hands have been remarkably fine. He uses menthol, Peruvian balsam, turpentine, eucalyptus, cypress and other oils, with dimethylformal, the latter consisting of two molecules of menthol to one of formaldehyd. He reviews his experiences in detail.

92. Medical Treatment of Uterine Fibromyoma.—Carini had occasion to treat a woman of 42, who presented an interstitial fibroma with firm and multiple adhesions. The anemic condition and solid adhesions contraindicated extirpation and medical treatment, according to Hildebrandt, was instituted, the ergot being supplemented by fluid extract of *hydrastis canadensis*, and a tonic containing iron arseniate. The tumors vanished, and the general health recuperated, the patient eats and digests well all kinds of food and considers herself cured.

100. Inspiration in Diagnosis of Tuberculosis.—Giulio advises examination of the inspiration in numbers of healthy subjects. This will educate the ear so that slight variations from normal will be readily detected, and the diagnosis of incipient tuberculosis thus be made possible. The best way is to auscult the lung region carefully, point by point, during inspiration, examining first one lung and then the other, at alternate inspirations, the ear over the symmetric points in turn. After careful study of the inspirations alone the expirations can then be examined.

103. Alimentary Glycosuria in Liver Affections.—De Rossi of Bacelli's clinic first established on healthy subjects the minimal amount of sugar that would induce glycosuria in health. He then tested a number of persons with some liver trouble, and tabulates the results of 38 tests. Adding these to those reported by Sachs, Strauss and Ferrannini there are now 75 cases of liver affections on record which responded positively to the alimentary test with levulose in all but 5 instances. Saccharose and glucose give very uncertain and contradictory findings, but the levulose glycosuria can be relied on. When levulose is given in doses surpassing 1.9 gm. per kilogram it induces glycosuria even in healthy subjects. The elimination of the levulose commences generally in an hour after its administration, and may continue for two to six hours, but usually lasts only three or four. The amount eliminated is very small, and not dosable in the clinic, requiring the Trommer test. The amount given ranged from 60 to 100 gm. of levulose, equivalent to 1.25 to 1.84 gm. per kilogram of body weight.

104. Determination of Blood in Contents of Digestive Tract.—Fittipaldi remarks that all the tests for determination of "occult" blood in the feces and stomach content presuppose that the blood is dissolved, which is not necessarily always the case. It is frequently inclosed in mucus, especially in catarrhal conditions, and this prevents the action of the re-

agents on the blood. He has been using a technic which overcomes this difficulty, while its simplicity, facility and reliability in the most difficult cases render it superior in other respects, as has been demonstrated in three years of experience at De Renzi's clinic. The solid flakes in the stomach content obtained by lavage or in diluted feces are heated with 5 or 6 tablets of caustic potash to each 40 c.c. of fluid, until the mucus is completely dissolved. In case of the presence of blood, a characteristic reddish tint is imparted to the fluid, and a film with greenish reflexions forms on the surface. It is then set aside for five or six hours, when the filtered fluid will show still more characteristic tints, the reddish brown shading into green reflexions. The most characteristic sign, however, is the vanishing of the reddish tint when the filtrate is shaken up, exposed to the air, the oxidation causing the red to change to a brownish yellow. This technic is sufficiently accurate for most cases, but may be supplemented by spectroscopic examination.

112. **Exophthalmic Goiter.**—De Renzi prefers to treat febrile conditions in this affection with antipyrin rather than quinin. Thyroid treatment aggravates instead of improving the symptoms. He advocates absolute repose and isolation, even plugging the ears to keep out sounds.

113. **Ergography of Knee-jerk.**—A number of tracings are given showing the knee-jerk as mechanically elicited by a hammer and pendulum automatic contrivance. The tracings are of three types: high curves at first, gradually declining, the normal type; low at first, then increasing, then declining, the type observed in neurasthenics; and high and continuously high, the exaggerated reflexes of hemiplegia. The character of the tracings indicates that the knee-jerk is in reality a direct response of the quadriceps to sudden excitation of its tendon.

116. **Micro-organism of Pulmonary Phthisis.**—The discovery by von Schrön of the phthisiogenic micro-organism has already been chronicled in THE JOURNAL, page 478. In this description, written by one of his assistants, the announcement of this discovery is styled "one of those great scientific events which cast new and unexpected light on the old arguments." Schrön's lecture on the subject was accompanied by stereoscopic views, but the details of his technic have not yet been published. [De Renzi's *Nuova Rivista Clinico-Terapeutica* contains a letter from von Schrön, dated June 20, in which he states that the most important result of his researches is the demonstration that the caseous masses in the phthisic lung are formed principally by a large microbe, entirely different from the tubercle bacillus. It starts its growth as a delicate thread, straight at first, then tortuous, then ramifying to distinct tree formation, with subsequent enlargement and growth of the side branches until it resembles a lichenoid fungus in its development. When fully developed it grows capsules, somewhat similar to spores. At first these capsules are homogeneous little spheres, staining readily. In time they become granulated, and then pass into a phase in which their contents seem to be nothing but threads, mited in bunches in the ripe capsule. These threads differ completely from bacilli, spirilla and vibrios. When they escape from the capsule they invade the epithelial cells of the alveoles in the lungs. A cell thus invaded looks like Medusa's head, as only part of each thread bores into the cell, and the rest projects. The protoplasm of the cell soon becomes entirely consumed, and the nucleus alone persists. The threads grow and assume the arborescent form, with final capsule fruit formation to complete the cycle. The senile forms undergo fatty and mucous degeneration, thus originating the caseous detritus, and the cavity thus formed enlarges by the constant invasion of the tissues by the proliferating microbe. The tubercle bacillus may also find lodgment in the cavity, but the two processes are distinct entities. Schrön believes that the tubercle bacillus is generally the pioneer. Serum treatment of tuberculosis has always failed in phthisic subjects. Success is attainable only when the toxins of the phthisiogenic microbe can be included in the treatment. Drop pure cultures of this microbe have

been obtained, and also cultures in symbiosis with the tubercle bacillus, but no pure cultures have yet been secured *in vitro*. —Ed.]

ETIOLOGY OF CHOLECYSTITIS AND CHOLELITHIASIS.*

WALTER L. BIERRING, M.D.

Professor of Theory and Practice of Medicine and Clinical Medicine,
College of Medicine, State University of Iowa,
IOWA CITY, IOWA.

In considering the diseases of the gall bladder it is necessary to recognize that this viscus constitutes one of the most vulnerable points for infection in the abdominal cavity, and in this respect is analogous to the fallopian tube and the appendix.

A difference is noted in comparison with the appendix in that in the latter structure infective agents are more or less constantly present in its lumen normally, while the gall bladder is generally free from micro-organisms; furthermore, infection of the gall bladder concerns itself more with the contents than the walls, the sterile bile becoming a culture medium for micro-organisms, while in appendix infection the coats are more prominently involved.

The liability of the gall bladder to disease is due mainly to its position, interposing itself as a guard between the bacterial hordes of the intestine and the liver; and in the immunity which the liver appears to possess the gall bladder exerts a very important rôle.

In the majority of instances the bile is free from micro-organisms during health, this being particularly true of the gall bladder, the cystic and hepatic ducts, while the common duct usually contains a greater variety of micro-organisms.

Netter,¹ Naunyn,² Leubuscher, Gilbert and Girode³ and Myaki⁴ found the bile free in healthy animals. Fraenkel and Krause⁵ examined the bile in 130 cases at autopsy and found it sterile in 105 instances, and in 11 cases of gallstones it was also free in 5 cases.

Mieczkowski⁶ made cultures of the bile in 15 cases during life and found it sterile in all cases. Mikuliez, in examinations of the bile in 23 cases of operations for gallstones, found micro-organisms present in 18 cases; in the other five instances the bile was sterile.

It has been a matter of some discussion whether the bile acts as a bactericide or if micro-organisms find in the bile a good culture medium. While formerly it was

supposed to be antagonistic to the growth of bacteria, it is now demonstrated that a great many pathogenic micro-organisms flourish in it quite vigorously.

Dominici and Rodet found that micro-organisms which cause infection of bile passages thrive in bile media. Maly and Ernich, Leubuscher, Rohman, Bates, Fraenkel and Krause,⁵ and Mieczkowski⁶ observed that both typhoid and colon bacilli develop well but slowly in human bile.

It has been noted that when bile is thick it specially favors the growth of colon bacilli. Again, Ehret and Stoltz⁷ observed that fresh, non-sterilized bile has bactericidal properties and their observations confirm those of Mosse, finding it a poor culture medium. Mignot⁸ and Myaki⁴ report that colon bacilli live for many months in the gall bladder, there being some lessening in the virulence, but this is readily regained when developed in proper media. There are considerable observations to show that bacteria, like typhoid and colon bacilli, streptococci and staphylococci, which are normally present in the intestine, develop very or moderately well in bile, which, from personal work, I have been able to confirm.

In a contribution of Talma, bile is regarded as a mild bactericide of the colon bacillus and more strongly so for diphtheria and typhoid bacilli. Fütterer⁹ and Lauriac found living typhoid bacilli in the gall bladder months and years after an attack of the disease. These observers also claim that the bile contains normally substances which inhibit the growth of a majority of colon and typhoid bacilli.

The number of micro-organisms exerts a great influence on the fate or vitality of the contained micro-organisms, and again the bacterial activity is much more prominent in the gall bladder than in the bile ducts. It is further noted that the epithelium of the bile passages and liver cells resists infections greatly.

The question now arises, How and when does infection of the gall bladder take place? From clinical and experimental observation it is evident that infection occurs principally in two ways—first, by way of the blood, descending, or hematogenous; second, ascending, or by way of the common bile duct; the latter way is observed far more frequently clinically.

The first form is exemplified chiefly by the infections following typhoid fever, the avenue of infection being usually the portal or systemic circulation.

Infection of the gall bladder through contiguous tissues may take place, but it is not very common in human pathology. By reason of its isolated position it is but rarely involved in general infection of the peritoneum.

That the infection is facilitated by an interference with the drainage of the gall bladder is very evident, because so long as there is no obstruction to the flow of bile to cause stagnation the liver is able to excrete large numbers of micro-organisms through the bile. Experimentally the elimination of bacteria by the bile from the general circulation is demonstrated by the researches of Fütterer⁹ and Chiari,¹¹ Myaki⁴ and Cushing,¹² in connection with typhoid bacilli; Ferraresi, Quarries, with glanders bacilli; Corrado, Nicati, Oemler, Strauss and Chamberland, Oresti, Pernice and Alessi, Bernabei, with staphylococci and pneumococci; Friedlander with anthrax bacilli and cholera spirilla; Blachstein, Letienne, Biedl and Krause and Mengel with streptococci and colon bacilli. Clinically bacteria are demonstrable in the gall bladder in systemic diseases like pneumonia, typhoid, septicemia, pyemia and tuberculosis. The importance of typhoid bacilli in connection with the gall bladder has been specially emphasized in the work of recent years; in most instances the route of passage has been the circulation, but again migration by way of the common bile duct is very probable in certain cases. In connection with typhoid fever the typhoid bacilli have been demonstrated in the gall bladder by Chiari,¹⁰ Naumyn,¹¹ Chauffard, Cushing,¹² Welch, Sailor,¹³ Stockton²⁴ and others, both in a pure state and associated with other bacteria. In many instances the bacilli were found a long time after the typhoid infection; by Welch, three to four months; Miller,¹⁵ seven years; von Dungen,¹⁶ 14½ years; Groba,¹⁷ 17 years, and Hunner,¹⁸ 18 years after an attack. Flexner states that 50 per cent. of the cases of typhoid at autopsy contain typhoid bacilli in the gall bladder, and Keen reports 75 cases of typhoid bacillus infection of the gall bladder in typhoid fever. Again, typhoid bacilli have been in the gall bladder without any previous history at all of typhoid infection. It is thus illustrated that typhoid bacilli may exist dormant a long time in the gall bladder and yet retain their vitality and virulence.

There is little doubt but that the ascending form of infection of the gall bladder by way of the common bile duct is unquestionably the more frequent; and this is certainly the more common mode of invasion observed clinically, which is usually an extension of inflammation from the duodenum. The kinds of micro-organisms found correspond to those naturally inhabiting the small intestine, the colon bacillus always predominating.

EXPERIMENTS.

That any obstruction of the bile facilitates this migratory infection is shown by frequent illustrations. So long ago as 1876 Charcot and Gombault¹⁹ found stones and bacteria in bile after ligating the common duct in dogs. Netter²⁰ in 1886, after aseptic ligature of the common duct in rabbits, obtained cultures of bacteria from bile. In ligation of the common duct above the ampulla it takes but a few days before the same organisms appear in the bile and liver which are present normally in the duodenum and in that portion of the com-

mon duct distal to the ligature. Even injection of bacteria below the point of ligation is followed by passage through the ligature. In personal experiments I have noted that infection into the gall bladder of very virulent bacteria, as pneumococci and colon bacilli, when the flow of bile was not interfered with, was always without serious consequences. The introduction of aseptic foreign bodies in connection with bacteria greatly favors the growth of the bacteria injected. In the experiments of Ehret and Stoltz²¹ this increase in the number was found to be progressive, as the bile was examined from time to time. The conclusion to be drawn from this is that under normal conditions, if the gall bladder is free from stones and foreign bodies, it contracts and empties its secretion, which goes unhindered to the intestine; but when foreign aseptic bodies or gallstones are present the normal muscular action of the organ is interfered with, and a certain amount of bile becomes stagnant between the foreign bodies and greatly favors the growth of bacteria.

The rôle of gallstones in promoting infection of the gall bladder is purely contributory, and we know also that they may lie in the gall bladder a lifetime and no symptoms be produced until the bile becomes infected. From present knowledge we are able to state that any interference with the contractility of the gall-bladder musculature, or presence of foreign bodies in the gall bladder, or ligation of the common duct, disturbances that affect the circulation, or secretion of bile, causes a marked increase in the number of micro-organisms in the biliary passages, and, furthermore, that aside from the infective agent, a number of predisposing influences are still necessary to produce inflammation of the gall bladder.

CLASSIFICATIONS.

Clinically cholecystitis is divided into acute, sub-acute and chronic forms; anatomically into catarrhal, suppurative, phlegmonous, diphtheritic, gangrenous and fibrous (adhesive or obliterative). A further division is permissible in calculous and non-calculous by reason of the frequent association of gallstones with cholecystitis. The acute inflammation occurring in typhoid fever with the presence of a pure culture of the bacillus typhosus constitutes the classic instance of uncomplicated cholecystitis. The micro-organisms that are associated etiologically with cholecystitis aside from the typhoid bacillus, are the colon bacillus, streptococcus, staphylococcus, pneumococcus, proteus vulgaris, and tubercle bacillus.

In most instances the severity of the resulting inflammation is simply indicative of the degree of virulence of the infective agent and presence of conditions lowering the physiologic resistance of the tissues. The non-calculous form of cholecystitis rarely progresses beyond the purulent state. An obstruction of the cystic duct produces the so-called empyema. The severer forms of cholecystitis are usually attended by the presence of gallstones; these assert their influence on the inflammation by pressure on the tissues, obstruction of the bile or disturbance in the circulation, and may give rise to fulminating suppurative cholecystitis, diphtheritic, phlegmonous, ulcerative or gangrenous inflammation, which then sometimes leads to perforation and pericholecystitis, there being no doubt that gallstones promote infections often of the gravest character.

Musser states that suppurative cholecystitis is based altogether on preceding development of gallstones and parasitic invasions.

20. Netter: Progrès Médical, 1886, p. 992.

The principal factors concerned in the production of a gangrenous cholecystitis are: (a) Thrombosis of nutrient vessels; (b) bacterial infection; (c) absence of drainage and consequent tension. The chronic fibrous (obliterative-adhesive) form of cholecystitis while indirectly due to bacterial invasions, is yet not more than the sequel of a prolonged catarrhal or suppurative inflammation or some of the more severe destructive forms.

The close association of cholecystitis and cholelithiasis is apparent to every clinician, and accordingly that which pertains to the etiology of gallstones will be contributory and in most instances causative of cholecystitis. Yet gallstones are not always present in connection with cholecystitis and gallstones may exist without inflammation. In a certain percentage of cholelithiasis cases the contents of the gall bladder are sterile and fail to reveal any definite infective agent.

In the study of the causes of gallstones it is very evident that while our knowledge is much more complete than it was a decade or two ago, it is equally certain that no common etiologic factor has been demonstrated that is applicable to all cases, and the importance of a union of several contributory conditions is not to be overlooked. Among the predisposing influences that we have come to associate with gallstones are age, sex, pregnancy, indolence, gluttony and constipation. Cholelithiasis is very rare in early adult life and occurs most frequently after the age of forty. That it is far more frequently a disease in women than in men is noted by all observers, different writers giving a proportion of from three to one and five to one when compared with its occurrence in the male. It is so common, in fact, in women that it may be said to be characteristic of the sex, and is, like the floating kidney, distinctly peculiar to women. In seeking an explanation for this greater frequency we find it in the influence of child-bearing, prevalence of tight lacing, greater tendency to sedentary habits and constipation, all influences which constrict or encroach on the area of the gall bladder and interfere with its drainage.

The two classes of men that are affected with gallstones principally are first, the obese, and second, the glutton and he who is peculiarly indiscreet in connection with dietary rules. That certain diseases are contributory to the development of gallstones is also a matter of common experience. The relation of cholecystitis has been referred to, and in this connection, of course, typhoid fever occupies a prominent rôle, and all those gastric and intestinal disorders which by extension lead to cholecystitis.

Furthermore, heart disease predisposes probably by reason of the inactive life and passive congestion of the liver which the cardiac disease engenders. The conditions of gout and diabetes also seem to dispose to their formation. Cancer of the biliary passages is so commonly associated with gallstones that it must be regarded as having a predisposing influence. Mosher found nephritis associated with gallstones in 72 per cent. of his cases, and the fatal issue in operation for gallstones can often be attributed to the complicating nephritis. Adiposity, with its sedentary mode of life, and constipation are prominent predisposing factors.

Cholelithiasis has come to be regarded as closely associated usually with some structural change in the lining of the gall bladder, so that the etiology of cholecystitis and cholelithiasis have many points in common. The relation of bacterial invasion of the gall bladder and

direct connection of bacteria with the formation of gallstones has received very prominent consideration. Among the earliest contributions on the subject were those of Charcot and Gombault¹⁹ in 1876. Netter and Martha,²¹ in 1886, finding staphylococci and streptococci in connection with gallstones; Brieger and von Leyden, in 1886, with colon bacilli. Naunyn,² in 1891, found colon bacilli in connection with stones. Welch, in 1892, isolated bacteria from the center of gallstones, principally typhoid and colon bacilli. Crude substances, silk ligatures (Homans,²² Kehr²³) have also been found to occupy the center of gallstones.

The French observers, Mignot, Fournier and Gilbert,²⁴ have developed experimental cholelithiasis in animals and found that in order to produce a calculus it is necessary to have infection of the biliary passages. (Ushing,¹² M. W. Richardson,²⁵ and Lartigau²⁶ have also successfully produced gallstones in animals by promoting a mild infection in the gall bladder by the use of attenuated cultures of typhoid and colon bacilli.

The nidus in most instances is composed of mucus, degenerated epithelium or shreds of tissue so that in a majority of cases the nucleus of a stone is composed of bacteria or the results of bacterial infection of the gall-bladder mucosa.

Chemically gallstones consist chiefly of calcium salt with bilirubin and cholesterol, and of the salts carbonates and phosphates are most common. They have a framework of organic matter which is impregnated by the other materials. A large number are pure cholesterol masses. The question naturally arises as to the source of these constituent materials and the influences that promote their increase in the gall bladder.

Cholesterol occurs normally in the blood and various organs of the body, and is present in the bile in a proportion, according to different authors, of from .045 to 1.18 per cent. There is really no proof that the liver excretes cholesterol from the blood or that it is the result of hepatic metabolism, so we are driven to the conclusion that it is formed in the bile ducts or gall bladder, yet it is found in passages where bile does not exist, hence there is no reason to believe that it is formed from any constituent of bile. According to Naunyn,² it is rather a product of the epithelium of the bile passages; in fact, it is a secretion of mucous membranes generally. C. A. Herter²⁷ finds that the normal amount of cholesterol secreted by the epithelial cells of the gall bladder is trebled under pathologic conditions, which is also true of calcium salts, both substances being increased by the same irritants. This is significant, for if calcium increases beyond a certain point it is liable to combine with bilirubin and produce a compound known as bilirubin-calcium, which forms the nucleus of a great many stones.

There seems to be no doubt that catarrh of the mucous membrane of the bile passages increases the amount of cholesterol present, and the longer the bile remains in the gall bladder the more cholesterol it will contain. So that anything which causes stagnation of bile, as the

27. Herter, C. A.: Symposium Congr. of Am. Phys. and Surgs., May 13, 1903.

remote causes formerly mentioned, like age, sex, habits, dress, diet, diathetic conditions and disease processes, predispose to the formation of gallstones. Catarrh of the gall bladder may cause both of the above conditions in that it leads to stagnation of the bile by (1) producing a paresis of the muscular coat, and (2) by increasing the amount of cholesterol present. All of which adds emphasis to the fact that the normal gall bladder can not form stones and only a diseased gall bladder can form them or aid in their formation.

After gallstones are once present they increase in number and size, which is indicative of the formation of an increased amount of cholesterol in the gall bladder. In a recent case of my colleague, Dr. Jepson, he observed distinct layers of cholesterol crystals on the surfaces of the stones as they still lay in the gall bladder.

Some interesting observations have been reported recently regarding the constitutional origin for an increased formation of gallstone constituents. C. A. Herter²⁷ fed dogs on fat almost entirely and at the end of three months minute masses of bilirubin calcium were formed in the gall bladder, and in one instance a distinct concretion. It is important to note the possibility of increasing the quantity of cholesterol by means of chemical irritants without the presence of infection. It is likewise possible that constitutional conditions may bring about such changes in the bile that it may cause irritation to the bile passages and thus play an important part in the pathogenesis of gallstones.

The influence of diet was formerly accorded considerable significance, but it is by no means proven that the amount of cholesterol is in any way dependent on the diet. Jankan and Thomas²⁸ have shown experimentally that diet has no influence on the percentage of cholesterol in the bile.

From the accumulated experimental and clinical knowledge on the pathogenesis of gallstones we can make the deduction that while the essential cause usually is a cholecystitis, there are evidently always other factors at work beside infections, and special consideration must be given to those infectious diseases and states of altered metabolism which promote a change in the quality of the bile chemically, so as to constitute an irritant (Herter).

It is further evident that cholecystitis and cholelithiasis are at all times secondary affections, and if it were possible to eliminate such influences as age, improper wearing apparel, lethargic habits, constipation, gastric and intestinal catarrhal disorders, cholelithiasis would soon become a very rare disease.

THE RELATION OF CHOLELITHIASIS TO DISEASE OF THE PANCREAS.

EUGENE L. OPIE, M.D.
BALTIMORE.

The intimate relation of pancreatic disease to lesions of the liver is forecast in the embryo at a time when that part of the pancreas which will subsequently contain the larger pancreatic duct makes its appearance as two diverticula situated beside the embryonic hepatic duct where it enters the intestine. One of these rudimentary structures disappearing, the duct of Wirsung, which will subsequently become the outlet

for almost the entire pancreatic secretion, enters the intestine in conjunction with the common bile duct. The smaller duct of the pancreas, the duct of Santorini, has its origin in an embryonic diverticulum situated nearer the stomach. The two parts of the gland subsequently unite to form the adult organ, but the two ducts are subject to considerable variation, differing in their relation to one another and to the common bile duct.

Anatomic peculiarities which have an important bearing on the relation of the liver to the pancreas may be recalled: 1. In one of ten individuals the duct of Wirsung does not join the common bile duct before it enters the duodenum, but the two ducts terminate side by side at the summit of the bile papilla. 2. In the majority of individuals the duct of Wirsung which terminates in the bile papilla is larger than the duct of Santorini, which terminates nearer the stomach, but in approximately one of ten instances the duct of Santorini equals or exceeds in size the duct of Wirsung. 3. In approximately nine-tenths of all cases the two ducts anastomose within the gland, but in a large proportion of these instances they are united by such a narrow twig that one is not capable of acting as an outlet for the secretion of the other.

The physiologic significance attributable to the close anatomic relation of the biliary and pancreatic ducts has recently been emphasized by Pawlow¹ and his students. Their experiments, confirming the observations of other physiologists, have demonstrated that the bile affords a favorable medium for the action of the pancreatic ferments, increasing their digestive efficiency two or threefold. The presence of bile has been found particularly favorable to the action of the fat-splitting ferment of the pancreatic juice. The same observers have shown that the bile and pancreatic juice are simultaneously poured into the intestine, the flow of each being increased and diminished by the same factors. Considerable importance, therefore, may be attached to the fact that the two secretions are mixed even before they enter the intestine. The increased efficiency of the pancreatic ferments in the presence of bile doubtless explains in part the severity of the lesion which results when bile finds its way into the pancreatic ducts.

The junction of the common bile duct with the larger duct of the pancreas serves to explain a variety of acute and chronic lesions of the pancreas, which occur in association with the presence of calculi in the bile passages. Such lesions may follow the impaction of a gallstone in the common part of the biliary and pancreatic ducts, or may be the result of an inflammatory process caused by the presence of gallstones in the bile passages and hence transmitted to the ducts of the pancreas.

HEMORRHAGIC PANCREATITIS.

Those who have described the lesion known as acute hemorrhagic pancreatitis have not failed to note its association with cholelithiasis. From the literature I have previously collected and tabulated² a considerable number of cases in which this lesion, often accompanied by jaundice, has been associated with gallstones present in the gall bladder or in the bile passages. In several of these cases a calculus, found at autopsy in the terminal part of the common bile duct, had doubtless exerted a deleterious influence on the pancreas. A case³

3. Bulletin of the Johns Hopkins Hospital, 1901, vol. xli, p. 182.

which I have described in detail has demonstrated a mechanism by which bile is diverted from its usual outlet and forced into the pancreatic duct. A very small calculus occluding the duodenal orifice of the diverticulum of Vater had converted the two ducts into a continuous channel through which bile forced by the gall bladder was injected into the pancreas. The ducts of the gland, where spared by the extensive hemorrhagic lesion which resulted, were stained by bile. A series of experiments performed on dogs demonstrated that the bile of one animal injected into the pancreatic duct of a second causes typical acute hemorrhagic pancreatitis, accompanied by disseminated fat necrosis. That bile injected into the pancreatic duct is capable of producing these lesions experimentally has been further shown by Flexner and Pearce,⁴ and very recently by Hewlett.⁵ Especially noteworthy is the fact that acute hemorrhagic pancreatitis occurs in the absence of bacterial infection, and in the case due to impaction of a calculus just cited, careful bacteriologic examination of the pancreas gave negative results.

In this connection it is of interest to note that Claude Bernard,⁶ nearly fifty years ago, injected bile mixed with oil into the pancreatic duct of a dog, causing death within eighteen hours. The autopsy, he says, showed an intense peritonitis, and the tissue of the pancreas, which had a red color, exhibited numerous ecchymoses. It is not improbable that the lesion thus produced was hemorrhagic pancreatitis.

During the past few years many cases of acute hemorrhagic pancreatitis have been described and especial attention has been directed to the condition of the bile passages. A considerable number of instances give confirmatory evidence of the frequent association of cholelithiasis and pancreatic disease. Such cases not included in my table previously mentioned have been described by Tornqvist,⁷ Flynn,⁸ Halley,⁹ and Shäcker.¹⁰

Of especial interest is the case of Tornqvist. Three weeks before death the patient passed by rectum a gallstone the size of a pea. At autopsy the pancreas was the seat of hemorrhagic and gangrenous inflammation; the gall bladder, ductus hepaticus and ductus choledochus contained calculi, two of which, the size of beans, were wedged in the diverticulum of Vater. In this instance it is difficult to decide whether the lesion was caused by these stones, or, perhaps, by the calculus which was passed several weeks before death.

No data at present available indicate with how great frequency acute hemorrhagic pancreatitis is caused by gallstones. In four of five cases which have come under my observation this association has existed. Other etiologic factors have been suggested, but direct evidence in favor of their occurrence is wanting. In many cases, doubtless, gallstones have been overlooked at autopsy. In a number of cases, however, their presence has been excluded by careful examination of the biliary tract. Such cases, for example, have been recently described by Lando¹¹ and by Pond;¹² in one case which I have examined no calculi were found. It is possible that the bile passages may have contained a single calculus which, causing the lesion, had escaped

into the intestine. Pearce¹³ has described an instance of the disease which illustrates this possibility. Two weeks before death jaundice had been present. Hemorrhagic and gangrenous pancreatitis was accompanied by fat necroses; no calculi were found in the gall bladder, gall ducts or intestine, but the orifice of the bile papilla was dilated, and in the common bile duct, one centimeter from its termination, occurred a circular dilatation one and a half centimeters in circumference, thus suggesting that a stone had previously occupied this position. This case resembles closely an instance of hemorrhagic pancreatitis described by Thayer;¹⁴ the orifice of the common bile duct was widely dilated and a calculus was found within the duodenum.

Calculi found in the gall bladder at autopsy suggest that hemorrhagic pancreatitis has been caused by their presence, even though none is found in the diverticulum of Vater, but their complete absence does not give conclusive proof that the lesion is not referable to cholelithiasis. It is not improbable that a pancreatic calculus impacted at the orifice of the diverticulum of Vater might cause the lesion, but such an instance has not been recorded.

The most characteristic feature of acute hemorrhagic pancreatitis occurring spontaneously or produced experimentally in animals is widespread necrosis affecting both parenchyma and interstitial tissue of the gland. The so-called gangrenous pancreatitis represents a later stage of the hemorrhagic lesion, when, doubtless as the result of bacterial invasion, the tissue infiltrated with blood has assumed a black color and has perhaps become softened; evidence of previous hemorrhage is frequently demonstrable. Peritonitis limited to the lesser peritoneal cavity is usually present. Among the cases in which the pancreas has been regarded as gangrenous gallstones are frequently found in the bile passages at autopsy, and the passage of a calculus is doubtless responsible for the pre-existing hemorrhagic lesion.

Cases of this character have been recently described by Deaver,¹⁵ Mayo Robson¹⁶ and Baldwin.¹⁷ The following case may be added to the list of those in which acute pancreatitis of gangrenous type has accompanied cholelithiasis:

CASE 1.—The patient, a man, aged 37, was admitted to the service of Dr. Halsted in the Johns Hopkins Hospital.

Present illness.—The present illness began seven months previously with pain in the epigastrum, accompanied by vomiting, which lasted two days. The pain disappeared and the patient was well for four months. A second attack began two weeks before admission, with epigastric pain, vomiting and constipation; chills occurred.

Examination.—There was no jaundice, but swelling in the region of the gall bladder was noted. On admission there was slight distension of the abdomen in the epigastric region, to the left of the median line; slight spasm of the muscle was present in the epigastric region and on palpation an indistinctly defined mass was felt.

Blood Count.—The red blood corpuscles numbered 1,400,000. The leucocytes 33,700.

Treatment.—An exploratory laparotomy was performed on the day following admission; death occurred four days later. The temperature varied from 101 to 104.

Postmortem.—An autopsy was performed by Dr. R. Van Wart through the wound made at operation. After cutting through the transverse mesocolon the lesser peritoneal cavity was found to contain dark red semifluid blood, together with

particles of firm, opaque, grayish-white material. A perforation with fairly smooth edges $1\frac{1}{2}$ centimeters in diameter was present in the wall of the transverse colon. Two perforations through the posterior wall of the stomach and two through the wall of the duodenum communicated with the abscess cavity. The greater part of the head of the pancreas had the appearance of the normal gland, but the remainder consisted of grayish, opaque friable material, having a fecal odor; here and there occurred areas of hemorrhage. The duct of Wirsung and the common bile duct united to form a diverticulum of Vater 1 centimeter in length. The bile ducts contained no calculi, but in the gall bladder were nine faceted gallstones of small size, the largest being only 5 millimeters in diameter.

The symptoms of acute hemorrhagic pancreatitis have been so carefully described by Fitz and by other writers that it is not desirable to review them here. Since this pancreatic lesion may become a complication of gallstone colic, the distinctive peculiarities of the former are important. The intensity of the pain, its diffuse epigastric character, with occasional localization on the left side, and the profound prolapse usually present, according to Thayer,¹⁸ give evidence that the pancreas is implicated. The following case, which has recently come under my observation through the kindness of Dr. P. H. Ingalls, may be cited as an illustration of the course of rapidly failing pancreatitis:

CASE 2.—A man, aged 47 years, who gave no history of gallstones, was suddenly seized at midday with intense pain in the upper part of the abdomen. A few hours later the features were drawn, the skin was clammy, and the pulse rapid and feeble. There was continued hiccough. During the following night vomiting began, and persisted with considerable severity. The abdomen was tender on pressure and was slightly distended immediately below the sternum. On the third day after the onset of symptoms the temperature rose to 104, and death occurred only three days after the beginning of the attack.

Postmortem.—At autopsy the pancreas was found much enlarged, and, save for scattered patches of relatively normal tissue, had a nearly uniform reddish-black color. The omentum was studded with foci of fat necrosis. The gall bladder contained a single large calculus, about 2 centimeters in diameter.

DIAGNOSIS OF HEMORRHAGIC PANCREATITIS.

The foregoing has shown, I believe, that cholelithiasis is the usual, if not the only, cause of acute hemorrhagic pancreatitis. The diagnosis of this often obscure condition may be aided by evidence which tends to establish the existence of cholelithiasis. A history of previous attacks of gallstone colic is, therefore, important. In many instances the fatal attack is accompanied by jaundice, which is doubtless due to impaction of a calculus at the duodenal orifice of the common bile duct. Since such impaction prevents the entrance into the intestine of both bile and pancreatic juice, well-marked digestive disturbances, particularly the presence of undigested fat in the stools, are to be expected, and in two of my cases the stools or the contents of the large intestine at autopsy have had a grayish-white or clay-like color. In cases of which the symptoms suggest acute hemorrhagic pancreatitis much importance might be attached to the discovery in the feces of a calculus of such small size that it could occlude the duodenal orifice of the diverticulum of Vater without filling its cavity. For this purpose the evacuations in cases which are not rapidly fatal should be carefully examined.

Recent studies offer hope that the diagnosis of acute hemorrhagic pancreatitis with fat necrosis may be facilitated by examination of the urine. Several years ago I suggested that the fat-splitting ferment of the pan-

creatic juice is with these lesions excreted by the urine and described a case¹⁹ in which a reaction indicating its presence was obtained with the urine. By a careful experimental study, Hewlett²⁰ has shown that this fat-splitting ferment appears in the urine of dogs with acute hemorrhagic pancreatitis produced experimentally. Cammidge²¹ has lately described a reaction which is, he believes, peculiar to the urine of those suffering with pancreatic disease.

The etiologic relation of gallstones to acute hemorrhagic pancreatitis makes obvious the importance of their removal when, at operation, the presence of fat necrosis directs attention to the existence of pancreatic disease. For even though that calculus which has caused the lesion has finally escaped into the intestine, anatomic conditions being such as favor the occurrence of the disease, the passage of another stone may cause a recurrence of the hemorrhagic lesion. Should a calculus be found within the diverticulum of Vater, its removal is imperative.

In a case operated on by Dr. Howard A. Kelly recovery followed the removal of a large number of small calculi from the gall bladder. In a case described by Wiener²² fat necrosis found at operation, two days after the onset of symptoms, gave evidence of acute pancreatic disease; a calculus was removed from the cystic duct, cholecystectomy was performed, and recovery followed.

SUPPURATIVE PANCREATITIS.

Several recorded cases demonstrate that acute suppurative pancreatitis may be a consequence of cholelithiasis. There can be little doubt that the lesion, like suppurative inflammation elsewhere, is caused by the invasion of micro-organisms, and in several ways the presence of calculi may favor such invasion. Partial occlusion of the pancreatic duct by a calculus lodged in the diverticulum of Vater may favor the entrance of bacteria into the duct from which pancreatic secretion can not readily escape. The probability of infection is much increased when the presence of biliary calculi have previously caused a suppurative inflammation of the bile passages. Mayo Robson¹⁶ has recently described two cases in which abscess of the pancreas accompanied cholelithiasis with suppurative cholangitis. In certain instances pancreatic abscess is, perhaps, the result of infection secondary to localized hemorrhagic pancreatitis caused by a gallstone lodged in the diverticulum of Vater. Especially interesting is a case recorded by Fuchs.²³ A man aged 32 years had suffered with recurrent attacks of abdominal pain, accompanied by vomiting, and on one occasion by jaundice. At operation a calculus said to have been the size of a bean was found within the diverticulum of Vater, while in the head of the pancreas was a small abscess. Removal of the calculus was followed by recovery. In an example of suppurative pancreatitis recorded several years ago by Deickhoff,²⁴ biliary calculi had actually found their way into the duct of Wirsung.

CHRONIC INTERSTITIAL PANCREATITIS.

Chronic inflammation of the pancreas is a more common complication of cholelithiasis than the acute lesions previously mentioned. Reidel²⁵ first directed attention

to the indurated condition of the head of the pancreas not infrequently encountered at operation undertaken for the removal of gallstones, and pointed out its resemblance to carcinoma, for which it has been repeatedly mistaken. In three of 122 operations the head of the pancreas exhibited such dense induration that malignant growth was suspected; in two patients recovery followed, while in the third chronic interstitial pancreatitis was demonstrated by autopsy. Mayo Robson²⁶ has given especial attention to the occurrence of chronic pancreatitis recognizable at operation by well-marked induration of the gland, and Robson and Moynihan²⁷ have described seven instances in which jaundice and other symptoms of biliary colic have suggested the presence of gallstones. Calculi, however, were found in only two of these cases, in one of which it was possible at autopsy to demonstrate that the induration noted at operation was the result of chronic inflammation.

A case which I have recorded²⁸ demonstrates that a large calculus impacted within the diverticulum of Vater may cause chronic interstitial pancreatitis. I have shown that a small calculus, on the one hand, lodged at the duodenal orifice of the diverticulum of Vater can cause acute hemorrhagic pancreatitis by diverting bile into the pancreatic duct. A larger calculus, on the other hand, occludes both ducts and causes an interstitial inflammation similar to that which follows ligation of the pancreatic duct in animals. In six cases described by Moynihan²⁹ induration of the pancreas has been associated with the presence of calculi lodged in the common bile duct.

Doubtless, however, chronic interstitial pancreatitis may be caused by cholelithiasis even though the pancreatic duct is not obstructed by a calculus impacted in the terminal part of the common bile duct. An acute inflammation of the bile passage due to the presence of calculi in the gall bladder or elsewhere may be transmitted to the pancreas by way of its larger duct, and may finally cause chronic changes in the gland. In two cases which I have studied at autopsy chronic pancreatitis accompanied suppurative cholangitis with cholelithiasis, though no calculi were found compressing or occluding the pancreatic duct. In one of these cases the history of the patient gave no evidence that calculi had passed from the gall bladder to the intestine. In both cases the ducts of the pancreas were the seat of acute inflammation, which probably had its origin in the acutely inflamed biliary passages.

I have previously confined my attention to cases in which changes in the pancreas have been secondary to lesions of the biliary passages. Mayo Robson has described a group of cases in which chronic interstitial pancreatitis has caused, he believes, such compression of the common bile duct that jaundice has resulted. In these cases the pancreas has been found at operation unusually hard, and though jaundice has been present, no calculi have been demonstrable within the bile ducts. The common bile duct, it is well known, lies in contact with the head of the pancreas, and in 62.5 per cent. of individuals, according to Helly,³⁰ it is completely surrounded by pancreatic tissue. Pourtoy³¹ has described a case in which a sharply localized focus of chronic pancreatitis, obscure in origin, had caused constriction of the common bile duct with jaundice. In none of the

cases collected by this writer has dissection demonstrated that a diffuse chronic inflammation of the head of the pancreas is capable of causing jaundice by constricting the bile duct.

Chronic pancreatitis caused by cholelithiasis produces no symptoms which, with our present knowledge, make its presence recognizable. Mayo Robson finds that tenderness in the epigastrium, together with some fullness above the umbilicus, are usually present; loss of weight, he says, becomes marked, and pain may be present to the left of the median line, perhaps in the region of the kidney, or even below the scapula. For recognition of the condition, Robson attaches much importance to a reaction which Cammidge has recently described. What influence the occurrence of chronic pancreatitis exerts on the course of cholelithiasis is as yet obscure. Its importance lies in the fact that induration of the head of the pancreas observed at operations undertaken for the removal of gallstones may be mistaken for malignant growth. After removal of calculi the pancreatic lesion does not, in some cases at least, cause further serious harm.

CONCLUSION.

The following conclusion is, I believe, justified by the facts which have been cited: Whenever a biliary calculus passes through the diverticulum of Vater into the duodenum the pancreas is subjected to the danger of injury, the character and extent of which are dependent on the size of the calculus and the duration of its impaction.

DISEASES OF THE GALL BLADDER AND BILE DUCTS IN RELATION TO DISEASES OF THE GASTROINTESTINAL TRACT.*

BERTRAM W. SIPPY, M.D.

CHICAGO.

Owing to the close anatomic proximity of the gall bladder and bile ducts to certain portions of the gastrointestinal tract, disease of one of these structures may be readily transmitted to the other. The symptoms arising from disease of these parts are often hopelessly confused, as illustrated by the difficulty at times in differentiating cholelithiasis and gastric ulcer. No wonder, for, as Fleiner states in effect, one may well say gallstone disease may not only simulate all of the diseases of the gastrointestinal tract, but it may produce them, namely, stomach cramp, intestinal colic, vomiting, diarrhea, bloody vomit, bloody stools, symptoms of ulcer, actual ulceration, tumor, stenosis of the pylorus, duodenum and colon, gastric hypersecretion and tetany.

The disorders of the stomach and intestine arising from disease of the gall bladder and bile ducts may be conveniently divided into those nervous or reflex in origin, and those due to a direct extension of the anatomic disease.

NERVOUS OR REFLEX DISORDERS.

These may be sensory, motor and secretory.

Sensory and Motor Disturbances.—I will simply refer to the nausea, eructation and vomiting that accompany nearly every attack of biliary colic. The nausea and vomiting may be purely reflex, brought about by the irritation of the nerves involved in the gall-bladder and bile-tract disease. In many cases, however, a di-

rect effect is produced on the gastric muscle reflexly. A temporary relaxation of muscular tone arises, as evidenced by distended epigastric region, a high tympanitic percussion note over the self-inflated stomach. A temporary gastric myasthenia or reflex relaxation may persist for several days. This accounts for the feeling of epigastric distension, pressure and weight, so frequently complained of after the acute colic has subsided. In many cases direct extension of inflammation to the pylorus or duodenum is the cause of similar clinical manifestations. A parietic condition of the muscle of the intestinal tract is frequently evidenced by diffuse abdominal distension, during and subsequent to an attack of cholecystitis. Siredey has reported a case of paralytic ileus arising reflexly from the irritation of a gallstone in the common duct. Rarely a reflex diarrhea is said to occur. It might be difficult in a given case to determine that the diarrhea was due entirely to the colic.

Reichmann claims that gallstones may give rise to gastralgia, and that they may reflexly cause cramps of the pyloric and cardiac muscles. While this can not be denied, it is more than probable that such pains are for the most part due directly to local anatomic conditions, such as adhesions, obstruction, etc.

Secretory Disturbances.—It is stated by most authors that cholelithiasis is accompanied by excessive gastric acidity or hyperchlorhydria. This statement does not seem to be based on the results of a systematic stomach analysis of any large series of cases. It is worthy of note that of the relatively limited number of cases of pyloric obstruction due to cholelithiasis that have been accurately reported, lactic acid was present in the stomach contents of several cases. This is interesting when we remember that non-malignant stenosis in general is rarely associated with the presence of the lactic acid.

Finally, it may be said of the nervous disorders, that the functional activity of the stomach and intestine is influenced in a reflex way by disease of the biliary tracts, but no serious permanent effect is likely to result. On the other hand, the direct extension of anatomic disease from the bile tracts to the stomach and intestine may be fraught with most serious consequences.

ANATOMIC DISEASE.

The readiness with which disease is liable to extend from one of these parts to the other is appreciated when one bears in mind the anatomic relations. About two inches from the pylorus the duodenum lies directly behind the neck of the gall bladder; above and behind it are the cystic and common bile ducts. The common duct passes directly behind and to the inner side of the descending portion of the duodenum, into which it empties. The gall bladder and bile tracts are thus in very close contact to the first five inches of the duodenum. Both structures are more or less firmly fixed, so that this relation is constant. The hepatic flexure of the colon is so near the right side of the gall bladder that after death it is frequently found stained with bile. The remaining portion of the intestine is more or less removed from the biliary tracts, and hence it is that the pyloric end of the stomach, the first and second portions of the duodenum, and the hepatic flexure of the colon are the parts most frequently involved by direct extension of disease from the gall bladder and bile ducts. As to the frequency of such complications, the statistics of Hildenstab show that of 320 cases operated on for cholelithiasis, 30 had pronounced stomach symptoms. This paper will discuss the pathologic conditions of

the stomach and intestine that result from cholelithiasis, cholecystitis and cholangitis. The effect of malignant and other disease will not be considered.

The rôle played by cholangitis is so slight that it deserves merely mention. Langenbuch claims that adhesions may arise from a simple cholangitis due to bacterial invasion from the blood and from the duodenum.

Cholelithiasis and cholecystitis may produce gastrointestinal disorders by causing, first, simple adhesions; second, obstruction to the lumen of the digestive tract due to inflammation and its results; third, fistulous communications; fourth, ileus due to gallstones.

As to the frequency of adhesions due to cholecystitis, exact statistics are wanting. According to Riedel, adhesions occur in 75 per cent. of all cases. In 128 gallstone operations, collected by Merck, adhesions were present in 38 per cent. of cases. According to Riedel, in 55 subjects showing an abnormal gall bladder at postmortem, adhesions were present in 25 per cent. of cases. The same author concludes as a result of an extended study of adhesions that, so long as the gallstones are in the gall bladder, the adhesions are usually confined to the omentum and transverse colon; if a stone wanders into the cystic or common duct, adhesions to the stomach in the region of the pars pylorica are likely to take place; the duodenum is usually the last to be drawn in by the plastic exudate.

Simple adhesions, when not producing obstruction, rarely cause serious symptoms. A few cases have been reported in which gastralgic pains, apparently due to adhesions, were relieved by operation. If the colon is extensively involved, constipation may result. This, however, seems to be a rare effect.

Clinically, duodenal and pyloric obstruction are by far the most common and serious pathologic conditions that arise.

As to frequency, in 1896 Alex found only 12 cases in the literature of pyloric and duodenal stenosis due to bile-tract disease. In 1897 Tuffier and Marchaise collected 19 cases. In 1899 Petersen reported from the Heidelberg clinic 55 cases of benign duodenal and pyloric stenosis, of which 8 were due to gall-bladder disease. In this series cholelithiasis, next to ulcer, was the most common cause of stenosis. Since attention has been directed to the condition, a great many other cases have been reported. During the last year I have had 3 cases under observation, so that pyloric and duodenal obstruction from cholecystitis is common enough to be taken into account seriously when evidence of pyloric stenosis exists.

The obstruction may arise in various ways. An acute pericholecystic exudate may surround the duodenum and pylorus, making compression. Simple extension of inflammation to the muscular coats of these structures may paralyze their contracting power, and give rise to clinical dilatation of the stomach. A mass of pericholecystic adhesions may contract and obliterate the lumen of the pylorus or duodenum. Adhesions may cause kinking and obstruction. A gall bladder distended with stones or exudate may compress the duodenum. A large stone in the cystic or common duct may have the same effect. Perforation of a stone into the duodenum may result in cicatricial stenosis.

Relative to the clinical picture produced, when the obstruction is due to an acute inflammatory exudate, symptoms of acute clinical dilatation of the stomach arise, usually following the onset of cholecystitis by a few days or two or three weeks. Tenderness in the pyloric region, and perhaps temperature, may be present.

Peristaltic waves are likely to be absent, because of the insufficient time for the development of pronounced hypertrophy of the gastric muscle.

When the obstruction is due to an old process, such as cicatricial bands, etc., a history of an attack of cholecystitis several months or even years before is usually obtained. Peristaltic waves are pronounced, and other symptoms of a chronic clinical dilatation of the stomach are present. Cramp-like pains and vomiting may take place at the time the stomach is emptying, and thus the symptoms of gastric ulcer may be simulated. A palpable tumor is sometimes present, which is frequently mistaken for carcinoma. In all cases of pyloric obstruction, with or without tumor, the possibility of an original cholecystitis should be considered.

Relative to palpable pyloric tumors, experience leaves no doubt in my mind that even among those better qualified to diagnose conditions, lives are constantly sacrificed by assuming on insufficient evidence that a palpable tumor at or near the pylorus is malignant.

Stenosis of the intestinal tract below the duodenum due to cholelithiasis is relatively rare. In 1903 Ranke could find only 10 cases of stenosis of the colon, 4 in the transverse colon and 6 at the hepatic flexure. In only 4 of these had the diagnosis of cholelithiasis been made. The caliber of the colon and the long mesentery of the transverse colon apparently protects it from stenosis. The hepatic flexure is more frequently stenosed, probably because it is more fixed and in closer proximity to the gall bladder. Obstruction in the ileum from the extension of inflammation attending gall-bladder disease is exceedingly rare. Ranke could find but one case reported.

The subject of biliary fistulæ communicating with the stomach and intestine may be disposed of in a few words. As to frequency, the statistics of Snively of recent date, taken largely from Courvoisier, gives:

Fistulæ between the gall bladder and stomach.....	8
Fistulæ between the bile ducts and stomach.....	12
Fistulæ between the bile ducts and duodenum.....	108
Fistulæ between the gall bladder and duodenum.....	93
Fistulæ between the gall bladder and jejunum.....	1
Fistulæ between the gall bladder and ileum.....	1
Fistulæ between the bile ducts and colon.....	1
Fistulæ between the gall bladder and colon.....	49
Fistulæ between the common duct and colon.....	1
Total	323

There are no characteristic symptoms of biliary fistula communicating with the gastrointestinal tract.

According to Mayo Robson, "Many of the biliary fistulæ are mere pathologic curiosities, quite undiagnosable, and only capable of being discovered postmortem. Many must form and heal, leaving the patient cured, and thus are they not only not discovered, but probably not even suspected. Fistulæ between the bile passages and hollow viscera, in the majority of cases, heal spontaneously, leaving only visceral adhesions, so that the fistulæ are comparatively rarely found postmortem."

Relative to the management of stenosis of the colon and fistulous communications, I shall say nothing. Old cicatricial bands at the duodenum or pylorus causing obstructive dilatation of the stomach may require gastroenterostomy in addition to treatment directed to the cholecyctic disease.

I wish to refer especially to the management of duodenal and pyloric obstruction arising during or immediately following an attack of cholecystitis. The inclination to do an immediate gastroenterostomy to re-

lieve the obstruction will usually be great. I believe I am stating it fairly when I say it is generally conceded among surgeons that if the condition of the patient will permit, it is good surgery to advise gastroenterostomy or some plastic operation on the pylorus as soon as the diagnosis of a high-grade pyloric obstruction from any cause is made.

Within the last year I have successfully managed two typical cases of high-grade pyloric obstruction due to cholecystitis by absolute rest and rectal feeding for four or five days, followed by gradually increasing quantity of milk and cream by mouth, testing the motor power of the stomach each morning by aspirating its contents. In these cases vomiting had been copious and persistent. Food taken on previous days had been vomited. Sarcina were abundant. Great thirst and reduction in quantity of urine, loss in weight and other signs of high-grade obstruction at the pylorus were present. In both cases, when first seen, the temperature had practically subsided, the local tenderness was diminishing, a moderate leucocytosis was present. The local condition did not demand immediate operative interference, and hence it was thought best to defer operation. The obstruction disappeared entirely after rest and rectal feeding, and both cases were thereby spared a gastroenterostomy that on first sight seemed strongly indicated.

If, in a given case, the local inflammation has reached its height, absolute rest to body, pylorus and duodenum favor rapid absorption of the plastic exudate. After it is demonstrated that food can pass the pylorus and duodenum, operation to remove stones, drain the gall bladder and relieve the local disease should be performed. On the other hand, if symptoms, such as high temperature, increasing pain and local tenderness, high leucocyte count, etc., indicate that the local inflammatory condition should be relieved without delay, operation directed to that alone should be performed. Very rarely, indeed, should a gastroenterostomy be done at the same time, unless there is evidence that the obstruction is due to old cicatricial tissue. Absorption of the plastic exudate causing obstruction takes place rapidly when the local cause is removed.

To recapitulate: In duodenal and pyloric obstruction due to recent cholecystitis, the advice is not to operate until the patency of the pylorus is tested by rest and rectal feeding, except in those cases in which immediate operation is necessary, on account of the seriousness of the local inflammation. In such cases operation should be directed to the relief of the local inflammation alone. Gastroenterostomy should rarely be performed at the same time, except when there is evidence of old pyloric or duodenal obstruction. If it is demonstrated that the obstruction does not grow less under the influence of rest and rectal feeding, then operation for the cholecystitis may be combined with gastroenterostomy if the condition of the patient will permit.

GALLSTONE ILEUS.

After a gallstone has reached the gastrointestinal tract, it usually passes with the feces without further trouble. Now and then a stone occludes the lumen of the bowel, and statistics show about 50 per cent. of such cases die as the result. In 1891 Schüller was able to collect 150 cases of gallstone ileus. Since then the number has greatly multiplied. A study of the literature shows that gallstone ileus is not in all cases due to simple occlusion. The size of the stone alone is not responsible. While it is true that large stones more

readily cause obstruction, deadly ileus may arise from small stones. On the other hand, Holz has reported a case in which a stone, 13 by 9 centimeters, was passed to the anal sphincter before causing trouble. Gallstones have occluded the bowel at practically all points between the pylorus and the rectum. The most common seat of obstruction, however, is at or near the ileocecal valve, where the lumen of the intestine is smallest. Obstruction from stone is rare in the duodenum and jejunum, and relatively rare in the colon. The following causative factors enter into gallstone ileus:

1. Large stones may actually occlude
2. Stones of moderate size may cause irritation and reflex contraction of the bowel about the stone.
3. A paralytic condition of the bowel may be the final result of continued irritation from the stone.
4. A stone may cause ulceration of the bowel, and the resulting peritonitis, with or without perforation, may result in occlusion.
5. Pathologic narrowing of the bowel may lead to obstruction by stone.

It is noteworthy that at the time of operation and at postmortem, gallstones causing intestinal obstruction are frequently found quite movable. The diagnosis of ileus due to gallstones can rarely be more than a probable diagnosis. A majority of the large stones causing occlusion have reached the intestine, usually the duodenum, by ulcerating through the gall bladder or cystic duct. Relatively rarely do large stones pass the common duct. Hence icterus does not commonly precede the occlusion. Peritoneal adhesions frequently unite the gall bladder to the intestinal tract, and by a slow process of ulceration a large stone may gain access to the bowel without causing serious symptoms. Thus, in many cases, history pointing to previous cholecystitis may be entirely absent. In most cases occlusion takes place after the stone has been in the bowel for a long time.

Owing to the many factors entering into the occlusion, the symptoms are exceedingly variable. Contraction of the bowel about a small stone may cease for a time and then recur, giving an interval of freedom from symptoms. Obstruction from gallstones seldom occurs until after the sixtieth year. As a rule, the obstruction is in the small intestine. In general, there is nothing absolutely characteristic about the symptoms of gallstone ileus. However, in addition to what has been said, the following special features may be borne in mind: In no other form of obstruction is fecal vomiting so likely to occur at the same time that abundant gas and feces are passed by the bowel. Obstruction being high, early and profuse vomiting takes place, yet often with relatively less shock and prostration than in other forms. As a rule, the pain is not so severe, the pulse not so rapid, the meteorism is not so great, the general symptoms are less severe than in obstruction due to strangulation of the gut, volvulus, and other conditions associated with grave circulatory disturbances in the bowel.

The treatment should be operative, after a reasonable effort has been made to overcome the occlusion by medicinal and physical means.

An extended study of the relation of typhoid fever to cholecystitis and cholelithiasis will not be attempted here. The work of Richardson, Cushing, Gilbert, Fournier and others has abundantly demonstrated the causal relation between typhoid fever and cholelithiasis.

DIAGNOSIS.

I have already alluded to the difficulty in differentiating gall-bladder disease and its results from primary disease of the stomach and intestine. The difficulties in diagnosis at times are insurmountable. Time will permit me to consider only the differential diagnosis between ulcer of the stomach and duodenum and cholelithiasis. I shall dwell on certain points only. It is of great value in diagnosis to simply remember that there is not a single symptom in gastric or duodenal ulcer that may not be present in cholelithiasis, and *vice versa*. Thus temperature may be present in ulcer as a result of perigastritis. A tumor from secondary glandular enlargement and perigastritis may develop in ulcer. Icterus, as a result of duodenal ulcer, is easily explained. It may develop from adhesions and inflammatory swellings complicating gastric ulcer. After all, icterus is relatively rare in gallstones. Riedel says that if one were to diagnose gallstones only when icterus is present, the diagnosis would be made in no more than 10 per cent. of the cases. Even the symptom, hemorrhage, so valuable in the diagnosis of ulcer, is not altogether reliable. It is present in less than half of the cases of ulcer, and vomiting of blood occurs in less than one-fourth of the cases that are diagnosed. Vomiting of blood may take place in gallstones, first, from excessive vomiting alone; second, gallstones may perforate the duodenum or stomach and cause hemorrhage; third, thrombosis of the venous radicles of the portal vein attending the spread of inflammation about gallstones may give rise to hematemesis or melena.

Hyperchlorhydria is an important symptom in ulcer. It is by no means constant. Gallstones may give rise to a reflex hyperchlorhydria. When pyloric obstruction develops as a result of cholelithiasis, the retention of the ingesta induces hyperchlorhydria and even continued secretion may arise, as in one case recently under observation.

In gastric ulcer the complexus of symptoms characterized by discomfort coming on from one to two hours after eating caused by the hydrochloric acid irritating the ulcer, pain gradually increasing until about three hours after eating may become severe, cramp-like, and finally result in vomiting with relief, is well-nigh diagnostic of the condition. It is well to remember that these symptoms, almost characteristic of ulcer, may be found in cholecystitis that has resulted in adhesions about the duodenum and pylorus. The pain is produced from two to four hours after eating, when the food is being forced through the narrow pylorus and duodenum. Tenderness on pressure in the pyloric region may be present in both. The ordinary symptoms of so-called dyspepsia, feeling of weight, fullness after eating, associated with eructation of gas, may be identical in ulcer and cholelithiasis. The examination of a test-meal is important, because, other things being equal, normal secretion and normal motor power speak against a stomach disorder.

As disheartening as the attempt at differential diagnosis may appear from an analysis of the individual symptoms of the two conditions, in typical cases there is no difficulty whatever in differentiating gall-bladder disease from gastric ulcer. One may say that in the majority of cases a fairly accurate differential diagnosis can be made between the two conditions if the whole clinical picture is carefully studied. Mistakes are likely to occur when evidence is faulty or incompletely elicited, or when too much stress is laid on some individual symptom.

DIAGNOSIS OF CHOLECYSTITIS AND CHOLELITHIASIS.*

PARKER SYMS, M.D.

NEW YORK CITY.

According to generally accepted statistics, one adult in every ten is the subject of gallstone. Of these about 5 per cent. suffer from symptoms of the disease. A proportion of these cases show such marked symptoms that the diagnosis is easily made, and the condition is readily recognized. A larger proportion of cases, however, present such vague symptoms, or symptoms so little understood by the general practitioner, that diagnosis is not made, and many patients who are much in need of relief which surgery might give, continue as chronic invalids for years until some severe crisis brings them to an untimely end. Owing to the efforts of many able scientists, prominent among whom are Mayo Robson, Kehr, Brewer, the Mayos, Murphy and Richardson, much has been done toward throwing the searchlight of knowledge into that region which has been called the mysterious realm of surgical romance, namely, the right upper quadrant of the abdomen. And to-day we are quite safe in eliminating from our list such conditions as gastralgia, gastric colic, neuralgia of the gall bladder, neuralgia of the stomach, etc., and we have learned that every case of chronic indigestion which can not be relieved by the internist should be handed over to the surgeon, for by his skill a solution of the difficulty may be found. To-day diseases of the gall bladder and gall ducts do not belong to the domain of internal medicine, but to the domain of surgery, just as much as is true of appendicitis. To-day the internist must recognize the fact that the diagnosis of gall passage disease does not depend entirely on jaundice. He must know that certain forms of this disease may only be recognized by a careful study of the patient's history and by a most discriminating investigation of the symptoms which he presents.

The important diseases of the gall passages are embraced under the following heads:

1. Inflammatory disease of the gall bladder and gall ducts with or without stone.
2. Gallstones in the gall bladder and gall ducts with or without inflammation.
3. Inflammatory condition of the region surrounding the gall passages causing obstruction by pressure or distortion.
4. Neoplasm of the gall passages, benign and malignant, with or without gallstones, and with or without inflammatory disease.

SYMPTOMS.

The prominent symptoms produced by gall-passage disease are: Pain, tenderness, fever and chills, vomiting, change of pulse rate, collapse, tumor, jaundice, urinary changes, blood changes, changes in the stools.

Pain.—In this disease the pain is to be distinguished by its character, which is usually colicky, more often occurring when the stomach is empty, hence the attacks usually come on at night. It is situated in the region of the gall bladder, extending toward the right shoulder and the back. It is frequently relieved by eating, and is generally relieved by the escape of gas from the bowel. Pain is claimed by Kehr and many authorities to be almost entirely dependent on inflamma-

tory changes, though Murphy, Ferguson and many others claim that it is due to the effects of stone or to distention of the gall bladder or ducts independent of infection. The characteristic features of the pain are its acute onset, its colicky nature, and, as described by Lambert, the patient experiences a sense of something boring through the abdomen to the vertebra.

Tenderness.—As in appendicitis, tenderness localized to the region involved is, perhaps, one of the most characteristic symptoms. In the main its maximum point of intensity is just below the free border of the ribs, opposite the juncture of the ninth rib with its costal cartilage. The Mayo Robson point, comparable to the McBurney point in appendicitis, is above and to the right of the umbilicus at the junction of the upper two-thirds, with the lower third of a line drawn from the ninth rib to the umbilicus. This is the point of maximum tenderness in the majority of cases. Mayo Robson says that this is true, even in cases where the liver and gall bladder are considerably displaced, as it is really the site of reflected pain passing along the splanchnic to the eighth and ninth dorsal nerves, and thence reflected to the surface of the termination of these nerves.

Fever and Chills.—With a characteristic attack of gallstone colic the fever is of the acute type. There is very frequently with the pain a sudden and severe rigor, the temperature rising rapidly, and as rapidly subsiding with the subsidence of the pain. As pointed out by Murphy, the temperature chart in this disease is characterized by a series of angles instead of curves. In cases of infection of the gall bladder going on to suppuration, of course the fever may continue as a septic fever, having the characteristic phases.

In cases of acute inflammation of the gall bladder in which gangrene results, the onset and progress of the disease may be very sudden and rapid, but, as in analogous cases of appendicitis, a period is reached, when gangrene first takes place and before general sepsis has occurred, in which there may be an almost complete subsidence of symptoms. It should be very alarming if the condition is recognized, for the pain ceases, the tenderness decreases, the nervous phenomena are reduced to the minimum so that the temperature and pulse may recede toward the normal, and one may be led into the mistake of believing that the disease has subsided. Of course, when perforation has taken place or when peritoneal sepsis begins, all the characteristic symptoms will be again exaggerated.

Vomiting.—Vomiting is a very frequent symptom in acute attacks, coming on suddenly with the pain. It is of reflex character, and is independent of nausea. In some cases a severe paroxysm of vomiting may result in dislodgement of the stone from the common duct it either passing into the intestine or by relaxation receding into the dilated portion of the common duct, when a temporary subsidence of the attack will take place.

Pulse.—During an acute attack of biliary colic the pulse is accelerated and its tension is increased. During inflammatory disease of the ducts or gall bladder, of course, the pulse will be in keeping with the febrile disturbance.

Collapse.—Collapse is a frequent occurrence in severe attacks of gallstone colic. It may be so severe as to mask all other symptoms and to render diagnosis obscure. According to Mayo Robson, the acute agonizing pain may of itself cause death. Of course, collapse will be a marked and final symptom of phleg-

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

monous cholecystitis, perforation of the gall passages, or of any condition resulting in fatal peritoneal sepsis.

Tumor.—In cases of inflammation of the gall bladder or of obstruction to the common duct or cystic duct, the distended gall bladder may be felt. Projecting below the free border of the ribs it may be of almost any size, sometimes reaching far below the umbilicus. It is usually a pyriform, fluctuant mass, which is continuous with the free border of the liver, and which moves with the liver on respiration. It may be exquisitely tender or not. On several occasions I have been able to palpate a gall bladder distended with gallstones; in some cases the crepitation of the stones rubbing on each other could be distinctly made out. In one case there was a single stone measuring $7\frac{1}{2}$ inches in circumference, the patient's abdominal wall was thin, and the hard mass could be very distinctly felt.

Jaundice.—Jaundice may be either present or absent; it may be persistent or it may be intermittent; it may be pronounced or slight, depending on the amount of obstruction to the flow of bile into the intestine. Thus, with obstruction of the cystic duct, we may have no jaundice; with obstruction of the hepatic duct we may have partial jaundice; with obstruction of the common duct we may have pronounced jaundice. A stone impacted in the common duct may leave a valve-like opening which permits of the escape of bile into the intestines. Then jaundice will not be present or will be but partial. When a distended common duct has become sufficiently open to allow the stone to float from its position of impaction, the jaundice may be relieved by the flow of bile into the intestine, the stone becoming again impacted; then the jaundice will be intermittent. Jaundice may be caused by inflammatory swelling in the common and hepatic duct, or it may be caused by inflammatory constriction or torsion of the common duct, or it may be caused by malignant disease of the duct or of tissues in the neighborhood of the duct.

To sum up, jaundice may be caused by stone in the hepatic duct; in the common duct; by inflammation of the hepatic duct or common duct; by carcinoma of the gall bladder (late); by tumors of the hepatic duct; the common duct or the neighboring viscera; and by localized peritonitis constricting or distorting the common or hepatic duct by adhesions.

Prolonged persistent jaundice with progressive loss of weight is very indicative and suspicious of carcinoma in this region.

A careful consideration of the above will show that jaundice is by no means a constant symptom of gall-passage disease. According to Brewer, it is absent in from 80 to 90 per cent. of all operative cases, and the clinician should never hesitate to make a diagnosis of disease of the bile passages because of the absence of jaundice.

Urinary Changes.—Examination of the urine is principally of interest in determining the presence and degree of jaundice.

Blood Changes.—Examination of the blood will aid in determining the presence and degree of jaundice, and the amount of leucocytosis will also aid in determining the presence of suppuration.

Stools.—By examination of the stools one may determine the presence or absence of bile, the stools being light in color to clay color, depending on the amount of jaundice, and the consequent absence of bile from the intestines. One may also determine the presence of gallstones after a characteristic attack during which gallstones have passed from the ducts

X-RAY EXAMINATION.

So far diagnosis of gallstones by the x-ray has been rather unsatisfactory. Very thorough and painstaking work has been done in this field, and skiagraphs of gallstones have been made. Of course, when a positive finding is obtained, it is of the greatest use, but, on the other hand, the many failures and the uncertainty of the process leave us in the position that a negative finding does not necessarily mean that gallstones are not present.

DIFFERENTIAL DIAGNOSIS.

Bile-passage disease is to be distinguished particularly from the following conditions: Gastric ulcer, appendicitis, renal colic, pancreatitis, phlebitis portalis, angina pectoris, empyema, subphrenic abscess, malignant disease of the pylorus, duodenum, pancreas, liver, kidney, etc.

Gastric Ulcer.—An acute attack of indigestion dependent on a gastric ulcer may simulate biliary colic. In gastric ulcer the pain is of a different character, less severe and not so paroxysmal; tenderness, when present, is higher and nearer the median line; the vomiting is preceded by nausea; chill and fever are usually absent; the attack comes on after eating while the stomach is full, while in biliary colic the attack usually comes on at night, and is rather dependent on an empty stomach.

Diagnosis is to be made by the above facts and by a hematemesis, the examination of the stomach contents, the absence of jaundice, the absence of tenderness at the Mayo Robson point, and a careful consideration of the preceding history.

Appendicitis.—In typical attacks no difficulty would be found; in certain cases where the appendix is displaced upward and the disease is toward its tip, or where former adhesions have possibly connected it with the upper quadrant of the abdomen, difficulty in diagnosis may be experienced. The characteristic signs of appendicitis are the extreme rigidity of the right rectus muscle, the nature of the onset of the attack, the difference in character of the temperature, the difference in character of the pain, of its site and of its direction of radiation; the vomiting is often reflex, and preceded by nausea and indigestion; there is absence of jaundice. In severe cases where the signs are very confusing, Hotchkiss has pointed out the fact that for the same period of the disease—say the end of twenty-four or forty-eight hours—a patient with gall-passage disease will be in much better condition than will be a patient suffering from a comparable attack of appendicitis.

Renal Colic.—In renal colic the onset of the attack, the paroxysmal nature of the pain, and the rigor may lead to confusion, but there is absence of the tenderness at the Mayo Robson point, of jaundice, of palpable tumor at the site of the gall bladder, and the pain radiates in entirely different directions.

Angina Pectoris.—Biliary colic may be mistaken for angina pectoris in certain irregular cases, because the pain may be precordial. It is to be distinguished by the presence of its characteristic signs and by the absence of the signs which will be found on auscultation of the heart.

Pancreatitis.—Acute pancreatitis may be differentiated from acute cholecystitis and from phlegmonous cholecystitis with great difficulty. Aside from the history of the attack and the patient's previous history,

the only distinguishing point may be the presence of fat in the stools.

Phlebitis Portalis.—I have seen two cases of phlebitis portalis as a remote sequel of appendicitis. They were both fatal. They showed the characteristic temperature of septicemia, and there was tenderness in the region of the liver and a mild form of jaundice. These cases were to be distinguished from bile-passage disease by their precedent history, by the characteristic temperature range, and by the lack of the prominent characteristic symptoms of disease of the gall passages.

Empyema and Subphrenic Abscess.—Certain cases of encysted empyema and cases of subphrenic abscess on the right side, owing to their situation, may be confused with disease of the biliary passages. They are to be distinguished by the lack of symptoms of biliary colic, by their preceding history, and by the physical signs which may be found on careful examination by percussion, palpation and auscultation. Of course, occasionally diagnosis in these conditions can only be arrived at by an exploratory incision.

Just here let us say that in any case where there exist symptoms indicative of grave disease which the internist can not cure by hygiene or drugs, and where the symptoms are sufficiently vague or masked to make an accurate diagnosis impossible, we should turn without hesitation to the employment of exploratory incision, for these symptoms must mean some disease intractable to any except operative treatment, and by properly applied surgery many lives may be saved which otherwise would be lost during a period of prolonged doubt and hesitation.

Malignant Disease of the Pylorus, Duodenum, Pancreas, Liver, etc.—In my experience a certain proportion of cases of cancer of one of the organs in this region can not be definitely differentially diagnosed except by exploratory incision. Of course, much light may be thrown on the subject by an examination of the stomach contents, by a careful consideration of the entire history of the case, taking into account the presence or absence of important characteristic symptoms.

SPECIAL DIAGNOSIS.

In this brief paper I have only attempted to elucidate certain points which may enable one to make a diagnosis of disease of the gall passages, and space will not permit me to go elaborately into the finer questions which would aid one in making an accurate diagnosis and estimate of the special conditions present, but for this purpose the physician is referred to Brewer's¹ diagnosis chart of diseases of the gall bladder and ducts, for I feel it to be the most concise and accurate epitome of this subject in literature.

To-day surgery of the bile passages is on a very sound footing, and thousands of lives are being saved by the work of skilled operators; but many more thousands of lives are being sacrificed on account of the difficulty of diagnosis, and of the fact that a large proportion of cases urgently needing surgical relief are unrecognized or continue to be treated or neglected as cases of gastralgia, of indigestion, of neuralgia of the stomach, neuralgia of the gall bladder, etc., and if the foregoing remarks may in any way aid in the recognition of these diseases, I shall feel well repaid for my humble efforts.

THE TREATMENT OF CHOLECYSTITIS AND CHOLELITHIASIS.*

LUCIUS W. HOTCHKISS, M.D.

NEW YORK.

That the Chairman of the Section on Practice of Medicine has called on two of his surgical colleagues to prepare papers on the diagnosis and the treatment of gallstone disease which, but a very few years ago, was considered entirely within the domain of internal medicine, is suggestive of the change which has taken place in medical thought and practice and of the better understanding which has risen between the internists and the surgeon. The growing tendency to place these diseases of the gall bladder and bile ducts within the category of surgical affections is due largely, perhaps, to the very effective work of surgeons in extending the knowledge of the pathology of these diseases, by recording the conditions directly observed on the living, and by comparing these with the symptoms manifested in each case. In this way not only has the pathology to an extent been rewritten, but also the diagnosis has been established on a firmer basis.

The foundation of rational treatment has in this way been definitely established, and we are prepared now to go ahead and endeavor by continued observation to render the diagnosis more certain, for on these two points—definite pathology and exact diagnosis—all progress in treatment must rest.

The treatment of cholelithiasis and its complicating cholecystitis forms a most important chapter in the consideration of this subject. Obviously, the whole question is too broad a one to be considered at length within the limits of this brief paper, and attention will be chiefly directed to the modern interpretation of the various forms of treatment as based on physiologic and pathologic research, and conditions observed under the scalpel of the surgeon.

Treatment in cholelithiasis may be divided into two classes: First, the medical or palliative; second, the surgical or radical and curative. While our knowledge of the diagnosis of surgical conditions of the gall bladder is receiving constant additions, it is still too inexact in many cases, and many of our operative attacks are still largely exploratory. Bearing this in mind, we must admit that our medical brother may still often be justified in applying palliative measures and waiting for developments in many of his cases. Although the treatment of gall-bladder infection is undoubtedly surgical, there are so many factors to be considered in various cases that the radical or curative treatment is by no means unfortunately always available or even allowable. Hubert Richardson,¹ in an admirable paper, "Physiology and Pathology of Biliary Secretion," makes a plea for medical treatment in gallstone disease, which is based on some very interesting physiologic experiments on the action of the bile salts. As it has been shown by Herter that the bile salts act to hold the cholesterol in solution in the bile, their administration ought logically to prevent its precipitation and consequently gallstone formation. Since inflammation of the gall bladder invariably increases the amount of cholesterol and diminishes the amount of bile salts in all cases of cholecystitis, the administration of sodium glycocholate should theoretically be indicated. The

possibility of the solution of gallstones *in situ* is of the greatest clinical importance, and the search for such a solvent is as eager as that for the philosopher's stone, but thus far, unfortunately, quite as evasive. Recently Wakelin Barret² experimented by inserting large gallstones aseptically into the healthy gall bladder of dogs, and found that in from six months to one year they were dissolved, proving that healthy bile had the power to dissolve gallstones. He found, however, if stones were similarly inserted and an infective cholecystitis produced, they were not dissolved, showing that the bile under such conditions had no solvent power.

Austin³ has shown by analysis of the bile obtained from operative fistulas that the cholalic acid is from 1/3 to 1/8 of the cholesterol, while, according to Hammerstein, the normal ratio is as 12 to 1. It is evident, then, Richardson thinks, by administering sodium glycocholate, that it may be possible not only to prevent the formation of gallstones, but also to dissolve those already formed.

Heppel found that 5 per cent. olein, 10 per cent. bile salts, and 50 per cent. soap, will hold in solution their own weight of cholesterol; hence by administering alkalies and bile salts with a diet rich in fat the solution of gallstones ought to take place and their formation be prevented. This treatment proposed by Richardson comes, as he says, under the head of organotherapy, in that it is an administration of a secretion of the liver which is reabsorbed from the intestine, and so acts on the bile secretion through the blood.

The treatment by olive oil, adopted so enthusiastically by the profession a few years ago, has not fulfilled the hopes of its advocates as a specific, and is believed to have no direct action, but by relieving congestion of the intestine to aid indirectly in draining the biliary ducts. As there is no doubt that catarrh of the mucosa lining the biliary passages tends to increase the amount of cholesterol, and the longer the bile remains in the gall bladder the more cholesterol it will contain, it follows that whatever leads to the regular emptying of the gall bladder and the ducts tends to clear out any detritus, cholesterol crystals, mucus, etc.

Hence the rationale of the treatment which aims to clean out the intestinal tract, relieve congestion and increase the flow of bile is perfectly sound. The system of treatment adopted at some of the famous "Cures" abroad, notably Carlsbad, combining diet, exercise and the free consumption of certain mineral waters, seems often to be followed by very marked benefit, especially in the milder cases of catarrhal cholecystitis and cholangitis. When a patient has suffered from one or more attacks of biliary colic a course at Carlsbad may be of lasting benefit or entirely without effect. In a patient who can afford it, and in whom the disease has not progressed to such an extent as to menace his safety, such a course may be perfectly well prescribed.

A recent monograph by Fink⁴ of Carlsbad gives the results in a large series of cases observed by him, and an analysis of the results obtained by the water cure alone and the "cure" plus a surgical operation. As he very properly states, the great point to be determined is the borderline between balneologic and surgical treatment, i. e., when the former should cease and the latter be commenced. In his series of cases he presents abun-

dant material, affording a glimpse at the results of the Carlsbad "cure," and out of this material he presents a string of references which stands in intimate relation to this question. A perusal of the whole article is to be recommended.

What cases, then, shall be treated expectantly and what surgically? As the indications for operative interference in cholecystitis are further extended and better understood, there will come a full agreement between surgeon and internist as to the limitations of medical and the indications for surgical treatment. In the meantime, until such an understanding is reached, and in order that the medical man and the surgeon may understand each other's point of view, it may be proper to discuss the general effectiveness of surgical treatment, its advantages and its dangers, and, so far as possible, some of the reasons why its results fall short of the ideal. Inasmuch as the necessity for radical treatment is now pretty plainly recognized by all progressive practitioners, the number of cases "treated by procrastination and the direct encouragement of the opium habit" is each year growing less. Still, too many cases are encouraged to drift along and only counseled to submit to operation when the general condition is bad and the local ones such as to render necessary some of the more elaborate, difficult and dangerous operations. It should be remembered that the surgeon must take the case generally as it is brought to him, and the practitioners ought not, in justice to the good work which has been done in gall-bladder surgery in this country and abroad, to frame his opinions and judgment merely on the results of operations in desperate cases.

The promise of the future in gallstone surgery lies not so much in further elaborations of technic as in the prompt diagnosis by the internist, and his co-operation with the surgeon in advising one of the simpler prophylactic operations which may be done before serious infection, adhesions, duct invasion and blood changes have made any undertaking more severe, more hazardous and less effectual. As greater certainty in diagnosis is reached, there will be less call for the more difficult and dangerous operations on the common duct and a decreasing number of cases requiring cholecystenterostomy. Wherein, then, lies the danger in operation? Principally in delay. The statistics from our hospitals and private sources show a mortality so low in cholecystostomy and primary cholecystectomy that the internist may feel entirely justified in offering a surgical operation as a prompt, efficient and safe measure in any proper case, and as the only radical and curative means of which we have any knowledge. The danger of delay has been pointed out by the readers of every paper, and should be well understood both by the patient and the physician. With the diagnosis of obscure biliary affections discovered by means of exploratory laparotomy, Lawson Tait's name will always be associated, and following his example, many surgeons have not hesitated to make the diagnostic cut which, though undoubtedly capable of great abuse, can not to-day be questioned as not only frequently justifiable, but also necessary in obscure diseases of the gall bladder and ducts.

When we consider that the first deliberately planned cholecystostomy was done by Marion Sims in 1878, and the first cholecystectomy by C. Langenbuch in 1882, it will be seen what great progress has been made in this department of work in the last twenty years. In 1892, Murphy published his account of the applica-

tion of his button for the purpose of effecting an anastomosis between the gall bladder and the intestine. A number of operations have been proposed for stones impacted in the cystic and common ducts. Tait's cystico-lithotripsy or crushing *in situ* in 1854. Lithotomy,⁵ or extraction of stone in the cystic duct through an incision in another part of the biliary passages by Courvoisier in 1858. Cystotomy, or incision of the cystic duct, by Lindner in 1891. Cystectomy, or resection of a portion of the duct proposed by Zielewicz in 1887, and cystico-enterostomy by Roth in 1888. Operations on the common duct are numerous, though many are obsolete or often impracticable. Hansfield Jones, in 1878, proposed choledochic massage, which has not had much success, either having been followed by complete failure or by choledolithotripsy (Langenbuch, 1886, Sprengel, 1890, Mayo Robson, 1891). Choledochotomy, proposed by Langenbuch in 1884, was developed by Parkes in 1885, and is to-day one of the most important operations for stone in the common duct. Five years later Kocher gave it his support. The first typical operation of this sort was done by Knowlesley Thornton in May, 1889, and at about the same time by Marcy, Ferguson and Fenger. It is now established on a sound basis. A few years ago before the Association, Mayo of Rochester proposed an important and ingenious device for drainage after this operation. The question of omitting sutures in choledochotomy was broached by Parkes in 1885, and they were left out by Hoehenegg in 1890, and since that time the proposition has grown constantly in favor as the benefits and necessity of drainage in cholemic cases are better understood. Removal of impacted common duct stone by incision through the duodenum was first done in this country by McBurney in 1891, and retroduodenal choledochotomy was proposed by Berg of New York last year, 1903. Choledochostomy, choledochectomy and choledoch-enterostomy are only possible in rare conditions.

Operations on the hepatic ducts are still in their infancy, owing to the infrequency of operative work in this region. Hepatico-lithotripsy was done by Kocher in 1890. Hepatico-colic massage was unsuccessfully used by Elliot in 1894. Hepatico-lithotomy was attempted by Courvoisier in 1890, by Abbe in 1891, and others. Hepaticotomy was done by Kocher in 1899, removing a stone by the transhepatic route. Finally, hepatico-enterostomy has been experimentally studied, but not done clinically. Looking over this list, it will be seen that American surgery has played no unimportant part in the pioneer work of the operative treatment of gallstone disease, and in the later developments of important modifications in technic.

With this brief reference to the great progress of surgery in cholelithiasis, we must pass on directly to the consideration of the treatment of cases as they present themselves to us. Although there is not as yet a full agreement as to the limitations of medical and the indications for surgical treatment, it can no longer be held that the surgeon is rash in advising operation in any case wherein any considerable degree of infective cholecystitis has been diagnosed. Although an infected gall bladder may be entirely restored to the normal, as Naunyn has shown, the proportion of cases of recurring severe attacks is large enough to give the surgeon full justification in urging earlier operation in many cases. Hence we must consider two classes of cases

in cholelithiasis—one in which expectant treatment may still be advised, and another in which surgery is the only resort, recognizing, of course, that ultimately the only real treatment for all well-marked cases is surgical.

As has been shown, the period of "latency" may be reached at any period in the course of the case, provided the stone does not obstruct the passages or additional infection occur to disturb it by setting up inflammation, or traumatism to suddenly alter the position of the stone. The variability of this "quiet" period is very great, and is the chief factor relied on by those who favor palliative measures, since it may be very long and the attacks of colic comparatively mild.

What shall be our advice to patients suffering from cholecystitis and cholelithiasis? Shall we operate early or shall we wait? What is the present state of opinion and practice?

Cases seen in the first and mild attack, such cases, by the way, as are seldom seen by the surgeon, where the symptoms are slight and there is no peritonitis, where the inflammation in the gall bladder quickly subsides under medical treatment, are properly cases for observation.

In a certain proportion of these cases there is only one stone or small stones or mucus which are passed out into intestine and the cholecystitis disappears, about 10 per cent. (Elsberg⁶). In about 70 per cent., however, the stone remains in the cystic duct or drops back into the gall bladder, remains latent for a variable time, and the swollen gall bladder disappears.

Cases may be seen in subsequent mild attacks, where the patient may have had several mild seizures and has perhaps passed a stone or stones. Under these conditions at present, I think, most surgeons are inclined to wait, especially if the periods of "quiet" are long and the patient can be under proper medical surveillance. This is done in the hope that it may be the last attack and that the last stone has passed. These cases, however, are in some respects ideal ones for cholecystectomy, and the operation is here often very simple and the treatment perfectly rational, especially if the attacks are severe and frequent. The work of Lilienthal of New York in primary cholecystectomy, with practically no mortality, is certainly suggestive and worthy of our careful consideration.

In a personal communication he reports 47 cases with one death from pre-existing streptococcal infection. In cases with repeated severe attacks, when the patient is practically incapacitated for business and the general health begins to be affected, and resort to morphia gives rise to the fear of establishing the opium habit, nothing is to be gained by delay, and a golden opportunity is lost for radical cure if the cases are allowed to drift on. In these cases cholecystostomy is always justifiable, and the operation of choice, perhaps, by many surgeons, in that it is easy, safe and with modern technic not liable to be followed by fistula. These cases also offer a fair field for the primary cholecystectomy, which here, again, is often an easy operation, and in practiced hands a safe and certainly radical one. Park, Riedel, Winiwarter, Lilienthal and others are its strong advocates.

There is another set of cases which for a few days show evidence only of mild local infection, which suddenly change and develop signs of local peritonitis with heightened fever, rapid pulse and signs of general sep-

5. Fowler: Historical and Critical Observations on the Surgery of the Liver and Biliary Passages, Brooklyn Med. Jour., December, 1900.

6. N. Y. Med. Jour., March 26, 1904.

sus. These cases require early operation, lest perforation or rupture into the peritoneal cavity occur or abscess outside the gall bladder be formed with its attendant evils, primary and remote. In these cases the gall bladder and more or less of the cystic duct is involved, and the contents are either thick septic bile or mucopurulent fluid, or stones with thin purulent fluid, and there is local peritonitis with recent adhesions between gall bladder and neighboring organs. Here the treatment is prompt cholecystectomy with drainage of the cystic duct, or cholecystostomy. These cases frequently do very well.

In cases of common duct obstruction by calculus, where the obstruction is acute and recent, it is generally advisable to treat expectantly for a week or two, unless septic symptoms or peritonitis supervene, in order to determine if possible whether the obstruction may not be due to swelling, which will subside and allow the stone to pass. Or if the stone has passed, the signs will rapidly subside. In most cases the clinical picture of calculus obstruction is sufficiently distinctive for the diagnosis to be made from neoplasm. The indications for treatment are the removal of the stone by incision through the common duct, choledochotomy, or if it be too low or impacted in the ampulla of Vater, by transduodenal or retroduodenal choledochotomy. The practice of careful suture of the incision in the common duct has been pretty generally abandoned, unless the duct be drained through an opening in the gall bladder, as the necessity for drainage has been shown by Mayo Robson, Kehr, Mayo and many others. It is advisable practically in all these cases to drain the common and hepatic duct, as small stones otherwise may be overlooked or the patient die cholemic, which is of much more importance.

Cholelithotripsy is no longer done and cholecystenterostomy is of far less frequent occurrence as the cases are sent earlier to the surgeon.

As is well known, the common duct cases are the most dangerous, because more often neglected or overlooked, or in a condition of exhaustion and cholemia when they come to the surgeon for operation.

It is surprising how well many of them react after operations and go on to complete recovery of health. Modern surgery has made even this possible and has many lives to its credit, but too much should not be expected of it; chronic jaundice often defeats the best planned operation or the most perfect technic, and the hemorrhagic oozing generally persists to a fatal termination in spite of any treatment thus far devised.

The senseless delay which makes this possible is one of the great causes which militate against ideal results in the surgery of gallstones, and this delay, while often due to the patient's fear of operation or to causes which would render any operation inadvisable, is still too often traceable to the lack of knowledge or confidence on the part of the family physician in the great resources of modern surgery.

CONCLUSION.

In conclusion, then, after this most careful review by the readers of the various papers on the pathology, the diagnosis and the complications of cholelithiasis, it will be seen that the treatment in these cases must ultimately be surgical, for when all has been said, it must be admitted that medical science has thus far discovered no sure solvent for gallstones *in situ*, nor devised any means, other than surgical, for the certain drainage of the gall bladder and the biliary ducts.

DISCUSSION

ON PAPERS OF DRs. BIERRING, OPPE, SIPPY, SYMS AND HOTCHKISS.

DR. J. M. ANDERS, Philadelphia.—It is doubtless true that cholecystitis and cholelithiasis are of microbial origin and also that the particular micro-organisms are either the colon bacilli or streptococci. Dr. Bierring has emphasized a point of importance, namely, that the mere presence of these micro-organisms in the gall bladder and ducts is not sufficient to give rise to these conditions. In all cases, therefore, something has occurred before these conditions arise as a result of microbial infection. The predisposing factors should be more emphasized than they have been by recent writers, and these are, so far as my observations go, some forms of local irritation or congestion, including inspissation of the bile. The contributory factors are very numerous and many refer to the various products of abnormal metabolic processes. Nobody questions the relation of cholecystitis to cholelithiasis; these conditions most probably stand to one another in the relation of cause and effect. Of course, there are many cases of cholecystitis which subside without giving rise to cholelithiasis; but the conditions remain which favor the development of gallstones and subsequent infection of the gall bladder may lead to active biliary colic. Dr. Sippy's paper treated of the relation of the gall bladder and bile ducts to diseases of the stomach and intestines. I am not ready to admit, since it is contrary to my previous experience, that ulcer of the stomach and intestines arises secondary to disease of the biliary passages and gall bladder. But I have seen rather grave forms of gastrointestinal disturbances from this cause, and quite recently two cases of pyloric obstruction. I believe with Dr. Sippy that the motor functions are more decidedly disturbed than the secretory functions of the stomach. One of the most important points from a diagnostic standpoint is to obtain a clear history whenever possible; this will very often throw light on the case diagnostically. I mention this because it seems to me that scarcely sufficient emphasis has been laid on it in the paper. Dr. Sippy pointed out two very important practical lessons. One was that medical measures may suffice, together with rest and proper diet, to overcome pyloric obstruction due to disease of the gall bladder and ducts. The other fact was that surgical operation, when undertaken to overcome pyloric obstruction, should be in part directed to the relief of the causes of the gastric condition. To remove the pathologic conditions presented by the gall bladder, the adhesions and the like, must go far toward effecting a cure of this stenosis. With regard to the diagnosis of cholelithiasis, my observation is that, immediately preceding the attack of gallstone colic, pain is referred to the back, to the right of the tenth dorsal vertebra; this pain may last but a few minutes. So far as I have been able to observe, this is not present in cholecystitis of pure and simple form. This is followed, as a rule, by the rapid development of hepatic colic. I agree with Dr. Hotchkiss that it is highly important to make an exact diagnosis before instituting treatment. It is important to differentiate whenever possible between cholecystitis and cholelithiasis. Simple cholecystitis is still looked on by the majority of authorities as being largely a medical affection. On the other hand, cholelithiasis is a surgical disease. I do not mean to say that the diagnosis of cholelithiasis should always be followed by operation, but I do mean that the medical man should have the conservative surgeon's advice in such a case. Dr. Hotchkiss has emphasized the fact that the cause of failure was not so much due to bungling operations or operations poorly done as to the fact that operation is, as a rule, too long delayed; he is right.

DR. WILLIAM J. MAYO, Rochester, Minn.—I think it is well for us to consider that gallstones are essentially foreign bodies, and as foreign bodies a diagnosis can only be made when they are giving trouble, and, other things being equal, they should be removed. Gallstones may "slumber" for years, but when they awaken the probabilities are that they will not permanently regain an innocent quiet, but rather tend to bring about those complications which give rise to serious and often incurable disease. Of these, one has but to mention chronic liver changes from jaundice and duct obstruction, inflammation of the pan-

creas, fistula, abscess and perforation. That cancer possibility is also a legitimate risk was pointed out by Musser and Kely-nack years ago. In looking up evidence, we must bear in mind the statistics from simple gallstone cases and keep these sharply separated from those cases in which complications have occurred. The oration which Dr. Dock presented the other evening was exactly to the point. When a medical man is called to see a patient he must say that the prognosis in cases of simple gallstone disease surgically treated is remarkably good and depends more on the condition of the patient than on the operation itself. So the remarks that I shall make are based on gallstone disease in patients who are otherwise in good condition. The mortality of simple gallstone operation, while the stones are still in the gall bladder and that viscus is not seriously infected, does not exceed 3 per cent. This mortality is largely accidental, and is not above that of simple appendectomy in the interval in patients of the same age and general condition. In contrast, I wish to call attention to the statistics given by the greatest of German gallstone operators. He has taken a rather conservative position, which American surgeons are not inclined to follow. In his last 450 cases, taken as they come, there were 72 deaths, a mortality of 16 per cent. This high mortality was in the cases that had been carried too far. Therefore, I think the physician, in making a statement to these sufferers, should properly place the situation before the victim, because they have the right to a choice in the matter; in equity, it must not be entirely settled by the physician. The patient should be told that if in good health the removal of uncomplicated gallstones is accompanied by a mortality not above 3 per cent., but if the condition be left to run on and become complicated, then the mortality may jump to 16 per cent., as it did in the hands of the operator referred to. The complications cause the mortality. Few patients will deliberately elect the conservative course, if the facts are fairly laid before them, and the physician who fails to acquaint his patient with the whole truth does less than his duty and takes on himself a serious responsibility, for which he will ultimately be held accountable. After the removal of gallstones many secondary conditions of the gastrointestinal tract, and especially of the pancreas, may subside. Chronic inflammation and enlargement of the pancreas may be expected to disappear after drainage of the biliary passages. On a number of occasions I have found that a blocking of the duct of the pancreas by a common duct stone has led to an enlargement of the head of the pancreas, behind which the common duct stone became hidden; at a second operation, some months later, it was found that drainage had reduced the size of the head of the pancreas and revealed a stone which had been *in situ* during previous operations, giving rise to the trouble, but was undetected by duct palpation. In chronic pancreatitis with jaundice, the common duct should be opened and explored to the very papille for fear that a stone may be overlooked.

DR. WILLIAM S. THAYER, Baltimore.—In the beginning of Dr. Opie's paper he refers to the recent work of Pavlov of St. Petersburg, showing that the admixture of bile and pancreatic juice increased the activity of the latter from three- to four-fold, and especially increased the activity of the fat-splitting ferment. It has been shown, both clinically and experimentally, that the entrance of bile into the pancreatic duct produced an acute pancreatitis in a large number of instances. Therefore, is it not probable that this action of the bile in increasing the activity of the fat-splitting ferment would cause an acute pancreatitis and the fat necrosis that goes with it?

With regard to Dr. Sippy's paper, these cases of gallstones impacted in the cystic duct are very interesting. I saw such a case, and it was a clear case; but the interesting feature was that some months before pain was complained of in the region of the gall bladder on taking food; she became much emaciated because of the pain, which was supposed to be due to adhesions of the pylorus. An operation revealed the cause. She had a very large dilatation of the stomach, due to adhesions at the pyloric end of the stomach and duodenum. This was not recognized until operation. The largest stomach dilatation I have ever seen was due to this cause. Another diffi-

culty is sometimes encountered in attempting to distinguish between attacks of gastric ulcer and gallstone colic. I recently saw an interesting case. The patient was believed to be suffering from biliary colic. She never had any jaundice and had pain in the median line. She finally thought she would like to be operated on. She had not seen a physician for six months before coming to me. I found a large dilated stomach. The operation revealed two duodenal ulcers and a tight stricture of the duodenum. One of the greatest dangers encountered in these cases is through delay, especially in cases accompanied by jaundice. The development of hemorrhagic jaundice is an exceedingly grave thing.

DR. J. C. HEMMETER, Baltimore.—In June, 1903, I had an interesting experience with a case of cholelithiasis, which may serve as a type of three others of a similar nature seen by me. The wife of a physician was operated on for gallstones, and the surgeon resected the entire gall bladder. He took out twelve stones. The pains continued, and a second operation was deemed necessary. In the intrahepatic bile ducts were found three small gallstones, which had not been seen at the time of the first operation. I am by no means prepared to concede to the surgeon the entire control of all cases of gallstone diseases. When operation is necessary, the surgeon is indispensable. But we should remember that the diseases which lead up to gallstones are the most important thing for our consideration, also the abnormal conditions of metabolism that favor deposition of solid matter from bile. I think that the deductions of Dr. Biering are very important, especially regarding those cases of infection of the gall bladder with germs, causing stagnation and catarrhal swelling, etc., but there is another very important class of cases of gallstone disease, the causes of which are to be sought in abnormal hepatic metabolism. We may have changes in the composition of the bile followed by precipitation of solid constituents in the intrahepatic and intercellular canaliculi. We need the surgeon, and we must have him, but I am not in a position to say to-day that the surgeon should have entire charge of these cases. Before the surgeon gets them, would it not be best for us to attempt to recognize the changes that lead up to cholelithiasis? In a rough but practical way we may speak: first, ascending causes of cholelithiasis; second, descending causes of cholelithiasis. The ascending extend upward from the duodenum. They include the upward progression of duodenal catarrh, stenosing the gall duct and producing catarrh of the gall bladder, also the infections of the ducts and bladder with the micro-organisms of the intestine. The second group of causes may roughly be called descending, because they originate in the hepatic cells and lead to deposition of minute concretions in the intrahepatic bile canaliculi; these eventually may reach the lower and larger ducts and the gall bladder. It is these metabolic and intrahepatic concretions that cause the recurrence of the symptoms of gallstones, even after stones have been removed and gall bladder resected by the surgeon. The operation in these cases may, of course, be a life-saving step, but it can no more cure the metabolic cholelithiasis than cutting out a concretion of sodium bicurate from a gouty knee joint can cure gout. While I admit the expediency of operation, I uphold the absolute necessity of preceding and succeeding medical treatment. It is these cases of recurring gallstone attacks after very radical operations that led Hans Kebr to send numerous cases to Carlsbad. There is no doubt in my mind that persistent and judicious drinking of alkaline waters (2 to 3 liters daily), together with the diet advocated at Carlsbad, may prevent the metabolic hepatic disturbances that lead to the second form of cholelithiasis mentioned above. The bile salts act in a similar manner. The alternating Scotch douche applied daily over the hepatic region is an available aid to this treatment. Many a case of cholelithiasis is a neglected or unrecognized case of chronic acid gastritis or duodenitis. In a number of cases proven to be cholelithiasis by operation I was able to watch the development of duodenitis from a gastric hyperchlorhydria or a chronic gastritis acid. Such cases have been studied for from ten to twelve years, when eventually cholelithiasis supervened, and it is plausible to assume that

the gastritis set up a duodenitis, and this in turn stenosed the common gall duct. Dr. Sippy has spoken of the relation of disease of the gall bladder and bile ducts to disorders of the stomach and intestines. We should study more the effect of diet and alkaline waters on the composition of the bile and the effect of gastric and duodenal diseases, leading to stenosis of the common duct. It has been asserted that there is great difficulty experienced in differentiating between the pain of gastric ulcer and gallstone attacks. I have in mind one or two practical points which I think are of value. In gastric ulcer we may find pepsin in the urine, and it is found there because the epithelium is denuded in the stomach, and the pepsin is absorbed as such and is excreted by the urine and will digest a certain amount of fibrin or boiled egg. There is another point of value in making a differential diagnosis. It has always been considered desirable to possess a substance which would relieve gastric pain if applied locally in patients afflicted with gastric ulcer. For this purpose I have administered orthoform. If orthoform is given in cholelithiasis the pain will not cease, but if given in a case of gastric ulcer it will cease promptly, especially if an alkali be combined with it.

DR. FRANK BILLINGS, Chicago.—On the subject of cholelithiasis I have positive views. These are based on my experience with patients suffering from the disease. We know that the chief source of cholesterol is an excretion or a secretion of the cells of the gall bladder. In all probability, little if any cholesterol is precipitated from the bile, consequently any treatment directed to lessen the precipitation of cholesterol is futile. I think our present knowledge does not admit of the use of the so-called solvents for gallstones. As we have no medication which will probably dissolve gallstones *in situ*, nor do we know of a drug which we can say will be excreted by the epithelium of the gall bladder, so our medical treatment is, I think, limited to the use of drugs which will diminish the infection of the gall tracts. This may probably be done by the so-called internal drainage by the use of cathartics like the salines, of which sprudel salts has the greatest reputation. So patients visit Carlsbad and other springs and are relieved of the infection which is associated with gallstones. The same relief may be afforded in many instances by a corresponding treatment carried on at home. In that event, with infection removed, the gallstones as foreign bodies may remain in the biliary tracts. As foreign bodies, we may not recognize the harm they may produce. We do not know that an intoxication may not be present with these latent symptoms and produce deleterious effects which are for the time unrecognized. We do not know, for instance, but that this condition of the gall tracts may have something to do in the production of arteriosclerosis, of which we have heard so much at this meeting. And then, the patient who carries his gallstones even in this latent condition is subject at all times to more acute attacks, which may, like an acute appendicitis, place his life in danger and make the operation an emergency one. I, therefore, look on gallstones, when the diagnosis is surely made, as a surgical disease and look to the surgeon as the proper individual to treat the patient. In my estimation, an operation done at the proper time in uncomplicated cases is of less risk to the patient than the continued presence of the gallstones. Dr. Hemmeter has raised the question of preceding stomach or duodenal disease as etiologically related to gallstones. This is undoubtedly true, but we must not hesitate, in my opinion, to operate even if there be a recognized stomach or intestinal disease as a cause of the gallstones. I desire to emphasize that, if an operation is done for gallstones, it should be performed by the most skillful surgeon whose services may be obtained, and thus so lessen the risk to the patient that, in consenting to the operation, he takes a less risk than in keeping the gallstones.

DR. JAMES TYSON, Philadelphia—Two cases which occurred in my own practice illustrate the difficulty in diagnosis of some of the conditions which present themselves in the upper right quadrant of the abdomen. One patient, a man, had frequent recurring attacks of pain in the neighborhood of the gall bladder without jaundice, and the condition extended over a considerable period of time. The attacks were especially prone to come

on very early in the morning, when the stomach was empty, and would often awake him from sleep. Examination otherwise was negative. It is true that a tumor was thought to be palpable by one or two physicians, but I could not realize this myself. The case came to operation, Dr. Edward Martin operating. The gall bladder was exposed, and it was entirely normal in size and contents, but in its vicinity were found adhesions between the pyloric end of the stomach and the adjacent bowel. I do not recall whether there were any adhesions between the pylorus and gall bladder itself or not. A rapid recovery followed the operation, and there was no recurrence of symptoms. What relation an original cholecystitis may have had to this condition I do not know. It was suggested there had been a gallstone which was the original source of irritation and cause of the symptoms, which had existed for years. The symptoms were relieved by the operation. Another case bearing on the diagnosis of these conditions was that of a woman who had had many attacks of biliary colic and had been treated at Carlsbad and at home. The physician in Germany said he could feel the bladder, and that there was no stone present. Dr. John B. Beaver operated and removed one hundred stones from the gall bladder, doing at the same time an operation for appendicitis. The patient is now perfectly well.

DR. ALLEN A. JONES, Buffalo—Symptoms which are presented to us are very often misleading and not sufficient to enable us, in many cases, to diagnose the number of stones nor the condition of the gall bladder itself. There are cases in which there are repeated attacks of biliary colic and in which the lives of the patients are rendered extremely uncomfortable, and here sometimes there is presented a single round stone, about the size of a pea, the stone being found floating in the gall bladder, containing a large amount of fluid, or impacted in the beginning of the cystic duct, or somewhere in the cystic duct. These cases are relieved by a cholecystotomy. There have been instances in which a single stone has been found impacted in the cystic duct, and yet no stones were found in the gall bladder. It has been my lot to find such a condition in a young girl. Symptoms of severe gallstone disease occurred at about the age of 14 years. In such cases there is brought up the question of a differential diagnosis between a floating kidney and a dilated gall bladder. While such a diagnosis may seem easy to the tyro, it is not a simple matter by any means. In such a case a surgeon of experience went in for a floating kidney, and, unable to find it, finally concluded, after considerable search, that he had to do with a dilated gall bladder, which was found and operated on. Occasionally we meet with cases in which there are impacted two or three large stones in the common duct, with the gall bladder empty. With regard to the symptomatology, we have found an intolerance of the stomach, which manifests itself after eating and not on an empty stomach. In fact, the patients constantly aver that the stomach is at fault because they can not eat anything. In a large number of cases I have found the stomach practically normal in secretion and in motion after the gall bladder was emptied. In such cases it has not occurred to us that the patient had gastric disease. There are other cases in which gastric disease is due to gall bladder disease, as, for instance, dilation, preceded by or accompanied by biliary disease.

DR. J. C. WILSON, Philadelphia—There are two classes of practitioners who hesitate to accept the fact that in the present state of knowledge gall bladder disease is a surgical rather than a medical affection. First, those who demand too many of the classical morbid phenomena for the diagnosis, and, second, those who accept periods of latency for cures. The modern literature, representing the experiences of the most advanced investigators, makes it clear that recurrent paroxysmal pain with interparoxysmal tenderness in the right hypochondrium points to cholecystitis, and that jaundice and recognizable gall bladder tumor are not at all necessary to the diagnosis. The every-day experience of the observant practitioner renders it equally clear that both in cholecystitis and cholelithiasis, especially in the latter, there are periods of latency simulating recoveries which are attributed by the unwary to treatment that may have been employed. It is true

that such periods may be prolonged, and in some instances constitute true recoveries. But such an event is exceptional and not to be foreseen in any given case.

DR. PARKER SYMS, New York—In the chronic cases of gall bladder disease with stones, where the stones remain latent, the diagnosis is often impossible. But in the great minority, if not the majority, of the cases where the symptoms are present, the failure to make a diagnosis is absolutely due to failure to make a careful examination. Nothing more important can be set forth to-day than the importance of making a careful and exact diagnosis of the cases and of advising an early operation.

POISONING BY WOOD ALCOHOL.

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS.

FRANK BULLER, M.D.

MONTREAL.

AND

CASEY A. WOOD, M.D.

CHICAGO.

(Continued from page 1062.)

CASE 81.—(From Dr. John E. Weeks, New York City.)

E. V., aged 38, came to the New York Eye and Ear Infirmary, Dr. Weeks' service, Nov. 21, 1903. In the early part of August the patient suffered from intermittent fever, and on August 7 he drank a cupful of wood alcohol for the purpose of breaking up the fever. On the following day the vision of the left eye failed almost entirely, and the vision of the right eye became impaired. The maximum failure of vision was reached at the end of 48 hours. Since then, according to the patient's statement, there has been some improvement.

At the present time the vision of the right eye equals 30/40; the vision of the left eye equals fingers at eight feet. There is (see Fig. 1) concentric limitation of the field of vision, most marked in the left eye, an absolute central scotoma in the left eye and a relative central scotoma in the right eye.

The patient has been seen from time to time, and since November 21 the vision has remained approximately the same.

CASE 82.—(From Dr. D. Emmett Welsh, Grand Rapids, Mich.)

J. D., aged 15, living in the country, was in the habit of visiting quite frequently a neighboring village, where he acquired the drink habit. It was his custom to become intoxicated on wood alcohol, in the company of farm laborers, and sleep off his fits of indulgence in the barn. When at home he procured and drank Jamaica ginger. One morning after such a spree he awoke to find himself completely blind. Dr. Welsh was consulted some time afterward and found him very shaky and nervous, speech difficult, general muscular tremor, marked anemia and complete loss of vision in all parts of the field. The fundi exhibited white atrophy of both nerves. In spite of treatment, vision was not improved, and he was finally sent to one of the state institutions for the blind.

CASE 83.—(From Dr. D. Emmett Welsh, Grand Rapids, Mich.)

J. M., aged 14, acquired the drink habit and, "as it was so cheap," bought wood alcohol ostensibly for burning in a lamp, but really for use as a beverage. Previous to consulting Dr. Welsh he had never had any ocular defect. When seen he was totally blind in both eyes, but treatment improved his sight somewhat, until he now has about 3/200 in either eye. This boy exhibited the same degree of nervousness and anemia as the other boy, whose history is given elsewhere, and like him presented the fundus picture of optic atrophy.

CASE 84.—(From Dr. Joseph White, Richmond, Va.)

A young man, S. N., was brought to Dr. White June 22, 1897. On May 1 he drank quite a quantity of Jamaica ginger; it is not known exactly how much. The next morning, May 2, he woke up vomiting. He walked home, six miles, over the mountains and arrived there exhausted, with cold feet and legs. He went to bed sick and continued nauseated for three days, during which time his sight gradually left him. When he came to Dr. White his vision was so bad that he could hardly make out the 20/200 type at four inches. His fields, taken with a light, seemed to be very much contracted. The fundus was normal, except some pallor about the outer third of the disc. The diagnosis was retro-ocular neuritis, with atrophy of the papillo-

macular bundle. He remained under treatment for ten days and went home. The only information received from him subsequently was that he made no improvement whatsoever.

CASE 85.—(From Dr. Joseph White, Richmond, Va., and Dr. W. R. Williams, Richlands, Va.)

In March, 1898, Dr. White saw a young man, S. W., clerk, 21 years of age, who had been on a spree February 12, when he drank four bottles of essence of lemon, each bottle containing between two and three ounces. On Sunday morning at 10 o'clock he began to lose his vision. He also suffered great difficulty in breathing, the respirations reaching 40 to the minute, with no radial pulse, widely dilated pupils, general collapse and stupor. In spite of all treatment, he continued in a sort of stupor for two days. When he recovered from this mental condition he had no light perception. Five days later light perception began to return, and when Dr. White first examined him, three weeks afterward, his vision was 3/300. The pupils were widely dilated and not responsive to light, the retina was normal, the outer and central parts of the disc were bluish-white and slightly excavated. Dr. White made a diagnosis of optic atrophy from methyl alcohol. He heard from the physician who brought him, some time afterward, that the patient had made no improvement under treatment. In a report to Dr. White, dated May 8, 1904, Dr. Williams, who originally saw this case, says that the patient's vision improved for three or four months, so that he could resume his duties as clerk. However, he again took to drinking and smoking, his sight again deteriorated, fell to 3/20, and has so remained ever since.

CASE 86.—(From Dr. Jay Philon Whitney of Vinton, Iowa, and Dr. Lee Wallace Dean, Iowa City, Iowa.)

W. H., aged 37, married, printer, of regular habits up to 1900. At that time he began to drink whisky heavily and con-

Figure 1.

tinued for about a year, when, on being refused liquor at various places, he began to take Jamaica ginger. He was soon refused this at the drug stores, but was in the habit of handing boys small sums of money and inducing them to obtain it for him. In the early months of 1901 he began to notice failing eyesight and consulted various opticians and oculists for relief, but obtained none. He complained that if he stood so as to look down at his type case that he could see fairly well, but on raising the eyes he noted a very distinct blurring. About April, 1902, after taking on Sunday a considerable quantity of peruna and Jamaica ginger, on attempting to go to his work on Monday morning he became entirely blind and had to be led back home. "I saw him one hour later; the vision was totally lost, the pupils did not respond to light and shade, dyspnea was urgent, pulse rapid, feeble and irregular; cyanosis was present, the extremities cool. From this precarious condition he rapidly recovered his vision and usual health, and returned to work in about ten days. In June of the same year, after drinking freely of Jamaica ginger on Thursday evening, he awoke the next morning to find himself entirely blind. I saw him about one hour later; the same symptoms were present as in the first attack, but coma supervened about 1 p. m., and he died quietly about 5 p. m."

CASE 87.—(From Dr. Jay Philon Whitney, Vinton, Iowa, and Dr. Lee Wallace Dean, Iowa City, Iowa.)

C. F., aged 36, married, printer, of regular habits, except an occasional prolonged spree; no eye defect. About Jan. 15, 1903, began to drink whisky heavily and continued for two weeks, when he was unable to obtain any more liquor. He sobered up at that time and remained sober until Feb. 4, 1903. About 7 o'clock that evening he called on his former employer,

arranged to take up his work again and remained with him until 9 o'clock. At 11 o'clock, according to the testimony of his landlady, he returned to his hotel somewhat the worse for liquor and went to bed unassisted. On the following morning he awoke to find that he was totally blind. He managed to get into his clothing and reach the hotel office unassisted. His employer was telephoned for and saw him 30 minutes later. The patient told him that on the night previous, after leaving his office, he fell in with some kindred spirits and drank one dozen small bottles of essence of lemon. At that time he had an essence of lemon bottle with a small quantity in it on his person. He was then entirely blind, dyspneic and cyanotic; the extremities were cool. He felt a sense of impending dissolution and desired that his people be communicated with. An attempt was made to get him back to his room, but on the first landing he had a convulsive seizure and they were obliged to carry him the rest of the way. The dyspnea and cyanosis increased, the extremities became quite cold, and he died quietly at 11 a. m. Dr. C. C. Griffin, Jr., and Dr. A. R. Fellows also saw this man.

CASE 88.—(From Dr. James P. Widmeyer, Rolla, N. D.)

One of at least ten Indians of the Turtle Mountain Reservation, who went on a spree with lemon extract and Florida water, drank half a teaspoonful of the latter. He had intestinal pains, burning in his stomach and nausea. After walking a couple of miles from the scene of the spree he vomited freely and did not suffer as did his nine companions, who all died. Along with the blindness (exact details of which could not be obtained) he had a marked dysuria. One other survivor also complained of difficulty in passing his urine. The poison was drunk Aug. 31, 1904, and the amblyopia was noticed a few days afterward.

CASE 89.—(From Dr. Hiram Woods, Baltimore, Md.)

"The wife of a laboring man, to improve her digestion, has been in the habit, at intervals for several years, of taking three or four tablespoonfuls of Jamaica ginger daily. She is about 40 years of age and her husband now reports that her sight has recently failed and that attempts to obtain glasses to improve it have met with no success. He also said that she sees better to one side than straight ahead. So far he has not brought the patient to my office, as I urged him to do, and I can not speak more definitely, but the case certainly looks like one of methyl alcohol amblyopia."

CASE 90.—(From Dr. Emil Bories, Seattle, Wash. Reported by Dr. Hamilton Stillson, Seattle, Wash.)

On May 23, 1903, Dr. Bories was called to attend S. M., German, aged 32, painter by trade, who had drunk about three ounces of Columbian spirits (wood alcohol), the same being used in the shop for dissolving shellac. Had frequently drunk alcohol in large quantities, and not being able to read the English labels, and supposing from the smell that the stuff was alcohol, he drank it, not knowing it was poisonous. Dr. Bories found him at his residence, where his fellow workmen had taken him. They noticed that he acted very strangely and, becoming alarmed, carried him to his home. One of the workmen stated that he had seen him drink alcohol before, but had never seen him so affected by it. General symptoms, pulse very weak and became countless, temperature subnormal for nearly three days; total blindness, could not discern light; had a ghastly, vacant expression; sighed often and deeply; lips bloodless. In dread of dying; was getting weaker; could not extend his hand; respiration stertorous; movements of limbs convulsive, constantly jerking; speech finally inaudible. Gave him at once 1.60 strychnia and pilocarpin, had him wrapped in blankets which had been wrung out of hot water, syphon to stomach; followed the same by pouring down about 6 ounces of hot, strong, unsweetened coffee, which was retained. Gave him a large enema of salt water. Also gave hypodermic injections of glonoin and had ice-bags placed on top of head and spine. Instructed wife and friends to rub the body well and constantly. Pupils dilated, conjunctiva very much inflamed. After two hours of hard work he showed signs of returning sensibility. One pupil contracted, but the other remained dilated. Lips showed better circulation, body became warmer and he was able to answer questions coherently, but was not able to discern light, although a bright electric light was burning. The following morning he was much better and retained nourishment. Blindness continued for three weeks, when sight was gradually restored. Dr. Kibbe saw the patient three days after he was taken home and advised a continuation of treatment. About ten days after, at the suggestion of Dr. Kibbe, performed venesection, without beneficial results.

(C) CASES HITHERTO UNPUBLISHED OF BLINDNESS FROM METHYL ALCOHOL ABSORBED BY THE LUNGS OR SKIN, OR BOTH.

CASE 1.—(From Dr. W. McL. Ayres, Cincinnati, O.)

W. E. C., aged 44, painter. Six or eight years ago had symptoms of lead poisoning, but his eyes were unaffected by this intoxication and were, so far as he knew, perfectly healthy. Shortly before he was seen by Dr. Ayres (October, 1901), he had been varnishing and shellacking the inside of the closets in one of the large Cincinnati hotels. The shellac had been cut by, or dissolved in, wood alcohol instead of grain alcohol. While in one of the closets he became dizzy, had an intense headache and was forced to stop for a time and get some fresh air. After this he returned to work, but was again attacked by nausea, vomiting and headache, that forced him to discontinue his work entirely for several days. On the third or fourth day his eyesight began to fail, and at the end of a week central vision was 5/100 in each eye.

Examination with the ophthalmoscope disclosed a double optic neuritis, which in a few months was followed by partial atrophy, with a large central scotoma in both eyes. At present he is practically helpless and unable to do any work requiring the use of his eyes.

CASE 2.—(From Dr. Daniel Conboy, Bad Axe, Mich.)

On Nov. 3, 1903, a call was received to visit Mrs. H., aged 58, bright and intelligent, and withal good looking, the latter partly due to the good (though on this occasion, unfortunately, excessive) care she took of her complexion. She was found with sight very much diminished, "almost blind," as she described her condition, central acuity being especially impaired. A large parlor coal-burner about 10 feet distant was recognized by its outline only. The eyes of a person four feet distant appeared like dark spots on a white background, no color or form being distinguishable. This fact, after the exclusion of nephritic and diabetic retinitis by urinalysis, led to a provisional diagnosis of an ocular affection of toxic origin. The trouble had been coming on gradually for two weeks. She also had had vertigo occasionally, particularly at church, and would have fallen the Sunday morning previous had it not been for her husband's help. Antointoxication was suspected, but nothing abnormal was discovered about the digestive tract. Inquiry was then made with regard to the use of Jamaica ginger, with the explanation that the essence of Jamaica ginger, of lemon and similar flavoring and culinary mixtures sometimes contained methyl alcohol, which might cause the condition from which she was suffering. The patient immediately raised her hands in surprise, and stated that she had been using wood alcohol for weeks, both for heating her rheumatic bath and as a cleansing application to her head and face daily, especially on Sunday mornings before church. The alcohol was at once discontinued and sodium salicylate administered *ter in die* after meals. The usual diminution of sight was arrested immediately, but the impaired vision remained *in statu quo* for four or five days, when it began to improve. Both on account of her blindness and the continuous stormy weather, she was unable for over a week to come to the office for ophthalmologic examination. The fundi even then presented an interesting picture. The temporal half of each optic disc showed a pallor very much emphasized by the hyperemia and neuritis of the remaining part. At the first office examination, nearly two weeks after patient was seen, the vision for distance was, R. 7/40 and L. 7/50. On November 18, R. = 7/30, and L. = 7/30. On the 24th, R. was 7/20 and L. 7/30. December 3, one month after first visit, R. = 7/20 and L. = 7/30. December 7, R. = 7/20 — and L. = 7/30 +. December 9, R. = 7/20 and L. = 7/30 +. The last examination was on December 18, when both R. and L. were 8/20, which the patient thought was about the same vision that had existed before she used the "nasty stuff." When the papillitis had vanished from both fundi, strychnin in increasing doses was administered in the hope of preventing optic atrophy.

CASE 3.—(From Dr. W. E. Driver, Norfolk, Va.)

E. L., male, white, aged 54, consulted Dr. Driver on June 15, 1901. He gave the following history: In August, 1894, after shellacking the benches and interiors of several school houses he awakened in the morning of the second night to find that he was totally blind. Prior to that time he had not had trouble with his vision. He remained totally blind for about two weeks, when the sight began to improve, especially in the left eye. He thinks the vision in the left eye has improved somewhat during the past two years. The shellac used had been dissolved in wood alcohol.

The general appearance of the eye was that of ordinary nerve atrophy. The pupils were widely dilated and the cornea appeared unusually bright. Right eye, V.—light perception. Iris slightly active to light. Optic nerve bluish-white, showing marked atrophic condition. Tension normal. Left eye, V.—20/100; with +50 D. Sph.—20/70. Cornea very bright and clear. Pupil widely dilated, as in the right eye. Iris slightly active to light. Optic nerve white, showing marked atrophic condition. No other visible disease of fundus.

The diagnosis was optic nerve atrophy from inhalation of wood alcohol.

CASE 4.—(From Dr. Harold Gifford, Omaha, Neb.)

A woman of about 35 came in the spring of 1902, complaining of gradual loss of sight for the past two weeks. Dr. Gifford found the fundus of each eye normal, except for a slight pallor of the outer quadrant of each disc, which might easily be physiologic. Vision, 20/200, each eye, not improved by glasses. Outer limits of the fields normal, but the center of each field showed a large relative scotoma about 30 degrees in diameter, in the center of which the color sense was practically abolished. On being questioned about the possibility of methyl alcohol poisoning, she positively denied ever having drunk methyl or any other alcohol, or any of the various commercial products which are apt to be adulterated with it; but she had been burning methyl alcohol in an alcohol lamp with a large, flat wick for heating water in her room. Her custom for two or three months had been to light the lamp nearly every evening and allow it to burn out. This was during the winter season, in a small bedroom, without any other fire, so that it can easily be imagined that the ventilation must have been somewhat defective. She had nothing else wrong with her that could be discovered. Her vision began to improve almost immediately after Dr. Gifford advised her to stop burning the methyl alcohol, when it gradually rose to 20/20 in the right eye and 20/70 in the left (the left eye had had convergent squint since childhood.) It seems probable, therefore, that the amblyopia was due to the fumes of the methyl alcohol or to the formaldehyd generated in burning it. Considering the relative quantities of the substances which must have been present in the air of the room; it seems more likely to have been the formaldehyd; but whatever the fact in this respect, the case suggests an additional way in which the eyesight can be injured by this villainous stuff.

CASE 5.—(From Dr. J. A. Lippincott, Pittsburg, Pa.)

S. E. S., aged 44, April 12, 1902, worked a whole day varnishing tanks in a brewery, using a varnish which had been mixed with wood alcohol. In the evening when he left his work—according to the statement of his physician, Dr. Brock of Waynesburg—he acted like an intoxicated man, and two hours later went into a comatose condition, which lasted 24 hours. When aroused the sight of the right eye was somewhat impaired and that of the left eye was entirely gone. His vision since then has improved considerably. The pupils on both sides small (2 mm.) and sluggish. T. normal. R. E., V.—15/lxxx. No glass helps. Field of right eye shows moderate concentric limitation. That of left a more decided contraction, and also a small complete central scotoma. The ophthalmoscope showed right disc hazy, left swollen and blurred at margins and vessels tortuous. Advised jodid of potassium, salicylate of soda and nux vomica. June 24, 1904—Did not see the man subsequently, but Dr. Brock, in reply to a recent note, states that the vision of the left eye in time failed entirely. He also states that soon after the poisoning he was taken with left-sided pneumonia, from which recovery was never complete. About six months ago tubercular trouble developed and ended in death June 8, 1904.

CASE 6.—(From Dr. Nelson L. North, Jr., Brooklyn, N. Y.)

H. E. W., German, aged 48; not robust, light weight and poorly nourished. He was employed, with a companion (to whose history this one bears a close resemblance), as a varnisher of closed beer vats. These vats were badly (if at all) provided with ventilation, and wood alcohol was employed to dissolve the shellac used in the varnish. While engaged in this work he experienced the usual constitutional symptoms of methyl alcohol intoxication, and he began to have foggy vision. When seen in hospital by Dr. North, central acuity had fallen to 20/70 in each eye. Optic papillæ pale. Fortunately, in this case prompt treatment was followed by improvement to almost normal in either eye.

CASE 7.—(From Dr. Nelson L. North, Jr., Brooklyn, N. Y.)

A. H. S., German, aged 35, strong and healthy, weighed 190 pounds. He was employed as a beer vat shellacer. During the winter of 1900-1901 he was engaged in his employment of var-

nishing the interior of ill-ventilated vats with shellac dissolved in wood alcohol. He began to suffer from loss of eyesight, and when seen by Dr. North his vision was 10/200 and there was every indication of optic atrophy, the discs being very white. Abstinence from work and long-continued treatment brought about some amelioration of vision, but improvement of central sight did not extend beyond 20/50.

CASE 8.—(From Dr. W. T. Salmon, Oklahoma City, Okla.)

A. J., infant, 6 months old, December, 1903. Parents noticed something wrong with the eyes and thought she could not see. Pupils contracted. After dilatation optic discs were found to be pale, more so on the temporal sides, and the arteries narrow. Parents said they had been burning a wood alcohol lamp by the crib in which the infant slept. Discontinued lamp, and child improved slowly. Total recovery.

CASE 9.—(From Dr. Norton L. Wilson, Elizabeth, N. J.)

O. E. H., aged 42, workman in the cabinet department of a large factory where Columbian spirits were used in mixing shellac and other polishing mixtures. His vision was reduced to 10/200. His discs were pale and the vessels were small. He was also a whisky drinker, but said he never drank wood alcohol to his knowledge. He probably absorbed it through his hands, as he frequently bathed his hands in Columbian spirits to "cut" the shellac.

It has been claimed by some observers that serious intoxication from inhalation or from "alcohol rubs" is not only highly improbable, but that its occurrence has not as yet been experimentally proven. They assert that sufferers from methyl alcohol blindness who have been working with the poison in closely confined chambers have drunk some of the methylated liquor and have suppressed the fact. Moreover, the amount actually absorbed must have been too small to produce serious effects. It is further claimed that amblyopia among workers in hat factories, where the air is highly charged with the fumes of methylated spirits used in dissolving the resins required for "stiffening" the straw, rarely or never occurs.

On the other hand, many of the alleged cases are so well authenticated; a few of them have occurred in children; it is well known that in those people who are not immune to the poison a very small quantity of methyl alcohol is sufficient to produce blindness, and, finally, the absorption of rebreathed air with wood spirit fumes certainly adds to the toxicity of the latter; in hat factories, also, the fumes are constantly diluted by fresh air. If this be true of wood alcohol inhalation, it is probably also true, albeit to a less degree, of the poison absorbed by the skin. On the whole, we must conclude that it is safer to avoid absorption of the poison in any of its forms.

(D) CASES (HITHERTO UNPUBLISHED) OF DEATH FROM METHYL ALCOHOL POISONING, WITHOUT HISTORY OF PREVIOUS BLINDNESS.

CASE 1.—(From Dr. Emil Bories, Seattle, Wash. Reported by Dr. Hamilton Stillson, Seattle, Wash.)

J. F., Irish, tramp by occupation, was, Feb. 8, 1902, picked up in an alley in a state of collapse after drinking a large quantity of "union spirits" (wood alcohol). When found he had a bottle in his pocket which originally contained about four ounces, from which at least one-half had been taken. He was taken to the city jail. No method of treatment sufficed to revive him, and he died about 45 minutes after reaching the jail. Pupils widely dilated, bloody mucus running from mouth, involuntary defecations from bowels. Patient was a well-built and apparently robust man.

CASE 2.—(From Dr. Randolph Brunson, Chicago.)

B. M., a negro woman, aged about 40, was in good health and apparently had no organic lesions of any kind. She was in the habit occasionally of getting on a "spre" of two or three days' duration, drinking whisky. After having been on one of these debauches two days, she was found on her bed uncon-

4 As taking a drink from the supply of alcohol kept for dissolving the gums used in making varnishes is a very common habit among varnishers, it is probable that this patient drank wood alcohol, thinking it was ethyl spirits, or not knowing that the dissolvent was poisonous.—C. A. W.

scious, and died about an hour afterward. A pint bottle labeled Columbian spirits was found on the table, and more than one-half of the contents had evidently been drunk. It is a not uncommon custom for negroes and "poor" whites to mix equal quantities of whisky and alcohol and drink it, as the alcohol is cheaper, and the results the same as if whisky alone is used. The subsequent investigation disclosed the fact that this woman had purchased the bottle of alcohol at a drug store, the druggist supposing that she wanted to use it as a burning fluid. There seemed every evidence that she had been drinking the Columbian spirits. No ophthalmic examination was made, as she was dying when found.

CASE 3.—(From Dr. George A. Fagan, North Adams, Mass.)

Dr. Fagan saw Mrs. X., aged 29, at 10 a. m., Feb. 15, 1904. The patient was the mother of five children. Nationality, French-Canadian. He found her in bed, unconscious; eyes partly opened, dull and lusterless. The pupils were somewhat contracted and the reflexes abolished. The face was drawn; mouth opened a little. The muscles of the trunk seemed rigid rather than lifeless. The pulse was not felt at the wrist; heart rapid and feeble; respiration shallow and accompanied by a moan. Body was moist and cold. The temperature was not taken. The woman was a chronic drunkard and had been drinking during the week. Sunday at breakfast she seemed to be pretty well, but suddenly complained of dizziness and weakness, was put to bed and became unconscious. A bottle of Columbian spirits for use in a lamp was found empty, as was a bottle of Jamaica ginger. She was known to indulge in the latter.

Odor of breath aromatic and smelled of alcohol. Dr. Fagan gave intravenous injections of adrenalin and strychnin, also salines by rectum. Body warmed and pulse returned to wrist, but in an hour she died in convulsions.

CASES 4, 5, 6.—(From Dr. Homer Collins, Duluth, Minn.)

Six or eight Indians on one of the Minnesota reservations procured a supply of essence of peppermint and drank freely of it. All suffered severely from gastrointestinal symptoms, and three died from the effects of the poison; one of them blind. Two escaped without, so far as is known, any serious damage, while the sixth (one of the survivors) became totally and permanently blind. The cases of blindness are elsewhere described in this report.

CASE 7.—(From Dr. W. G. Craig, Hartford, Conn.)

J. P., Polish, aged 45, drank, April 30, 1902, a mixture of sugar, water and Columbian spirits as a beverage. This was followed first by nausea and vomiting and later by repeated convulsions, coma and death in 24 hours.

CASES 8, 9, 10, 11.—(From Dr. Joseph Springer, Coroner's Physician, Cook County, Ill.)

About April 10, 1904, five negroes, laborers, between 25 and 40 years of age, bought a large amount, probably a gallon, of wood spirits and drank an unknown quantity of it. Four of them, Thomas Smith, James E. McCarthy, Edward Williams and Silas Robinson died from the effects of the poison. Two, the first mentioned, were found dead, while the others were discovered in their boarding house unconscious. On removal to the hospital (Samaritan and Cook County), one of the three recovered. Dr. Springer found, in each of the fatal cases, the stomach and intestines very much congested and soft. The blood was dark and very fluid. Liver congested and friable. Spleen engorged with dark blood; very friable; tore on removing it. Patches of extravasation in the lungs; hemorrhages into the kidney structure, which showed a passive congestion. The odor and other indications supplied by the stomach contents clearly pointed to poisoning from wood alcohol.

CASE 12.—(From Dr. G. G. Davis, Philadelphia, Pa.)

"The only case of poisoning by wood alcohol coming under my notice occurred late last June or early in July, 1903, at Lily Bay, Me. A lumberman (from New Brunswick, Canada) died from drinking wood alcohol used in painting. He was wildly delirious and died in a few hours."

CASE 13.—(From Dr. J. F. Dickson, Portland, Ore.)

Two men, teamsters, strong, healthy and under 30, who had been working very hard all night, arrived at a friend's cabin in the early morning, much fatigued. The friend told them he would give them something that "would make them feel better." He prepared a drink containing wood alcohol, sweetened with syrup. One man took several drinks, and shortly afterward fell to the floor, unconscious. They picked him up and put him to bed, supposing he was simply drunk. He was found dead that same evening, but the exact hour of his death is not known.

CASE 14.—(From Dr. J. A. Dingman, Spring Valley, N. Y.)

In June, 1903, the doctor was called to see A. McK., aged 47, domestic servant, addicted to chronic alcoholism, who had drunk about 3 p. m. an unknown quantity of fluid from a bottle labeled "alcohol." She was unconscious on his arrival and died in deep coma the next day, about 20 hours after taking the poison. The bottle contained wood alcohol.

CASES 15, 16, 17.—(From Dr. John A. Donovan, Butte, Mont.)

Over two years ago a man in this locality was tried, convicted and sent to the penitentiary for selling intoxicating liquor to the Indians. It was proved that the alcohol in the liquor was methyl alcohol. Three Indians died from the poisonous effects of the drug.

CASES 18, 19, 20, 21, 22, 23, 24.—(From Dr. W. E. Driver, Norfolk, Va.)

R. N., male, white, aged 29, patient of Dr. Hargroves of Deans, Va. With two friends, patient visited Portsmouth, Va., on Sunday, Sept. 27, 1903. Not being able to procure intoxicating drink, they all imbibed freely of essence of lemon. He was made drunk and otherwise ill. Sight not affected. He did not recover from the effects of the intoxication and gastritis, and died on the sixth day. The two associates of this man died after a week's illness, never having recovered from the debauch. During Dr. Driver's investigations of three cases of methyl alcohol amaurosis (reported under class B), he learned that four other people—boon companions of the patients who survived and subsequently became blind—had died with the usual symptoms of acute wood alcohol poisoning. As these cases occurred in a part of the country not covered by any report included in this investigation, we may safely publish them as four additional examples of death from drinking methylated preparations, in spite of the lack of more definite information.

CASE 25.—(From Dr. Calvin R. Elwood, Menominee, Mich.)

C. H., cook in lumber camp, while in woods went on a spree with lemon extract in November, 1903. On Tuesday he received 12 bottles of the extract, and by Friday had drunk seven of them. He spat some blood on Thursday, and his fellow workman warned him that the lemon extract was killing him. He replied that it was, but he couldn't leave it alone. He continued the debauch the following day and evening, when he suddenly fell over dead, taking his last drink only a few minutes before death. This man was a habitually heavy drinker, and had been on a rather protracted spree just before he received the consignment of lemon extract.

CASE 26.—(From Dr. Charles Enfield, Jefferson, Iowa.)

In 1901 an adult, being unaware of the poisonous character of wood spirits, and only knowing it to be a cheap form of alcohol, purchased a pint in Jefferson for use as a beverage. He drank it all while on his way to a neighboring town and died in a few hours. These facts were fully established at the coroner's inquest.

CASE 27.—(From Dr. H. P. Engle, Newton, Iowa.)

Mrs. N., Mingo, Iowa, aged 20, drank, as evidenced by sworn testimony, a "few ounces" of diluted Columbian spirits. This was followed by gastrointestinal irritation and sudden death in 20 hours.

CASE 28.—(From Dr. H. P. Engle, Newton, Iowa, and the Des Moines, Iowa, Register-Leader of May 31, 1904.)

Mt. Ayr, May 30, 1904 (Special).—"Abe Baker is dead, Glenn McLeish is so ill as to require the attendance of two physicians, and others of their party are suffering as a result of drinking wood alcohol at the close of a protracted spree. The scene of the tragic occurrence is in Worth County, Mo., near the town of Allendale, and about three miles south of the line of Middle Fork Township, this county. The men had been on a spree for several days, and late Friday evening Baker and McLeish were found not far from the latter's home, about 13 miles southwest of Mt. Ayr. They begged bed clothing from the tenant on Joseph Dehart's place and slept in an unoccupied house, declining an invitation to spend the night in the dwelling. The next morning Baker was discovered dead and McLeish in a critical condition, while reports came that others of the crowd were suffering. The coroner's jury decided that Baker's death was due to drinking wood alcohol. Baker was single, about 30 years of age, and a good deal of a wanderer, having lately returned from the west. McLeish is about 17 years of age and the only son of a widowed mother."

CASE 29.—(From Dr. W. H. Ford, Sulphur, Ind. Ter.)

About Oct. 1, 1903, four men, from 30 to 40 years of age, went on a spree with bay rum made from methyl alcohol. Two were barbers and two Territory sportsmen. One of the barbers, W. A., aged 39, was found dead after drinking probably a

quart. Autopsy showed the mucous membrane of the stomach extremely congested; it "resembled a piece of black rubber." The odor of wood alcohol was very strong.

CASES 30, 31.—(From Dr. Allen A. Greene, Anniston, Ala.)

Two employes, McK. and C., of the Interstate Roofing Company in Anniston were sent, June, 1898, to Montgomery, Ala., to assist in building a roof over the passenger station there. Wishing to get a drink, and finding the saloons closed, they sent, in the afternoon, to a drug store and purchased eight ounces of alcohol, not specifying the kind they desired. The druggist sent wood alcohol. They invited an employe of the L. & N. Railroad Company to join them and proceeded to drink the poisonous fluid. When toxic symptoms set in a physician was summoned, who used a stomach pump. In spite of his efforts, two of the men died within a few hours after drinking the mixture. The railroad employe, who survived, stated that he had taken only a small quantity of the wood spirits and on a full stomach.

CASES 32, 33.—(From Dr. Allen Greenwood, Boston, Mass.)

Several years ago three painters, living in the adjoining town of Newton, were in the habit of drinking alcohol mixed with water, taking the alcohol (used as a solvent) from the barrel in which it was kept. Wood alcohol was substituted in this barrel for ethyl alcohol, with the result that two were poisoned and died.

CASE 34.—(From Dr. G. E. Hartshorn, South McAlister, I. T.)

G. G., white, barber, of Haileysville, I. T., drank a pint of bay rum, March 23, 1904. Death occurred in 12 hours.

CASE 35.—(From Dr. G. E. Hartshorn, South McAlister, I. T.)

Ed. W., aged 16, on Dec. 23, 1902, drank nearly a pint of wood spirits, thinking it was grain alcohol. Died in six hours.

CASES 36, 37, 38.—(From Dr. Reid Hunt and Dr. H. A. Stansfield of the Public Health and Marine-Hospital Service, Washington, D. C.)

In California, about 1894, when Dr. Stansfield was connected with a drug store, he sold four Italian woodchoppers a quantity of wood alcohol. They went on a "speer" with it, and three of them died. None of these cases have been included in other reports furnished for this investigation.

CASES 39 and 40.—(From Dr. Reid Hunt, Public Health Service, Washington, D. C., being two autopsy reports of Dr. L. W. Glazebrook, Coroner for the District of Columbia, 2022 P St., N. W., Washington, D. C.)

Autopsy Cases, vol. xii, p. 4, No. 566. Dated Dec. 21, 1903. Arthur P. Baer, died, Washington Barracks; color, white; occupation, soldier. Previous history: "Man has been drinking, so the authorities say, for some time, and used every means to get intoxicants." Odor of wood alcohol about mouth. Stomach markedly distended, and acutely irritated; marked odor of wood alcohol. Remarks: Man had had access to the place in which wood alcohol was kept.

Autopsy Cases, No. 150, Jan. 24, 1899. Name, Joseph Washburn, negro, cook, aged 48. Drank a gill of wood alcohol early one morning. He groaned and had intense cramps and vomiting. The alcohol was for use in a coffee urn burner. He was sent to the Emergency Hospital and died at 9:45 a. m. Stomach had marked odor of wood alcohol. At the base of the brain two ounces of water infusion. Marked odor of wood alcohol.

CASE 41.—(From Dr. Reid Hunt, Public Health Service, Washington, D. C., and the Baltimore News, Feb. 27, 1904.)

E. E., a woodsman, said to be from St. Louis, died at Horton, W. Va., yesterday, from drinking "hot drops" as a substitute for whisky. Analyses of these same hot drops, sold in Virginia two or three years ago, showed the presence of about 95 per cent. wood alcohol.

CASE 42.—(From Dr. J. H. Jamar, Elkton, Md.)

While acting as surgeon to the jail in Elkton, Dr. Jamar had under his care three cases of wood alcohol poisoning in habitual drunkards. The first case was that of a woman, who, with a male companion, tramping about the country, begged money and bought six ounces of methylated spirits. They went on their way and when three miles from town proceeded to drink the mixture. The woman was soon unconscious and was removed to a neighboring farmhouse. She shortly afterward died comatose, in spite of Dr. Jamar's efforts to revive her.

CASES 43, 44, 45.—(From Dr. G. L. Knowles, Maquon, Ill.)

About December, 1902, the newspapers reported that in a suit Mrs. D. of Maquon obtained damages for the death of her

husband, poisoned by lemon extract, and that two others also died from the same debauch. Dr. Knowles has kindly furnished the following comments on these three cases: "No. 1 was that of a farmer, aged about 35. He had been an intemperate man all his life, or from early manhood. I have no knowledge of his last symptoms. An eight ounce bottle, one-fourth full, labeled lemon extract, was found in his possession. So far as I know, no analysis was made of any of the cases. No. 2 was that of a blacksmith, aged 65, an inebriate from boyhood. He was found dead in his bed, and lying beside him was a bottle similar to that used by No. 1, about a quarter full of lemon extract. No. 3, a farmer, was a victim of the same poisoning and was very ill for two or three days prior to death. The two prominent features of these cases is that they were all backsliding graduates of the "Keeley Cure," and that it required about six ounces of the decoction to kill each individual.

CASE 46.—(From Dr. R. H. Main, Barry, Ill.)

Dr. Main reports a recent death (June 30, 1904) of a man, aged 40, from drinking Jamaica ginger. The victim was a pedler, apparently in good health, who sold this essence about the country. It was manufactured by a patent medicine "concern" in Peoria, Ill. Dr. Main's analysis of the liquid showed it to be made from methyl alcohol. The patient, unaware of its poisonous qualities, drank the compound for its intoxicating effects.

CASE 47.—(From Dr. J. G. McKinney, Barry, Ill.)

April 18, 1904, G. K., a painter, aged 25, was greatly addicted to drink. He was employed to do a job of painting, and drank the methyl alcohol that was intended for filling the knots in the wood before painting. Death followed in a few hours as a result of the drink.

CASE 48.—(From Dr. H. S. Miles, Bridgeport, Conn., and the Bridgeport Telegram-Union, July 23, 1904.)

Sheridan Knowles of this city, aged 45, a private in the United States Coast Artillery, stationed at Fort Terry, Plum Island, N. Y., died yesterday afternoon after drinking a quantity of wood alcohol. Knowles had been drinking heavily of late and made visits to New London, Conn., at every opportunity during the week. Each time he imbibed freely, and finally returned to the island for the first time Thursday. He was finishing his spree, and could not stop entirely from drinking liquor, so that the temptation to drink the wood alcohol was more than he could resist, although he knew well the deadly effects of the poison. He was the barber of the fort, and so had no difficulty in getting what he wished from the barber shop. He drank the wood alcohol, and inside of an hour was dead. This is the seventh case of wood alcohol poisoning at Fort Terry within a few months.

CASES 49, 50.—(From Dr. J. E. Minney, Topeka, Kan.)

In the year 1889 nine Poles, living in this vicinity, together indulged in a spree, toward the end of which they bought and consumed nearly two gallons of wood alcohol. Two promptly died from the acute intoxication; the other seven recovered. As related elsewhere, one of the latter became blind.

CASE 51.—(Newspaper report, Feb. 1, 1903.)

P. O., engineer in the Straube Piano Company, Downer's Grove, Ill., was found dead in his room in East Grove. Near his body was a bottle of wood alcohol, from which he had evidently been drinking. It is not known, however, whether he drank the fluid by mistake or intent.

CASES 52, 53, 54.—(Newspaper report, Philadelphia, October, 1903.)

Frank Helms, aged 43; Thomas Helms, 24, and William Conn died to-day from drinking wood alcohol. The first two, who were brothers, died while on their way to the hospital; the third, after reaching it.

CASE 55.—(Newspaper report, April, 1903.)

The death is announced, in Rockland, Mass., of Mrs. Frank Progin from drinking wood alcohol.

CASE 56.—(From Dr. J. A. Patton, Stillwell, Ind. Ter.)

L. G., aged 63, carpenter. Had drunk lemon extract for three or four days in company of friends, whose cases are also described in this report. He lived alone, and some friends, hearing of the death of one and the sickness of his other companion, went to his room about 10 p. m., Feb. 28, 1904. He answered and seemed all right. At daylight, the morning of the 29th, other parties, getting no answer to their questions, broke into the house and found him dead. Dr. Patton saw him soon after death; his limbs were flexed, head drawn back, and he presented every appearance of having died in a convulsion.

The lemon extract was analyzed and shown to contain wood alcohol.

CASE 57.—(From Dr. George H. Powers, San Francisco, Cal.)

5. Charlotte, N. C., Medical Journal, 1903, p. 164. This and the next case, although previously published, are recorded here as they are not referred to in other recent articles on this subject. —C. A. W.

A. C. G., aged 26, took during the night a single dose of wood alcohol with suicidal intent. He was found dead in bed next morning, the interval of the ingestion of the poison and the fatal issue being less than eight hours. Dr. Powers was present at the autopsy, which revealed great congestion of the vessels of the stomach and intestines, and a very strong and characteristic odor of wood alcohol.

CASE 58.—(From Dr. E. H. Robb, Newton, Iowa. Reported by Dr. H. P. Engle.)

G. C., a barber, aged 60, after a debauch, drank three or four ounces of bay rum made with wood alcohol. Shortly afterward gastrointestinal irritation, dilated pupils, irregular heart action and death in 36 hours.

CASE 59.—(From Dr. O. J. Short and the Coroner of Garland County., and Dr. A. D. Shaw, Hot Springs, Ark.)

W. T. was one of three young men who went on a spree and drank an unknown quantity of wood alcohol. All three suffered from severe abdominal distress and lost consciousness. One of them survived and testified that on awakening from his stupor he found himself alone. Search was made, and the bodies of his companions (see next report) were discovered.

CASE 60.—(From Dr. O. J. Short and Dr. A. D. Shaw, Hot Springs, Ark.)

J. A., the companion of the man mentioned in the foregoing report, was found dead after a wood alcohol debauch. A third party to the spree vomited almost immediately after drinking the alcohol, and, although he had cramps in his stomach and became unconscious for a time, finally recovered, apparently without permanent damage, and was able to give an account of what had happened previous to the death of his fellow sufferers. A postmortem examination revealed all the appearances of wood alcohol poisoning.

CASE 61.—(From Dr. C. Storz, Toledo, Ohio.)

W., man, aged 42, painter and paperhanger by occupation, died April 16, 1904, at the Marine Hotel, East Toledo. He drank a few ounces of wood alcohol and succumbed within two and one-half hours. This alcohol he had used as a liniment on a limb which he had broken about five months before. He woke his roommates and complained of terrible pains in his stomach and abdomen and said that he had drank some of the alcohol. He asked them to open the windows, as he was in want of fresh air, and suffered a great deal. When the physician arrived he was unconscious, and died within a few minutes.

CASE 62.—(From Dr. W. T. Salmon, Oklahoma City, Okla.)

R., aged 36, October, 1900, Indian Territory. A protracted spree on bitters. He died on the third day, with symptoms of wood alcohol poisoning.

CASE 63.—(From Dr. C. Storz, Toledo, Ohio.)

I. B., a well-educated Hebrew, aged about 40, died at the infirmary hospital of wood alcohol poisoning, April 9, 1902. The man was addicted to the habitual use of alcohol and, consequently, was very much demoralized. In tramping from one town to another he reached Toledo a few days previous to his death. Being too poor to obtain liquor in the usual form, he bought four ounces of wood alcohol in a drug store and drank most of it. He soon became very ill, complained of pains in his abdomen, and in a couple of hours became unconscious. He was sent to the infirmary hospital and died soon after his arrival, possibly within three or four hours, without regaining consciousness.

CASES 64 and 65.—(From Dr. J. W. Seales, Pine Bluff, Ark.)

J., male, aged 45, and S., male, aged 42, both of Ogama, Ark., drank, each, three bottles of Jamaica ginger and two of bay rum in December, 1900. Both died during the following night, with all the symptoms of wood alcohol poisoning.

CASES 66, 67, 68.—(Courtesy of the Surgeon General of the Army and of the surgeon in charge of the post at Fort Terry, N. Y.)

Private J. W. R., aged 36, Company C, A. Had been habitual drunkard. Returned to post after protracted spree, Feb. 26, 1904. About noon, February 29, went to hospital complaining of abdominal pain and showing evidences of spree; was not seen by surgeon at the time. At 8 p. m., same day, he returned to hospital; condition of profound collapse; intense pain in abdomen and lumbar region; temperature, 96; pulse thready, 50; respiration, 12, sighing; cyanosed; extremities, cold; surface of body, clammy; said he had "drank a little Florida water" and wanted something for the pain in abdomen. Assistant Surgeon R. was called immediately, but when he reached the patient he was unconscious, with above symptoms intensified. Temperature, 92; pulse, 42, scarcely perceptible; breath cold, but reeking of alcoholic fumes, which even at the time smelled peculiarly of the acid property of the methylated alco-

hol, or the pyrolicuous acid in it. Heroic stimulation was of no avail, and the man died, 8:49 p. m.

"Investigation showed that this man and four others had been drinking the day previous from a large bottle of Columbian spirits, not knowing that it was wood alcohol, or not caring what it was, just so it was "splits" (alcohol). This Columbian spirits had been used by the company barber to mix his toilet articles, and he told us he had bought it as, and for, such. The odor and burning properties confirmed his assertion."

Corporal T. O'B., 23 years, Company C, A., was found in quarters, at time of investigation, drunk (this was about 9 p. m., February 29). When shown the bottle and told of death of Private R., he became nauseated, through fear it is believed, but declared he had not taken any of the contents of the bottle, nor had he ever seen bottle before. Corporal O'B. was sent to hospital; temperature at 9:30 was 95.5; pulse 82, soft; mind clear, conversation rational. Temperature taken every half-hour during the night ranged from 95.5 to 96 at 7 a. m., when the collapse came, the temperature dropping to 92. Pulse during night from 80 to 94, soft. Became unconscious at 7:16, a moment after he had "cusseed out" the attendant for his trouble. Same profound collapse as in the previous case. In addition to the treatment used previously, a varying strength of galvanic electricity was used, the heart only responding for a minute or so to each stimulation. About five minutes before death clonic spasms beginning with the orbicularis palpebrarum and extending thence downward over the entire body and limbs, to the number of about ten, ensued at about ten seconds' interval. Death.

Private M. O'C., 36 years, Company C, A., was found in his bunk at the same time others were found, but was too drunk to take to hospital, and his condition was only what one would expect in such a case, the bottle of whisky being found in his locker. Denied hoisterously that he had taken any wood alcohol. Next morning he was apparently no worse than was expected; temperature, 99; pulse, 86, fair. Protested strenuously against being put in hospital, again declaring that he had not touched the wood alcohol. He was watched all that day and temperature taken every half-hour, ranging from 99 at time of admission to 97 at 2 a. m., March 2, when it dropped to 92 at 2:15 (this collapse coming just after he had finished a tirade against all the medical corps for not believing what he told us). His symptoms from that on were identical in every way with those of previous case, even to the spasmodic contractions. Death at 3:05 a. m.

CASE 69.—(Reported to the Surgeon General of the Army by the acting assistant surgeon at Fort Banks, Mass.)

"I have the honor to make the following report of an autopsy made on the body of Private A., who died at this hospital on June 21, 1900 (Case No. 709, sick and wounded report for June). The man had been drinking heavily of late, and the day before his death had been asking one of the mechanics at the post for some wood alcohol, which request was refused. This information relative to his asking for wood alcohol was not obtained until after I had made the autopsy. The man was moribund when admitted to the hospital at 4:35 a. m., June 21, 1900, and died the same morning at 5 o'clock. The autopsy was made six hours after death. The body was that of a well nourished man. Rigor mortis and lividity of the dependent parts were noted. No external marks were visible. Brain slightly edematous and presented strong odor of wood alcohol; lungs normal except for strong odor of wood alcohol; heart normal in size, slight thickening of endocardium, blood in right and left auricles liquid and black, and had a strong odor of wood alcohol; liver normal except for a strong odor of wood alcohol; spleen small, dark in color and of good consistency; stomach contained about six ounces of dark greenish fluid, which had strong odor of wood alcohol; lining membrane of stomach covered with mucus, with areas of reddened patches and points due to submucosal hemorrhages; kidneys normal in size, capsules not adherent, cortex appeared perfectly normal, pelvis and calices filled with pus; intestines normal with the exception of the sigmoid flexure which had two distinct strictures; bladder normal and contained about two ounces of urine, highly perfumed with wood alcohol. Cause of death, acute poisoning from methyl alcohol; source unknown."

CASES 70 and 71.—(Reported to the Surgeon General of the Army by the surgeon at Fort Terry, N. Y.)

Record Case No. 809. Private B. was admitted to hospital at about 9:15 p. m., Oct. 30, 1902, with acute alcoholism. He was put in bed, heat applied and aromatic spirits of ammonia given, and later 1 60 of a grain of strychnin hypodermically.

At about 9:15 he had a convulsion followed by collapse. Stimulation with strychnin, whisky and ether had little effect, and he died from cardiac paralysis at 10:07 p. m.

At this time Private C. was found on the floor of his quarters (tailor shop) in a state of profound collapse, and was brought to the hospital. Heat was applied and stimulants given, but without avail, and he died without regaining consciousness shortly after admission.

On investigation it was found that these men had been drinking heavily for several days, and being unable to procure more liquor, they concocted a punch from 13 bottles of bay rum, one of witch hazel, one of vanilla extract and one of hair oil, with sugar, lemons and water, of which mixture they drank deeply.

CASE 72.—(Report to the Surgeon General, U. S. Army, through the chief surgeon, Department of Dakota, by the surgeon at Fort Snelling, Minn.)

"I have the honor to submit the following report of two cases of methylic alcohol poisoning caused by drinking for purpose of intoxication an inferior quality of bay rum made from bay oil dissolved in wood spirit. A. was admitted to the hospital March 16, 1904, complaining of severe pains in the stomach and persistent vomiting with headache. His mental condition was not clear. His temperature was 98.4. He denied having been drinking. His urine contained albumin in large quantities. The patient became gradually unconscious, his respiration became labored and he died about 6 p. m. on the day of admission from paralysis of respiration. The heart continued to beat for some time after the cessation of respiration. Postmortem examination showed the following conditions: Brain much congested, blood dark and fluid, mucous membrane of stomach showing evidences of irritation with numerous small ecchymoses; no odor of bay rum or wood alcohol; kidneys markedly congested; liver and spleen somewhat congested; heart filled with dark fluid blood. Organs otherwise normal.

The other man, Private B., did not report at the hospital, but in investigating the cause of Corporal T. O'B.'s illness it was found that he had been drinking bay rum in company with Private B., who was the company barber, and that B. had been lying on his bunk in the barracks sick all day, but had not reported at the hospital. He was sent for at once and brought to the hospital on a litter. He complained of pain in stomach and persistent vomiting. His temperature was 97.6. His urine contained albumin and epithelial tube casts. The albumin in the urine continued present in lessening amounts until March 23, when it disappeared, and he made a satisfactory recovery and was returned to duty March 27.

CASES 73 to 81 inclusive.—(From Dr. James P. Widmeyer, Rolla, North Dakota.)

On the evening of Wednesday, Aug. 31, 1904, an unknown number of Indians of the Turtle Mountain Reservation went on a spree, and being unable to obtain the ordinary alcoholic beverages, secured a large number of bottles of "Florida water" and, it is reported in the papers, lemon extract, and drank freely of them. Nine Indians died, most of them Friday morning, September 2, and a survivor is known to have become blind. Empty "Florida water" bottles were found in the Indian encampment after the debauch. All who partook of the spirits complained of burning in the stomach and bowels, pain in the head, slow pulse (as low as 43); finger nails and lips were blue and they finally died comatose. Investigation showed the fluids to be largely methyl alcohol.

CASE 82.—(From Dr. G. H. Woodward, New York City.)

"A man of my acquaintance (from Longdale, N. Y.), died from drinking essence of lemon and witch hazel. He got on pretty well with the lemon, but died very soon after taking the witch hazel."

(To be continued.)

A SIMPLE METHOD OF CYSTOSCOPY.

M. C. MILLET, M.D.
ROCHESTER, MINN.

Specialists, and a gradually increasing number of the profession, regard cystoscopy as a diagnostic measure of merit. A multiplicity of instruments and variety of technic have contributed not a little to a feeling of distrust and reluctance to accept it by the profession at large.

Of the many kinds of cystoscopes most of them have been devised or modified by the pioneers in genito-urinary diagnosis. In the hands of its originator probably each instrument is a success, but in the hands of a stranger many are more or less of a failure.

Water dilatation of the bladder seems the rational method. The difficulty or impossibility of examining an occasional bladder, from blood or pus clouding the inflating fluid, led to the devising of instruments to be used with air dilatation. Air in the bladder is a foreign body and by the conscious patient is treated as such. Frequent sponging to remove urine or blood is provocative of further hemorrhage and increases the difficulties. Nevertheless, it may be possible to make a fairly satisfactory inspection of a bleeding bladder by means of an air inflation where many of the water instruments would fail.

A clear fluid readily transmits light, therefore a column of clear water filling the shaft of a cystoscope will do the same. The avenue of ingress and egress for air will just as readily admit water. The air-dilating cystoscope is a large open cylinder made to admit of ready sponging. This very fact makes irrigation through it very thorough and rapid. By attaching a fountain syringe filled with sterile saline solution to an instrument of this character one secures the advantages of water inflation, together with the possibility of quickly evacuating the fluid, in case it becomes clouded, and replacing it with clear. The only interruption to the inspection is the few seconds required to empty the bladder. As soon as the clear fluid is again allowed to flow in, the examination can be resumed, the inflowing fluid transmitting the light as readily as if it were stationary. The stream is entirely under control; by means of the stopcock with which all air instruments are supplied, it is stopped or started; by raising or lowering the irrigator, its force is increased or decreased. Under the guidance of the eye the stream can be directed toward the suspected areas; blood clots and clinging mucus or pus may be dislodged and the margins of ulcers thus clearly exposed. Tumors which appear as flat elevations on the bladder walls may be demonstrated to be villous by directing the stream against them or around their edges. Cloudy urine discharging from a ureter may obscure the field in that part of the bladder, but a single jet of clear fluid will clear that neighborhood and the ureteral opening may be located before the next discharge of urine occurs. The area surrounding the ureteral openings can be mechanically cleansed by directing the force of the stream to that neighborhood.

The above specific instances may serve to illustrate the applicability of this method to almost any bladder condition. Practically, it means transforming an air inflating cystoscope into an irrigating instrument; an instrument, too, which admits of rapid and thorough irrigation and permits the guiding of the inflowing stream where one wills, and of greater efficiency than many which have been specially constructed for irrigation. Discomfort from distension or clouding of the fluid is the signal for

Report of Antimalaria Expedition to East Africa.—The *Zeitschrift f. Hygiene*, xlv, No. 3, 1903, publishes Ollwig's report of the application of Koch's method of malaria prophylaxis to the Dar-es-Salaam region in eastern Africa. The conditions were peculiarly unfavorable for its success, owing to the shifting population, the dampness of the surroundings, etc., and consequently the result was not a complete success. It proved possible, however, to materially reduce the morbidity from malaria and prevent its spread.

removing the window and allowing the bladder to empty. Turn on the water, replace the window and resume the examination. This may be repeated many times in an ulcerated, contracted bladder, or in one which is freely bleeding, and makes possible a satisfactory examination of any bladder.

Three years' use of the above technic, with air inflating cystoscopes, justifies its recommendation as a safe, simple and practical method.

BONE CYSTS.

A CONSIDERATION OF THE BENIGN AND ADAMANTINE DENTIGEROUS CYSTS OF THE JAW AND BENIGN CYSTS OF THE LONG PIPE BONES.*

JOSEPH C. BLOODGOOD.
BALTIMORE.

Recent accumulated experience, in the ultimate results after amputation for sarcoma of the long pipe bones, and complete resection for sarcoma of the upper and lower jaw, has demonstrated that local recurrence is unusual, but death from internal metastasis is common in a certain number of cases. When these cases are studied pathologically it is found that the patients who have remained well suffered from special types of sarcoma essentially different from the tumors removed from the patients who ultimately succumbed to internal metastasis. In other words, we were not accomplishing a cure in the latter group of cases even after amputation at the highest joint, because internal metastasis takes place early and is present at the time the patient seeks surgical treatment, and we were subjecting the first group of patients to an unnecessarily extensive operation.

In 1899¹ I discussed the literature and the experience of the surgical clinic at the Johns Hopkins Hospital in regard to the different relative malignancy in sarcoma of bone, and that in certain varieties much less extensive operations would accomplish a cure with as great a certainty as amputation at the highest joint.

Experience has demonstrated that, in some cases, curetting is sufficient; for example, the benign bone cysts of the long pipe bones, dentigerous cysts of the jaw and medullary giant-cell sarcoma. The latter was advocated many years ago by Koenig. In other cases resection, the extent of which is indicated by the local infiltration of the disease. For example, the various forms of epulides of the upper and lower jaw; the periosteal and medullary giant-cell sarcoma; the periosteal fibrosarcoma and osteosarcoma; the myxochondrosarcoma and a special tumor of the jaw—the cystic adamantin epithelioma. Such local resections as against amputations have been advocated by von Mikulicz, Weisinger, Morton, Karewski, Hinds.²

Amputation is indicated in these varieties of sarcoma only when the necessary resection would result in a useless limb. Infiltration of muscle is not a positive indication for amputation. In this group of cases amputation at the highest joint, except due to the position of the tumor, is never indicated.

In April, 1901, in a discussion before the Philadelphia Academy of Surgery,³ I advocated this more con-

servative procedure. Since then the further experience of Dr. Halsted's clinic and my own and the reading of the literature have accumulated additional facts justifying the more conservative operation in this group of sarcoma of bone, of relatively low malignancy.⁴

In December, 1902, I removed with the curette a large medullary giant-cell sarcoma filling and expanding the upper third of the tibia.⁵ This patient has no evidence of recurrence and a limb with unimpaired function.

The experience of the surgical clinic in tumors of the jaw and long pipe bones can be expressed in a few words.

In Group 1 the patients have remained well since operation, the time varying from six months to twelve years. There has been a slight operative mortality, and a few cases in which, on account of the size and position of the tumor, the disease was considered inoperable.

Benign Cysts of Long Pipe Bones.—Three cases; one died after operation (Fig. 2); 2 cases are well.

Benign Dentigerous Cysts.—Ten cases (upper jaw, 4; lower jaw, 4; ethmoid, 2 cases). Inoperable, no cases. Death after operation, 2 cases (Figs. 5 and 6). In these two instances a complete resection was performed. Well, 8 cases. In these 8 cases the operation consisted in partial removal of the bony wall, curetting and packing.

Adamantine Epithelioma.—Twelve cases; inoperable, one case (Fig. 8). Death after operation, 1 case (Fig. 9). Well, 10 cases. In one instance there was a second operation for local recurrence; this patient has remained well eight years since the second operation.

PERIOSTEAL SARCOMA.

Epulis.—Twenty-three cases; upper jaw, 13; lower jaw, 10. One patient died of pneumonia; in this case, an extensive giant-cell tumor of the lower jaw, it was necessary to do tracheotomy and perform a complete resection of the jaw. Well, 22 cases. In all of these cases the operation consisted of removal of the tumor with the alveolar border of the jaw. In only one case was there a local recurrence, and this patient has remained well since the second operation.

Spindle-cell Fibrosarcoma or Myxosarcoma.—Eight cases; antrum, 3, all well; lower jaw, 3, 2 well, 1 died of pneumonia after complete resection; orbit and antrum, 2 cases; 1, a young child, died after an extensive operation; the other, also a child, has remained well since the less extensive operation, two years.

Osteosarcoma.—(I employ the term osteosarcoma only in those periosteal tumors in which new bone formation predominates.) Eight cases. Lower jaw, 4; 2 well, 2 refused operation. Upper jaw, 2, both well. Long pipe bones (humerus and fibula), 2; both well.

Giant-cell Sarcoma.—Those situated on the jaw and called epulis have already been considered. It is a rare tumor of the long pipe bones. We have observed three cases: Ulna, 1 case, resection, well twelve years. Tibia, upper third, 2 cases, both well; in both the tumor was recurrent; in one the tumor was excised without destroying the continuity of the tibia, in the other the limb was amputated at the thigh.

MEDULLARY SARCOMA.

Giant-cell Tumors (Myeloma).—Eight cases, all well; lower jaw, 1; long pipe bones, 7.

Myxochondrosarcoma.—Three cases; one involving the sacrum, inoperable; one involving the upper third of the humerus, well; one of the femur, death two years after operation from tuberculosis of the lungs.

Seventy-eight bone tumors in this group are either benign or of relatively low malignancy. Sixty-nine cases are well, two inoperable; two refused operation; seven died after operation. In six of these cases the

* Read at the Fifty-fifth Annual Session of the American Medical Association. In the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

1. *Progressive Medicine*, December, 1899, p. 234.

2. *Progressive Medicine*, December, 1899, pp. 38-42.

3. *Annals of Surgery*, 1901, vol. xxxiv, p. 94.

4. *Progressive Medicine*, 1902, pp. 151-186.

5. *Johns Hopkins Hospital Bulletin*, May, 1903.

tumor involved the upper or lower jaw. In these six cases, I believe, a less extensive operation could have been performed which would have reduced the dangers of the operation, but not the probabilities of an ultimate cure.

Group 2 includes patients who have not been cured, either because the condition was inoperable when they presented themselves at the clinic, or because of death from internal metastasis after operation.

PERIOSTEAL TUMORS.

Spindle and Round-cell Sarcoma.—Six cases; lower jaw, 2; long bones, 4.

Perithelial Angiosarcoma.—Long bones, 2 cases.

MEDULLARY TUMORS.

Spindle and Round-cell Sarcoma.—Long bones, 4 cases.

Perithelial Angiosarcoma.—Long bones, 2 cases.

In these 14 cases a complete operation was performed. In the 12 cases of the long pipe bones a high amputation; in the 2 jaw cases, an extensive resection. In every case death has taken place, usually within a year after the first symptom of the tumor. In only 1 case was the duration of life longer than two years.

Sarcoma of the Upper Jaw Involving the Antrum.—Clinical diagnosis: Six cases, all inoperable.

Carcinoma of Upper Jaw.—Twenty-one cases; inoperable, 16; 1 death of pneumonia; remainder not cured.

We have, therefore, observed 41 cases of tumors involving bone of a relatively high malignancy, none of which has been cured as compared with 78 of a relatively low malignancy, of which 69 are well.

These facts demonstrate the hopelessness of the more malignant varieties of bone tumors.

Surgeons who take the view advocated in this paper must educate themselves to recognize clinically, or through the Roentgen negative, or at the exploratory incision, the different varieties of sarcoma of bone, and govern the extent of the operative procedure by the relative malignancy and extent of the tumor.

In this paper I shall discuss only the benign bone cysts of the long pipe bones, the dentigerous cysts of the jaw and the cystic adamantinoma epithelioma.

BENIGN BONE CYSTS.

The benign bone cysts of the long pipe bones are rare tumors. Up to the present time we have observed but 3 cases in the surgical clinic.

CASE 1.—Bone cyst of the humerus. White girl, aged 7, tumor one year, pathologic fracture. Operation, curetting and drainage, June, 1904, ten months, well.⁸ I saw this patient in August, 1903. The parents gave the following history:

History.—The apparently healthy child one year ago fractured the upper third of the humerus of the right arm after a slight fall. The fracture was treated by their family physician and united. After the dressing was removed a swelling was observed which has never disappeared. If the swelling had been present before the fracture, it had not attracted the attention of the parents or the physician who treated the fracture. For a year there were absolutely no symptoms except swelling. Three days ago, after a very slight fall, the child refused to use the arm because of pain, and for this reason was brought to the surgical clinic.

Examination.—On examination there was a fairly uniform expansion of the upper third of the humerus, easily seen, greatest toward the surgical neck. On palpation the soft parts were normal, but one could feel the normal shaft of the humerus expanding into a thin shell of bone. The surface of this shell of bone was not smooth like the normal shaft, but irregular. In a few places one could elicit definite parchment crepitation, first

described by Dupuytren, or what I have called "ping-pong ball" crepitation. The arm was very tender.

Clinically, a diagnosis of bone cyst was suggested, because so far in my experience every sarcoma of the more malignant type in children at this age had caused death by internal metastasis within a year.

The only medullary tumors of the long pipe bones which, in their growth, expand the bone and produce a definite shell, are the bone cysts, the myxochondrosarcoma and the giant-cell sarcoma. Of the latter two we had no observations in the clinic, in patients at this age, and so far I have been able to find none in the literature. The Roentgen negative is illustrated in Figure 1.

Operation.—At the exploratory operation the tissues were normal until the periosteum was separated. The bone beneath was irregular and varied in thickness from 1 to 4 mm. On removing a piece of the shell of bone a cavity was exposed filled with blood; there was no connective tissue lining, and no evidence of cartilage, but as only sufficient bone was removed to allow curetting of the cavity, one can not exclude the possibility that cartilage was present in some part of the wall. After curetting, the cavity was partially packed with gauze, the remainder allowed to fill with blood-clot. Eight weeks after operation an x-ray picture demonstrated that the cavity was almost completely filled with new bone.

The origin of these bone cysts has been demonstrated by Virchow, Zernicke, Schlang, Koenig and others to be due to liquefaction of misplaced islands of epiphyseal cartilage, and in the majority of cases cartilage has been found in some parts of the wall.⁷ In the two other cases observed in Dr. Halsted's clinic cartilage was demonstrated in the wall of the cyst.

CASE 2.—Colored woman, aged 37. Expansion of the lower end of the right femur, four years.

History.—The swelling shown in Figure 2 reached its greatest height about one year after the onset, and during the last three years there has been little or no increase in size. This patient refused amputation. Five years and eight months later she returned to the clinic.

Examination.—The tumor had increased in size, but had not changed its characteristics. The shell of bone was rough, similar to Case 1, but thicker, and one could not elicit parchment crepitation. The x-ray showed a shadow somewhat similar to Case 1. The diagnosis lay between a bone cyst and a myxochondroma. The long duration and the preservation of the shell of bone excluded a malignant bone tumor.

Operation.—The findings at the operation by Dr. Follis, the resident surgeon, were similar to the case just discussed, except that cartilage was present within the shell of bone in many parts of the wall.

CASE 3.—The age, clinical history, appearance and x-ray shadow were almost identical in this patient with Case 1, except that the first pathologic fracture had been five years instead of one year before the patient came under observation. The expansion of the upper two-thirds of the femur in this case was produced in the upper portion by cartilage, in the central portion by a cyst filled with blood, and in the lower portion by a fibromyxomatous connective tissue which extended down the medullary cavity of the femur some distance below the point of its expansion (Fig. 3).

Dr. Halsted exhibited this patient and the specimen at a recent meeting of the Johns Hopkins Hospital Medical Society. Later a detailed report, with the interesting histologic findings, will appear. The extensive formation of fibromyxomatous connective tissue histologically like otitis fibrosa, described by von Recklinghausen, is, I think, a unique finding in both cysts.

Koch⁹ gives the most complete résumé on the subject

of bone cysts, collecting from the literature, in addition to his own observation, 32 cases.

Heincke⁹ has recently published the first case of multiple bone cysts in which x-ray negatives were made. He is inclined to the conclusion that the cystic degeneration is part of a general osteomalacia. I have recently learned that Dr. Goldthwaite in Boston has under observation, confirmed by x-ray studies, a similar case of multiple bone cysts, in which there is no doubt clinically as to the presence of osteomalacia.

The etiology of these multiple cysts is apparently entirely different from the single cyst, but in every case numerous x-rays should be taken to exclude multiple cysts. Codman¹⁰ in Boston reports a very interesting tumor in the digital phalanx which undoubtedly represents the cartilage stage of the benign bone cyst.

The benign cyst of the long pipe bones can not always be recognized clinically, nor does the x-ray negative differentiate it from medullary giant-cell sarcoma or the myxochondrosarcoma. As a rule, these three tumors can be distinguished from the more malignant and rapidly growing medullary sarcoma. However, if there is any doubt, one should never proceed with an amputation without excluding these tumors of less malignancy by an exploratory incision.

BENIGN DENTIGEROUS CYSTS.

Ten cases. Upper jaw, 4 cases; lower jaw, 4 cases; ethmoid, 2 cases. The age of the patients varied from 6 to 30 years; 4 were under 15 years of age, 6 between 20 and 30. The duration of the tumor varied from three months to thirteen years. Whether the tumor is situated in the upper or lower jaw, it is of slow growth and usually painless. There is a slow expansion of the jaw, and on palpation one can feel a smooth, thin shell of bone. Usually there is parchment crepitation. At the exploratory incision the periosteum is normal. The outer shell of bone is smooth; lining the bone there is a thin, vascular connective tissue membrane. The contents of the cyst is usually a blood-stained serum.

Microscopically, one finds frequently cholesterol crystals, blood corpuscles and degenerated cells, which suggest epithelium. Histologically, however, I have never been able to demonstrate an epithelial lining.

Usually the cyst is single; now and then there are thin partitions. In a few cases the cysts are multiple. Complete resection is unnecessary. Partial resection with curetting and drainage will accomplish a cure. In three of our cases a non-erupted tooth was found in a recess of the cyst. These dentigerous cysts are apparently due to the distension of the connective tissue capsule of a non-erupted tooth.

CASE 4.—Figure 4. The patient was a white boy, aged 15.

History.—The swelling of the body of the lower jaw was of three months' duration. Because of the painless and uniform expansion, the distinct shell of bone and parchment crepitation, I made the diagnosis of a dentigerous cyst.

Operation.—The exploratory incision revealed the pathologic findings already described. The outer expansion was cut away with the chisel without destroying the continuity of the lower jaw. The connective tissue membrane and tooth were removed. The bone cavity was then curetted, allowed to fill with a blood-clot and the skin incision closed. The wound healed *per primam*.

Result.—June, 1904, six years after operation, there is a slight depression in the jaw at the site of the scar, but no other deformity.

CASE 5.—Figure 5. The patient was a white girl, 8 years of age, the tumor of some years' duration.

Operation.—Complete resection was done. The child's hemoglobin was but 52 per cent. at the time of the operation, and although there was no loss of blood the patient died of shock. The tumor was a very large one and extended from the zygoma almost to the symphysis of the jaw. I believe incision and curetting would have been sufficient in this case.

CASE 6.—Figure 6. The patient was a colored girl, 19 years of age, the tumor of thirteen years' duration. Complete resection was performed. (Fig. 7.) The patient died at the end of the third week from abscess of the lung.

In the remaining five cases of dentigerous cysts, two of the upper jaw and three of the lower, the operation was similar to that followed in Case 4. The patients recovered and have remained well for from two to eight years since operation.

The two cases of cysts of the ethmoid bone presented themselves clinically with a tumor projecting from the angle between the nose and the supraorbital ridge, producing slight exophthalmos. On palpation the tumor was smooth and presented a thin shell bone giving parchment crepitation. In both, partial excision with curetting and drainage was performed. The patients have remained well, one four years and the other eighteen months since operation.

ADAMANTINE EPITHELIOMA.

Of these there were 12 cases. In 4 the tumor projected from the alveolar border of the jaw (3 lower, 1 upper). The tumor was covered with normal mucous membrane and did not invade the bone. In 8 cases the epithelial tumor was situated within the body of the jaw (1 upper and 7 lower), and in its growth produced an irregular expansion very similar to a dentigerous cyst. The age of onset varied from 18 to 61 years. The majority of cases were 20 and 35 years of age; the duration of the tumor from seven months to twenty-nine years, the majority from six to twenty years. In one case the condition was considered inoperable. (Fig. 8.) In the remaining 11 cases a complete resection of the diseased area was made. Nine cases have remained well for from one to twelve years. In one instance there was a local recurrence, but this patient has remained well eight years since the second operation. One patient (Fig. 9) died after complete excision of a huge tumor involving both upper jaws.

This epithelial tumor is apparently of a very low grade of malignancy. In none of our cases was there metastasis to the glands of the neck. The tumor can be differentiated from the more malignant neoplasms of the jaw by its very slow growth. The adamantine epithelioma involving the alveolar border can not always be differentiated clinically from the connective tissue epulis. The epulis is more apt to be associated with ulceration of the mucous membrane.

When the adamantine epithelioma originates in the body of the jaw and produces expansion, with the formation of a thin shell of bone, it can not be differentiated from a benign dentigerous cyst until the exploratory incision is made. Then, when the shell of bone is incised, we do not find a cavity, but a white, finely granular tumor containing connective tissue trabeculae, and usually many small and large cystic cavities. The gross appearance is well illustrated in Figure 10. This patient (Fig. 11) was a colored man, 42 years of age, tumor of eight years' duration. The patient has remained well three years since operation.

The microscopic appearance is well illustrated in Figure 12.

9. *Beiträge z. klin. Chir.*, 1903, vol. xi, p. 481.

10. *Boston Med. and Surg. Journal*, vol. cl, No. 8, p. 211, Feb. 25, 1904.

CASE 6.—Figure 13. The patient was a white woman, aged 52.

History.—Four years ago, when 48 years of age, she observed a tumor like a gumboil on the outer side of the alveolar border of the left lower jaw, opposite the canine and first molar teeth. At the end of two years, when it had reached the size of a hickory nut, it was removed. A local recurrence took place within six months.

Operation.—The tumor was removed by turning back flaps of mucous membrane which were not adherent to the tumor. Then the tumor and the alveolar border of the jaw were removed in one piece. The patient has remained well since the operation, a period of ten years.

Appearance of Tumor.—The fresh appearance was quite typical: white, friable, granular alveoli of various sizes and cysts in a definite fibrous stroma.

Fig. 1.—Characteristic shadow thrown by any medullary tumor which in its growth produces a shell of bone. A pathologic fracture is also seen.

Fig. 4.—Sketch of reconstructed lower jaw in a case of dentigerous cyst. The expansion of the body, chiefly on the outer side, is well shown and the recess containing the non-erupted wisdom tooth.

Fig. 2.—Bone cyst of lower end of femur of four years' duration.

Fig. 5. Photograph of the alcohol specimen of an excised lower jaw, in which the dentigerous cysts are multiple.

Fig. 3.—Bone cyst of upper portion of femur. Dr. Halsted's case.

Fig. 6.—This illustrates the huge size which a dentigerous cyst of the upper jaw may reach.

Examination.—The recurrent tumor is the size of an egg and involves the alveolar border of the left lower jaw from symphysis to within one centimeter of the angle. The tumor is present on both sides of the alveolar border. It is distinctly circumscribed. The mucous membrane at one point has ulcerated, exposing a small cyst.

Under the microscope (see Fig. 13) one sees the normal mucous membrane of the gum, then a zone of connective tissue, beneath which is the circumscribed tumor. The tumor is composed of branching epithelial alveoli in a connective tissue stroma. Some of the alveoli are cysts lined by the typical basal adamantine epithelium. Other alveoli are solid, with cells showing the various morphologic changes of the adamantine epithelium.

DISCUSSION.

DR. F. J. HALL, Kansas City, Mo. It would be of interest to know what distinction, if any, Dr. Bloodgood makes between the cystic bone tumors of the long bones; in particular, two varieties of pathologic bone condition: one is the myeloma

central portions of the tumors were occupied by these cysts, and I should like to know if Dr. Bloodgood has had any experience with these other two varieties of conditions, and what relation they bear to the conditions which he has described.

DR. JOSEPH C. BLOODGOOD, Baltimore—I am inclined to think that what you mean by myeloma is a giant-cell tumor.

DR. HALL—Yes, sir.

DR. JOSEPH C. BLOODGOOD—Dr. Hall, in his question in regard to myeloma, undoubtedly means the medullary giant-cell sarcoma. This tumor is one of a relatively low grade of malignancy. We have observed about 10 cases; all have remained well since operation. I have reported them in the Johns Hopkins Hospital Bulletin for May, 1903. In regard to the question as to the origin of the blood cysts in the condition called

Fig. 7.—Photograph of the alcohol specimen of Figure 6 after removal.

Fig. 8.—Colored man, aged 54; tumor of twenty years' duration.

Fig. 9.—Dentigerous cyst of upper jaw. Death followed complete excision.

and the other is the traumatic myositis ossificans. Several cases of both these conditions have occurred in my own territory, and three of the cases of myeloma—so-called central sarcoma of the bone—have been operated on, and none has recurred. Three cases also of myositis ossificans have occurred wherein the

Fig. 10.—Photograph of resected lower jaw; *a*, large smooth-walled cyst; *b*, bony capsule; *c*, smaller cysts; *t*, friable, white, adamantine epithelial tissue; *t*, teeth and symphysis of jaw.

Fig. 11.—Patient from whom tumor shown in Figure 10 was removed.

myositis ossificans, they are probably due to hemorrhage. Recently there has appeared in the literature a number of interesting articles and reports of cases on this subject. These I have reviewed in *Progressive Medicine* for December, 1903. With or without a history of trauma an indurated mass associated with some pain and tenderness is observed by the patient in one of the large muscles, most frequently the thigh. The tumor rapidly becomes bony in hardness. In some cases the x-ray demonstrates a zone of normal tissue between the shaft of the bone and the osteoid tissue in the muscle. In other cases the two bony shadows are in contact. This has given rise to two views as to the etiology of the new bone

formation in the connective tissue between the muscle bundles. A number of authorities conclude that the bone is a product of detached pieces of periosteum, others that it rises from the connective tissue cells between the muscle bundles. Clinically the condition is not difficult to recognize, especially with the aid of the x-ray. However, when the new shadow rests directly on the shaft of the neighboring bone it will be difficult to differentiate the ossifying myositis from a condition called

do not think there is any relation between the hemorrhagic cysts observed in myositis ossificans and the cysts of the long pipe bones.

As to the question of the origin of the giant cells, recent investigation would indicate that the periosteal or medullary giant-cell tumor is probably an angioma or an angiosarcoma, and that the giant cells are due to budding of the endothelial cells of the vessels in these very vascular tumors. The most interesting publication on this subject is by Friedländer.* Further investigation, however, should be made of this most interesting tumor.

Fig. 12.—Microphotograph of a section of an adamantine epithelioma, involving chiefly the alveolar border of the lower jaw. In this section the basal columnar cell and its various morphologic changes toward the center of the alveolus are well shown. (Sent me by Dr. Steensland.)

Fig. 13.—Microphotograph of a section of an adamantine epithelioma of the gum.

traumatic exostosis or ossifying periostitis. Blood cysts have been observed only in the ossifying myositis. Extensive operations are not necessary. One should remove as much of the new bone production as possible without destroying function. Slight local recurrences of the bone formation are to be expected. Fortunately the amount is never great, gives little or no discomfort, and second operations are rarely necessary. I

EXPERIMENTALLY PRODUCED GENUINE EPITHELIAL METAPLASIA IN THE STOMACH,

AND THE RELATIONS OF EPITHELIAL METAPLASIA TO CARCINOMA, AS DEMONSTRATED BY CASES REPORTED IN THE LITERATURE.

GUSTAV FÜTTERER, M.D.

CHICAGO.

As the observations on epithelial metaplasia to be reported in this paper were made in a series of experiments on the stomach of rabbits, undertaken for the purpose of studying the relations between mechanical irritation and development of carcinoma, I think it necessary to state this fact, merely to show under what circumstances the findings were made. My views concerning the rôle which mechanical irritations play in the etiology of carcinoma, and how those views have been formed, have been fully explained in former writings, and I can, therefore, refer the reader to them, in order to prevent repetitions, which would make this article too extensive.¹

Some observations of importance have been made which I do not report, because they need corroboration, but they certainly encourage further efforts along the same lines.

In a series of experiments on the stomachs of 94 rabbits, a genuine epithelial metaplasia was found in five cases, only two of which will be described in detail, as a description of the others would cause an unnecessary repetition, for while the findings differ somewhat in all the cases, they are the same in principle. It may also be mentioned that I have specimens of epithelial metaplasia from a former experiment, bringing the total of cases to six.

In each case a piece of mucous membrane of the stomach was resected and hypodermic injections of a solution of pyrogallic acid were made, to reduce the percentage of hemoglobin, and thus prevent the healing of the defect, the edges of which were then exposed to friction by solid food. At first, as in former experiments, circular resections of mucous membrane around the pylorus were made, but the feeding of the animals was not carried out according to orders given, and they all died, postmortem examination revealing very much dilated stomachs filled with solid food, while only liquid food was to be given during the first four days. Not being able to get better care of the animals at the time, I had, in order to reduce the mortality, to resect pieces of mucous membrane near or further away from the pylorus, and later, when Dr W. H. English, to whom I am very much indebted, kindly took it on himself to supervise the keeping of the animals, my results became very much better.

Fig. 2. Case 1. Hematoxylin-eosin stain. Bausch and Lomb, ocular 2, obj. 1/2 inch, magn. 250. In the middle of the field is found the part marked lead. (Fig. 1), with higher magnification. P. Peg of squamous epithelial cells. Cyl. Dilated glands, with very high cylindrical epithelium.

METHOD OF OPERATING.

1. The skin over the region of the stomach was shaved.
2. Ether narcosis.
3. The skin was cut with a knife.
4. The muscles were held with pincers, and the abdomen was cut open with scissors.
5. Sterilized gauze was packed around the wound, the stomach was pulled out almost entirely, and gauze was packed all around it.
6. The stomach was opened with scissors on the anterior walls in the pyloric portion.

7. The contents of the stomach were removed with a teaspoon.
8. A part of the posterior wall of the stomach was pushed through the wound with the fingers.
9. The mucosa of this part was cut with scissors and a grooved director was introduced into the submucosa, loosening the mucosa plus the muscularis mucosa from its bed, and then the loosened piece was cut off with scissors.
10. Two catgut sutures, one uniting the mucosa and one the rest of the wall of the stomach, closed the anterior wound of the organ.

11. The stomach was allowed to fall back into the abdominal cavity, the gauze strips were removed, and the abdomen was closed by sutures.

12. The animals operated on received regular injections of 0.14 pyrogallic acid in solution hypodermically at different intervals, as they were needed to destroy hemoglobin. Hemoglobin examinations were made once a week, and all the animals were weighed.

On the whole, I must say that the results, so far as the production of certain forms of ulcers was concerned, were not entirely satisfactory, but I believe that the experience gathered will enable me in the near future to be more successful in this direction. The work to be reported here consists of a series of experi-

globin, 85 per cent. Operation Jan. 8, 1904; died Feb. 1, 1904. January 23, hemoglobin, 60 per cent.; weight, 2½ pounds. January 30, hemoglobin, 50 per cent.; weight 2¾ pounds. One hypodermic injection of .14 pyrogallic acid in solution had been made.

In this case, as in Case 2, an infection of the right hand prevented me from performing the postmortem myself. When the stomach was handed to me, shortly after it had been removed from the animal's body, thickening and hardening of the part of the posterior wall of the stomach where the resection had been made, and where a regeneration of the mucosa had occurred, were recognized. In the mid-st of the regenerated portion could be seen a very small indentation and microscopic examination revealed here the presence of a peg of squamous epithelial cells, as is represented in Figure 1, with low power.

ments conducted between Dec. 6, 1903, and April 2, 1904.

REPORT OF THE FIVE CASES OF METAPLASIA.

The five cases of metaplasia recorded in our table have their principal features in regard to origin, the formation of pegs of squamous epithelium and their growth into the wall of the stomach in common, while there are some differences in the development and differentiation of the layers constituting the pegs.

CASE 1.—(Operation No. 32.)

Rabbit of white color; female, weighing 3½ pounds; hemo-

and in Figure 2, showing its origin from the mucosa, with high power.

Microscopic Findings.—With low power an epithelial peg was seen, the upper end of which reached but slightly above the mucous membrane at both edges of the indentation, before mentioned. The epithelial peg had three branches, one in the upper layer of the muscularis propria, and the two others deep in the outer layers of the muscularis propria, through which the main part of the peg had almost penetrated and reached the serosa. The peg was isolated, on all sides surrounded by mucous membrane, and no similar formations were found anywhere. Only in one place was the peg firmly connected with

Fig. 4.—Case 2. Hematoxylin-eosin stain. Bausch and Lomb, ocular 2, obj. $\frac{1}{3}$ inch, magn. 325. (G.) Glands of the mucosa. P. Peg of squamous epithelial cells. Cyl. Metaplasia. The cylindrical epithelium of the glands of the mucosa, changing into squamous epithelium. The nuclei contain a great deal of chromatin and the body of the cells becomes much longer. The glands themselves are dilated. It is of importance to notice that the epithelium lining the glands and undergoing metamorphosis shows perfectly regular arrangement, as under normal conditions, and it can easily be recognized that these cells are the regular columnar cells of the glands and not implanted skin cells, which would fill the lumen of the glands.

Fig. 5.—Case 3. This case was only mentioned, but not described in the text, because it was so similar to Case 1 that it was thought unnecessary. A section from this case was selected for microphotography, because it was thinner and better stained than those of the other case, which, however, showed the same findings. Str. c. Stratum corneum. Str. l. Stratum lucidum (only indicated). Str. gr. Stratum granulosum. D Change of direction of the nuclei. Str. m. Stratum malpighii. Musc. m. Muscularis mucosae. Str. p. Formation of a papilla.

the mucous membrane of the stomach, and this place has been marked rad., i. e., radix, presumably the root of the peg. The indentation was filled with vegetable matter, the muscularis propria was very much hypertrophied, and the peg itself had, with its ramifications, invaginated the hypertrophic muscularis mucosae, pushing it almost clear through the muscularis propria, without breaking through it anywhere. The structure of the epithelial peg, which was not perfectly solid, resembled that of the skin in many ways, but there were some important microscopic differences to which attention will be called later.

Figure 5 shows well the resemblance of the structure of the walls of the peg to the layers of the normal skin. The specimen photographed has been taken from Case 3, not because Case 1 did not show the same structures, but because the sections happened to be thinner, and on account of this and their staining were more suited for microphotography.

Figure 5 shows: 1. A stratum malpighii with a dense layer of oval nuclei containing a great deal of chromatin, many karyokinetic figures and long cells, more or less at right angles to the longitudinal axis of the epithelial peg. Upward, the nuclei become more round and more pale, containing less chromatin, and then rather suddenly they appear more drawn out, more cylindrical, and as if drawn by a different current, they change their position, their longitudinal axis, rather suddenly, becoming parallel to the longitudinal axis of the peg itself, thus forming a well-differentiated stratum granulosum. In those three cases I have not been able to find prickle cells, which may be due to their absence or to the thickness of the celloidin sections, and to the fact that the cells of the stratum malpighii lie much more closely together than they do in the normal skin. 2. A papillary body is well developed. 3. The stratum granulosum shows a deeper hematoxylin stain than the upper parts of the stratum malpighii, and between this layer and the stratum corneum there are lighter portions, which seem to indicate a stratum lucidum, although I have not been able to convince myself that such a stratum really exists. 4. There is a sufficiently well differentiated stratum corneum, with considerable keratohyalin and with Gram's method small patches of hornification could be demonstrated in Case 1 and Case 3. In this case, as in the others, some striped muscular tissue was found in the parts of the muscularis of the stomach near to the epithelial peg.

After what has been said, it is clear that the epithelial peg described represents a formation of epidermis in the stomach, but the question arises whether this is really an epithelial metaplasia, or rather a development from an aberrant germinal deposit or an ingrowth of epidermis or an implantation.

As to a development from a germinal deposit, by looking at the question in general, it would seem as if such an origin can never be excluded, because if, for instance, a single squamous epithelial cell is found in a field that should only be lined with cylindrical cells, then this one cell may represent an embryologic deposit, and things would become more complicated, if more than one of such cells were present.

In this case the epithelial peg was found in the center of the regeneration filling the artificial defect. If there had been a germinal deposit, it would have been removed at the operation, and as the peg was absolutely isolated, no ingrowth from a possible germinal deposit at the edges of the artificial defect can have come into play. It may be said here that in Case 2, Figure 4 shows clearly the development of metaplasia from the columnar cells of the gland, and I consider those findings alone as conclusive. An ingrowth of epidermis is absolutely to be excluded, as there was no fistula in any of the cases, as the metaplasias were found in about the middle of the stomach, and as each one was perfectly isolated.

There remains the possibility of an implantation during the operation.

Against the possibility of an implantation the following reasons can be advanced:

1. The possibility of a successful transplantation of detached normal epithelial cells has never been demonstrated. I myself have made use of every occasion for many years to transplant normal epithelial cells, under most favorable conditions, in hundreds of cases, and neither I nor anyone else has ever observed a further development of the cells transplanted. If these were implantations, they would be the first successful cases of implantation of detached epithelial cells on record, and that would be a matter of great importance in view of the sudden downward growth of the transplanted cells.

2. The description of the method of operation employed in our experiments seems sufficient to show that an implantation of epidermis cells can not have taken place, and if it should have occurred it would have been under the most unfavorable circumstances. The cells would have been transferred to a bleeding surface, and been subjected to the mechanical influences of the food, the contractions of the stomach and digestive influences of the gastric juice. If cells transplanted under most favorable conditions do not thrive, how can they develop under such most unfavorable conditions? I have often tried to transplant epidermis cells into the submucosa of the stomach, but have never been successful.

3. Sixty-nine of the animals operated on died during the first week after the operation, and as no microscopic examinations of their stomachs were made, we have five metaplasias out of 25 cases, which would be a very high percentage, indeed, for implantation.

4. It has been mentioned that the development of the layers forming the pegs differed very much, and that would not be the case in implantations.

5. Figure 2 and Figure 4 show plainly the development of the pegs from the epithelium of the glands which, particularly in Figure 5, shows its normal arrangement along the walls of the gland, without any disorder in position. If an implantation had occurred, the implanted cells could never show such an arrangement, but they would fill the lumen of the glands. I have specimens of an implantation into the glands of the mucosa of the stomach from a carcinoma of the esophagus, and that gives entirely different findings.

6. Hornification is only found in very small spots. An implantation would very probably show more of it.

7. But very few prickle cells have been observed. Many specimens were examined before a few were found. An implantation would have furnished more of them.

8. In the unstained specimens no pigment was seen.

9. If an implantation of skin had occurred, the vigorous down-growth from the very start of the development of the pegs, occurring in every case, would very much need an explanation.

CASE 2.—(Operation No. 27.)

Rabbit; female, brown, weight and hemoglobin at time of operation not recorded. Operation Jan. 7, 1904; died Feb. 19, 1904.

	Per cent.	Weight.
January 23 hemoglobin.....	45	3¼ pounds.
January 30, hemoglobin.....	38	3¼ pounds.
February 6, hemoglobin.....	45	3¼ pounds.
February 13, hemoglobin.....	38	3¼ pounds.

During the last six days no weight has been recorded, and it can not, therefore, be stated whether any loss of weight occurred during this period.

When the freshly removed stomach was handed to me I saw

* Healed defect; but in its place a thickened and hardened mucosa. † Death from ether.

Number of cases, 94; deaths, 94; death during the first week after operation, 69; postmortems, 35; ulcers, 20; healed defects, 3; hemorrhages, 1; perforations, 3; peritonitis, 1; microscopic examinations, 8; metaplasias, 5; purulent infiltration of the edges of ulcers, 3; purulent infiltration of the edges of the ulcers with liver abscess, 2; death from ether, 6; deducting 69 cases that died during the first week, and in which no examination of the stomach was made, we have 5 metaplasias out of 25 cases.

examined the whole primary growth, and he, therefore, can not exclude a metaplasia having occurred there, as we have seen it in other cases reported.

Cullen⁹⁷ reports a number of cases of squamous cell carcinoma of the uterus and cervix.

We have already mentioned a number of cases of combination of cylinder cell carcinoma with squamous epithelioma reported in literature, and there is no reason to suppose that such a combination could not occur in the stomach as well as in other organs, particularly since Borst has reported his squamous epithelioma of the stomach. To the reports, which I have mentioned above briefly, I only wish to add the conclusions to which Eichholz⁹⁸ has come in his experimental work. They are: "1. Stratified squamous epithelium can become so similar to epidermis that the two can not be differentiated. 2. In epidermoidal changes of transitional epithelium a metaplasia can not always be excluded with certainty, although in most cases, as in my experiments, it is to be supposed that an ingrowth has taken place. 3. Cylindrical epithelium can never form epidermis. This is proven by my experiments and by my examinations of human material. If an epithelial metamorphosis occurs in an organ, with cylindrical epithelium, then both, the cases reported in literature and the results of my own experiments, ingrowth of squamous epithelium or a development from an aberrant germinal deposit, furnish the explanation."

If Eichholz had given the cases reported in literature a more unbiased consideration, he would not have come to such radical conclusions. He would find it hard, indeed, to mention only one instance, to explain the occurrence of squamous epithelioma in the gall bladder, in cases where no fistula exists, without admitting a genuine metaplasia to be at least highly probable.

As regards the cases reported in literature, many of them must no doubt be classed as genuine forms of metaplasia, while others may have to be eliminated, but the process of sifting, in order to be of real value, must be done with great care.

If we review the cases recorded, adding our own, we can probably differentiate between three different forms of metaplasia, namely:

1. A more superficial form in the nose and its accessory cavities, and in the ear, where the massing of the desquamated cells often leads to the formation of cholesteatoma.

2. Metaplasias with considerable thickening and hornification, such as occur in the urinary tract and in the uterus, often in the course of time, followed by the formation of a squamous epithelioma.

3. Metaplasia which leads to squamous epithelioma so early that it is hard or impossible to find metaplastic changes in the mucous membrane surrounding the metaplastic tumor.

4. My own cases of metaplasia show strong downward growth at once, and it looks as if they belonged to the former class, but I should like to have it distinctly understood that they do not represent carcinoma yet, and that only further experiments can show what eventually becomes of them.

As to the causes of epithelial metaplasia, we have seen that hydroptic conditions of the mucosa of the antrum of Highmore may lead to metaplastic changes. Catarrhal conditions, rhinitis and influenza rhinitis are pointed out as causes by Suchanek and others. Gonorrhoea may lead to metaplasia in the urethra; tuberculous ulcers in the air passages, stones in the gall bladder and concretions and stones in the urinary tract play

an important part, but the importance of mechanical factors is very clearly indicated by the fact that some animals who have to break up hard food in the stomach have a physiologic metaplasia with hornification reaching down to the pylorus.

In my own cases I think it very probable that friction has been the cause of the metaplasia.

In closing this paper, I wish to state that the frequent allusions to the close relation between metaplasia and carcinoma found in the literature here reported, and also in the report of my own work, are intended only to point out the actual relations as they exist, that the reader may receive a fair idea of them. The cases which have been reported make it very clear that epithelial metaplasia is very often followed by the development of a carcinoma, but what the real relations are between my metaplasias and carcinoma is a matter that can only be made clear by further experimental work.

LITHEMIC NASOPHARYNGITIS DUE TO SYSTEMIC DISTURBANCE.*

J. A. STUCKY, M.D.
 LEXINGTON, KY.

Inasmuch as closer and more accurate observation has been made, new facts brought out, old theories exploded, and better results obtained, since the reading and discussion of this topic at the Western Section of the American Rhinological, Otological and Laryngological Society held in St. Louis two years ago, I do not feel that it is necessary to offer any apology for bringing the subject again before you. I desire to emphasize in the very beginning that it is full and free discussion that we are after.

In the treatment of all disease, whether due to pathologic condition or functional disturbance, the fact as to the cause of the existing condition is what concerns us most. What is the matter and why does it exist, and what will relieve or palliate most effectually the condition that confronts us, are the perplexing questions that we must face.

By the term lithemic nasopharyngitis is meant that type of disease having a close etiologic relationship to rheumatism, or the so-called lithemic diathesis, and has its origin in autointoxication caused by the absorption of by-products from the intestinal tract, or in the faulty metabolism occurring in the liver.

It may be defined as an acute congestive rather than an inflammatory process.

In the former paper, I believed the cause to be acid urates which had not been eliminated by the proper channels, or the absorption of products from the alimentary tract, the exact nature of which was unknown. In a record of one hundred cases where the urine has been carefully examined, and indican in excess found, as soon as that form of treatment was followed which

eliminated this, the patient was relieved, and as this was found more frequently than the excess of acid urates, I conclude it is the most potent excitant of the nasopharyngeal irritation. Hence more stress is put on its elimination than on uric acid. The local manifestations of this so-called diathesis may not be confined to the pharynx, but may exhibit itself in affections of the laryngeal, nasal, auditory, and gastrointestinal tract, without any special organic or systemic symptoms.

The attack causes primarily no lesion, and there is no distinct pathologic alteration, this being a local manifestation of a systemic condition. These cases were almost invariably neurotic, good liver, leading more of a mental than an active physical life. They complain of always taking cold, sneezing, have a stuffy, full feeling in the head, one nostril always stopped up, copious and frequent discharge from the nose, greatly annoyed by accumulation behind the palate and crackling noise in the ear. In addition to these nasal symptoms, attention will be called to a stiffness in the throat, with the sensation of a foreign body, like a piece of bread-crust or fish-bone in the tonsil. Altogether they are a miserable, snorting, snuffling, handkerchief using, irritable, and generally uncomfortable set who blame all their ills on a "catarrh."

Interrogation reveals the fact that more or less constipation exists and some laxative is frequently needed. Little water is drunk. Meat and sweets are freely used as well as salads, acids, coffee and tea. The skin is abnormally florid or muddy, in the former case suggesting too free use of alcoholics, in the latter so-called "bilioousness"; in both cases the liver is most unmercifully suspected if not damned. A case with such a history leads me to suspect at once indicanuria with probably an excess of uric acid.

My observation is that where there is an abundance of indican in the urine in cases such as I have described there is no satisfactory and permanent relief until the treatment thoroughly eliminates this and the insufficient functioning of the large and small intestine be remedied and improper diet corrected. It is not so much a question of diet as of regulating the intestinal tract. In aggravated cases, I always have the gastric contents analyzed after giving a suitable test meal, in order to know how much, if at all, the stomach is at fault, for if gastric digestion is not complete, and the contents of the stomach are discharged into the duodenum in a hyperacid condition, the secretion of this organ is not sufficient to neutralize the acidity and, as a result, intestinal digestion is inhibited. The result is a putrefactive fermentation of the mass, developing disagreeable flatulence, dyspnea and intestinal distress. Many of the cases have more nasopharyngeal annoyance, in the form of sneezing, running at the nose, either immediately or several hours after eating. In the former case we suspect the trouble to be reflex gastric irritation; in the latter intestinal toxemia, due to indigestion.

It has been demonstrated that ingestion of citric, melic, or the fruit acids during peptic digestion inhibit secretion of hydrochloric acid and the peptic juices and increases fermentation of the carbohydrates, and the elimination of fruit in the diet, especially with meals, has been most beneficial. Where the patient craves an acid, and many of these patients do, dilute mineral acid drinks, preferably hydrochloric, are given with meals. When the cause of suboxidation is found and removed the victory is won, and in order to bring this about treatment must be directed toward elimination, atten-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Maknen, George L. Richards and John F. Barnhill.

tion to hygiene, and proper selection of diet, exercise in the open air to increase the oxygenating power of the blood, and the free and liberal use of non-medicated drinking water between meals.

The intestinal tract with its varied and complicated organisms being out of adjustment, restoration to health (or the normal) means a readjustment of the basic function, and the function needing the most attention is the eliminative. Metabolism refers to the income as well as to the outcome of cell life, and where there is more put in and kept in than can be put out, poison is the result. The chief question to bear in mind is not what drug or what remedial application, but how best to remove the cause and restore the organs to normal.

TREATMENT.

As stated in a former paper local treatment is of little use, the disease being a local manifestation of a systemic disturbance. Sprays, gargles, etc., tend rather to increase the irritation. Any application containing astringents, cocain or similar drugs is contraindicated. In the beginning of the attack, if the parts are swollen and markedly congested, thorough cleansing of the pharynx, tonsils, postnasal space and anterior nares, with hot alkaline saline solutions by means of lateral and postnasal sprays, affords marked relief by removing the retained and viscid secretion.

The cause of the trouble being within the body and the result of absorption of by-products from the intes-

ted with a perforated stopper containing a small tube, to which is attached an ordinary atomizer bulb. (Fig. 1.)

The nurse or hospital orderly is carefully instructed in the method of giving the treatment, the procedure being as follows: The flushing is given late in the afternoon, an hour before the evening meal, the patient being in bed properly prepared, a rapid flow fountain syringe with capacity of three quarts is filled with soapsuds or normal saline solution, and brought close to the bed on a douche pole. To this is attached the colon tube thoroughly oiled, the best lubricant being castor oil, the cut off is tested, the cheeks of the buttocks are separated with fingers of left hand, and grasping the end of the colon tube an inch from the distal extremity, it is gently inserted past the sphincter ani. When this is done the cut off is released and the water allowed to flow, the tube being rapidly pushed into the bowel. The liquid separates the fold of the gut or floats any obstructive fecal mass out of the way, and makes the successful administration of the fluid not unpleasant. Should there be any pain before the tube is fully inserted or at least two quarts of fluid injected, the flow is stopped for a few seconds till this subsides, then started again. Any marked discomfort is due to moving of gas or the rough handling of the tube. When the full amount is injected, the tube is withdrawn, and the patient allowed to pass the contents of the bowel as soon as desired.

Experience has shown that the injection of the oil is followed by better results when given several hours later, the bowel having recovered from the effect of the washing, and the patient prepared for bed for the night, the oil is retained with more satisfactory results. In giving the oil, the patient is prepared as before, the injecting bottle being filled with olive oil and placed in a pan of hot water. The colon tube is slowly and gently inserted the full length, the tube of the injector is inserted into the projecting end of this, the injector bottle of oil lifted out of the pan of hot water, held upright, the cut off is released and the oil immediately begins to flow, the rapidity of flowing being increased by gently forcing air into the bottle by means of the rubber bulb. The time consumed in inserting the oil is not more than a minute or two, and the sensation to the patient is in no respect disagreeable, a good night's sleep is usually the result, and a copious evacuation of old fecal matter, with many scybalous masses and much gas is the result of the bowel movement the next morning.

Should there be much muscular tenderness or general malaise, strontium salicylate in 10 gr. doses is given every two hours till this is relieved. As a rule, this treatment given four or five days, then once or twice a week, is all that is necessary to give the patient a rapid and satisfactory start toward health. In a majority of cases observed the relief has been so pronounced, the patient so delighted at having found the source of trouble and been taught how to remove it and avoid its recurrence that the gratification has only been equaled by the satisfaction of the physician. Of course, careful attention must be paid to diet, avoiding the eating of much meat, saccharin food, or salads and use of alcohols, and drinking freely of water between meals, attention given to the skin and caution as to leading too sedentary a life. Such a course when adhered to has given some of my chronic and intractable cases complete relief, not only of the nasopharyngeal trouble, but of other systemic lithemic affections.

If I am correct in my observations and conclusions that absorption of products of putrefaction from the in-

Fig. 1.—Oil injector devised by Dr. Julian McClymonds.

tinal canal, our treatment must be directed toward removing the cause. The first indication is to clean out the alimentary canal and give nature a good start and fair chance. The patient is put on a restricted diet and plenty of water given, an average of six ounces every hour. A dose of calomel and salol five or ten grains each is given, followed in six hours by a saline, preference being given to the Seidlitz salt.

In the afternoon, an hour before the evening meal is taken, the colon is filled and flushed with two or three quarts of soapsuds, by means of a thirty-inch-double-eyed colon tube. Three or four hours later, after the patient has been prepared for bed for the night, the colon tube is carefully reinserted the full length, and eight ounces of warm olive oil injected; the tube is then gently withdrawn, patient cautioned to keep quiet and go to sleep. The bowels rarely ever move till morning, or about eight hours after the oil is placed, if the patient is kept quiet. The injector which I use is the device of Dr. Julian McClymonds, gastrologist, who has rendered me valuable service in ascertaining and locating the source of irritation by examination of the gastric contents after a test meal. Also by chemical and microscopic examination of the urine.

The injector consists of an ordinary nursing bottle with two openings, one at top and one at bottom. In the lower opening a suitable conical tube about 14 inches long is inserted full length. The upper opening is

testinal canal is the cause of lithemic nasopharyngeal irritation, it is of paramount importance that the canal shall be thoroughly cleansed in the beginning of the treatment, and I know of no remedy given by the mouth that will satisfactorily do this without greatly taxing the vitality of the patient. In many of these cases the appearance of the scybalous masses removed after as many as ten of these treatments of the soapsuds followed by the oil, indicated they had been lying in the folds of the gut for weeks or months. Dr. McClymonds had several cases of intestinal toxemia that he observed very closely, and not until after the treatment had been given daily for several weeks was he reasonably sure that the canal was clean. The fact that the patient has one or more evacuations from the bowels daily does not prove the absence of retained toxic fecal matter. The effect of the colon flushings and oil treatment is: 1, mechanical, the scybalous masses being softened and separated from the folds of the canal; 2, the oil is broken up into fatty acids and glycerin, the absorption of the glycerin causing watery flow of bile from the liver, and these treatments must be followed by such remedies as will give tone to the muscular coat of the bowels and stimulate peristalsis. For these nux vomica and cascara sagrada should be given at first in full doses, then in gradually decreased doses, until it is no longer needed.

It is interesting to note the rapid decrease in the amount of indican in the urine as is shown by daily tests.

It is by no means necessary for the patients to quit their business and go to bed in order to take this treatment. Some of my patients spend the evening and night at the hospital for a week, others employ a trained nurse to come to the residence. Confinement to bed or to the house retards the progress. Emphasis is put on the free and liberal use of non-medicated water. Patients are urged to take at least six pints of plain water in twenty-four hours, and few can drink this much of alkalinized or salined water without feeling uncomfortable on account of the increased blood pressure. Distilled or pure rain water is not so rapidly absorbed, much of it going through the bowel, assisting in carrying off the waste material and favoring free and satisfactory evacuation.

While there is an excess of uric acid in addition to the presence of indican in the urine, the drugs indicated are those that will hyperalkalize the blood and increase its solvency for urates. Subalkalinity of the blood indicates diminished oxidation, and consequently retarded nutrition, both being favorable to the formation of uric acid in the body as well as to the growth of pathologic micro-organisms, in this way favoring auto-intoxication.

Mild cases of lithemic nasopharyngeal irritation do not require the detailed treatment referred to, but are relieved by alkaline cathartics. The beneficial results from these are not so much from the absorption of alkaline substances into the blood as from antiseptic, antiputrefactive or antifermentative effect on the intestinal contents. The point made by Dr. Ballenger is: "One of the most beneficial effects is the retarding of the putrefactive process, especially that which produces the toxins so poisonous to the system; the chief indications are we should not attempt to do so much by dieting as by regulating the intestinal tract." Daily or twice daily laxative doses of sulphate of magnesium or sodium phosphate have given good results.

DISCUSSION.

DR. L. C. CLINE, Indianapolis—Dr. Stucky's paper calls attention to a class of cases that needs to be more emphasized and carefully studied. Most of us pay more attention to the methods of surgical treatment and equip ourselves with the latest improved instruments for doing surgical work. We have been passing through a wave of operative procedure regardless of causes that if cared for early would obviate the necessity for surgery in this particular class of cases. There is no question but many of us lose sight of the most important thing—hygienic and eliminative treatment. I have had a good deal of experience along these lines and thereby avoid operations. I fully recognize that some require surgery when first observed, while others need only cleansing and medicinal treatment. We are in some respects a peculiar people; we eat too much, exercise too little, spend too much time at business indoors, and as a result we all have the faulty metabolism and accumulation and retention of effete material mentioned in the paper. We should put these patients in good condition and correct their faulty habits. Instead of surgical instruments it might be better for some of us to carry home with us the doctor's syringe for injecting oil, improvised from a nursing bottle, and learn how to use it. None of us would think at first of operating on an enlarged hyperemic nose following specific infection, as it rapidly subsides under proper treatment. Cases referred to in Dr. Stucky's paper will do likewise. Attention to diet, exercise and care of the skin will accomplish much.

DR. S. F. SKOW, Syracuse, N. Y.—The tendency of the specialist is to become narrow, and Dr. Stucky has shown us that in this lithemic study narrowness has no place. He makes one observation with which I can not agree, that local treatment is of little importance. My experience has been that in all sensitive conditions of the nasal mucosa, though we may find the patient at first with nostrils apparently free, on second examination we will find the region of the middle turbinal congested. Perhaps three-fourths of the man's life has been spent with an enlarged turbinal pressing on a sensitive area. I question very much if, when these parts are overgrown, correction of the other parts of the system thoroughly removes the trouble. I agree as to the importance of removing systemic disturbances and have written and discussed papers on this subject. I do not think we can give it too much consideration, but I think we must consider the local treatment as well. Dr. Stucky has given us his methods in handling these cases, the injection of water, etc., and though I can not use his method in my narrow practice, I believe his ideas are based on sound reasoning. These points are of material importance in every case of hypersensitive catarrh.

DR. E. L. VANSANT, Philadelphia—After getting the patient in good condition an aseptized diet is of the greatest importance. If the patient will leave off all uncooked food and eat aseptic food it will be of immense benefit in the case. I have seen several patients getting along beautifully until they ate some salad made with oil which was not pure, which indiscretion was followed the next day with all the symptoms of which they had previously complained.

DR. D. McALLISTER, New York City—I gather from the paper that Dr. Stucky believes indican to be the irritant that causes the trouble. It appears also from my work that these are cases of local irritation and not systemic, and this is proved by the fact that the administration of rhubarb or soda has the same effect as treatment of the other end of the canal. This part of the throat is at the crossroads of the respiratory tract and the alimentary tract, and the inflammation is more that of the alimentary tract than of the respiratory. It is simply a condition of plethora, and treatment of the alimentary canal relieves the plethora. I think the cure is to be obtained by relieving the acid condition.

DR. C. H. BAKER, Bay City, Mich.—As has been said, we go home with a kit of surgical tools and are disappointed because the majority of our cases are not amenable to surgical treatment. Probably nine-tenths of the patients coming into our offices do not require operative treatment to secure satisfactory

results. I think Dr. Stucky has sounded a timely note and has offered a solution of this difficulty. After twenty years' practice, during which I have believed that auto-intoxication was at bottom the chief cause of so-called nasal catarrh. I have been hoping that some one would tell us what chemical agent or agents are the cause of the inflammation of these mucous surfaces. We have been told that it is due to uric and o her acids, to leucemains, to the products of intestinal fermentation and to all kinds of conditions, and at last it appears we have found the exact substance. I would like to have Dr. Stucky give us a short method for detecting indican which every busy man can apply in a few minutes and which will tell comparatively the amount of the toxic agent present. Dr. Stucky referred to the action of fruit acid in producing these conditions. The typical American breakfast starts out with fruits, cereals and predigested starches, and ends up with meats and other things that combined make an ideal culture medium for bacteria whose growth produces the chemical products which are so irritating to the digestive tract. It is not surprising that Americans are stigmatized as people suffering with catarrh. We are also known as sugar eaters. I would like to ask if these hay-fever people, who are nearly always lithemic, suffer more from indican during that period than any other.

Dr. J. HOLINGER, Chicago—How long after Dr. Stucky has given that course of treatment does the patient stay cured? A man goes back to the same mode of living, and in less than six months he is as bad as he ever was. The treatment must be repeated. After two or three years you have a neurotic patient who relies mainly on his rectal tube. We all know these patients and how much they bother us. If we can make a man understand that he has his muscles to use, his legs to walk with and his arms to exercise, we will accomplish much more than with these cures, which tend to substitute one evil for another.

Dr. R. C. MYLES, New York City—For several years, in conjunction with a specialist on gastrointestinal work in New York City, I have been working along this line and have obtained practically the same results in these obstinate cases. We have relied principally on olive oil, placed in the bowel at night. Dr. Stucky's apparatus, however, is far superior to anything we have. There can be no doubt about the toxins from the colon manifesting themselves in the nose and throat. The edema, the character of the secretions, the decaying odor of the chemical changes, are all due to these toxins, as we have demonstrated in our treatment. This is much better than local treatment, though, of course, we use that also.

Dr. J. A. STUCKY—I am sorry that I can not go deeper into this subject, for I am just beginning to learn something about it. As to Dr. Vansant's aseptic diet, if we get the canal thoroughly emptied and give the patient a good start it does not make much difference what he eats. I can not believe that this is simply a surface irritation. I have tried local treatment thoroughly and have become convinced that the local condition is a manifestation of the systemic condition. I do not know whether indican will be found in the secretions of the nose or not; it is the result of intestinal putrefaction. For three or four years I have been watching several cases of hay fever before and during the attack, and where I can get hold of them before the attack, thoroughly empty the canal, diet them and get rid of the indican, they either escaped the attack entirely or it was very much diminished. I am inclined to believe that this same cause has much to do with vasomotor coryza. As to how long these patients remain cured, it all depends on how long they take care of themselves. They are usually high liver, overfed and underworked: I have never seen any laboring man with indican in his urine. These patients are mental workers, and those who take sufficient exercise eliminate these products. The neurosis spoken of is due to the absorption of the indican, and my experience is that the relief obtained is sufficient to induce them to take care of themselves, and that it is not a habit.

SPONTANEOUS TONSILLAR HEMORRHAGE.*

LEWIS S. SOMERS, M.D.

PHILADELPHIA.

Spontaneous hemorrhage from the tonsillar region independent of traumatism or surgical measures, but as the result of destructive inflammation from a tonsillar or peritonsillar abscess, occurs but infrequently and in the majority of recorded cases the bleeding has resulted fatally. The following case is therefore recorded inasmuch as it presents several features of importance, namely, its successful issue without operative interference; the age of the patient and the harmful results following too conservative treatment of pus collections in or about the tonsils.

Mrs. A., aged 71 years, of excellent surroundings, had been ill for one week with a peritonsillar abscess of the left side.

History.—She had never had any trouble with her upper respiratory tract so far as she could remember, this being her first attack of tonsillitis. Her family physician attended her and the treatment consisted of strychnia, nutritive enemata and gargling with an alkaline solution. Two days before I first saw her the abscess had discharged profusely and she was emaciated, extremely weak and refused all mouth nourishment on account of the intolerable pain consequent on swallowing. I was called to see her at midnight for the first time, when the nurse stated that she was bleeding to death.

Hemorrhage.—During the evening she had suffered from great pain in the throat, and a few moments before I was summoned the nurse heard her groaning and strangling. It was then found that a column of blood was pouring from her mouth, and when I arrived a large basin was filled with bright arterial blood, the patient's clothing and bedclothes were covered with it, and a stream was still gushing from the mouth.

Treatment.—Pressure as forcible as possible was made over the carotid artery of that side; on account of the patient's prostrate condition and the inability to obtain proper illumination of the pharynx, it was impossible to ascertain the vessels involved in the bleeding, but with the unengaged hand forcible pressure was made by means of two fingers over the tonsil, compressing the pillars together, and a saturated solution of tannic acid was poured in the mouth, the hemorrhage diminishing sufficiently in amount to allow of this procedure. Strychnia and ergot were administered internally and within fifteen minutes the hemorrhage had practically ceased, but enough arterial blood still oozed away to stain the handkerchief. Fifteen minutes later the hemorrhage had entirely ceased and there seemed to be no further immediate danger.

Condition of Throat.—The following day a more careful examination of the throat was possible, as no more bleeding had occurred, although considerable pus had been expectorated. The abscess had destroyed the entire tonsil and in this way had involved several small vessels, while the main volume of blood was evidently derived from the artery of the anterior pillar of the fauces, through which there was a large ragged opening. The pharynx and pillars were much inflamed and the site of the tonsil was covered with a large ulcer, which in turn was covered with pus. Subsequently no further bleeding took place, but it was fully six weeks later before she had again returned to her normal condition.

PATHOLOGY.

The pathologic changes in these cases essentially embrace a purely destructive process, the tissues sloughing away before the eroding action of the confined pus, and although the statement has been made that this can only occur as the result of a gangrenous process, yet such is not the fact, as the few cases reported and also my own

* Eight Epitheliomas Removed from a Single Tongue.—In the course of 21 years a recurring epithelioma on the tongue was removed eight times in a case described by P. Reclus of Paris.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

show none of the phenomena allied to a gangrenous condition.

Jenkins,¹ in an epidemic of 65 cases of tonsillitis, observed one of these fatal cases in a child of six years, where the left tonsil completely sloughed away on the ninth day, with death from hemorrhage, and Bokay and Alexey,² in a boy of four years, with tonsillitis for three weeks, observed two hemorrhages followed by death and the autopsy showed that the tonsil and the surrounding tissue were filled with pus, while the destructive process had produced a perforation of the common carotid artery. Jacobi and Ewing³ report an instructive case showing the pathologic changes in a child, where death occurred after tonsillitis of two weeks' duration, as the result of four hemorrhages at intervals of several days. The autopsy was not made until five months later, when it was found that there was a large cavity filled with blood between the right tonsil and the pharyngeal wall and the internal carotid artery was perforated; the first three hemorrhages apparently being derived from rupture of large veins and arteries attacked by the suppuration, while the fourth and fatal hemorrhage resulted from the opening of the carotid by the tissue destruction.

So long as the purulent matter is confined, the destructive elements remain actively at work and while the softer tissues are necessarily involved at first, yet if the pus be not evacuated by artificial means, or spontaneous evacuation is unduly delayed, the vessels are ultimately involved, the walls softening and final rupture must ensue. Various arteries may be involved in this destructive action, branches of the lingual, the ascending palatine and tonsillar from the facial and even the facial itself as in a fatal case recorded by Bosworth,⁴ the ascending pharyngeal; the descending palatine; or finally the internal carotid as usually occurs in the majority of cases. The smaller arteries are, however, but infrequently involved in a hemorrhage of any magnitude, but that the blood flow is arterial in origin may usually be readily determined by its cessation or diminution when the carotid is forcibly compressed and also by the character of the blood.

The rupture of the affected vessel seems apparently to be the direct result of the local severity of the purulent process and not dependent on general causes such as hemophilia for instance, although the presence of another affection such as arteriosclerosis or the general impoverished condition of the patient may have some effect in determining the extensive purulent process. Such an implied condition being shown by a case of Keiper's,⁵ in which the tonsillitis was considered albuminuric in origin and hemorrhage took place several times and was controlled with extreme difficulty. Seven days, however, after the tonsillar hemorrhages had ceased permanently, the patient died.

RELATION OF HEMORRHAGE TO RUPTURE OF ABSCESS.

As would be expected in these cases of tonsillar hemorrhage, the bleeding does not take place until usually late in the second week of the disease, or as in several of the reported cases, moderate hemorrhage would occur after the suppuration had existed for a week or ten days, and as the tissue destruction increased in extent, additional smaller vessels would be opened until finally the loss of blood from a large vessel would oc-

casional the death of the patient. Such a case illustrating this point was reported by Brewer⁶ in a man of twenty-five years, with peritonsillar abscess of over one week's duration. Then spontaneous rupture occurred followed by slight hemorrhage, repeated several times; while one of the hemorrhages was so profuse as to cause syncope, yet it was controlled until the final hemorrhage taking place, caused the death of the patient from exsanguination.

The relation of the hemorrhage to the time of rupture of the abscess has been especially noted in several cases and, as a rule, the flow of blood of any magnitude does not take place for several hours, or even a day or more after the pus has spontaneously evacuated; this, of course, being in harmony with the course of the tissue destruction, depending undoubtedly to some extent on the loss of support afforded the involved vessels by the pent-up purulent mass, in addition to the direct destructive action on the walls of the arteries. In the case reported here the abscess ruptured two days before the destruction had reached the vascular walls, while in a case reported by Dunn,⁷ of abscess of the right tonsil discharging spontaneously, the hemorrhage was first noted twenty-four hours later; this was again repeated in forty-eight hours and, as during the following three days, several severe hemorrhages occurred and the condition of the patient had become critical, the common carotid was ligated with resultant rapid recovery.

In several instances, two, three or more severe hemorrhages took place before the patient succumbed or radical measures were resorted to for the control of the bleeding, and undoubtedly its cessation under such circumstances was dependent not only on the milder measures such as local medicinal applications, but to a considerable degree on the loss of blood producing a marked lowering of the arterial pressure, with consequent syncope and clot.

PROGNOSIS.

In all instances of such hemorrhage from the tonsillar region, the outcome must of necessity be a most grave one. Immediate death has occurred in several instances, while in others the fatal issue was delayed until several hemorrhages had occurred. In a case reported by Chappell,⁸ the hemorrhage was controlled by making an incision through the anterior pillar, washing out and packing the abscess cavity. The same author in reporting this case found ten similar instances in the literature in which the hemorrhage occurred after spontaneous rupture of the tonsillar abscess and of these but two recovered, both being in cases in which the carotid artery was tied.

DISCUSSION.

DR. W. E. CASSELBERRY, Chicago—I have no personal experience to relate, but I recall one case with the circumstances of which I was familiar, where the life of the patient was saved by the method ascribed to Dr. Chappelle. The abscess cavity was opened freely, washed out and packed with iodoform gauze. This is the most rational procedure, provided digital compression and perhaps compression by the Mieluzie clamp have failed. If the cavity is such that it can not be made to retain the gauze I would consider ligation of the carotid artery indicated, provided the hemorrhage is immediately jeopardizing life.

Clinical Reports.

OBSTRUCTION OF THE BOWEL DUE TO A ROUND WORM IN THE APPENDIX.

W. ALBERT NASON, M.D.

ROARING SPRING, PA.

The following case has some unique features which make it of sufficient interest to report.

Patient.—M. E. H., girl, aged 15 years, of Coalmont, Pa., was taken sick Tuesday, Aug. 16, 1904, vomiting freely, for which home remedies were tried.

History.—Wednesday, August 17, at 4 p. m., Dr. Evans of Saxton, four miles away, was called. Friday, August 19, Dr. Evans was again called, as vomiting persisted and was accompanied by some pain. Saturday morning, August 20, a consultation was held with Dr. Schum of Hinvingdon. It was concluded that there was an obstruction of the bowels and that an operation probably would be necessary.

Examination.—I reached the case Saturday evening and found the patient suffering some pain, though it was not severe. Temperature had been normal each time when taken and was then normal. Pulse 120. Abdomen considerably distended. There was some tenderness, but at no particular spot. The vomiting was decidedly stercoraceous and had been so since Friday.

Operation.—All efforts to move the bowels had been unsuccessful, therefore operation was decided on. I made a median incision and found the bowels much distended, especially in the ileocecal region. On endeavoring to bring up the bowel I found it firmly bound down and the appendix wrapped around the small bowel. In the colon I detected peculiar feeling substances which proved to be two worms. One of these was in the appendix and had wrapped itself with the appendix around a loop of the small intestine and then the tip of the appendix had become adherent to the bowel and thus formed a constricting band. I was unable to free the appendix until, after opening the colon, I grasped the worm and drew it out. I also removed its companion and was then able to draw up the appendix and remove it, thus releasing the bowel. The contents of the bowel, being liquid, poured out over the intestines, which were afterward washed off with a carbolic acid solution, as it was impossible to procure sterile water.

Result.—The temperature remained 98, with pulse 120, till Monday, when it went up to 99. An enema on Monday produced a fair result. Salines began Tuesday caused large, free evacuations Wednesday. The highest temperature was 101 on Thursday. The stitches sloughed and were removed Wednesday. Patient made a rapid recovery.

The species of worm was the *Ascaris lumbricoides*.

A CASE OF POISONING FROM BELLADONNA PLASTER.

WILLIAM E. SANDERS, M.D.

ALTA, IOWA.

Patient.—Mrs. W., aged 79, called me at 7 p. m., August 24.

History.—I learned that at 10 a. m. she had applied a belladonna plaster 5x7½ inches over the lumbar spine. During the afternoon her face became flushed and there was a blue discoloration of the lips. She experienced difficulty in swallowing and complained of vertigo and dryness of the mouth. She had taken a dose of Paine's Celery Compound, and to this she attributed her symptoms.

Examination.—There was active delirium, restlessness, rigidity of the flexor muscles, carphologia, bounding pulse (102), temperature 100 F., difficult articulation and extremely dilated pupils.

Treatment.—Pilocarpin nitrate, gr. ¼, was given hypodermically at once, and the belladonna plaster was removed; and after an hour morphin gr. ¼, with pilocarpin gr. ¼, was given hypodermically.

Result.—In an hour the patient became quieter and regained consciousness about 3 a. m., August 25.

A SIMPLE OPERATION FOR SENILE ENTROPION.

CLARK W. HAWLEY, M.D.

Professor Ophthalmology Post-Graduate Medical School.
CHICAGO.

The patient, 80 years old, has suffered many years from trachoma and its following ills, among others senile entropion of the lower lid. The ptosis, the entropion and the corneal disturbance of the left eye is of very old standing, but the right entropion of the lower lid was of recent origin and was causing such corneal opacity that the patient's ability to get about was very much curtailed; she, therefore, asked for relief.

Entropion of this character has to do with the entire folding in of the lid and not to the contraction of the cartilage, and is not uncommon in elderly people not suffering from some other disease. It often seems to be due to a lack of tone in the muscles and skin about the eyes. She was not very hopeful, as one operation on the left lid proved a failure, but was anxious that something be done because of the severe pain and rapidly failing vision. I noticed that by making traction of the skin down and outward, accompanied by massage over the lower lid, that it would remain in its proper position for some time; I was tempted to try massage, but concluded that it would

Fig. 1.—Senile entropion. Dotted line shows where thread was placed.

result in temporary relief only, so decided to try the following simple procedure:

I double-needled a piece of heavy silk thread; then, clamping the lid, a few drops of 4 per cent. cocaine were injected into the skin; removing the clamp, one needle was inserted just below the margin of the lid, about the center, and carried down and outward slightly and as close to the cartilage as possible, passing on to the margin of the orbit, where I caught up the periosteum coming out on the skin. The other needle was inserted about three millimeters away from the first entrance and carried down parallel to the first thread, passing through the periosteum and coming out near the other exit. The two ends were then tied over a piece of cotton with sufficient tension to retain the lid in position, and allowed to remain so for two days, when the loop was fished out from the skin, and every day the threads were drawn back and fourth. At the end of two weeks a heavy band of cicatricial tissue formed; the threads were then removed, the lid being held firmly in position. The result is well shown in the photograph. I propose to treat the other lid in a similar manner.

The operation was performed in April, 1904. In September the patient reports that the result is still as good as at first, so that it gives every evidence of being permanent.

No claim is made for originality.

THE SITUATION AS REGARDS THE SERUM TREATMENT OF HAY FEVER.

The exasperating resistance to treatment of the disease commonly known as hay fever makes it one of the most interesting subjects to the practitioner. The great interest shown of late in the serum treatment and the present visit to this country of Dr. William Dunbar, who is a native of this country, and whose serum is being used so extensively for hay fever, make it of interest to review briefly some of the facts that have previously appeared in our own columns and in the literature on the subject.

The disease has been described under a variety of names, summer catarrh, hay fever, hay asthma, pollen catarrh, rose cold, June cold, concert fever, railroad fever, sun fever, dust fever, autumnal catarrh and peach cold. Many theories have been put forward to explain the phenomena of the affection. The pollen theory, especially supported by Blackley, was one of the earliest. The heat theory, the light theory, the nervous theory and other theories are familiar to all. Gradually the view became widespread that at least two factors are concerned in the etiology: a predisposition and an exciting cause. The theory of a bacterial origin found many supporters. Dunbar began by searching for a causal bacterium, but in the course of his studies became convinced that the disease is not due to bacteria, but to the irritative effect of pollen on the mucous membrane of susceptible persons.

Dunbar, in several papers,¹ has detailed the progress of his studies. Suffice it to say here that his experiments indicate that it is neither the mechanical action of the pollen grains themselves nor any oily or volatile constituent of them which sets up an attack, but instead, some proteid constituent of the nature of a toxalbumin. Of the pollens prevalent at the time of the early summer catarrh or hay fever proper, those of rye and maize contain the poison in largest quantities. In the autumnal catarrh of this country golden-rod (*Solidago*), ragweed (*Ambrosia*) and wormwood (*Artemisia*) have been held responsible. As little as 1/40,000 of a milligram of the rye-pollen toxin placed in the conjunctival sac will call forth in susceptible individuals a paroxysm of hay fever lasting several hours. This quantity of toxin corresponds to only two or three pollen granules. Dunbar asserts that

while the toxalbumin constantly calls forth an attack in susceptible persons, it is without effect when instilled into the eyes or placed on the nasal mucous membrane of non-susceptible individuals. Liefman² proved that during the hay-fever period in Germany there is more than enough pollen in the air to account for the toxic effects on hay-fever patients, his researches thus confirming the earlier ideas of Blackley. He has shown also that on days when hay-fever patients suffer greatly there is more pollen in the air than on days when they are relatively free from symptoms.

Dunbar found on mixing the toxalbumin with the serum of animals which had been previously treated with pollen or the extracted poison that the former was rendered innocuous. Unlike diphtheria antitoxin, the hay-fever serum is not to be used subcutaneously, for subcutaneous injections give rise to unpleasant symptoms—itching, swelling and erythema. Experiments have shown that the local application of the serum to the irritated mucous membrane is more effective than its introduction hypodermically.

The serum has been patented under the name of "pollantin" in Germany, England and the United States. To the liquid serum 1/4 per cent. phenol is added, but this amount is not sufficient to delay bacterial growth, if the bottle has been opened and contaminated. Some people, too, have an idiosyncrasy for phenol and can not bear the application even of minute amounts. Instead of the pollantin liquid the substance is now supplied preferably in the form of pollantin powder, the latter being obtained by evaporating the serum to dryness, powdering it finely and mixing it with a little milk sugar. It is maintained that the substance is entirely harmless even in large doses. A single dose, it is emphasized, does not completely immunize the patient against all further attacks. On the contrary, during the hay-fever season the treatment has to be resorted to frequently, best every morning just before rising. Used in this way, it will, it is said, keep a patient free from attacks for several hours, sometimes for the whole day, even when he spends it in the open air.

This new method of treatment of hay fever originating in laboratory experiment, is rapidly being submitted to the test of clinical experience. In this country we have reports from Mayer, McCoy and Somers, and the articles of Bailey, Lockwood, Henderson and Dupuy also deal with the subject. The most complete review of clinical work thus far is that of Lübbert and Prausnitz.³ They have collected some 222 cases of ordinary hay fever and some 63 of the autumnal form, 285 cases in all, which have been treated with the serum. Of the 222 ordinary hay-fever cases, 127 are said to have yielded a favorable result, 71 a partly favorable result, and in 24 the result was negative. That is to say, in 57

1. Dunbar, W. P.: Zur Ursache und spezifischen Heilung des Heufiebers. Münch. n. Berl., 1903; see also Deutsche med. Woch., 1903, No. 9, and Berl. klin. Woch., 1903, Nos. 24-26, 28.

per cent. of the cases marked relief was obtained; in 32 per cent. the relief was more or less marked and in 11 per cent. no benefit was derived. Of the 63 cases of autumnal catarrh 44 (or 70 per cent.) yielded positive results, 12 (or 19 per cent.) partly positive, and 7 (or 11 per cent.) negative. In view of the short time which has elapsed since this attempt at rational therapy has been begun, and considering the difficulty which physicians have in such a treatment in inducing patients to follow directions strictly, the results thus far gained must be regarded as favorable.

We think, however, that the whole question of the value of the treatment is as yet in the experimental stage. In a disease like hay fever, where at least in a large majority of the cases an oversensitive nervous system plays an important rôle, the greatest care must be exercised, especially in the judgment of the effects of therapeutic measures. We must await a much larger mass of clinical evidence before we pronounce positively in the matter. The disease is so widespread, however, and measures which are purely suggestive are; as a rule, so short-lived, that we can be tolerably sure in the course of the next few summers of arriving at definite conclusions regarding the efficacy of the serum treatment.

A word as to the commercial exploitation of the serum. Pollantin, as has been mentioned above, has been patented. Very vigorous business methods are being utilized to sell it. In Germany medical men think it no breach of medical ethics to patent a new remedy. Physicians feel differently about these matters in America. Should the serum treatment ultimately prove to be positively efficacious in the treatment of hay fever, it is highly desirable that it be furnished to the great host of sufferers at a nominal cost and not for purely commercial gain.

THE DECREASING BIRTH RATE IN NEW SOUTH WALES.

In view of the fact that the birth rate of New South Wales was apparently steadily declining, a royal commission was appointed to investigate the causes. This commission consisted of thirteen members, six of whom were physicians, with Dr. Charles Kinnaird Mackellar as president.

The first volume of the report of this commission has just been received. It contains the general considerations and conclusions and the testimony of the statistical authorities. The special medical testimony of physicians will appear in the forthcoming second volume. The commission found that the decline of the birth rate is a very serious fact in New South Wales, and concluded that the diminution of fertility and fecundity in recent years is due to the deliberate prevention of conception and the destruction of embryonic life and the pathologic consequences following on the means used and the practices involved therein. There is no evidence of any increase of physiologic sterility in the colony nor have they been able to trace the decline of the birth rate to

any well-defined economic cause. Nevertheless, the commission report that they can not overlook the fact that restrictive regulations of trade designed to abolish competition and interfering with continuity of employment, rendering the income of those employed more precarious, indirectly discourage the existence of large families and the natural increase of the population.

The fall of the birth rate, which had been gradual between the years 1867 and 1887, was suddenly accelerated in 1888 and 1889, and has been marked since then, the fall reaching a total of 30 per cent. or more in the last twenty years. New South Wales alone, it is estimated, has lost since 1864 280,000 citizens from this cause alone, and Australia nearly 1,000,000. There is also a certain diminution in the natural increase of population in New South Wales, though the death rate there is less than in some other countries. In 1872 the natural increase was 24 per thousand; in 1902 it was only 15.22, a drop of 36 per cent. from 1872. With these figures, the time is not far ahead when the population will be actually on the decrease, provided present tendencies continue. The report goes at length into the questions of illegitimacy and other subjects bearing on the matter in hand, but space is insufficient to cover all these points. While the ratio of decrease of birth rate is still less in New South Wales than in some other lands, the rapidly progressing diminution is a very alarming fact. The defective birth rate is aggravated, moreover, to some extent in its effects by an excessive infant mortality.

In their conclusions the commission dwell more particularly on the moral effects on the community of the condition of affairs revealed. If Australia is to be a great nation and a power in the world, the present tendencies must be checked. Even if its present natural rate of increase is maintained, it will be forty-six and a half years before Australia will have doubled its population of 3,275,000; a poor prospect, indeed, when we consider the different state of affairs existing in its rivals for the supremacy of the western Pacific Ocean. The possibility of maintaining a "white Australia" is seriously imperiled by the present state of affairs. The commission say: "In whatever way the waning birth rate of New South Wales is viewed, whether in its effects on the health, character or social worth of individuals; on the value of the family as the basis of national life; on the quality and dignity of civic life; on the character of the people; on their social, moral and economic progress; on their national aims and aspirations; on their capacity to survive in the rivalry of nations; whether it is viewed in the light of history or of science, it is seen as a grave disorder, sapping the vitals of a new people, dispelling its hopes, blighting its prospects and threatening its continuance." They conclude with an appeal to the patriotism of the colonies to prevent the loss of the fair heritage of the British race in the southern seas which

is foretold by present conditions. The volume is a valuable contribution to the literature of a problem that is coming to the fore in other civilized countries than New South Wales.

BERI-BERI.

The appearance of beri-beri (beri is Singhalese for weakness) among the soldiers now engaged in bloody conflict in the far east calls our attention to a hitherto little noticed and, therefore, so to speak, new terror of war over which medical science as yet has little or no power. Beri-beri (or kakke, as it is called in Japan) is the pest par excellence of the Malay archipelago and peninsula, but given certain special conditions, it may occur apparently almost anywhere, as witness its occurrence among Newfoundland fishermen and in British prisons. It is widely disseminated in many tropical countries, including the Philippine Islands.

From the clinical and anatomic points of view, beri-beri may be described briefly as a peripheral neuritis, with changes in the central nervous system. Naturally, the disease may manifest itself in varying degrees of intensity; its manifestations will also vary greatly in the different periods of its evolution. For these reasons various classifications have been proposed, and of these the one by Hamilton Wright recommends itself especially for its comprehensiveness and simplicity. Wright separates beri-beri into three principal forms, namely: 1. Acute pernicious beri-beri. 2. Acute beri-beri (running a course of from three to six weeks, leaving the patient paralyzed). 3. Beri-beri residual paralysis.

Any one at all familiar with the clinical picture of acute peripheral neuritis and its consequences can readily reconstruct in his own mind the general clinical aspects of the second and third forms outlined in this grouping. Acute pernicious beri-beri—the first form—may terminate life quickly. Its main symptoms are great dyspnea, cyanosis and cardiac failure, symptoms that indicate that in this form the process attacks specially the nerves concerned in respiration and cardiac function. In some forms of acute beri-beri there may be a pronounced anasarca (wet beri-beri), and pernicious symptoms may arise in the course of such cases even when the progress appears satisfactory. Hence the prognosis in the acute forms of this disease, especially when associated with edema, is uncertain. So far as known, the course of the disease can not be materially modified by treatment. The gross appearances presented by the organs after death are not strikingly or positively characteristic of any single disease, so that, without the knowledge of the clinical history, it is not likely that a correct diagnosis of acute cases would be made postmortem without microscopic study of the nervous system, the central, and especially, of course, the peripheral. There may be more or less edema for which it might be difficult to account in the presence of normal kidneys and normal though dilated heart. Hamilton

Wright lays great stress on the presence of congestion and erosion of the pyloric end of the stomach and of the duodenum, which are said to be constant in the acutely pernicious cases. Wright regards these lesions as the result of the localization of the unknown microbial cause of the disease, which here develops a readily absorbable and powerful neurotoxic substance.

Wright's interesting and plausible hypothesis as to the etiology of beri-beri was discussed in these columns of THE JOURNAL May 21, 1904. The hypothetical organism does not seem to have been described as yet, and it is sincerely to be hoped that this new theory does not only add one more to the long list of theories already advanced to explain the pathogenesis of this disease, which Manson says has been attributed to all sorts of causes: "to damaged fish, damaged grain; to rain, wind, heat, cold; to rheumatism, and many other things, including malaria." Still, in view of the large number of poisonous substances known to be capable of producing multiple neuritis and central nervous changes—lead, arsenic, copper, zinc, ergotin, alcohol, phosphorus, carbonic oxid and sulphid, chick-pea, bad maize, and the products of many microbial infectious agents as seen in the cases of primary and secondary infectious neuritis—it would hardly be surprising if it turned out that the term beri-beri as now used includes a variety of processes due to different causes. Certainly nervous tissues have a remarkable affinity for many harmful substances of diverse nature and origin.

The reactions between the components of nervous tissues and such substances now demand investigation, especially from the chemical side, if we are to understand better the mechanisms that lead to such grave disturbances in the structure and function of the nervous system. All additions to our exact knowledge of neuritis of whatever cause will help to unravel the difficult problems connected with the etiology, treatment and prevention of beri-beri. At the present time progress in these directions appears to hinge largely on the determination of the question whether the disease is microbial in nature or due to faulty hygiene and bad food.

COPPER SULPHATE AND WATER PURIFICATION.

The widespread current interest in the question regarding the effect of copper sulphate on public water supplies dates back to some important observations published last May by Moore and Kellerman in a bulletin of the Department of Agriculture.¹ The experiments, having in view the application of this salt (CuSO_4) to the water of reservoirs, appear to have been undertaken in the first instance with the aim of discovering a means of preventing the unpleasant odors and tastes due to the growth of algae in stored water. A possible extension of this method to the destruction of pathogenic germs was considered by the writers of this bulletin incidental to their main investigation. The wide publicity given

1. Bureau of Plant Industry, Bulletin 64.

to the authors' experiments on the action of copper sulphate on pathogenic microbes appears not to have been foreseen by them. It is certainly true that some have drawn unexpected conclusions from the data presented in the bulletin mentioned. We are very glad to publish in this issue a letter² from the secretary of the Illinois State Board of Health concerning experiments which show the germicidal power of copper receptacles to have been greatly overestimated—at least in the popular press.

As regards the successful inhibition of algal growth by minute quantities of copper sulphate (0.25 parts per million), there can be no question. The first reservoir treated by this method was one at Winchester, Ky., which was grievously infested with the alga *Anabana*, a well-known pest of water-works. The treatment there applied resulted in freeing the reservoir from the cause of offense in the most satisfactory manner. At Elmira, N. Y.; Cambridge, N. Y.; Butte, Mont., and Belchertown, Mass., a similar method of treatment has been practiced with what is thought to be eminent success. The cost of application of the salt is very low, and where the local conditions are carefully studied and the amount of copper sulphate added is in suitable proportion, there can be little doubt of the efficacy of the treatment. The highly toxic properties of copper salts and of colloidal copper have long been familiar. Naegeli's observations on the "oligodynamic" action of metallic copper are a well-known biologic classic. More recently Ficker has shown that such effect is perceptible even in dilutions of 1 to 50,000,000, and has brought out the interesting fact that the walls of glass containers once used in experiments of this character are extraordinarily difficult to free from all manifestations of such oligodynamic action.

It is another matter, however, to assume that a cheap and easy means of ridding water from disease germs has been discovered. It must be remembered that laboratory experiments are rarely if ever applicable without further investigation to complex natural conditions. It is well known, for example, that temperature profoundly affects the action of disinfectants, and this seems to be a point to which sufficient consideration has hardly been given in the present instance. The matter of simple inhibition versus destruction is also one calling for careful discrimination. Perhaps more important than all from the practical standpoint of water purification is the fact that the application of copper sulphate to an ordinary surface water leaves the turbidity unaffected, and yet it is well known that the problem of clarification is often one of the most difficult and expensive to solve. On the physiologic side, the evidence regarding the effect on man of the ingestion of small quantities of copper salts is so conflicting, and various investigators differ so vitally in their judgment of this matter, that a definitive conclusion on this issue at the present time seems hardly possible.

All things considered, the enthusiasm manifested in some quarters in favor of copper sulphate as a substitute for sand filtration seems hardly warranted by the facts at hand or by the conservative recommendations in the original publication by the Bureau of Plant Industry. It is worth while to bear in mind the caution of Moore and Kellerman, that "it would be a matter of regret if the method proposed here should ever be regarded as a universal panacea to be used by everyone, regardless of the organism to be eradicated and the condition of the water."

SUCCESS OF PROPHYLACTIC CAMPAIGN AGAINST YELLOW FEVER IN TEXAS.

We made reference last May to the yellow-fever situation on the Texas-Mexican border, and to the good work which was being done by the Public Health and Marine-Hospital Service, co-operating with the state health authorities of Texas and with the health authorities of Mexico, in preventing the recrudescence of the fever.

The usually accepted season for the appearance of yellow fever having passed, it is gratifying to note that there have been no cases of yellow fever along the Rio Grande during the present year. This result is in striking contrast with the history of epidemics of yellow fever in preceding years, when a greater or less number of cases denominated sporadic, for want of a better term, have always appeared in years succeeding an epidemic outbreak. The outcome is a cause for congratulation, but required much care and labor. For more than six weeks a daily inspection of every house in Laredo was made, and all cases of a febrile nature, due to no matter what cause, were screened from the access of mosquitoes. With the co-operation of the local authorities, who passed ordinances to make the work effective, a vigorous campaign was entered into for the elimination of all mosquito-breeding places, destruction of mosquitoes, and for the fumigation of all premises in which yellow fever or suspected yellow fever had occurred the year before. Sanitary expeditions were made along the railroads radiating from Laredo, and the aid of the state health officer, local health officers, railroad corporations and the communities themselves, was enlisted in a campaign of mosquito destruction, the prevention of mosquito breeding and the fumigation of buildings where cases were supposed to have occurred.

Summer having passed, therefore, without the appearance of the disease, so far as known, in any part of Texas, it may fairly be claimed that the efficacy of antimosquito work in the elimination and prevention of yellow fever has been vindicated. Due credit must be given the Mexican authorities for the sympathetic assistance they rendered by instituting like measures in areas and towns in Mexico infected and liable to infection at any time by the introduction of yellow fever from infected seaports in Mexico. There was little difficulty in enlisting the interest of the Superior Board of Health of the Republic of Mexico, and measures of

² See correspondence department on page 1156.

the same kind pursued in Texas were at the same time going on in Mexican seaports and in places and towns in railroad connection with the same. This experience has demonstrated the usefulness and practicability of international agreement on sanitary matters.

MORE DEATHS FROM WOOD ALCOHOL.

The importance of the subject of poisoning by wood alcohol, treated of in the article by Drs. Buller and Wood, which is now appearing in *THE JOURNAL*,¹ receives marked emphasis in the death of twenty-five persons in New York City from drinking whisky made with that poison. All the victims lived in a section known as Stryker's Farms, and had been indulging in a carousal. Samples of liquor were secured by the coroner, and showed the presence of wood alcohol. This poison was also found in the stomachs of some of the victims. A mob attacked a saloon where some of the poisoned whisky was bought, the saloonkeeper is under arrest, and the occurrence has created great indignation and alarm in the districts mentioned. This is the largest number of fatalities from this cause in a single group, and it will certainly give emphasis to the need of adequate restriction in the use of this poison.

HOW THE FRENCH REGARD SURGICAL CARELESSNESS.

A distinguished Paris surgeon is reported, according to the cable dispatches, to be under indictment for homicide, because he inadvertently, it is presumed, left a portion of a broken instrument in the patient's abdomen after an operation. There are many surgeons who have had a like experience, so far as the accident goes, but this is the first case in which we have heard of a criminal indictment following such an event. Civil suits are not unknown. If the French law is such as to make such oversights criminal carelessness, it will be a special inducement to greater care against the occurrence. Of course, conviction in such a case is by no means a certainty. There are others beside the surgeon who should share or take the responsibility. The engrossing nature of a capital operation, requiring almost every faculty to be at special attention to the operative details, and the absolute necessity in many cases of trusting to assistants, such as can be had, should be very seriously considered. A little inattention on the part of the surgeon to the details of his own manipulation or its diversion to matters that have to be left to others, may be as dangerous to human life as the risk of the possibility of the inattention on the part of the subordinates to the details of counting sponges, artery forceps, etc. Surgery is a perilous business at the best, and there is nothing truer than the old saw that accidents will sometimes happen in the best-regulated families.

THE PSYCHOLOGY OF CHESS.

While the average chess player makes his moves with comparatively little foresight, in the high science of

chess, as played by experts each move for several moves ahead on both sides, including all the contingencies, is carefully thought out. Success depends on the perfection with which this is done, and the method is illustrated to some extent in a recent article in *Everybody's Magazine*, where the performances of the champion chess player, Pillsbury, in so-called blindfold chess, are discussed. Blindfold chess playing is playing without seeing the board, and requires an exercise of visual memory that is almost inconceivable. Pillsbury, it is said, has thus played sixteen simultaneous games with expert players, winning twelve, drawing three and losing only one. He was compelled to remember the position of each of the thirty-two chessmen on each of the sixteen boards. The enormity of the mental task may be suggested by the fact that on one board alone many thousands of different culminations are possible as the result of the first three or four moves. Pillsbury, of course, has a certain system and is permitted to choose his own openings, but this does very little to diminish the astounding character of the performance. It is probable that high-class chess playing is largely, if not exclusively, a matter of visualization, and this involves a kind and degree of mental strain that can not be considered other than abnormal. It is, in fact, practically an exercise in hallucinations—external projections of visual energies mentally conceived—and only possible with a probable special development of the visualizing centers and apparatus of the brain. This implies a certain abnormality, and unless the person is just so constituted and specially resistant to the possible influences, it may work damage to the general mentality. Great chess players, Morphy, for example, and others beside him, have broken down mentally to a certain extent, and this may be, perhaps, the cause. Others who have possessed this faculty of reproducing visual images have likewise shown the evil effects of its overexercise. The English painter, Blake, was a notable example. His power of reproducing the visual images of his sitters developed in time to a hallucinatory insanity. While the usefulness of the accomplishment in many walks of life is self-evident, its abuse may work serious damage, as in the cases mentioned. It is possible, indeed, to suppose that some chess players may be able to play chess well without this power, but it would be impossible in blindfold playing. Mathematicians do not seem to particularly possess it above other men, and the mathematical faculties are probably the purest intellectual ones that we possess. It may be that the visualization power commonly employed checks development in other directions. Galton, in his "Inquiries on Human Faculty," quotes second-hand the dictum of the great Napoleon that no man who habitually formed a picture (tableau) was fit to command. This may be an extreme view. It is referred to here simply as the opinion of one whose words have weight. Chess being, therefore, a game that more than others requires the exercise of this faculty, is an excellent amusement, but may be carried too far, and as some examples seem to show, may have possible dangers even for its masters. It would be interesting to know the real cerebral development, especially of the occipital lobes, of the great masters of chess.

1. THE JOURNAL A. M. A., Oct. 1, 8, 15, 22 and 29, 1904.

THE PREVENTION OF MALARIA.

Several interesting papers were read and discussed before the section on tropical medicine at the late meeting of the British Medical Association bearing on the question of the prophylaxis of malaria. The special point of interest and criticism was the reported ill success of the fight against malaria at a British military station in India. The conclusion reached by the reporters, Drs. Christophers and James, of the Indian medical service, was that mosquito brigades and similar methods of destroying malarial infection were practically futile or very doubtful in their results. The general opinion, however, seemed to be that when sufficiently carried out such measures have in many localities proved to be effective. Havana and Ismailia were quoted instances. It was also pointed out that the experiment of Mian Mir was carried out on entirely too limited a scale and under special conditions that were unfavorable. In fact, the experience of many years long prior to any organized efforts against malaria is, perhaps, almost as valuable in settling the question as the recent brilliant local results in Havana and elsewhere. There are large sections in the Mississippi valley where malaria was formerly very prevalent, but where it has almost, if not entirely, disappeared since cultivation and drainage have become more general. On the other hand, especially in tropical or warm regions, a careful study of the malaria-bearing mosquitoes should accompany or precede any extensive prophylactic measures. If, for example, it is found, as claimed in some Indian localities, that the malaria-bearing mosquito breeds only in running water, the petrozing of the breeding places would more or less be ineffective. Irrigation is another very serious problem. If it is done away with in India or China, the result is famine. With it, we have malaria. Six hundred years ago the abolition of rice culture was ordered in certain sections of Spain on account of malaria, which was observed to be its constant attendant, as quoted by Dr. Crombie in the discussion. The dilemma is not a satisfactory one, and it is possible that in certain regions where irrigation is necessary malaria will be more or less persistent, but even there it would seem probable that the evil could be modified, if not abolished. If we could prevent the introduction of the germs by the human species, the mosquito might be comparatively innocuous. Recent experience in Massachusetts points this way. The anopheles must have existed there, but it was only after the introduction of the genus by Italian laborers that malaria became prevalent. Malaria is a contagious disease, and the recognition of this fact is the most hopeful phase of the question of its prevention. The other prophylactic methods beside larva-killing, such as isolation of cases, the free use of quinin, the use of door and window guards, are none of them to be neglected. They are all essential, but the main part of the war against malaria will have to be an offensive one against the malaria-bearing insects. Mosquitoes, perhaps, have their utility in the order of nature, but there is no reason why, under like conditions, one locality may not dispense with their presence as well as another. Even the so-called harmless ones are a nuisance, and there is no reason why it should not be abated.

THE OHIO HOSPITAL FOR EPILEPTICS.

The thirteenth annual report of the Ohio Hospital for Epileptics is just out, and contains matter of general interest. Under the present superintendent the institution has progressed along several lines, as indicated by the report of the board of trustees. The original institution, while prettily situated in the valley of the Ohio River at Gallipolis, was little better from an architectural and institutional point of view than a series of unlovely barracks, closely grouped, of severe lines and cheerless. The so-called "cottages" were designed for from fifty to seventy-five patients each, admitted of little or no clinical segregation of cases, and were much too large for discipline. In fact, the original plan of the institution apparently was the creating of a special almshouse for the housing of the state's epileptics. Numerous small cottages are being built on modern lines, admirably adapted to the care, treatment and study of differing stages of the disease and of patients of divergent social states. The patients now have systematic outdoor and indoor sports and exercises, as well as more outdoor labor for the male patients. The rigid enforcement of proper discipline on patients and attendants has brought the institution to a much higher degree of efficiency, but, of course, has brought the originator of this improvement the opposition of the political sponsors of some of the worthless employes who were allowed to depart. The discharges necessary to obtain discipline have been made the pretext for numerous public attacks on the superintendent, and also for much political intrigue looking to his removal and the substitution in his place of a man who will better suit the politicians who have political debts to pay. This institution is one of the few in the country that seems to be conducted entirely apart from political considerations and solely for the benefit of the unfortunate inmates. Word reaches us that the medical profession of Ohio is aroused to the situation, and is closely watching the trend of events. No doubt the Ohio physicians can be trusted to see that full justice is done to Dr. Ohlmacher, and in this they will have the active sympathy of medical men everywhere, who feel intensely the paramount necessity of keeping out of "politics" and out of the game of "graft" at least every institution designed to care for the unfortunate helpless wards of the state. The superintendent's report contains much interesting matter under the heads of "Statistics of Population," "Medical Statistics," "Occupation and Amusements," "The Scientific Work," "Scientific Papers Issued from the Pathologic Laboratory of the Hospital for Epileptics During the Year 1903," etc. All these deserve further review than space here permits. During the year of report an increased amount of pathologic work was accomplished and recorded. This hospital remains one of the foremost in the United States for its contribution to scientific literature, and is one of the few state institutions at which scientific work is systematically pursued. Of course, the figures regarding the cure of cases are not imposing, but the report shows that much has been and can be done to ameliorate the condition of these most unfortunate of mankind. The relentless progress of so many of the patients after

epileptic dementia is once established is graphically portrayed. The whole report makes a most creditable document.

Medical News.

ARKANSAS.

College to Open.—The medical department of the University of Arkansas, Little Rock, opens for the year on October 17.

Missing Physician Returns.—Dr. Richard G. Lightle, announced as having been burned to death several months ago, and later accused of an attempt to defraud a life insurance company, has returned to Searcy.

Smallpox is said to be epidemic at Dee, Craighead County, where 21 cases have been reported.—The city physician of Argenta, Dr. Homer L. White, reports that during the recent visitation 50 cases of smallpox occurred with 9 deaths, and that the total expense to the city was \$1,701.82, or \$29.34 per capita.

COLORADO.

Tent City for Consumptives.—A tented city, built up under the auspices of the Jewish Consumptives' Relief Society, on a 20-acre tract near Denver, where consumptives, regardless of creed or financial condition, will be housed and treated, was dedicated September 4.

Must File Certificates.—Dr. Alexander C. Magruder, Cripple Creek, the newly-appointed state medical examiner for Teller County, has notified all practicing physicians to file their certificates with the county clerk, in order that he may ascertain the names of the unqualified.

Petition for Rehearing.—In the case of Dr. L. Carrie Johnson, Pueblo, sentenced to imprisonment for 15 years in the state penitentiary for performing a criminal operation, after the Supreme Court had refused to grant a writ of supersedeas, her attorneys have petitioned for a rehearing.

Deaths and Diseases.—During August 809 deaths occurred in the state, equivalent to an annual rate of 16.34. Of these 31 died from typhoid fever, 8 from diphtheria and one from scarlet fever. During the month 82 cases of diphtheria, 26 of scarlet fever, 31 of smallpox and 250 of typhoid were reported, an increase in diphtheria and typhoid fever and a decrease in scarlet fever and smallpox as compared with the previous month.

GEORGIA.

Will Build.—The Atlanta College of Physicians and Surgeons is to erect new college buildings at a cost of \$100,000.

College Open.—The Medical College of Georgia, Augusta, opened for the seventy-fourth year, October 3, with the largest class ever matriculated. Dr. DeSaussure Ford, the dean, delivered the opening address.

Stabbed in Fight.—Dr. John M. Spence, Waresboro, representative from Ware County, was stabbed and seriously wounded September 23, by a man whom he accused of having circulated false and slanderous reports about him.

Staff Changes.—Dr. R. H. Thigpen has resigned as head interne at the City Hospital, Augusta, and has been succeeded by Dr. J. M. Sigmen. Dr. J. B. Carter, Jr., has been advanced to junior interne and Dr. Asbury Stall has been made ambulance surgeon.

ILLINOIS.

Slayer Adjudged Insane.—George Wilkinson, who shot and killed Dr. Samuel L. Chapin of Saybrook, August 13, was adjudged insane October 3 and ordered to be committed to an asylum.

Smallpox.—Chatsworth reports five cases of mild type.—A case is reported from Charleston.—Shotgun quarantine was unsuccessfully attempted by a town lying between Belleville and East St. Louis.

Personal.—Dr. and Mrs. James W. Van Derslice, Oak Park, have returned from Europe.—Dr. and Mrs. H. Schafer, Freeport, have returned after a year in Europe.—Dr. William E. McClelland, Beason, is seriously ill with appendicitis.—Dr. Harry H. Whitten, Peoria, started, October 1, for Europe.

Chicago.

Popular Lectures Inaugurated.—The first of the series of popular lectures under the auspices of the Chicago Medical Society was delivered October 6 by Dr. Norman Bridge, on "Tuberculosis."

Personal.—Dr. Ralph R. Campbell has returned from a vacation trip to Johnstown, Pa., and Canada.—Drs. David F. Monash and E. J. Doering have returned from their European trip.

Fined for Fraud.—Dr. William S. Maharg, formerly city chemist, was arrested, together with four women, who garbed as sisters of charity, secured contributions from an alleged home for consumptives claimed to be operated by Dr. Maharg at an empty building on North Clark Street called the "Nazarene Mission." He was fined \$100 and the women were recommended.

The Week's Mortality.—During the week ending October 8 410 deaths from all causes were reported, being equivalent to an annual death rate of 11.10 a thousand. Acute intestinal diseases caused 62 deaths; apoplexy, 7; nephritis, 26; bronchitis, 6; consumption, 49; cancer, 25; convulsions, 9; diphtheria, 6; heart disease, 30; nervous diseases, 20; pneumonia, 27; typhoid fever, 11; violence, 22; whooping cough, 3, and all other causes, 99.

Nephritis in Chicago.—The bulletin of the Health Department for the week ending Oct. 8, 1904, states: "It is not reassuring to learn that nearly 6 per cent. of Chicago's male population in early manhood is afflicted with Bright's disease; and yet such is the inference warranted by the results of the examination made during the week by department physicians of 489 applicants for appointment to the city fire department. Of this number 29 (or 5.9 per cent.) were rejected for kidney trouble. When it is reflected that the principal cause of such trouble is exposure to cold and wet after a drinking bout, the figures do not speak well for the habits of Chicago's young men. The first death from Bright's disease in Chicago was recorded in May, 1864, but it was not until 1868 that deaths from the malady were reported in sufficient number to compute rates. In the annual report of the commissioner for 1894 it was shown that the rate had increased 84 per cent. in twenty years, that is in the decade 1885-1894, compared with that of the decade 1868-1877, and it was then said—speaking of the group of steadily increasing diseases—that: 'Sanitary administration can do little with these diseases or with the increase of Bright's disease and of diseases of the nervous system. The high tension of modern life—nowhere higher than here in Chicago—with its besetting temptations to irregular habits and to excesses of various kinds, and its great strain on the most complex and most important mechanism of life—is something that the sanitarian can but recognize and regret; its relief and remedy will come only through saner views and modes of life.' 'Saner views and modes of life' have not yet arrived, and the death rate of Bright's disease has increased upward of another 80 per cent. in less than a decade—that is, from 5 in the 10,000 of population in 1894 to 9.09 in 1903, or \$1.8 per cent in nine years. The apostle of 'The Simple Life' has not arrived in this country any too soon. Chicago needs him."

INDIANA.

Unlicensed Practitioner Fined.—Dr. George W. De Camp, Terre Haute, arrested on the charge of practicing medicine without a county license, was fined \$25 and costs, on September 24.

School Inspectors Appointed.—The Indianapolis Health Board met September 27 and appointed 31 physicians, who will conduct the medical inspection of public and parochial schools and kindergartens.

Inspection of Schools.—A plan has been formulated by the Indianapolis Board of Health whereby the city is to be divided into 16 districts, and the children in each school in each district will be inspected at least twice a week.

Barrel of Alcohol Under Hospital.—An explosion of alcohol in the basement of the Marion Hospital, September 26, resulted in the fatal burning of a careless attendant, serious burns about the head and face to Dr. Albert Davis, superintendent of the hospital, and a panic among the patients. Little damage was done by the fire.

Personal.—Dr. Lee F. Hunt, Anderson, was recently operated on for appendicitis in Indianapolis.—Dr. Seymour C. Wilcox, New Albany, celebrated his eighty-sixth birthday an-

anniversary September 20.—Dr. Whitefield Bowers, Michigan City, while engaged in target practice, September 28, was seriously burned by the premature explosion of a cartridge.—Dr. Augustus F. Tulley, Brazil, was painfully injured in a runaway accident, September 26.—Dr. W. R. Cunningham, Bonrbon, has started for China, where he will establish and have charge of a hospital under the auspices of the Presbyterian mission board.

KENTUCKY.

City Hospital for Paducah.—After a third of a century Paducah is at last assured of a modern hospital to cost \$25,000, which is now in course of construction on a high bluff at the confluence of the Ohio and Tennessee rivers.

Personal.—Dr. W. L. Montgomery, Lockport, in an altercation with the town marshal, was stabbed in the hand, arm and body by that officer, who was held to the grand jury.—Dr. William E. Truesdell, Newport, fell while alighting from a car, breaking a finger and cutting his leg.—Dr. John M. Chambers, Independence, has been critically ill from the effects of a fall from a horse.

MARYLAND.

Baltimore.

Personal.—Dr. T. C. Gilchrist has returned from Europe.—Dr. H. B. Jacobs is back from summering at Newport.—Dr. Charles O'Donovan was elected chairman of the section on clinical medicine and surgery of the Baltimore City Medical Society, under the new arrangement of the Baltimore branch of the Medico-Chirurgical Faculty of Maryland.—Dr. H. Warren Buckler has been appointed a member of the tuberculosis commission.

New Surgical Building Open.—The event of the week was the opening of the new surgical building and clinical amphitheater of the Johns Hopkins Hospital, October 5. Addresses were made by Judge Henry D. Harlan, president of the board of trustees of the hospital; Prof. T. Clifford Allbutt of Cambridge University, England; Professor Louis A. Stimpson of Cornell University; Dr. W. S. Halstead, Dr. A. Jacobi of New York, and ex-President Daniel C. Gilman. In the absence of Dr. Henry M. Hurd, superintendent, Dr. William H. Welch presided. A luncheon was served, after which the tablet to Dr. Lazer was unveiled, Dr. William Osler presiding. Speeches were made by Drs. William Osler, W. S. Thayer and John J. Carroll of the Army. The surgical building cost \$150,000, is four stories high and in general appearance conforms with the buildings of the hospital already erected. At night the medical school was opened with an address by Professor Allbutt.

Wants Embryos.—Prof. Franklin P. Mall has sent out a circular to the physicians of Baltimore soliciting donations of embryos, especially those of the first three months. The embryologic collection of the anatomic laboratory of the Johns Hopkins University owes its origin to the interest of the local profession. All the specimens are carefully preserved and catalogued and the good ones cut into serial sections. It is now one of the best collections, if not the best collection in existence, is used extensively for research and is often studied by advanced students of anatomy. From time to time either sections or whole series are sent to different parts of the country, and sometimes to Europe, which shows that these valuable specimens are appreciated and used by investigators in other laboratories. While the series are of the greatest scientific value, there are many stages still missing. Specimens are to be placed at once and without handling in a 10 per cent. solution of formalin or in the strongest alcohol and sent to the laboratory by express or messenger, the laboratory paying all expense.

MASSACHUSETTS.

Street Car Ventilation.—Cambridge has resumed its efforts through the Board of Health to secure purer air in its closed street cars.

Extermination of Mosquitoes.—Brookline has conducted a successful warfare on the mosquitoes this past summer; every cesspool was visited eight times and thoroughly petzolezed; pools have been filled or drained.

Enlarged Emergency Hospital.—On October 1 the remodeled Emergency Hospital opened, as an emergency and general hospital. The new building is four stories in height and contains new optical and dental departments and a surgical supply room in addition to the usual wards, consultation rooms, etc.

Leprosy in Chelsea.—A Portuguese sailor from Providence, 32 years old, is a patient at the Marine Hospital in Chelsea, afflicted with leprosy, of which he says all the other members of his family have died and from which he has suffered for the last nine years.

English Health Officer in Boston.—Dr. Francis E. Freemantle, county health officer of Hertfordshire, visited Boston, in the course of a tour around the world, and inspected the contagious disease hospital, the vaccine and antitoxin plants, the sewerage outlet, storage basin, pumping station and the Lawrence filtration beds.

New Hospital Buildings.—The three new buildings erected for the Boston Insane Hospital, Dorchester, were opened for public inspection September 22. The buildings have been constructed at a cost of \$350,000 to carry out the idea of classifying patients. There are at present 611 patients in the hospital, many of whom will be transferred to the new buildings.

Meeting of Boards of Health.—The quarterly meeting of the Association of Massachusetts Boards of Health will be held at Mt. Tom, Oct. 13, 1904, the Holyoke Board of Health being hosts. Papers will be read descriptive of the Mt. Tom Reservation, on the new plant for the preparation of the supply of free vaccine for the state, on the results of Boston's examination of bacteria in milk, and in regard to the recent epidemic of typhoid fever in Boston. Of the last disease 54 cases were reported for the week ending October 8, an increase of 90 per cent. over last year.

Thousands for Hospitals.—Mrs. Sarah E. Potter of Boston, in her will, made the following bequests to hospitals and similar charities: Kindergarten for the Blind, \$100,000; Boston Medical Library, \$150,000; Boston Home for Incurables, \$50,000; Hospital Cottages for Children, Baldwinville, \$50,000; Free Hospital for Women, Brookline, \$50,000; St. Luke's Hospital, New Bedford, \$30,000; Convalescent Home of the Children's Hospital, \$25,000; New England Peabody Home for Crippled Children, \$25,000; the Children's Hospital, Boston, \$25,000; Massachusetts Charitable Eye and Ear Infirmary, \$25,000; Boston Floating Hospital, \$20,000; West End Nursery and Infants' Hospital, \$10,000; New England Hospital for Women and Children, \$10,000; St. Luke's Home for Convalescents, Roxbury, \$10,000; Industrial School for Crippled and Deformed Children, \$10,000; the Consumptives' Home, Boston, \$10,000; Sharon Sanatorium, \$10,000; Boston Lying-in Hospital, \$5,000, and Children's Island Sanatorium, Salem Harbor, \$5,000.

Boston.

Vital Statistics for Boston.—For the nine months ending September 30 there were reported to the Boston Board of Health 8,186 deaths; 2,541 were under 5 years and 1,805 less than 1 year old. During July, August and September there were 1,032 deaths under 5 years, and of these 809 were under one, while the total for that three months was 2,625. In the nine months there were reported 3,566 cases of measles, with 78 deaths; 1,920 cases of diphtheria, with 153 deaths; 1,618 cases of consumption, with 986 deaths; 885 cases of typhoid fever, 77 deaths; 733 cases of scarlet fever, 35 deaths, and 978 deaths from pneumonia.

MICHIGAN.

Personal.—Dr. Ovidus A. Griffin, Ann Arbor, has returned from Europe.—Dr. J. A. Cameron, Pickford, has disposed of his practice and expects to go abroad.

Michigan College Opens.—The Michigan College of Medicine and Surgery, Detroit, opened for its fall term, September 21, with an illustrated lecture by Dr. Heneage Gibbs, and addresses by other members of the faculty.

Comparative Prevalence of Disease.—For the month of September, compared with the average for the month in the ten years, 1894-1903, smallpox and puerperal fever were more than usually prevalent; and dysentery, intermittent fever, pleuritis, remittent fever, erysipelas, whooping cough, pneumonia, meningitis, measles and inflammation of brain less than usually prevalent.

The Most Dangerous Communicable Diseases.—Meningitis was reported present in Michigan during September at 8 places, whooping cough at 17 places, measles at 28 places, pneumonia at 33 places, diphtheria at 68 places, smallpox at 69 places, scarlet fever at 73 places, typhoid fever at 196 places, and consumption at 294 places. Meningitis was reported present at 1 place more, whooping cough at 7 places less, measles at 10 places less, pneumonia at 7 places more,

diphtheria at 2 places more, smallpox at 37 places less, scarlet fever at 1 place less, typhoid fever at 35 places more, and consumption at 9 places more, in September, when compared with the preceding month.

NEBRASKA.

South Omaha Hospital.—Beginning September 1, South Omaha has agreed to make a monthly appropriation of \$100 to the South Omaha Hospital Association.

Personal.—Dr. Carleton S. Shepard, Omaha, has been seriously ill with appendicitis.—Dr. Ray G. Pheasant, Osceola, has gone to Europe and expects to be away for two years.

Jonas Convalescent.—Dr. A. F. Jonas, Omaha, who was operated on last December for gallstone disease, and was again taken ill in June, the symptoms becoming more severe until July 20, when a calculus was removed from the common duct, writes that after a severe and tedious convalescence due to infection of the bile passages, he is now able to do some work. He intends to start for Germany some time this month, to remain three or four months.

NEW YORK.

Warning.—The profession should be warned of a man claiming to be a German physician in distress in this country, who is visiting physicians soliciting funds.

Jamestown's Water Good.—Dr. W. G. Bissell of the Department of Health, who examined Jamestown's water supply at the request of the water commission of that city, reports the water in excellent condition.

Personal.—Dr. Louis A. Weigel of Rochester has been made seriously ill as the result of the frequent use of the Roentgen rays in his practice. He has had two fingers amputated and there has been but little improvement in his condition since the operation.

Guarding New York's Water Supply.—Owing to the prevalence of typhoid in New York City extreme precautions are being taken by the authorities throughout the entire watershed region. The trees and underbrush bordering immediately on the water have been cut down. The sewage system of Mount Kisco, where there has been some typhoid and where there is doubt as to the condition of the sewage system, is being thoroughly investigated. If any danger threatens an appeal will be made to the State Board of Health.

Typhoid Fever at Summer Resorts.—The State Department of Health has issued a bulletin calling attention to the insanitary conditions prevailing at summer hotels and ascribing the epidemic of typhoid fever at Albany to that cause. The bulletin states:

This epidemic and many others investigated in the past have shown that hundreds of persons are infected every summer with typhoid fever at country resorts, and return to the city before the disease manifests itself, thus making the number of cases reported to the city boards of health unusually large in the early fall. The same circumstances doubtless surround the increase of typhoid fever in cities in the spring when many persons return from the resorts of the South.

The department suggests that the proprietors of hotels will doubtless be glad to co-operate with the authorities in making their surroundings more healthful.

Buffalo.

Scarlet Fever Abates.—There are no further cases of scarlet fever arising from the infected certified milk. The state agricultural department is instituting proceedings against Mr. Briggs for having unlawfully sold milk under the label of certified milk.

Free Examination of Sputum.—The Department of Health has issued a circular to physicians asking them to co-operate in instructing the public generally and in availing themselves of the privilege of free examinations of sputum and to report cases of tuberculosis, and in furthering the efforts of the department to control the disposition of sputum and the disinfection of the patient, his clothing and domicile.

New York City.

The Mackay Fair.—This fair, which was held for the benefit of the Nassau Hospital, netted \$10,750. Of this sum \$2,000 is to be used annually for three years in defraying running expenses and the bulk of the remainder is to be added to the endowment fund.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending Oct. 1, 1901, 356 cases of tuberculosis, with 147 deaths; 221 cases of diphtheria, with 31 deaths;

136 cases of typhoid fever, with 18 deaths; 88 cases of scarlet fever, with 1 death; 51 cases of measles, with 5 deaths; 16 cases of variella, and 13 deaths from cerebrospinal meningitis.

Typhoid Cases Below Normal.—Dr. Darlington of the Health Board states that typhoid statistics are better than in the several preceding years. For the first thirty-nine weeks of 1902 2,148 cases were reported; in 1903, 2,565, and in the same number of weeks this year, 2,042. In the thirty-ninth week of 1902 155 cases were reported; in 1903, 119 cases, and this year, 102.

Personal.—Dr. Elizabeth Gillispie of Brooklyn has obtained a verdict of \$1,000 against the Brooklyn Heights Railroad Company in a suit for damages caused by the use of abusive language by one of its conductors.—Drs. Clifford Allbutt of London and B. Laquer of Wiesbaden were guests at the Academy of Medicine, October 6.—Dr. L. Duncan Bulkeley returned from the continent, October 4.

New Anti-Smoke Ordinance.—The Board of Health has amended the section of the sanitary code in regard to the smoke nuisance. The amendment now makes it unlawful to permit smoke to issue from any building "to the detriment or annoyance of any persons not being therein or thereon," or to permit the smoke "to enter any other building or to pollute the air in any street or thoroughfare within the city limits."

OHIO.

School Opens.—The medical department of Western Reserve University, Cleveland, opened October 3 for the year 1904-1905.

Damages in Libel Suit.—In the suit of Mayor John S. Muddell of Oxford against Dr. Robert Harvey Cook of the same city for libel, the offense alleged being that the defendant in a circular charged the plaintiff with untruthfulness and suggested that he could be bought, the jury decided for the plaintiff and gave him a verdict for \$1,400.

Condensed Courses.—The trustees of the Ohio Medical University propose to shorten the academic and medical courses one year, allowing academic students in their senior year to take the first year of work in the medical school, receiving the A.B. degree at the conclusion of the year, and the M.D. degree three years later, thus condensing the combined courses into seven years.

Personal.—Dr. John A. Caldwell has resigned his position as resident physician at the Cincinnati Sanitarium to enter private practice in Cincinnati, and has been succeeded by Dr. Charles B. Rogers, formerly of Massillon State Hospital and late of Fair Oaks Sanitarium.—Dr. Allen B. Thrasher has been elected professor of laryngology of the Medical College of Ohio, Cincinnati.—Dr. Henry R. Mallory, the oldest practitioner in Hamilton, is seriously ill with apoplexy.—Dr. and Mrs. John E. Myers, Springfield, have gone to Cuba for the winter.—Dr. and Mrs. E. D. Burton, Cleveland, celebrated their fiftieth wedding anniversary, October 4.

PENNSYLVANIA.

Diphtheria in Chester.—Diphtheria continues present to an alarming extent in Chester, and by special order of the Board of Health several of the public schools have been closed. The sewage plant of the city is in extremely bad condition and the persistent presence of the disease is attributed to this condition. A malignant type of diphtheria has also made its appearance in Monarch, Schuylkill County. More than a score of children are afflicted with the disease and several deaths have occurred. The public schools have been closed.

Report of State Hospital for the Insane.—According to the twenty-fifth annual report of the State Hospital for the Insane at Norristown, there were treated in the institution during the year just ended 1,175 persons. Seventy-six patients were discharged as cured, 10 as improved and 3 unimproved. There were only 78 deaths during the year. The greatest number of patients in the hospital at one time was 1,196, and the total number was never less than 1,126. Ten of the patients marked as absent from the hospital are escaped criminals. The death rate for the year just closed is lower than for fifteen years previously.

Philadelphia.

Personal.—Dr. and Mrs. S. Lewis Ziegler, Dr. and Mrs. A. O. J. Kelly, and Dr. and Mrs. McCluney Radcliffe have returned from Europe.

Prominent Foreigner Here.—Dr. G. Marcelle of Brussels, and surgeon to the Charity Hospital of that city, visited here and studied the methods in the various hospitals. Dr. Marcelle was a special representative of his country to the St. Louis exposition.

Isolation Ward for University Hospital.—A contract is awarded for the erection of an isolation ward in the rear of the University Hospital. The building will be firebrick, with all the modern appliances for the isolation and treatment of all forms of contagious disease. The cost when completed will be \$13,000.

Officers of New Chestnut Hill Hospital.—The physicians attached to the new Chestnut Hill Hospital are Dr. John H. Musser, in charge of the medical department, and Dr. Harry Wharton, consulting surgeon. The superintendent is Miss Rena Wood, formerly of the Children's Hospital. The president of the institution is Dr. Radcliffe Cheston; vice president, Rev. Dr. J. Andrews Harris; secretary and treasurer, J. Andrews Harris, Jr.

Money for His Alma Mater.—By the terms of the will of Dr. Spencer Norris of the class of 1871, the trustees of the University of Pennsylvania received a sum exceeding \$10,000. This is to be invested and the income resulting therefrom is to be awarded each year to the medical student graduating who shall pass the best final examination. It will be known as the Doctor Spencer Norris prize and the income will amount to about \$400 annually.

Health Report.—The total number of deaths for the week numbered 280, a decrease of 19 from last week, and a decrease of 15 for the corresponding period of last year. This is the lowest weekly death rate recorded in the city for many years. There were 88 new cases of typhoid fever reported, an increase of 8 over the previous week. There were 219 new cases of contagious diseases with 16 deaths reported, as compared with 200 cases and 17 deaths for the previous week. No new cases of smallpox were reported.

Loving Cup for Provost Harrison.—The medical students of the university, to show their appreciation of the efforts of the provost, presented him with a beautiful loving cup on the opening day of the college. The cup is 20 inches high, and is inscribed as follows: "A token of love and esteem in appreciation of his earnest efforts and interest in the advancement of the medical school. This cup is presented to Provost Charles Custis Harrison by the students of the medical department of the University of Pennsylvania, Sept. 30, 1904."

New Italian Hospital Opened.—The Italian Hospital erected in the heart of the Italian colony was opened for the admission of patients October 5. The building is a three-story structure and has an enclosed roof garden to be used for convalescent children, and also for the isolation of tuberculous patients. The staff of the institution at present is as follows: Dr. Ciccone, superintendent; Drs. Bey, De Stefano, Ruffel, Lowenburg, Menah, Hurlong, Craney, Louis Jacobs, H. I. Cathrall and Georgio Sparano. Miss Lida Reeves Neal is the superintendent of nurses.

Fresher Milk for the City.—An effort is being made by Director Martin, chief of the Health Department, to secure a fresher supply of milk for the city. The milk received in the city at the present time is practically two days old before it reaches the consumer. This is due to the fact that the milk shipped from the surrounding counties does not reach the city until the afternoon or the following morning. Efforts are being made to have the evening milk shipped in time to bring the milk here in the early morning, by having the railroad companies arrange a suitable schedule. A change in the Philadelphia milk supply has long been needed.

Work of the Hospitals.—At the Methodist Hospital during the month of September 2,704 visits were made to the dispensary and 76 patients were admitted to the wards. In the Howard Hospital on an average of 60 patients a day were treated, and during the month 1,681 were treated in the different dispensaries. Seventeen hundred and seventy new patients were treated in the Polyclinic Hospital, and with the return visits to the various dispensaries brought the total to 8,456 cases. In the Medico-Chirurgical Hospital 5,692 patients were treated; in the St. Agnes Hospital 594 new and 2,571 old cases were treated; in St. Mary's Hospital 144 patients were admitted to the wards and 3,100 patients were cared for in the different dispensaries.

TEXAS.

State Board of Health.—At a meeting of the Bexar County Medical Society, October 6, the advisability of establishing a state health board was discussed. At present Texas has a health officer, whose duty it is to attend to all matters of quarantine and public health. Many members of the profession, however, believe that a state board of health should be created and that all matters relating to quarantine and public health should be passed on by that board. They also claim that the quarantine now maintained by the state of Texas along the Texas coast and Mexican border should be turned over to the Federal authorities, as the points are national boundary lines and should, therefore, be cared for by the national government. They point out also that state boards of health prevail in Louisiana, Mississippi, Alabama, etc., and that they have been successful in handling quarantine matters. The society passed a resolution, the object of which is to prevent any action by the legislative committee of the state association until it can hear the views of the legislative committees of the 140 county societies. The resolution provides that as medical legislation of vital importance to the public health of the state will probably be asked of the next legislature and the medical profession will be called on to lend its aid in securing such legislation, and that as the profession of the state have a right to be thoroughly enlightened on the measures they are expected to support, the Bexar County Medical Society asks the other component county societies to join in requesting the chairman of the committee on legislation of the state association to call a meeting of the committees on legislation of the county societies and that each county society request of the chairman of the committee on legislation of the state association copies of the bills intended to be presented to the state legislature.

UTAH.

A Travesty on Justice.—J. W. Pidcock of Ogden was fined by Judge J. A. Howell for practicing medicine without a license from the state board of medical examiners. Our reporter says that defendant had a contract with a druggist whose influence tempered justice, and he remarks that such mock justice tends to discourage the efforts of physicians to maintain a better standard of medical fitness.

New Salt Lake Hospital.—Dr. Joseph S. Richards, chief of staff of the new Groves Latter-Day Saints' Hospital, Salt Lake City, has gone east to procure the equipment for the institution. The staff members thus far selected are Drs. Fred Stauffer, Leslie W. Snow, Joseph S. Richards, Samuel H. Allen and Charles F. Wilcox. Up to date the building has cost about \$150,000, of which \$45,000 was a bequest of the late Dr. Groves.

CANADA.

Opening of Medical Department of Toronto University.—On September 4 the medical faculty of Toronto University reopened for the session of 1904-1905. Prof. J. Algernon Temple, in the opening lecture said that the experience of the past year had demonstrated beyond question the wisdom of union of Trinity and Toronto.

McGill University Celebrates Its Seventy-Fifth Birthday.—Principal Peterson delivered the lecture commemorating the seventy-fifth anniversary of the founding of McGill University, and sketched the history of the university and the progress it had made. The lecture served also to honor the anniversary of the birthday of the late Hon. James McGill, its founder.

St. Paul's Hospital, Vancouver, B. C.—The new annex to St. Paul's Hospital, Vancouver, B. C., was opened recently. The new wing is 45 feet wide and 145 feet long, and consists of three stories with a basement. One of the wards was fitted up through the generosity of Dr. Langis of Vancouver. This hospital can now accommodate about 400 patients. The institution is non-sectarian and is open to every race and creed.

General Gift to Toronto General Hospital.—Toronto General Hospital has been given \$100,000 by Mr. Cawthra Mulock of Toronto to erect an out-patient building, so much needed by the institution, and to provide satisfactory clinical teaching for the University School of Medicine. It is not yet decided whether this out-patient department should be erected as a wing to the present hospital or built adjoining the medical building of the university to serve a better purpose for clinical instruction.

Toronto General Hospital.—There were 211 patients in the Toronto General Hospital on Aug. 31, 1904. There were admitted during September 290 patients; births, 13; total in September, 514. Patients discharged in September, 224; died in September, 27; patients in the hospital September 30, not including infants, 244. During the month 1,112 patients were treated in the externe departments. Two hundred and thirty-one accident cases received first aid at the emergency branch of the hospital. Of the 27 deaths five were from tuberculosis.

FOREIGN.

Golden Jubilees of Physicians.—Among the physicians who have recently celebrated their golden wedding with medicine, that is, the celebration of the termination of fifty years of practice, are Prof. M. Blancas, one of the most prominent medical authorities of Buenos Ayres, and Professor von Voit of Munich, Germany.

A Chemical and Pharmaceutical Congress.—An international exposition is to be held at Liège, Belgium, opening in July, 1905. In connection therewith there will be a congress of chemistry and pharmacy, organized under the auspices of the Liège Pharmaceutical Association and the Chemical Society of Belgium. Questions relating to legislation and professional ethics will be discussed in addition to technical matters. Address for further particulars M. J. Raymond, 16 Place des Carmes, Liège.

Bubonic Plague.—*Public Health Reports* states that the Transvaal is now free from plague. A report from Brisbane, Queensland, states that the last case of plague in man in that state occurred on June 12, and the last plague-infected rat was found July 29. In Fuchau, China, there is an epidemic of plague in the native portion of the city. So far as is known, there are no cases in the foreign quarter. In Bahia, Brazil, there are a number of cases of plague, and several deaths from the disease have occurred. Vaccination against the plague is being practiced on a large scale, and the government is considering the establishment of anti-plague vaccination stations throughout the city.

Hygiene of the Barber Shop.—The *Lancet* mentions that ten countries have adopted regulations for controlling barbers and hairdressers to prevent contagion. Among them are Japan, Sweden, the State of New York, Uruguay and San Salvador. It suggests, further, that as brushes are so hard to disinfect, the use of formalin is probably advisable. Powder puffs should be replaced by pieces of cotton, which can be burned after using. The barber should wear an apron without pockets, and should wash his hands between attending on customers. An important regulation which should be decreed is that no one suffering from an obvious disease of the scalp or face should be served in a public barber shop.

Australian Lepers.—Wherever possible the government of New South Wales departs Chinese lepers. There are now seven of these unfortunates in the leper lazarette at Little Bay and arrangements are being made to send them back to China. Victoria has one Chinese leper and the health authorities of the two states are arranging to send him to China with his countrymen from New South Wales. The patient has no objection to returning to China, but asks the government for £150 (\$750) with which to start in business in Hongkong. In similar cases the Victorian government has made grants ranging from £60 to £120 (\$300 to \$600), as the repatriation of such cases even with a substantial gratuity means a saving to the treasury.

Suit Against a French Surgeon for Homicide.—Dr. J. A. Fort of Paris performed an operation on a patient for the relief of a stricture of the esophagus. The patient died a few days afterward. Eight months later the aid who had assisted at the operation denounced the surgeon as having caused the death of the patient by a piece of an instrument left during the intervention. The bulging tip of the thin, flexible sound he was using had been broken off by a spasmodic contraction of the stricture, but as the digestive tract tolerates readily much larger foreign bodies than this, he did not regard the incident as at all serious. The body was exhumed and during three hours' examination by three physicians besides Fort, nothing was discovered to show the slightest damage from the tip of the sound, which was found in the intestine. Nevertheless, the authorities have formally instituted suit against him for homicide by imprudence, as mentioned in an editorial on page 1150.

Present Status of Medical School Inspection in Germany.—A full report on this subject is published in the *Allg. med. Ct.-Ztg.*,

September 17. In Dantsic the school inspectors are members of the board of education. The number includes 4 ophthalmologists and 12 physicians. The former examine the children's eyes on their entering school, and thereafter at two-year intervals. Charlottenburg has 12 medical inspectors. They make out a health chart for each child, which accompanies it from grade to grade. Each month the medical inspector holds a conference with the principal and the teacher of each grade, and the children are inspected at least once a quarter. The heating, cleaning and ventilating of the buildings are also under his jurisdiction. In Breslau the children are examined after they have had two or three months of school life. In Paderborn the demand for medical school inspectors was rejected by the city authorities on the ground that, as the state did not think them necessary for the higher institutions of learning, they were not needed in the lower grades. In Leipzig the regulations require the inspector to visit each school once a month to confer with the principal and examine such children as are presented to him. The inspectors are also required to accompany the architects and the board in their rounds of inspection of the school buildings. These Leipzig regulations are proving exceptionally satisfactory.

An Exposition of Irregular Methods.—The "Naturforscher" Congress is one of the events of the year in Germany. It is an annual gathering of physicians and workers in other sciences for the purpose of presenting and discussing the various achievements in science during the past twelve months. The medical section is always particularly interesting, and physicians flock from near and far, the total attendance at the congress reaching well up into the thousands. The seventy-sixth annual session was held at Breslau Sept. 18-24, and one of its features was an exhibition of the measures and practices of quacks and charlatans as encountered by medical men. Dr. Carl Alexander had the matter in charge, and several addresses were made by editors and physicians on the subject of quacks in general. The exhibition included the advertisements of all kinds of quacks and charlatans, as well as the advertisements of proprietary medicines and secret remedies, the various cures "without poison" and "without the knife," faith cures and pseudo-science cures, the institutions conducted by "nature healers," their periodicals, books, etc., in short, the entire history of charlatanism during the last decades. An important feature of the exhibition was the statistics and data collected by physicians in regard to the persons practicing these irregular methods. They show that 70 per cent. had barely an elementary education. The literature is shown to be enormous; the principal organ of the German "nature healers" is in its thirty-second year and claims 125,000 subscribers. Dr. Reissig has collected data which prove that the number of books and treatises on "nature healing" sold during the past fifteen years amounts to a total of more than \$3,000,000. More than a million copies of Bilz' book have been sold, and more than a quarter of a million of Kneipp's, not to mention Mrs. Eddy's book. Specimens of all of these were on exhibition. It is proposed to keep this collection together and throw it open to the public as a means of instructing the people in regard to quack practices and methods, using every means to render it more instructive in this respect. The effectual organization of the charlatans must be met by concerted action on the part of the profession. Lejars remarks in a letter on the subject in the last *Semaine Méd.*, that all the members of the profession do not suffer in the same degree from the ravages of quack practices, and consequently the physicians whose influence would be most powerful in the matter are the very ones who regard it with apathy and selfish indifference. The matter is so appallingly serious, however, he adds, that it threatens the very existence of the liberal, honest medical profession, and effectual organization to combat it is imperatively needed. The German Society for the Repression of Charlatanism was founded in 1902, and Holland has had a similar organization since 1880. The present exhibition is due to the initiative of the German society. Some of its previous efforts were mentioned on page 384 of the last volume of THE JOURNAL.

Correspondence.

State Supervision of Public and Private Care of the Insane.

EAST ST. LOUIS, ILL., Oct. 2, 1904.

To the Editor:—In your editorial, September 17, with the above title, your reference to Illinois institutions may admit of a little explanation. You speak of the "ruin" wrought and

their "fall" under the present system, as shown in articles in the *Illinois State Medical Journal*. I am aware that some such articles were published, but I believe the profession generally understands the animus and circumstances under which they were published. But when such reference to our charitable institutions is made in a journal of national circulation the matter assumes a different aspect.

Now, I am deeply interested in these institutions, am a visitor of them, and of similar institutions in other states, and if it can be pointed out to me in what particular, in any one of these institutions there is a defect, I will make an effort to remedy it. If any defects can be shown in the medical treatment of our insane, any want of efficiency or kindness on the part of nurses, any harsh treatment on the part of attendants, any lack of cleanliness or sanitary condition in the buildings or grounds; if, indeed, there is any point in any one of these institutions that will not compare favorably with any other institution for the insane in this country, I most earnestly want to know it.

I will gladly accompany you, Mr. Editor, or the former editor of the *Illinois State Medical Journal*, to any of these institutions you may select for this observation.

With reference to "the loss to the state of eminent medical men," I can recall but one change in superintendents during the present administration, that at Jacksonville, and that was certainly not for political reasons.

H. C. FAIRBROTHER, M.D..

Member State Board of Charities.

[We do not question the good faith of the author of this letter. As to the editorials in the *Illinois State Medical Journal*, we know nothing of their "animus" nor of the "circumstances" under which they were written. They appeared in the editorial columns of a highly respectable medical journal and, as we recall, they were warmly commended at the time by the leading Republican daily of Chicago, and were indorsed in the issue of THE JOURNAL, Feb. 20, 1904, because they seemed to us to show, without personality or partisanship, the evil effect of political influence on a body of institutions whose directing spirit should be purely that of medical science.

The writer of the above letter states that he has no knowledge of any defects in the Illinois institutions, but expresses an admirable willingness to remedy them if any can be shown to him. It would be no difficult task to do this. The subordination of the Illinois institutions to party politics has been so evident that it is now a public issue in the state, and neither party dared to frame a platform this year without a plank demanding a merit system for the appointments to these institutions. A powerful voluntary organization of representative men throughout the state has been formed for the express purpose of securing a state civil service law, and, as its reports will show, the primary need of this law was found in the condition of the state institutions. For the past eleven years, since the inauguration of the spoils system in 1893, at least 90 per cent. of the offices, over 2,500 in number, in the state charitable and penal institutions, have been used for the payment of political debts or the purchase of political power. This system has naturally resulted in a deterioration in the management of our institutions. At the present time, in at least nine cases out of ten, fitness and experience combined have no influence in obtaining a position even in the insane hospitals.

There is one respect in which the institutions of Illinois do not compare favorably with "other institutions for the insane in this country." There is no governing body whose members are appointed and hold office in a way that makes it a proper body to hear complaints and investigate charges. The State Board of Charities is appointed by the same head who appoints the superintendent and chief officers of the various institutions, and as a consequence they are naturally inclined in all investigations to shield the management rather than to protect the

inmate. For specific instances we may point to the Kankakee investigation, to the Elgin investigation, and to the attempted investigation of the Illinois Industrial Home for the Blind. It is fair to say that the instances referred to occurred before Dr. Fairbrother's very recent appointment to the board. For details we refer him to the "Plea for a State Merit Law" published by the Illinois Civil Service Association. That Illinois has lost the good name she once boasted of is shown by the fact that a commission appointed a few years ago by the governor of Pennsylvania to visit the various state charitable institutions and report on the same, passed through Illinois, stating in a personal interview with the representatives of the press in Chicago that they could learn nothing from the Illinois state charitable institutions, as they were among the lowest in point of efficiency.

Our correspondent questions our assertion as to "the loss to the state of eminent medical men" and says he knows of but one change in superintendents in the "present administration." We can not state too emphatically that we intend no reflection on the "present administration" of Illinois or of any other state. THE JOURNAL does not lend itself to partisan politics, nor does it hold any one administration responsible for the general situation, but it has been repeatedly pointed out that political control of public medical charities under any administration always has been and always will be disastrous.

We are sorry to say that, unlike our correspondent, we are able to recall a considerable list of excellent alienists who by various "methods of elimination" have been removed from the service of Illinois since 1893, when the period of political control set in. Among these are a pathologist of national reputation, the successful heads of three large institutions in other states, the superintendent of another public insane asylum which is now among the most progressive in America, and others equally meritorious but less conspicuous.

We would remind our critic that the points mentioned in his letter are not the only ones in which we have a right to demand a high standard for our insane asylums. Let him compare the medical, surgical and laboratory work in the asylums of Illinois with that carried on now in New York, Minnesota, Michigan and Ohio—the actual volume of scientific, clinical and pathologic work as evidenced by publications in the current literature. Cleanliness and kind treatment are certainly necessary, but the twentieth century has advanced beyond these points, and so long as mechanical restraint still obtains in our asylums, so long as they still retain the "Utica crib," and so long as they fail to keep up with the march of modern psychiatry, so long shall we be justified in our criticism of them.—
EDITOR.]

Copper Containers Not Sufficiently Germicidal to Typhoid Bacilli in Water.

SPRINGFIELD, ILL., Oct. 5, 1904.

To the Editor:—According to newspaper reports of the latter part of August Dr. Edward Martin, director of public health and charities, Philadelphia, stood sponsor for the following statement: "Typhoid fever germs may be removed from water without boiling or filtering. It is only necessary to let water stand for four hours in a copper kettle in a living-room temperature or twenty-four hours in a refrigerator. The water will receive sufficient colloidal impregnation from the vessel to kill typhoid fever and cholera germs."

At about the same time the newspapers published an announcement that municipalities and communities suffering from or threatened with the presence of typhoid germs in drinking water were requested to call on the Secretary of Agriculture to render assistance; that the Department of Agriculture, after exhaustive investigations, had found a remedy for the destruction of typhoid bacilli in the simple retention of infected water in copper vessels.

Further, about September 5, Dr. George T. Moore of the Department of Agriculture was quoted as saying: "I am perfectly willing that the press should say for me that the death rate in any community from typhoid fever, so far as the disease is caused by infected drinking water, may be wiped out by the scientific use of copper as a germicide."

The wide publicity given to this subject by the press, and the simplicity, economy and alleged certainty of the process, caused serious apprehension on the part of the Illinois State Board of Health, lest local authorities of the state might advocate and adopt the method without further investigation, neglecting the more thoroughly tried and approved methods of the prevention of water-borne diseases. To determine the accuracy of the claims made, the State Board of Health immediately undertook a thorough and painstaking investigation of the germicidal powers of copper and its salts, under the direction of Prof. John H. Long, of Northwestern University.

These investigations have been completed and show conclusively that typhoid bacilli may live in water in copper containers or in water brought in contact with copper, at ordinary room temperature, not only for four hours, but for twenty-four or even forty-eight hours. According to Professor Long's report, "while in sterilized water in contact with copper, the 'death rate' of typhoid bacilli is high, their persistence for two or three days, and the possible persistence for longer periods in larger amounts of water, render the method impracticable for use in rendering a suspicious water safe for household use."

There is no question but that the contact of copper with water contaminated with typhoid bacilli brings about more rapid destruction of these bacilli, and some germicidal power must be admitted, but that this germicidal power can not be depended on, especially in the small space of time suggested in the newspaper reports, is made apparent by the persistence of the bacteria for over forty-eight hours under conditions in which this germicidal power is stated to be at its highest.

It is to be remembered that the disappearance of typhoid bacilli from water in a copper vessel, at the end of forty-eight hours, can not be entirely attributed to the germicidal action of the copper. Typhoid bacilli disappear from ordinary water in from one to ten days, and from Chicago tap water, they are, as a rule, entirely absent five days after seeding. Hence, the disappearance of the bacilli forty-eight hours after seeding, in a copper vessel, may be due, not only to the action of the copper, but to the natural destruction of the bacilli in water.

It must be further remembered that water which receives sufficient "colloidal impregnation" to destroy typhoid fever and cholera germs may receive also sufficient poisonous properties to render it unfit for drinking purposes. Be that as it may, there is no question but that the copper-lined canteen, advocated and said to be under consideration by the government for the uses of the Army, would be more deadly in its results than are the typhoid bacilli to-day. Lacking the germicidal properties to destroy the germs of water-borne diseases, they present merely an added danger from the contamination of the water from material of their own construction.

The "purification" of water by the destruction of bacterial poison through the addition of chemicals which may be in themselves poisonous, has ever been a theory untenable to the logical sanitarian or physician. The interest manifested in the earlier reports of this "copper kettle water purification" justifies the assumption that even greater interest will be shown in the results of accurate investigations determining the truth or error of the earlier theories or assertions.

J. A. EGAN.

Secretary Illinois State Board of Health.

Should the Appendix Be Removed When the Abdomen Is Opened for Other Conditions?

BALTIMORE, Oct. 4, 1904.

To the Editor:—I beg leave to make a slight correction in an admirable article by Dr. Floyd McRae in THE JOURNAL, Sept. 24, 1904, on "The Diagnosis of Appendicitis. Should the

Appendix Be Removed When the Abdomen Is Opened for Other Conditions?" He writes as follows: "Kelly, in his classical work on gynecology, gives the opinion of a number of the leading surgeons and gynecologists in this question. Most of them were of the opinion that the removal of the appendix, unless markedly diseased, should not be a routine practice, the author agreeing with them." My remarks on this subject were published, not in my "Operative Gynecology," but in a paper entitled "Under What Circumstances Is It Advisable to Remove the Vermiform Appendix?" which appeared in THE JOURNAL of the American Medical Association, Oct. 23, 1902. The point in regard to which I asked for opinions was not "whether the appendix should be removed unless markedly diseased," but whether it should be removed when it deviated in the slightest degree from normal, my question being: "When the abdomen is opened for other causes and the perfectly normal appendix is easily accessible, is it your rule to remove it?"

HOWARD A. KELLY.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ELIGIBILITY OF SECTARIANS TO COUNTY MEDICAL SOCIETIES.

MINNEAPOLIS, Sept. 25, 1904.

To the Editor:—I write to you in behalf of the board of censors of the Hennepin County Medical Society of Minneapolis, to ask you what has been the practice of societies in affiliation with the American Medical Association with regard to admitting homeopathic physicians into membership. We wish to ask especially: Are homeopathic physicians, if they practice "non-sectarian medicine," eligible for membership? Is there a precedent for receiving them? If so, what society affiliated with the American Medical Association has received such? If they are admitted can they still retain their positions as professors in homeopathic medical colleges, their appointments as visiting physicians on the homeopathic staffs of hospitals, and their memberships in homeopathic medical societies?

DAVID OWEN THOMAS.

ANSWER.—The members of a number of county medical societies have been more or less puzzled to find an answer to the question propounded in the above letter, namely, whether the new plan of organization commands, recommends or permits the reception into membership of sectarians. The provision governing action on this point as suggested in Article III of the "Standard Constitution for County Medical Societies" is as follows: "Every legally registered physician residing and practicing in ——— county, who is of good moral and professional standing and who does not support or practice, or claim to practice, any exclusive system of medicine, shall be eligible for membership." The difference between this and the earlier practice lies in the fact that the school of graduation and the former practice of an applicant for membership no longer act as a bar, provided that the applicant now fulfills the conditions laid down in the article quoted—that is, does not limit himself, either in his claims or in his practice, to any exclusive system. However, the autonomy of the county society is complete and it has full power to decide under exactly what conditions any individual applicant may be admitted. Those who have professed to practice an exclusive system in the past, but who now renounce such claims, are declared to be "eligible for membership," and it is recommended that they be admitted. No compulsion exists. There may be other reasons for refusing to accept such applicants; the county society must decide. Under the new order of things and by reason of the complete freedom of decision as to membership that rests with the county society, the practice of societies varies in different counties. A society in Ohio and another in Iowa received into membership all the irregulars in their respective counties. This may have been a permissible procedure and the result of the experiment is being watched with interest. Some difficulties have arisen in the effort to keep straight some of the former irregulars. On the other hand, some decided good has been accomplished. Sectarians who retain their claims, practices and college, society and hospital affiliations are not supposed to be eligible. It seems wisest to construe the statute with liberality when deciding an individual case. It may be better, in some instances, to admit than to reject one whose status is not perfectly clear, because the very admission, through its fellowship with men of high professional ideals, may prove the turning point of a career begun in error and continued for the lack of opportunity to retrace false steps taken in ignorance and innocence.

CONTRACT PRACTICE—AN EXPERIENCE.

A physician, who desires his name withheld, writes from Indian Territory regarding contract practice, endorsing the movement in

opposition thereto. He gives a view obtained from his own experience, which it would be well for others who have a desire to do such work to read? He says: "I have been much interested in the discussion of contract practice from time to time. I am a married man of 29 years, with both literary and medical degrees obtained in first-class institutions, after the prescribed course, and have had five years of practice. After graduation, on account of ill health and financial stress, I was compelled to accept a contract mining practice at this place. I am thoroughly disgusted with contract work, and have been from the start, but necessity demanded me to take it up. I would that your time would permit me to tell what I know of the work. It is the most humiliating, degrading and unsatisfactory work one could engage in. Once in it it is next to impossible to relinquish. I know many contract physicians in this section, but have never known one to voluntarily give it up. I started a movement to try to abolish it in this vicinity, but it met a dismal failure."

RECIPROCIITY BETWEEN OHIO AND ILLINOIS.

PAULDING, OHIO, OCT. 7, 1904.

To the Editor:—Does the Illinois board recognize licenses from the Ohio board?

G. E. BRATTAIN, M.D.

ANSWER.—Yes, in case of licenses issued on examination to graduates of recognized medical colleges. For further particulars consult Dr. J. A. Egan, secretary of the Illinois State Board of Health, Springfield, Ill.

Marriages.

REGINALD SMITH, M.D., New York City, to Miss Neva Scott, in Chicago, September 26.

FRED R. JEWETT, M.D., to Miss Emily Pryor, both of Cambridge, Mass., September 28.

MOTON E. CUMMINGS, M.D., to Miss Ida Sargent, both of Malden, Mass., September 28.

WILLIAM J. BUSSEY, M.D., to Miss Winifred Streeter, both of Sioux City, Iowa, October 1.

ISAIDORE J. WOLF, M.D., Kansas City, Mo., to Miss Leah Marks of Cincinnati, September 26.

HENRY S. PLUMMER, M. D., to Miss Daisy Louise Berkman, both of Rochester, Minn., October 6.

C. E. STEPHENSON, M.D., Portland, Ind., to Miss Blanche Miller of Decatur, Ind., September 28.

CHARLES A. DAWSON, M.D., to Miss Berenice Inez Potter, both of Glyndon, Minn., September 29.

WILLIAM M. NEWMAN, M.D., Spokane, Wash., to Miss Nellie Levens of Albert Lea, Minn., October 5.

L. B. CAMBREATH, M.D., Cambria, Iowa, to Miss Daisy May Wells of Keokuk, Iowa, September 28.

FRANK WALLACE SMITH, M.D., to Miss Sophie Vinal Bowen, both of York Village, Maine, October 1.

J. RANDOLPH GRADHAM, M.D., New York City, to Miss Bessie Knight Ward, at Winchester, Va., September 28.

ISAIAH BENNETT, M.D., to Miss Grace S. Pearson, both of Wilsonville, Neb., at Clayton, Mo., September 29.

FREDERICK WALTON, M.D., Plymouth, Pa., to Miss Mary Martha Weiler, of Flemington, N. J., September 28.

FREDERICK H. THOMPSON, M.D., Fitchburg, Mass., to Miss Katherine Livick of Roxbury, Mass., September 28.

CHARLES L. HARMER, M.D., Farnington, Mo., to Miss Goldie Alice Beach of Mount Vernon, Ohio, September 28.

DENNIS FRANCIS FITZPATRICK, M.D., to Miss Maurice Pauline Murphy, both of Iowa City, Iowa, September 28.

FERDINAND GEORGE BENN, M.D., Kuhl, N. D., to Miss Elizabeth Helen Kane of Escanaba, Mich., at Long Prairie, Minn., September 29.

Deaths.

J. Merrick Bemis, M.D. Castleton (Vt.) Medical College, 1852, for many years assistant and superintendent of the Worcester Insane Hospital; physician in charge of Herbert Hall, Worcester; a member of the Massachusetts Medical Society, Worcester Medical Society, and American Medico-Psychological Association, died at his home in Worcester, October 3, from Bright's disease, aged 84.

Thomas Lincoln Axtell, M.D. Bellevue Hospital Medical College, New York City, 1881, a member of the Connecticut Medical Society and the Waterbury Medical Society, some-time

surgeon to the Second Infantry, Conn. N. G., died at his home in Waterbury, Conn., from paralysis of the heart, September 26, aged 51.

T. James Owens, M.D. Bellevue Hospital Medical College, New York City, 1873, assistant commissioner of agriculture of New York, and a practitioner for many years in Steuben and Remsen, N. Y., died at his home in Utica, N. Y., September 28, after a lingering illness from diabetes, aged 57.

William J. Williams, M.D. Rush Medical College, Chicago, 1887, a member of the American Medical Association, one of the most prominent and beloved physicians of Dallas County, Iowa, who has been in declining health for several years, died at his home in Adel, Iowa, September 30, aged 50.

Samuel E. Freeman, M.D. College of Physicians and Surgeons in the City of New York, 1858, the fifth of that name in direct line to practice in Woodbridge, N. J., died at his home in that city, September 24, from apoplexy, after an illness of two months.

John W. Jones, M.D. Tulane University of Louisiana, New Orleans, 1861, for many years ordinary of Crawford County, Georgia, died at his home in Knoxville, September 30, from injuries received six days before in a runaway accident, aged 63.

Frederick Marshall, M.D. Harvard University Medical School, Boston, 1904, interne in the Boston City Hospital, was instantly killed by an explosion of dynamite under a trolley car on which he was riding, near Melrose, Mass., September 22.

David Decker Wickham, M.D. College of Medicine, Syracuse University, New York, 1875, the oldest practitioner in Orange County, died at his home in Port Jervis, N. Y., October 1, from pneumonia, after an illness of three weeks, aged 74.

Henry McDonnell, M.D. Tulane University of Louisiana, New Orleans, 1870, a member of the state and county medical societies, died at his home in Huntsville, Ala., October 2, after an illness of several weeks, from typhoid fever, aged 56.

Isaac MacBride, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1854, died at his home in Philadelphia October 2, as the result of injuries received in a fall from a trolley car two months before, aged 73.

John E. Hutton, M.D. Marion Sims College of Medicine, St. Louis, 1891, for several years demonstrator of anatomy in Barnes Medical College, St. Louis, died at his home in Mexico, Mo., September 30, aged 34.

Van B. Thornton, M.D. National Medical College, Washington, D. C., 1861, physician and health officer of the Prairie View State Normal and Industrial College, died recently at his home in Houston, Texas.

Leroy M. Taylor, M.D. University of Georgetown, Medical Department, 1860, a Confederate veteran, died at his home in Washington, D. C., September 27, from acute Bright's disease, aged 66.

James H. Gray, M.D. Chattanooga (Tenn.) Medical College, 1894, of Chattanooga, died at Grayville, Tenn., from disease of the stomach, after a long illness, September, 30, aged 49.

Jefferson F. Lytton, M.D. Kentucky School of Medicine, 1866, of Wheatland, Ind., was found dead in his buggy, three miles from Wheatland, October 2, from heart disease, aged 71.

Joseph Newton Johnston, M.D. Cooper Medical College, San Francisco, 1886, died at his home in San Jose, Cal., September 21, from tuberculosis, after a prolonged illness, aged 40.

Cicero D. Rounds, M.D. Michigan College of Medicine and Surgery, Detroit, 1894, died at his home in Detroit, September 25, after an illness of five months, aged 51.

Theodore Schultz, M.D., the oldest physician of Evansville, Ind., died at his home in that city, September 30, after an invalidism of several years, aged 88.

William H. Moore, M.D. Tennessee Medical College, Knoxville, 1893, died at his home in Fountain City, Tenn., October 4, after a brief illness.

Reuben S. Myers, M.D. University of Vermont, Burlington, 1875, died at his home in Clarence Center, N. Y., September 30, aged 75.

Melvin W. Wilson, M.D. Castleton (Vt.) Medical College, 1852, died at his home in Oakland, Cal., September 27, aged 76.

William H. Knepple, M.D., died at his home in Wakarusa, Ind., September 27, from gallstone disease, aged 73.

Caleb C. Harris, M.D. Illinois 1878, died at his home in Dousman, Wis., September 24, from peritonitis, aged 69.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Examiners for the State of Texas (Regular), Dallas, October 18. Secretary, M. M. Smith, M.D., Austin.

State Board of Medical Examiners of New Jersey, Trenton, Tuesday, Tuesday evening and Wednesday, October 18-19. Secretary, E. L. B. Godfrey, M.D., Camden.

Louisiana State Board of Medical Examiners, New Orleans, October 21-22. Secretary, Felix A. Lurie, M.D., New Orleans.

Board of Medical Examiners of the State of California, San Francisco, October 25. Secretary, Charles L. Tisdale, M.D., Alameda.

Nebraska State Board of Health, November 9-10. State House, Lincoln. Secretary, George H. Brash, M.D., Beatrice.

College Entrance Supervision in Indiana.—The secretary of the Indiana State Board of Medical Registration and Examination has notified the secretaries of the various medical colleges of the state that all documentary evidence of preliminary education offered by freshmen entering the college must be submitted to the board for approval. This relieves the colleges of the responsibility of accepting or rejecting students on educational grounds and insures a uniform standard of education for all students. It is urged that a thorough preliminary education should be insisted on for all students entering medical colleges because, while it does not mean that it will make them more successful as practitioners, it at least enables them to study medicine understandingly.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending Oct. 8, 1904:

Billingslea, C. C., asst.-surgeon, ordered to proceed not later than Nov. 1, 1904, from U. S. General Hospital to Presidio of Monterey, and accompany troops to Fort Riley, Kan., and report to the commanding officer of that post for duty.

Keller, W. L., asst.-surgeon, relieved at Fort Riley, Kan., and ordered to proceed not later than Oct. 12, 1904, to Fort Leavenworth, Kan., to accompany troops to Presidio of San Francisco, and report to the commanding general, Department of California, for assignment to duty at the U. S. Army General Hospital, Presidio of San Francisco.

Smart, Robert, asst.-surgeon, now at San Francisco, is relieved from duty in the Philippine Division and will accompany troops from the Presidio of San Francisco to Jefferson Barracks, Mo. On completion of this duty will proceed to Fort Du Pont, Del., and report to the commanding officer of that post for duty.

Fuller, L. A., asst.-surgeon, granted twenty days' leave of absence.

Winter, F. A., surgeon, granted leave of absence for twenty days from Oct. 10, 1904.

Smart, Charles, asst.-surgeon general, arrived at Army and Navy General Hospital, Hot Springs, Ark., for treatment.

Reutes, James, contract surgeon, ordered from Fort Keogh, Mont., to Fort Yellowstone, Wyoming, for temporary duty.

Sievers, Robert E., contract surgeon, ordered from Fort Harrison, Mont., to Fort Assiniboine, Mont., for temporary duty.

Koyle, Fred T., contract surgeon, relieved from duty at Fort Brown, Texas, and ordered to duty at Fort Bliss, Texas.

Burr, Rollin T., contract surgeon, left Fort Rodman, Mass., October 4, on leave of absence for three months, which he will pass at Pomona, Cal.

Mahry, William C., contract surgeon, returned to duty October 3 at Fort Sheridan, Ill., from leave of absence.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Oct. 8, 1904:

Steele, John M., surgeon, ordered to the Naval Station, Baltimore.

Ledbetter, R. E., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from Oct. 19, 1903.

Den, J. H., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from May 4, 1904.

Seaman, W., Richardson, R. R., and Asserson, F. A., commissioned P. A. surgeons, with rank of lieutenant, from May 18, 1904.

Smith, A. W., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from June 22, 1904.

Sutton, R. L., asst.-surgeon, ordered to the Naval Hospital, New York.

McDonell, W. N., asst.-surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Strite, C. E., Smith, H. W., and Clifford, A. B., asst.-surgeons, appointed asst.-surgeons, with rank of lieutenant (junior grade), from Sept. 27, 1900.

Strite, C. E., asst.-surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Carpenter, D. N., surgeon, ordered to the Naval Hospital, New York.

Owels, R. T., P. A. surgeon, detached from the Naval Hospital, New York, October 4, and ordered to the *Chatanooga*.

Richardson, R. R., P. A. surgeon, detached from the *Wabash* and ordered to the Navy Yard, Mare Island, Cal.

Dunn, H. A., asst.-surgeon, detached from the Naval Proving Ground, Indian Head, Md., and ordered to the Naval Hospital, Newport, R. I.

Judd, H. W., A. A. surgeon, ordered to the Naval Proving Ground, Indian Head, Md.

Public Health and Marine-Hospital Service.

List of the changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ending Oct. 5, 1904:

Danka, C. E., surgeon, granted extension of leave of absence for twelve days from September 27.

Richardson, T. F., P. A. surgeon, to proceed to Eagle Pass, Texas, for special temporary duty.

Trotter, F. E., P. A. surgeon, relieved from duty at Plague Laboratory, San Francisco, and temporarily assigned to exclusive duty in connection with the examination of aliens at San Francisco.

Lord, C. E. D., asst.-surgeon, relieved from duty in connection with the exclusive examination of aliens at San Francisco and directed to proceed to Mare Island, New York, and report to Surgeon G. W. Stone, for temporary duty.

Bogges, J. S., asst.-surgeon, granted leave of absence for fifteen days from October 16.

Trucker, W. C., asst.-surgeon, Bureau letter of September 12, granting fourteen days' leave of absence from September 15, amended so that said leave shall be effective September 16; and Bureau telegram of September 26, granting three days' extension of leave of absence, revoked.

Collins, G. L., asst.-surgeon, granted leave of absence for three days from Sept. 30, 1904, under Paragraph 191 of the Regulations.

Tuttle, Jay, A. A. surgeon, granted leave of absence for four days from September 19.

Wibb, C. K., A. A. surgeon, granted leave of absence for fourteen days from September 25.

McDonald, Jeanette, medical inspectress, granted leave of absence for three days from Sept. 25, 1904, under Paragraph 210 of the Regulations.

LaGrange, J. V., pharmacist, granted leave of absence for seven days from Sept. 26, 1904, under Paragraph 210 of the Regulations.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Oct. 7, 1904:

SMALLPOX—UNITED STATES.

Illinois: Chicago, Sept. 25-Oct. 1, 3 cases, 1 death.

Louisiana: New Orleans, Sept. 25-Oct. 1, 1 case.

Massachusetts: Sept. 25-Oct. 1, Fitchburg, 1 case, 1 death; North Adams, 2 cases.

New York: Buffalo, Sept. 25-Oct. 1, 1 case.

Ohio: Cincinnati, Sept. 23-30, 1 case.

Pennsylvania: Philadelphia, Sept. 25-Oct. 1, 1 case.

Tennessee: Nashville, Sept. 25-Oct. 1, 2 cases.

Wisconsin: Milwaukee, Sept. 25 Oct. 1, 1 case.

SMALLPOX—FOREIGN.

Brazil: Bahia, Aug. 27-Sept. 3, 1 death.

France: Paris, Sept. 10-17, 16 cases.

Great Britain: Glasgow, Sept. 16-23, 1 case, 1 death; Sept. 10-17, London, 1 case; Manchester, 7 cases; Newcastle-on-Tyne, 6 cases.

Italy: Palermo, Sept. 10-17, 17 cases, 1 death.

Mexico: City of Mexico, Sept. 3-17, 7 cases, 4 deaths.

Russia: Moscow, Sept. 3-10, 4 cases, 1 death; Warsaw, Aug. 6-13, 23 deaths.

Turkey: Beirut, Sept. 10-17, present; Constantinople, Sept. 11-18, 22 deaths.

Venezuela: La Guayra, Sept. 10-17, present.

YELLOW FEVER.

Mexico: Tehantepec, Sept. 18-24, 2 cases, 2 deaths.

Venezuela: La Guayra, Sept. 17, present.

CHOLERA.

India: Bombay, Aug. 31-Sept. 6, 18 deaths.

Turkey: Bagdad and vicinity, July 31-Aug. 20, 423 cases, 392 deaths.

PLAGUE.

Africa: Cape Colony, Aug. 20-27, 3 cases, 1 death; Tringa (German East Africa), Jan.-March, 47 cases, 41 deaths.

Brazil: Bahia, Aug. 27-Sept. 3, 6 deaths, verified.

Chile: Arica, Sept. 3, present.

Egypt: Aug. 26-Sept. 2, Achmm, 1 case, 1 death; Alexandria, 5 cases, 3 deaths.

India: Bombay, Aug. 31-Sept. 6, 51 cases; Karachi, Aug. 28-Sept. 4, 5 cases, 4 deaths.

Peru: Aug. 27-Sept. 3, Callao, 1 case; Chichlayo, 2 cases, 1 death; Eten, 3 cases, 2 deaths; San Pedro, 3 cases, 5 deaths; Lima, Aug. 20-Sept. 3, 15 cases, 4 deaths.

Turkey: Smyrna, Sept. 5-7, 2 cases.

Medical Organization.

Ohio.

WAYNE COUNTY MEDICAL SOCIETY.—Physicians of Wayne County met with Dr. T. Clark Miller, Massillon, counselor for the Sixth District, at Wooster, September 15, and reorganized the county society on the standard plan, electing the following officers: Dr. Hugh A. Hart, Wooster, president; Dr. Henry L. Blankenhorn, Orville, secretary; Dr. George W. Ryall, Wooster, treasurer, and Drs. John W. Irvin, Creston, and the secretary and treasurer, committee on revision of by-laws.

Pennsylvania.

ORGANIZATION IN PENNSYLVANIA.—It is a privilege for any one interested in a progressive medical profession to attend a meeting of the Medical Society of the State of Pennsylvania.

The meeting at Pittsburg last month was hardly up to the average in attendance, as the location was not central, but the program was an unusually interesting one and the spirit was fine. (A report of the meeting will be found under society proceedings. The officers elected were named October 8, page 1071).

Although young in point of years when compared with New Jersey, Rhode Island or Massachusetts, the membership of this society is the second largest in the country. In personnel, professional zeal and scientific work it also ranks deservedly high. For these reasons, and this has been especially noticeable since the creation of a House of Delegates in the American Medical Association, its representatives exert a great and conservative influence in the councils of the national body. Its delegates are selected with commendable care, and in everything one gets the impression that veterans are at the helm.

Some of the leading members are a little sensitive over the frequent criticisms that the society is not organized on the model plan, and this is not unnatural when the earnest efforts which have been made in this direction are understood. The county society has always been the unit of organization here, with practical coincident membership in the state society, and the total membership is 4,025. Of 67 counties 59 are well organized, nearly all of them years ago, and 2 are now in process of organization. The others are in the sparsely settled oil and mineral regions, and most of the physicians in them hold their membership in adjacent counties.

The reorganization movement started while Dr. Keen was president of the American Medical Association and Pennsylvania was one of the first states to take favorable action in this direction. Before the model constitution and by-laws were completed, a committee reported and the society adopted a plan of organization which was thought by all to be in perfect accord with the Association ideas. In fact, with county societies and coincident membership in the state society long established, it seemed that little remained to be done except to form a separate legislative body for the transaction of routine business, called here "the Judicial Council," but corresponding to the House of Delegates of the Association; and an executive committee of this body, called here "the Board of Trustees," and corresponding to our council. Of course, the difference in name is of little or no importance, but the provisions relating to the makeup of these bodies here are indefinite and confusing. As many of the members thought they had adopted and were working under the Association plan the latter has been held responsible, to some extent, for these unsatisfactory conditions.

At the meeting at York in 1903 a strong committee was appointed to report what changes were needed, if any, to adapt the new constitution and by-laws to the present needs of the society, and the model plan was offered and referred to it. The committee reported progress at Pittsburg and was continued for another year. As to whether the inequalities of the existing plan can best be cured by amendments or the uniform plan adapted to their needs, presents a practical problem which this committee will work out. The Association plan would relieve the confusion in the legislative body at the annual meetings by giving a more definite and uniform representation from the county societies, and, through its council, more assistance to, and better organization of, these local societies, but the disadvantage of frequent changes in plans and methods has also to be considered. In any event, it may be expected that this society will practically have the plans and lead in all the best things for which the Association stands, in the future as in the past.

Under the impetus of the organization movement, in spite of the difficulties indicated and generally recognized, much gain has already been made in this state. Largely owing to the coincident membership feature of their old plan, an unusually full per cent. of the profession was already enrolled. Still the net gain since 1902 has been 623. This gain has been as marked in Philadelphia as in the county districts, and is expected to increase even more there under the systematic efforts which are being made. The councilor feature of the Association plan would be especially helpful here, and, because of the good work already done, would soon give Pennsylvania the most perfect organization in the union in every respect.

The following officers were elected: President, Adolph Koenig, Pittsburg; vice-presidents, E. V. Swing, Coatesville; W. S. Stewart, Wilkesbarre; John Carson, Chatham Run, and J. B. Ewing, Fayette; secretary and editor of the *State Journal*, Cyrus L. Stevens, Athens; treasurer, George W. Wagoner, Johnstown; trustees, Henry Beates, Jr., Philadelphia; L. B.

Kline, Catawissa, and William H. Hartgell, Allentown; delegates to the American Medical Association, H. S. McConnell, New Brighton; John B. Roberts, Philadelphia; William L. Rodman, Philadelphia, and F. W. Frankhauser, Reading.

Virginia.

ALGUSTA COUNTY MEDICAL SOCIETY.—This society met at Staunton, September 21, and reorganized on the standard plan. All but 8 of the 42 physicians in the county are members of the society. The following officers were elected: Dr. Joseph S. De Jarnette, Staunton, president; Drs. Marshall P. Jones, Churchville, Albert C. Fox, Waynesboro, and Walter S. Whitmore, Mount Sidney, vice-presidents; Dr. John W. Freed, Hermitage, secretary; Dr. Thomas M. Parkins, Staunton, treasurer, and Drs. John B. Tuttle, Spottswood, John B. Catlett, Staunton, and Benjamin Blackford, Staunton, censors.

Washington.

LEWIS COUNTY MEDICAL SOCIETY.—Lewis County physicians met at Centralia recently and organized a society on the standard plan, with Dr. John T. Coleman, Chehalis, president; Dr. Harding, Pe Ell, secretary, and Dr. Thomas Primmer, Centralia, treasurer.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905

New York State Medical Association, New York, October 17-20.

Medical Society of Virginia, Richmond, October 18-21.

Hawaiian Territorial Medical Society, Honolulu, November 5.

Oklahoma State Medical Association, Oklahoma City, November 9

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-fourth Annual Meeting, held at Pittsburg, Sept. 26 to 29, 1904.

The President, Dr. William B. Ulrich, Chester, in the chair.

Addresses of welcome were made by Mr. J. A. Blair, on behalf of the city; Dr. T. M. T. McKennan, president of the Allegheny County Medical Society, on behalf of that society, and William J. Holland, Ph.D., LL.D., curator of the museum of the Carnegie Institute.

Dr. Philip Marvel of Atlantic City, N. J., delegate from the New Jersey County Medical Society, made a few remarks on the work of that society, the oldest in the United States.

Reports of Committees.

At the executive council session, the reports of the various officers and committees were received, including the secretary's report, which showed at the present time 59 county societies, five having been established within the past year, with an aggregate membership of 4,025, a net gain of 360 during the past year; and the report of the State Board of Medical Examiners, giving in detail the results of the two examinations for licenses to practice held during the year.

The election of officers has been already mentioned on page 1071, October 8, and a report on the organization aspects of the meeting appears elsewhere in this issue.

At the afternoon session the addresses in medicine, surgery and hygiene were read.

Qualifications of the Practitioner.

The address on medicine, on this subject, was delivered by Dr. Henry Beates, Jr., of Philadelphia. He stated that medicine was essentially the consequence of cause and effect, and that the highest physical and mental health and character were necessary to a physician in order that he might properly execute the bond of trust existing between himself and his patient. He dwelt on the detrimental effect of the spirit of commercialism which to some extent is invading the ranks of the professions, as well as the electropaths, osteopaths, etc., and urged the necessity for the education of the laity to the value of consulting only a qualified practitioner. He urged the neces-

sity for the better fundamental education of the medical student before he be allowed to matriculate at colleges, and that only those should be permitted to enter who possessed the required preliminary education.

Malpractice Suits.

The address in surgery, on this subject, was delivered by Dr. Winters D. Hamaker, Meadville, in which he dwelt particularly on the disadvantages of the physician when sued for malpractice, assigning as reasons: 1. His prosecutor is in nearly all cases without property, and the juries know that the counties must pay the costs if the suit fails. 2. In many of the cases the poor results have been brought about by neglect or disobedience on the part of the patient or his friends. 3. Before a jury a case may be made out worse than it really is or can be "made up" entirely. 4. Courts will not allow an examination under an anesthetic in order to make a complete diagnosis. 5. The profession has devised no system of common defense. 6. The juries are ignorant of the subjects discussed. 7. So-called experts, very often ignoramuses, are brought in to testify against the defendant. 8. The impossibility of obtaining good results in many cases of severe injury.

He urged that the surgeon in complicated cases should have frequent consultation or x-ray examinations, and insist on strict obedience from the patient. He referred to the insurance companies which had been formed to defend physicians from such attacks, and recommended that the society appoint a committee to investigate this matter, as well as to consider the advisability of attempting to secure more favorable legislation.

Hygiene and State Medicine.

The address on this subject was read by Dr. Alexander Abbott of Philadelphia. He stated that the subject should include nuisances and places which under improper care might become such, the compilation of vital statistics, the management of contagious diseases and the establishment of hospitals for the reception, as well as maritime and, when necessary, inland quarantine. He referred to the fact that the statistics showed larger mortality rates in contagious diseases than those of the rural districts, because therein illness, death and interment could take place without any record being made thereof. He especially urged the value of vital statistics of the regions from which the water and milk supplies of cities are obtained, and the prevention of the deposit of human waste in channels which would lead to the water supply. He believed the examination of the physicians for a license should be less theoretical and more practical. He particularly commented on the value of vaccination, giving detailed statistics of the recent Philadelphia epidemic.

The Need for Systematic Study of Individual Characteristics as Manifested by the Organisms' Reaction to Sensory Stimuli.

DR. WALKER, Dixmont, urged the importance of the individual study of each case, particularly the chemical and physical phenomena of nutrition and the vasomotor and secretory conditions.

The Physicians and the State.

This paper, by Dr. Benjamin Lee of Philadelphia, was read by Dr. Eugene E. Matson, Pittsburg. It called attention to the duties of the man entering the medical profession to his fellow citizens and the state, particularly his duty to have a cultivated mind, thoroughly trained in all the branches of the medical art. It also commented on his duty to the state in the compilation of vital statistics and in notifying the health authorities of contagious diseases. The paper stated the belief that it was the duty of every physician offered a place on the board of health to accept.

Personal Recollections of Drs. John L. and Washington L. Atlee.

DR. B. H. DETWILER, Williamsport, reviewed the life and work of these men, referring particularly to the introduction of ovariectomy by Dr. Washington L. Atlee.

DR. S. P. HEILMAN of Heilmandale referred to the remarkable vitality of Dr. John L. Atlee, at the age of 81 years, at which time he had performed an operation for him.

Indicanturia Complicating Typhoid Fever.

DR. JUDSON DALAND, Philadelphia, after going into the technique of the analysis for this substance, gave in detail the diet and treatment employed therefor, and expressed the belief that the condition was frequently present in these cases.

Remarks on Some New Clinical Methods.

DR. H. E. WETHERILL, Philadelphia, described a centrifuge in which the speed is attained by means of a twisted cord, and an instrument for measuring the perspiration.

The first session of Section A was called to order Wednesday by the president of the state society, Dr. William B. Ulrich, Chester, and was then presided over by Dr. M. V. Ball.

Drugs Vs. Other Methods of Treatment.

DR. T. W. GRAYSON, Pittsburg, referred to the present tendency among physicians to give greater attention to the use of diet, electricity, massage and hygienic measures generally, and not to depend so exclusively as formerly on drugs alone. This is shown by the text-books and by the fact that much besides drugs has been used in the treatment of tuberculosis, gastrointestinal diseases, malaria, rheumatism and typhoid fever. He did not wish to be termed a "therapeutic nihilist," but emphasized the fact that, though a certain drug may sometimes meet the condition, a better remedy is found in the use of hygienic measures which may be much harder for the physician to find and more troublesome for the patient to use than a bottle of medicine or a few tablets.

DISCUSSION.

DR. JAMES TYSON referred to the subject of polypharmacy and cited an instance of a prescription containing six different ingredients, and in which two capsules were necessary for a dose.

DR. BOYCE, Pittsburg, believed that no true physician would be ignorant of what may be done by diet, exercise and physio-medical measures, yet these could not be employed with the physiologic effect as could drugs. However valuable physical means might be, he would be sorry to see them put into the hands of men ignorant of the use of morphia, digitalis, and the drugs for treating symptoms.

DR. DILLER, Pittsburg, said that there should be obtained the true proportions between the relative value of hygienic measures and drugs and that there ought not to be any controversy between mechanical means and the use of drugs. He believed that polypharmacy was decreasing and was surprised that Dr. Tyson was able to cite such a remarkable case.

Asthma; Its Varieties and Their Treatment.

DR. S. SOLIS COHEN, Philadelphia, said that no condition exhibits so many individual peculiarities as asthma, which condition he declared to be a group of symptoms and not an independent disease. The underlying affection must be discovered before the diagnosis can be complete. In the presence of definite lesions in the heart and kidneys and so-called cardiac and uremic asthma supervene, the condition is not usually pure asthma, but dyspnea dependent on heart failure—sometimes, it is true, aggravated by the presence of uremic toxins. True asthma presents clinically four varieties: 1. Asthma dependent on vasomotor ataxia; 2. asthma dependent on bronchial spasm, muscular, and, perhaps, vascular; 3. asthma associated with chronic bronchitis and emphysema; 4. asthma associated with nasal turgescence and sometimes with polypi and other mechanical obstructions, or with enlarged glands and other sources of irritation in the nose and nasopharynx. These are not pathologic divisions, and are not co-ordinate, but permit useful working rules for practice.

In treatment, asthma dependent on vasomotor ataxia is to be prevented by constitutional measures and the administration of remedies which raise vascular tone. For the relief of the paroxysm he suggests the use of suprarenal spray or in-

halation, or, if necessary, hypodermic injection. The local application of suprarenal is especially useful in the nasal variety and any mechanical obstruction should be removed. Spasmodic asthma is to be prevented by avoidance of exciting causes and by the use of such agents as the nitrites. In cases associated with emphysema and chronic bronchitis, treatment with iodid of potassium during the intervals is especially useful. Especially useful is exhalation in rarefied air, and, when emphysema is not too excessive, this may be useful by combining with inhalations of compressed air. In this, as in all other measures of treatment, physical individualization is needed.

DR. JAMES TYSON believed that the use of the term asthma had become exceedingly careless, and said that the so-called pneumonic asthma is the result of a weak heart which has become dilated and unable to push the blood through the lungs; in the effort to get more air, there is edema of the lungs and sometimes consolidation. The application of the term asthma, therefore, to bronchial asthma is really speaking no more correct than the extension of it to the so-called uremic asthma. Dr. Tyson is apt to prescribe in the condition more commonly known as asthma, the iodids and belladonna, and with surprising success.

DR. G. HUDSON MAKEN cited a case of nasopharyngeal irritation as a cause of asthmatic breathing, which was cured by operation.

The Diagnosis of Major Hysteria.

DR. THEODORE DILLER, Pittsburg, read this paper, and emphasized the diagnostic importance of the condition. Failure in recognition of the condition he attributed to the too limited conceptions of its manifestations, a too great insistence on crying or laughing spells or convulsions as expressions of the affection, the failure to recognize that the symptoms may change little and persist for years, and that the disease may be thoroughly chronic and the failure to recognize the great diagnostic value of sensory changes. A clear recognition of hysteria and a positive statement to patient and friends that the disease is well understood constitutes the first step in treatment.

DISCUSSION.

DR. S. SOLIS COHEN referred to two great errors on the part of physicians in the treatment of hysteria: Vague diagnosis and an air of mystery which is maintained in even recognized cases. He agreed emphatically with Dr. Diller that a definite statement, even if incorrect, is better for the patient, for the family and for the physician than to allow the patient to consider himself the subject of some mysterious ailment, perhaps of some supernaturally inflicted visitation. Dr. Cohen further called attention to the importance of the better recognition of traumatic hysteria. He thought many physicians were to blame for their testimony in court tending to belittle the condition brought about.

DR. C. C. HERSMAN cited several cases of hysteria incorrectly diagnosed, and followed by consequent fatal results.

DR. J. M. FISHER, Philadelphia, emphasized the importance of certain gynecologic conditions which often bring about the symptom complex recognized as hysteria. Illustrative cases were cited which had been cured by the correction of disturbances of the pelvic organs.

DR. MAYER, Pittsburg, agreed with Dr. Diller that hysteria is a mental disease akin to insanity, and believed that physicians are prone to forget that the hysterical symptoms are due to a primary mental condition, that there is a congenital psychosis inherited in the individual.

Amnesia.

DR. C. C. HERSMAN, Pittsburg, reported the following clinical case: A man, aged 40, left his home in 1892 without cause. He thought he was going to the Atlantic coast, but went to Cleveland, returning in four days, when he wanted to start for his home in Austria. He was treated in a hospital for two weeks and at his home for three or four weeks, with complete recovery. In 1903 he left the city, not knowing where he went. Does not know where he first came to him-

self. He left Boston for Jamaica. He was under different names, which condition he thought was imperative. He felt as though he were undergoing a transformation, and a part of the time thought he was dead. He returned in six months, placed himself under treatment, and again made a complete recovery.

Lax Sanitation; the Cost of It.

DR. S. P. HEILMAN, Heilmandale, made a plea for a more united effort to secure legislation which shall prevent laxity in applying those sanitary precautions and safeguards to which the public is entitled. As a representative of the Society of the Associated Health Authorities and Sanitarians of Pennsylvania, he referred to two propositions made at the last annual meeting: 1. That the Medical Society of the State of Pennsylvania should be asked, with other societies, to unite in drafting a bill for the registration of vital statistics of the state. 2. That the society shall lend its influence to the enactment of law which shall provide for a county health officer and a deputy township health officer, who shall be under the instruction and direction of the State Board of Health, to supervise sanitary affairs of every township, independent of any local influence. Statistics were quoted showing the enormous pecuniary loss to New York and Pennsylvania in the last year from preventable diseases.

DISCUSSION.

DR. COHEN said that the public needed to be told such facts as had been stated, and suggested the advisability of such papers being read often where they could be heard by those who needed to be informed on such matters. What the physician needed to know was, what can he do toward the enforcement of proper legislation? With that knowledge given him, he personally was willing to do what he could.

The paper was also discussed by Drs. W. J. Campbell, Huntington; McKinley, Somerset; Erdman, Lehigh, and Bishop, who were all heartily in accord with Dr. Heilman.

(To be continued.)

Travel Notes.

XII.

AUSTRALIA.

ITS CLIMATE, DISEASES, PEOPLE, NATIVES, SYDNEY, HOSPITALS, MEDICAL PROFESSION.

NICHOLAS SENN, M.D.

CHICAGO.

ADELAIDE, AUSTRALIA, August 11, 1904.

The voyage from Auckland to Sydney takes four days. The first two days we encountered a strong northwesterly gale which, on shifting to southwest, brought with it the cold breath of the south polar region. Sailing in a southwestern direction the cold gradually increased until we entered the magnificent harbor of Sydney. Saturday evening, July 30. It was soon after leaving Auckland that it became apparent that we were in the vicinity of an entirely new world, with strange animals, trees, plants and flowers by the appearance of a rare and strange bird—the albatross. About half a dozen of these giant sea-gulls accompanied us from coast to coast, but carefully avoided the harbors. It is a magnificent bird with snow-white body, yellow straight bill, the upper part of which at its distal end is bulbous and its tip sharply curved downward, overlapping the lower; the enormous wings, measuring from tip to tip from eight to twelve feet, are white underneath, and the upper surface brown with the exception of its inner fourth, which is also white. These birds live on the waste material which is thrown overboard by the passing vessels. They fly with and against the wind nearly with the same velocity and with very little effort on their part, three or four strokes of their immense wings sufficing to start their graceful sailing movements, and by poising their body and wings in proper attitude they ascend, descend and make all kinds of curves

and circles with very little if any effort until a few active movements of the wings again become necessary to keep up the necessary momentum. They are very fast flyers and multiply many times the distance made by the steamer in their ceaseless to-and-fro flights in search for the very irregular and often scanty food supply. Many people are still under the erroneous belief that Australia is an island, and few, indeed, have a correct conception of the magnitude of this great continent which probably emerged from the bosom of the Pacific Ocean before the other continents saw daylight. It is nearly as large as the United States, inclusive of Alaska. Australia was first discovered by the Dutch and Spaniards in 1601-1606, and Captain Cook visited it in 1770, entering Botany Bay, near where Sydney is now located, April 28, where he landed and took possession in the name of King George III. For a long time England used it as a penal colony. There is perhaps no other country that presents to the stranger more characteristic features than Australia. Many things are the reverse to those who live north of the equator. When we have summer it is winter here. The tropical part of Australia is in the north and the frosts and occasionally a flurry of snow in the south. The crescent of the moon appears to us turned around. The animals are strange. It is the home of the strangest of all known animals, the duck-bill platypus (*Ornithorhynchus paradoxus*), which forms the connecting link between quadrupeds and birds. It is about two feet in length, has a flat black bill, webbed feet and body covered with a brown, silky fur skin like a beaver; it lays eggs and supplies the young with milk from its breasts. Australia is also the land where the giant emu (*Dromaeus nova-hollandia*) lives, a bird with only rudimentary wings and in size as large as the ostrich of Africa. Among the other strange animals there are the kangaroo, the wallaby, the kangaroo rat, flying fox, blind snakes and a small species of bear not larger than a guinea-pig, and the cassowary, a turkey as large as the emu, and more than sixty varieties of parrots. The vegetable kingdom is characterized by its great variety. The vast forests are composed of eucalyptus trees which are evergreen, but instead shed their bark annually; 400 species of this tree have been described; more than 10,000 of its indigenous plants have been classified. The great variety of the fauna and flora of Australia alone should be a sufficient inducement for all those who take interest in natural history to visit this land so full of Nature's strangest productions, all of which seem to point to the great age of this part of the world.

THE KANGAROO.

The kangaroo is a striking freak of Australia's fauna. For the purpose of increasing its speed, its only defense, Nature has supplied this animal with a fifth leg in the form of a long and powerful tail. Shorten the ears of one of our jack-rabbits one-half, lengthen the hind legs four times and add the tail of a kangaroo and it would be converted into a kangaroo on a small scale. This animal has a special interest for the surgeon, as the numerous delicate tendons of its tail have supplied a good substitute for catgut as a suturing and ligature material. For more than twenty years my friend, Dr. H. O. Marcy of Boston, has expounded the virtues, advantages and use of the kangaroo tendon in surgery, and through his influence it has become a very popular substitute for catgut in the practice of many American surgeons. I was somewhat astonished to find that American surgeons entertain a more favorable view of the utility of the kangaroo tendon than their Australian colleagues. Some of the latter never use it, some occasionally, and very few, if any, use it exclusively. It will interest the devotees of the kangaroo tendon ligature and suture to know that what they have been using is, as a rule, not the tendon of the kangaroo, but of the different species of wallaby. The kangaroo tendon is very coarse, at least the size of an old-fashioned knitting needle, altogether too large for general use. The wallaby is a very much smaller animal of the kangaroo family and yields a much finer material. There are three large species of kangaroo—the red kangaroo (*Macropus rufus*), the great gray kangaroo (*Macropus giganteus*), Bennett's tree kangaroo (*Dendrolagus Bennettianus*). The wal-

labys that furnish the tendon supply are represented by Parry's wallaby (*Macropus Parryi*), agile wallaby (*Macropus agilis*), brush-tailed rock wallaby (*Petrogale pericillate*), black wallaby (*Macropus robustus*). The rat kangaroo has a tail like a kangaroo and its fine, extremely delicate tendons, I am informed, have been used by some ophthalmic surgeons. The real kangaroo has become quite rare, as their skins are valuable and the price paid to market hunters was a sufficient inducement for them to carry on a war of extermination. For the same reason the wallabys have also become much less numerous. These animals are now protected during certain seasons of the year, which will, it is to be hoped, prevent them sharing the same fate that we meted out to our buffalo. The tendons are obtained by divesting the tail of its skin, cutting off its tip, grasping each tendon with forceps and extracting it with a jerk. The proximal end of the evulsed tendon is a little larger and more flattened than its distal end.

CLIMATE.

The Australian has a wide range from which to make a selection of climate, as it is influenced by latitude, elevation and distance from the coast. Floods and drought are the bad things which have seriously interfered with the continuous prosperity of the country, and they likewise have a decided influence on the climate. The northern part of Australia is tropical and has a tropical climate, and the vast forests secure for that section of the country an abundant rainfall and a luxurious vegetation. In the vast dry plains of the interior the heat during the summer months is intense; here the thermometer has been known to register as high as 140 degrees F. The Australian Alps consist of a range of mountains in the southeastern part of the country called Warragong by the natives. The highest peak is Mt. Kosciusko, which rises to an elevation of 7,176 feet. This forest-clad mountain range has a decided influence on the climate of the surrounding country, breaking the force of the icy winds from the south in winter and the land breezes from its summit moderating the heat during the summer months. The climate of Sydney is very much like that of Naples, with a mean annual temperature of from 58 to 62 degrees F. Frosts in winter are common; the highest temperature in summer does not exceed 104 degrees F. At Melbourne, 500 miles south of Sydney, very thin pellicles of ice are sometimes seen during midwinter on small, quiet pools of water; the summers are decidedly cooler than in Sydney. At Sydney the average annual rainfall is over 49 inches, and during the summer, from December to the beginning of March, the sky is cloudless and the nights generally cool, sufficiently so to remind the people of the use of woolen blankets. For the American visitor winter is the proper time to see Australia, as he will then escape our summer heat and will enjoy the Australian winter with its flowers and invigorating cool breezes.

PREVAILING DISEASES.

With few exceptions the prevailing diseases of Australia are the same as of our middle states. It has escaped the ravages of cholera. Sydney recently has had a number of cases of bubonic plague, but the rigid sanitary precautions resorted to by the Board of Health have succeeded in stamping out the disease. Malaria is met with only in the tropical part of the country. Pneumonia of a very virulent type occurs most frequently during the winter season. Acute articular rheumatism is quite rare. Influenza, scarlatina and measles make their appearance from time to time. Typhoid fever appears to be more frequent in the country and villages than in the large cities, as the latter have an excellent water supply. At Melbourne this disease is most prevalent during the holiday season, when the people leave the city for their vacation and live in the country towns, where the danger of infection from contaminated water is much greater. Isolated cases occur in the cities and can usually be traced to infected wells, which are still in use in parts of the cities that remain outside of the reach of the regular water supply. The skill of the medical men is well shown by the very low mortality which attends this disease and which does not exceed 6 per cent.

Prof. F. D. Bird has operated on three cases of typhoid fever in which a fatal termination from sepsis was imminent. He opened the abdomen, where he found a small quantity of serum, flushed with a hot saline solution, closed the wound and had the satisfaction of saving all of them, marked improvement being noticed as soon as the patients recovered from the immediate effects of the operation.

Tuberculosis of the lungs, joints, bones and lymphatic glands is met with in about the same frequency as with us. Leprosy prevails to some extent in Sydney and its vicinity. There are at present 17 cases in an isolation hospital on the coast at Botany Bay, several miles from the city. If a patient affected with leprosy has sufficient means to support himself in a house sufficiently isolated from other habitations he is not molested; if this is not the case he is compelled to seek the shelter of this "leprosy." Although actinomycosis is quite a frequent affection among cattle it is almost unknown in man. Blastomycosis is very rarely seen. Not a single case of hydrophobia has even been seen in Australia, although it has a large dog population, and the dingo or wild dog is numerous, as well as other animals capable of transmitting this disease. Tetanus is not more common than with us. In every large hospital from two to four cases are treated annually. In the acute form of the disease antitetanic serum has been found absolutely worthless as a curative agent. Hydatids are very common in the southern part of Australia, Adelaide and Sydney furnishing the largest percentage. The physicians attribute the disease to the drinking water. It affects most frequently the liver and lungs, but spares none of the internal organs. Operations on the brain for hydatid cysts figure in almost every hospital report. In all of the museums may be seen beautiful specimens of hydatids of the bones obtained by operation or postmortem specimens, illustrative of the extensive destruction of the entire shaft of the large long bones. It is also frequently found in the fascia and omentum. The disease is very rare in Queensland, resembling the geographic distribution of the disease in Germany, where it is very common in the northern part and rare in the southern. It has been observed in children from 3 to 4 years old. It pursues a more rapid course in the young than in the aged. Its course varies in different individuals. It may become latent when the cysts shrink and the symptoms subside. As the disease is often multiple, more especially in the liver and omentum, a number of operations may become necessary, as the surgeons have learned by experience that it is not wise to undertake too much at one time. Dr. Bird operated on a patient suffering from hydatids of the omentum nine times before he was able to eliminate all the cysts. The *x-ray* never fails in locating cysts affecting the upper surface of the liver; this diagnostic resource invariably yields a negative result when the under surface is affected. The methods employed in operating for hydatid cysts of the liver are not uniform. Dr. Bird cuts down on the cyst, makes a free incision, inserts the index finger, brings up the margins of the cut and stitches them to the external wound, extracts the lining membrane and drains. In operating for a cyst on the upper surface of the liver he resects a short piece of the eighth rib near the costal cartilage and through this wound deals with the cyst in a similar manner. He always drains. Dr. Fiaschi of Sydney, on the other hand, is in favor of suturing the wound at once, without drainage. In nine cases he was obliged only once to reopen the wound. At the Children's Hospital in Melbourne it has been observed that in 90 per cent. of the cases of hydatid cysts operated on an urticaria develops in from a few minutes to two hours after the operation, which disappears in the course of from one to two days and which is attributed to an intoxication by the contents of the cyst absorbed from the wound surfaces or the peritoneal cavity. The contents of monocytes are much more virulent than cysts which contain daughter cysts. In rare cases, after tapping or operation, speedy death from this cause takes place; tapping has consequently been abandoned.

THE PEOPLE.

Most of the original settlers of Australia came from England, Scotland and Ireland. These people have reserved their

habits and customs to a large extent, but in the course of time a new generation has grown up whose methods of life have been molded by climate, occupation and environments. The English, Scotch and Irish accents have not suffered on Australian soil; if anything, they have become accentuated, more especially the English. This accent is bad enough in London, but is worse here. In rapid conversation some words are unintelligible to the American. It does not take long for the stranger to find this out, as all he has to do is to tackle one of the big policemen and ask him for directions to find a certain street or place of business, and he will have to listen very attentively to interpret his brogue. The real Australian is determined to make the best of the present and enjoy life. His desire for great wealth is a very moderate one, and he will not sacrifice his personal comfort to obtain it. He is satisfied with an income that will insure for him an easy existence and the cherished personal comforts. He agrees with Juvenalis:

"Wretched is the guardianship of a large fortune."

You will fail to find here the careworn, determined faces that throw a gloom over the restless throngs that crowd the streets of Chicago and other great American business centers. The Australians are excessively fond of outdoor sport. Men and women, young and old, are equally determined to throw away the cares of life as often as possible and enter with heart and soul into the enjoyment of all sorts of outdoor sports. Every Saturday noon business is suspended and the whole afternoon is devoted to pleasure. Yachting, races, baseball, golf and cricket are the most popular outdoor amusements. On the Saturday I was in Sydney 30,000 people attended a game of baseball, and as a yacht race was going on at the same time and the many events elsewhere were well patronized, it is evident that nearly every family contributed its share to the vast outdoor crowds. Sunday is respected as a day of rest. All shops and saloons are closed. In the morning the churches are filled to overflowing and during the hours of worship all tram cars come to a standstill. In the afternoon the houses are deserted and the people congregate in the many public parks, botanical and zoological gardens. The Public Domain, across the street from the Botanical Garden, is the place for the stranger on Sunday afternoon if he is desirous to obtain a good idea of Australian life. On the Sunday I visited this park, which includes about forty acres, I found a moving sea of human beings, in the center of which a military band played martial music. A short distance from the periphery of this immense gathering were smaller groups in all directions. The first one I approached was an old-fashioned Methodist exhortation meeting with a leader on one side of the small open space. After each stirring song someone would step forward and in a few words relate his religious experience and encourage others to do the same. Almost within hearing distance of these revivalists was a much larger crowd listening to a fiery political speech, the subject of which was the pending election. In the middle of the next group, and it was not a small one, a tall, lean, long-bearded man was discoursing on personal magnetism, illustrating his smooth talk with crudely drawn pictures. He explained to the gaping men, young and old, the mysteries of love and how to prevent shipwrecks in the matter of the selection of a partner for life. He had fathomed the human heart to its very depth and evidently had his share of this world's experience. For the time being he gave his advice free and liberally, but undoubtedly at the end of his harangue he supplied his audience with his address so that they would have no difficulty in finding him to obtain further details. Several fake physicians were expounding the virtues of their specific remedies which would cure all kinds of chronic diseases which still baffle the skill of the medical profession. These men had their stuff with them and were lining their pockets with silver. The next orator was talking to a large crowd of laboring men on the evils of monopolies and our millionaires received their full share of condemnation. The Salvation Army and temperance people were also well represented in this complex of gratuitous humane endeavors. In the evening the great thoroughfares presented a similar

spectacle. Australia has more than its share of orators who firmly believe in the power of eloquence.

"Nothing appears to me nobler than to keep assemblies of men entranced by the charms of eloquence, wielding their minds at will, impelling them at one time, and at another dissuading them from their previous intentions."—Cicero.

The orderly behavior of the people and the close attention they paid to the speakers is deserving of well-merited praise. What Australia needs to develop its slumbering resources and to increase its prosperity is a larger population. The present population of this great country is less than 5,000,000, and statistics show that for the last ten years it has rather decreased than increased. Japanese and Chinese immigrants are, by a recent act, absolutely excluded. For some time these yellow people paid \$500 for the privilege of entering the country. Abject poverty and begging are almost unknown. All classes of people take a keen interest in educational and charitable institutions. The typical Australian is neither a European nor an American; he exhibits qualities that indicate the geographical location of his country half-way between the European and American continents, from each of which he has assimilated habits and customs which characterize his thought and action. He has acquired the business tact of the American and retains the love for recreation and amusement of the Europeans.

THE NATIVES.

The aborigines of Australia appear to be quite a distinct race and have nothing in common with the South Sea Islanders. They bear a closer resemblance to the Africans in the black or dusky brown color, thick lips, short flat noses, narrow, high and sloping forehead; copious growth of jet black straight hair. Mentally they are far beneath the Polynesians. They live a nomadic life without a permanent habitation and rely on fish and game for sustenance. They were a fierce, warlike people who with spear, arrow, clubs and boomerang, fought the whites persistently until they became convinced of the utter uselessness of their efforts to resist the superior force of the invaders. Even now the natives of Queensland in the dense forests and jungles occasionally show a hostile attitude toward the pioneers in the steadily advancing line of civilization. The natives, who numbered hundreds of thousands when the white man took possession of the country, as the result of a war of extermination, and acute and chronic infectious diseases introduced by the whites, have been reduced to a very small number. The census taken in 1902 shows that the present native population consists of 52,157 blacks and 7,128 half castes. The Tasmanians fared even worse than this. In 1803 the island had at least 5,000 inhabitants. The whites began a war of extermination which lasted thirty years. The crude implements of native warfare proved powerless against the firearms of the invaders, and when resistance ceased there were few left to relate the story of the heroic struggle made in the defense of their beloved island, and the whites could ease their conscience by asserting:

"It is the right of war for conquerors to treat those whom they have conquered according to their pleasure."—Caesar.

The race became extinct with the death of the last Tasmanian in 1876. Such is the cruel fate of the primitive races. Tuberculosis and syphilis are doing their insidious deadly work among the survivors of war and the ravages of acute infectious diseases, and their complete extermination is only a question of time.

THE MIKA OR KULPI OPERATION.

This custom was first noticed by Eyre (1845) in the country around the great Australian Bight, and is well described by Professor Stuart of the University of Sydney in a paper read before the Royal Society of New South Wales, June 3, 1896. The operation practically consists in, generally at the age of puberty, cutting the floor of the urethra so that it is slit completely open from below, the cleft sometimes extending only half-way back, sometimes the whole way back to the scrotum.

Sometimes a more perforation is made. The intent of the operation is to prevent impregnation and came into use as a safeguard to prevent a too rapid increase of the population, serving thus a useful purpose in diminishing the struggle for existence. The operation consists in creating a partial or complete hypospadias. "The incision is made with a sharp-edged piece of quartz, shell, flint, or, in more recent times, glass. These fixed with resin, twine, etc., into handles constitute the 'mika-knives.' The bleeding is stanching with sand, and the edges of the wound are burnt, Lemholz says, with hot stones—perhaps, as Etheridge suggests, to cauterize them—and keep from adhering again and healing by being kept apart with bits of stick, wood, bark or bone inserted between them, or by being filled with clay, or by being rubbed with a broad-edged stone." The operation constitutes a kind of a ceremony and is performed sometimes eight days after birth, but more frequently between the ages of 14 and 18. The men thus operated on are given privileges that are not within reach of the non-kulpi men. In regard to the effect of this mutilation on the chances of impregnation opinions differ. Eyre, who first described this condition, says: "This extraordinary and inexplicable custom must have a great tendency to prevent the rapid increase of population, and its adoption may perhaps be a wise ordination of Providence for that purpose, in a country of so desert and arid a character as that which these people occupy." Professor Stuart summarizes his very instructive paper in the following conclusions: 1. Nothing whatever can be definitely stated as to the origin of the custom. 2. The operation does not necessarily render the man sterile. It merely diminishes his fertility; what the degree of diminution may be will depend entirely on circumstances.

THE SURVIVING ABORIGINES.

A large number of natives still live in unexplored parts of northern Australia in their original state. The civilized portion has become a government charge like our Indians. They are extremely lazy and depend almost entirely on the government support. I visited two of these settlements, one at La Perouse on Botany Bay, seven miles from Sydney, and the other at Coranderk, near Healeville, forty miles from Melbourne. At each of these places there are about sixty persons, most of them half-castes. The first colony lives on a forty-acre tract of land; the latter has 5,000 acres set aside by the government for their exclusive use. At La Perouse they live in small huts made of corrugated iron; at Healeville there are small frame or brick houses. Some of the oldest members of these settlements retain their original type and were children when Sydney and Melbourne were villages. All of them speak English and the children have lost the language of their parents.

SYDNEY.

Sydney is a prosperous, growing city with 450,000 inhabitants. The houses are built of stone, brick and cement or brick alone. Most of the main thoroughfares are paved with hard-wood blocks, the spaces between them filled in with cement. The electric lighting and electric tram system, water supply and sewerage, the many public parks, library, museum, botanical and zoological gardens are the best proofs of the wide-spread public spirit of its citizens. The university, public and private schools, hospitals and other charitable institutions and the many churches speak well for the intellectual quality of its people. The location of the city on the hills inclosing the magnificent harbor compares well with Naples. The country around Sydney surpassed all my expectations. Dr. Hinder gave me an automobile ride of sixty miles and we passed through a country dotted with orange groves and fruit orchards, and a part of the faultless macadamized road led over mountains 900 feet high, through virgin forests skirting dark, deep ravines, with inspiring glimpses of country scenes in the far distance. The orange trees are small and not over six feet in height, with dark green shining leaves in such strong and beautiful contrast with the heavy burden of golden fruit. The forest, or as it is here called, the bush, was resplendent with flowers of all hues and blooming shrubs.

HOSPITALS.

Sydney has made ample provision for its sick poor. The public hospitals are supported by donations and annual subscriptions; the latter are doubled by the government, besides the government pays for each charity case \$5 per week. None of these hospitals has private rooms, but the patients who have means pay what they can toward their support, the maximum charge being \$5 per week. Medical and surgical service is rendered gratuitously by the members of the staff. The lack of private rooms in all of these institutions makes it necessary to establish private hospitals, a number of which are conducted by nurses; others are owned and managed by the surgeons themselves.

SYDNEY HOSPITAL.

The Sydney Hospital was founded in 1814 and the original building remains as a wing of the new building. It is a massive three-story stone building adjoining the Houses of Parliament. It is the largest of the hospitals, the number of beds aggregating 460. Two large marble tablets in the main hall are inscribed with the names of its donors in gilt letters. The smallest amount that entitles a person to this distinction is \$250; the largest contribution among the more than 100 names I noticed was \$11,500. The ceilings are high and the wards well lighted and ventilated. Scrupulous cleanliness prevails throughout. There are two operating rooms, one for aseptic, the other for septic cases, and both are well equipped for modern work. Ether is the favorite anesthetic and biniodid

land, M.B. (Ch.M. Sydney). The medical staff has an equal number of members. The specialists are well represented in this institution. A very interesting feature in this hospital is the meeting of all attending men for consultation every Tuesday evening. At these meetings cases are presented and difficult diagnoses settled, and advice freely given as to the best treatment to be pursued. This phase of the medical service has much to recommend for imitation in our great hospitals. Dr. Fiaschi, who conducted me through the hospital, showed me many cases of gastric and intestinal surgery, all doing well, and a number of cases of hydatids recently operated on. Operations for stone in kidney and bladder and removal of hypertrophied prostate are of very frequent occurrence. Dr. Fiaschi is in favor of the suprapubic route in both of these operations, while some other surgeons prefer the perineal in performing prostatectomy. I was somewhat surprised to learn that the ligature remains popular in operations for hemorrhoids. The annual report shows that 19 cases of hydatids were operated on with no death. Of these cases 13 involved the liver and the remaining other parts. Of 8 cases of prostatectomy 5 were cured, 1 relieved and 2 died. No mortality in 20 ovariotomies and only one death in 12 cases of operation for myofibroma.

ROYAL PRINCE ALFRED HOSPITAL.

This is a modern hospital in every sense and has accommodations for 250 patients. It is a solid red brick building three stories high, built on the pavilion plan. It is in this hospital

Fig. 1.—View of Sydney Hospital from the northwest.

Fig. 2.—The operating theater, Sydney Hospital.

of mercury 1 to 500 is used for hand disinfection, and catgut has the preference over kangaroo tendon as a suturing and ligature material. In the surgical wards I found many cases of fracture and excision of joints. Plaster of paris is used extensively as a fixation material, both in the treatment of fractures and after resection of joints. Hip-joint resections are usually made through the anterior Luecke incision. Asepsis is carried out in a thorough manner, as was evident from the many primary wound healings I saw. The medical staff is assisted by ten internes, graduates of the Sydney University. The appointment of internes is made on the merit of their standing in their college work. Those who have the best record go to the Prince Alfred Hospital; the Sydney Hospital has the next choice, then come the remaining hospitals. The internes receive a small salary, serve for one year and receive the benefit of all departments by transfer every three months. The Sydney Hospital has an excellent training school for female nurses which occupies a separate wing, the Nightingale wing. The course of training extends over four years. The nurses are in charge of a matron and five Protestant sisters. They receive a small compensation during their pupilage. A well-equipped laboratory and a complete Roentgen outfit add much to the scientific work of the institution. The attending surgeons are called "honorary surgeons." The present surgical staff consists of W. Chisholm, M.D. London, M.R.C.S. England; R. Steer Bowker, L.R.C.P. Edin., M.R.C.S. England; Thomas Fiaschi, M.D. and M.Ch. Univ. of Pisa; H. L. Mait-

that the students of the Sydney University receive their clinical teaching and training. It was founded in 1871 in memory of the Duke of Edinburgh, who visited Australia in that year and was wounded by a crank who shot him. It was framed as a general hospital and medical school for the instruction of students attending the Sydney University, and for training of nurses for the sick. It is managed by a board of fifteen directors. The chancellor of the university and the dean of the faculty of medicine are directors *ex-officio*; three directors are appointed by the government and the remaining ten are selected by the government and subscribers. The medical officers are all appointed by a conjoint board, consisting of the senate of the university and the directors of the hospital. The selection is made from the teachers of the medical school and the appointment is made for six years. The medical staff is composed of three physicians, three surgeons, two gynecologists, one ophthalmologist, one dermatologist, one rhinologist and aurist. A resident medical superintendent and six internes reside in the hospital. The clinical amphitheaters are small, furnished with wooden benches and desks, the latter a great convenience for the students in recording their observations. The training school for this hospital has seventy pupil nurses who remain for four years, but receive a small salary after their period of probation.

I found in this hospital, under the guidance of Dr. Alexander MacCormick, professor of surgery in the Sydney University, many rare and interesting cases of gastrointestinal surgery.

Professor MacCormick has a very large service in this institution. The remaining members of the surgical staff are Messrs. Charles P. B. Clubbe and H. V. C. Hinder, both of them eminent and successful surgeons. The gynecologic practice is in the hands of Messrs. Foreman and Thring, whose reputation extends far beyond the limits of Australia. The last annual report of this hospital shows some very remarkable statistics. Of 20 cases of hydatid of the liver operated on all recovered. In 30 cases of cholecystotomy operated on 26 recovered and 4 died. No death in 64 radical operations for hernia. In 16 cases of suprapubic and perineal cystostomy 2 died and 14 recovered. Sixty-five cases of simple appendectomy without a death; 27 cases of appendicitis with abscess formation with 7 deaths; 14 cases of appendicitis with rupture and peritonitis, 7 deaths and 7 recoveries. Three cases of pylorectomy without a death; 33 abdominal hysterectomies with 3 deaths; 60 cases of salpingo-oophorectomy for tubal disease with 2 deaths; 11 tubal gestations with no mortality. The operative records of this hospital make an excellent showing and would compare well with those of any hospital in America and Europe. The outdoor department is in a separate building and furnishes an enormous amount of material for the teaching of minor and casualty surgery.

MEDICAL PROFESSION.

The medical profession of Sydney is fully imbued with the spirit of modern medicine and surgery. Isolated as Australia is from the other continents, its medical profession keeps pace with the newest and best in medicine and surgery. The country has no lack of the very best medical talent. The three medical schools furnish an abundant supply of young, enthusiastic and well-educated doctors to fill the gaps made by death, retirement and removal, and for this reason the country has no need of medical men from without. The doctor's social standing in Australia is much superior to our own. His financial possibilities compare well with that of any other country. A fair average fee for a capital operation is \$250; maximum, \$500; consultation from \$10 to \$25, and visits average \$2.50; obstetric fee from \$10 to \$25. There are several men in Sydney whose annual income amounts to \$30,000. The country practitioners, of course, do not fare so well, but their expenses are so much less that at the end of the year their bank account makes a fair showing. The relations between the members of the medical profession are cordial and the commercial element is not nearly as rampant as with us. The requirements for entrance into the practice of medicine are not at all stringent. A licensing board examines the credentials of the applicant and, if the candidate is in possession of a diploma from a recognized medical school, he is admitted without passing an examination. The local branch of the British Medical Association meets monthly and the sessions are usually well attended. The Australasian Medical Congress meets every three years and includes New Zealand.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Tuberculous Peritonitis.

Jour. des Practiciens gives the following suggestions:

ACUTE.

The treatment of this condition may be outlined in general the same as for any acute peritonitis: ice on the abdomen, opium, and milk diet.

CHRONIC.

Surgical interference is rarely demanded; never, perhaps, unless there is intestinal occlusion or a suppurative process.

MEDICINAL TREATMENT.

External.—Paint the abdomen with tincture of iodine; when this is dry apply collodion. The following has also been recommended:

- R. Guaiacal m. xv | 1
- Olei olivæ m. cl | 10

M. Sig.: Paint the abdomen and cover warmly with cotton.

Brisk friction with soap has been tried. The actual cautery and fly blisters have relieved pain; the urine should be examined before blistering. The following soothing ointment is recommended:

- R. Extracti belladonnae |
- Extracti hyoseyami |
- Extracti conii, 5â gr. xv | 1
- Chloroformi m. xlv | 3
- Adipis benzoatæ 5i | 30

M. Ft. ointment. Sig.: Use morning and evening.

Internal.—Care should be taken not to disturb the digestion. Cod-liver oil is not well borne. The following is prescribed by the French:

- R. Infus. walnut leaves 5i 3 | 10
- Garus' elix. 5i 2/3 | 50
- Sodii arsenatis gr. 3/20 | 01
- Syrupi cinchonæ 5v | 160

M. Sig.: Two tablespoonfuls daily.

Garus' elixir is a favorite French compound of cloves, aloes, saffron, myrrh, cinnamon, nutmeg, vanilla, maidenhair fern, orange flower water, sugar and alcohol. As this elixir probably could not be obtained in the United States a substitute might be used.

In cases of diarrhea, instead of giving the arsenic internally, hypodermic injections of sodium cacodylate should be administered; these might be alternated with injections of lecithin or the glycerophosphates.

Thomas of Geneva advises:

- R. Olei morrhuae 5iii 1/3 | 100
- Creosoti (beechwood) gr. viiiss | 50

M. Sig.: Use for a daily enema.

For diarrhea, bismuth, opium, and tannic acid are indicated; for constipation, castor oil.

GENERAL HYGIENE.

As in pulmonary tuberculosis, hygiene is important, plus good and nourishing foods, e. g., eggs, broiled meat, fresh butter, milk, milk stews. Fresh air, plenty of rest, and the seashore is advisable when the fever has subsided.

Facial Paralysis.

Pritchard, in the *Internat. Clinics*, vol. i, gives the following outline of treatment for this condition:

1. Massage the face daily with inunctions of lanolin.
2. R. Strychnin sulphatis gr. 1/25 | 0025
- Quinin sulphatis gr. i | 06
- Ferri carbonatis gr. iii | 2

M. Ft. capsule No. i. Sig.: One such capsule three times a day.

3. The application of electricity in the form of galvanism is made three times a week. An Erb electrode, 2x4 inches, is applied back of the neck, and to the paralyzed side of the face an adjustable (pliable, flexible) Erb electrode, 2x4 inches, is applied. Five to seven milliamperes of electricity are introduced by means of the rheostat and the seance lasts from 10 to 25 minutes. Faradism, with a current of high tension, on alternate days would prove advantageous, especially in preventing atrophy. The empirical use of potassium iodid is sometimes of benefit, when given in doses of from 5 to 10 grains well diluted.

Influenzal Sciatic Neuritis.

1. Functional rest so far as possible. It may be necessary to put patient to bed; it may be necessary to apply the long hip splint so adjusted that local applications of heat or cold

may be made along the course of the nerve. The actual cauterization may be advisable at times.

2. If drugs are necessary for the pain it is not worth while to waste time with the coal tar products or anti-rheumatic remedies, but resort to morphin in sufficient doses.

3. Electricity applied as follows is useful: Galvanism daily, from 5 to 10 milliamperes through the largest sized Erb electrodes, one under the right foot and the other under the buttocks, the patient sitting on the well-protected electrodes.

4. Massage given daily, gently at first; all so-called Swedish movements being avoided.

5. For general internal medication the author recommends the following:

R. Strychnin sulphatis	gr. 1/40	0016
Acidi arsenosi	gr. 1/50	0013
Quinin sulphatis	gr. i	06

M. Ft. capsule No. i. Sig.: One such capsule three times daily.

The author urges the utmost conservatism in surgical intervention, and recommends the thorough study of the case for a possible causative factor; e. g., diabetes, gout, malaria, pelvic tumors, hyperplastic conditions of the bones, aneurisms, varicose veins. Flat foot may induce symptoms closely resembling sciatica.

Intercostal Neuritis.

The author recommends the following two formulas, the second one having given the best results:

R. Quinin salicylatis	gr. iiii	20
Codein	gr. ¼	016
Quinin sulphatis	gr. i	06

M. Ft. capsule No. i. Sig.: One such capsule every four hours.

R. Strychnin sulphatis	gr. 1/25	0025
Caffein	gr. i	06
Quinin sulphatis	gr. ii	12

M. Ft. capsule No. i. Sig.: One capsule every three hours.

Brachial Neuritis.

The undershirt is lined with lamb's wool fleece covering the shoulder and arm down to the wrist. Daily injections of lanolin by very gentle massage are given. Galvanism is given daily as follows: one electrode, 2x4 inches, heavily protected back of the neck, the extended hand resting comfortably on the other electrode, which is of the same size. The current is introduced cautiously for the first two or three treatments and the quantity must not exceed 3 milliamperes. Gradually the current is increased to 3 or 4 and even to 8 milliamperes. The following is recommended for internal use:

R. Codein	gr. ¼	015
Quinin sulphatis	gr. i	06
Sodii salicylatis	gr. iiii	2

M. Ft. capsule No. i. Sig.: One capsule every four hours.

Diet in Diabetes.

Hutchinson, in the *London Practitioner*, gives the following suggestions for the dietetic treatment of diabetes:

In severe cases a change of diet must be made very cautiously. If the addition of a few drops of a solution of the perchlorid of iron causes the urine to assume a dark port wine color, such a patient is in danger of coma, which may apparently be precipitated by any sudden change in dietetic habits. The carbohydrates should be reduced very slowly, and bicarbonate of soda given in doses of from one-half to one ounce daily. If the patient shows signs of failure and coma by the gradual withdrawal of the carbohydrates and the substitution of the proteids and fats, it is best to abandon all attempts at a rigid diet and allow a definite quantity of carbohydrates in the form of bread and milk. In any event in this class of cases it is not advisable to give more than the equivalent of 500 grams of nitrogenous food daily.

If the perchlorid of iron test is negative a more strict diet may be adhered to without much anxiety. The sudden or the gradual method may be used; the latter is to be preferred. Eliminate from the diet sugar, and all the grosser forms of the carbohydrates, then the farinaceous foods, then bread, and finally even milk, each of the articles being replaced as it is

withdrawn, by a carbohydrate-free substitute. The author gives the following as the final strict diet:

Breakfast: Bacon or buttered eggs, or both, or some cold ham; casoid-meal bread with plenty of butter; coffee made with sugar-free milk and sweetened with saccharin.

About 11 a. m.: A glass of sugar-free milk and a diabetic biscuit or rusk.

Luncheon: Any animal food, e. g., a little cold meat or game, or some fish; cheese; salad with plenty of oil; some starch-free bread; as a beverage, any natural wine or a little spirit and aerated water.

Afternoon: Tea with plenty of thick cream and a diabetic rusk or two, or biscuit, with plenty of butter.

Dinner: Any clear soup with the addition of some grated cheese; fish; any meat; green vegetables with melted butter; baked custard made of sugar-free milk and eggs; beverage as at luncheon.

At bedtime: A glass of sugar-free milk and a diabetic rusk or biscuit. If after a few weeks the patient has been doing well a small quantity of weighed bread may be allowed and the condition of the urine carefully watched.

FATTY FOODS.

"It may be truthfully said that the usefulness of any article of diet to a diabetic is in direct ratio to the amount of fat which it contains. Fat is the only nutritive constituent of food, which can not do a diabetic any harm; it never increases the output of sugar." "The best forms of fatty food are bacon and butter (each of which contains about 80 per cent.) cream (60 per cent.), and salad oil or olive oil (which are pure fat). Every diabetic should learn to consume at least a quarter of a pound of butter a day; his bread should be soaked in it, and it should be used as a sauce for green vegetables and fish. Cream may be taken in tea or coffee. If there is difficulty in digesting enough fat, the administration of a little alcohol at meals will often improve matters."

Medicolegal.

Improper Questions for Judge to Ask Expert Witness.—The Supreme Court of Georgia holds, in *City of Columbus vs. Anglin*, that it is error for a trial judge, after an expert witness has testified, to ask him questions so framed as to intimate an opinion that the testimony of the witness is improbable or erroneous.

Insanity or Unconsciousness as Defense.—The Supreme Court of California says, in the case of *People vs. Nihell*, a prosecution for assault with a deadly weapon, that the instruction given the jury that the burden of proof is on the defendant where the defense of insanity is relied on was, as a proposition of law, correct. It was contended, however, that the defense in this case was not insanity, but that the defendant was unconscious of the act. But this could not render the instruction prejudicially erroneous. The theory of the defense on the trial seemed to be that the defendant was unconscious from the dual effects of liquor and epilepsy. The jury could not fail to see that the instructions regarding insanity related to that peculiar mental condition that the defendant claimed to have been in, by whatever name it might be called. And, thus understood, it was correct to say that the burden was on him to establish the peculiar mental condition which he relied on as a defense. Men are presumed to be conscious when they act as if they were conscious, and if they would have the jury know that things are not what they seem they must impart that knowledge by affirmative proof. The rule as to the burden of proof was correctly stated, whether it be applied to insanity or to unconsciousness as a defense; and the refusal of instructions recognizing the opposite rule was proper.

Power to Quarantine—Construction of Health Laws.—The Supreme Court of Minnesota says, in *Town of Isoco vs. Board of Commissioners of Waseca County*, that the town, during the months of February and March, was afflicted with one case of diphtheria and a smallpox epidemic. It was claimed that un-

der the statutes the board of supervisors of the town, together with the physician to be employed by them, when, in their judgment, necessary, constituted the board of health, and that the duty of ordering and enforcing a quarantine rested with that body as a legal entity; hence that the action of the chairman of the board of supervisors of the town, who immediately, on notice from the secretary of the state board of health, proceeded to employ a physician, and then take steps to enforce a quarantine, was without authority, and furnished no sufficient basis for subsequent reimbursement against the county. But the court holds that where the chairman of the town board of supervisors, on information of the secretary of the state board of health, received information that an epidemic of smallpox was prevalent in his town, and incurred expenses to quarantine the persons afflicted therewith, but without receiving specific authority therefor from the town board of health, and the expenses were audited and paid by such board, the want of authority to order the quarantine was sufficiently ratified to authorize reimbursement from the county under the statutes in force at the time. It says that the provisions of law for the protection of the public against the spread of a pestilence are remedial, and to be largely and beneficially construed, to advance and subserve, but not embarrass, the purpose of their enactment. Effective regulations can not be promptly and successfully enforced without the employment of efficient means to accomplish that result, which requires the speedy use of the necessary remedial agencies. To delay the institution of a quarantine until the board of supervisors can be called together might defeat the very purpose of the statute, and deprive the community of the benefits intended by the health laws of the state. Hence, under an emergency such as was found to have existed in this case, where the chairman of the town board acts immediately in good faith, incurring expenses of a beneficial nature to the public, the court regards it as its duty to hold that a practical construction of the statute must be given to accomplish the purposes intended thereby. To sensibly give effect to the health laws to secure a protection of the public, a liberal and sensible view must be taken of the law to secure its object, and no technical objection that would prevent its enforcement according to the spirit and purpose of the statutory regulations should be sanctioned.

Validity of Practice Act.—The Supreme Court of California says, in *ex parte* Whitley, with reference to the constitutionality of a statute exempting from its requirements those practicing at the time of its passage, that in some instances the question arose under acts regulating the practice of medicine, and in others, as here, regulating the practice of dentistry; but the same reasoning would apply and the same constitutional principles govern as to the validity of provisions of a dental as of a medical act, because the profession of dentistry is but a special branch of the medical profession, and the power of the state to regulate as to both in the interests of the public is equally clear. Such legislation has been uniformly upheld. It is neither special nor class, and no privileges or immunities are conferred thereby on one class to the detriment of another. Nor does the court find any merit in the contention that the statute arbitrarily creates three classes of persons who may practice dentistry in the state after examination: 1, Graduates of reputable dental colleges; 2, graduates of high schools or similar institutions of learning requiring a three years' course of study, who have served an apprenticeship of four years with licensed practitioners within the state; 3, dentists from other states who have been licensed practitioners for five years. The court says that it is entirely within the power of the legislature to fix any reasonable standard for determining the competency of an applicant for admission to the practice of dentistry. It might, as under the act regulating the practice of medicine and surgery in California, where only those who are graduates from a medical college can be admitted to practice, have also made a similar single standard, limiting admission to practice dentistry to those alone who had graduated from some dental college. As this might have been the sole condition on which an applicant could be examined, it can

not be said that legislation which enlarges the right and extends it to others can be said to be discriminatory. The law, no doubt is discriminatory, but not in any constitutional sense. It does not discriminate between classes. The discrimination goes to the degree of learning and skill which all applicants for examination must possess. It is a discrimination which, in the interest of the public welfare, it is the duty of the legislature to make, and concerning the necessity for which, and its nature and extent—whether an examination and right to practice shall depend on the possession by the applicant of a diploma of a dental college only, or be extended to others and how far—depends primarily on the judgment of the legislature which, when reasonably exercised, the courts can not control. And the court says that the power to determine whether a college was reputable had to be lodged somewhere, and it was properly committed to the only body which could fairly and intelligently determine, not only the qualifications of the applicant, but on the reputation of the college whose diploma he claimed to possess—the state board of dental examiners.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

6. *Present Status of the Etiology of Malignant Growths. Raymond Wallace.

1. **The Radical Cure of Hernia.**—The adoption of the important suggestions of a number of different surgeons with reference to the radical cure of hernia is advocated by Tinker, who believes that such a combination operation is superior to any of the numerous methods which have been devised. The Ferguson method of closure, with the imbrication or overlapping method of Andrews, with excision of the veins of the cord, as suggested by Bloodgood; transplantation of the rectus muscle, by Woelfler, and transplantation of the neck of the sac behind the internal oblique, probably would give the results necessary to a radical cure. This composite method has all the advantages of any of these single methods, and a great many advantages not possessed by most of them. Of course, the value of faultless surgical technic can not be overestimated. Tinker also advocates local anesthesia, principally because of the lessened danger to life. He uses a 1 to 500 cocaine solution to which a 1 to 120,000 solution of adrenalin chlorid is added. This prevents oozing by delaying the rapidity of absorption, practically eliminates all danger of poisoning, at the same time adding greatly to the efficiency of the anesthesia. The solution does not need to be freshly made, and it can be boiled without deterioration.

2. **Dust Infection and Dust Disease.**—Under the name dust disease, or dust fever, Hessler describes an acute infectious, endemic disease, due to the inhalation of dust contaminated by sputum. The specific diseases which can be transmitted through the agency of dust or which may follow the inhalation of dust, such as pneumonia, tuberculosis, typhoid fever, etc., are not included in the definition, but only those heretofore vague and illly defined symptom-complexes that are variously referred to or misdiagnosed as "colds," "biliousness," sick headache or migraine, hypochondria, etc., or as atypical cases of influenza, rheumatism, neurasthenia, gastritis, malaria, etc., or as cases of a rheumatic or gouty diathesis, or of lithemia, not to mention autointoxication, eyestrain, etc. Dust disease is characterized clinically by an irritation of mucous membranes; vague wandering pains throughout the body, mostly referable to the mus-

cles or ligaments; lassitude, headache, feverishness, and anorexia, up to vomiting, marked nervous disturbance and severe localized pain. It is often followed by other specific diseases. The disease is most prevalent in crowded cities, although country people may become affected or attacked on going to the city. It is absent among arctic explorers and weather observers in high mountains. Dust disease belongs to that class of affections in which there are no marked or recognizable pathologic lesions. Mucin may play an important part. The causative factor is infective dust. It is most common in the fall and spring, when high winds prevail and when the streets are not sprinkled. The practical application of the recognition of dust disease or of a knowledge of the evil influence of the dust lies along the line of prevention, pointing out to the afflicted the nature of their ailment and its cause. The inhalation of a sputum-contaminated atmosphere, also a history of attacks after similar exposures, and the absence of the disease while living in a good atmosphere, are important points in making a differential diagnosis. The treatment is principally prophylactic.

4. **Ethyl Chlorid.**—Craig says that the merits of ethyl chlorid as a general anesthetic are not fully appreciated. The drug is peculiarly adapted to conditions requiring brief anesthesia, such as the various minor surgical procedures occurring in dispensary service of general surgery and gynecology; in a fairly wide field in obstetric practice, and in much of the operative work of the nose and throat specialist. Its use is especially indicated in young subjects. Only the pure preparation of the drug should be used for general narcosis, and the best method of administration is some form of the "open" method—either the Ware mask or the ordinary gauze compress, the former requiring a smaller amount of the drug. It is not suited for prolonged operations, as it does not produce complete muscular relaxation.

6. **Etiology of Malignant Growths.**—Wallace summarizes his paper as follows:

It would appear that as the dividing line between various neoplasms is so difficult to determine, and the transition from a non-malignant to a malignant growth depends on such slight conditions, that contrary to all infectious conditions which might be considered analogous, exceedingly few cases have been recorded of malignancy in the newborn, and exceedingly few cases in childhood, which also militates against any theory of direct heredity; a multiplex and varying etiology must seem the most plausible. Intrinsic irritation of the cell-proliferating mechanism in the nucleus may, with the advance of cell chemistry, yield certain autogenous factors; but as extrinsic factors, may be summarized; various physical, chemie and physiologic irritations and the irritations caused by parasitic life, any of which cause an evident disturbance in cell-proliferation, as it were, a loss of equilibrium, which leads to insane proliferation and the consequent formation of neoplastic growths. The degree of malignancy would then depend on the rate and type of proliferation, and the loss of function and consequent reversion of type in the proliferating cells, attest the theory of nuclear or chromatin alteration or rearrangement. The foregoing argument, based on both clinical observation and pathologic data, is offered, perhaps, as a slightly different phase of a much-discussed and ever-important subject.

9. **Professional Responsibility.**—The professional responsibility of the medical attendant or examiner employed by the party sued for damages and that of the doctor of the patient, says Roberts, are identical. The duty of both is to obtain, as soon as possible, restoration of the victim's health and a just settlement of the pecuniary debt of the agent responsible for the accident. The writer emphasizes two points: 1. That an ignorant, careless or injudicious doctor may be the real cause of many cases of traumatic hysteria and neurasthenia, and, 2.

that prompt settlement of damage suit is an inestimable aid in the cure of accidental injuries associated with litigation.

10.—This article has appeared elsewhere. See THE JOURNAL of September 10, title 82, page 759.

11. **Headache and Diseases of the Nose.**—Headache as a symptom is mentioned in connection with the following diseases of the nose and nasopharynx: Acute rhinitis, specific rhinitis, hay fever, asthma, hyperesthetic rhinitis, hypertrophic, atrophic, fetid and non-fetid rhinitis, morbid conditions of the osteo-cartilaginous framework, such as deflected septum, thickening of the septum, pressure on the septum, exostoses, synechia, and caries; sinusitis; benign growths of the nasopharynx, such as adenoids, polypi, syphiloma, echondroma, papilloma, osteoma, and rhinoscleroma; malignant growths of the nasopharynx, first, by pressure on the nasal membranes from their rapid growth, and, secondly, a constitutional condition due to cancer cachexia; finally, foreign bodies in the nose and rhinoliths.

12. **Sigmoid Sinus Thrombosis.**—Bacon's patient, following an attack of gripe four years ago, had an acute mastoiditis on the right side, which subsided promptly under treatment. The present illness began three weeks ago, when she had another attack of gripe followed by a severe throbbing pain in the left ear and side of the head. Four or five days later there was a discharge, profuse and thick at first, and tinged with blood. On cutting down on the mastoid process, the cells were found to be filled with pus. The mastoid tip was removed, and the sigmoid sinus exposed for one inch below the knee. It was covered with granulations, and in removing these the sinus wall was accidentally injured. In spite of every precaution, sepsis developed, necessitating a second operation. On incising the sinus between two points of compression, it was found that a thrombus was forming at the bulb. After this operation the temperature gradually came down and the patient made an uneventful recovery. Bacon thinks it probable that the infection of the sigmoid sinus is due to the accidental injury of its wall during the mastoid operation, although it is possible that the infection had already reached the sinus in the usual way. Although there was but a slight flow of blood from the bulbular end of the sinus during the second operation, he did not ligate the interior jugular vein, believing it unnecessary, as the clot in the vein had not broken down. The symptoms of sepsis subsided as soon as the parietal clot in the bulb was removed with a curette.

13. **Hereditary Abnormality of Little Finger.**—Mundorf's paper is the result of an examination of 38 persons, all descended from one individual. The deformity was a permanent flexion of the little finger, resembling the condition known as Dupuytren's contraction. In the members of this family, consisting of grandfather, children and grandchildren, the deformity occurred in 14; in one hand in 11 persons, and in both hands in 3 persons. In 10 cases the little finger of the right hand only is abnormal, and in one case the little finger of the left hand only is abnormal. Each of the five children also suffered from hallux valgus, but the deformity was not transmitted to the grandchildren, except in one case. Mundorf believes that these findings point to a strong hereditary influence.

17. **Cytodiagnosis in Pleural Effusions.**—With a view to establishing the value of cytodiagnosis in pleural effusions, especially those of tuberculous origin, Carter carefully examined 56

cases, 10 of which were of known tuberculous origin and 20 of probable tuberculous origin. In 6 cases the effusion followed lobar pneumonia. His results are extremely suggestive, and because of their uniformity in the various series of cases, certain facts may be accepted as positive. He found that all true pleural effusions have a specific gravity over 1010, usually much higher, with an average of about 1017.9; a high fibrin and albumin content. Pleural transudates, on the other hand, have a low specific gravity, the average being about 1008, a small fibrin and albumin content. An almost certain diagnosis of tuberculous pleurisy can be made by the morphologic examination of the fluid. It rests on its having a high specific gravity—1012 to 1024, average 1018.6; a large amount of fibrin and albumin, with an accompanying lymphocytosis. If a polymorphonuclear leucocytosis is found before the third or fourth day of a tuberculous pleurisy, subsequent examinations will be necessary to establish a positive diagnosis. Post-pneumonic serous effusions have a very high specific gravity, averaging 1016.5; large fibrin and albumin content, with a polymorphonuclear leucocytosis, 58 to 92.5 per cent., averaging 71.7 per cent. A differential diagnosis between a pleural transudate and a tuberculous pleurisy can not rest alone on a differential cell count, as they both show a lymphocytosis, but must rest on a more complete examination, including the specific gravity and the amount of fibrin and albumin. The fluid should be examined as promptly as possible after aspiration. The color, turbidity, specific gravity, reaction and relative albumin content are then obtained. When the fluid cools the presence or absence of a fibrin clot is noted. This is a gelatinous mass when seen fresh and undisturbed, but on agitation of the fluid collects into a small oblique mass of more dense fibrin, resembling that seen after whipping fresh blood. Guinea-pigs may be inoculated for bacteriologic diagnoses with from 2 to 9 c.c. of the fluid, the injection to be made subcutaneously into the anterior chest wall. To complete the examination, a conical tubeful of the fluid is rapidly centrifuged for five minutes and the sediment stained on a cover slip with Jenner's differential stain. A differential count is then made of the leucocytes; the endothelial cells, erythrocytes and general characters noted.

18. **Venous Thrombosis in Typhoid Fever.**—Thayer has gathered together statistics with regard to cases of venous thrombosis occurring in the course of typhoid fever. Out of 1,463 cases of typhoid fever, there have been 39 instances of venous thrombosis, a percentage of 2.6. Two cases were admitted during convalescence, while one case, a patient who had suffered from double iliac thrombosis coming on during typhoid fever, entered the hospital for treatment two years later. In all these cases the onset occurred almost invariably in the third week or later. Local pain and fever were usually the first symptoms. The fever sometimes preceded the localizing symptom. In 28.2 per cent. of these cases there were chills, the chill in several instances preceding the appearance of localizing symptoms. As a rule, the condition was associated with an increase in the number of leucocytes, the leucocytosis apparently depending on the extent of the lesion. In mild cases it may be absent. The thrombosis was commonest in the lower extremities, especially on the left side. The femoral vein was most often involved. Thayer says that in the event of a sudden severe pain in the lower part of the abdomen, coming on during the latter part of typhoid fever, and associated with a leucocytosis, the possibility of iliac thrombosis should always be considered. Venous thrombosis in a lower extremity is always a serious complication of typhoid fever. Although the immediate danger is not great, the after-results are often grave. In thrombosis of the popliteal or deep veins of the calf alone, the permanent changes are much less severe, though the leg always remains larger than the other. In thrombosis of the femoral vein a greater or less part of the blood from the affected extremity is often carried up by the iliac vein of the opposite side, the current crossing the abdomen through an anastomosis in the hypogastrum, resulting in a characteristic triangular area of varicose veins.

19. **Treatment of Simple Rectal Fistula.**—Kelly describes a

method which he has tried in five cases, with three successes. However, to employ his method successfully, the fistula must be simple and direct. He empties the bowel thoroughly, having the patient under his care for at least two days before the operation. The rectum is dilated under anesthesia, and a pack is inserted within the ampulla. The external orifice of the fistula, which must be free from any signs of surrounding inflammation, is then circumscribed, and after being grasped with forceps, the fistulous tract is carefully dissected out up to its abutment of the mucous surface of the bowel, in the region of the internal sphincter muscle. The rectal orifice is next carefully excised through the wound so as to make a transverse opening parallel to the sphincter fibers, when the excision is completed and the fistula removed. If the wound is a shallow one, it may be closed with a few interrupted silk-worm-gut or silver-wire sutures, extending from the skin surface down to the bottom, care being taken to draw the circular muscle fibers together above and below the rectal orifice, and to avoid leaving any dead spaces. The margin of the bowel is next everted and the operation concluded by closing the opening on the mucous surface with fine silk suture. It is a good plan, says Kelly, to cut away some of the mucosa below the rectal end of the fistula, so that when the mucous membrane is sutured the mucosa from the upper margin of the opening is drawn down and sutured to a point a centimeter or more below the orifice, in this way covering it in by withdrawing the line of suture from any direct relation to the deeper wound. No effort should be made to move the bowel for from five to seven days, keeping the patient on a diet consisting of nothing more than sips of albumin water. If suppuration occurs, the infection breaking through into the bowel, Kelly advises passing one blade of a pair of scissors or a bistoury through the opening, dividing it with one cut and packing it, the patient in that event being no worse off than if an ordinary incision and packing operation had been done.

23. **Study of Cancer.**—Some of the more striking features of the review by Galbraith of the study of cancer covering the last two hundred years are: 1, That cancer is almost wholly absent in the tropics; 2, that cancer is very rare among savage races; 3, that with the advance of civilization and the increased prosperity of nations there has been a steady and marked increase of cancer; 4, that this disease is more prevalent among the well-to-do and wealthy than it is among the poor; 5, that it is more common among men; 6, that it is hereditary; 7, that it is a disease par excellence of the climacteric; and 8, that in order for tumors to become malignant a lessened physiologic resistance of the whole tissues or of the body in general is necessary. As to treatment, the first step taken must be in the direction of prophylaxis; when a woman reaches the age of 40 she must be placed in the best possible position for the resistance of this disease. Should cancer make its appearance, an immediate operation is imperative. If the case, when first seen, is too far advanced to make operation advisable, or should there be a recurrence of the disease, the x-rays and violet rays, combined with serumtherapy, offers the greatest hope. Based on the absence of cancer in the tropics, and that other well-known fact that light is capable of killing the tubercle bacillus, treatment by direct sunlight should be instituted.

28. **Peculiar Nervous Symptoms Following Operation.**—Blalock removed a cystic tumor in a young woman, aged 22, who, seventy-two hours after the operation, began to have slight twitchings, not confined to any special muscles. Soon after the

patient became unconscious, the right leg and arm were extended, the left was drawn up; the jaws were locked; the pupils were normal. When she was allowed to be perfectly quiet for awhile the lower jaw was dropped, but as soon as she was touched the jaws would close violently. This condition lasted eight days, during which time the patient received large quantities of normal salt solution. The temperature never exceeded 99, and only once did the pulse rise to 130. The patient eventually made a complete recovery.

- 34 Examination of Pleural Fluids with Reference to Their Etiology and Diagnostic Value. (Continued.) Percy Musgrave.

32. **Liver Abscess Following Abdominal Infections.**—Jones has collected 114 cases of abscess of the liver following abdominal infection from the literature. Of these, the appendix was the focus of infection in 100 cases; salpingitis or pelvic cellulitis in 11 cases, and perforating gastric ulcer in 3 cases. The most frequent situation was the right lobe, close to the posterior superior surface. It was the seat of the abscess in 50 per cent. of the cases, both lobes in 44 per cent., the left lobe in 6 per cent. The varieties of abscesses found were: 1, Multiple abscesses, usually situated near the periphery, and varying in size from that of a pinhead to that of a walnut; 2, the single abscess, usually situated close to the periphery, but may be found in any part of the organ; 3, large single abscess surrounded by a colony of small ones; 4, two or more large abscesses, widely separated; 5, several large abscesses which may connect; or, 6, one large abscess, with the remainder of the liver filled with small ones. The portal vein was found to be infected in 55 cases; in 38 it was not stated whether the vein was infected, while in only 21 was it stated that it was not infected. Of 114 cases, 16, or 14 per cent., were operated on for drainage of the abscess; 7 cases, or 44 per cent., recovered, while of those not operated on none recovered. It is interesting to note that of the 7 recoveries, in 3 one or more ribs were resected; in 2 the abscess was in the left lobe and drained through the abdomen; in 1 it was in the right lobe and drained through the abdomen; while in another, after an abdominal incision had been made and closed, the abscess ruptured through the incision. Jones adds to this list of cases culled from the literature, 4 cases seen by him, 2 of which were undoubtedly the result of appendicitis. One was possibly due to the result of appendicitis, though there was no definite proof of this, and 1 was the result of an abscess in the region of the pylorus, probably a perforated gastric ulcer. All of these cases were operated on, but only two recovered.

33. **The Effect of Strychnia on the Blood Pressure in Fevers.**—Cabot noted the effects of strychnin on the blood pressure in 31 cases of typhoid, 4 of pneumonia, and 15 others with a variety of diagnoses. In 32 cases the strychnia was given by mouth and in 18 subcutaneously. The total daily dose was usually 1.8 grain, sometimes 1.6 grain. Records were taken for days and occasionally for weeks before and after the drug was given. All measurements were taken with Stanton's modification of the Riva-Rocci instrument at intervals of a few minutes to several hours, succeeding the administration of the strychnin. The observations extended over about eight months, and included about five thousand measurements. The total result was negative. Cabot was unable to convince himself that strychnin exerts any influence on the blood pressure of febrile cases when given in the manner and dose mentioned above. There was no change in the blood pressure following the administration of the drug in 24 cases, a fall in 17, a rise of 5 millimeters or more in 16 cases. The average pressure in the 50 cases that received a daily dose of strychnia was no greater than in 18 cases without any drug.

39. **Feeding and Rest Cure in Typhoid.**—Hare fails to see any reason that would justify disordering metabolism by the institution of a rigid single diet, and is fully impressed, from personal experience as well as from physiologic facts, with the utter inadequacy of the pure milk diet in the treatment of typhoid fever. It is his custom to give all patients after the first week of typhoid from one to two soft-boiled eggs a day in addition to the ordinary allowance of milk, and to vary their diet by the use of curds and whey, rice which has been boiled to a pulp, barley, wheat, and oatmeal gruel, and a cup of cornstarch with vanilla or some other flavoring substance of a like character. As a result of this diet he very rarely sees marked ataxia, which is so common a symptom in convalescence and typhoid; and the patient's nutrition is so well preserved that he is but little more emaciated than many cases of acute pneumonia at the time of recovery. Secondary complications like furuncles and bedsores are unknown. He believes that the average case of convalescent typhoid fever is a fair mark for any infection, because the patient is half starved. Recognizing that typhoid fever is characterized by a deficient secretion of digestive juices, all his patients receive hydrochloric acid and pepsin with their proteid foods, and taka-diastase and pancreatin when carbohydrates are used. He is utterly opposed to the use of beef tea, which he believes acts as a first-rate culture medium and frequently increases tympanites and diarrhea, and the stools become infected under its use. Hare considers that the value of the modern method of treating typhoid by cold depends in great part on the fact that when cold bathing is used the patient, who is undoubtedly suffering from a form of toxic neurasthenia, receives a form of rest cure which maintains strength and puts him in first-rate physical condition. The free use of cold water is not the chief factor for good in these cases, but the rubbing or massage which follows these baths is of the very greatest importance, aiding the dissipation of body heat, readjusting the circulation and exerting on the patient the beneficial effects which follow the use of massage as seen in the rest-cure treatment of neurasthenia. Therefore, he advocates the employment of the Weir-Mitchell rest cure in the treatment of typhoid fever. Equally good results can be obtained if these patients are properly sponged, with friction, instead of being plunged. The sponging possesses the additional advantage that the patient does not have to be moved from his bed, that the great muscles of the back can be given more attention than the anterior portion of the body, thereby increasing the dissipation of heat very greatly and preventing the formation of bedsores. Patients with a temperature below 102.5 should be given tepid baths with friction. Since he has been feeding his patients, Hare finds that he is giving them less alcohol than formerly, probably because the patient burns up food products in the body instead of burning up alcohol. He throws out the suggestion that alcohol may act as a stimulant on the functions which are connected with immunity and the ability of the body to resist infection.

41. **Vertigo.**—The entire subject of vertigo is discussed by Aldrich, and several cases are reported. He emphasizes the value of the hemadynamometer in making a differential diagnosis in certain forms of vertigo.

43. **Sodium Chlorid and Silver Nitrate.**—The use of a solution of sodium chlorid after the application of silver nitrate to any

part of the urethra has shown itself, in the hands of Griess, to be of great value. The indications and reasons for the employment of sodium chlorid are: 1, The silver salt can be used with greater comfort to the patient, as all excess silver is precipitated; 2, the desired effect from silver nitrate is accomplished quickly, therefore an excess should not remain in the urethra, as it not only causes unnecessary pain, but actual harm; 3, the caustic effect of the silver salt is eliminated to a great extent; 4, the stronger per cent. solutions of the silver salt, which are often necessary, can be used, for overaction or caustic effect need not be feared; 5, the application can be made more general; 6, clinical evidence shows that this method of application yields excellent results and that the proper per cent. solutions to really do good can be used. The application of the solution of sodium chlorid should be in a manner the same as is employed when the silver was injected, by means of a deep urethral syringe. Enough time should elapse after the application to allow the operator to remove the syringe, wash it out, and then proceed as he did with the first injection.

45 *Intracranial Tumors in the Insane, with a Report on Two Cases. Irwin H. Nell.

46 The Study of Pathology. George Dock.

47 Remarks on Biliary and Hepatic Surgery. Hal C. Wyman.

45. Intracranial Tumors in the Insane.—Owing to the difficulty in securing a subjective history, and also to the resistance often offered by the patient to the necessary examinations, cases of brain tumors in the insane are quite frequently overlooked or remain unrecognized during life. Nell reports two cases of brain tumor, both patients being pronounced insane at the time of admission to the asylum. In one case the psychical condition was thought to be dependent on syphilitic brain disease; in the other case, epilepsy was believed to be the cause. A short time after admission to the asylum, a diagnosis of brain tumor was made in the first case, but its exact site, which proved to be basal, was undetermined. In the second case a large subcortical sarcoma, involving one entire hemisphere and extending to the opposite side, was recorded as an anomalous case of parietic dementia; but during the latter months of the patient's illness a brain tumor was suspected. Both cases had a clear history of syphilis, but at the autopsy neither of them showed the characteristic lesion of luetic brain disease. Nell considers the first case a particularly interesting one, as it demonstrates that an intracranial pressure can be directly responsible for not only the general symptoms of brain tumor, but also for "focal symptoms," which are commonly ascribed to localized lesions. The tumor was located about the center of the middle cerebral lobe, and was quite extensive. There was no infiltration of brain tissue, but simply absorption from pressure. The tumor had a definite capsule composed of very thin fibrous tissue. The interesting factors in the second case, a sarcoma of the entire left cerebral hemisphere, extending to the right basal ganglia, the right temporosphenoidal and about one-half of the frontal lobe, were the persistence of fixed and systematized delusions of persecution; the disturbance of speech; active and severe attacks of delirium, and symptoms indicating "focal disease."

51 *A Clinical Study of the Diazo Reaction. W. Taylor Cummins.

52 A Note on Laboratory Teaching in the University of Pennsylvania. Alfred Stenzel.

48. Circulatory System in Pregnancy and Puerperium.—Stenzel and Stanton have made a very careful study of the heart and circulatory system during pregnancy and the puerperal state in 60 cases, in order to determine what changes, if any, take place. They conclude that there is not, during pregnancy, any hypertrophy of the left ventricle, nor any special increase in its work. That the increase of dullness toward the

left is due to the upward displacement of the diaphragm and the consequent displacement of the heart in an upward and outward direction. That after labor the heart returns rapidly to its normal position. The extension of dullness toward the left in the second and third interspaces, the frequency of distinct pulsation and a systolic murmur in the same area, the authors believe to be due to distension of the conus arteriosus and the root of the pulmonary artery. They are convinced that during the later months of pregnancy there is some continuous dilatation of the right ventricle, though this is apparently of very moderate degree. In multiparae, separation of the recti materially lessens the tendency to displacement of the diaphragm and diminishes in a corresponding degree the displacement of the heart during pregnancy. After delivery this distention of the recti may occasion a downward displacement of the apex of the heart, and the contrast before and after labor may be quite as pronounced as in the primipara. Later, if the separation of the muscles is not considerable and the normal tone of the abdominal walls is regained, a restitution to the normal of the heart and its apex occurs. The investigations of the blood pressure made by the authors show that there is no material increase either before or after labor. During labor there may be a notable increase in the blood pressure, which may be explained by the holding of breath, the expulsive efforts, etc.

51. The Diazo Reaction.—Cummins has investigated the value of the Diazo reaction as an aid in diagnosis, and sums up his paper as follows: 1. The Diazo reaction is of importance in differentiating a relapse from a complication in typhoid fever. 2. It may be of assistance in separating measles from German measles. 3. It has great prognostic significance in pulmonary tuberculosis. It does not appear until late, and is usually noted in a rapid case. When it once appears it persists until death. The average duration of life after the appearance of the reaction is about six months. An unfavorable prognosis should be given in every patient presenting this reaction. 4. The Diazo reaction at a dilution of 1 to 40 is of some value in the diagnosis of typhoid fever, but on employing a dilution of 1 to 150 other conditions are eliminated (except a small percentage of tuberculous cases), and the test, therefore, is considerably enhanced in value.

53 *Some Remarks on the Diagnosis of Typhoid Fever. Greer Banghman.

54 Treatment of Typhoid Fever. Wm. S. Gordm.

55 Modification of Fracture Splints for Thigh Fractures. G. A. Baxter.

53. Diagnosis of Typhoid.—For the diagnosis of typhoid in the first week, Banghman says the practitioner will have to depend on: 1. The history of malaise, anorexia, chance of infection, headache, etc. 2. Temperature curve. 3. Pulse (out of proportion to the fever and sometimes dirotic). 4. Tympanitis; gurgling in the right iliac fossa; tenderness. 5. Rose spots at the end of the week. 6. Widal's reaction. 7. Blood examination, normal leucocytes, but increased mononuclears and decreased polymuclear count. 8. Diazo reaction. 9. Isolation of bacilli in feces. 10. Isolation of bacilli from blood and rose spots or splenic puncture, when practicable.

56.—See abstract in THE JOURNAL of September 10, title 37, page 756.

57. Succinic Peroxid.—According to Yarbrough, this is an organic peroxid derived from succinic acid. It is a fluffy, finely crystalline powder, soluble, colorless, stainless, odorless, non-poisonous, non-volatile and practically non-irritating. It does not coagulate albumin. It is also non-corrosive to animal tissues, non-explosive and non-hygroscopic. It is useful for the sterilization of the hands, local surface areas, instruments and

appliances, dressings, sponges, etc., taking the place of bichlorid, hydrogen peroxid and carbolic acid. It may also be used internally as a wash, gargle, injection, in the form of the powder, for insufflation and as a dusting powder.

59. **Eclampsia and Vaginal Cesarean Section.**—Severe continuous puerperal convulsions, says Carstens, are often fatal, or leave serious sequelae, hence require the most heroic treatment. Prompt delivery affords the best—in fact, the only—chance for success. Vaginal cesarean section enables the accoucheur to deliver promptly.

 70 *Ecarache. G. Hudson Makuen.
 71 Typhoid Fever. R. Myers.

62. **Appendicitis.**—Langfitt reports a case of suppurative appendicitis in which, after operation, the condition of the patient became progressively worse because of obstinate constipation. Finally a fecal fistula established itself at the stump of the appendix, and much fecal material was discharged through it. The temperature on the following day was normal; the patient in fine condition, with the fistula discharging and the bowels moving freely. Ten days later temperature rose to 102, vomiting reappeared, with great pain and distension. Examination revealed the fistula to be closed. Langfitt made a second fecal fistula, and an enormous amount of fecal material was discharged through the new opening. On the following day vomiting ceased and pulse and temperature were normal, and remained so throughout convalescence. The immediately improved condition of the patient after the formation of each fistula is convincing evidence of its worth.

70. **Ecarache.**—Makuen discusses the causes of ecarache and the treatment, at the same time advising that every physician familiarize himself with the use of the head mirror and the aural speculum so as to enable him to diagnose diseases of the external auditory canal and the tympani. It is essential to detect middle ear complications in their incipency.

 73 Report of a Case of Perforation of the Gall Bladder in Typhoid Fever. Park W. Willis.
 74 *Humanity and Common Sense vs. Idealism in Venereal Prophylaxis. G. S. Peterkin.

74. **Venereal Prophylaxis.**—The object of Peterkin's paper is to demonstrate that the best and most logical method of venereal prophylaxis is the education of the individual; that the educator must realize that every man must and will make his own morality; that the educator's line of argument, to be efficient, must deal with universal and necessary principles and be based on natural conditions, not idealisms; that from a standpoint of morality, there are many men in various degrees of moral evolution; that they evolve by degrees; that different arguments appeal to different degrees of evolution; that to appeal to all classes and any individual, one must possess a good knowledge of every side of the subject to be dealt with and the principles that govern its action. He advises that scientific facts should be stated in a systematic, concise, yet acceptable manner, so that men and women, knowing them, will see the necessity of protecting themselves, and in so doing will limit the spread of venereal disease. He suggests that these facts may be arranged in pamphlet form under the following heads: 1. Facts for all men. 2. Facts for some young men. 3. Statistics showing the dangers and monetary losses caused by venereal diseases. 4. Personal prophylaxis against venereal disease for men during sexual indulgence. 5. Personal prophylaxis against venereal disease for women during intercourse.

 78 *Trephining of Skull Twelve Years After Accident. Will S. Smith.

75. **Stab Wound of the Heart.**—Smith reports the case of a man, aged 22, who received a stab wound in the left breast, between the fourth and fifth ribs, two inches to the left of the sternum, the knife blade penetrating the right ventricle. When seen thirty minutes after the infliction of the wound the radial pulse was imperceptible; the heart sounds were barely audible. A curved incision, about six inches long, was made, beginning at the upper border of the fourth rib, extending through the stab wound to one inch to the right of the left border of the sternum. Two inches of the fourth and fifth ribs were resected, together with a portion of the sternum. The pericardium was opened, and the heart brought up into the field of operation. The laceration was ragged and parallel with the heart muscle. It was closed with a continuous silk suture. The pericardial cavity was washed with normal salt solution and the sac sutured with a continuous silk suture. Silkworm gut was used to unite the skin flaps, a gauze drain being inserted. Moist bichlorid dressings were applied, and over these a pad of absorbent cotton and a binder. During the operation, which lasted about fifty minutes, the patient was receiving normal salt solution in both thighs. The patient felt well and was doing nicely up to the time of death, which occurred seven days after operation. The cause of death was pericarditis. At the autopsy it was found that the laceration in the pericardium and in the heart wall had healed perfectly and there was not the slightest oozing. The sacs contained an apparently healthy fluid, but with adhesions from the sac to the heart. The posterior surface of the heart and left ventricle was covered by plastic inflammatory exudates. The heart wound was filled with healthy granulation tissue.

76. **Ectopic Gestation.**—The case reported by Coffey was operated on at the eighth month of pregnancy because the patient had ceased to feel life. The skin of the fetus was slightly macerated; the membranes were intact on the head and lifted over the scalp at the hair line like a cap. The patient gave a history of a severe pain and hemorrhage at the end of the first month of pregnancy, at which time, no doubt, the embryo was passed into the abdominal cavity, where it continued to develop among the intestines. Considerable difficulty was experienced in removing the placenta, but eventually the patient made a splendid recovery.

78. **Trephining Twelve Years After Accident.**—Smith's patient consulted him twelve years after sustaining a compound fracture of the skull, with depression of the inner table, because of a persistent, dull, aching pain on the left side of the head, which also affected the muscles of the neck and was referred downward to the left hand. A very strange symptom was that the patient could turn his head to the right side without turning his body, but when he tried to turn his head to the left side he would have to turn his body to the same side. The depression corresponded internally to a point about the middle third of the central convolution. The under surface of the bone was chiseled away to correspond with the size of the external opening; the underlying thickened portion of the dura was removed, and the wound closed with silkworm gut, a gauze drain being inserted for the first twenty-four hours. The operation was successful in every way. Worthy of note in this case is the action of aseptic ergot, which the patient received hypodermically twice a day after the operation. The ergot not only relieved the pain, but also produced a quiet, refreshing sleep.

1. Arteriosclerosis.—During the past seventeen years Savill has made a careful study of arteriosclerosis, especially in regard to arterial hypermyotrophy and the other morbid changes which occur in the muscular tunic of the arteries. He contends that the pathology of the different tunics of the arterial system should be studied separately, just as are the different coats of the heart. That advanced atheroma and a considerable degree of intimal and adventitial sclerosis may exist without serious consequences and be compatible with extreme old age, provided the muscular tunic is unaffected. The prime importance of the muscular tunic, relatively to the intima and adventitia, in that it constitutes the functionally active structure of the arterial system and the regulator mechanism of the whole body, should not be overlooked. There is no doubt that arterial hypermyotrophy, as a substantive generalized change in the arterial system, exists, and its importance must be recognized by reason of the potential evils in the way of circulatory derangements, circulatory accidents, nutritional disturbances, disturbance of the balance between the heart and artery and the degenerations which are apt to ensue. Arterial hypermyotrophy is the first step toward senile decay, and it is the main cause of senile or postural vertigo at any age. The combination of arterial hypermyotrophy and focal necrosis of the media is a most deadly one and may produce death by hemorrhage at a comparatively early age. The condition may result from chronic renal disease, but it has many other causes, all of which probably produce the condition of high arterial tension.

3. Death from Bronchopneumonia.—Hardy presents an analysis of 150 cases of death from bronchopneumonia in children under 13 years of age, and on which postmortem examinations were made. He endeavors to show that the feeding of the children by bottle instead of at the breast increases the mortality enormously. Out of 64 cases under 4 years of age in which the method of feeding was known, 32 were breast-fed and 22 were bottle-fed—that is, the deaths from bronchopneumonia were equal, but according to the author's computation, the ratio of mortality among bottle-fed and breast-fed children is as 69 to 9—that is, the mortality from bronchopneumonia is 7.7 times as great in bottle-fed as in breast-fed children. There were well-marked signs of rickets in 25 of the 150 cases, or 16.7 per cent. Of 95 cases between the ages of 6 months and 3 years, there were 21, or 22.1 per cent., while of the 59 cases between the ages of 1 and 3 years—the rickets period par excellence—there were no less than 15, or 25.4 per cent., showing well-marked signs of this disease. In 15 cases the disease occurred during, or followed immediately on, an attack of measles. Of these, 4 patients were under the age of 1

year, 5 were between 1 year and 2 years, 3 between 2 and 3 years, 2 between 3 and 4 years, and 1 between 6 and 7. Twelve cases occurred during an attack of diphtheria. The youngest patient was under 1 year and the oldest under 4. Whooping-cough was a contributory factor in 7 cases. Eight cases occurred during an attack of meningitis; 5 during epidemic cerebrospinal meningitis, and 2 during an attack of suppurative meningitis secondary to suppurative otitis media. There were 5 cases of suppurative otitis media, 3 of general pyemia, 3 were thought to be due to the administration of an anesthetic, 2 occurred during an attack of typhoid fever. Scalds and burns preceded the illness in two instances. In one case the bronchopneumonia followed the impaction of a coin in the esophagus, and in another it was secondary to erysipelas. Twenty-one cases were initiated by vomiting and diarrhea. The right lung was alone affected in 9 cases, the left also in 9 cases; both lungs in 132 cases. There were 6 cases of massive bronchopneumonia, 15 cases of suppurative bronchopneumonia, 4 associated with suppurative otitis media, 4 with empyema, 2 with peritonitis, and 3 were part of a general pyemia, while 1 occurred with acute suppurative periostitis. Fifteen cases were complicated by acute fibrinous pleurisy, 1 by a pleurisy with effusion, 16 by empyema.

7. Tuberculosis in Childhood.—With a view to determining the correctness of Koch's statement that tuberculous milk is not a source of danger to the human subject, Kingsford has analyzed the postmortem records of 339 cases of tuberculosis in children of all ages up to 14 years. Of this number, 162, or 48 per cent., occurred during the first two years of life, and 270, or 80 per cent., during the first five years, while there is a steady decline in the proportion among older children. Regarding middle-ear cases as infected by inhalation, the tonsil cases as an alimentary infection, and the remaining pharyngeal cases as doubtful, the inhalation accounted for 216 cases, or 63.7 per cent., and ingestion of the 65 cases, or 19.1 per cent., the remaining 17 per cent. being of doubtful origin. So far as can be judged from these methods of investigation, Kingsford concludes that the danger from inhalation far exceeds that from the ingestion of tuberculous material. With regard to the importance of tuberculous milk, however great the potential danger may be, the real danger is greatly exaggerated, probably owing to the children not drinking tuberculous milk of the virulence and in the quantity usually affirmed. Still, the fact that nearly 20 per cent. of the cases of tuberculosis among children are primarily alimentary, makes out a good *prima facie* case against tuberculous milk, and Kingsford believes it will be shown that one of the chief differences between the conditions of life among children at home and abroad which could have any effect in predisposing to primary abdominal tubercle exists in the greater frequency of tuberculous milk in England. Although attention should be directed toward the restriction of the sale of tuberculous milk, it is chiefly to the improvements in the conditions of life, such as cleanliness, ventilation, disinfection and better housing, that we must look for the diminution of tubercle among children.

8. Prevention of Epidemic Diarrhea.—Nash has had printed for distribution among the laity two pamphlets. One, among other matters, calls attention to the dangers of long tube bottles, poor condensed milk, miscalled infant foods, and gives simple directions for preparing milk for hand-fed infants according to age. The second pamphlet contains the following:

DIARRHEA.—This disease is very dangerous and rapidly fatal in young infants. It is, therefore, necessary to know how to prevent it rather than to hope to cure it. Several causes contribute to this disease. Any or some or all of these causes may operate in a particular instance. It is important to know what they are and to take the necessary precautions to prevent all, if possible. They are, in one word—dirty. In more than one word, they are: (1) unclean milk and other food; (2) unclean jugs and bottles; (3) unclean hands; (4) unclean surroundings; (5) unclean air (from overcrowding, etc.); (6) unclean flies; (7) unclean dust.

Diarrhea is more common and fatal in hot weather than in any other time. Why?

1. Because there are more flies, which settle on dirty refuse heaps, dirty closets, dirty napkins, etc., and then settle on the food or tumble into the baby's milk, or get into the open tin of condensed milk, or walk about the sugar.

2. Because there is more dust, which is blown in at the open window to milk and other food left exposed.

3. Because germs are really very small microscopic plants, which like nearly all other plants, grow best when the weather is warm. Fortunately boiling will destroy nearly all germs. Therefore, during the hot weather, to prevent young infants from getting diarrhea from milk, boil all milk directly it comes into the house. But this is not everything. If after milk is boiled it is put into a half-cleaned jug or cup or bottle, or is left exposed so that flies can settle on the margin or fall into it, it will rapidly become contaminated again. Therefore, after boiling, always keep the milk in clean vessels and covered over with a clean cover. The milk should also be kept as cool as possible. A good plan is to stand the covered milk jug in a basin of cold water. A mother or nurse should always wash and dry her hands just before preparing the baby's meal. A large number of people in a room contaminate the air of the room and impart to it properties which will rapidly spoil milk. Therefore, it is important not to allow several people to come into the kitchen or near the ladder.

Every precaution should be taken to prevent flies settling on food and to destroy flies in the house. All animal and vegetable waste should be burned as soon as possible. If put into the dustbin or left about in the kitchen or larder, they cause offensive smells and attract and breed flies. Cleanliness in every detail is the great preventive measure against diarrhea.

When a case of diarrhea occurs in a house great care should be taken to at once place soiled napkins, etc., in a disinfectant solution and to burn all infected articles as soon as practicable. If napkins, etc., are left exposed flies can settle on them and carry back infection to the baby or to other children in the same house or in neighboring houses.

23. Enterectomy.—Syme says that the ideal intestinal union is one that will hold until cicatrization is complete and firm; one that will not allow contamination of the peritoneum by capillary oozing; that will not contract too much the lumen of the bowel or form too much of a diaphragm in its interior, and that can be performed rapidly. The Murphy button, when it is properly constructed, perfectly applied, and when it acts as it is intended, gives nearly this ideal result. Unfortunately, it is not always perfectly constructed and applied, and does not always act as it is intended. A case is described of carcinoma of the descending and pelvic colon, which infiltrated into an adjacent loop of jejunum. Enterectomy was done, the jejunum being united by suture and the colon by a Murphy button. The patient died about two weeks after operation, and at the autopsy the sutured anastomosis was found intact, but the button anastomosis was a slough with a circular hole, over the lateral aspect and upper edge of the button where the bowel wall was in contact with the abdominal wall. A second case cited was one of perforation of the uterus during curettage, with laceration of the bowel and the mesentery. Fifty-nine inches of small intestine were resected and end-to-end union by suture performed, continuous through all the coats, and then continuous Lambert. The patient made an uneventful recovery. Syme raises another objection to the Murphy button—that it may never be passed. A case is referred to where a portion of bowel was resected for carcinoma and an anastomosis done with the Murphy button. When the patient died of recurrence of the tumor twelve months later, the button was still in place. He advises against the use of all mechanical appliances toward intestinal approximation.

24. Intracranial Abscesses.—Webster cites a case of chronic suppuration in the left ear, followed by extradural abscess in the middle fossa, cerebellar abscess and sinus phlebitis. A

very extensive operation was performed, consisting of opening the mastoid cells, the middle fossa, cerebellum, sigmoid and lateral sinuses and the middle ear, with evacuation of a large quantity of pus. The patient made an almost uninterrupted recovery.

25. **Three Cases of Eye Injury.**—The first case reported by Ryan is one of infection of a corneal wound and threatened panophthalmitis six days after extraction of the cataract. He believes that an attack of influenza, which came on about the third or fourth day after the extraction, may have been a factor in the eye trouble. The patient recovered, with fair vision. The second case was one of monocular neuroretinitis in a boy of 10 years. There was no apparent cause for the condition. Ryan suggests that it may be due to a tumor of the optic nerve, and gives a bad prognosis. The third and last case was one of suture of an unhealed corneal incision nineteen days after extraction of a cataract, the material used being two fine silk sutures passed through the entire thickness of the sclera. The wound had healed within a week, when the sutures were removed.

Revue de Chirurgie, Paris.

26 (XXIV, No. 9.) *De l'intervention opératoire dans les néphrites et dans certaines affections médicales du rein (of kidney). A. Yvert (Dijon).

27 *Des sténoses tuberculeuses de l'intestin grêle chez l'enfant (of small intestine in children). L. Berard and H. Leriche (Lyon). (Commenced in No. 5.)

26. **Operative Treatment of Kidney Affections.**—Yvert discusses the results of surgical intervention in acute and in chronic nephritis, as well as in various other kidney affections. In acute nephritis the reports published to date indicate that nephrotomy is preferable, with nephrectomy later, if it proves inevitable. The former has a mortality record of 5 and the latter of 33 per cent. Decapsulation is still on trial. In case of pyonephrosis resulting from a concrement, nephrolithotomy, incising the convex margin of the kidney down to the seat of the stone, is the operation of election. He attributes to Pousson the merit of systematic operative treatment of chronic nephritis. Out of 9 cases of chronic nephritis treated with nephrotomy by himself or others, 5 of the patients were completely cured, 2 much improved and 2 died. In case of doubt as to which kidney is involved, the reno-renal reflex is an important guide, and an incision on each side would banish every doubt. Nephrectomy has been done in 5 cases of chronic nephritis, with 5 cures. In 2 cases the intervention was limited to capsulotomy with the actual canter, both cured. Decapsulation does not seem to offer many more advantages than simple nephrotomy, while it is a more serious operation. The future alone can decide whether it is preferable to nephrotomy; the evidence to date seems to be in favor of the latter. Rovsing's nephrolysis or destruction of adhesions after nephrotomy was successful in the 3 cases in which it was applied. It seems to be indicated when the adhesions are particularly extensive and thick. In case of essential nephrorrhagia, nephrotomy is indicated after failure of other measures, as Israel's experience has been so favorable with it. It is likewise indicated in case of rebellious nephralgia, and for the same reasons. In a desperate case of puerperal eclampsia, after failure of all other measures, Yvert would not hesitate to perform nephrotomy, bilateral if necessary, following Edebohl's certain way, but not to the extent of decapsulation. Pousson has performed nephrotomy in a case of rebellious anuria from hysteria, with the cure of the patient for a few months, but recurrence later. He operated only on suspicion of an actual affection of the kidneys, and cautions against similar surgical intervention in pure hysteria. On the whole, Yvert concludes that kidney affections are coming more and more into the realm of surgery. Operative treatment is indicated only after medical treatment has proved powerless, but under these circumstances it should not be abused, but should be resorted to without fear. Of all the modes of intervention proposed to date, the incision along the convex margin of the kidney, simple nephrotomy, seems to be the most effectual, while it is certainly the simplest and most inoffensive.

27. **Stenosis of Small Intestine in Children.**—Twelve cases are reviewed, including one personally observed, in which intestinal tuberculosis caused single or multiple stenosis of the small intestine. The symptoms are insidious and vague. They are noticed as diffuse pains in the abdomen; digestion is tedious and laborious; sometimes there is vomiting, and there may be alternations of constipation and diarrhea. Colic in sections, Hochenegg's "combined ileus," is characteristic when it occurs, but this is rare. The pains are sometimes accompanied by gurgling sounds. The vomit is exclusively of food. The stools may be bloody, or there may be all the signs of subacute occlusion. The abdomen is generally distended, especially in the flanks. Peristaltic waves reveal the painful efforts of the intestine against the obstacle within. Then the pain subsides and the abdomen becomes flatter, although local tympany may persist with gurgling sounds and dullness over the point. The stenosis in children is usually in process of evolution and not cicatricial stenosis, such as is more liable in adults. The stenosis is due to submucous infiltration in the course of enteroperitoneal tuberculosis. The symptoms of the tuberculous peritonitis may predominate. The general condition is bad, the children usually in such a precarious condition that one is tempted to defer the operation, although surgical intervention offers the only chance for recovery. The course of the affection is inevitably progressive. Enteroplasty is seldom indicated. Enterectomy should be done whenever practicable—that is, when the lesions are not extensive and the general health satisfactory. In other cases, the choice must be between exclusion and entero-anastomosis. The site of the stenosis will dictate the mode of intervention. In presence of very extensive foci, simple laparotomy remains the last resource to relieve the phenomena of inflammation, to cause the retrogression of the lesions, and possibly render a secondary resection practicable, while in more cases than one would suppose possible it may lead to the complete recovery of the child.

29. **Passive Congestion in Treatment of Joint Affections.**—Laqueur has applied Bier's technic of passive congestion by elastic constriction in 40 cases of various joint affections. The patients could use the limb freely after the tourniquet was applied, and all experienced relief from the pain almost at once. The passive congestion also had marked influence in promoting dissolving and absorption. In long established cases this influence was felt less, but in every instance the relief from pain and the improvement in the function were noticeable. It proved a valuable measure not only in chronic articular rheumatism, but also in arthritis gonorrhöica, and its cheapness, simplicity and ready application justify its more general adoption in joint affections. Bier's technic was strictly followed. It was described in THE JOURNAL, XI, page 69.

30. **Stomach Content in the Aged.**—Seidelin tabulates the findings in 70 subjects, grouping them by the decades after 50. He was surprised to find that the stomach secretion can be retained to an advanced age, even when the subject exhibits signs of pronounced senility in other respects. On the other hand, quite a number presented achlorhydria, and a certain connection between this condition and existing arteriosclerosis seemed to be unmistakably evident. The symptom of achlorhydria in elderly persons, therefore, should not be regarded as important in the diagnosis of cancer or other affections.

32. **Ptois of Abdominal Aorta.**—Stifler describes the form of ptois accompanied by dilatation and the form in which the aorta is contracted. The latter is evidently the result of some inflammatory process, and is the key that solves certain puzzling cases of abdominal ptoses, as well as many vasomotor and secretory anomalies and the symptom-complex of what he calls "sympathicisms." One of the most frequent predisposing causes is defective correction of a wandering kidney by unsuitable bandages. Ptois of the abdominal aorta is often treated by attacking the symptoms rather than the cause. The therapeutic indications are in general the same as for enteroptosis, but require more delicate application of local hyriatic and electric measures, as also of the supports to be worn. The latter require special medical experience to fit them to the individual case. In his experience with ptoses in general, Stifler has observed about 15 per cent. in which the abdominal aorta was involved or alone affected. He describes a few typical cases. In one, both kidneys were abnormally movable and there was painful gastric pulsation and distress in moving. The dilated, abnormally movable aorta could be distinctly palpated below the umbilicus. One kidney was fastened in 1901 and the other a year later. When seen in 1904, the right kidney had worked partially loose and lay crosswise. The aorta was nearly as wide as two finger breadths, palpable to the left and below the umbilicus; there was a systolic vascular murmur, and the left renal artery was likewise pulsating and dilated. Pain upward to the heart was elicited by pressure on the dilated aorta, with pain radiating to the left costal arch and up to the left scapula. When fatigued or lying partially on the left side, there was the typical gastric beat, weakness and sensation of faintness, but the ability to move and work had improved since the operation on the kidneys. In another case described, the dilatation of the aorta coincided with cardioptois, and finally kidney symptoms occurred similar to those observed with true aneurism of the aorta. By repose, suitable supports and hyriatic procedures the cardioptois was cured; the dilatation of the aorta persisted for some time longer, but finally yielded also to treatment. Another patient had suffered from paralysis agitans for years and both kidneys had become abnormally movable, with probably secondary dilatation of the aorta. The kidney and aorta troubles were cured by appropriate bandages alone. A patient with the irritative form of aorta ptois exhibited a painful pulsation through the entire abdomen below the stomach, most pronounced after exertion, with consecutive heart agitation, frequent vomiting, obstipation and sometimes polyuria. This patient was subject to attacks of stomach migraine. The aorta could be palpated as a movable small cord to the right of the umbilicus, with pain on pressure, radiating upward to the heart and to the scapula on both sides. Pressure on the aorta above the umbilicus induced vomiting and violent, persisting pains, with "inexpressible nausea" for a day afterward. A systolic vascular murmur was evident over the aorta. The left kidney was low and lay crosswise and was sensitive both spontaneously and on pressure. In another case nervous diarrhea, tremor of the entire body, heart cramps and distressing stomach pulsation were all traceable to some irritation of the peritoneum or muscular diastasis resulting from the trauma of a preceding childbirth. The aorta was sensitive to pressure, contracted, movable, sinuous and with strong pulsation, its course lying to the left of the umbilicus. By repose, bandages and packs the patient was practically cured, although there is still pulsation in the aorta a week before and

after menstruation. The aorta can still be palpated to above the umbilicus, and it is irregularly thick. The patient still feels the need of an abdominal support, but is otherwise in apparent health.

33. **Norwegian Scabies.**—De Amicis thinks that the individual conditions must be the reason why this form of scabies differs so much from the ordinary forms. The contagion was unmistakably derived from a person suffering from the ordinary form in both the cases he observed. The subjects were rachitic and poorly nourished.

34. **Virulent Inherited Lues in the Second Generation.**—Boeck reviews his observation of 4 unmistakable cases, and remarks that the conditions in Christiania enable the family history of the 4 subjects to be accurately known. The affected members in each generation applied to the same hospital, and careful records were kept of each. He adds that in his thirty years of practice he has never known an instance in which inherited lues could be satisfactorily traced to the father. Some trace of the manifestations of syphilis will invariably be found in the mother on careful search. He has encountered only 2 cases in which there was a suspicion of inheritance from the father and they were in society people, and an examination of the mother was impossible. The virulent syphilitic taint in the 4 children described was undoubtedly derived from the inherited syphilis of the mothers, of which they themselves were ignorant. They were all over 20, but this long interval is not so very unusual. Boeck knows of a woman of 47 who bore a syphilitic child thirty-seven years after she had herself been infected at 10. The great theoretic interest of such cases is that they show not only that the virus of syphilis may persist for many years in an organism long after it has lost its apparently virulent properties and has ceased to be contagious under ordinary circumstances, but they also show that this virus, when transmitted to the child through the placenta, can continue in the child. When the child is born and ceases to be under the influence of the maternal organism and of its alexins, the virus resumes its highly virulent properties, and they persist until the child's organism has in turn had time to develop its own necessary antibodies, which then transform the virus again into a non-virulent form.

36. **Cutaneous Lesions of Chronic Appendicitis.**—Fournier proclaims that chronic appendicitis is much more common than is generally recognized, especially those inflammations which are chronic from the start, never presenting an acute attack, but merely a train of vague protean symptoms. He heartily indorses Lucas-Championniere's views in regard to the part played in its etiology by meat-eating and grippe and the lack of the old-fashioned purges. He knows of many persons who seem to live only for the pleasures of the table, and yet, by means of regular purges and enemas, they keep in good health and live to an advanced age. Meat-eating is liable to induce a general vasoconstricting action and, by the toxins which it engenders, to produce irritation of the intestines, causing spasmodic contraction of the intestine, with obstinate constipation. This installs an infectious condition which throws wide the gate for all kinds of complications, and from enterocolitis may lead to chronic appendicitis. The cutaneous manifestations of this condition have not been much studied hitherto, although Moty has called attention to the flush in the right cheek, rarely missing in febrile appendicitis, and resembling the congestion noted in pneumonia in the cheek of the affected side. Labial herpes is also frequent. In one case of chronic appendicitis he noticed sudation of the head and neck on the right side. This hypersecretion extended exactly to the median line and persisted during the ten years of the chronic appendicitis, vanishing after appendicectomy. He noticed it also in a case of acute appendicitis. Fournier's experience has been that a number of cases of purpura, eczema, pruritis, urticaria, prurigo and acne are due directly to chronic appendicitis. The colon bacillus was found in the purpuras of some of de Benedicti's patients, demonstrating the intestinal origin of the toxemia. The purpura in one of Fournier's patients never reappeared after appendicectomy. In another pa-

tient no possible cause for the prurigo could be detected until slight tenderness at McBurney's point was discovered. He was put on a vegetable diet and the prurigo vanished. He grew thinner during the six months he kept up this diet, but his skin was entirely free from the eruptions which had previously annoyed him. In another patient, anal pruritis and eczema around the lips always appeared when intestinal troubles were noted, but since the latter have been avoided there has been no recurrence of the former. A pruriginous acne in another patient is undoubtedly due to chronic appendicitis, and Rournier anticipates a cure so soon as the patient is willing to have the appendix removed. The cutaneous manifestations in these and other cases were the clue to the ignored inflammatory process in the intestines. Whenever a recurring, obstinate cutaneous affection is encountered, which can not be referred to any other cause, the appendix should be suspected. The patients can be operated on at once or they may be cured by instituting a suitable diet, etc. The inherited or acquired neuropathy which is generally the cause of the primary enteroneurosis frequently misleads the physicians into regarding these patients as merely hypochondriacs, which they really are in the true sense of the word. Their descriptions of their symptoms can be relied on, as they are usually excellent observers. Siredey has well emphasized this point in his study of the "formes frustes" of appendicitis: "Beware of dyspepsia refractory to rational dieting and not traceable to any definite cause. All the subjects may not be affected with appendicitis, but the majority are, and the appendix should in every instance be carefully scrutinized." The presence of a refractory dermatosis may be an aid in diagnosing, especially when associated with a dull or "bilious" complexion, freckles or "liver spots," predisposition to goose-flesh, itching and urticaria.

38. Some of Jonathan Hutchinson's Opinions.—Merely to cite a few, may be mentioned Hutchinson's contention that syphilis should rank as a specific fever, and that the most convenient mode of treating it is in the form of pills of hydr.: cum Creta, 1 to 2 grains for a dose. The course should be kept up for a year or two without interruption. During the last ten years very few of his patients have known any other symptoms than the indurated chancre and the bubo. He allows marriage after two full years from the chancre. He does not believe in the possibility of transmission of syphilis to the third generation, but accepts that of transmission of syphilis from the father without direct infection of the mother. When the father only is the source of the taint, it is seldom that any except the first-born suffer. The virus probably exists in the ovaries much longer than it does in the testes. A great many instances of second attacks of syphilis have come under his notice. He believes that yaws, framboesia, parangi and thaku are forms of syphilis. In his experience, the characteristic teeth are commonly associated with interstitial keratitis, but the subjects of phagedaenic ulcerations very often do not show the teeth and sometimes escape the keratitis. Almost all the affections which pass under the names of prurigo and purpura urticans, lichen urticatus, bullous and chronic urticaria in children, and some of those called strophulus, are due to insect bites, he thinks, and gives nearly a dozen convincing arguments to sustain this view. Urticaria pigmentosa is the result of bug bites in persons of peculiar idiosyncrasy. He is a firm believer in the curability of leprosy with a liberal supply of good food and absolute abstinence from fish, with chaulmoogra oil, internally and externally, as an adjuvant. The relapses of leprosy in Norway are probably the result of a return to a fish diet. He regards it as probable that the bacillus of leprosy and of tuberculosis are differentiated forms of the same organism. He further believes that gonorrhea in all stages is best treated by parasiticide injections, and that the long continued use of arsenic, externally or internally, increases the tissue proclivity to malignant growth. The latter is not due to parasitic infection, but to heritable proclivities on the part of the tissues, essentially the same for the various forms of malignant disease. Certain other mineral drugs may share with arsenic this property of tending to increase the proclivity to cancer.

39. Hematogenic Dermatoses.—Jadassohn relates a number of examples to demonstrate that acute and chronic infectious diseases, even including pyemia and gonorrhea, are liable to cause metastases in the skin. The resulting exanthemata are acute or chronic, as the case may be, varying with the nature of the morbid germ, the essence of the fundamental process, and with the number of the bacteria penetrating into the skin. These dermatoses display a marked tendency to dissemination and to symmetrical localization, and are polymorphous not only in different individuals, but in the course of the same disease. The efflorescence may range from the smallest roseola patch to a diffuse dermatitis, from a superficial papule to the nodules suggesting deep erythema nodosum, from insignificant superficial necrosis to deep-reaching gangrene. Hematogenic inflammation generally involves the veins rather than the arteries, and the bacteria settle in the smaller rather than in the large veins. They plug the veinules or penetrate from them into the surrounding tissues. When the large veins are involved the process is usually on the extremities, especially in the legs. The germs arriving by way of the blood cause milder lesions than those of exogenic origin, with few exceptions. Hematogenic cutaneous infections display a marked hemorrhagic tendency and also a tendency to moderate necrosis and softening. The article is continued.

41. Eosin Phototherapy.—Pick has had 22 patients treated at his clinic by exposure to concentrated sunlight after preliminary injections of eosin. The subjects included 12 with lupus, 5 with tinea, 1 with *ulcus rodens* and the others with excised patches of lupus. The results were eminently encouraging, as is seen from a few typical cases described at length.

43. How and Where Shall Children with Inherited Syphilis Be Treated?—Vejlander's question is answered by the results attained at the small asylum which has been built near Stockholm exclusively for the use of such children. They are kept from infecting others by their segregation here, while every condition is supplied to enable them to develop into healthy adults, with intermittent antisiphilic treatment as indicated. The institution is already overcrowded with 13 inmates; 22 have been under its care in all. It was founded by charitable enterprise, and the annual expenses average \$1,500.

44. Treatment of Chronic Empyema of the Maxillary Sinus.—Friedrich has treated 7 patients by the technic he describes, including a few cases of long standing fetid suppuration. All were rapidly cured. He opens up the sinus, not only enough to expose it amply, but also to establish a broad communication between it and the nose. He turns back the soft parts of the nostrils and makes a rectangular opening through the anterior bony wall, close to the floor of the maxillary sinus, and removes the wall between it and the nose for about 1 by 3 cm. It may be necessary to remove a small portion of the inferior turbinate. The nasal orifice of the lachrymal duct is not injured, but the sinus is widely exposed and all irregularities and suspicious points can be easily treated. The entire cavity is then tamponed, the end of the gauze brought out through the nose, and the incisions sutured. The tampon is removed after a few days; the sinus is rinsed out a few times and then

left to itself. The epithelium rapidly forms again from the remnants left after the partial excochleation of the cavity. One of his patients had had the empyema on one side for thirteen and on the other for eleven years, and had been constantly under the treatment of specialists, without relief. He has been radically cured during the nearly three years since this intervention, and is one of the most grateful patients that Friedrich has ever encountered in his surgical practice. The details of the incision are shown in a couple of illustrations.

45. Entrance of Ankylostoma Larvae Through the Skin.—A few years ago, Looss, of Cairo, announced that the larvæ of ankylostomata were able to penetrate into the circulation through the intact skin. Schaudinn's experiences and tests have fully confirmed this possibility, and at the recent International Congress of Zoology, Looss showed specimens demonstrating the mechanism by which the larvæ find their way from the intact skin into the intestines. They get into the superficial veins, then through the right heart into the capillaries in the lungs, thence into the alveoles, and then find their way through bronchi, trachea, throat, esophagus and stomach into the intestines. Some of the larvæ get into the lymphatics and thence into the veins. Schaudinn's experiments were made with monkeys, Looss' with dogs. The latter's attention was attracted to the subject by infection of his own person, which could be explained only by the assumption of percutaneous infection.

46. Eye Symptoms with Paralysis of the Arm.—Volhard analyzes 4 cases of paralysis. In 2 there was total paralysis of the right arm, accompanied by ocular symptoms which have a bearing on the prognosis. In all there was slight asymmetry of the eyes, myosis, inability to open the eyes wide and slight exophthalmus on the paralyzed side, but the movements of the eyes were unrestricted and the reaction of the contracted pupil to light and accommodation was retained. These same symptoms were observed also in the 2 other patients, although the paralysis was of a different nature. In one it was the result of a stab wound in the back of the neck, between the third and fourth cervical vertebrae, the entire right side becoming paralyzed below the lesion. The other patient had a carious affection of the gray matter in the region of the eighth cervical and first dorsal segment. Volhard explains the mechanism of the eye symptoms in each case. In the first 2, in which the paralysis was due to traumatic injury of the plexus, the eye symptoms indicated that the roots nearby had also been injured. This contraindicated surgical intervention, as the roots are not amenable to an operation. The prognosis is not rendered materially unfavorable by their involvement, as such a lesion may heal. The hyperextension of the arm causing the injury to the plexus should be spoken of rather as an overstretching of the nerve of the region.

47. Workers in Poisonous Chemicals.—Brat reviews the experiences in various manufactures in which the workmen are exposed to the action of poisonous substances. So much has been done to protect the workmen that the cases of poisoning have been very much reduced in number and severity. This is due to private initiative on the part of the proprietors and care on the part of the workmen. He does not think that legislation on the subject is necessary. Lewin replies to him that if private initiative is enough in certain instances, it can by no means be relied on in all. He hints that Brat's views on the subject may be influenced by the fact that he is physician to a certain industrial establishment, and reaffirms his own views, previously summarized in these columns, page 231.

48. Abnormal Stools in Pancreatic Affections.—A number of cases are described with the special features of the abnormal stools to decide the diagnostic importance of the latter for the assumption of a pancreatic affection. The passage of fluid fat, separate from the rest of the feces, and the lesser splitting of fat are strongly suggestive of an affection of the pancreas in a diabetic, provided the stools are formed and there is no icterus. These abnormal stools are not pathognomonic, as they may be the relics of some severe affection of the small intestine. Fat diarrhea is now considered suspicious of some

lesion in the small intestine even in adults. In one case described, as also in a certain proportion of diabetics, the stools showed abnormal reduction of the utilization of the food on a diet which is assimilated readily by a normal subject and by the overwhelming majority of diabetics. Whether this is due to some pancreatic affection can be decided only by post-mortem examination. Volhard thinks that it is possible, with a little practice, to detect an abnormal amount of undigested muscle fiber in the stools. Disturbances in the motor, absorbing and secretory functions in the domain of the small intestine (including the cases of missing pancreatic secretion) can induce an increased elimination of undigested muscle fiber. The article aims to show that it is necessary to examine the stools for the naked eye, microscopic and possibly chemical findings in case of suspicion of a pancreatic affection, but that the findings must be carefully weighed, as the clinical symptoms of a number of other affections are liable to simulate the stools of pancreatic disease.

56. Hyperglobulia and Enlargement of Spleen.—Preiss reports 2 cases of hyperglobulia with cyanosis, enlarged spleen and albuminuria. He explains the condition by assuming that the diseased spleen engenders some substance which passes into the blood and stimulates the bone marrow to excessive production of red corpuscles. The tuberculin test will determine the cases due to a tuberculous process.

58. Coagulating Power of Gelatin.—Kaposi demonstrated the coagulating properties of gelatin in respect to the blood by first inhibiting coagulation in animals by extract of leeches, and then injecting gelatin. The latter induced coagulation visible to the naked eye even under these conditions. He recommends Krause's technic for sterilizing the gelatin, as he found it invariably reliable, while its coagulating and other properties were not affected. The gelatin is heated by steam to 100 C. for half an hour on five successive days.

59 and 60. Sauerbruch's Air Chamber for Operations Within the Thorax.—The air chamber and the possibilities it offers for operations without fear of pneumothorax have been fully described in THE JOURNAL, XIII, pages 930 and 1191. This article is the complete report to date, containing also the writer's researches on the pathologic physiology of pneumothorax and on the physiology of normal lung action. In case of pneumothorax the collapse of the lung is the danger. The trouble arises from the fact that the collapsed lung receives too much blood and the intact one too little. The air chamber at present in use is large enough to hold the patient and three operators. A suction pump reduces the atmospheric pressure to minus 10 mm. Hg. The head of the patient protrudes from the air chamber, and the abdomen and legs are enclosed in a bag, which also communicates with the outer air, thus avoiding danger of venous congestion. Sauerbruch first thought of and finally rejected the plus pressure method advocated by Brauer as liable to prove dangerous for reasons which he enumerates. This method is the filling of the lungs through a tracheal canula with air under plus pressure. This technic is apparently simpler, as it obviates the necessity for the air chamber, but the conditions in the circulation which it induces are menacing, especially to a debilitated subject in need of surgical intervention.

[The Sauerbruch air chamber has established its usefulness in the clinic, having already passed the tentative stage. Mikulicz had operated on ten patients with its aid up to the middle of August. The article is fully illustrated, the curves of the

various experiments being likewise given. The periodical in which it appears is published by G. Fischer, Verlag von G. Fischer, Jena, Germany.—[Ed.]

61. Absorption of Albumin by the Newborn.—The experimental and clinical research reported from Prague has established that albumin foreign to the body, introduced into the alimentary canal, is absorbed comparatively unmodified. It can be detected again in the blood by means of the biologic test. The age limit up to which time this is possible was the seventh day of life in the experiences reported. When a very large amount was introduced it could be detected in the blood even in somewhat older subjects. The experiments with puppies, kittens, rabbits, etc., were conclusive, and the eighth day was invariably the limit. In infants the age limit seems to be a trifle later. In case of a gastrointestinal affection, inducing lesions in the alimentary canal, the absorption can occur likewise at a later age. The research further established that albumin thus absorbed induced the production of an antibody. This suggests that the administration of foreign albumin to a normal newborn infant, or to an older infant suffering from some gastrointestinal trouble, is liable to do harm as it passes unmodified into the blood and starts the specific reaction on the part of the organism. The experimental parental administration of foreign albumin always entailed emaciation in the young and generally also illness, frequently fatal.

62. Portals of Entry for Tuberculosis.—Among the arguments presented by Fischer to prove the fallacy of von Behring's recent announcements is the fact that pulmonary tuberculosis is as common in Japan as in Europe, and yet, for religious reasons, the children are never given cow's milk, but are always nursed by their mothers or wet nurses. In one point, however, von Behring's views deserve the widest attention and acceptance. This is that the war against tuberculosis must begin with the infant. The child must be removed from a tuberculous environment, its food must be germ-free, and its body must be rendered so robust that it will come out victorious in the almost unavoidable conflict with tuberculous infection later.

63. Essence of Tuberculosis.—Wolff's experience at the great sanatorium at Reiboldsgrün, and his deductions from what has been written and learned in regard to tuberculosis, have convinced him that it is essentially a chronic, constitutional, infectious disease, with hematogenic dissemination of the infection to all organs. A single infection—which usually occurs in childhood—suffices for the later development of phthisis, but a second infection of an already infected subject remains a superficial affection, without further consequences.

66. Quantitative Test for Various Albumins in Urine.—Oswald recommends the technic described as a simple beside quantitative test for fibrinogen, euglobulin, pseudo-euglobulin and albumin in the urine. It is a combination of the method of fractional precipitation with neutral salts and the Esbach albuminometer. Four of the albuminometers are used, and in A the total albumins are determined with the Esbach reagent as

usual. In B a saturated solution of ammonium sulphate is added to the urine in the proportion of 2.5 to 7.2 urine. This will precipitate the fibrinogen. In C the proportion must be 3.6 to 6.4 urine—the euglobulin fraction. In D the proportion must be 5 to 5 urine to precipitate the pseudoglobulin. The albuminometer B gives the proportion of fibrinogen or fibrinoglobulin; C minus B gives the proportion of euglobulin in the urine; D minus C gives the proportion of pseudoglobulin, and A minus D gives the albumin. He tabulates the findings in 5 cases, the total albumin ranging from 4 to 12 per thousand; no fibrinogen; the euglobulin, from 2.5 to 2.5; the pseudoglobulin, from .5 to 1.5, and the albumin, from 3 to 11.5. All were cases of acute or chronic nephritis, one scarlatinal. In the latter, the figures were respectively: 10, 0, 2.5, 1.5 and 6 per thousand.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

LECTURES TO GENERAL PRACTITIONERS ON THE DISEASES OF THE STOMACH AND INTESTINES. With an account of their Relations to Other Diseases and of the Most Recent Methods Applicable to the Diagnosis and Treatment of Them in General; also "The Gastro-intestinal Clinic," in which All Such Diseases are Separately Considered. By Boardman Reed, M.D., Professor of the Department of Gastro-Intestinal Hygiene and Climatology in the Department of Medicine of Temple College, Philadelphia. Illustrated. Cloth. Pp. 1021. Price, \$5.00 net. New York: E. B. Treat & Co. 1904.

A PRACTICAL TREATISE ON DISEASES OF THE SKIN. For the Use of Students and Practitioners. By James Nevins Hyde, A.M., M.D., Professor of Skin, Genito-urinary and Venereal Diseases, Rush Medical College, Chicago, and Frank Hugh Montgomery, M.D., Associate Professor of Skin, Genito-urinary and Venereal Diseases, Rush Medical College, Chicago. Seventh and Revised Edition. Illustrated with 107 Engravings and 34 Plates in Colors and Monochrome. Cloth. Pp. 938. Price, \$4.50. Philadelphia and New York: Lea Brothers & Co. 1904.

DISEASES OF THE NOSE, THROAT AND EAR, and Their Accessory Cavities. By Seth Scott Bishop, M.D., D.C.L., LL.D., Honorary President of the Faculty and Professor of Diseases of the Nose, Throat and Ear in the Illinois Medical College. Third Edition. Thoroughly Revised, Rearranged and Enlarged. Illustrated with 94 Colored Lithographs and 230 Additional Illustrations. Cloth. Pp. 564. Price, \$4.00 net. Philadelphia: F. A. Davis Co.

TEXT-BOOK OF NERVOUS DISEASES AND PSYCHIATRY. For the Use of Students and Practitioners of Medicine. By Charles L. Dana, A.M., M.D., Professor of Nervous Diseases and (ad interim) of Mental Diseases in Cornell University Medical College. Sixth Revised and Enlarged Edition. Illustrated with 24 Engravings and 3 Plates in Black and Colors. Cloth. Pp. 690. Price, \$4.00. New York: Wm. Wood & Co. 1904.

HAND-BOOK OF THE ANATOMY AND DISEASES OF THE EYE AND EAR. For Students and Practitioners. By D. B. St. John Roosa, M.D., LL.D., Professor of Diseases of the Eye and Ear in the New York Post-graduate Medical School, and A. Edward Davis, A.M., M.D., Professor of Diseases of the Eye in the New York Post-graduate Medical School. Cloth. Pp. 300. Price, \$1.00 net. Philadelphia: F. A. Davis Co.

THE URINE AND CLINICAL CHEMISTRY OF THE GASTRIC CONTENTS, THE COMMON POISONS AND MILK. By J. W. Holland, M.D., Professor of Medical Chemistry and Toxicology, Jefferson Medical College of Philadelphia. Forty-one Illustrations. Seventh Edition. Revised and Enlarged. Cloth. Pp. 172. Price, \$1.00 net. Philadelphia: F. Blakiston's Son & Co. 1904.

THE NERVOUS AFFECTIONS OF THE HEART, Being the Morison Lectures Delivered Before the Royal College of Physicians of Edinburgh in 1902 and 1903. By George Alexander Gibson, M.D., D.Sc., F.R.C.P. Ed., F.R.S.E., Honorary Member of the Medical-Chirurgical Society of Newcastle. Cloth. Pp. 93. Edinburgh and London: Young J. Pentland. 1904.

DIET AND FOOD CONSIDERED IN RELATION TO STRENGTH AND POWER OF ENDURANCE, TRAINING AND ATHLETICS. By Alexander Haig, M.A., M.D. Oxon., F.R.C.P., Physician to the Metropoli Hospital and the Royal Hospital for Children and Women. Fifth Edition. With Seven Illustrations. Cloth. Pp. 128. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

MANUAL OF PHYSIOLOGICAL AND CLINICAL CHEMISTRY. By Elias H. Bartley, B.S., M.D., Ph.G., Professor of Chemistry, Toxicology and Pediatrics in the Long Island College Hospital. Second Edition. Revised and Enlarged. With 47 Illustrations. Cloth. Pp. 188. Price, \$1.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

ZEITSCHRIFT FÜR OPHTHALMOLOGISCHE CHIRURGIE EINSCHLIESSLICH DER HELYGRAPHIE UND MASSAGE. Herausgegeben von Dr. Albert Hoffa, Geh. Medicinalrath, o. Professor an der Universität Berlin. Band XIII. Heft 1. Mit 34 in den Text gedruckten abbildungen. Paper. Pp. 230. Stuttgart: Verlag von Ferdinand Enke. 1904.

ENLARGEMENT OF THE PROSTATE. ITS TREATMENT AND RADICAL CURE. By C. Mansell Moullin, M.D. Oxon., F.R.C.S., Senior Surgeon and Lecturer on Surgery at the London Hospital. Third Edition. Cloth. Pp. 204. Price, \$1.75 net. Philadelphia: P. Blakiston's Son & Co. 1904.

LAMINECTOMY.

A FURTHER CONTRIBUTION.*

JOHN C. MUNRO, M.D.

BOSTON.

Five years ago, at the Columbus session of this Association, I reported 18 cases of laminectomy for various conditions. To these I can add twelve more operations, including two sections of the posterior cervical roots, five acute crushes, myeloma of the spine, a fracture of the odontoid process, etc. There is very little that is new that I can offer to-day, but there are, however, one or two suggestions that have come to me in studying my cases that I believe point to the possibility of the existence of certain phenomena seen at operations, that have not been and probably can not be demonstrated in the laboratory nor on the cadaver. These observations, if accurately made, may help to settle the question of operative benefit *per se*, that has been so bitterly fought on the one side by the neurologist and on the other side by the surgeon. I still believe that a simple technic, as emphasized in my first paper, has much to do with the comparative harmlessness of the operation.

FRACTURE-DISLOCATIONS.

If we collect the various scattered cases that have been reported within the last few years, favorable results following operation come more and more into evidence. It is useless at this time to go into a discussion of the question as to the possibility of equally good results in corresponding cases treated conservatively. The partisans on both sides are still too unyielding in their views. Being a partisan on the side of interference, I merely wish to present, as fairly as I can, the question as it appears to me personally. Fractures in the lower dorsal and in the lumbar regions are especially open to surgical interference, because of the relative harmlessness of laminectomy and because there is no valid reason for not subjecting the elements of the cauda equina to the same operative relief as in the case of any peripheral nerve. In the cervical fractures, however, there is much greater risk to life, whether operation is done or not. In watching quite a considerable number of injuries at this level, in the last few years, not subject to operation. I have been impressed with the fact that they die a day or so earlier and that they suffer no less than similar patients who have had a laminectomy. In several instances it has been possi-

ble to watch the progress of two patients—one operated on, the other not—as nearly similar in injury, age and physical conditions as is possible, using one as a control experiment, as it were. This impression has not a scientific basis; it is merely the general impression of a partisan observing the cases in hopes of being convinced that he advocates interference unnecessarily.

In studying the cases of cervical and high dorsal injuries treated without operation at the Boston City Hospital within the last ten years, I found that, of 30 patients, only one lived and partially regained his functions; 24 died within eight days of injury. The remainder, not including the one recovery, lived from three weeks to five months. In that same period I have seen, at the same hospital, at least three practically complete recoveries where a laminectomy was done. I have included the high dorsal injuries with the cervical because clinically the progress appears to be exactly the same. When we get below the mid-dorsal region, however, the story is a far different one.

Lloyd, in 1901, and various authors since that time, have reported recoveries after operation where the indications pointed to complete crushing of the upper cord. In addition, I have knowledge of a few more in the practice of my colleagues that help to confirm my views that, if the patient otherwise is able to undergo operation, it is better in the long run to offer him that chance; but the surgeon and the patient should realize all the time that at the very best the outlook is extremely poor.

Lloyd places great stress on withholding interference where shock is an element of danger, and I emphatically believe he is right. Some of these cases, as soon as they react from shock, show improvement in their cord symptoms, and should be let alone; but with a halt in the progress or a retrogression, operation should be done at once. His dictum that patients with a complete obstruction of the cord should be let alone ought to be modified, because these symptoms are occasionally misleading. This is shown in the recent report of two cases by Mixer and Chase. In one "there were present all of the clinical symptoms on which authorities had previously based their opinion that operation was contraindicated because it suggested total transverse lesion with a crush of the cord beyond repair." Nevertheless, there was marked and steady improvement following operation for eleven months, when death from septic nephritis took place.

A most interesting series of sections of the cord showed that "normal sensory and motor axons exist at the seat of the lesion, though their functions were interrupted at the time of injury, which suggested total destruction of the cord." Their second case, in a similar way, exhibited all the symptoms of complete transverse crush, yet he recovered sufficiently to return

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest, Willard, Charles A. Powers and J. E. Moore.

to his business. Walton, in 1902, stated that "though we may value the classification of Kocher, Bastian, Thorburn and others, the terms complete and incomplete lesions should not imply that the symptoms of the former are necessarily incapable of amelioration." All of my patients with acute crush of the cervical cord have died, whether operated on or not, but the recovery that followed operation in two of my chronic cases indicates that there is something effected by removal of pressure not produced by the bony parts, by which the functions of the cord are restored; and it is not wild reasoning to conclude that if laminectomy can accomplish so much good after prolonged pressure, whatever its nature may be, it may accomplish as much good, relatively, when done within the first few days after injury.

In the first of these cases the local cervical symptoms having persisted for a year in spite of conservative treatment, disappeared gradually after laminectomy. The second case, under hospital treatment for nine weeks, for paralysis from the arms downward, without any benefit, steadily improved after operation until he is now practically well. All that was found in this case was a collection of fluid under a distinct arachnoid membrane. A similar condition was found in a case of syringomyelia reported in my first paper, and yet the removal of this insignificant pressure produced marked amelioration in the pressure symptoms. If to these we add the total disappearance of a paraplegia following the removal of myeloma insignificant in its bulk, soft, not penetrating the dura, I am inclined to think that there is a something that produces grave paralysis that is demonstrated clinically, appears totally inadequate, and for which we have no corresponding experimental nor postmortem explanation.

My two cases of section of the posterior cervical roots for severe brachial neuritis, both followed slowly by a Brown-Séquard paralysis, have taught me that in future the operation would be better performed in two stages. At the first sitting all the work down to exposing the dura could be done. A few days later, when the danger of even slight oozing would be over, the dura could be opened in a dry field, the roots divided and ligated if necessary and the dura closed. In cervical laminectomies there is always more hemorrhage than at lower levels and certain types of oozing are impossible to control without prolonged packing. The consequences of that oozing or the adhesions of the pia consequent on packing is later paralysis, which may or may not disappear.

These few meager conclusions are all that I feel justified at present in deducing from my own observation. More experimental work is demanded in this line of cases, but what I believe is equally important is that a corresponding amount of work in clinical observation is necessary, no matter how discouraging and hopeless it is by its very nature.

CASES OF ACUTE FRACTURE-DISLOCATIONS.

CASE 1.—Man, aged 36, was seen at the Somerville Hospital in consultation with Dr. Buffum and Dr. J. J. Thomas, in May, 1902.

History.—Two days before I saw him he had been struck in the head by a bale of leather, bending it acutely forward. He was not rendered unconscious, but suffered pain in the neck. At first he had fair motion in the legs and was able to control his bladder. The hand grasp was fair and the knee jerks were present. The day following he was obliged to be catheterized and the motion of the legs diminished. He suffered great pain on motion of the head, in his neck and between the scapulae.

Examination.—There was flexion and extension of the wrist and fingers, extension of the forearm and partial flexion of the thigh. Respiration was diaphragmatic. Knee jerks were normal. No ankle clonus. Babinski reflex of both sides. Pain and touch sensations were slightly diminished up to the third rib and along the ulnar side of the hand and forearm. There was no zone of hyperaesthesia. The neck was slightly tender over the lower cervical vertebrae, but there was no abnormal bony prominence. Diagnosis of probable temporary dislocation of the cervical and the dorsal spine.

Operation and Result.—At operation, under ether, the seventh, sixth, and part of the fifth cervical laminae were removed. The dura was tense, not pulsating, translucent and thin. It was not opened. There appeared to be no local bony compression and the wound was closed, with temporary drain. On the following day his temperature rose and there was slight delirium, from which he recovered, and the mental condition became normal. No improvement in his physical condition followed, however, and he died some weeks later after progressive wasting from bedsores.

CASE 2.—Woman, aged 18, was aroused by fire in her house, jumped from the window, falling three stories, and was brought to the Boston City Hospital at once. At entrance she was unconscious and in profound shock, with a pulse of 180.

Examination.—There were scalp wounds, but no fracture of the skull could be determined. The abdomen was tympanitic and lax, and sensation as tested by a pin was apparently normal throughout. Under stimulation the patient slowly regained consciousness and about twenty-four hours after injury there was found complete paralysis of both legs and abdomen, with absence of sensation in the right leg and diminished sensation in the left thigh, increasing to absence of sensation below the knee. Sensation was practically absent on the abdomen and back up to a line at the level of the xiphoid cartilage, above which the sensation and motion were normal. Urine was passed involuntarily. Deep and superficial reflexes of the legs and abdomen absent. No ankle clonus. Complete loss of pain and temperature was also found.

Operation.—Under ether a laminectomy was done, the fifth dorsal spine being found loose and the fifth lamina on the right driven forward against the peridural fat. The fourth to the seventh laminae, inclusive, were removed. The peridural fat was found infiltrated with blood, bulging slightly and containing a few clots; and though there was a persistent hemorrhage from some hidden vessel in the peridural tissue, it did not seem to be sufficient to account for the cord lesion. The dura was opened and an excessive quantity of clear serum escaped. No pressure elsewhere on the cord could be found. The peridural space was packed with gauze to control hemorrhage and the wound closed, allowing for temporary wicks. The patient stood the operation without shock.

Result.—No improvement in the paralysis followed for about a week. Then she developed beginning sensation in the lower extremities. The temperature was irregular all this time, varying from normal to 103; the pulse remained persistently at about 120. Two weeks after operation she complained of pain in the right side and a slight pleurisy was found. The wound healed kindly, but a bed sore, in the lower lumbar region, developed and increased gradually in size. A month after operation vomiting began, the bedsores increased, cystitis developed, and two and a half months after operation she died, without any improvement in her condition.

CASE 3.—Man, aged 44, fell about ten feet, striking his head and shoulder on the pavement, and was paralyzed in his lower extremities at once.

Examination.—He was taken to the Boston City Hospital relief station and anesthesia below the level of the nipples was found, with knee jerks present on both sides. Ankle clonus and plantar reflexes were absent. The abdomen was distended and tympanitic. A day later he was transferred to the main hospital. The knee jerks had disappeared, and paralysis of the sphincters came on. At first the temperature was elevated. At the end of two weeks his condition remained the

same as regards his anesthesia and paralysis, but he was steadily losing ground and operation was advised.

Operation.—A laminectomy was done under ether and the sixth and seventh cervical laminae were removed. In the muscles were evidences of old hemorrhage and laceration. No fracture was found in the spine. The dura was opened and a small amount of fluid escaped. Pushing up against the dura was a firm arachnoidal membrane, beneath which there was a large amount of clear fluid. This was opened and drained. The cord itself appeared normal. The wound was closed with a temporary rubber tissue drain. There was practically no shock. The temperature rose on the afternoon after the operation, but rapidly fell to normal, and there was considerable escape of fluid from the wound.

Result.—He developed the ability to flex and extend the forearms slightly, which before operation were completely paralyzed, but had no control of the hands. A beginning bed-sore developed at the base of the spine about three weeks after operation. The operation wound healed by primary union, but the bedsores steadily increased, and his general condition grew worse. He developed incontinence of urine and feces, mild delirium supervened, and about five weeks after operation he died.

CASE 4.—Man, aged 22, fell from a team, striking on the top of his head, and broke his neck.

Examination.—He was brought to the Boston City Hospital with total paralysis of the upper and lower extremities and anesthesia below the second rib. Reflexes were absent. In front of the neck, on deep pressure, a projection of the displaced body of a vertebra could be felt. The head could be rotated and was not held in the position of a simple dislocation. He was conscious.

Operation.—Under ether a laminectomy was performed. A wide space was found between the fifth and sixth cervical laminae, admitting the finger easily to the dura. The fifth lamina was removed; the fourth lamina, found to be pressing on the cord posteriorly, was removed also. Above or below this no compression could be determined by exploration. An attempt to reduce the dislocation of the vertebral body was made, but was unsuccessful, the deformity probably being due to a crush as well as a dislocation. There was no extra-dural bleeding and there appeared to be no indications for opening the dura. The wound was closed, allowing for a capillary drain. There was no shock.

Result.—A few hours afterward the patient, who had been comfortable, was suddenly seized with pains, the head was drawn back, and he became unable to swallow. The pulse rose to about 130, but gradually grew weaker and slower, although the temperature rose to 107 degrees. He became unconscious and died about twelve hours after operation.

CASE 5.—Man, aged 33, entered the Carney Hospital in November, 1903, after falling downstairs, striking the side of his head and neck.

Examination.—He was unconscious for a few moments and was instantly paralyzed in his arms and legs. He vomited a few times and required the catheter for the first few days. There was flaccid paralysis of both upper extremities and paresis of both lower extremities. Dr. Bullard examined him and found the right pupil larger than the left, sensation stronger on the outer and dorsal surface of the arm and forearm than along the inner surface. On the right forearm the posterior surface seemed duller than the anterior; on the left, sensation was essentially the same. On the top of the shoulders sensation was stronger. All sensation, however, seemed diminished, but his answers were not fully reliable. Triceps reflex negative. Left patella reflex present. Right patella reflex slight. No ankle clonus. A diagnosis of crushed cord was made. He became delirious (evidently alcoholic) and nothing was done for eight days after entrance, until he had recovered from the delirium. Examination of the eyes by Dr. Kilburn showed the right pupil larger than the left under all circumstances. The pupillary reflexes were excellent and nothing pathological was found in the fundus.

Operation.—At operation by Dr. Bottomley the fifth, sixth

and seventh cervical spinous processes were removed with their laminae; the dura was found distended with clear fluid, which escaped in considerable quantity. Over the cord, at the level of the fourth and fifth vertebrae, was a thin blood clot, adherent and several days old. The wound was closed, allowing for a rubber tissue drain to the subdural space. Patient recovered well from the operation, but soon developed bedsores and passed bloody urine for several days. Nine days later the temperature suddenly rose, vomiting began, and he gradually failed, and died twelve days after operation.

No autopsy was obtained.

FRACTURE OF THE ODONTOID PROCESS.

CASE 6.—Man, aged 42, entered the Carney Hospital in April, 1904.

History.—Two years ago the patient fell from a staging, landing on the top of his head. Ever since the accident he had been compelled to hold his head flexed, with the chin resting on his chest, being unable to rotate it actively or passively without pain.

Examination.—He had lost the power of extending his head voluntarily, although there was no paralysis of the muscles. Over the second cervical spine there was marked prominence. There had been no paralysis, and a year before I saw him the left posterior neck was explored by the orthopedic department, with negative results. He was then fitted to a form of chin support which held the head in normal position. As soon as this was removed the head immediately fell forward and the patient was unable to extend it voluntarily. For about a year he had complained of pain in his left shoulder, arm and leg, varying in severity. He was not so strong as formerly in his arms and legs, and he had been unable to work on account of the impairment of his head motion. He entered the hospital seeking operation and we hoped that possibly some relief might be obtained.

Operation.—Under ether an incision was made down to the spinous process of the axis. This was apparently normal, as were also the third and fourth spines and laminae. The vertical distance from the tip of the second spinous process to the posterior tubercle of the atlas appeared normal. The atlas rotated with the occiput through a normal arc. Extension and flexion of the occiput on the atlas were normal. By directly pushing the head backward the atlas moved with the occiput without change of their mutual relations, but the atlas slid backward on the axis so that its posterior tubercle lay in the same plane as the second spinous process or, in other words, the atlas slid backward and forward on the axis for at least one-half an inch, their vertical relations remaining normal. It seemed clear that this could be accounted for only by a fracture of the odontoid process at its base, allowing the structures above to move forward and backward within the limits of the anterior and posterior ligaments between the occiput, atlas and axis. Although rotation without ether was limited, under ether it was free in both directions. It did not seem possible that the normal position of the bones could be restored and maintained by any operative procedure, so the wound was closed in layers and the patient returned to the ward. He recovered quickly and was discharged in ten days, wearing the chin support and claiming that the pain in his shoulder was not so severe as before operation.

SUBACUTE FRACTURE-DISLOCATION.

CASE 7.—Boy, aged 14, entered the Boston City Hospital in August, 1902.

History.—Nine weeks before the patient, an acrobat, while turning a back somersault from a man's shoulder, fell, landing on the back of his neck. He arose immediately to his knees, but was unable to rise any farther. He was then carried to the anteroom and since then had been unable to walk. He recalled that he was unable, positively, to move the lower extremities on the day following the injury, but that he could use his hands awkwardly. Three days after the injury he went to a hospital in Virginia, where electricity was applied to his arms and legs. Since the accident he had remained in bed, the forearms and hands becoming atrophied. His appetite

had been good and he had been able to control his rectum. For six weeks he had incontinence of the bladder, and for a short time after the accident he had had pain in the neck.

Examination.—At entrance to the City Hospital he lay completely relaxed. Pain, tactile, hot and cold sense, and stereognostic sense were normal in his upper and lower extremities. The pupils were normal, knee jerks lively, and the cremasteric reflex was present. The motions of the head and neck were complete. Flexion and extension of the forearm were strong, but there was atrophy and weakness of both the flexors and the extensors of the fingers. Extension of the wrist was incomplete, the hand grasp was weak, and the muscles of the thumb, especially, were atrophied. In the thighs there was complete paralysis, at times flaccid, at other times spastic. There was slight prominence of the seventh cervical vertebra.

Operation.—At operation the seventh cervical and first dorsal laminae were removed. The dura was translucent, not pulsating, and on being opened a small quantity of fluid escaped. Pressing against the dura was an arachnoid sac, with much serum under pressure. The arachnoid was attached to the dura and laterally to the cord and nerve roots, so that in freeing it fresh bleeding took place. It was freed as far as a probe could reach, and opened. Both membranes were left open and drained by a small rubber wick carried out at the lower angle of the superficial wound, which was closed. The wound healed by primary union after a few days' drainage of serum.

Result.—His general condition improved, but he did not regain control of his legs at once. Three weeks after operation he began to see improvement in his arms, and was discharged four weeks after operation, relieved. After his return home the paralysis of the lower extremities disappeared, he steadily gained, and when seen nine months after operation he was at work, able to run, walk, and use his hands almost normally, exhibiting only a slight atrophy of the back of the forearm.

CHRONIC CERVICAL PACHYMENINGITIS.

CASE 8.—Man, aged 40, entered the Carney Hospital in March, 1904.

History.—Twenty years ago he had had syphilis, for which he was treated successfully at the time. Sixteen months ago he noticed a slight weakness of the left arm, which gradually increased until he lost control of the left hand and arm. The right hand began to grow weak two months ago and the patient complained of severe pain in the back of his neck and the base of his head, which was especially marked on walking, relief being obtained by lying down.

Examination.—There was no ataxia, but some pain in his feet and toes. Dr. Bullard's examination showed that the pupils were equal, reacting normally. The external orbital muscles were normal. There was slight unsteadiness of the right eye on convergence. No tremors of the tongue. Numbness below the occiput, stiffness of the muscles of the posterior neck, especially on the right side. Pains shooting up the right neck to the right ear. Occasionally very difficult swallowing. The right side of the neck posteriorly appeared flattened. The right shoulder was slightly lower than the left; the sides of the chest were about equal. Passive motion of both arms normal. Both triceps reacted normally. Some diminution of the sense of touch and pain in the left arm; some atrophy of the left upper extremity, most marked in the left hand, but the interossei were not affected. Atrophy of the thenar and hypothenar eminences. Left arm smaller than the right. Knee jerks active. No clonus. Babinski absent. Left arm 1 cm. smaller than right. A little later some diminution of sensation was found over the left deltoid and the upper two-thirds of the anterior and outer surfaces of the left arm; there was, possibly, slight diminution of pain. Still later, a week before operation, there was involuntary twitching of the left posterior muscles of the neck, more marked on the left than on the right. Atrophy of the right shoulder more marked. Triceps reflex in the left arm better than in the right. There was diminished sensation over the left deltoid. He complained of a dead pain from the left shoulder down the left arm. The pains in the right posterior part of the neck were increased on walking, but disappeared immediately when lying down.

Operation.—At operation by Dr. Bottomley the fifth and sixth cervical laminae were removed. The dura bulged and was evidently under considerable pressure. On incision a clear fluid spurted out, several ounces escaping. The probe passed downward met with no obstruction, but on being passed upward met with fairly firm adhesions, which were broken up by the probe. There was free hemorrhage from the veins of the dura, controlled by hot wicks. The dura was partially closed with catgut and the wound closed, allowing for a temporary drain.

Result.—By the end of two weeks the grasp of the right hand began to improve and in another two weeks the patient went home, with still more marked improvement and with beginning improvement in the left hand. Since that time he has steadily been gaining.

SECTION OF POSTERIOR ROOTS FOR PARALYSIS. TWO CASES.

THREE OPERATIONS.

CASE 8.—Man, aged 55, has been reported in detail by Dr. Morton Prince,¹ and from his account I will condense a few details that concern us surgically.

History.—The patient, struck by a train, received a Colles fracture of the left wrist and developed a complete paralysis of nearly the whole left arm; the paralysis, typical of a neuritis of the brachial plexus, had persisted for over a year. The most diseased fibers were apparently from the fifth, sixth and seventh cervical segments, while those from the eighth cervical and first dorsal were partially implicated. He suffered most intensely from pain located chiefly in the thumb and forefinger.

Treatment.—He was under treatment in the clinic for nervous diseases of the Boston City Hospital for a long time, and for the relief of the pain, which was intense, three different operations were undertaken at various times; that is, the radial was stretched in the forearm without relief; later he underwent some other operation at another hospital, the nature of which could not be learned; later still, fifteen months after the accident, I explored the brachial plexus in the axilla and found that all the nerves looked normal, except the ulnar, from about three inches from its origin downward. It had lost its striated, opaque look, was translucent in the center and somewhat crinkled. There was thickening about the humerus, apparently from cicatricial tissue of the soft parts. The plexus was thoroughly freed from the scar tissue and the wound closed.

Operation.—He derived no benefit from this operation and, at Dr. Prince's suggestion, in October, 1899, a laminectomy was done under ether. A long incision was required because of a thick, fat neck. There was much bleeding in the first part of the operation, requiring tedious hemostasis. The sixth, fifth, fourth, and part of the third cervical laminae were removed. On opening the dura at the lower angle some vessels of the subdural space were injured and caused troublesome venous bleeding that could be controlled only by packing under the lamina. So far as could be determined, the left posterior roots of the seventh, sixth and fifth nerves were found and freely cut close to the cord. The dura was then sutured, but not completely closed, and the wound closed except for a wick, which was placed down to the subdural space to control oozing. The operation was long and tedious, but the patient had comparatively little shock. The wound closed aseptically, and from the moment of coming out of ether the patient was free from pain in all the previously affected areas.

Result.—After he began to get about, however, it was noticed that he exhibited a limp and weakness of the left leg, and examination showed a moderate Brown-Séquard paralysis. Dr. Prince, at the time of operation, feared the possibility of a clot forming within the dura and called my attention to it at the time, and it is probable that the paralysis was due to pressure from this source. Gradually the patient developed severe pain posteriorly in the neck and at the time of discharge from the hospital, three months after operation, he still suffered from severe pain, though in a different region from that

originally affected; the cause of the pain in the neck, according to Dr. Prince, being undoubtedly due to a neuritis following injury to some nerve at the time of operation or during healing. Although the arm itself was free from pain, it was useless, and the patient was anxious to have it removed. This was promised if he was unable to make use of it at the end of a year. Five months after operation Dr. Prince examined him and found great improvement in his condition and that the operation had relieved his pain, for which it was undertaken. At the same time the neck pain had also disappeared, but he complained of pains about the shoulder, due, probably, to the weight of the paralyzed arm dragging on the capsule. The Brown-Séquard paralysis had improved very much, although the left leg was still weaker than the right. He still desired to have the arm amputated. Dr. Prince has made an interesting and able study of the areas of the anesthesia, for which reference to the original article must be made. About a year after operation the patient, probably dissatisfied with his general condition, committed suicide. No autopsy was obtained.

CASE 9.—Man, aged 29.

History.—In 1898 his right arm was burned between two hot rollers and amputated at once at the Massachusetts General Hospital. Nine months later he entered the City Hospital for painful stump. At various times neuromata were removed from the median and from the ulna nerves. The median, ulna and internal cutaneous nerves were injected with osmic acid and in May, 1900, portions of these nerves were removed. A year later there was reamputation of the stump and severing of the nerves high up. From none of these operations did he derive relief. The patient was markedly hysterical and probably unreliable in his statements throughout. A marked hyperesthesia was found over the scapula, shoulder and anterior portion of the deltoid and the stump, where he could not bear the slightest touch on the skin. In spite of his marked general neurotic condition he was advised to have the posterior nerve roots cut to relieve his pain.

Operation.—In February, 1902, under ether, the laminae of the fifth to the seventh cervical vertebrae, inclusive, were removed. On opening the dura much clear fluid escaped. As well as could be determined by previous careful measurements the sixth, seventh and eighth cervical posterior roots were cut. There was very slight bleeding from the stumps for a few moments. The dura was not sutured. The upper angle of the wound was packed with gauze tape, as there was a slight persistent oozing of blood from this point that could not be otherwise controlled. The wound was closed throughout, allowing for the wick and for a small rubber tissue drain to the subdural space at the lower angle.

Result.—Apparently pain in the stump diminished to a considerable extent, as it could be handled when the patient was asleep without arousing him although he winced if it was touched when awake. He complained of pain in his neck and head after operation but there was no satisfactory explanation therefor. The wound closed except for a superficial stitch abscess due, probably, to the through-and-through silkworm-gut sutures. On their removal healing progressed satisfactorily. A month after operation the patient showed some delusions and at one time was so noisy that he was transferred to a lower ward. This passed away gradually and his general condition improved except as regards his neurotic symptoms, and two months after operation he was discharged, with very slight hyperesthesia of the stump, to be treated by the neurologic out-patient department. Several of the neurologists who examined him considered that the trouble was "cerebral" rather than confined to the nerve tracts.

Subsequent History.—Three months or more after operation a paraplegia of the lower extremities developed gradually, and since July, 1902, he had not been able to stand, and at times complained of difficulty in micturition. He also complained that pain in the right upper extremity had returned.

Examination by Dr. W. N. Bullard, neurologist to the Carney Hospital, showed a total paraplegia of the lower extremities, with rigidity in extension, but with normal sensation to touch and pain. In addition there was a spinal epilepsy of

the lower extremities, a knee clonus on the right, but on the left it could not be obtained on account of the rigidity. Ankle clonus and Babinski present on both sides; cremasteric reflex on the right, not obtained on the left. No numbness was obtained over the back or chest. There was hyperesthesia to light touch on the right upper extremity, but the sensation of pain was normal.

Second Operation and Result.—At the second operation at the Carney Hospital, 1904, an incision was carried down through the scar, which was found adherent to the cord posteriorly, not involving the left roots, but slightly involving the region of the right roots. The adherent tissue was easily freed from the cord, but posteriorly there was no evidence of any spinal fluid until the level below the former operation was reached. The left posterior roots appeared normal. The cord itself appeared of normal size and consistency, but without evidences of any pial vessels. In the lower third of the wound were fibers of probably the first dorsal root, which had not been cut at the preceding operation. Above this the root stumps were atrophied, lying flat, adherent to the cord, except one small fiber, which apparently had not been cut or else had reunited. This fiber and the intact root below it were severed and the stumps trimmed down to a level with the cord. The remains of the dura were then freed laterally from the cord above and below and some fine silver foil placed against the cord, over which the dura was sutured with catgut. The wound was sutured in layers and a cocoon dressing applied.

After operation the patient was sitting up early and the wound united *per primam*.

Examination ten days later showed that the pain in the upper extremity had diminished, that there was diminution of sensation to pain from the fourth to the sixth space in the right nipple line, no hemianesthesia on the right and abdominal sensation normal. The paraplegia remained as before operation, though some voluntary motion of the toe was reported. No hyperesthesia of the stump was found. Slight diminution of sensation all down the right back and thigh was found, but as it varied at different times, it probably was functional.

MYELOMA OF THE SPINE.

CASE 10.—Man, aged 39, was seen with Dr. Hunting of Quincy, in consultation with Dr. J. J. Thomas, in December, 1900. It was reported before the American Neurological Association by Dr. Thomas in June, 1901, and from his article I shall quote freely.

History.—The patient, a lawyer, without any previous history of importance, in August, 1900, was seized by severe pain in the shoulders, which confined him to bed for four or five days. Since that time there had been more or less pain, but not confining him to his bed. Beginning with October of the same year, he noticed slight uncertainty in the use of his legs, and once, while stooping, fell on the floor. This was more noticeable in the dark than in the light. He had noticed numbness in the feet and tightness about the abdomen, together with difficulty in holding his urine after the desire to micturate had come on, and at times there was difficulty in starting the urine.

Examination.—The pain in the back was aggravated on motion and diminished with rest. Sensation to touch and pain was diminished below the level of the spine of the eighth dorsal vertebra on the eighth rib.

Treatment and Result.—The diagnosis of pressure on the cord, probably from tumor, was made and he was placed on anti-syphilitic treatment and a plaster jacket was applied. A month later the gait had become slightly ataxic, with incoordination. The knee jerks increased, the other reflexes varying at different times. Pain and temperature sense became diminished and the patient complained of an increase in the uncertainty in his gait. A month later the gait was slightly spastic and ataxic. The pupils at this time reacted rather sluggishly to light and the left was slightly the larger. There was a slight swelling on the left fifth rib, which had been noticed before, but it was not tender.

Operation.—Operation was advised and done on December 20

at the Quincy Hospital. On the day of operation the urine, which had previously been normal, was suddenly found to give a heavy precipitate, with heat, disappearing partially on boiling the urine. This was thought to be albumose and its presence was confirmed later. At operation the first, second, third and fourth dorsal laminae were removed. The lamina of the fourth on the left side was thin and bluish, with the cortex destroyed on the upper posterior surface over a small area. The medulla of the spinous process and the lamina was filled with a soft reddish material and on being traced to the left it was found extending anteriorly through an opening alongside the head of the rib, admitting a finger, the rib itself not being eroded. This tract continued to the left side of the vertebral body, where the bone was loose and rough, easily bleeding and evidently infiltrated with a new growth. In all probability some of the same growth lay anterior to the lamina, pressing on the dura, but otherwise without infiltrating it. The dura looked healthy and was not tense. Through the unopened dura the cord felt normal. There was no evidence that the growth had pushed anteriorly to the posterior mediastinum. As much growth as possible was curetted out, the cavity in the vertebral body packed with iodoform gauze and the wound closed, allowing for the gauze drain. The patient stood the operation well and the pulse was excellent at the close.

Result.—Following operation the patient developed a complete paraplegia, with retention of urine. This gradually improved and the wound healed well. Two weeks later, when seen by Dr. Thomas, all movements of the legs and feet were performed normally and with good strength, and there was marked gain in sensation. Heat, cold, pain and touch were perceived fairly well almost everywhere, though in various small areas the improvement was not so great as in general. He could control the bladder for the most part. Careful analysis of the blood, urine and growth was made—for which the reader is referred to Dr. Thomas' original article—the urine showing albumose and examination of the tissue showing myeloma. Dr. Hunting then placed the patient on bone marrow and Coley's toxin and by March he was attending to his business and was feeling as well as ever in his life. At various times myelomata appeared in one rib and another, but there were no more symptoms of cord pressure.

Dr. Thomas has carefully examined the literature of these cases, which will not be considered in this article.

On June 1, 1904, Dr. Hunting wrote me as follows: "About one month after operation I began treatment with bone marrow and Coley's serum, increasing up to 15 minims, dependent on the reaction produced. I gave it at first three times a week, then twice, and during the summer I stopped it altogether while the patient was away in the country. For the last two years he has had about 7 minims of the serum once a week. At first the injections caused fever, delirium and pain at the point of myelomatous swelling. Of late, however, only pain and a feeling of malaise is produced, which passes off in about a day. He has had a good many points of pain, swelling and tenderness on different ribs, with three or four subcutaneous fractures. There is quite a marked kyphosis at the fourth dorsal vertebra, due, probably, to collapse of the vertebra and lack of support from the ligaments of the spine. He has refused to wear a jacket, as it presses on the tender points in the ribs. He has had several twists and falls, a severe bronchitis, and recently a mild pneumonia. He has attended to his business except when temporarily laid up, has a good appetite and digestion and sleeps well, his urine varies in quantity, but is always increased and contains from a trace to $\frac{1}{2}$ per cent. of albumin, albumose and globulin. His present condition is fair. He attends to business, but is easily tired, occasionally but not often complains of weakness and numbness of the legs and feet. Most of his pains are apparently due to intercostal neuralgia or to collapse of the vertebrae."

DISCUSSION.

DR. F. B. LUND, Boston—Dr. Munro has rightly stated that these cases are among the most discouraging that a surgeon has to treat. There can be very little question but that in

many cases falls from heights form a large proportion of the causes. There are some cases in which the cord is pressed open where the symptoms do not differ from those of a crushing of the cord itself. Many of the Army surgeons advocate letting these injuries alone. It is difficult to get at the laminae and elevate them without damaging the cord. I have seen a burly ice man who had fallen from a great height brought to the hospital with sufficient pressure on the spine to probably cause death from shock. By properly constructed forceps the operation may be done with moderate shock, and in cases in which the patients come into the hospital in a state of shock it is well to wait a certain length of time. I have seen a case where the cauda equina was pressed on, and removal of the lamina against which the cauda equina was pressing enabled the patient to walk out of the hospital. I have had no fatalities from similar cases, but know in some that I did no good. If one does not remove the bone nor attempt to see how badly the man has been hurt, one has not done his duty to the patient nor given him a chance for recovery.

DR. HARVEY CUSHING, Baltimore—Cases of hematomyelia must be carefully selected from those of fracture.

RUPTURE OF MESENTERIC GLANDS DURING TYPHOID FEVER

SIMULATING INTESTINAL PERFORATION; REPORT OF A CASE WITH OPERATION AND RECOVERY.*

ROBERT G. LE CONTE, M.D.

PHILADELPHIA.

The profession has long recognized that among the various lesions which may produce a peritonitis in the course of typhoid fever, rupture of the mesenteric glands is one, and yet in the many text-books which have been consulted there is not a reference given to a specific reported case. Nothnagel's "System" and Osler's "Practice," for example, fail to give a single instance of a mesenteric gland producing peritonitis; but each mentions it as a possible cause of such a complication in enteric fever. Keen's records references under this heading, but all of them prove to be cases of obscure peritonitis of unknown origin, where the reporter has only suggested the possibility of a ruptured mesenteric gland being the cause. It would, therefore, seem that such an occurrence is very uncommon, and a search through the recent literature on the subject tends to confirm this view, for I can find but one recorded case, and another unpublished record from the Episcopal Hospital notes. These two cases terminated fatally. I therefore propose in this article to review the theories advanced for enlargement of the mesenteric glands during enteric fever, and to discuss the probable causes which lead to perforation of the mesentery with a resulting peritonitis.

ANATOMY.

The mesenteric glands constitute one of the most important glandular centers in the human system.² Their number varies from 130 to 150, and they may be divided into three more or less distinct groups, which vary in importance and significance.

1. The primary group comprises some small glands placed in the course of the terminal arterioles springing from the last anastomotic arch of the vessels. This

2. Foriere, Cuneo and Delamere: The Lymphatics. English translation by Cecil H. Leaf.

group may be considered as a simple interrupting glandular nodule which has no morphologic fixity.

2. A second group comprises the glands placed in the course of the primary branches of the superior mesenteric artery, and at the level of the first anastomotic arch formed by these vessels. These glands, which are larger than the preceding, are the true regional glands of the ileum, and it is the enlargement of this group which concerns us most in typhoid fever.

3. A third group is found around the trunk of the superior mesenteric artery, and more particularly around the commencement of this vessel. This group does not properly belong to the jejunoleum, as it receives in addition the efferents of the regional glands of the cecum, ascending and transverse colon, duodenum, and even the afferents of certain glands connected with the stomach.

The second group of glands are especially numerous in that portion of the mesentery which corresponds to the jejunum. There is a progressive diminution in their number in each given segment of the mesentery until the terminal segment of the ileum is reached. Here, in this terminal segment and in the ileocolic region of the mesentery, the glands reappear in numbers and form an important mass around the ileocolic artery. It is this group of ileocolic glands which generally shows the greatest change and enlargement in typhoid fever. The collecting trunks for these glands form two systems relatively independent of each other, one of which is attached to the mucous layer and the other to the muscular coat of the bowel.

PATHOLOGY.

The changes that take place in the mesenteric glands are intimately connected with the lesions of the intestine.³ They are as constantly enlarged as the lymphatic structures of the intestines, and exhibit the same characters of medullary infiltration. In general, the localization of the process in the glands corresponds to that customary for the intestinal lesion, so that the glands in the lower part of the ileum, cecum and adjacent regions of the colon are most frequently involved, and in the greatest degree. Under exceptional circumstances profoundly involved portions of the intestine may exhibit slight glandular involvement, while, on the other hand, a slightly developed intestinal lesion is sometimes associated with disproportionate glandular hyperplasia. The involvement of the mesenteric glands is practically simultaneous with the infiltration of the lymphatic structures of the intestine. The glands become prominent as early as the first week, and attain their maximum size at the height of the disease. They may vary from the size of a pea to that of a walnut or an egg; they are tensely elastic, grayish-red or bluish-red in color, globular, smooth, or of a somewhat nodular surface. On section the projecting glandular structure is more markedly reddened in the cortical than in the medullary portions, the latter at times presenting a grayish-red, or in the center even a yellowish-red appearance.

Ribbert⁴ claims that the primary swelling in the intestine and mesenteric lymph nodes is due to the typhoid bacillus getting into the lymph sinuses and causing an acute inflammatory exudation of serum and leucocytes into the outer portion of the lymph nodules and the adjoining tissue. After a certain time the exudation disappears and is followed by an intense prolifera-

tion and desquamation of the endothelial cells lining the reticulum of the lymph spaces. These cells are occasionally phagocytic; the real lymphoid nodules, according to him, play no part in the process. Later necrosis and softening of the newly formed tissue occur, and repair by granulation tissue follows.

Mallory,⁵ on the other hand, does not believe that the presence of the typhoid bacillus in the lymph sinuses is essential, and that the proliferation of the cells is due to a diffusible toxin present in the blood and organs. This toxin is produced by the typhoid bacillus in the intestinal tract, and as a result of its absorption it stimulates the endothelial cells to active proliferation. He calls attention to the fact that the lymph sinuses are always more affected than the nodules and cords of the lymphoid cells. They become widely dilated and filled with large phagocytic cells, containing mainly lymphoid and plasma cells, but also occasionally red blood globules. These large cells are derived in part, if not entirely, from the endothelium lining the loose reticulum of the sinuses. In the lymphoid tissue between the sinuses a proliferation of the large cells lining the reticulum takes place, just as in the intestine. Sometimes it is most marked centrally; sometimes diffusely or peripherally. These phagocytic cells invade the coats of the smaller blood vessels, penetrating to the intima, where they degenerate and cause occlusion of the veins and capillaries by forming fibrinous thrombi. Necrosis in the lymph nodes takes place in the same manner as in the intestine through thrombosis of the blood vessels. When it occurs it is always most marked and most extensive in the lymph sinuses. Sometimes the typhoid process extends outside the lymph nodes into the adjoining fatty tissue, and these areas may also become necrotic. In many cases the lymph nodes do not undergo necrosis, but instead resolution takes place. The cells rapidly show signs of degeneration and disappear. Apparently resolution can occur even when fairly extensive necrosis exists in the lymph sinuses. Mallory, therefore, believes that histologically the typhoid process is proliferative and stands in close relationship to tuberculosis, but that the lesions are diffuse and bear no intimate relation to the typhoid bacillus, while the tuberculous process is focal and stands in the closest relation to the tubercle bacillus.

The postmortem examinations made at the Pennsylvania Hospital by Dr. W. T. Longcope are interesting in this connection. During the last three hospital years—from May, 1901, to May, 1904—1,958 cases of typhoid fever were under treatment in the institution. Of this number, 158 died, a mortality of 8.07 per cent. Of the 158 cases that died, 65 came to the postmortem table. In many of these cases the ileocolic group of mesenteric glands were enlarged to the size of walnuts, soft in consistency and of a reddish-gray color. The capsule was thickened, tense and firm, and in no instance showed signs of degeneration. To the naked eye the glands presented no signs of necrosis, although the microscopic sections showed minute necroses usually to be present. The mesenteric tissue outside of the glandular structures showed little or no sign of inflammatory products. In the majority of instances the typhoid bacillus was present in the glands in large numbers and in pure culture. No one of these 65 cases showed the slightest evidence of softening of the capsule of the glands, nor any tendency toward perforation.

4. Lehrbuch der pathologischen Histologie.

5. Histological Study of Typhoid Fever. Jour. Experimental Med., vol. III, p. 611.

We may, therefore, conclude that whatever the cause of the pathologic changes in the glandular tissue, whether due to a diffusible toxin secreted by the typhoid bacillus in the intestinal tract, or to the presence of the bacillus in the glandular structures, we have present as constant elements of the disease: 1, Active proliferation of the cells with great enlargement of the gland; 2, thrombosis of the veins with the production of minute areas of necrosis and softening which ultimately end in resolution; 3, thickening and strengthening of the glandular capsule.

CAUSES OF PERFORATION.

To produce perforation of the gland we must, therefore, look for some causes other than those just mentioned; something, perhaps, of an accidental nature which may very occasionally take place. In this connection I would suggest two possible causes from a theoretic standpoint alone, as I have no clinical evidence to bear them out.

First.—Through extension of the typhoid process outside of the glandular capsule the coats of some of the larger veins or arteries may be infiltrated by the phagocytic cells, producing occlusion of the vessels and interfering with the blood supply to the glandular capsule. Under such circumstances we would naturally expect necrosis of the capsule to follow, with perforation and liberation of the contents of the gland.

Second.—The accidental presence of staphylococci or streptococci in the glandular tissue which have gained entrance through the eroded mucous membrane of the bowel. If such pus-producing organisms should gain entrance to a gland already filled with minute necroses, it is easy to believe that they would soon gain a firm foothold, rapidly multiply and liquefy the glandular tissues, with ultimate perforation of the capsule.

Pennsylvania Hospital, Case 2175.

History.—M. D., Hungarian, aged 22, was admitted to the Pennsylvania Hospital Oct. 14, 1903, under the service of Dr. J. A. Scott. The patient did not speak English. He had been sick for eight days with fever, diarrhea, prostration and pain in the head and abdomen.

Examination.—On admission he was found to be a well-nourished man. The conjunctivæ were slightly injected; tongue moist, coated, tremulous; chest negative except for a few râles at the base of the right lung, posteriorly; abdomen soft; spleen enlarged and palpable; urine negative; leucocytes 5,700; Widal reaction suggestive; temperature ranging from 101 to 104 degrees; pulse 86 to 100; respirations 24 to 28.

October 18. Twelfth Day.—Typical rose spots appeared over the back and abdomen. Tubing, which had been ordered, was discontinued, owing to the marked cyanosis produced in the patient. Blood culture gave pure cultures of typhoid bacillus.

October 23. Seventeenth Day.—Continuation of the typical symptoms of a moderate attack of typhoid fever. Leucocytes 4,300.

November 4. Twenty-ninth Day.—Abdomen painful and distended; relieved by enema. Temperature on a lower level, ranging from 100 to 102.

November 8. Thirty-third Day.—Abdomen again very much distended and painful. Leucocytes 3,500; pain and distension not relieved by enema.

November 9. Thirty-fourth Day.—During the night there was a sudden rise in temperature to 104.3/5, but by morning the temperature had dropped to normal; distension had increased; slight rigidity of the right rectus muscle; considerable tenderness; liver dullness almost obliterated; abdominal pain complained of only on coughing. Two leucocyte counts a few hours apart were made, each one showing 3,500 white cells. Pulse and respiration unchanged. No sign of collapse.

A consultation was held and it was decided to await developments.

November 10. Thirty-fifth Day, 5 a. m.—Patient complained of sudden, very severe abdominal pain. Temperature subnormal; pulse and respiration not increased; distension, tenderness and rigidity about the same as on previous day. 10:30 a. m., leucocyte count 5,400; condition about the same, pain continuing; operation decided on.

Operation.—11 a. m. Ether administered. Three-inch incision through the outer border of the right rectus; a small amount of ascitic fluid without odor escaped. Localized peritonitis present. The lower portion of the ileum much inflamed, covered in places with patches of lymph, with some deep ulcers, one of which looked as though it was about to perforate. These suspicious areas were folded in with Lembert sutures. The mesentery at the junction of the ileum and cecum was much thickened and inflamed and the ileocecal glands were much enlarged, one of them having broken down and perforated through the peritoneal coat. In the immediate neighborhood of this gland the mesentery was very thick and infiltrated with inflammatory products. A portion of the broken-down and extruded gland was found free in the peritoneal cavity. The gland was curetted and the remaining cavity in the mesentery packed with a strip of gauze. The abdominal cavity was then flushed with sterile salt solution and the area surrounding the perforated gland walled off from the remaining part of the peritoneal cavity with gauze. The abdominal wound was not sutured.

Recovery.—For three days the temperature ranged from 99 to 100, then dropped to normal and subnormal for a week, when there was again a slight elevation of temperature for five days. On November 19 the last of the gauze packing was removed, and by November 30 the wound was practically closed. The convalescence was uneventful.

Pathologic Report of Specimen and Cultures by Dr. W. T. Longcope.—Section through a small mass of the tissue showed a necrotic tissue suggesting lymph gland with indefinite lymph sinuses filled with necrotic cells, blood vessels and reticulum in which lie necrotic cells. In some places there was nothing but a pinkish necrotic material. About the periphery there were a few clumps of poorly preserved lymphoid cells, together with many large, partially necrotic phagocytic epithelioid cells.

Sections stained in polychrome methylene blue showed enormous numbers of small bacilli, but no cocci were found.

Diagnosis: Necrotic typhoid lymph gland.

Cover-slips made at time of operation from intestinal exudate showed a few poorly staining bacilli, often vacuolated, with moderate numbers of leucocytes and fibrin. Bacilli did not stain by Gram's method. Culture from peritoneal fluid and exudate from intestinal surface showed no growth after 48 hours at 36.5 C. Cultures from fibrin showed no growth after 24 hours' test. At the end of 48 hours they were overgrown by *B. subtilis*. No cultures were made from the glandular tissue.

We may consider in this case two distinct causes for the production of the local peritonitis: 1, A highly inflamed segment of the ileum, showing deep ulceration and patches of lymph, but no perforation of the bowel; and, 2, a softened, ruptured ileocecal gland with extrusion of its contents into the peritoneal cavity. The patches of lymph removed from the ulcerated area of the bowel proved sterile; cultures from the peritoneal fluid also remained sterile, but the cover-glass smears from the peritoneal fluid about the mesentery showed a few vacuolated bacilli. We may fairly conclude that bacilli had not penetrated to the peritoneum through the intestinal coat, and that those extruded from the gland had not gained as yet a foothold, but were inhibited in their growth by the peritoneal secretions. The ruptured gland showed large masses of bacilli, and it would seem probable that these would soon have overcome the resisting power of the peritoneum, with the

production of a general peritonitis. It is to be regretted that cultures were not made from the glandular tissue removed.

Two similar observations recorded by others are briefly as follows:

CASE 1.—H. C. D. (Episcopal Hospital Records; unpublished). Male, aged 25 years; operation Sept. 14, 1899, on the sixteenth day of the disease, 36 hours after a supposed perforation. Exploratory incision showed no marks of peritonitis; intestines very much distended; no perforation found; drainage; death in three days.

Autopsy.—Ruptured and suppurating mesenteric gland; no perforation of intestine.

CASE 2.—J. C. M.^o Male, 27 years old. Early in the disease he had slight tenderness in the upper abdomen, but no further signs developed until the day of operation, when mild delirium began. At 7:30 a. m. pulse rose to 120, the face looked pinched and white, and he became semi-conscious. At 8:45 a. m. he collapsed, with a rapid pulse. The left side of the abdomen became more distended than the right, but no spasm or rigidity was noted. He grew worse, and Dr. Munro saw him in consultation a few hours later, when he obtained the following additional history: About five hours before operation he had collapse, with increasing pulse, tender and painful abdomen and increasing delirium. He found spasm not definitely localized, though the pain had started in the left iliac fossa. The patient was in a very poor condition and operation was advised as a last resort.

Operation.—Ether; median incision; slight excess of fluid; no pus; no suppuration; swollen glands; too ill for careful examination; death in about 12 hours.

Autopsy.—This showed two swollen glands, softened and purulent, which had ruptured and caused a local peritonitis with adhesions of the adjacent gut.

STATISTICS.

We may judge of the rare occurrence of perforation of the mesenteric glands in typhoid fever in two ways: 1, The very few cases that are reported in literature, and 2, from the statistics of the Pennsylvania Hospital, where on an average more than 600 cases of typhoid fever are under treatment each year. The case reported above is the first one we can find any record of in the hospital. As previously stated, during the past three years 1,958 cases of typhoid fever were under treatment in the institution, of which 158 died, and in 65 of these a post-mortem examination was made. In this number we had ocular proof of 29 cases of perforation of the bowel, either on the operating table or on the post-mortem table, but there were in addition several cases that had all the clinical symptoms of perforation, in which operation or a post-mortem examination was refused. We can readily see, then, that compared with perforation of the bowel, perforation of a mesenteric gland is extremely rare.

CONCLUSIONS.

1. Swelling of the mesenteric glands is a constant lesion of typhoid fever.
2. That such enlargement is due principally to a proliferation of the endothelial cells lining the lymph sinuses.
3. That these cells by penetrating the walls of the capillaries and smaller veins produce thrombosis, with resulting minute necroses.
4. That such necrosis ends in resolution.
5. That perforation of the capsule of the gland is dependent on some causes other than the presence of the typhoid bacillus and thrombosis of the smaller glandular vessels.

6. That perforation is probably due either to the presence of the staphylococcus or streptococcus in the gland, or to thrombosis of larger vessels of the mesentery outside of the gland.

DISCUSSION.

DR. L. J. HAMMOND, Philadelphia.—The five cases in literature sufficiently analogous to this one enable us to draw conclusions as to the cause or mode of invasion of the infection. From these five cases we learn that only two of them had lesions of the bowel sufficiently extensive to justify the belief that the infection took place through this source, while the additional grave complications were sufficiently great to overshadow the intestines as the focus of infection. In three cases there was associated splenic abscess, liver abscess, thrombus of the superior mesenteric vein and septicemia. At the autopsies in three cases the intestinal ulcers were not sufficiently extensive to justify the probability of infection from this source. It is doubtless a fact that the second group of glands, already described, convey the infection from the spleen, as occurred in one of the cases in this group, thus leaving out the intestinal tract as a factor *per se* in the production of this type of infection in the larger percentage of the cases. There are 29 other cases recorded of abscess where no perforation of the peritoneal coat had as yet taken place, liberating the pus in the peritoneal cavity; the glands were, however, so distended with pus that it was natural to assume the fluid would have soon been free in the peritoneal cavity. An analysis of these cases shows that the involvement of the glands need not necessarily correspond in proximity to the usual position of the lesions in the intestinal tract. We also learn that the gland is in all probability not involved simultaneously with the intestinal tract, but on the contrary the records show very clearly that the suppurative process takes place much later. Most of the cases show that seldom earlier than the thirtieth day were there symptoms such as rigor or chill, accompanied by increased pulse, elevation of temperature, and a lump discovered in this region. A distinct lump, at first hard, later soft and fluctuating, was present in all the cases in various positions, but in every instance to the right of the hypogastrium. In none of the cases did the evidence of the glandular involvement appear earlier than this. This complication may be looked for during the early convalescence, but in one case the evidence in the shape of tumor in the right iliac fossa did not appear until four and a half months after apparent recovery. As to the theories advanced concerning the channels of infection, it seems quite probable, in view of the study of the history of these cases, that the correct theory is that the infection takes place during the endothelial cell proliferation and is due to the products of typhoid process rather than to a direct bacillus infection. This theory is confirmed by the fact that in but one of these cases was the typhoid bacillus found in the pus. The hyperplasia of the lymphatic gland is, while generally found, not a constant symptom of typhoid fever. I have found, in a record of 72 autopsies on typhoid subjects, 3 cases where there was no enlargement of the mesenteric glands discoverable.

DR. L. L. McARTHUR, Chicago.—I have had one case, which occurred three months ago. The patient was in the seventh week of typhoid and had been showing for a week evidences of a localized peritonitis. Examination of the patient revealed what I thought was a retrocecal appendiceal inflammation, with pus formation. It was possible to readily open the abscess without opening the general peritoneal cavity. Twenty-four days after opening the abscess, and with the local symptoms all gone, the patient died of pneumonia. At the post-mortem a broken-down gland situated near the ileocecal junction was found as the source of the pus. The appendix was normal.

DR. D. N. EISENDRATH, Chicago.—I desire to add another case which is similar to the one which Dr. Le Conte has just reported. The patient entered the medical service of Michael Reese Hospital with all the typical symptoms of typhoid. The Widal test was positive, and the course of the disease sustained the diagnosis. Suddenly, during the third week, the patient began to complain of pain in the right half of the abdo-

men: the temperature became subnormal, with symptoms of collapse, and rigidity of the abdomen. A diagnosis was made of intestinal perforation, and laparotomy was performed, but no perforation was found. The patient continued to have the same symptoms for thirty hours, and died. The autopsy showed the typical typhoid lesions in the small intestine, but no perforation. One of the mesenteric glands, enlarged to the size of a walnut, contained pus and had ruptured. There is scarcely a doubt in my mind that this case belongs to the class that has been described by Dr. Le Conte as a rupture of the mesen. cren. gland in typhoid.

Dr. C. E. THOMPSON, Seranton, Pa.—I recall a case of typhoid which in the sixth week developed a pain over the kidney on the left side. Examination showed a thickening, and under cocaine I evacuated six ounces of pus. In a few days pain developed on the opposite side and the temperature went up. I made an incision under cocaine on this side and evacuated eight ounces of pus. The patient then went on to a recovery.

A CASE OF RETROPERITONEAL FIBROLIPOMA.*

GEORGE BEN JOHNSTON, M.D.

Professor of Surgery in the Medical College of Virginia, and Surgeon and Chief of Staff to the Memorial Hospital.
RICHMOND, VA.

The following case of a retroperitoneal fibrolipoma is so typical of this rare form of abdominal tumor, at the present time receiving in general but indefinite recognition and differentiation, that it seems to justify a detailed presentation. On account of the necessity for anticipating the malignant degeneration to which all such connective tissue tumors are more or less prone, as well as preventing the serious involvement of various organs even by a benign overgrowth, an early diagnosis is of great importance. This, in view of the frequent paucity of symptoms and obscure local signs, is difficult and but infrequently made before the condition has rendered an operation impossible or extremely hazardous.

In 1897 Adami¹ gave the immediate mortality from operation of the twenty-six instances he was able to collect at 53.9 per cent. One recurrence increased the mortality to 57.7 per cent. I have collected in addition to these three successful cases, one abandoned at operation and one death without operation. This mortality from an almost benign growth is higher than that obtained by many operators for carcinoma of the breast, and it is to be hoped that further attention to this affection and systematic detailed reports of all cases will give the condition a better prognosis from surgical intervention.

Broca's² case, reported in 1850, seems to be the first definitely recognized instance of this disease. Terrillon,³ in 1886, collected the fifteen cases published up to that time with one of his own. Terrier and Guillemin,⁴ in 1892, reviewed Terrillon's work and added two cases of their own. Several other cases which they report at the same time are of omental or doubtful origin. Josephson and Vestberg,⁵ in 1895, published an excellent article, collecting twenty-nine cases with one of their own. They divide these growths histologically into fibro-myxolipoma and myxolipoma.

Adami,¹ in 1896, published the best article that has been written on the subject, collecting forty-two cases including two of his own, with a very full bibliography. One of his cases weighed forty-one and the other forty-one and a half pounds.

His most important contribution to the subject is a classification of these retroperitoneal lipomas according to origin: 1, those definitely perirenal; 2, doubtful; 3, mesenteric, thus calling attention to the two distinct points of origin, perirenal and mesenteric fat. This division should certainly, as he suggests, "be of service in calling the attention of future observers to the need for more exact descriptions of the position of the tumor when first recognized, and relationship at operation or autopsy."

Of the forty-two cases about twenty-four were considered of perirenal origin; my own belongs to this class likewise. I have been able to collect five cases, which with my own bring the total to forty-eight so far reported.

Horn,⁶ in 1894, reports four cases which are not mentioned by Adami. Two are probably of mesenteric origin and two doubtful. Horn's own case, that of a woman 53 years of age, was successfully operated on by Fritsch, the tumor, a myxolipoma, weighed seventeen pounds.

In Laurenhaus' case, a retroperitoneal lipoma weighing thirteen and a half pounds was successfully removed by Olshausen from a woman of 42 years. The kidney and spleen were in normal position; the ascending colon covered the growth. Koefoed abandoned his case after exploratory laparotomy, on account of the extent of the mass. The growth was a myxolipoma of the mesentery. Horn⁶ also mentions a case which Professor Kirstner operated on successfully. Mudd⁷ reported a case in 1889 in which a retroperitoneal lipoma weighing sixty-six pounds was found at autopsy. The abdomen was very pendulous, extending on to the thighs.

Thus it is seen that this condition is one of great rarity, the present case being but the forty-eighth so far reported, and as the fully developed condition presents a striking picture, it is not likely that many cases which have come under observation have been lost.

It is to be deprecated that these growths should be confused and regarded in the same category as retroperitoneal sarcoma. Only three of the cases, those of Waldeyer,⁸ Adami¹ and Stewart, have shown any tendency to sarcomatous degeneration and but one case, Tillman's,⁹ has ever recurred after removal. They are definitely benign tumors and deserve distinct recognition from other retroperitoneal growths. Their structure is primarily adipose tissue with varying amount of the fibrous structure and frequently some myxomatous tissue, so that they may be denominated lipomata, fibrolipomata or myxo-fibro-lipomata, according to their individual character. Occasionally they may show cartilaginous or bony formation, as in the case of Dreschfeld.¹⁰ According to Adami, where sarcomatous embryonic tissue is found in these large slow-growing tumors, it must be considered as a relatively recent alteration in the structure, which began as an overgrowth of highly developed tissue. It can not be regarded as a primary sarcoma with fatty changes.

About one-third of the cases originate in the perirenal

fat and in their growth either push the kidney to one side or flatten and partially imbed it, as occurred in the case I report. The rest originate in the subperitoneal fat, for the most part near the origin of the mesenteric folds, and in growing separate the folds and come to lie below the intestine, which stretches across it. Thus practically all of these tumors will have a loop of the intestine running over them: the perirenal growths, either the ascending or descending colon, and the mesenteric, either colon or small intestine, according to origin. Omental or ligamentous fatty tumors are not included.

ETIOLOGY.

Of this nothing is known. They are about 30 per cent. more common in women than in men, and the large majority occur between the ages of 30 and 60.

SYMPTOMS.

These are particularly striking by their absence in many cases. It is really remarkable how such an enormous growth can take place in the immediate neighborhood of so many important organs and remain almost unnoticed by the patient. The first symptoms are usually of a dragging sense of fullness, not often amounting to actual pain. This may be associated with slight gastric irritability not usually inducing actual vomiting until a late stage.

Gradually the effects of pressure become more and more pronounced, the gastric symptoms may increase in severity, as in Madelung's¹¹ case, and may produce marked emaciation. Obstruction to the veins may induce edema or a compensatory circulation. Obstruction to the intestines, as in one of Roux's¹² cases, may produce recurrent attacks of vomiting and colic, or chronic constipation, flatulence and gurgling. Pressure on the diaphragm causes dyspnea, and the hepatic or common duct may be occluded with the production of jaundice. Albuminuria, although present in my case, has been but seldom found. Still later, pressure on the lumbar plexus may cause pain down one or both legs. There is usually no tenderness.

DIAGNOSIS.

This has been but rarely made previous to operation or autopsy. The frequent mistake is through diagnosing cyst from the semifluctuant sensation imparted by the fat. So definite may be this impression that the diagnosis of cyst has been persisted in even after several negative aspirations. A dry puncture into a fluctuating tumor should always suggest lipoma. Mesenteric cysts are to be distinguished by Augagneur's triad of symptoms: great mobility, situation in middle line, and zone of tympany in front. Echinococcus cysts move with inspiration, may give the so-called "hydatid thrill" of Briangon, and have dullness continuous with that of the liver, which is increased above.

Ovarian cyst should be determined by vaginal palpation of the appendages, and are uniformly dull on percussion anteriorly.

Ascites should not often enter the possible diagnoses of these cases, though the mistake has been made.

Hydronephrosis or pronephrosis usually shows marked tenderness, presents urinary changes, and may be revealed by cystoscopic examination or ureteral catheterization. Distended gall bladder has no intestine anteriorly, descends on inspiration, has a suggestive history, is continuous with liver and is not felt in the flank.

Sarcoma is distinguished by more rapid growth and greater constitutional disturbances and by firmer consistence.

Retroperitoneal cysts would evidently make extremely difficult differential diagnosis. They are rare. Emmet,¹³ in 1895, could only collect nine cases, including one of his own. According to Obalinski, they are probably of fetal origin, as remnants of the Wolffian or Müllerian ducts. They are in general more rounded and regular in outline; more movable and more tense.

A diagnosis of cyst of the pancreas may, as in my case, be strongly suggested from location.

TREATMENT.

This is necessarily operative and, unfortunately, the procedure has usually become very dangerous by the time assistance is sought or interference consented to.

The dangers are threefold: 1, destroying the blood supply to the overlying length of intestine crossing the tumor, with resulting gangrene; 2, shock from operating for the necessary length of time in the exposed abdomen; 3, tearing the vena cava in separating it from the growth. In order to avoid the first danger, Adami advises operating through a lateral incision and accomplishing the removal from below the intestines and peritoneum. Though this is theoretically the ideal route,

Fig. 1.—Retroperitoneal fibrolipoma.

from my experience in this one case I should consider the attempt extremely hazardous. Even with exposure from above, I found it very difficult to clear the vena cava and secure other large vessels. This, I believe, would have been impossible by the lateral route.

Vander Veer¹⁴ advises incision in linea semilunaris, and suggests separating peritoneum from internal border of tumor and then attaching it to the internal border of the abdominal wound, so making the field extraperitoneal. This scheme, which is so valuable in prolonged gynecologic operations, such as the complete operation for cancer of the cervix, as advised by Sampson, would scarcely be applicable in the case of a large mass nearly filling the abdomen, and in earlier cases the ease with which they peel out would scarcely justify the time necessarily consumed by such a procedure.

A median incision probably gives the best exposure and light, and greater ease in manipulation. After packing off the intestine as much as possible to the side, the peritoneum covering the growth is then divided and reflected, great care being taken to preserve the mesenteric blood supply and to injure the peritoneum as little as possible. No general rule can be laid down for proceeding after the tumor is reached, as the method of removal in each case will depend entirely on the extent and location of the growth and the organs involved. If the

mesenteric attachment and blood supply of the crossing loop of intestine be destroyed, immediate resection is the only course left to prevent gangrene. This has been the most frequent cause of fatal termination. Great care has to be exercised in freeing the vena cava. If the kidney and ureter are embraced in the growth, they are removed with the tumor, after ligating vessels and the ureter, and after positive recognition of the presence of a second and normal kidney.

After complete removal the large cavity had best be drained through the flank, and the posterior peritoneum then united over it, rendering the artificial cavity and drainage extraperitoneal and restoring the abdomen *in toto*.

The successful operators so far are as follows: Fritsch, Küstner, Ohlschlaussen, Alsborg,¹⁵ Buckner,¹⁶ Bruntzel,¹⁷ Belkowsky,¹⁸ Lundin,¹⁹ Hedborn, Lauwers,²⁰ Madelung,²¹ Monod,²² Pean,²³ Pernice,²³ and Roux.¹² Alsborg¹⁵ removed seven inches of transverse colon; Madelung, eight inches small intestine; Lundin, eight inches transverse colon, and Roux, four feet of small intestine. Usually there is no evidence of inflammation, the peritoneum is smooth and clean, and the tumor peels out with comparative ease.

My specimen, which belongs to the perirenal variety of retroperitoneal lipomata, was successfully removed in one and a half hours. I report it in full.

Patient.—White woman, unmarried, age 35; was admitted to the Memorial Hospital April 7, 1904, complaining of indefinite dragging pains in abdomen and of being "run down."

Family History.—Negative as to similar affection.

Personal History.—Always very healthy; usual diseases of childhood; had typhoid fever twelve years ago. No pneumonia, malaria nor acute articular rheumatism. Appetite good; bowels constipated; six years ago, discharge from right ear which continued for two years. Menses began at 14, always regular; severe dysmenorrhea throughout flow. Has not menstruated for two months. Occasional slight leucorrhœal discharge. Urinary findings negative; no blood, no pus, no pain, no increased frequency of micturition previous to present illness. Her normal weight is 164 pounds.

Present Illness.—For at least two years she has had more or less "indigestion," with occasional attacks of vomiting. During this time there was no pain. Eleven months ago a fullness or tumor was noticed in upper portion of abdomen, and symptoms gradually increased in severity with the growth of the tumor. Some nausea and aching pain were experienced, most marked after eating, and the vomiting attacks became more frequent, especially at night. Considerable flatulence with gurgling and eructation was experienced. Decided loss in weight was apparent and has amounted to forty pounds in past eleven months. A dry, irritating cough has troubled her for some months and night sweats have been constant for past two months. For the past few weeks there has been dyspnea on slight exertion and considerable general weakness, also frequency of micturition and some dyspnea. Constipation is more pronounced. Stools, normal color. No jaundice. No edema.

Physical Examination.—Patient looked weak and poorly nourished. Lips and mucous membrane pale, tongue coated. Pulse 100 to a minute; regular in force and rhythm.

Thorax: Expanded fairly well and equally. Percussion resonant throughout. Breath sounds clear except an occasional moist rale behind.

Heart: Apex in fourth interspace, just inside nipple line. Area of cardiac dullness not increased. Sounds clear. Second aortic slightly accentuated.

Abdomen: On inspection a prominence was noticeable in upper portion of abdomen, rather to right side. This apparently did not descend on deep inspiration. Umbilical fold was almost obliterated. Liver dullness began above at lower border of fifth rib in front and three fingers' breadth below angle of scapula behind. Below, liver dullness was continuous with that of the tumor, which everywhere presented absolute flatness.

The edge of the liver could be made out distinct from tumor, one finger's breadth below costal origin and was felt to descend on inspiration in contrast to underlying fixed tumor. The mass was felt to occupy practically the whole right side of the abdomen from just below the ensiform cartilage to the pelvic margin. The outline was smooth and presented evidence of at least two lobules. Pressure in the flank gave decided forward impulse to mass. The consistence of the tumor imparted an indefinite though suggestive sense of fluctuation. Per vaginam the tumor could be felt extending over rim of pelvis. The pelvic organs were apparently normal.

Urine: Clear, yellow, specific gravity 1,020. Trace of albumin, no sugar, no casts.

Blood Examination: On admission, leucocytes, 10,400; red blood corpuscles, 4,000,000; hemoglobin, 37 per cent. By morning of operation hemoglobin had risen to 49 per cent.

Operation.—Anesthesia, nitrous oxid, ether sequence. Median incision from ensiform cartilage to symphysis. On retracting the abdominal walls the enormous mass was seen to fill the entire right side, extending up under diaphragm and below pelvic brim, and by its elongated, somewhat crescentic shape, suggested a gigantic kidney. All the intestines, including the ascending and transverse colon, were crowded beyond the median line into the left side, thus accounting for the uninterrupted flatness on percussion. After carefully walling off the intestine into the left half of the abdomen with gauze, the peritoneum was divided along the whole length of the tumor and reflected, first on the left side, then on the right. No difficulty was experienced, as the membrane was smooth and stripped off easily. This now exposed the kidney lying flattened in front of the tumor and half buried in it.

The substance of the mass was seen to be quite similar to ordinary perirenal fat. As it was deemed impossible to save the kidney the ureter was followed to the bladder and then ligated and divided and the renal vessels then similarly disposed of.

The enucleation of the mass with the kidney was then begun. In order to facilitate the procedure it was necessary to divide the mass horizontally above the kidney and the two portions were removed separately. In greater part the tumor came away without trouble, though now and then a portion would be bound down by firm adhesions. The most painstaking dissection was necessary to free the vena cava, which was completely buried in the mass, from its bifurcation to its exit in the diaphragm. The upper portion was traced to the head of the pancreas, to which organ it seemed attached. The liver, gall bladder with ducts and spleen, were normal.

The enucleation left an enormous cavity and an anatomic dissection of the abdominal vessels. An incision was made in the flank, through which a gauze strip drained the cavity posteriorly; the posterior fold of peritoneum was then closed over the drain, restoring the abdominal cavity entire. The peritoneum was closed with continuous catgut suture and the abdominal walls closed with interrupted through-and-through silk worm suture. The operation, which was well borne, lasted one and a half hours.

The drain was removed on the sixth day and an uneventful afebrile convalescence was completed by discharge from the hospital on the thirty-second day after operation.

On the third day after operation the leucocytes were 6,900; red blood cells, 3,800,000; hemoglobin, 50 per cent.

Albumin could not be detected in the urine after the fourth day. The pulse, which averaged 88 to 100 before operation, varied afterwards between 64 and 80.

For the following pathologic report I am indebted to Dr. Eugene Opie, of the Johns Hopkins Hospital.

Macroscopic Examination.—The specimen forms an immense tumor mass, divided into several parts. The largest mass is of great size, measuring 31.5x17.5x19 cm., and weighing 3,920 gm. It has a smooth, lobulated surface and exhibits no evidence of having invaded any adjacent structure. It is covered over about one-third of its surface by a smooth membrane, doubtless the peritoneum, which can be readily removed. Examination demonstrates that the entire mass is made of large rounded lobules, varying much in size and shape, the larger being 10 to 15 cm. across. Such lobules are in large part separated by loose areolar tissue, which is readily broken, thus isolating masses which remain attached to one another only by a small basal part. The surface of these lobules is smooth except for the presence of rounded indentations here and there. The substance of the tumor varies much in consistence, being everywhere firm, but in some places hard and tough. The color is in some parts bright yellow and resembles ordinary fat, save that it has a grayish tint and is far firmer in consistence. Those parts of the tumor which are firmest in consistence have a gray color, and on section one sees a distinctly fibrillated appearance, striations of gray color alternating with tissue of translucent appearance. Such tissue though tough is very elastic; it is of gray fibrous appearance and contains poorly defined areas of variable size where the bright translucent yellow appearance of fat is marked. One kidney, which is apparently normal, is attached by its ureter to the peritoneum covering the tumor.

A second mass (measuring 23.5x10x12 cm., and weighing 990 gm.) is wholly composed of dense bright yellow tissue resembling fat, but is of somewhat grayish tint, and is far harder in consistence than normal fat. A very small part of this mass has the tough, fibrous character above described. An adrenal gland, which appears normal, is attached to the mass.

In addition to the above are three smaller masses, weighing together 595 gm., the largest, measuring 12.6x10x6.8 cm., represents an isolated lobule of the tumor. It is irregularly oval in shape and has a smooth surface with occasional rounded indentations. On section this tissue has a dense fibrous appearance save for small areas, about 0.5 cm. across, having the color and consistence of fat. To a smoother small mass of fat-like tumor tissue is adherent adrenal tissue. There is no appearance of invasion and cortical and medullary substances are definable.

Microscopic Examination.—Sections for microscopic examination were made from various parts of the tumor. The tumor substance consists of two kinds of tissue combined, in correspondence with the varying character of the gross appearance in varying amounts. In places it consists almost wholly of ordinary fat cells and resembles fat except that the lobulation is much more irregular than is usual. In other sections, corresponding to those parts in which the tumor substance is toughest, a fibrillated tissue containing many cells is present. In most parts of the tumor both fibrous and adipose tissues occur side by side, numerous fat cells being situated in a fibrous stroma.

This fibrous tissue is loose in texture, containing delicate bands of white fibers together with fluid material which separates both cells and fibers and gives the tissue an edematous appearance. Cells of several types are numerous. Fibroblasts are abundant. Lymphoid cells often form collections of considerable size and nearby are plasma cells. Very numerous are somewhat larger cells with abundant protoplasm and a round or oval nucleus. These cells contain vacuoles in varying number; at times a single vacuole displaces the nucleus. Such cells, which pass by transitions into fully formed fat cells, represent the latter in process of multiplication. In addition to the above, varying much in number in different parts, occur very large multi-nucleated cells—giant cells. They are usually irregular in shape, at times round or oval, at times spindle

shaped. Six or more nuclei may be present in a cell. Often, however, separation of nuclei is incomplete, so that the appearance of a budding nucleus is produced. At times transitional forms suggest that these giant cells are derived from young fat cells.

The tumor is a fibrolipoma doubtless arising from the retroperitoneal tissue. Though it has reached an immense size, it must be regarded as a benign tumor, there being no tendency to invade adjacent structures.

APPENDIX (October, 1904): By one of the strange coincidences which are so frequently met in dealing with medical anomalies, I was called on to treat a second case of retroperitoneal fibrolipoma two months after the one described above. This second case is probably one of mesenteric origin, illustrating the other of the two classes into which Adami divides retroperitoneal lipomas.

The patient, a white woman, aged 47, married. Previous family history negative.

History.—The swelling was first noticed in the right side of the abdomen about six years ago. It continued to increase gradually until the period of admission to the hospital. Until within the past twelve months there was but slight pain, and that of a dragging character, in the upper right side. During the past two years the growth has been more rapid, and within the past twelve months there has been considerable inconvenience from the size of the tumor, much sharp pain, frequent vomiting and labored breathing.

Examination.—Physical examination shows an enormously distended abdomen which, extending above, gives a somewhat barrel shape to the thorax. The superficial veins of the abdomen are greatly extended; percussion note over the tumor is flat. The general character and semiautomatic sensation imparted by the tumor suggested an ovarian cyst as the most probable diagnosis.

Operation.—At operation the tumor weighed 28½ pounds, and was successfully removed through a median incision extending from the ensiform cartilage to the pubis. On opening the abdomen the tumor presented, covered with many adhesions and firmly fixed to the posterior pelvic and the abdominal walls, particularly on the right side. A trocar inserted deeply failed to bring fluid. The tumor lay behind the peritoneum, apparently having its origin under the right broad ligament. Peritoneal flaps were reflected, vessels being clamped as met. The tumor was finally peeled out by blunt dissection and removed *in toto*. The patient did well for forty-eight hours, and then developed symptoms of extreme exhaustion, with atony and obstruction of the bowels. She sank rapidly and died on the third day.

Autopsy.—The following is a pathologic report by Dr. Jos. C. Bloodgood of the Johns Hopkins Hospital:

Diagnosis: Retroperitoneal; angio-fibro-lipoma.

Gross pathology: The tumor is fairly well encapsulated and lobulated. It measures 29x20x12 cm. Weight, 9,850 gr. (about 14 pounds). The tumor has a distinct capsule, and when separated from the tumor we find between the capsule and the tissue beneath a loose "cobweb" connective tissue. The tumor is composed grossly of three distinct parts. There is a large encapsulated fibroma, surrounded by a zone of fat. At one place it has the appearance of an ordinary lipoma, in which the connective tissue stroma in places has increased. The tissue in one place is characterized chiefly by hollow spaces suggesting venous blood canals. In places this tissue is blood stained. The tissue between the blood spaces has not a distinct white fibrous appearance nor a yellow fat appearance, but looks like very condensed adipose tissue with a good deal of connective tissue stroma. The central zone of the tumor is a mixture of the three areas just described. The gross appearance of the tumor, therefore, suggests the diagnosis—angio-fibro-lipoma.

Microscopic Study.—Naked eye appearance typical of fibroma. The tissue is composed of dense fibrous tissue taking the eosin stain. Very few nuclei taking the hematoxylin stain

are seen. There are quite a number of spaces; these spaces have no distinct wall and contain no blood. Special stain not made. Typical adipose tissue, considerable increase of the connective tissue stroma. Each space has apparently a distinct lining like the intima of a vein. The tissue between is composed of fat and very cellular connective tissue. Unfortunately, the original preparation of the huge tumor was incomplete, and the cells take the stain so poorly that it is quite impossible to study in detail their morphology and arrangement. In the smaller spaces there is a suggestion of blood corpuscles. The connective tissue about the blood vessels is far in excess of the adipose tissue, and so far as one can make out resembles a fibro-spindle-celled fibroma—the so-called cellular fibroma. In the sections studied I can see no evidence of epithelial tissue or any suggestion of kidney tissue, nor is there anything in the last section to indicate the possibility of an adrenal; nor is there anything in this section to suggest the possibility of a sarcoma.

THE FAMILY PHYSICIAN

AS A FACTOR IN THE SOLUTION OF THE TUBERCULOSIS PROBLEM.*

S. A. KNOPF, M.D.

Associate Director of the Clinic for Pulmonary Diseases of the Health Department; Visiting Physician to the Riverside Sanatorium for Consumptives of the City of New York; Hon. Director of the Gaylord Farm Sanatorium at Wallingford, Conn.; Consulting Physician to Sanatorium Gabriela, Gabriels, N. Y., and the Consumption Hospital of West Mount, Scranton, Pa.
NEW YORK.

In choosing this subject as a contribution to the Section on Practice of Medicine of our great Association. I have borne in mind that this Section is composed mainly of general practitioners; that is to say, family physicians. Before outlining what can and should be done by the family physician as a factor in the solution of the tuberculosis problem, you will permit me to give you my conception of what the family physician should be and what he should represent in a civilized country and in this enlightened century.

Of late there has been in the minds of the laity and even among the profession a tendency to depreciate the value and the standing of the general practitioner. In the profession this tendency has been particularly pronounced among its younger members; the result is that the number of family physicians relative to the number of specialists and also relative to the number of population has materially decreased. In an address which I delivered a few years ago before the American Academy of Medicine on the subject, "The Family Physician of the Past, Present and Future," I endeavored to explain the reasons for this decrease in number of family practitioners and the decrease in the esteem in which so important a position is held by the community. Permit me to quote from my address what I then said concerning the causes of this situation: No individuals, no one class of persons, but rather scientific events and our present social conditions are responsible for the scarcity of family physicians, and the disinclination of many even well-to-do families to attach to themselves a general practitioner in this capacity. The discoveries of bacteriology and the advances in sanitary science, the wonderful strides made in surgery, the multiplication of specialties, and last, but not least, the multiplicity of different systems of medicine, such

as homeopathy, eclecticism, etc., not to mention Christian scientists, faith-healers, osteopaths, somnopath, and other paths, are responsible for the passing away of the older type of family physicians.

The family physician of the present is rarely held in just esteem. In some families he is called in simply to decide what specialist should be consulted; in others he is allowed to attend to minor ailments, while in serious cases the specialist is often called in without the family physician being consulted. Again, individual members of one family often manifest a preference for this or that system of medicine. Having myself had for a preceptor one of that old type of physicians who could not bear the idea that there should be any but the one regular school of medicine, and to whom the designation allopath was as distasteful as homeopath, I had imbibed his dislike, his distrust and his disdain for any system of medicine but the regular. Shortly after graduation I was fortunate enough to become the physician to a well-to-do and cultured family. I had been successful in attending the head of the family, and I flattered myself to have gained thereby the confidence of all the members. Soon, however, I found out that I was never called in when any of the children were sick. I endeavored to comfort myself with the belief that it was probably my youth which was the cause, and that these good people did not care to trust the precious lives of their children to so young a physician. A subsequent event, however, taught me that it was not discrimination against me, but rather discrimination against the school of medicine in which I had been reared and to which I was so proud to belong. One day I met a homeopathic physician coming out of the house of this family, and later I received the explanation from the father which was to the effect that his wife would never allow her children to be treated by any physician not belonging to the homeopathic school. My idealistic conception of a family physician received a severe shock, and since then it has received a good many more. I know now of a family where the husband goes to a physician of the regular school, the wife to an osteopath, the two daughters to a homeopathic lady physician, and the mother-in-law to a Christian scientist.

Such is the status of the family physician to-day, and such the situation as it has confronted many a young practitioner and confronts many a middle-aged and old family practitioner to-day. Yet if we could only impress on the community at large, and more particularly its intelligent members, the great importance of having a family physician, his position would again rise to that height and esteem which it enjoyed of yore. Again, could the family only be made to understand how much sickness, suffering and sorrow might be avoided by having a family physician who visits and watches over those entrusted to his care, whether there is any member of the family ill or not, the people would soon learn that it is just as much and even more in the power of the family physician to save lives by the prevention of disease than it is by heroic surgical operations.

Coming nearer to our subject, "The family physician as a factor in the solution of the tuberculosis problem," I will point out the invaluable services which the family physician can render as a teacher, hygienist and prophylactiker—if you will pardon the German expression. Pulmonary tuberculosis, discovered early and treated early, has from 60 to 75 per cent. of chances of cure; the later the disease is discovered the fewer are the chances of cure, and the more is there a likelihood

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

of a chronic invalidism with a fatal termination after a few years of suffering and loss of earning capacity. If the sufferer is the head and breadwinner of the family, the suffering is often not confined to the invalid alone, and privation and discomfort follow in the train of this chronic and costly disease, and thus it affects the other members of the family.

Let it be once understood that it is not only in the interest of the physical, moral and mental welfare of a family to have a conscientious physician for its regular visitor and guide, but that there must inevitably follow a financial and economic gain by such a procedure, and the family physician will become an indispensable personage of every well-to-do household.

The family physician should not only be indispensable in the families of the rich and well-to-do, but he should be the same to the families of the poor. The municipality which will inaugurate such true and practical philanthropy as to assign a competent physician as family practitioner to a number of families not able to pay for one, will be the ideal municipality of the future. In a few years it will be able to prove that it is cheaper to prevent disease than to treat it.

The tuberculosis problem, in which I have been interested for a number of years, has taught me many things which are applicable to general medicine, to the duties and vocation of the family physician, and to the solution of the social position of the general practitioner of to-day. The one positive conclusion I have arrived at, through what I believe to be an earnest, unbiased and careful study of the subject, is that the tuberculosis problem will and can never be solved without the help of the family practitioner, and that consumption as a disease of the masses will never be successfully combated until the day in which every family has its family physician. No matter how strict the sanitary regulations which boards of health may issue, no matter how many sanatoria and special hospitals for the consumptive poor we may have, we must look to the family physician for the bulk of the work in fighting the "great white plague," or to use the graphic expression of that master of masters in medicine, Professor Osler of Baltimore: "In the warfare against tuberculosis the man behind the gun is the general practitioner; the battle can not be won unless he takes an active, aggressive and accurate part."

We must look to the family physician for the discovery of the early and curable cases. The stooping shoulders, the badly developed or deformed chest, the pale appearance, the slightly hacking cough, a marked irritability, a loss in weight, a lack of appetite, the glistening eye, pasty skin, the bright color of the cheeks, a frequent rise of temperature in the afternoon, a dislike to pleasures or to duties which were formerly easy to perform, should put the family practitioner on his guard, and indicate that the individual having these attributes, signs and symptoms is a subject for a most careful physical examination.

The bacteriologic examination in individuals with such early symptoms, even if repeatedly made, is but rarely positive, for there is not enough disintegration to show the presence of the bacilli. A careful examination will be helpful, and in this history should include the possible inheritance of a predisposition. The determination whether the suspected patient is the first, second, seventh, eighth or ninth born, and in the latter case the often hereditary physiologic poverty; the possible sources of infection, the contact with consumptive individuals, all should be taken into consideration.

The physical signs of early pulmonary tuberculosis, such as voice fremitus transmitted along the affected side, which is often observed as a subjective symptom by the patient himself and brought in evidence by a humming sound, dullness on percussion, decreased respiratory murmur, rough breathing, rales of small magnitude, a blowing sound in the subclavical or pulmonary artery, bronchial breathing, all these are symptoms too well known to need to be dwelled on longer. When these symptoms are found, in part or all, one can be reasonably certain that he is in the presence of a beginning pulmonary consumption. The fluoroscope will often confirm what the ear has discovered. I can not discuss here the question whether or not the tuberculin test is justified; as for myself I am willing to be placed on record as disapproving its use categorically. In the presence of a case where the careful bacteriologic and physical examination and the x-ray leave me in doubt, I would treat the suspected case dietetically and hygienically for a few weeks; in other words, would treat him as if he were an early case. I am sure that I would never do any harm by pursuing this method, and I am not sure I would not do harm if I injected tuberculin. It is here that the family practitioner can do the greatest good. Whether the case is suspected or confirmed, we must look to him for the carrying out of the sanitary regulations; without him, for rich and poor, and particularly for the poor, there will be a constant supply of new tuberculosis cases, created daily in the insanitary tenements of the poor.

What has been said of tuberculosis is certainly applicable to nearly all other diseases. Most ailments increase in severity where nothing is done to check their progress. Many diseases have their etiology in ignorance, and here again you will have to pardon me if I use for illustration that most characteristic disease of the masses, namely, tuberculosis. Malnutrition of the poor we are apt to attribute to want of food. Those of us, however, who have some experience in the tenement-house life of large cities will know that there is relatively more waste of food substances in the houses of the poor than in the houses of the well-to-do. It is often nothing but ignorance on the part of the willing but untrained housewife of the laborer which makes his food expensive but not nutritious. The poor girl from the shop or factory, when she marries, does not know the art of choosing the right food and preparing it appetizingly and tastefully. The result is often not only malnutrition of husband, wife and children, but alas! also discontent, love for stimulating liquors, crime and disease. In a wealthy family, if a child or grown person grows thin in spite of plenty of food, the family physician would be consulted, and not infrequently would discover the cause of malnutrition to be the fact that the food given to the patient was not the proper kind, and with a change in the right direction the patient would improve. The poor alone have no one to turn to for advice; they only go to the dispensary when really sick; they have not time nor are they observant enough to discover slight ailments, such as an impaired digestion and lack of assimilation, conditions which are the true forerunners of consumption and other grave diseases. Again, those familiar with the life of the ordinary workingman will know how he and his family often shrink from the thought of entering a hospital. These men will make all possible sacrifices in order to keep the sick member of the family at home and provide such medical attendance for him as they are able to procure. But timely and regular attendance is rather

the exception than the rule among poor families where there is a consumptive or any other kind of invalid. These poor people will first try all kinds of quack remedies, and ask their druggist for advice, or, attracted by some glaring advertisement of a sure cure, fall into the hands of some unscrupulous charlatan.

Think of the world of good the family physician can do to the family of the honest laboring man by preventing these people from falling into the hands of the numerous quack concerns which thrive on the ignorance of the poor. If the money could be counted which is annually spent for patent medicine by the average family of working people, the sum would be larger than would be necessary to pay a reasonable honorarium for a family physician and the little medicine which he would probably think necessary to prescribe. The family physician to the honest toilers would prevent so much disease and save to the members of families who might be breadwinners so many days of idleness, that they would be financial gainers in the end.

The monetary loss coming to a family from the use of patent medicines is trifling when compared with the serious results this senseless self-drugging leads to. Let me give you a few instances: A certain malt whiskey, not exactly advertised as a patent medicine, but brought before the public in glaring advertisements, and in some instances with the picture of a venerable clergyman endorsing the use of this "medicine," is recommended as a well-nigh infallible remedy in consumption. As medical men, we all know that while whiskey may be useful in a few rare instances as a temporary adjuvant in the dietetic or symptomatic treatment of tuberculosis, it never replaces food, and when taken continuously will almost invariably result disastrously. The alcoholic drink referred to is the so-called "Duffy's malt whiskey." While the claims of the manufacturers and its endorsers that "it cures coughs, colds, most forms of grip, consumption, bronchitis, pneumonia, catarrhs, dyspepsia, and all kinds of stomach troubles," and that "it never fails to build up a worn-out system, to soothe the tired nerves, to bring perfect health to the whole being," must awaken surprise if not suspicion in every person of average intelligence, this product has at least the merit of being in the market under its proper name. Far more dangerous are some of the products known as patent medicines, which are swallowed by the gallon by the public as innocent remedies, and not only by men, but also by women and children. From personal experience I know that many of these drugs, containing as much as 40 per cent. of alcohol, are taken in teaspoonful and tablespoonful doses from three to six times a day by persons who are avowed temperance people and strongly opposed to taking intoxicating liquors in the ordinary form.

Permit me to give you here a little array of these widely advertised medicines, patent medicines, nerve tonics, bitters, etc., and state at the same time the percentage of alcohol that each contains, as ascertained by an investigation made by order of the State Board of Health of Massachusetts. I have arranged this list according to the percentage of alcohol (by volume). The original compilation appeared in the report on Food and Drug Inspection for the year ending Sept. 30, 1902, kindly sent to me by Dr. S. W. Abbott, the secretary of the board:

Hof's Extract of Malt and Iron.....	5.24
Copp's White Mountain Bitters, "not an alcoholic beverage".....	6.00
Pierce's Indian Restorative Bitters.....	6.10
Warner's Vinegar Bitters, "contains no spirit".....	6.10
Hop Tonic.....	7.00

"Beet Tonic".....	7.00
Dr. Kilmer's Swamp Root.....	7.32
Radway's Resolvent.....	7.90
Corbett's Shaker Sarsaparilla.....	8.80
Thurston's Old Continental Bitters.....	11.40
Hop Bitters.....	12.00
Second Clinical Bitters.....	13.10
Howe's Arabian Tonic, "not a rum drink".....	13.20
Allen's Sarsaparilla.....	13.50
Brown's Sarsaparilla.....	13.50
Dana's Sarsaparilla.....	13.50
Wheat Bitters.....	13.60
Dr. Peter's Kurko.....	14.00
Kingsley's Iron Tonic.....	14.90
Pulmonine.....	16.00
Good's Bitters.....	16.10
Baxter's Mandrake Bitters.....	16.50
Mensman's Peptonized Beef Tonic.....	16.50
Moses Atwood's Jaundice Bitters.....	17.10
Greene's Nervura.....	17.20
Carter's Scotch Bitters.....	17.60
Langley's Bitters.....	18.10
Dr. William's Vegetable Jaundice Bitters.....	18.50
Good's Sarsaparilla.....	18.80
Wheeler's Tonic Sherry Wine Bitters.....	18.80
Vinol, Wine of Cod Liver Oil.....	18.88
Schenck's Seaweed Tonic, "entirely harmless".....	19.50
Jackson's Golden Seal Tonic.....	19.60
Brown's Iron Bitters.....	19.70
Faith Whitcomb's Nerve Bitters.....	20.30
Kaufman's Sulphur Bitters, "contains no alcohol" (as a matter of fact it contains 20.50 per cent. of alcohol and no sulphur).....	20.50
Lydia Pinkham's Vegetable Compound.....	20.61
Hooker's Wigwam Tonic.....	20.70
Paine's Celery Compound.....	21.00
Flint's Quaker Bitters.....	21.00
Shony's German Bitters.....	21.50
Thayer's Compound Extract of Sarsaparilla.....	21.50
Warren's Bilious Bitters.....	21.50
Gardner's Physical Extract.....	21.90
Puritana.....	22.00
Hartshorn's Bitters.....	22.20
L. T. Atwood's Jaundice Bitters.....	22.30
Liverpool's Mexican Tonic Bitters.....	22.40
Leitch's Compound Cocoa Beans Tonic.....	23.20
Burdock Blood Bitters.....	25.20
Hooftland's German Bitters, "entirely vegetable and free from alcoholic stimulant".....	25.60
Ayer's Sarsaparilla.....	26.20
Colden's Liquid Beef Tonic, "recommended for treatment of alcohol habit".....	26.50
Colton's Bitters.....	27.10
Z. Hertz's Sarsaparilla.....	27.90
Whiskol, "a non-intoxicating stimulant, whiskey without its sting".....	28.20
Penna.....	28.59
Jobb's Sarsaparilla Bitters.....	29.00
Atwood's Quinlin Tonic Bitters.....	29.20
Hooftland's German Tonic.....	29.30
Drake's Plantation Bitters.....	33.20
Rush's Bitters.....	35.40
Warner's Sarsaparilla Bitters.....	35.70
Parker's Tonic, "purely vegetable," recommended for inebriates.....	41.60
Boker's Stomach Bitters.....	42.06
Hosette's Stomach Bitters.....	42.30
Richardson's Concentrated Sherry Wine Bitters.....	47.50

The dose recommended on the labels of the foregoing preparations varied from a teaspoonful to a wine-glassful, and the frequency also varied from one to four times a day, "increased as needed."

I often wonder if some of our distinguished statesmen, clergymen and otherwise highly intelligent citizens, who are in the habit of giving their endorsement to such remedies, have ever thought of the fearful responsibility they incur when recommending a remedy, the composition of which is as foreign to them as the chemical formula of phenyl-dimethyl-iso-pyrasolene (antipyrin). Many of the above enumerated remedies I have seen used by consumptives who, as we all know, are so very apt to ascribe their sufferings to stomach or nervous derangements, and eagerly try any thing which they imagine will give them temporary relief. In such cases it is the strong mind and the authority of the family practitioner who alone can stop the pernicious habit of self-drugging.

I know from experience in my own practice how the continued use of even a mild cocaine solution will make cocaine fiends. A typical case was recently related to me by a friend, the proprietor of a leading journal. It shows the danger in the advertised local catarrhal remedies, containing as active principle the hydrochlorate of cocaine. A young boy in my friend's office was advised by his own father, an employe of the same paper, to use

a certain widely advertised sure cure for his nasal catarrh. The directions given for the use of this remedy were to apply it by the aid of a spray to the mucous membrane of the nose. When the father thought the boy had used the costly remedy long enough the boy had already become addicted to the use of cocain. Since the father no longer bought the remedy and the young man's means did not suffice to pay for the costly drug, the boy became a thief. When finally caught and taken into the private office by his employer, a complete confession revealed the cause of his downfall. The "sure-cure" remedy for his slight nasal catarrh had made him a cocain fiend, and as it is with all habits of this kind, his moral and ethical conception had decreased in the ratio of the increase of the craving for the drug. Fortunately for the boy, the father handed him over to a conscientious physician, under whose close observation a complete recovery resulted. Yet we all know that only the smaller number of cases of men and women addicted to alcohol, cocain, morphin or chloral, acquired by the continued use of these drugs, pure or in the guise of patent medicines, have such a fortunate ending as the case just quoted. I endorse most heartily what Mr. Bok has to say in this respect in a recent issue of the *Ladies' Home Journal*: "It is not by any means putting the matter too strongly to say that the patent-medicine habit is one of the gravest curses, with the most dangerous results, that is inflicted on our American national life."

Of the incalculable harm which the many advertised absolutely sure consumptive cures do among the poor and ignorant sufferers from pulmonary tuberculosis, I could tell you heartrending stories. The so-called Koch concern, for example, the dealers in "Kochine" or in "inhalation tuberculin," will ask the poor sufferer, under promise of cure, to pay a certain sum in advance. He will, of course, not receive any benefit from the treatment, but on re-examination by the "professor" he is assured that his lungs are better and the result is another advance payment; and this re-examination and finding the lungs better is continued until there is no more money. What happens then? The patient is told that in view of his improvement and for reasons of pity, the "professor" will continue the treatment without payment, but in lieu of this, the patient must sign a certificate saying that he has been thoroughly cured of his disease through the medicine of the "great and good professor," although two prominent physicians had pronounced his case to be a hopeless case of true consumption. Thus these concerns get their testimonials. They will shrink from nothing to beguile the public.
