They have used, and still use, the name of that great scientist and benefactor, Prof. Robert Koch of Berlin, as though he were associated with them in their business and treatment. They advertise his picture beside that of an individual with a similar name, and head their advertisements with "Professor Robert Koch's Cure." While the medical profession at large is, of course, aware of this evident fraud, the public does not seem to be, and in order to be able officially to deny any such connection, I wrote some time ago to Prof. Robert Koch of Berlin, Germany. The professor's answer was a lengthy one and full of indignation, and I will give you only the substance of it. He says that the alleged "lung cure" of Dr. Edward Koch, or under whatever name this system of treatment may be presented to the American public, is a very base fraud, and that he, Geheimrath Prof. Dr. Robert Koch, has no relations whatever with Dr. Edward Koch, with any other indi-

vidual who may be connected with this concern, nor with any of its methods of treatment; neither has he ever had any relations with the same. He hopes that an end will soon be put to the manipulations of these base and fraudulent concerns, and adds: "This is to be particularly desired in the interest of the many poor consumptives who have been deceived by the use of my (Prof. Robert Koch's) name in connection with the so-called "Koch's Consumption and Asthma Cure."

For reasons best known to themselves, even some of our best known and reputable newspapers continue to publish advertisements of the Koch's consumption cure concerns, and few are willing to lend a hand to the exposure of these frauds.

What a power of good could the family physician be in protecting poor ignorant consumptives from the fearful harm which is done to them through such dangerous charlatanism.

I desire to touch on one more point regarding the prevention of consumption. It is a delicate point, I confess, but I feel keenly on the subject, and have no hesitation in this audience of physicians to express my opinion frankly. The family physician, who should not only be the medical adviser but also the friend of the family, will be listened to more readily than any other person when there is a question of marriage to an individual of doubtful physical integrity; in other words, it is the family physician and friend more than any other person who will be able to prevent the marriage to a consumptive or between consumptives. If tuberculosis develops in husband or wife after marriage, it will be again the family physician's duty to point out to both that, although tuberculosis is not hereditary directly, there is a great likelihood that a strong predisposition may be transmitted from the consumptive parent. Such a couple should also be made to understand that pregnancy in a consumptive mother ameliorates her physical condition only temporarily, and after childbirth there is often noticed an exacerbation of the pulmonary trouble. Wherever there are consumptive parents I am willing to take the responsibility before the law and my Creator for advising them not to procreate the race.

A last word on the importance of the family physician and the valuable service he can render to the consumptive poor if he is fortunate enough to practice among the well-to-do. While much gratitude toward the physician is not invariably a virtue to be met with among the rich, it is not so infrequent as the pessimists in our ranks like to make it out. Some rich patients are truly grateful; they will not only pay the physician handsomely, but will make him their adviser and friend. The grateful, well-to-do patient will often ask his physician what institution, what hospital, what kind of patients most need the help of the philanthropist. What golden opportunity is here offered to the family physician to help toward the solution of the tuberculosis problem by telling his noble-hearted patient a little of the life of the tenement dwellers which he learned to know when, as a young physician, he practiced in those regions. No one better than he knows how to describe the suffering of the consumptive poor, lacking not only the ordinary comforts so essential to the successful hygienic and dietetic treatment of consumption, but often lacking the barest necessities. The family physician, more than any one else, can point out to his wealthy patient the surest and most direct path to relieve the woes of the needy and suffering, and if the physician is a true friend of him who wishes to leave his wealth so

as to be productive of the most good, he will show such a man that his money could not be better invested than in the creation of more sanatoria and special hospitals, seaside sanatoria for children, agricultural colonies, better tenements, more parks and playgrounds, all tending toward the solution of the tuberculosis problem.

16 West Ninety-fifth Street.

PROBLEMS FOR THE TUBERCULOUS CONVALESCENT.*

A. MANSFIELD HOLMES, M.D.
DENVER.

For many centuries, and, in fact, until the last decade, tuberculosis was generally believed to be an incurable disease. An unceasing warfare against the disease, however, has gradually added to our knowledge of its causes and nature until its terrors have been lessened, and its victims are no longer overshadowed by a prognosis destitute of hope.

The autopsy records of the great medical centers have furnished abundant evidence of pre-existing tuberculous lesions that had long since healed, or had assumed latent states, while death eventually resulted from other causes. A review of vital statistics shows a high and increasing percentage of recoveries.

These facts have established more hopeful views concerning tuberculosis, which cause it now to be recognized as one of the readily curable diseases.

Notwithstanding that year by year we are forming a clear conception of the influences which bring about the tuberculous state, and, on the other hand, that we have gained a clearer understanding of the necessary steps to overcome this condition when established, the mortality rate for tuberculosis continues higher than for any other disease known to humanity. To lessen this appalling mortality rate, efforts must be directed toward means of prevention as well as methods of cure. To diminish the number who become tuberculous is, indeed, an important phase of the tuberculosis problem, for tuberculosis is distinctly a preventable disease.

For the present, however, our attention will be directed especially to the problems pertaining to recovery. Granting that tuberculosis is a curable disease, it may be of interest to ascertain the cause, or causes, of the existing high death rate. Many important lessons may, therefore, be learned from a study of the mortality records of tuberculosis. A study of these records reveals the fact that a large percentage of mankind possesses by inheritance, or acquires from their mode of life and the nature of their environment, a type of weakened tissues which furnishes a fertile soil for the tubercle bacillus.

These persons offer little or no resistance to tubercle bacillus when it finds a lodging in the weakened tissues of such persons. As a result, these patients are, in a large measure, hopeless from the beginning of infection. For such patients, treatment should have been prescribed for their ancestors many generations before, with a view of producing a progeny with stronger resisting power.

There remains, however, a large percentage of fatal cases that might have been cured or improved had conditions been more favorable during the course of the disease.

In considering the factors which are most potent in favoring recovery, an early diagnosis should rank first in importance. It is only recently that the significance of the early symptoms of tuberculosis have been correctly interpreted. Heretofore a slight cough, a loss of appetite, sleeplessness, loss of weight and strength, were interpreted as a mild but general impairment of health. Even to-day the significance of such a series of symptoms is often passed over by the laity without attracting special attention.

It is also a lamentable fact that many physicians have yet to learn the supreme significance of the early but insidious symptoms of a beginning tuberculosis. The gravity of the case, therefore, is too frequently overlooked until serious tissue loss has developed.

When these subtle but significant early warnings are not recognized, important opportunities for treatment are lost, and the possibility of arresting the disease is greatly diminished. Hence the responsibility for the lack of an early diagnosis should be traced to its legitimate source. The placing of responsibilities which involve such serious risks, and on which lives may rest, requires the consideration of questions of a domestic and sociologic nature that are by no means easy of solution. The existing social and domestic customs make it possible, under varying conditions, to place the responsibility of a neglected diagnosis on the patient, the family of the patient, the family physician, or the public.

It becomes extremely important, therefore, to place the responsibility of a recognition of the true nature of the trouble during the early stage of infection. Who is at fault if the patient fails to consult a physician for what he considers an insignificant or temporary trouble? Who is at fault if the general public is not informed concerning the importance of an early diagnosis? Who is responsible if the disease is not recognized until it has advanced beyond the stage when hope of recovery may be expected?

The subject resolves itself into a need for a general campaign of education with a view of impressing on the public the necessity of an early diagnosis, and on physicians themselves the necessity of greater skill in recognizing the long list of early symptoms which forms a picture that can scarcely be mistaken, if once thoroughly recognized. The ultimate responsibility for the accomplishment of these results rests with the public and devolves on the state to take the initiative.

It is an undeniable fact that many curable patients die. A failure to recover may be ascribed to two causes—a lack of effort or an irrational effort.

In the light of past experience it is my opinion that the problems presented to the tuberculous convalescent are equally important, and often more difficult of solution than those presented when the disease is first detected. After months and years of effort and expense, many patients fail to overcome the disease because of a lack of proper knowledge of a few fundamental laws of convalescence.

If it is permissible to use an analogy in the discussion of a medical subject, the struggle of a tuberculous patient may be likened to a nation defending its life or its honor. Similar questions are presented for solution, and identical conditions are to be met. War between nations and war against disease are often declared with little warning. When such occurs, the defenses are frequently found in a weak condition, the finances at low ebb, and the strongholds in a neglected state. The na-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

tion that fails to prepare for war in time of peace will be able to make but a feeble resistance when danger is threatened. An army sent to the front is certain of defeat unless plans for furnishing supplies have been carefully formulated. The inevitable result is well known if the line of communication is broken and the supplies cut off. Such a catastrophe means an indefinite siege, with indescribable deprivation and suffering. On the other hand, the equipment and supplies may be inexhaustible, and yet if the commanding officer lacks judgment he may lead his brave men into dangers that mean inevitable defeat.

Those who have observed the army of tuberculous patients who are traversing every highway and byway of this disease-infected globe, have witnessed object lessons not easily forgotten. Many a patient for a time makes a good fight, and for lack of conservative judgment or on account of overconfidence, what seemed to be a certain victory is turned to a sudden defeat. In warfare against disease, as in warfare between nations, the nature of the campaign should be well studied before rushing to meet the enemy. The course pursued should depend on the resources at hand. Good judgment and cunning strategy are essential.

Before a campaign is undertaken, an attempt should be made to estimate the approximate cost; every effort should be made to procure the necessary funds; the field for operation should be selected with a view of securing the most favorable conditions and the strongest defenses; the source and nature of the supplies should be well considered, and a commander chosen to direct the forces whose experience and judgment are above reproach. When these precautions are not taken, defeat is inevitable. How many tuberculous patients plan a campaign with skill and judgment? Too frequently they leave all judgment at home. They take with them a good supply of bravery, but few or no supplies; they frequently choose a battlefield with no natural defenses, and are often unskilled in proper methods of utilizing their available defenses. Frequently, with little or no knowledge of the strategy of their common foe, they attempt to command their own forces, and for some rash act of foolish bravery or lack of judgment what might have been a victory terminates in disappointment and defeat.

I recall the case of a young man of fine business training, recently employed as cashier of a large business concern in one of our eastern cities. From daily handling large amounts of infected currency, he himself became infected. His family was of moderate means and he its chief support. Each day that he continued to hold his lucrative position, after the nature of his disease had been determined, lessened his chances of recovery. To give up his position meant a heavy drain on his savings, as well as the cutting off of his only source of income. An important question was before him for definite decision. He tendered his resignation, and with his small savings sought a more favorable climate. An out-of-door life for one year found him well on the road to recovery. His trouble had been reduced to a quiescent state. His weight and strength had increased, and his old ambition began to develop. He began to long for the familiar scenes of home. On the other hand, his finances were exhausted. When he was really ill, he was brave. But he had almost won the battle, and he was brave no longer. He had arrived at a critical point. Another decision was required. He finally decided to return to his old home, against the advice of his physician and friends. He once more as-

sumed his former duties, and once more was self-supporting. But before he was aware of the fact the old trouble developed anew, and the labors and hardships of a long convalescence were soon at an end. He had mistaken a convalescence for a cure and returned too soon to the environment and conditions that had once threatened his life, with a bravery that was destitute of judgment.

The brief statement of the foregoing case illustrates a few of the practical problems that are presented to the tuberculous patient. These problems require the exercise of shrewd judgment and a final and definite decision, and the nature of the decision frequently seals the fate of the patient. To continue in the environment in which the disease developed is fatal to most patients; a return to the same environment when hope has revived, but before the disease is cured, is equally dangerous.

Patients who are forced to face these problems seldom realize the significance of the decision which they are required to render. The exuberance of feeling which accompanies a pronounced convalescence is deceptive and often leads to excesses and relapses. The necessity of becoming bread-earners often forces a convalescent too soon to undertake an employment, or to enter an environment that is unhealthful.

Problems such as these tax the skill and judgment of both physician and patient to their limit. And as long as the bread-earning problem remains so closely allied to the problems of tuberculosis the difficulty of solution will remain very great.

As has already been indicated, there are cases which are diagnosed almost immediately on the appearance of clinical evidence indicating the existence of an active tuberculous condition, and although immediate steps are taken to correct the trouble, yet at no time can they be said to be classed as convalescents.

On the other hand, it is difficult to find a case, if discovered early, that does not, at some period during the course of the disease, and often at frequent intervals, show strong evidence of being classed as convalescent. These periods of apparent convalescence, unfortunately, are of short duration. The smallest disturbing factor is sufficient to terminate such a convalescence, without any apparent cause except on the ground of a new infection starting in tissues already too weak to resist further invasion.

It is rare, indeed, to find a case pass through a successful convalescence without some form of complication or relapse. The very conditions which lay the foundation for tuberculosis tend to prevent recovery, tend to delay convalescence, and tend to bring about a relapse after convalescence seems to be well established.

One of the chief duties of a physician to his tuberculous patients is that too often neglected duty of repeatedly presenting to the patient the essential rules for wholesome living. Many who are required to care for the tuberculous are content with having outlined the essential rules for healthful living, expecting patients to remember them and to put them into daily practice. I have more than once been surprised, after having spent not a little time and effort in presenting concise rules to govern their daily routine, to find that, in a great majority of cases, they had completely disregarded such advice. One becomes more and more impressed with the fact that too little attention is given to the consideration of the private life of the patient. The physician too seldom sees the patient in the environment of home. Unless a relapse occurs in the form of a hemorrhage, or

some complication making it necessary to call the physician, the patient usually calls at his office. I have, therefore, frequently found occasion to call at the home of patients when they were not expecting me, for the purpose of ascertaining how nearly they had been carrying out the instructions that had been given them. Such a visit will reveal the nature of the home environment and often explain why convalescence has not been more pronounced.

FACTORS AFFECTING CONVALESCENCE.

The important factors affecting convalescence are: 1. An early diagnosis. 2. An early abandonment of the habits of life, or the environment, by which the patient was surrounded during the development of the disease. 3. The immediate adoption and continued enforcement of rigid rules for healthful living.

The difficulties presented to the tuberculous convalescent in securing remunerative employment is a most important retarding factor. The establishment of remunerative industries in connection with the well-endowed sanatoria may do much toward overcoming the "bread" problem for the great middle class afflicted with tuberculosis.

TREATMENT DURING CONVALESCENCE.

The treatment of convalescence should be directed, first, with the view of correcting temporary symptoms; second, with the object of aiding body nutrition. It may be stated with emphasis that any form of treatment which tends to impair the digestion or assimilation of food, not only can do no good, but on the contrary does absolute harm.

Out-of-door life is pre-eminently the treatment for tuberculosis. Without open-air life convalescence is impossible. The climate which admits of the longest period of uninterrupted open-air life is best suited to the tuberculous patient. That region which admits of the greatest amount of outdoor life, with least discomfort, is the ideal climate. A cool, dry atmosphere is not only more agreeable but less enervating to patients than a hot, dry atmosphere. A tent, or tent-cottage, furnishing a good ventilation without exposing the patient to a draught, one capable of being adjusted to suit all conditions of the weather and all seasons of the year, furnishes the most rational mode of outdoor life, provides all the comforts that a patient requires, and is much less expensive than the indoor treatment.

A few practical points should be carefully noted in connection with the care during the convalescent stage:

Pure air and sunshine can avail but little if the patient is not provided with an abundance of suitable food.

The wisest advice to patients will avail nothing if they are not sufficiently impressed with the importance of proper living to put into practical operation the advice given them. Too often the rigid discipline is lacking in the home. It is chiefly in this respect that the sanatorium treatment surpasses the home treatment of tuberculosis.

CONCLUSIONS.

To know when health is restored to the tuberculous patient is both important and difficult. It is a well-known fact that foci of infection lie concealed in a latent state long after all subjective symptoms have disappeared. Tubercle bacilli may have disappeared from the sputum, or may never have appeared there, and yet there may be and often are concealed foci, active or inactive, which are by no means easy to detect.

To form a correct estimate of convalescence, one must form a composite picture of all the available clinical

evidence. If there is a gradual gain in weight extending over a comparatively long period; if the gain in weight is accompanied by a gain of strength; if the gain of weight and strength are permanent; further, if the cough, sputum and bacilli diminish, and finally disappear, and if this condition is maintained for a comparatively long period, a cure may be considered as practically established.

Finally, if it is evident from the clinical symptoms, physical signs or personal history, that the case was ever truly tuberculous, the conservative physician will use great caution in giving advice which will make it possible to lead his patient too near a danger.

It is safe to state that a person who has had tuberculosis, and who has been sufficiently fortunate to arrive at the advanced stage of convalescence, or even if he had been discharged as "cured," should always exercise care and should never venture too close or remain too long in the environment in which the trouble originally developed.

THE DIFFERENTIAL LEUCOCYTE COUNT AS AN AID TO THE DIAGNOSIS OF FEVERS.*

WM. KRAUSS, M.D.

MEMPHIS, TENN.

The factors influencing the movements of leucocytes are but imperfectly understood, hence a system of diagnosis based on a variation of the colorless elements in the peripheral blood is not without some hazard, yet it must be admitted that practically all we know of the physiology of the blood has been worked out in the clinical and pathologic laboratory. Stimulated by the reports to the Royal Society and observations of other workers in malarial districts, and feeling guilty of some negligence in this field in the past, I made random observations for some years which led to a systematic investigation of some 200 blood spreads with a view to ascertaining the diagnostic value of the malarial leucocyte variation.

Malarial blood has been found to vary within very wide limits, and the colorless cells show a percentage so nearly like that of typhoid fever, from which we have to differentiate most often, that it did not seem a very promising field, and I so stated at our meeting a year ago, yet, after eliminating the chief sources of error and using the clinical signs as collateral evidence, we can frequently make a positive diagnosis without searching for parasites or waiting for the appearance of the Widal reaction. This method is not to replace, but to supplement, other diagnostic methods.

It is the purpose of this paper to prove that the malarial leucocyte variation does not persist long after all the infection is eradicated, and that it should settle the controversy as to whether it is too sensitive to be used in a malarial district—in other words, that it is not to be thrown aside as of too general occurrence to be worth anything as a test.

In considering any leucocyte variation, it is necessary to have a reasonable idea as to whether this is due to the increase of the one variety or the diminution of another. Is the increase or diminution absolute or relative? What factors other than the disease in question influence it, and to what extent? The accompanying rather

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

cumbersome table is adduced as a guarantee, so to speak, as well as to enable any one to criticise the conclusions drawn. The idea that it might be of use as a test that could be made on dried films away from the bedside and in the absence of facilities for culture methods, and that blood films might be exploited in other ways than generally in vogue, is what attracted me in advance of the actual work.

I believe that the enormous increase in large mononuclear cells, especially the very large macrophages, is because phagocytosis is a distinct and easily recognizable phenomenon in malarial infection and is responsible for the occasion of the hibernation of the plasmodia in the interior. We can find pigmented mononuclears after all the parasites have disappeared from the peripheral circulation, but the relative increase of mononuclears persists even longer, and, what is of more importance, is present more uniformly.

An inspection of the tables will show that in malarial infection the large lymphocytes generally nearly equal and frequently outnumber the small, with a total relative increase of lymphocytes and proportionate decrease of polynuclears, except in the beginning of a paroxysm up to about the fastigium, and frequently still later, when there may be a decided absolute and relative increase in polynuclears. Frequently, even here, however, the white cells behave as they do during the afebrile stage. Sometimes there is a marked polynuclear increase without the high fever, but, so far as observed, this is not the case in recent infection, and we generally ascribe this to the effect of quinin, especially in what is called the post-malarial condition.¹ It has so far not been otherwise observed unless a complication exists. I am inclined to regard a polynuclear increase, except under the above conditions, as positive evidence of some other disease, excluding malaria if the large lymphocytes are not in excess of the small. In my table this state of affairs has been found to be due to sepsis, cancer, syphilis with active manifestation, hemorrhage, peritonitis, rheumatism and pneumonia. We would also expect to find it in epidemic meningitis, but no such case has presented itself.

We find, then, that when we have a differential leucocyte count of over 75 per cent. of polynuclears in a presumably malarial patient, in which the large lymphocytes outnumber the small, and during the fever stage, we have a condition which might not be due to the *Plasmodium malariae*; but if due to it, we have a blood in which the parasites would be easily found. If we have a leucocyte count showing upward of 15 large lymphocytes and less than 60 polynuclears, in the absence of an adenopathy and prior to the third week of a fever, neither the presence of the malarial organism nor the absence of a Widal reaction is needed for a diagnosis. In influenza, measles, syphilis, tuberculosis and in typhoid fever after the disease is well established, the count sometimes approaches that of malaria. The leucocyte count is of especial value in determining when the infection has been eradicated in chronic cases, and here it frequently is the only means of diagnosis at our command. In latent malaria, and cachexia, especially when there is no fever, it is the rule to find only 50 per cent. polynuclears, the large lymphocytes being frequently the most numerous element.

In typhoid fever, according to the tables of Thayer, who records nearly 200 counts, the large lymphocytes also increase; but they do not, in my experience, reach

the great size and number found in malaria, and what is more practical, the diagnosis of typhoid fever should be well established after the second week, when this leucocyte confusion is most marked. When the onset of a typhoid is complicated by the lighting up of a latent malaria, the malarial feature overshadows the typhoid; but even here, if in the absence of baths, quinin therapy or other disturbing factor, the polynuclears rise and fall markedly with the fever, typhoid is very probably absent, and the therapeutic test eliminates both the fever and leucocyte variation due to the malaria.

When the diagnosis lies between malaria, typhoid or sepsis, the differential count more certainly decides the question than the absolute leucocyte count or the Widal reaction; the latter is especially fallacious in these cases. (See Table 3, Cases 2, 7, 14 and 31.) In one of these cases (14) there was a pseudo-reaction with Widal, and there appeared to be only a question of typhoid or malaria, but the differential leucocyte count at once excluded both and pointed the way to the diagnosis of malignant endocarditis. In another case, of which the record was accidentally lost, we had to differentiate between a typhoidal pneumonia, pulmonary typhoid, or a mixed infection, when the enormous polynuclear increase, the presence of only 2 per cent. of large lymphocytes positively excluded both typhoid and malaria, although there was marked tympany and abdominal pain. Subsequent events proved that it was a pure lobar pneumonia.

Syphilitic cases seem to show sensitiveness of the leucocyte proportion to the character of the lesion; in adenopathy the large lymphocytes increase, and in bone and skin lesions the eosinophiles appear increased, and when suppuration occurs we have the increase of the total number of white cells, with great preponderance of the polynuclears.

A number of counts in tubercular cases had to be thrown out because the data accompanying the films did not admit of proper classification as to fever, adenopathy, sepsis, etc.

I beg leave now to refer to the tables. Under clinical diagnosis, the preliminary clinical diagnosis is meant, the corrected diagnosis appearing in the last column. Stain No. 1 is fixation in alcohol and ether and staining in eosin and hematoxylin. No. 2, same fixation, stained with eosin and methylene blue in two steps. No. 3, same fixation, stained with eosin and polychrome methylene blue in two steps. Stain 4 is Goldhorn's, which fixes and double stains in one operation, but it has been found desirable to faintly re-stain with Loeffler's alkaline methylene blue. No. 5 refers to Ehrlich's method, and No. 6 to Jenner's, which has been found to answer best in inexperienced hands, but does not approach the modified Goldhorn in brilliancy of detail and fidelity of results. The basophile and neutrophile granulation are particularly well brought out. One of the precautions in the Goldhorn method needs to be mentioned, especially if it is desired to re-stain with blue, and that is to dilute the stain with good wood alcohol and give it double time, as else the leucocytes may be observed to "get up and leave" when examined under water to see if the contrast is good. There is, unfortunately, a personal factor in the separation of the mononuclear cells, and for this reason I have indicated the name of the observer by an initial letter in one column. I was particularly fortunate in securing the services of Dr. A. G. Love, whose patient and conscientious work represents nearly half of the counts, and almost all of these especially made for this paper. Where the number of cells

Total 31 controls—Small lymphocytes, 14.26; large lymphocytes, 74.49; eosinophiles, 2.80; polymorphonuclear leucocytes, 7.43; basophilicities, 0.46; myelocytes, 0.65. Norm. average—Small lymphocytes, 20; large lymphocytes, 8; polymorphonuclear leucocytes, 70; eosinophiles, 1.5; basophilicities, 0.3. (The dagger (†) represents plus.)

SUMMARY:

	Small Lymphocytes	Large Lymphocytes	Polymorphonuclear	All Others
Mean of last 125 cases	15.4	21.0	61.3	1.7
Total mean	10.6	17.0	70.0	2.0
200 cases during apyrexia	17.0	23.0	60.0	0.0
Twenty-five cases malarial anæmia (temperature under 101°)	21.5	29.7	46.4	1.9
Twenty-seven cases disease plus malarial infection	14.0	18.0	71.0	2.8
Thirty-seven cases without malarial	14.3	18.1	71.0	2.6
Thayer's cases typhoid fever:				
First week	12.9	12.4	71.0	0.5
Second week	14.6	14.6	63.3	0.9
Third week	14.6	11.6	63.3	0.9
Fourth week	50.1	14.4	65.0	0.4

Mean of last 125 cases
Total mean
200 cases during apyrexia
Twenty-five cases malarial anæmia (temperature under 101°)
Twenty-seven cases disease plus malarial infection
Thirty-seven cases without malarial
Thayer's cases typhoid fever:
First week
Second week
Third week
Fourth week

counted is under 300, it was due to the scarcity of cells in the spread, the whole film having been gone over with a mechanical stage.

In referring again to Table 3 we find three cases very probably malarial (8, 16, 24). They were positively exposed to it in proper season, in surroundings which precluded protection, although no parasites were found on the spreads. Of the balance, 11 cases had over 10 per cent. of large lymphocytes, and only 5 of these reached the obligate 14 per cent. of Christophers and Stephens. These were:

	Per cent.
One suspected secondary syphilis, with ulcers.....	18
One hepatic gumma with peritonitis.....	14
One leukæmia.....	16.1
One gripal pneumonia.....	15
One typhoid fever, third week.....	23

With the exception of the latter, they all had a marked leucocytosis, none had marked fever when film was taken, and the only question unanswered and unanswerable was, whether they had an associated malarial infection.

CONCLUSIONS.

1. It is not so much the absolute increased per cent. of large lymphocytes which is diagnostic of malarial infection as the relative increase over the small lymphocytes.
2. In cases of malarial infection without much fever and without quinin history, the polynuclears are markedly diminished and the large lymphocytes very much increased in proportion.
3. In the absence of an adenopathy, possibly also of influenza and measles, the above finding is positive evidence of present or very recent malarial infection.
4. During the rise of a malarial fever, or as a result of quinin therapy, the polynuclear leucocytes may reach 80 per cent., but in that event the large lymphocytes exceed in number the small ones.
5. In malarial hemoglobinuria any of the various blood findings characteristic of malarial fever may be present in any stage, and there is no evidence now at hand to explain this.
6. Malarial and typhoid fevers can be more positively differentiated from fevers of sepsis, pneumonia, rheumatism, malignant tumors, etc., by the differential leucocyte count than by the hemocytometer, and it can be done on dried films, away from the bedside.
7. Malarial infection makes a strong impress on the leucocytic relation, no matter with what other disease it is associated.
8. It is not safe to rule out typhoid fever when the malarial variation is found, but, as it calls for anti-malarial medication, the therapeutic test may decide before a Widal reaction would appear.
9. In a gradually developing fever, the absence of marked increase in large lymphocytes or polynuclears during the first week justifies a preliminary diagnosis of typhoid fever.

DISCUSSION.

DR. RICHARD CABOT, Boston.—What criterion is used in the classification of blood cells for a large and what for a small mononuclear? No two men agree, and no two men are likely to observe the same rules in regard to this point, and this uncertainty makes the results of Dr. Krauss and the English school less available. At the same time I am influenced toward the conviction that what he has given us will be of value in confirming the diagnosis of malaria. I am not convinced that it will take the place of the direct observation of malarial parasite, because the same amount of work required to demonstrate the percentage of large mononuclear cells would usually suffice to demonstrate the parasite itself. What has most in-

terested me in the paper is its tendency to prove the central importance of the examination of the film specimen; this implies that the count of the red cells is less important, and in many cases is practically of little value. I seldom count the red cells. What we should count is the white corpuscles, and especially note their differential relation to each other. If we know what actually can be obtained from the film specimen (dried on glass and stained) we know all that will give information of value as regards the diagnosis in four fifths of the cases; nothing more in many cases could be learned from an actual count of the cells.

DR. ROBERT N. WILLSON, Philadelphia.—Unless I have misunderstood his statement I think that there is an error in the assertion of Dr. Krauss that a high percentage of polymorphonuclear cells in the blood excludes malaria and typhoid fever from the diagnosis. I have personally had the privilege of studying a large number of cases of both typhoid fever and malaria with reference to the blood picture, and in common with many other observers have repeatedly found a high percentage of these cells in the presence of complicating conditions. In such cases, unless this fact is remembered, the count will hinder rather than help toward a proper diagnosis. One particular case which I have reported was that of a former member of this Association, a physician who died of perforation of the bowel in typhoid fever. In this instance the polymorphonuclear percentage remained almost constantly about 9 per cent., and was highest at the time when the total leucocyte count was at its lowest point (6,400). In one or two other cases of typhoid perforation, proved by autopsy, there was the same occurrence. One case seen recently, however, was of typhoid complicated by cystitis, in which there was a polymorphonuclear count of only 54 per cent., in spite of the presence of quantities of pus in the bladder and urine. With regard to the statement made by both Drs. Cabot and Krauss that in certain cases the malarial organisms failed of discovery because quinin had been given to the patient, it is interesting to note that in the Philadelphia Hospital I have studied a number of cases in which the parasite could not be discovered after a very careful search until after quinin had been given. This experience was shared by a number of other observers in the same hospital, and has extended over several years time.

DR. C. R. GRANDY, Norfolk, Va.—It often happens in my section of the country that the people will take quinin before coming to the physician for a diagnosis, and, therefore, in many of these cases a blood examination is made more difficult. I wish Dr. Krauss would state distinctly if he has found an increase of large lymphocytes in such cases.

DR. W. E. ROBERTSON, Philadelphia.—In the consideration of the differential leucocyte count, the influence of age is an important factor. As is well known, the younger the child the more pronounced the leucocytosis. Then too, up to the fifth year of life there is a marked lymphocytosis, the polynuclears being proportionately deficient.

DR. WILLIAM KRAUSS.—The difference between a large and a small mononuclear cell is an arbitrary one. The best way is to class all the cells the size of a polynuclear cell as small unless the protoplasmic margin is relatively large and contains scattered neutrophile granules, which stamps the cell as a "large" one. In refutation of Dr. Cabot's contention, English observers have found the leucocyte count a great saving of time in differentiating latent malaria and when plasmodia are absent in peripheral blood. If you make a slide spread a differential leucocyte count can be made in 20 minutes at the far edge of the film, whereas it might take two hours' patient search to find a parasite, and, even if found, it furnishes no information as to the possible presence of a complication. The polynuclears may be increased in malaria, but the relation of the lymphocytes is not interfered with, and when found at the height of a fever, the polynuclear increase points rather definitely to presence of malaria and absence of typhoid. The best evidence of the real value of this diagnostic measure is that in the tables, in which the diagnosis had to be bolstered up by all the collateral evidence available in order to prove my point—it was frequently the sole sign post to a correct diagnosis. The

answer to Dr. Willson's question appears in the tables. In answer to Dr. Grandy I would say that here it was that I found my best field; in persons cinchonized, the question: Should they not be further cinchonized? is best answered by the malarial lymphocyte variation, as it is more sensitive than the presence of plasmodia or pigmented leucocytes. As to Dr. Robertson's question, in children over one year old the variation is usually reliable.

PHYSIOLOGIC OPTICS.

NEW EXPERIMENTS FOR DEMONSTRATION AND NEW APPARATUS.*

WINFIELD S. HALL, M.D.

Professor of Physiology, Northwestern University Medical School, CHICAGO.

When it was proposed to establish a laboratory course in the physiology of vision, the head of the department of ophthalmology was requested to state what he wished students to know in this field when they presented themselves in his department for clinical work on the eye. The reply was in effect this:

Before the student can enter on the clinical study of the eye he should be acquainted with: the anatomy of the conjunctiva; the lachrymal apparatus, including the drainage and the extrinsic muscles; the circulation, extrinsic and intrinsic; the nerve supply of the muscles, the mechanism of muscle action, the gross and minute anatomy of the coats of the eyeball; the refractive media, the retinal circulation, and the ciliary apparatus. He should thoroughly understand the functions of all the parts studied. The student can not hope to succeed in clinical ophthalmology unless he has a clear understanding of the refractive media of the eye from an optical standpoint: the indices of refraction; the law of lenses and their influence on the path of a ray of light; in short, the dioptric system of the eye. He must understand the mechanism of accommodation and be able to determine its range; he must be able to outline the field of indirect vision for form and color, and to map the distribution of the retinal vessels through ophthalmoscopic examination of models and of the eyes of animals and of normal man.

In the development of a course to cover the required ground, several new appliances and methods have been devised to facilitate the laboratory instruction, and I take this opportunity to make a brief description of the more important of them together with diagrams showing their structure.

In these optical appliances three requirements are met: accuracy, simplicity and economy.

TO DETERMINE THE INDICES OF REFRACTION OF WATER AND OF GLASS.

A very convenient and sufficiently exact apparatus for making the required determination may be easily made as follows:

Take a carpenter's tri-square, constructed wholly of iron, from the angle x (Fig. 1), where the graduated limb joins the body, measure off centimeters on the inner surface of the body and cut them in with a file.

Locate on the inner edge of the graduated limb any point as y , 6 to 9 centimeters from the point. With files remove about one-half centimeter of the edge as indicated in figure, cutting deeply at z , so as to leave a slender point at y , as indicated.

Drill a hole in the inner surface of the body at o ; fit and drive a heavy brass or iron wire into this; sharpen the upper end of the wire. The length of the wire above the body must be two or three centimeters, greater

than the distance $x y$. Bend the point over so that distance $o p$ shall equal $x y$.

Place the instrument in the water pan; fill the pan, so adjusting it that both points p and y will just fail to touch the water, for the surface of the water at y must be absolutely plane. If the points touch it the surface will not be plane.

Bring a small rule, r , into position and clamp it to the limb of the instrument by means of heavy serre-fine forceps. So adjust the rule that as one sights along its upper edge the points a , y and 3 seem to lie in the same straight line. Lift the apparatus out of the water and lay it on the table, taking care not to disturb the adjustment.

With dividers measure the distance from the point y to line 3 . This is the radius. Determine the point where the circumference would cut the upper surface of the rule, say point b .

From this point determine the perpendicular distance to the edge of the limb at c .

Fig. 1.

The line $c y x$ is a normal to the surface of the water at the point y . The angle i is the angle of incidence; the angle r is the angle of refraction. Imagine a circle whose center is at y and circumference passes through b and 3 . The line $b c$ is the sine of the angle of incidence. The line $x 3$ is the sine of the angle of refraction.

DETERMINE THE RATIO OF SINE I TO SINE R.

In the same manner determine the ratio of these angles when the rule is also adjusted as to bring $a y 2$ or $a y 4$ apparently in one straight line.

If the instrument has been carefully constructed, and if the determination has been made with sufficient care, the ratio, $\text{sine } i : \text{sine } r$, will be found to be practically equal to the ratio, $\text{sine } i : \text{sine } r$; furthermore, the ratio for any substance such as water, is found to be constant. This constant ratio is called the index of refraction, and is conventionally represented by μ .

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

For water. $\mu = \frac{\text{sine } i}{\text{sine } r} = \frac{2.06}{2.00} = \frac{4}{3} = \frac{5.33}{4.00} = 1.33$

To determine the index of refraction of glass, proceed as in the case of water. Set the instrument on the table; the block of glass may be placed on the body of the instrument, the polished surfaces being placed above and below. If the distances between the polished surfaces is not equal to $x y$, a point y' may be located on the upper surface near the edge of the glass block by making a dot with ink where the line $x y$ cuts the upper surface of the block. This line is the normal.

Proceeding with the glass according to the same method as that followed in the case of water, one finds first, that,

the ratio $\frac{\text{sine } i}{\text{sine } r}$ equals the ratio $\frac{\text{sine } i'}{\text{sine } r'}$

further, that the ratio is constant and for crown glass equals 1.5.

TO DETERMINE THE FOCAL DISTANCE OF A LENS.

A simple method of determining a focal distance of a lens depends on the relation of the conjugate focal distances to the general focal distance. This relation may be expressed thus: The sum of the reciprocals of the conjugate foci is equal to the reciprocal of the focal distance, $1/o + 1/i = 1/F$.

When a lens throws on a screen the image of an object it is evident that the distance of the object o represents one and the distance of the image i represents the other of these conjugate focal distances; so one may say: The reciprocal of the distance of the object from the lens, $1/o$, plus the reciprocal of the distance of

Fig. 2.—Apparatus for determining the principal focal distance through the observation of the conjugate focal distances. o , Object; i , image. The conjugate focal distances of o and i may be represented by f and f' respectively. c , Lens carrier which slides along the guide on the bottom of the box.

the image, $1/i$, equals the reciprocal of the general focal distance, $1/F$; thus $1/o + 1/i = 1/F$. This formula enables one to compute the focal distance after first determining by experiment the values of o and i .

The apparatus necessary is very easily constructed. For the determination of the focal distance it is usual to have both object and lens movable. For our purpose this may be dispensed with, as it lends little to the reliability of the result and detracts much from the simplicity of the apparatus. Construct from half-inch pine boards a box 1 meter long and about 8 cm. high and wide (inside measurements). The box should be open at one side, while the inner surface of one end may be painted white and serve as a screen. The other end should have in its center a large hole. Over this hole on the inner surface of the end, fix a sheet of lead or copper in which some figure has been cut, o . Construct a lens carrier, c , whose pointer, p , will indicate on the scale, s , the position of the center of the lens. The use of the instrument will be somewhat facilitated if the distance between the surface of the screen and the surface of the lead or copper be purposely made 100 cm. One needs a lamp or candle to place behind the metallic screen at o (Fig 2).

Place a light behind the metallic screen; it shines through the figure cut through the screen. This illuminated figure is the object. Place a lens in the carrier and so adjust it that the plane which it represents

is perpendicular to the axis of the instrument and its center is in the same perpendicular plane with the index, p , of the carrier. Slide carrier along the base until the object is sharply focused on the screen.

Read from the scale, or measure with a rule, the distance of the lens from the image i . If the instrument is made just 100 cm. between the screen and the object, then the difference between 100 and the reading will be the distance of the lens from the object. The image is inverted.

We have now simply to use the general formula given above, substituting the values observed in the experiment.

(1) $\frac{1}{o} + \frac{1}{i} = \frac{1}{F}$ (2) $\dots \dots \dots F = \frac{o \cdot i}{o + i}$
 (3) $\dots \dots \dots$ But $o \cdot i = 100$ (4) $\dots \dots \dots F = \frac{oi}{100}$

From this form of the statement it is evident that the lens will throw a distinct image in either one of two positions. This may be demonstrated experimentally.

The value of the formula, $1/o + 1/i = 1/F$, is so great and its application in physiologic optics so frequent, that the student should thoroughly familiarize himself with the properties of lenses as revealed in the formula.

The following are some of the problems which may be solved with this apparatus:

1. When the object is twice the focal distance, what is the distance of the image?
2. When the distance of the object is $2F$, how does the distance of the image compare with $2F$?
3. When the object is at a very great distance (∞), at what distance will the image be formed?
4. What is the maximum focal distance that may be determined or verified with above-described apparatus? Discuss in detail.

TO LOCATE EXPERIMENTALLY IN THE MAMMALIAN EYE THE CARDINAL POINTS OF THE SIMPLE DIOPTRIC SYSTEM.

In the study of the glass lens, one takes into consideration the index of refraction and the radius of curvature of the surface of the lens. When one remembers that the eye possesses media of two different refractive indices bounded by three curved surfaces: Anterior corneal surface (radius, 7.829 mm.), anterior and posterior lens surfaces (radii, 10 and 6 cm., respectively), the complexity of the problem becomes apparent.

It has been shown mathematically that a complex optical system consisting of several surfaces and media, centered on a common optical axis, may be treated as if it consisted of two surfaces only.

Applying this principle to the eye, it has been found that the several media and surfaces may be reduced to two parallel spherical surfaces, whose radii are 5.215 mm. These surfaces cut the optical axis just posterior to the cornea, and are only one-third millimeter apart.

To further simplify the optics of the eye, it has been customary to reduce it to a simple dioptric system by assuming one refracting surface near the posterior surface of the cornea midway between the two computed surfaces.

A simple dioptric system is one in which the ray passes from one medium into a secondary medium of different refractive index, the surface of separation of the two media being a spherical surface.

The cardinal points of the simple dioptric system are:

1. The nodal point, which is the center of the curvature of the spherical surface (N, Fig. 3).
2. The principal axis—the line $o R N$ in the figure.

from either side. Let this be the point of fixation or the point where the line of vision falls on the surface of the board.

We propose now to draw on the blackboard a series of circles whose distances from one another shall represent an angular distance of 10 degrees. Reference to Figure 4 makes it evident that if the line AB represents the plane surface of the blackboard, and if the eye be placed at o, the equal increments of 10 degrees on the quadrant become a series of increasing increments on the surface of the board. The numbers at the right (Fig. 4) show just how many centimeters the radius of each successive circle should be, provided the distance of the eye from the board be taken at 20 centimeters.

After drawing the circles draw meridians which divide each quadrant into three or nine subdivisions. The complete blackboard chart will have the appearance and proportions shown in Figure 5. The circles and me-

Figure 6.

ridians should be traced permanently in white enamel on the surface of the blackboard. Any marks on the board in chalk may then be erased without disturbing the perimeter circles.

The most satisfactory test objects are pieces of fresh crayon not over 1 cm. in length. They may be held in wire loops of convenient length.

Each blackboard must be provided with a rest or contrivance to insure that the subject's eye is 20 cm. from the surface of the board. Whether this takes the form of a rod of wood extending out from the board and so adjusted that when the subject rests the most prominent infra-orbital region on its end the cornea will be 20 cm. from the center of the chart, or whether it takes some other form that insures the same results, is of little consequence.

In all observations which are subsequently indicated, it is taken for granted that the visual axis is perpendicular to the surface of the chart, that the center of the chart is the point of fixation, and that the accommodation is kept uniform, i. e., the eye is either uniformly focused on the center of the blackboard perimeter or uniformly relaxed; further, that the eye not under observation be closed or closely shaded.

Examine the upper median quadrant by sweeping a white test object around arc 60, keeping the test object as near the surface of the chart as possible. If the sub-

ject does not see the object, try arc 50 degrees. Having located the circle which seems to be near the boundary, locate on each meridian a point which indicates the limit of indirect vision in that direction. Join with a continuous line the points located, thus inclosing an area of indirect vision.

Test the lower median quadrant in the same way. Is the total area covered by indirect vision in this quadrant greater or less in extent than that in the upper quadrant?

Test the upper lateral quadrant and then the lower lateral quadrant. Are these two quadrants practically equal?

Is there any ready explanation why the outer two quadrants should contain such an excess of area over the inner two quadrants?

TO RECORD THE PERIMETER OUTLINE.

For this purpose one should have printed charts in which the circles are equidistant. They represent concentric arcs of a quadrant with 10° of the circle between each two, while the circle on the blackboard represents a radical projection of these areas on a plane tangent to the sphere at the point of fixation. In transcribing the perimeter on the record chart, one has only to locate twelve or more points located on the observation chart and join these points into a continuous perimeter.

In the above experiment we have determined the perimeter for light sensation only, the subject being conscious simply of a light or white spot on a dark ground, but not certain whether the spot is circular or square.

After determining and charting various color perimeters, as red, green and blue, we may inquire:

Have the color perimeters the same general form as the white perimeter? If not, describe any noticeable variations. Which of the color perimeters encloses the greatest area?

Take corresponding perimeter for the other eye. To use the same blackboard it will be necessary to turn it the other edge up. In what general respect do the perimeters differ from those of the left?

With the help of light perimeters of the right and left eyes determine the field of binocular vision. This is the field of binocular indirect vision.

Live Foreign Bodies in the Larynx.—Liaras of Alger has had occasion to observe 3 cases of leeches clinging to the wall of the larynx. He relates the cases in detail and reviews the literature on the subject of live foreign bodies in the larynx. The leech spontaneously traveled out in one case after gargling with tobacco water, and in the others he was able to seize and remove it with forceps. The presence of the leech causes coughing, bloody expectoration, altered voice and respiration and pain. The attacks of coughing may become convulsive and the attacks of suffocation more and more pronounced. He advises intubation as the rational mode of treating such cases. The physician can then wait in confidence that the leech will come out spontaneously to escape the pressure of the tube, this event hastened by sprays or inhalation of tobacco, iodiform, salt water, etc. If the animal is not dislodged by the end of five or six days, and the patient shows signs of anemia from the loss of blood or inflammatory reaction in the larynx, thyrotomy may be indicated as the last resort. In his communication to the *Revue Hebdomadaire de Laryngologie*, xxv, 11, Liaras remarks that the horse leech, hemipis, abounds in Algiers and Sicily, and that it is frequently found in the mouth, nasal fossae and pharynx of both man and animals. Chavasse observed two cases of its presence in the larynx and collected 17 others in his experience as an army surgeon in Algiers. Contrary to Liaras, he recommends immediate incision without wasting time on medical measures.

POISONING BY WOOD ALCOHOL.

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS.

FRANK BULLER, M.D.

MONTREAL.

AND

CASEY A. WOOD, M.D.

CHICAGO.

(Continued from page 1123.)

These additional cases of death and blindness from the ingestion of methyl alcohol, collected by Dr. Wood, demonstrate that the baleful influence of the poison is still on us in undiminished force. The form of the drink has, as might be expected, assumed a variety in keeping with its extended employment. Thus we find that in some hitherto unpublished instances the victims drank, in addition to the commoner forms of wood spirits, methylated "essence of peppermint," numerous patent medicines whose chief menstruum was "deodorized" methyl alcohol, "eau de cologne," "Florida water," "bay rum," "witch hazel," lemon "extract," "punch," "high-balls," "hot drops," and red ink. In other respects the histories parallel those collected by Dr. Buller. We propose to use the histories thus made available for a few additional remarks on the general subject of methyl alcohol intoxication.

TOTAL NUMBER OF METHYL ALCOHOL VICTIMS.

From Dr. Buller's tables of published histories we have a well-authenticated list of 54 cases of methyl alcohol amblyopia, to say nothing of the deaths that are incidentally mentioned, of which no particular record was made. As the proportion of deaths to survivals with blindness is a fairly constant one, and reading the reports intended to describe the blindness only, we may put down 40 as the minimum number of published deaths.

Reference has already been made to the experience of Dr. Moulton with deaths from wood alcohol on Indian reservations. Other ophthalmologists tell the same story about these "strictly preserved" localities. One observer, who has reported several cases of methyl alcohol amaurosis, says regarding them: "Almost the first question I ask an amblyopic patient from a reservation is, What have you been drinking? The answer almost invariably is, Columbian spirits, Jamaica ginger, or something of that sort. It is no trouble to find the deleterious effects of methyl alcohol among these people. As for Indians, they will drink anything they think has alcohol in it, even red ink."

Nor is the consumption of methylated compounds as a substitute for ethylic alcohol confined to Indian reservations. Wherever men in any walk in life are deprived of a chance of indulging in the usual forms of ethylated beverages, they are very likely to drink some tempting form of methylated mixture. Assistant Surgeon X. writes me: "The temptation of the men of this post is particularly great, as we are over ten miles from the nearest saloon. At the time the deaths occurred the men, having consumed all their grain alcohol, had to have something to 'sober up' on, so they got hold of Columbian spirits and drank it, hardly knowing or caring what they were taking." Perhaps if the United States Army had been supplied with a properly regulated canteen, where light wines and good beer were sold, these soldiers would have "sobered up" on non-poisonous drinks and not on wood alcohol!

The list of previously unrecorded cases of blindness, so far as Dr. Wood has been able to collect them, includes 89 well-authenticated cases from the drinking of methylated liquids. Absorption of the fumes is responsible for ten instances of amblyopia, while the deaths (without history of previous blindness) number 82. Altogether, then, we have 153 instances of blindness and at least 122 cases of death from methyl alcohol poisoning during the past few years—275 in all.

Our reasons for believing that these figures by no means complete the roll of serious intoxication from this poison we have already pointed out. How many cases of death and blindness (or both combined) have resulted from methylated preparations since the comparatively recent introduction of Columbian spirits is a matter of conjecture; probably 400 instances.

Since this article went to press, the newspapers report the deaths of twenty-five persons in a certain district in New York City from drinking whisky which contained wood alcohol and which was purchased in a saloon. The newspaper account continues: "The police to-night arrested Rudolph Fritsche, the proprietor, and closed the place. A chemical analysis of the stomach of one of the victims who died of acute gastritis showed the presence of wood alcohol, which also was found in a bottle of whisky purchased at the saloon."

COMMERCIAL FORMS OF METHYL ALCOHOL.

Although that nauseous and vile-smelling fluid is still purchasable as wood alcohol, wood spirit, pyroligneous spirit, wood naphtha and methylated spirit, its place in commerce has been almost altogether taken by the deodorized variety, of which "Columbian spirits" is easily the best known and most widely used. There are many other forms of this fluid on the market, such as "colonial spirits," "union spirits," "eagle spirits," etc., in the United States. "Green wood spirits" (mostly used for fuel) and "standard wood spirits" (a more thoroughly deodorized article) are largely sold in Canada and intended for the same purposes as the American Columbian spirits. The deodorized fluids all have the same volatile, agreeable, vinous odor, and the pungent, biting taste as pure ethyl alcohol, and it is often difficult for the average individual to distinguish them from grain alcohol. It is, therefore, quite easy to understand how the thirsty one, unaware of the danger to life and eyesight, might indulge in a drink of the methylated product. Manufacturers of all sorts of alcoholic potions have not been slow to take advantage of this fact; indeed, there is hardly a "liniment," an "essence," an "extract" or a "bitters"—hardly any nostrum or concoction, medical or domestic, in whose preparation alcohol is employed—that has not been, or is not now, adulterated with this poison. We have within the past few months had several proprietary remedies, suspected to have produced blindness, carefully analyzed; they all contained wood alcohol.

As stated on the highly ornate labels of the bottles intended for retail consumption, one form of methylated "spirits" is highly recommended for "bathing, burning and cleaning." Among the uses specified are "bathing and sponging the sick; making liniments; rubbing for rheumatism, bedsores, etc.; veterinary uses where alcohol is required; Turkish bath cabinets; burning under chafing dishes and in spirit lamps; removing oil and grease from brass and woodwork." In all these instances ample opportunity is afforded for absorption of the poison.

A few instances—there are hundreds of others—of the use of “deodorized” wood spirit as an adulterant of or substitute for grain alcohol may be given:

In the 1903 report of Dr. R. O. Brooks, state chemist of New Jersey, it is shown that from four to eight samples of paregoric (page 7) and from four to eleven samples of ginger (page 24) contained wood alcohol—a fact that would seem to indicate that drug adulteration with wood alcohol is still practiced to a considerable extent.

Scoville² reported that he found two out of six commercial liniments containing wood spirit; also the same poison in several brands of witch hazel.

Dr. Allen Greenwood of Boston found quite recently that two of his patients had been furnished tinctures whose menstruum was “Columbian spirits.” The druggist, on being called to account, stated that many tinctures are now being made with “spirits” of this kind!

The president of the New York Board of Health ordered in 1902 an examination of the ingredients in the Jamaica ginger and spirits of ammonia sold by druggists throughout the city. The official chemist found that 40 out of 215 drug stores were substituting wood alcohol for grain spirits. Warrants were issued for these offenders.

Dr. Warren, the pure food commissioner of the state of Pennsylvania, reports that to Feb. 5, 1904, he had collected and examined 1,000 samples of cheap whisky from all parts of the state. Over 95 per cent. of the samples contained varying quantities (some as high as 75 per cent.) of wood alcohol. He believes that 5,000 cases will be found in the state and is desirous to prosecute them.

In 1902 E. L. Patch of Stoneham, Mass., reported to the American Pharmaceutical Association that he found wood spirit in 40 out of 225 samples of spirit of camphor.

Without further multiplying examples of this brazen attempt at wholesale poisoning we finally present a recent report of the dairy and food department of the state of Minnesota, who condemned and pronounced illegal, because of their containing wood alcohol, samples of lemon “extract” from all parts of the state. These poisonous products were put up and sold by wholesale manufacturers of (?) respectable standing in Chicago, St. Paul, Minneapolis, Duluth and Milwaukee. In addition to this list they also found four cases in which methyl alcohol was used in the manufacture of Jamaica ginger, two cases of vanilla extract, one of pineapple and two of strawberry.

TOXICITY OF METHYL ALCOHOL.

While a study of the cases reported in this article must undoubtedly establish the fact that the majority of those who imbibe a moderate quantity—say two or three ounces—of wood alcohol or its equivalent of methylated liquids, escape permanent damage, i. e., most persons are, to some extent, immune to serious poisoning by small quantities of methyl alcohol, this is by no means true of larger quantities; nor does it, by any means, prove the immunity of every person from poisoning by very small quantities. Until the experiment has been made nobody can be assured of safety to eyesight from the ingestion of much smaller amounts of the poison. There are many well-authenticated instances in which the drinking of a couple of teaspoonfuls of wood spirits was followed by blindness.

The intoxication of persons from inhalation of the fumes of methylated alcohol is another example of poisoning by small quantities of the intoxicant, because the actual bulk of liquid so absorbed by the lungs and skin must be comparatively small.

The cumulative quality of methylism has been referred to by several writers. This matter will be further discussed in speaking of the pathology of the subject. Meantime our investigations undoubtedly demonstrate that in many instances no marked poisonous symptoms were noticed until twenty-four hours or longer, after the last of a number of doses (usually small “drinks”) had been taken. Unlike most poisonous agents that are

responsible for acute symptoms, these may not much disturb the patient for a relatively long interval after the ingestion of the poison. Indeed, it may be set down as a rule that, except in persons exhibiting an idiosyncrasy against wood alcohol, or unless a large dose of the poison is drunk within a few hours, not only may the severe abdominal symptoms, the cardiac and nervous collapse and the blindness be postponed, but even the fatal termination has, in some instances, been delayed for several days.

This information, derived from the histories just published demonstrate the fact that there is danger, albeit an unknown degree of danger, to life and eyesight attending the ingestion of *any* amount of wood alcohol. Moreover, while the acute, unmistakable symptoms of the ordinary forms of intoxication enable us to recognize them at once there can be no doubt but that much smaller quantities, taken into the system, as methylated quack remedies, adulterated food-stuffs (Jamaica ginger, “lemon extract,” essences), or the secret dram drinking of bay rum, cologne water, etc., may, in persons not immune, injure the digestion and permanently damage the vision.

There are very few poisons that more distinctly exhibit the selective character of the intoxication than wood alcohol. It has again and again been demonstrated that a minority of those who imbibe methylated fluids suffer no permanent damage from them. In other words, many people are practically immune to moderate doses of methyl alcohol. In most cases where small doses are taken serious intoxication means that there is in the poisoned individual an idiosyncrasy against this agent. It is owing to this fact that in times past many perfectly sincere observers asserted, and interested parties loudly proclaimed, the innocence of methyl alcohol. During the trial of the Baltimore suits against Gilbert & Co. a dramatic incident occurred, based on this belief. A chemist drank a quantity of methylated spirits in open court. Of course, we now know that, although this was a dangerous act, the chances were greatly in favor of the witness, especially if at the time his stomach were full of food, or if he took an emetic shortly after the draught of wood alcohol.

Prof. W. A. Puckner, in the *Western Druggist* for December, 1897, wrote:

“The only constituent of wood alcohol likely to be present in sufficient amount to be poisonous is acetone and, since methyl alcohol is comparatively free from this, the preparations now in the market are presumably also free from the poisonous properties ascribed to wood alcohol.”

Supporting this proposition, he took internally single, 30 c.c. doses of a commercial wood alcohol containing about 0.5 per cent. of acetone, and experienced no unpleasant results therefrom.

“Further doses of 15 c.c. taken at intervals of thirty minutes until 90 c.c. had been drunk, left the body temperature normal, at first somewhat accelerating, later slightly depressing the pulse—i. e., producing the characteristic effects of ethyl alcohol.”

On the other hand, Dr. Reid Hunt⁶ of Johns Hopkins showed that, in experimenting on dogs, the latter were all killed by doses of Columbian spirits and other fluids containing methyl alcohol, while animals survived the same and larger quantities of ethyl alcohol and pure acetone.

In considering the actual poisonous agent in the methyl alcohol of commerce, one must not forget the secondary organic compounds formed in the intestine*

and in the blood. It is quite likely that these play an important rôle in the damage inflicted on the system. Prof. C. S. N. Hallberg believes that the untoward effects of methyl alcohol are mainly due to formation of the poisonous formaldehyd.

In respect of its varying toxicity, however, this poison does not differ from many other lethal compounds, Paris green, for instance. The effect on the individual, in the case of this arsenical drug, will be largely governed by the amount ingested, the condition of the patient's alimentary tract, whether his stomach is full or empty, whether already irritated by other agents, whether vomiting sets in early or late, and whether absorption of the poison is complete or not. If the conditions are adverse a fatal termination might ensue from a small dose and in a short time; if favorable, the drinker might escape after the ingestion of a relatively large quantity of the poison.

The manufacturers of wood alcohol no longer contend that the internal use of their product is innocuous, but they do deny that any harm arises from its external application, or from its employment in the arts or as a fuel. This contention will be considered later.

The varying effects of methylated fluid on individuals is largely due to idiosyncrasy, exactly as in the case of ethyl alcohol and other poisons. For example, a peripheral neuritis, sometimes associated with blindness (toxic amblyopia), is one of the well-known results of ethyl alcoholism, but it does not so affect every drunkard. That about 50 per cent. of those exposed to the poisonous influences of wood spirit escape permanent damage is now a recognized fact, and this immunity is mostly due to a peculiar resistance inherent in the nervous and digestive apparatus.

Another fact, fully recognized by Reid Hunt in his laboratory studies, is clearly shown in the clinical history of those cases in which the poisoning was brought about by the ingestion of various mixtures containing different proportions of this drug, together with other things. In every instance the toxic action was that of methyl alcohol, as clearly and sharply defined as if nothing but the pure spirit had been consumed. It can, therefore, no longer be maintained that the poisonous effects of Jamaica ginger, lemon extract, bay rum, etc., are due to anything else than the methyl alcohol which some of these preparations are well known to contain.

PATHOLOGY OF METHYL ALCOHOL AMBLYOPIA.

The irregular onset and variety of the symptoms (especially the eye-signs) set up by methyl alcohol intoxication argues a variety in the lesions produced by it. There can be no doubt but that the ophthalmoscopic changes described in the foregoing case-histories bear out such an idea. In one series, for example, although the blindness was complete, no fundus alterations were discovered except, possibly, slight blurring of the disc outlines, or a faint congestion of the papillary vessels. These are, in all probability, cases of deep-seated retrobulbar optic neuritis, with no changes present in the nerve-head. In the course of time most of these cases suffer a postneuritic atrophy with abundant evidence of the lesion in the pallid papilla.

On the other hand, a well-marked anemia of the nerve is perceptible in many cases of intoxication a very short time after the ingestion of the poison. In this regard wood alcohol acts like quinin. It is a question whether this condition should be called "atrophy," first, because fairly good vision has been recovered in not a few of these cases, and, second, because sufficient

time to bring about true atrophic changes had not elapsed since the poisoning. Later on, without possibly any marked alteration in the ophthalmic picture, the sight grows dimmer with the occurrence of veritable optic atrophy.

A third picture is that of a mild papillitis. The outlines of the disc are obscured, the physiologic excavation is filled by an edematous swelling, and the vessels, especially the veins, are distinctly turgescient. Vision will, in these, as in other cases, depend on the extent to which the central bundles of optic fibers are affected. A well-developed neuritic process situated far behind the globe and not discoverable by the ophthalmoscope may result in an early, sudden, complete and permanent blindness, while recovery, sometimes complete, may follow a superficial papillitis or an early blanching of the nerve-head.

These apparent anomalies must not, however, blind us to the fact, certified by all careful observers, that in the great majority of instances of intoxication an early retrobulbar neuritis, whose signs and symptoms shortly improve (with more or less clearing of sight), is the precursor of a genuine postneuritic or secondary atrophy, from which most or all of the patient's useful vision is wiped out.

The lesions in the majority of instances of methyl alcohol amblyopia and amaurosis are local ones—that is to say, they are not secondary to central circulatory or nervous changes. Unlike other forms of toxic amblyopia, e. g., quinin, tobacco and ethyl alcohol, the poisoning is frequently accompanied by scleral and ciliary congestion, tenderness of the eyeball, painful excursions of the globe, pain in the eyes and forehead, and other evidences of an acute inflammation of the orbital or intraocular contents. The exact character of the morbid alterations that give rise to these symptoms and to the blindness probably varies somewhat, according to the severity of the intoxication.

Whatever the primary process may be—whether it affects first the retina and then the optic nerve, or *vice versa*—the final outcome is a rapid atrophy of the fibers of the nerve and retina. Friedenwald, Holden and Birch-Hirschfeld take the former view. They believe that there is a degeneration of the ganglion cells of the retina in general, and of all the percipient elements of the macular region in particular. This metamorphosis of the retinal nervous elements, they agree, is the result of a sudden interference with their nutrition, the result of vasoconstrictor effects of the poison on the retinal vessels. On the other hand, Gifford holds that the orbital pain and ophthalmoscopic evidences of positive neuritis met with in some cases, together with complete blindness, followed by a temporary improvement, indicate a primary affection of the optic nerve. Hotz, who has seen optic neuritis in this affection, considers that if the primary effect were to destroy the central nerve elements of the retina, a partial recovery, followed by a second lapse of visual acuity, would not be likely to occur, but that this would be the natural sequence of a nerve lesion of an inflammatory type, the effusion at first clearing away, with relief to the compression of the nerve fibers; then follows renewed pressure on these with the advent of atrophic changes. Gifford noticed in one case total absence of retinal changes, as seen by the ophthalmoscope, a few hours after the blindness had come on, and holds this to be proof that the primary lesion is not in the retina. On the other hand, De Schweinitz states that in animals experimented on with

methyl alcohol its toxic action is first on the ganglion cells of the retina, and that the optic nerve changes are secondary.

Certainly the early and often complete loss of vision can scarcely be regarded as other than positive proof of profound disturbance in the optic nerve, and the subsequent rapid alterations in the vision, without visible ophthalmoscopic changes in the fundus, seem to point in the same direction. There were changes in the optic nerves in Buller's third case which indicated a retrobulbar neuritis at an early period, but nothing that would justify the assumption of pathologic alterations in the region of the macula lutea.

The whole controversy reminds one of the difficulties that surround the question of the exact nature of the lesions in the amblyopia of chronic (ethyl) alcoholism and in the blindness from tobacco, especially as to whether the optic nerve degeneration, so well described and pictured by Uhthoff and others, is primary or secondary. On the whole, it seems highly probable that the ocular changes in methyl alcohol poisoning are mainly a peripheral neuritis affecting in some cases the nerve trunk only, sometimes the retinal fibers only, and sometimes both these tissues. Occasionally recovery follows, more or less rapidly, in all forms of the disease, but as a rule the changes proceed to entire destruction of the light percipient elements of the parts that had been primarily the site of the neuritis.

The clinical histories in both the recorded and unrecorded cases fully bear out this view of the pathology of methyl alcohol amaurosis. The ophthalmoscopic changes and other symptoms generally correspond to the amount and kind of the blindness, and enable one to foretell their character so far as vision is concerned, but this is not always the case. Recovery sometimes occurs even when evident optic neuritis is present, and, on the other hand, a patient now and then becomes blind when the mirror does not reveal any neuritic changes.

This, however, is less frequently the case so far as concerns the association of white atrophy and permanent blindness. Sooner or later we find the one in cases that exhibit the other.

SYMPTOMS OF METHYL ALCOHOL POISONING.

From a study of these cases we may conclude that there are three degrees of wood alcohol poisoning.

1. An ordinary mild intoxication, with perhaps some dizziness, nausea and mild gastrointestinal disturbance, terminating in perfect recovery within a few days, but occasionally followed by more or less serious damage to vision.

2. A toxic effect more pronounced in every way, dizziness, nausea, vomiting and gastroenteritis being conspicuous symptoms. Dimness of vision, often increasing to total blindness, is characteristic of this degree of poisoning.

3. An overwhelming prostration which terminates in coma and death.

The clinical picture of wood alcohol poisoning usually depends on the quantity taken, modified, of course, by the resisting power of the individual. Generally there will be observed the ordinary effects of alcoholic intoxication (vertigo, nausea, gastric discomfort, and general malaise), with disturbance of vision.

The more pronounced cases exhibit headache, muscular weakness, vomiting, dimness of vision, often progressing to complete blindness, with considerable gastrointestinal disturbance, and evidence of depression of the heart's action.

A step further and, with the exaggeration of all these symptoms, the patient becomes suddenly blind, or nearly so, with widely dilated, reactionless pupils, slow respiration, weak pulse, sweating, delirium or unconsciousness, often passing into coma and terminating in death.

It rarely happens that a patient suffering from methylic alcohol intoxication recovers if he once becomes comatose. He almost invariably dies unconscious, or, having regained consciousness, suffers a relapse and death shortly follows.

The characteristic feature in nearly all the severe cases not terminating fatally is bilateral, total blindness, coming on in a few hours, or perhaps not for several days; then a partial restoration of vision, which again in a few days or weeks gives place to more or less complete and permanent blindness, with atrophy of the optic nerve.

Surely this is a picture entirely different from any other known form of intoxication and sudden amaurosis, and it has been drawn by many observers from actual clinical observation over a widespread area. *It is a picture which methyl alcohol alone can create.*

VISION IN METHYL ALCOHOL AMAUROSIS.

As already noted, vision is frequently good for several days after recovery from the intoxication, when without warning blindness, often total, sets in. After a few days or weeks of darkness the eyesight returns, and the improvement may even be very marked—may, indeed, be almost as good as ever. Yet a relapse is almost certain to occur, and before long the blindness once more returns, and this time, as a rule, is permanent.

The visual field is nearly always contracted, and absolute central scotomata are rarely absent. The pupils are widely dilated and do not respond to light or accommodation. The optic neuritis characteristic of the early stages of methyl alcohol intoxication shows itself in blurring of the optic discs, congestion of the papillary vessels and slight swelling of the nerve head. Later the congestion of the optic papilla disappears and complete atrophy, with a white or grayish nerve head and contracted retinal vessels, is easily made out with the ophthalmoscope.

CASES OF MINOR DEGREES OF INTOXICATION.

The circular letter addressed by Dr. Wood to medical men throughout the country asked for reports of what he termed "partial intoxication," in which it was assumed that the patient escaped with small damage to eyesight—atypical cases exhibiting low degrees of amblyopia, with slight contractions of, or small scotoma in, the visual field. It was thought that, in susceptible individuals, small and repeated doses of this powerful poison might explain eye symptoms otherwise inexplicable. Persons who, unaware of the danger to health and eyesight, indulge in repeated "nips" of Columbian spirits (or of punch or other drinks made with it), methylated Jamaica ginger, bay rum, eau de cologne, or some patent medicine, or who use wood alcohol for "rubbing," or are exposed to the fumes of the poison, might suffer from failing eyesight, "dyspepsia" and headaches, without either themselves or the physician suspecting the cause of the trouble. Beyond an occasional "indigestion" or a mild "bilious attack," nothing might happen to draw the attention of either doctor or patient to the true character of the intoxication or the accompanying failure in vision. That such cases occur is evidenced by several of the published histories. Dr. Albert H. Brundage, president of the New

York State Board of Pharmacy, writes in this particular:

In two other cases where small quantities of wood alcohol were taken there were noticed nausea, headache, slight delirium, dilated pupils, finally developing blurred vision, which persisted on recovery from the other symptoms; also sweating, chilliness and quite marked debility. I have also thought I observed in two cases, where the external use of wood alcohol for "rubbing in" over quite an extensive surface was resorted to, mild but quite distinctive symptoms of a similar character. One of these cases was that of a man about 70 years old, suffering from cardiac dilatation and general debility. The other that of a child suffering from pneumonia. Therefore, the directness of the symptoms were somewhat uncertain. In the case of the old man the effect on vision was quite decidedly referable to the wood alcohol and was never fully recovered from.

That many instances of mild methyl amblyopia have been and are now attributed to other causes there is every reason to believe. The following cases, among a number seen by Dr. Wood and of which he has preserved records, are probably examples of methyl alcohol amblyopia, and yet the evidence is not so convincing that he felt justified in publishing them among the histories in Class B. Doubtless other ophthalmologists will recall similar instances. Whenever a patient presents himself with a history of recent "dyspepsia" or "bilious attacks,"

gray-white with shallow atrophic cupping, and arteries much smaller than normal. Retinal veins smaller left than right. On the whole, the mirror exhibits fewer signs of optic atrophy right than left. The visual fields (See Figs. 2 and 3) show a well-marked absolute scotoma in both eyes with decided contractions of their boundaries.

Treatment by strychnia, etc., was of no avail. In view of the history of acute indigestion, the bibulous habits of the patient, the condition of the fundi, the form of the fields, the progress of the disease and the probable exclusion of other causes of amaurosis, Dr. Gifford and Dr. Wood suspected a mild form of methyl alcohol poisoning, although it was not possible to trace the intoxication to its probable origin.

The second case is better defined.

CASE 2.—R. F. F., "burner" in a brickyard, aged 43, was referred to Dr. Wood April 19, 1904, by Dr. Seim of Blue Island, Ill.

History.—He is a man of good habits and has always enjoyed the best of health and good eyesight until six months ago. Since that time his vision has failed and he has had attacks of severe "indigestion," including vertigo, nausea, vomiting, headache and pain in the stomach. He now has foggy vision for both distance and near, and, suddenly he found he could not read even the coarsest print. On several occasions he has had aching in both eyeballs, when the vision seemed more foggy than before. He also thinks that during the attacks of "biliousness" his sight is worse. A careful examination of this man's urine, blood and internal organs generally show them to be all practically normal. There is no history of rheumatism, gonorrhea or syphilis. He has smoked considerably for several years. Feeling much fatigued by his work he began, six

Figs. 2 and 3.—J. E. B. Field of vision for white. 5 mm. object. Left eye: Absolute central scotoma for white; no field for green. Right eye: Slight blurring of white object at fixation point, more marked on the nasal side.

Fig. 4.—R. F. F. Visual field for white. 5 mm. object. Left eye: Central absolute scotoma for white; no field for red.

accompanied by failing vision and central scotomata and the symptoms are not otherwise clearly explicable, poisoning by wood alcohol in small doses should be suspected. One can never tell, without careful inquiry, which of one's patients may be secretly indulging in the delights of the cologne or bay rum bottle, or taking "XXX bitters" or cheap whisky, for his stomach's sake.

CASE 1.—G. E. B., patient of Dr. F. W. Cook, Plattsmouth, Neb., aged 40, machinist, was seen in consultation, first by Dr. Harold Gifford of Omaha, and on April 28, 1889, by Dr. Casey Wood of Chicago.

History.—Apart from a gonorrhoea (from which he entirely recovered) at 25 years of age there is no history of venereal or other general disorder. He has had many attacks of "dyspepsia" during the past few years which has not been treated with success. He does not smoke, but drinks "not much but many things." His knee jerks are unaffected and his pupil reflexes normal, although sluggish to light. Tension normal. On Sept. 28, 1898, he noticed a heavy sensation in both eyes, with some pain, photophobia and dimness of sight. After some decrease in pain and improvement in vision a steady lessening of vision followed, and now he sees "as if through a mist" at all distances. Objects also have a reddish or yellowish appearance.

Examination.—V. L. = fingers at 4 feet and Jaeger XX only; V. R. = 20/100, and with glasses words of Jaeger IV at 8 inches. The fundi show clear media, nerve heads

months ago, to drink wine fortified with various kinds of spirits, especially cheap whisky bought at saloons. Since the attacks of indigestion he has rather increased the amounts and number of these alcoholic potations although the stomacheal distress is rather worse than better. On two occasions the drinks of wine and spirits were followed by nausea and vomiting.

Examination.—His pupillary and patellar tendon reflexes are about normal. The pupils do not, however, respond quickly to accommodation. V. in each eye is 2 7, and words of Jaeger XIV; no improvement with glasses. The ocular media are clear, but the nerve heads are distinctly grayish and the papillary tissue is woolly, with indistinct edges. No changes in the vessels or retina. The fields of vision were measured at various periods (See Figs. 4, 5, 6 and 7), showing condition when first seen and after a month's treatment.

Treatment and Result.—All stimulants were stopped and the patient given pilocarpin sweats, followed by strychnia and iron tonics and large doses of strychnia hypodermically. Vision rapidly improved, so that on Sept. 17, 1904, he had 6/6 and Jaeger I almost, in each eye. A faint central scotoma for red and green can still be demonstrated in each eye. His general health is much improved.

DIFFERENTIAL DIAGNOSIS.

The picture presented by methyl alcohol intoxication is so uniformly clear and characteristic that, once the attention of the observer has been drawn to it, there

can hardly be any difficulty in recognizing any of the degrees of poisoning. However, as it is only in recent years that the signs of methyl alcohol intoxication could be studied, and as the meaning of its symptom-complex could, consequently, be understood only by a comparatively small number of practitioners, we may be pardoned for a few words on this subject.

When dilated pupils and blindness (total or partial, temporary or permanent) accompanies, or follows shortly after, an alcoholic debauch, the presumption is that the intoxication is due to wood alcohol.

The necessity of better knowledge on the part of physicians generally of the dangerous qualities possessed by wood spirit, in whatever form it may be taken, is well illustrated in the following brief history of a lethal case:

A physician was called to see a woman, 43 years of age, and found her comatose, fairly good pulse, sighing respiration, widely dilated pupils, and was informed that before his arrival she complained of loss of vision. He suspected uremia and returned to his office for a catheter, being gone about fifteen minutes. On his return she was dead. No urine was drawn off and found to contain albumin. No autopsy was made, but the cause of death was considered to be uremia, and, no doubt, certified accordingly.

Fig. 5.—R. F. F. Left eye: Field of vision for white and red. Relative scotoma for red, which is seen at the fixation point as dark red.

With slight variations in some of the symptoms, this brief exposition of a sudden and fatal illness is typical. It would be interesting to know how many practitioners could under similar circumstances arrive at a correct diagnosis. Just out of curiosity we have "supposed" this case to many, and so far have not found one who could even guess at its real nature. We have a right to assume, therefore, that many deaths may have occurred in a similar manner, without recognition of the causation. If this be true, thousands of people are daily exposed to the hidden danger which may bring about a similar result.

The fact that death has followed the drinking of spirituous liquor generally means that the deadly fluid was methylated, because, although large quantities of ethyl alcohol may cause death, such a result is extremely rare.

When blindness supervenes after symptoms of severe intoxication, the case might be mistaken for quinin amaurosis, but in acute cinchonism the deafness, ringing in the ears, the intense anemia of the whole fundus oculi, and almost total obliteration of the retinal vessels, serve to distinguish it from methyl alcohol amaurosis.

MIXED INTOXICATION.

Methyl alcohol poisoning, complicated with other poisons or with systemic diseases capable of producing some of the severer symptoms of methylism are, of course, not so easily diagnosed. Death from uremia in an ethyl-alcoholic, who has recently been imbibing quantities of grain alcohol, might easily be preceded by symptoms simulating wood alcohol poisoning, and it might require an analysis of the stomach contents to determine the cause of death.

In the same way, when a large dose of quinin, administered in cheap whisky or other suspicious alcoholic beverage, is followed by gastrointestinal disturbances, cardiac depression, headache and blindness, it may be difficult to say which of the two intoxicants, possible adulteration by wood alcohol in the menstruum or the quinin (or both), is responsible for the amaurosis. The following case illustrates a difficulty of this sort:

In May, 1904, Dr. Casey Wood examined, through the kindness of Dr. Oscar Dodd, whose clinic at the Illinois Eye and Ear Infirmary he attended, J. A. B., druggist, aged 33. On Nov. 27, 1903, he had a chill and took, as a remedy for it, three or four ounces of Armstrong's bitters, following this with 8 or 10 grains of quinin and some acetanilid. The same evening his

Figs. 6 and 7.—R. F. F. Field of vision for white and red. Right eye: Relative scotoma for red, which is seen as "gloomy" red. Left eye: Relative scotoma for red, which is seen at the fixation point as "dark" red.

sight suddenly failed and grew slowly worse for three weeks. On Jan. 13, 1904, he was admitted to the infirmary.

Examination.—V. R. = light perception; V. L. = shadows. Both pupils dilated. The ophthalmoscopic findings are the same in each eye, viz., disc sharply outlined and very white, lamina cribrosa plainly marked; arteries very small; some disappear a short distance from the disc. The veins are engorged.

Treatment.—Treatment, with pilocarpin and increasing doses of strychnia, was given until April 4, 1904, when he was discharged with light perception only in either eye.

When seen by Dr. Wood the retinal arteries were smaller than normal, but not so markedly reduced in caliber as one usually sees in quinin amblyopia; nor were the veins abnormally increased in size—conditions probably the result of treatment—but the nerve-heads were very white and sight was so reduced that it was impossible to outline the visual fields. There was no history of deafness. The remainder of the bottle of "bitters" was examined for Dr. Wood by Dr. Wesener of the Columbus Laboratory. No methyl alcohol was found in the concoction.

PREVENTION OF WOOD ALCOHOL POISONING.

Notwithstanding all that has been said and written in the last few years in reference thereto, the medical profession experiences difficulty in educating the people in any questions pertaining to public health. It is only by persistent effort on our part that a subject so important as the abuse of methyl alcohol has now become

will ever receive the recognition and attention it deserves, not from the public, but from their rulers, the makers of laws.

Here, then, we have a fair field for the exercise of preventive medicine. It remains to be seen how the evil may best be dealt with. Whenever these cases are brought before medical societies the unanimous opinion has always been that something should be done. So far, however, comparatively little has been done. It would be useless to try and educate the public to the knowledge that wood alcohol is a poisonous substance, since it appears under the disguise of many attractive names, such as Columbian spirits, cologne spirits, colonial spirits, Florida water, Jamaica ginger, lemon essence, essence of peppermint, etc., names intentionally misleading, and in no way suggesting the nature of the liquid, which, moreover, is further concealed by methods which remove most of its naturally unpalatable qualities.

Moreover, this new (1896) and distinct form of poisoning by a substance so widely and indiscriminately used in arts, trades, manufactures, and even in the preparation of many articles intended to be taken internally, either as food, condiments or medical preparations, is chiefly dangerous in consequence of new methods of manufacture, so cunningly devised that there is now produced a harmless-looking, and even palatable, fluid which unfortunately retains all the dangerous qualities of the crude and essentially repulsive form previously in general use.

Individual effort has done something in the way of reform. We might refer particularly to the work in this direction of Dr. Swan Burnett of Washington, D. C.; Dr. Joseph White of Richmond, Va., Dr. Harold Gifford of Omaha, Dr. H. Dickson Bruns of New Orleans, and many others.

Dr. Frank Buller has urged that in addition to, or as a substitute for, the poison label, the notice, "this fluid, taken internally, is likely to produce blindness," appear on each package. This label would be even a more effective warning than the word "Poison" and the pictured skull and crossbones familiar to us all. All of them would not be out of place under the circumstances.

In this connection it is of particular interest to know why there are so many cases of methyl alcohol poisoning in the United States and practically none in other countries. The explanation lies in the fact that a more palatable form of the drug has come into general use in this country; that, consequently, it is taken in larger quantities. This view is sustained by information obtained in regard to its use abroad, as in the contribution of J. C. McWalter to the *State Journal of Medicine*, in London, England.⁷

He states that the "methylated spirits" of commerce (in England) is a compound containing only 10 per cent. of wood naphtha, 2 per cent. of mineral oil and 64 per cent. of absolute alcohol. So long as its composition conforms to this formula, there is absolutely no legal restriction as to its sale, provided the seller obtains a license costing 10 shillings a year. He points out that this spirit contains a combination of three powerful intoxicants, capable of producing intensely greater effects than the most virulent form of raw whisky. Yet so unattractive is it as a beverage that no cases of poisoning result from its use.

He estimates that there are in Great Britain and Ireland about 10,000 retailers of methylated spirits, and

that three and a half millions of gallons are consumed annually; possibly half of this is used for legitimate purposes, as polishing, dressing, etc.

McWalter believes that he has discovered a growing tendency to use even the nauseating (British) methylated spirits as a drink for securing intoxication, and thinks its employment for such a purpose should be controlled by legislation; he suggests making it absolutely undrinkable by adding naphthalin. He also suggests placing it on the list of poisons, so that it can be sold only by licensed druggists, duly labeled as poison. In spite of this alleged use of methylated spirits as a drink, he does not allude to any ill effects on vision. He thinks that sometimes cirrhosis of the liver, splenic enlargement and albuminuria may occur in consequence of its abuse.

As before stated, the manufacturers of the various forms of "deodorized" methyl alcohol regard their products as poisonous when taken internally, and packages sent out by them are, as a matter of fact, labelled "not to be taken internally," but this notice, even if it occupied a more prominent place on the bottle than it generally does, is usually offset by the recommendations on and the harmless air imparted to the rest of the label. It is quite incompetent to protect the man in search of "any kind of alcohol for a drink."

The immunity of foreign countries from methyl alcohol intoxication gives us our clue to the only effective prophylaxis. No labelling of bottles and packages will guard against the evil effects of this powerful poison one-tenth as effectually as adding to it naphthalin or some other pungent ingredient in such quantities as, in the case of the corresponding German and British article, will prevent its employment for any of the poisonous purposes indicated in this investigation. As long as we allow deodorized wood alcohol to be sold in its present shape, just as long will we have the usual record of death and blindness from its entrance into the bodies of human beings. The reader will readily perceive that "deodorized" wood alcohol has no legitimate place in commerce. Its mere existence must always be a menace to the lives and eyesight of the community. As in Europe, safety lies in an untaxed mixture, for commercial uses, of ethyl alcohol, with some nauseous protective agent, corresponding to the "methylated spirit" of Great Britain and the "Brennspritus" of Germany.

TREATMENT OF METHYL ALCOHOL POISONING.

The conduct of some of the cases has been outlined in the foregoing reports. There does not seem to be any antidote to the poison in the common acceptance of that term, but one's efforts, if the case be seen early, should be directed to getting rid as promptly as possible of the poison from the alimentary tract, and so to prevent its absorption. Whether vomiting has set in or not, there seems no reason why careful use should not be made of the stomach pump, with an oily emulsion as a diluent. The subsequent treatment should be directed to the symptoms.

Lieutenant R., who recently had considerable experience in the treatment of five cases at Fort Terry, in which there was one complete recovery (neither death nor blindness), reports it as follows:

Private J. F. W., aged 27 years, was found on duty at the post exchange at the same time the other patients were found in their quarters. Though showing the effects of alcohol, he was able to go about his duties (cooking). He was sent to

the hospital, or, rather, carried, though he had walked to the quarters from the canteen, about 100 yards, a few minutes before. This man had sense enough to tell the truth; he admitted that he had taken about a pint of Columbian spirits, and also a pint of bay rum in addition, the "alcohol" on the day before and the bay rum on the 29th. When his fears had been sufficiently quieted, he was given 44 c.c. of oleum ricini, which only caused more vomiting than he had already experienced, of a mawkish, bay-rumish-acid smelling fluid. This was followed by 30 c.c. of whisky, and the dose continued every hour. Next morning the bowels were opened with enema. Temperature on admission (29th), normal; pulse, 68, soft; temperature during night varying from 97 to 99. Sleepless; complained of precordial pain and oppression and sense of impending danger. Next morning, condition fairly good; still complained of pain around heart, in bowels and in region of kidneys. General condition continued to improve on the whisky and strychnia treatment, though the pain around heart and weak pulse continued to a slight extent for two or three weeks. Returned to duty about the fifth day, but kept on strychnia for two weeks longer. The fact that this man told the truth about the affair, and thus was enabled to get most of the poison out of the alimentary canal, is, no doubt, the reason he is alive. Present condition, normal.

Dr. R. would call particular attention to the fact that none of the three deaths occurred within twenty-four hours of the ingestion of the poison, but took place in from twenty-eight to sixty hours thereafter. This long range (as to time) effect renders the stuff a most dangerous poison, for the reason that there seemed to be a paralyzed condition of the bowels, due, doubtlessly, to the methyl alcohol. It is the belief of Assistant Surgeon R., from his experience of five cases of poisoning, that methyl must be replaced by ethyl alcohol, in order to combat a collapse and sustain the patient's vitality. This, with the speedy clearing out of the poison from the alimentary canal and the continued stimulating and supportive treatment for several weeks, should constitute the principal aim in treatment.

Dr. Albert H. Brundage, who has had experience of several patients, thinks the acute, severe cases should be treated by thorough siphonage of the stomach, cold affusions to the head, cardiac stimulants, pilocarpin injections, inhalations of oxygen, external heat to body and extremities, moist heat over the kidneys, rectal injections of hot coffee and normal salt solution.

The treatment of the optic atrophy is not very satisfactory in the severe cases, although the use of pilocarpin, sweat baths and potassium iodid (as soon as the patient's condition permits) during the early stages of neuritis, followed by strychnia in full dose hypodermically, seems to have been beneficial in some instances by limiting the extension of the secondary atrophy.

CONCLUSIONS.

We believe that a study of the case histories in this investigation justify us in drawing the following conclusions:

1. Methyl, or wood alcohol, in any of its forms, as well as all methylated preparations made from it, are dangerous poisons, menacing both life and eyesight.

2. It is best known to us in its deodorized form as Columbian spirits, purified wood alcohol, cologne spirits, colonial spirits, standard wood spirits, union spirits, eagle spirits, green wood spirits, and a variety of other fluids.

3. It is used as an adulterant of, and substitute for, grain alcohol in cheap whisky and other alcoholic beverages, not to mention Jamaica ginger, lemon extract and many other essences and flavoring fluids.

4. Methyl alcohol is largely used in the preparation of many proprietary and patent medicines, witch hazel, domestic liniments, as well as bay rum, cologne water, Florida water and other perfumes.

5. To this date, at least 153 cases of blindness and 122 deaths have resulted from this poison; in all, 275 instances of lost life and eyesight. This total would probably be raised to 400 if a more thorough search were made.

6. The injury to the ocular apparatus consists chiefly of a destructive inflammation of the optic nerve fibers or retinal elements (or both), followed by their atrophy.

7. The symptoms of poisoning are gastrointestinal disturbances, more or less severe, accompanied by abdominal pain, general weakness, nausea, vomiting, vertigo, headache, dilated pupils and blindness. If recovery does not occur, there is marked depression of the heart's action, sighing respiration, cold sweats, delirium, unconsciousness, coma and death.

8. The blindness is bilateral and may set in a few hours after the inhibition of the poison, or it may be delayed for several days. It is generally complete, with a subsequent improvement, and, finally, a relapse into permanent blindness.

9. The visual fields are contracted and exhibit absolute central scotomata. The ophthalmoscope reveals at first a congested nerve-head, followed by grayish or white atrophy and contracted vessels.

10. The diagnosis can hardly be mistaken. Methyl alcohol poisoning presents a picture unlike that of any other intoxication. Acute abdominal distress, followed by blindness, should always awake a suspicion of methyl alcohol poisoning.

11. The prevention of poisoning by this insidious drug can only be brought about by prohibiting the sale of "deodorized" wood alcohol in all its forms. The number of deaths may meantime be limited by putting all methylated preparations on the list of poisons and prosecuting all persons adulterating foods and drinks with it. Labelling it with the notice, "This fluid, taken internally, is likely to produce blindness," will certainly have a deterrent effect.

12. Methyl alcohol intoxication is an example of idiosyncrasy. As in the case of several other poisons, some persons are largely immune so far as permanent damage to the organism is concerned. If ten persons drink, say, four ounces of Columbian spirits within three hours, all will have marked abdominal distress and four will die, two of them becoming blind before death. Six will eventually recover, of whom two will be permanently blind. With still larger doses, the proportion of death and blindness will be greater.

13. Poisoning by inhalation of the fumes of methyl alcohol generally occurs when the exhalations are mixed with rebreathed air, as in varnishing the interior of beer vats, small rooms, etc. It is also highly probable that in susceptible subjects repeated or even single methylated "alcohol rubs" may produce poisonous symptoms, through absorption of the spirit by the skin.

14. Chronic (or partial) poisoning from methyl alcohol (in the shape of "nips" of methylated Jamaica ginger, bay rum, punch made with Columbian spirits, etc.) is the most insidious and probably not an uncommon

form of intoxication. Its symptoms are not so pronounced or so easy of recognition as in the acute form, but the eyes, digestive apparatus and nervous system undoubtedly suffer.

15. The use of ethyl or grain alcohol in the arts, as in the manufacture of varnishes, as a burning fluid, for "stiffening" hats, lacquering brass, etc., is without danger to life or eyesight. By adding to it a small percentage of naphthalin, for example, the fluid would be undrinkable. A combination of ethylic alcohol with 10 per cent. of wood spirit would answer the same purpose. Such a mixture is the "methylated spirit" of Great Britain, where not a single case of acute poisoning or amaurosis from methyl alcohol is recorded, in spite of the extensive commercial use of methylated preparations in the British Isles.

16. The treatment of methyl alcohol intoxication consists chiefly in getting rid of the poison from the stomach and intestines by means of the stomach-pump and rectal injections; stimulants, especially ethyl alcohol, strychnia and coffee; heat to the body and extremities.

17. The treatment of the amaurosis is unsatisfactory. In the early stages pilocarpin and potassium iodid; later, strychnia hypodermically and by the mouth.

EDITOR'S NOTE: This concludes the report save for the tabulated summaries of the cases previously published elsewhere, which will appear next week.

REFLEX APNEA AND CARDIAC INHIBITION IN OPERATIONS ON THE RESPIRATORY TRACT.*

W. G. B. HARLAND, M.D.

Instructor in Laryngology, University of Pennsylvania,
AND

WILLIAM HARMAR GOOD, A.M., M.D.

Demonstrator of Physiology, Medico-Chirurgical College,
PHILADELPHIA.

The following case, reported elsewhere by one of us,¹ gives some idea of the practical importance of this subject:

In 1900 one of my students came to me for an explanation of certain curious phenomena that occurred during massage of an epithelioma of the lower lip. It was about 1 1/4 inches in diameter and surrounded by an indurated area. The center was very sensitive. When this part was massaged the patient cried: "Don't cut my wind off! You are choking me!" He gripped the chair and grew dark in the face, breathing hard, with a pulse of 100, subsiding quickly to 20; respiration about 12. Massage next day caused the same alarming symptoms.

No doubt it was a case of reflex inhibition caused by mechanical stimulation of the abnormally sensitive endings of the trifacial.

Reflex inhibition has not received from laryngologists the attention it deserves. The text-books do not refer to it, and yet it is a subject familiar to most general surgeons and physiologists. It seems worth while, therefore, to discuss in a brief way the subject as a whole. We would call attention to the value of inflation of the lungs when death seems imminent from cardiac inhibition.

CAUSES OF INHIBITION.

Reflex inhibition of heart and respiration is caused

in the following way: Afferent impulses, following irritation of the trifacial and sensory branches of the vagus (superior laryngeal and pulmonary), are carried to the cardioinhibitory center in the medulla. This center is thrown into greater activity, and strong inhibitory impulses are sent to the heart. At the same time the respiratory center is so acted on as to cause a cessation of respiratory movements, until the accumulated carbon dioxid again drives it into action. The consequent inflation of the air vesicles of the lungs then reflexly lessens the activity of the cardioinhibitory center,² and in this way inhibition is overcome.

Inhibition of this kind must not be confused with syncope or shock, for syncope is due to a sudden vasodilation; the blood, from gravity, collects in the abdominal viscera and dependent parts of the body, and loss of consciousness ensues from cerebral anemia. Inhibition following trifacial and superior laryngeal irritation, on the contrary, causes a reflex stimulation of the vasoconstricting mechanism and is not necessarily associated with loss of consciousness.

Of course, reflex inhibition can be produced by irritation of other sensory terminals than those in the respiratory tract; it frequently occurs in operative procedures on the trifacial area about the lips,³ teeth,³ eye¹ and ear.⁴ As this paper will deal with the respiratory tract only, we can now take it up in detail.

Nose.—Those who have inhaled strong ammonia know that it is several minutes before they can get their breath, or, technically speaking, before the inhibition of respiration passes off. Also, in etherizing rabbits, it is noticed that as soon as ether is applied to the nose the animal stops breathing over a more or less prolonged period. At the same time the heart is markedly inhibited—in fact, almost stopped. This reflex inhibition is also produced when applications of irritating solutions, e. g., dilute sulphuric acid, are made to the turbinates. Such result was observed by Kratschmar,⁵ who experimented with tobacco smoke as an irritant. Quite frequently in operations on septum reflex inhibition will cause a patient to suddenly feel faint, "lose his nerve," although, the tissues being cocaineized, he experiences no pain. Some of these cases can be ascribed to psychical causes, a few to the cocaine⁶; indeed, it is apparent at once that a large percentage of cases of so-called cocaine idiosyncrasy may properly be ascribed to reflex inhibition. Doubtless many of the deaths occurring in primary anesthesia can also be attributed to this cause. The effect of slight irritation of the nasal terminals of the fifth nerve is illustrated by the following case:

John C., aged 10 years. Acute purulent rhinitis. Pulse before examination, 100. During cleansing of nasal mucosa pulse fell to 66. Inhibition gradually decreased as cocaine was applied.

Rhinopharynx.—The rhinopharynx is also very sensitive to reflex inhibition. Applications to this region produce in some instances a momentary catching of the breath, and in the removal of adenoids a marked slowing of the pulse almost invariably occurs when the instrument—forceps, curette or finger—is introduced behind the soft palate.

CASE 1.—Edward C., aged 3 years. Adenoids operated on under ether. Before operation pulse was 145. No change in pulse occurred during removal of faucial tonsils; respiration was, of course, interfered with. The pulse immediately afterward

went up to 168. When forceps were used in the rhinopharynx the pulse suddenly slowed, and for 40 seconds remained about 90, at times running as low as 72 per minute. After operation the pulse ran up to 150.

CASE 2.—Dorothy T., aged 4 years. Adenoids removed under ether. Pulse before ether was applied, 120; under anesthesia it rose to 172; just before operation it was 160. During manipulations in postnasal space pulse fell to 66, increasing at once as soon as the instrument was removed. Three minutes after operation the pulse was 136. Two hours later it was 124. Respiration was also interfered with during operation.

CASE 3.—Josephine C., aged 8 years. Adenoids removed under ethyl chlorid. Before anesthesia pulse was 125. During early stages the pulse suddenly fell to 96 and respiration ceased for a short time (probably due to cold ethyl chlorid vapor irri-

pulse to fall, first to 96, later to 75. After operation it rose rapidly to 160; ten minutes later it was 132.

Jane R., aged 8 years. Adenoids under chloroform. Pulse before anesthesia, 160; under full relaxation, 120. During operation it fell to 72. Immediately after operation it rose to 150.

There seems to be no choice of anesthetic so far as cardiac inhibition is concerned.

Larynx.—We have found by experimental irritation of the laryngeal mucosa of rabbits with dilute sulphuric acid that reflex inhibition arising from the larynx is accompanied by a rise of blood pressure, unless the irritation is particularly well marked, when there may be a slight fall. If inhibition is prevented by division of both vagi the pressure is increased (40 to 70 mm.).

Tracing 1.—These tracings are one-fourth actual size. Upper line is the respiratory curve; at "a" and "b" the lungs were inflated with a pressure of 40 or 50 mm. mercury. The middle line is the blood pressure with the cardiac pulsations. The lower line is the seconds marked and zero pressure raised 25 mm. Tracing 1 is from a rabbit (morphin, gr. 1/3, injected hypodermatically). Dilute H_2SO_4 had been applied a few moments before to the nasal mucosa. At "x" it was reapplied. At "x" the apnea and cardioinhibition are well marked. As soon as the lungs are inflated the blood pressure falls and the heart begins to beat rapidly, the cardioinhibition returning as soon as the inflation ceases.

Tracing 2.—Rabbit (morphin, gr. 1/3, inj. hypoderm.). The animal was recovering from the effect of a previous stimulation of the nasal mucosa, when at "x" dilute H_2SO_4 was again applied to one nostril, and about 90 seconds later to the other nostril. The cardioinhibition in both cases is well marked and the blood pressure is increased; as soon as the lungs are inflated the heart commences to beat rapidly and the pressure falls at least 50 mm.

Tracing 3.—Rabbit (morphin, gr. 1/3, hypoderm.). Dilute H_2SO_4 applied to the nasal mucosa with the usual marked cardioinhibition, in this case from 250 to 40 beats per minute. The release from inhibition by inflation of lungs can not be made out in this tracing on account of reproduction being small.

tating the air tract). Later, when relaxed, the pulse was 120. During the removal of the adenoids the pulse was irregular, faulty, and 75 per minute. There was clonic spasm, similar to that seen in rabbits when the nasal or laryngeal mucosa is irritated. After operation the pulse was 120; five minutes later, 116; ten minutes later, 105.

In order to eliminate error due to individual fault of operator the following cases, operated on by Dr. Grayson, were studied with his permission:

James M., aged 8 years. Adenoids, under ether. Before anesthesia pulse was 110; before operation it was 180. Child completely relaxed. Manipulations in rhinopharynx caused

Crile⁷ has shown that irritation of the larynx, forcible dilatation of the pharynx and violent traction on the tongue will each cause reflex inhibition, and even death. He states that in 156 intubations inhibition was encountered six times, twice with fatal results. Simple obstruction causes cyanosis and a full pulse, whereas inhibition is characterized by pallor and by a slow, weak pulse—diagnostic signs of considerable importance.

Irritation of the trachea causes little or no reflex inhibition. However, in the rabbit, at least, cardiac slowing

7. Crile: Surgery of the Respiratory Passages, THE JOURNAL A. M. A., Feb. 22, 1902.

is at times observed when a tracheotomy tube is placed in position, especially when the tube is rather large.

Lung.—Brodie and Russell⁸ have shown that electrical irritation of the pulmonary vagal fibers, or irritation of their terminals in the alveoli, with irritant vapors, causes marked cardioinhibition, apnea and vasodilation. Their results we have been able to confirm on rabbits by injecting small amounts of dilute sulphuric acid into the alveoli through the chest wall. McWilliams⁹ caused well-marked cardiac inhibition in eels by irritating the gills, which have the function of lung alveoli. A case in point is reported by Brodie and Russell⁸ of a child that died on the withdrawal of a hypodermic needle that had been introduced two inches into the lung in a vain search for pus. The heart stopped at once; breathing continued for a short time, aided by artificial means. In another case¹⁰ death occurred after a few inhalations of ether. The fatal result was ascribed to irritation of lungs rendered abnormally sensitive by disease (multiple carcinoma).

The subject of this paper is one that invites to further study and elucidation. Enough has been given, however, to suggest the possible dangers that attend all operations on the air tract and to explain some of the causes in which heart failure and death have followed unexpectedly from what seemed insufficient causes. It is only necessary in this brief outline to say a word further on prevention and treatment.

PREVENTION.

We can not hope to prevent reflex inhibition in every case. Atropin is the one drug given internally that, theoretically, is of value. It paralyzes the peripheral cardio-

Tracing 4.—Sphygmogram. W. Z., aged 3 years, adenoids removed. The pulse fell from 140 to 50 when instrument was introduced into rhinopharynx. x. Operation commenced.

inhibitory ganglia in the heart, thus preventing cardiac inhibition, which is the most important indication, for apnea can be controlled by artificial respiration and lung inflation. Atropin must be administered early and in full dose to insure its absorption before ether is given or operation begun.

General anesthesia, when complete, prevents inhibition by abolishing the reflexes, but it is dangerous to abolish all the reflexes. Of the anesthetics ether is safer than chloroform, and probably safer than ethyl chlorid. Cocain, applied locally, prevents inhibition when the anesthesia is complete. In the larynx absorption is slow, and it can be used without much danger of toxic effect: in the nose the amount must be guarded. It is not always practicable to get cocain to penetrate deep enough, and when sawing through spurs on the bony septum inhibition will occasionally occur, even though the mucous membrane itself is insensitive.

Before ether is given a preliminary spray of 1 per cent. cocain, with 1 to 10,000 adrenalin chlorid,¹¹ into the nose and throat prevents not only irritation, congestion and excessive secretion, but also lessens the tendency to reflex inhibition. Applied with an applicator to the rhinopharynx, it is still more effective. Strychnin should probably not be given: it can not be expected to prevent reflex inhibition, as it increases the normal reflexes and,

according to Wood, probably stimulates the cardioinhibitory mechanism.

TREATMENT.

Treatment will vary with the severity of the symptoms. Usually a temporary withdrawal of the cause of irritation will suffice. In severe cases one can hardly rely on atropin, even if given hypodermically, as ten or fifteen minutes will elapse before it is absorbed. The prone position and artificial respiration, gentle traction on the tongue, etc., should be at once resorted to. If these prove without effect, then inflation of the lungs by mouth-to-mouth insufflation or with a bellows, keeping the lungs distended for five seconds, and repeating until the patient is revived. The value of this procedure has been demonstrated again and again. In a series of experiments on cats and rabbits (under morphin, inhibition having been induced by applications of sulphuric acid to the laryngeal or nasal mucosa), inflation caused the cardiac inhibition to at once cease, and the heart tended to beat even faster than normal. Hering² has shown that in normal animals moderate inflation (40 to 50 mm. of mercury) of the lungs causes a marked increase in the number of heart beats. He believes that the sensory nerves of the lungs stand in the same relation to the cardioinhibitory center as the nervus depressor does to the vasomotor center. In other words, irritation of sensory endings in the lungs by inflation causes, reflexly, a decreased activity of the cardioinhibitory center and a consequent increase in the number of heart beats. Jackson,³ in a case of marked reflex apnea and cardiac inhibition from trifacial irritation, resuscitated his patient by mouth-to-mouth inflation. "The effect was instantaneous; the chest expanded, the eyes opened, a sigh was breathed, and the heart pulsated a few seconds. The insufflations were repeated until the functions were re-established. There was another attack in the afternoon, without unconsciousness. She was restored by insufflation by her husband."

CONCLUSIONS.

Any part of the air tract, when irritated, is apt to produce reflex apnea, cardiac inhibition, and even death. Usually this can be prevented by the administration of atropin, by having the patient completely anesthetized before operating, when general anesthesia is used, and by the use of cocain locally. If severe inhibition does occur we have in moderately forcible inflation of the lungs a most valuable means for relieving this dangerous condition.

DISCUSSION.

DR. G. HUDSON MAKUEN, Philadelphia, said that the whole subject of reflex disturbances originating in peripheral irritation of various portions of the respiratory tract furnishes a fertile field for conjecture and speculation. Opinions differ with regard to it; some think that there is no such thing as a reflex neurosis, while others class almost all nervous symptoms in this category. When skilled neurologists, such as Dana of New York, openly declare that they find no special pathologic relationship existing between the mucous membrane of the nose, for instance, and the general nervous system, we must pause and think before making contradictory statements or advancing opposing theories. Dr. Makuen said that the cases reported show the effect of peripheral irritation of the respiratory mucous membrane on the heart. It would be interesting to note whether the rate of the pulse is actually diminished by placing the curette in the vault of the pharynx in all or only in selected cases. Dr. Makuen said also that an inspiratory crowing sound always takes place in one of his patients whenever any topical application is made to the mucous membrane of the nose, and that such phenomena are not surprising when we con-

sider the complexity of the network of nerves in this region. A reflex arc, in its simplest form, consists of an afferent sensory nerve, an efferent motor nerve and a cerebrospinal center or ganglion, which latter may also be connected with the higher cortical centers of the brain and to some extent controlled by these centers. It is only by keeping in mind the structure and functions of this arc that we can understand or explain the nervous phenomena that may occur during an intranasal operation. It is probable that no untoward symptoms will arise during such operations, provided the reflex arc is in good condition functionally and organically, and it is only when this reflex arc is impaired in whole or in part that we are liable to meet with accidents. Take a patient having what we call an unstable nervous system and prepare him for intranasal operation. He probably goes through several days of anxious thought about it. Cocain is then applied, the mechanical effect of which is sufficient in some cases to cause immediate disagreeable symptoms, and the systemic effect, a little later, coupled with the psychic impulses arising from the fear and dread of the operation, are often sufficient to cause the patient to collapse. When the operation is begun the patient grows pale, breaks out in a perspiration and, to use the common expression, faints. Is this collapse due to cocaine poisoning, to some psychic impulse of the brain, or is it the result of cardiac inhibition from the mechanical effect of the operation? This differential diagnosis is important. If the cause is found in the heart we should use more cocaine. If it is the result of cocaine poisoning then we should diminish the amount. The time may come when we shall be able to determine definitely just how much cocaine may be used in a given case.

DR. GEORGE L. RICHARDS, Fall River, Mass., said that he had operated on a child of 6 years for adenoids. The child was etherized by an expert nurse and yet cyanosis and complete apnea resulted before the operation was begun. The mouth was forced open with the finger and afterward artificial respiration was performed until at length a gasp came. The operation was completed without further anesthesia. He considered the facts that the adenoid was large and practically filled the nasopharynx and that the child was a mouth breather, as the explanation. When the anesthesia was complete there was complete closure of the mouth with resulting asphyxia.

DR. S. SOLIS-COHEN, Philadelphia, said that he avoids apnea from anesthetics by having the nostrils closed by the assistant before administering the anesthetic, and that he also avoids the use of anesthesia in operations on the air passages wherever it is possible to do so. In tracheotomy the patient loses his breath for a moment or two after the larynx is opened, and in removing growths from the trachea, irritation of the posterior wall of the trachea will sometimes affect respiration.

DR. EMIL MAYER, New York City, said that it would be of interest if Drs. Harland and Good would throw some light on why certain people are especially susceptible to this form of cardiac inhibition. We have known for a long time that it is to be looked out for, especially when chloroform is being used. The only death Dr. Mayer ever saw from chloroform was in a laryngologic case with a foreign body in the larynx. Adrenalin is of great value in cases where there is great danger of collapse. It should be added to the list of remedies recommended.

DR. E. PYNCHON, Chicago, divided the subject into two parts, because the prostrations which occur with general anesthetics are generally different from those resulting from cocaine. In general anesthesia the patients are usually at a hospital where assistance can be had, while prostrations from cocaine most often occur at the office, when no one else is present. In fifteen years' use of cocaine, Dr. Pynchon had had his share of prostrations, but no deaths, and in several cases the prostration was considerable. He has frequently applied cocaine to the fauces in strong solutions with a cotton applicator, and has never had prostration from its use in this locality and in this manner. Collapse has always occurred while applications were being made to the nose or when injected about the tonsils hypodermatically. Prostration was not due so much to the effect of the cocaine as to the irritation of the nasal mucous membrane. He mentioned the case of a healthy girl of 18,

who had been operated on several times, the tonsils and ridges from the septum having been removed. Applications of cocaine had in each case been made without any unfavorable manifestations. Lastly, there remained one other condition which demanded operation, and in cocainizing the middle turbinal a small applicator was pressed in between it and the septum. She had epileptiform convulsions, differing materially from cocaine prostration. Some time afterward he attempted to repeat the operation, using a weaker solution of cocaine, but the introduction of the probe in the same manner produced the same results.

DR. R. C. MYLES, New York City, said that it is difficult to account for these idiosyncrasies. It has always seemed to him that there was some condition of shock. The most difficult case he had ever had was that of a man on a football team, and he tried seven times before he was able to do the operation. The patient was an athlete of the higher order, but could not face the idea of having an operation performed. This condition is not confined to any one class of individuals; the point is to watch the patient and by studying him try to anticipate the result. Tracheal injections sometimes produce the same condition. Dr. Myles said he had injected solutions of vaselin into the trachea with the same results as from cocaine. Whenever he has occasion to try it now he first tests the case, especially if it is to be an application to the trachea, under a general anesthesia, and is particularly careful, because he once lost a patient on the table and could never account for the death. The patient was frightened. The anesthetic was administered by an expert. Investigation shows that the majority of deaths from anesthesia occur in operations about the throat, and a little preliminary tickling of the mucous membrane is the thing to do as an experiment.

DR. C. M. COBB, Boston, said that, in the removal of adenoids, he had had patients do almost everything except die, and that he did not feel justified in submitting a patient to ether in adenoid operation unless he had a mouth gag in use. It saves time lost in forcing a spasmodically contracted jaw open, possibly two minutes. It is just as easy to put the mouth gag in and have absolute control of the patient, and it may save the patient's life in an emergency. These adenoid patients are doing business on a small amount of oxygen, and the slightest disturbance of the mucous membrane makes them close the mouth and they can not breathe through the nose. Since he has adopted the practice of instructing the house physicians to put in a mouth gag as a routine measure he has had much less trouble.

DR. B. R. SUDRLY, Detroit, said that we are coming to use nitrous oxid more and more, and that it deserves a much wider use. He asked if any use of it has been made in the experiments.

DR. W. H. GOOD, said that it is very easy to prove this cardiac inhibition on rabbits by applying irritants such as ether to the nasal mucosa. The heart, normally beating at the rate of 300 a minute, immediately falls to about 60 a minute. Inflation of the lungs removes this inhibition, the heart running rapidly up to 300 beats or more a minute. In cardiac inhibition the thing to try first is simple inflation of the lungs for four or five seconds, repeating until the heart recovers. The apnea can be overcome by artificial respiration. It is the cardiac inhibition that kills these patients. The heart of a patient from whom a dentist was removing a carious tooth suddenly stopped, and after trying a number of things, he inflated the lungs. The heart started to work, but again stopped, and he repeated the process. The next day the cardiac inhibition returned without the loss of consciousness. The patient was at home, and the husband, who had been present at the dentist's office, blew into his wife's lungs and she recovered. Dr. Good said that adenoids make a very sensitive pharynx, and ether could have caused the condition without the blocking of the passage; he said he was unable to answer the query in Dr. Mayer's case. Adrenalin to be of service should be given intravenously, but he did not think it would overcome any of the indications. It causes increased blood pressure, but that is already present and it does not de-

crease the cardiac inhibition. He said that clonic convulsions almost invariably result from irritation of the mucous membrane of rabbits. Nitrous oxid had not been used in any of the experiments. When a patient is under the influence of any anesthetic this inhibition may occur. With cocaine the sensory endings of the nerves are paralyzed and inhibition does not occur. Using cocaine locally and giving a dose of atropin to paralyze the peripheral ends of the vagus in the heart prevents inhibition.

THE RADICAL TREATMENT OF NON-STRAN-
GULATED INGUINAL HERNIA FROM
THE STANDPOINT OF THE
MODERN SURGEON.

J. M. BANISTER, A.B., M.D.

Major and Surgeon, U. S. Army.

MANILA, P. I.

It has been well said that, owing to the anatomic construction of the inguinal canal, the occurrence of rupture in the human species must have been coeval with the appearance of man on the globe, and this being the case, it would not be preposterous to assume that to some early descendant of Adam belongs the credit of having invented the first crude retention apparatus.

In accordance with the trend of modern thought on the descent of man, we may with propriety consider this tendency to hernia on the part of the human race as one of the penalties resulting from the action of Adam and Eve in abandoning the quadruped method of progression of their immediate simian progenitors, and assuming the erect carriage which has since characterized the human family. The erect posture has certainly placed man, with his weakly constructed inguinal canal, in the very best position for the gravitation of a coil of the intestine into a patulous internal abdominal ring, and for its being forced through the opening and into the canal during strain of the abdominal muscles.

THE FIRST SUCCESSFUL METHOD OF CURE.

From the earliest times until the present day men of advanced ideas in our profession have persistently pursued the chimera of the radical cure of hernia, with ignominious failure as the constant reward of their efforts, and the treatment of hernia has, until the very present, continued to be the greatest opprobrium of those posing as the healers of the ills of humanity. Suffering mortals have continued to die from strangulated hernia with persistent regularity, and the coffers of the truss makers have grown full to overflowing. It remained for the surgical genius of the present day to devise a safe and permanent radical cure for this distressing and common infirmity, and from the publication in December, 1889, of the method of Halsted of Baltimore, and in 1890 of that of Bassini of Padua, must the radical cure of hernia be considered to date.

These methods, independently evolved by their distinguished authors and fulfilling the same indications, have solved the surgical problem of the ages. In this connection it is interesting to note that in 1890, just prior to the publication of Bassini's method, Dr. Bull of New York City published a paper giving the results in 134 cases of hernia subjected to operation in the preceding four years, with three deaths and 38 per cent. of relapses. In the paper referred to, Dr. Bull says: "In reflecting on the experience of these cases, I am obliged to conclude that in these methods which I have faithfully tried, there is no prospect of obtaining a radical cure in any form of hernia, and the majority

of cases will be found to relapse if followed for a sufficient time." Sir William MacCormack states in his Bradshaw lecture for 1893 that of the cases of non-strangulated hernia operated on in the London hospitals, 6 per cent. died. The opinions of such men, with such results as they recorded, served to create in the minds of many conservative men a serious prejudice against the radical operation for hernia, which has only been mitigated within the last few years, owing to the brilliant results obtained under our present system of aseptic technic by the methods of Bassini and Halsted.

The views expressed by Dr. Bull in 1890, which were formulated prior to the publication of the Bassini method, and which were founded on the results of operations since abandoned, are still quoted by some, against the radical operation. It is interesting to note in this connection that within a few years after the publication of this paper, Dr. Bull himself had become one of the ardent advocates of the radical operation for hernia by the Bassini method, and I had the opportunity, in the autumn of 1895, of seeing him perform this operation several times at the Hospital for the Ruptured and Crippled in New York City, where, with Dr. Coley, he was paving the way for the great permanent popularity of this operation in our own country.

Looking back at the infinite series of failures in the efforts to secure a radical cure for hernia already referred to, we, with our present knowledge, are not surprised that success was not attained. Such a fortunate result was impossible prior to the introduction of our modern aseptic surgical technic, no matter how ingenious or how well executed the method of operating might have been. The introduction of the absorbable animal suture has also had a great influence in making the radical operation for hernia a success, although it must be confessed that Halsted invariably uses silver wire for his buried sutures, while Bassini, at least in his earlier operations, used silk for the same purpose.

REQUIREMENTS FOR SUCCESS.

In order that an operation for the radical cure for hernia may be successful, the following indications must be met:

1. A perfect aseptic technic must be followed in all its details.
2. The hernial sac must be obliterated.
3. The internal abdominal ring must be narrowed closely around the cord or a new internal ring made.
4. The inguinal canal must be reconstructed.

The three anatomic indications are fully met in both the methods of Halsted and Bassini.

Without a perfect aseptic technic general sepsis or septic peritonitis may follow the surgeon's efforts or if such serious dangers to life are avoided, suppuration in the deep portion of the wound will be almost certain to result with a consequent failure in the efforts to effect a cure. This was the rock on which were wrecked the hopes of countless numbers of operators, who essayed to cure hernia with the knife prior to the introduction of our present aseptic methods.

The internal abdominal ring should be narrowed to closely embrace the spermatic cord, for it is a self-evident fact that unless this step is carefully carried out a fresh protrusion of intestine will work its way by the side of the cord down into the canal through the patulous opening thus left.

It is equally evident that the hernial sac must be obliterated, else a trap for intestine will be left, and it is

unnecessary to dwell on the importance of reconstructing the floor of the canal and thus forming a further buttress against hernial protrusion. When a case of hernia is presented to a modern surgeon for operation he may safely limit his choice of method to two operations, namely, the methods of Bassini and Halsted.

VARIOUS OPERATIVE METHODS.

The Bassini operation is most popular in the United States, and is most highly prized in Europe as well, especially in Italy and Austria. While Halsted's operation is a most excellent method in every respect, yet it must yield the palm to that of Bassini, which, in my opinion, is the most rational, simple, safe and successful yet devised for the radical cure for hernia. Nevertheless, Halsted's operation closely deserves the second place. Kocher's operation, which has yielded excellent results in the hands of its author, is, in my opinion, greatly inferior to the two operations just mentioned. This operation is very objectionable to my mind, from the fact that in this method the attempt is made to treat the sac through the external abdominal ring without the division of the aponeurosis of the external oblique muscle. In very many cases that have come under my eye this procedure would have been utterly impossible of performance. In addition, the passage of sutures to close the internal abdominal ring and narrow the inguinal canal through the intact aponeurosis of the external oblique muscle is a dangerous and unjustifiable procedure, owing to the proximity of such important structures as the internal iliac vessels, the deep epigastric vessels and the spermatic cord. The division of the external oblique aponeurosis, as practiced in the Bassini and Halsted operations, does not add one jot or tittle to the danger of the operation, while it confers on the operator the inestimable advantage of permitting a clear view of all the anatomic details, thus enabling him to strip and dispose of the sac under the direct guidance of the vision and to apply his sutures just where he desires to place them, without danger of wounding important structures. I have in my time had quite a personal experience with operations in the neighborhood of the inguinal canal, both as operator and assistant, yet I am free to confess that I would not dare to perform the Kocher operation as it is described in print.

The operation of Championnière is popular in France, and is seemingly an efficient method, though decidedly inferior to either the Halsted or Bassini operation. Championnière opens the inguinal canal through the external oblique aponeurosis, dissects out, ligates and excises the sac, and then narrows the internal abdominal ring and reconstructs the canal by the use of mattress sutures, which cause "the muscles at the upper border of the canal to overlap the lower border."

Dr. Newbern of New York removes the testicle on the affected side from the scrotum, wraps the cord snugly around it, and anchors all in the abdominal cavity in a pocket, which he constructs with the transversalis fascia of the abdomen near the internal ring. Having thus gotten rid of the testicle and cord without interference with their functions, he entirely closes the internal ring and reinforces the floor of the canal as in the Bassini operation. For cosmetic purposes he places a hollow celluloid sphere in the empty side of the scrotum.

DESCRIPTION OF THE BASSINI METHOD.

It is useless to mention other so-called operations for

the radical cure of hernia; they are all weak imitations of better methods, and serve no useful purpose except to furnish padding for surgical text-books and a little ephemeral advertising for their originators. I never think of operating for hernia by any other than the Bassini method. The steps of this most important operation are, briefly, as follows:

The patient is carefully prepared as for all abdominal operations and all the details of a rigid aseptic technic carried out. In all of my operations my assistants wore freshly sterilized rubber gloves. The incision is commenced at the spine of the pubes, and is carried upward and outward to the extent of about three inches. The external oblique aponeurosis will be recognized by its shining, fibrous appearance. The overlying fascia should be rapidly cleaned off by tearing between the two index fingers. Having located the external abdominal ring with the finger, the operator seizes with forceps the spermatic fascia, extending between the pillars of the ring, and rapidly tears through this tissue with the dull dissector. Through the opening into the inguinal canal so made, he introduces a grooved director, and on it divides the aponeurosis of the external oblique in the direction of its fibers to the extent of about one inch. The two index fingers are then introduced, and the incision of the aponeurosis enlarged by tearing to the requisite extent. This division of the aponeurosis of the external oblique muscle, which forms the anterior wall of the inguinal canal, lays open the canal and exposes its contents.

On strongly retracting the two aponeurotic flaps, the first structure in the anatomy of the canal to attract attention will be the muscular arch formed by the internal oblique and transversalis muscles over the internal abdominal ring. These fibers unite to form the conjoined tendon, which plays such an important part in the reconstruction of the canal, and which can be seen on the inner side of the canal passing down to its insertion into the crest of the pubes and pectineal line.

Poupart's ligament stands out in bold relief when the outer flap of the divided aponeurosis is strongly retracted after the loose overlying fascia has been cleared off with a piece of gauze. Emerging from the internal abdominal ring beneath the arch of the fibers of the internal oblique transversalis muscles before mentioned, will be seen the infundibuliform process of the transversalis fascia, which is continuous at its base, around the circumference of the internal abdominal ring with the transversalis fascia lining the anterior wall of the abdominal cavity, and which, in the case of an oblique hernia, contains the hernial sac and its contents. This fascia should be lightly seized with forceps just beneath the muscular arch, and rapidly torn through with a dull dissector until the sac is reached. Next the sac should be grasped and held up, while with a piece of gauze the tissue still covering it must be stripped off and the sac separated from the spermatic cord, which in an oblique hernia is behind the sac well down into the internal abdominal ring. The use of gauze for stripping the sac will be found most convenient and sufficient.

Having thus thoroughly stripped the sac, it is held in apposition perpendicular to the body, and is opened with scissors between two clamps. Having opened the sac, the index finger is introduced to explore its interior, and on this finger as a guide the sac is opened with scissors pretty well down toward its neck. If the sac is empty, it is pulled up by an assistant with some

degree of traction, its neck transixed with a needle threaded with kangaroo tendon, and the ligature so introduced, tied first on one side and then around on the other. The portion of the sac beyond the ligature is cut off and the stump allowed to retract into the abdominal cavity. If the sac contains intestine this must be reduced, all adhesions being carefully separated. Should there be found in the sac a large process of omentum, this must be separated if adherent, carefully unfolded, ligated in sections and excised beyond the ligatures, the stump being replaced in the abdominal cavity.

A small omental protrusion may be safely returned into the abdomen without further consideration. Having disposed of the sac, an assistant picks up the cord by means of a blunt hook or a strip of gauze and carries it well up into the angle between Poupart's ligament and the arching fibers of the internal oblique and transversalis muscles. The operator then passes a kangaroo tendon suture through the muscular tissue on the inner side and Ponpart's ligament on the outer just above the cord, and ties this suture at once. This constitutes a firm upper boundary for the new internal ring, which will very effectually prevent future stretching in this situation. Then the tissue of the same muscular arch is united to Poupart's ligament just below the cord, while the latter is held up by an assistant as close to the upper suture as possible. This second stitch completes the new internal ring, which should not constrict the cord to any degree, else orchitis or epididymitis, with subsequent atrophy of the testicle, might in all probability occur. Next, interrupted sutures of kangaroo tendon are passed in the same line from just beneath the lower suture of the two forming the new internal ring down as near as possible to the pubes. These sutures pierce the muscular fibers of the internal oblique and transversalis muscle, and when these fibers terminate in the conjoined tendon, this tendon is situated on the inner side and the margin of Poupart's ligament on the outer.

When these sutures are tied the margins of the conjoined tendon and Ponpart's ligament are united, thus constituting a new floor for the inguinal canal and affording a further buttress against intestinal protrusion. The cord is then laid on this new floor, and the divided aponeurosis of the external oblique muscle united over it, the last stitch completing the new external abdominal ring. The skin wound is closed in accordance with the taste of the operator and dressed with a dry aseptic dressing. I never use iodoform or any antiseptic in or on my non-infected wounds. The patient is kept in bed for three weeks, and at the end of this period is allowed to get up and gradually get about.

In the case of a direct hernia the intestinal protrusion does not occur at the internal abdominal ring, but forces its way up into the canal from under the external margin of the conjoined tendon, pushing in front of it the peritoneum constituting the sac and the transversalis fascia forming the floor of the canal. Consequently to reach the sac, the transversalis fascia must be divided over the protrusion. The spermatic cord will be found lying in a position external to the neck of the sac.

The deep epigastric vessels are external to the neck of the sac, while the reverse is the case in an indirect or oblique hernia. The sac in direct hernia is disposed of just as in the oblique variety, and then the divided floor of the canal may be united by a continuous suture of kangaroo tendon. The cord is lifted up, the new internal ring constructed around it, and the floor of the

canal reinforced by uniting the conjoined tendon to Poupart's ligament, just as in the operation for the radical cure of oblique hernia. I desire here to call attention to an anatomic fact which I have noted in every operation for direct hernia which has fallen under my observation, and that fact is this: That the conjoined tendon does not form a covering for direct hernia, either when the sac is confined to the inguinal canal, or has escaped through the external abdominal ring into the scrotum, as is erroneously stated in Gray's Anatomy and in other text-books. The hernia in every case of direct rupture pushes its way into the canal from under the margin of the conjoined tendon, and when once in the canal, passes on down toward the scrotum, lying to the outer side of the conjoined tendon. I have demonstrated this fact to the surgeons present at quite a number of operations for this variety of hernia, and within the last week have had the opportunity of making a similar demonstration to my assistants at the First Reserve Hospital.

In a case of oblique hernia of the congenital variety, the protrusion of intestine takes place directly into the patulous tunica vaginalis, which has remained open at its upper extremity, thus communicating with the general peritoneal cavity. In such cases it is necessary to divide the sac horizontally into two portions, the lower portion being stitched closely around the cord to form the tunica vaginalis testis, while the upper portion is separated from the cord and treated by ligation and excision in the usual manner.

Halsted's operation is so well known that I do not consider it advisable to take time to describe it.

STATISTICS.

For fear that I may be considered too enthusiastic on the subject of the radical cure of hernia, I beg leave to briefly present a few statistics with reference to the results of modern operations:

In September, 1895, by order of the War Department, on the recommendation of the surgeon general, the radical operation for hernia was made the routine treatment in the United States Army.

At that time the whole question was still *sub judice*, and the responsibility of proving the adaptability of the operation to the military service was placed on the pioneer operators of the medical corps of the Army, in which class I happened to be. Since that time, several hundred operations for the radical cure of hernia have been performed by the officers of the Medical Department on the officers and soldiers of the United States Army, with the most brilliant results, which have, beyond all cavil, proved the operation to be most admirably suited to the military service. There has been no mortality as far as I have been able to learn in the practice of the surgeons of the Army, with the exception of one death which occurred at the General Hospital in Washington, and the rate of relapses, even after the severe hardship and effort consequent on the arduous campaigning which has fallen to the lot of the United States Army since 1898, has remained so small as not to merit consideration.

I have lost count of the number of operations which I have performed, but I think I may fairly place my own cases in the neighborhood of 100. In this list there has been no mortality and no wound infection, except in one case, in which a small abscess developed under the skin after the skin wound had healed *per primam*. So far as I have been able to trace my cases I have had only three slight relapses, which were no more than

slight bulgings at the internal ring. One of these so-called relapses occurred in the case of a cadet at the United States Military Academy, who, after being returned to duty, was sent to the hard work of the riding school too soon after operation.

I operated on this patient a second time, and at the operation discovered that the union of Poupart's ligament to the conjoined tendon was perfect, and that the cause of the trouble at the internal ring had been the yielding and stretching of the latter. This was reduced by two kangaroo tendon sutures, and he has had no further trouble from his hernia. He completed his cadet life, graduated, and is now on duty in the Philippines. He called to see me the other day, and reported himself as being perfectly cured. Consequently, I have to my credit, or rather discredit, two partial relapses still remaining out of about 100 operations.

Dr. William B. Coley of New York reports¹ the final results of 1,003 operations for the radical cure of inguinal and femoral hernia performed between 1891 and 1902. Of these cases 937 were operations for inguinal and 66 for femoral hernia. Of the 937 inguinal cases, 756 were in the male and 181 in the female.

From the above list are excluded all cases operated on within six months of the time of the writing of the paper. In this list of 1,003 cases there have been two deaths, or adding the operations performed up to May 11, 1903, two deaths in 1,075 cases, which would constitute a mortality of one-fifth of 1 per cent. Dr. Coley's first death was due, he states, to ether pneumonia, in a child 6 years of age, and the second fatality occurred in a case of an adult with a large irreducible omental hernia.

At the Vienna Clinic, according to Dr. Coley's statistics, there were three deaths in 804 operations.

At Johns Hopkins the mortality rate has been only one death in 459 cases, and at Carle's Clinic in Rome there were only two cases of mortality in 400 operations, one being from pneumonia. It can be seen from these statistics that at the present day the danger of a fatal result at the hands of a careful and skillful operator is so infinitesimal as not to be worthy of consideration.

RELAPSE STATISTICS.

In the 937 cases of operation for the radical cure reported by Dr. Coley, 917 were typical Bassini operations with transplantation of the cord, in which list there were 11 relapses, a rate of 1.2 per cent. In 20 cases in which the cord was not transplanted and which consequently were not regular Bassini operations, 6 relapses have been observed by Dr. Coley. This, to my mind, is a very strong argument against leaving the cord *in situ*.

The Johns Hopkins' statistics show that in 307 operations for inguinal hernia by Halsted's method, there resulted 7 relapses and 4 cases of weak cicatrices. Counting the latter as relapses, there would be 11 relapses in this list, making a rate of 3.6 per cent.

In a series of 2,032 Bassini operations published by Matanowitsch, as having occurred in the practice of various surgeons, there were 74 relapses, which is a rate of 3.6 per cent. In 528 cases by Kocher's method, reported by this observer, there were 19 relapses, 3.8 per cent.

WOUND HEALING.

In the 1,003 operations for inguinal and femoral hernia. Dr. Coley reports 30 cases of suppuration, in only

9 of which cases was the suppuration deep, the remaining being limited to stitch-hole abscesses. Prior to March, 1899, when Dr. Coley and his assistants began to use rubber gloves, the cases of suppuration amounted to 4.2 per cent. Since the use of rubber gloves at this operation, Dr. Coley states that he has had only 5 cases of suppuration (1 deep and 4 superficial) in four years in about 400 cases, or 1¼ per cent.

At Halsted's Clinic, before rubber gloves were worn, the suppurations amounted to 24.13 per cent. In 226 cases in which gloves were used, there were only 4 suppurations, 1.7 per cent. I do not think that further proof of the great value of rubber gloves in surgical work could be demanded, even by the most skeptical.

The above statistics are conclusive, and I feel perfectly justified in claiming that a careful modern operator can easily hold his rate of suppuration close to 1½ per cent. In my own list it has been 1 per cent.

CONCLUSIONS.

In view of the facts adduced in the preceding pages, I feel justified in formulating the following conclusions:

1. By the methods of Bassini and Halsted, the modern surgeon has at his command two absolutely reliable operations for the radical cure of hernia.

2. With our modern strict aseptic technic, the operation is as safe as any in surgery, and the risk of a fatal termination in an operable case is so insignificant as not to be worthy of consideration.

3. The danger of relapse is so remote as to be of no moment in forming a decision with reference to the advisability of an operation in any given case.

4. If the above propositions are true, every operable case of hernia in patients between the age of 4 and 50 years and without disease of vital organs, should be subject to the radical operation, as is the custom of our military service.

ACIDOSIS.

EXPERIMENTAL EVIDENCE THAT ITS NERVOUS SYMPTOMS ARE NOT WHOLLY DUE TO LACK OF ALKALI.

RAY LYMAN WILBUR, M.D.

Assistant Professor of Physiology, Stanford University.

STANFORD UNIVERSITY, CAL.

Experiments performed in Professor von Noorden's Laboratory in the Städtisches Krankenhaus, Frankfurt a. M.

The following experiments were performed in the hope of throwing some light on acidosis and coma in diabetes. Coma is usually ascribed to the effect on the nervous system of the circulation of blood of diminished alkalescence in the blood vessels, and it is usually assumed that this blood change is due to the chemical union of certain acids, particularly betaoxybutyric, with the alkali of the blood. It is for this reason that sodium bicarbonate is administered by mouth in moderate acidosis, and sodium carbonate given intravenously for coma. These measures are not uniformly successful, and frequently much less so than theoretical considerations would lead one to expect. There are some facts pointing toward a specific toxic action of betaoxybutyric acid.

Intravenous infusions into forty rabbits were made with dilute solutions of sulphuric, acetic, lactic and betaoxybutyric acids, and with neutralized betaoxybutyric and lactic acids. These infusions were made in a normal saline solution at a body temperature, at a fairly uniform rate of 4 c.c. per minute. The femoral or one

of the ear veins was used. The acids produced the characteristic symptoms of acid poisoning, dyspnea, fall of body temperature, convulsions and death; and the toxic doses for each acid were fairly uniform per gram of body weight. The infusion of betaoxybutyric acid produced in no experiment a typical coma, although most of the rabbits passed through a stage, just previous to the convulsions, when they were very quiet and less susceptible to external stimulation.

The sulphuric acid (in $N/10$ sol.) was most toxic, about five times as toxic as betaoxybutyric acid; then the acetic ($2\frac{1}{2}$ per cent. sol. used), lactic (5 per cent. sol.), and betaoxybutyric (5 per cent. sol.). The average toxic dose of the latter was 0.03152 c.c. of a 5 per cent. solution per gram of body weight, while that of lactic acid was 0.0172 c.c. per gram of body weight.

Experiments of two kinds were performed to test the effect of the infusions of neutralized solutions of betaoxybutyric and lactic acids. The latter organic acid was used as a control to find out whether there was a specific toxicity of the betaoxybutyric acid salts. First, infusions were made, until a fatal result was obtained, with a 5 per cent. solution of betaoxybutyric acid neutralized with Na_2CO_3 or KOH , and, second, infusions were made with neutralized 5 per cent. betaoxybutyric acid until various proportions of the toxic dose were given, and then the 5 per cent. betaoxybutyric was administered until death occurred.

Two typical experiments follow.

EXPERIMENT 1.—Male rabbit, weight 1,800 grams. Infused 209 c.c. of a 5 per cent. solution of neutralized betaoxybutyric acid at the rate of 4 c.c. per minute. Bladder empty at beginning of experiment. No noticeable change in the condition of the animal until 67 c.c. were given, then the respirations began to increase. At 100 c.c. the breathing was of a snoring character, sighing at times and the animal was very quiet and kept the eyes closed. It moved only when disturbed.¹ (This condition was seen at times with the betaoxybutyric acid infusions, but was more noticeable in the neutral infusions.)

At 180 c.c. the respirations became rapid and irregular and various muscular movements began, especially twitching of the eyeballs. The pupils were somewhat enlarged. There was a gradual increase in the violence of these symptoms until 204 c.c. had been infused, when the first general convulsion took place. Recovery from this followed a cessation of the infusion, but when 5 c.c. more were given, a few minutes later, the terminal convulsion took place.

The urinary secretion began soon after the infusion, and continued even during the convulsive stage. In all, 220 c.c. of faintly alkaline urine (more than the fluid injected) were collected.

Postmortem.—No abnormal changes except a slightly yellowish color of the kidney cortex, a distended gall bladder, and markedly fluid contents in the small bowel.

This experiment shows that the neutralized solution was toxic in a dose of .116 c.c. of a 5 per cent. solution to gram of body weight, and is typical of similar results obtained in other rabbits. In general, the symptoms produced were similar to those obtained from the betaoxybutyric acid infusions, except that more of the neutralized acid was required. Similar experiments with the sodium salt of lactic acid were fatal in the dose of .118 c.c. of a 5 per cent. solution to gram of body weight, and the symptoms, except for the coma-like state, were practically identical.

1. It would be instructive to study the influence of neutralized betaoxybutyric acid on the nervous system of the monkey. In which the mechanisms of expression are so much more fully developed than in rabbits. Dr. C. A. Herter tells me that he has produced typical diabetic coma in monkeys by the intravenous infusion of solutions of betaoxybutyric acid. (See Transactions N. Y. Path. Soc., 1899.)

The second experiment given is to illustrate the effect of infusing a certain proportion of the toxic dose, as found, for neutralized betaoxybutyric acid, and following it with a proportionate dose of betaoxybutyric acid solution. This was to see whether the effect produced by the neutralized acid reduces the amount of acid required to produce death and vice versa.

EXPERIMENT 2.—Male rabbit, 1,330 grams body weight. (From average of former experiments we would expect about 150 c.c. of neutralized and about 41 c.c. of the 5 per cent. betaoxybutyric acid to be the respective toxic doses in a rabbit of this size.) Eighty-three cubic centimeters (about 55 per cent. of toxic dose) of the 5 per cent. betaoxybutyric salt was infused. The characteristic free diuresis began promptly, and the respirations began to increase at 75 c.c. Then after a short delay 24 c.c. (a little more than half of toxic dose) of 5 per cent. betaoxybutyric acid was given and the usual results, rapid breathing, convulsions and death, were obtained. During the infusion of the salt 90 c.c. of urine was passed, and 30 c.c. during the infusion of the acid.

Similar results were obtained from the infusion of varying proportions of acid and salt, giving sometimes the acid before the neutralized solution. The fatal result was particularly striking and prompt, when, after the infusion of enough neutralized solution to cause rapid breathing, a small amount (5 or 10 c.c.) of betaoxybutyric acid (5 per cent.) was rapidly given. This rapid addition of free acid seemed to exert more effect than was to be expected from its toxic acid value.

The above experiments show that in rabbits neutralized betaoxybutyric acid is toxic and that it produces symptoms similar to those of the acid itself. It seems probable that in some of the cases of diabetic coma the effects produced by betaoxybutyric acid production in the body are not due entirely to its withdrawal of alkali from the blood, but that its salts, arising from combination with the blood alkali, are still toxic, though in a lesser degree. The failure or only partial success of sodium carbonate infusions and of the alkali treatment in general is probably due to the poisonous action of neutralized organic acids which are not removed from the organism.

It thus appears that the pathologic effects of acidosis can not be wholly due to the withdrawal of alkali from the blood and various tissues, and this is the outcome of my experiments which I desire especially to emphasize.

Oxygen in Surgical Infections.—Dr. Thiriar recently communicated to the Belgian Académie de Médecine his further successful experience with the direct application of a stream of oxygen to infected tissues. He uses it in the form of a permanent application: a tube is inserted in the lesion, communicating with the oxygen tank, and left undisturbed for several days. Every case of infection of a serous membrane has been benefited by this treatment in his experience, but the results have been most striking in gaseous septicemia. The oxygen not only stimulates the tissues and promotes phagocytosis, but also kills the germs, substituting an oxygenated emphysema for the microbial emphysema. Oxygen applied under pressure to a furuncle or carbuncle has always aborted or cured it in a few days, and it has proved its usefulness in hundreds of cases of diffuse phlegmons, gangrenous erysipelas, suppurating complicated fractures and arthritis. He does not advocate it for generalized infections, although recent publications have proclaimed the feasibility of intravenous injections of oxygen, with which Thiriar has had no experience. The *Gaz. Méd. Belge* of August 6 gives the particulars of several cases of suppurating knee affections treated by Thiriar's method as an adjunct to operation, commenting on the rapid and perfect healing under the stream of oxygen.

A NEW METHOD OF LATERAL ANASTOMOSIS.

PRELIMINARY REPORT.

AXEL WERELIUS, M.D.
CHICAGO.

The object of this paper is only to record the technic of the operation. The result of experimental work now in progress will be published later.

STEP 1.—Fix by guy suture opposing surfaces of intestines, or stomach and intestine, as the case may be.

and sew (Fig. 1) with running through-and-through suture.

STEP 2.—Insert a silk or twine ligature or silver wire (Fig. 2), running into lumen of bowels, as in the McGraw ligature.

STEP 3.—Cover the silk ligature by folding adjacent parts of intestines over it and sew with through-and-through suture, leaving the free ends of the silk ligature on the outside (Fig. 3).

STEP 4.—An assistant holds the united tissues firmly on the opposite side of the free ends of the ligature. By alternate pulling of the right and left ends of the silk ligature, the tissues are neatly cut through and an anastomatic opening is made, the thread escaping through the minute slit between the sutures. Take one more stitch where the thread slipped through and the operation is complete.

By this last maneuver, which is the distinguishing feature of the operation, the bowel is cut through without exposure of the mucous surfaces. The operation is

complete at once, leaving no foreign body. There is no puckering.

It is extremely simple, and takes less time than any similar operation.

Clinical Report.

A PECULIAR CASE OF POISONING.

MATT A. REASONER, B.S., M.D.
MORRISONVILLE, ILL.

History.—Boy, aged 7, had in some manner acquired a taste for asafetida, and without the family's knowledge had been in the habit of eating it for six months. A large quantity of the drug was procured in order to prepare some hog medicine, and the boy found it and ate all he wanted.

Examination.—When discovered he was in a semi-stuporous condition, lying down, body relaxed and warm, pupils dilated, unable to stand erect without falling. Pulse weak, feeble, accelerated; respirations shallow, irregular and about 22 a minute; expectoration rather profuse. Within a couple of hours the odor of asafetida was plainly discernible in the different secretions, and for several days after in the diarrheal bowel movements.

Treatment.—I did not see the patient until probably one hour and a half after eating the asafetida. I used emetics, evacuants and stimulants. He was much better in two hours, but some of the effects remained for twenty-four hours.

New Instruments.

ACETYLENE HEADLIGHT AND REFLECTOR FOR NIGHT OPERATING.

EVAN O'NEILL KANE, M.D.
KANE, PA.

This acetylene light is designed principally for night emergency and other outside surgical work, and especially for illumination of the abdominal cavity. It burns with extraordinary brilliancy. It is almost equal to the sun's direct rays for at

position by a shoulder and waist strap. The whole affair is simple, easily operated, rapidly adjusted and can not, like an electric apparatus, fall out at the critical moment by getting out of order. All that is necessary is to be sure that the receptacles in the generator for carbid and for water are filled; simply touch a match to the burner and magnificent illumination is sure to result.

I have been experimenting with acetylene gas for this purpose for some time, and I am confident that my device is far superior to anything else now before the profession. The only drawback to this apparatus worthy of mention is its price, the expense of operating it being a mere trifle of a few cents; but when placed regularly on the market I am assured it can be obtained very reasonably. I have a few modifications and improvements still to make in this lamp, but even as it is I can promise any operator that he will consider it indispensable after once employing it.

Fig. 1.—The headlight, showing head band and tube.

Fig. 2.—Method of using headlight.

least three feet from the reflector. No heat is thrown back against the face or forehead. Fitted firmly on the brow, it enables one to throw the light in any direction, even vertically. Both reflector and light turn on a ball-and-socket adjustment.

The burner is fed through a rubber tube which passes over the head and down the back and is out of the way while operating. From the back the tube passes around to the side to enter the generator worn there. This generator is retained in

A NEW TONSILLOTOME.

E. E. STRAW, M.D.
MARSFIELD, OREGON.

The instrument here represented is a double-curved scissors, the blades of which are connected to the handles by means of a tube and shaft. The handles are held by a detachable and reversible lock, and the blades joined at the distal ends by a pin-lock. A slot one-eighth of an inch wide, running the entire length of the tube, allows the passage of the shaft in taking the instrument apart and putting it together. A separation or closure of the handles rotates the shaft inside of the tube and causes a corresponding motion of the blades.

This tonsillotome possesses the following advantages:

1. It engages the whole tonsil, and the curvature of the blades is such that any desired amount of tissue can be removed at the first cut without danger of injuring the faucial pillars.

2. The tendency of the blades is to pass behind and not through the tonsil, and by severing the blood vessels in the soft underlying tissue the danger from serious hemorrhage is diminished.

3. Little, if any, preliminary dissection is required.

4. The operator's hand is placed in a comfortable position and does not interfere with his view.

5. The blades can be thrown wide apart without any motion of the instrument in the patient's mouth.

6. It has reversible handles and therefore can be used for either tonsil.

7. Its construction is simple and it has no delicate parts that are liable to get out of order.

Absorption of Silk Sutures.—Silk sutures, when buried in the tissues, are considered non-absorbable, but Dr. E. Muirhead Little, in a letter to the *London Lancet*, reports a case in which silk sutures, which had been placed in a tendon, were absorbed after fourteen months.

MODERN PRISON SYSTEMS.

The United States Government has recently issued a "Report on Modern Prison Systems," written by Dr. Charles R. Henderson, which brings together some very interesting material especially concerning the present status of European continental prisons.

Probably few of the social contrivances of men have changed more than the prison and the penitentiary. It is not many centuries since our English forebears felt no responsibility for a prisoner beyond his literal safe-keeping. Bolts and bars were provided by government, but food, for instance, was to be obtained by the prisoner as best he could. Although it has been shown that in certain modern prisons conditions have been so prejudicial to health in very recent years that a ten-year sentence was "equivalent to capital punishment," yet in the main it is perhaps true, as Dr. Henderson points out, that a conscientious effort is now made in a number of our prisons for the conservation and improvement of the bodily health of the prisoner. Dr. Henderson says: "If we adopt the purpose which is coming to be decisive—that is, the protection of society through the rehabilitation of the prisoners—the physical care becomes a matter of fundamental interest, and this from several considerations. Physiologic psychology has demonstrated the causal connection between the will and normal conditions of the body; a man can not make a choice or decision and persist in a purpose without having a stored supply of physical energy. Perhaps the most distinctive trait in a body of criminals is not violence or cunning, but simply feebleness and low vitality. . . . Therefore, the intelligent warden or superintendent aims first of all to brace a man for the struggle of life by improving his physical health."

In view of this interesting and sanguine introduction, some of the details furnished from the official regulations of the penitentiaries in various countries are somewhat disappointing. The report considers the prisons of the chief European nations, with the exception of Russia, and along with general descriptions of prison organization gives much information as to dietaries and sanitary regulations. The dietaries in some of the foreign countries seem inadequate to American readers, though they may be proportioned to the general standard of living in the same countries. It is, however, startling to an American to learn that, out

of the twenty-one meals weekly in the prisons of Würtemberg, nine consist of a little more than half a pint of "soup" made of hot water and black bread. At two meals in each week and on extra holidays the prisoner is allowed a little less than a quarter of a pound of meat. The other meals consist principally of vegetable soups and various flour foods. The Holland dietary, though slightly more generous, is still very restricted in quantity and variety. It has been the reproach of English prisons up to very recent years that a prisoner was doomed always to be hungry. On the whole, it is probably true that the American prisoner is the most liberally fed of all. However, among the thousands of county jails and city prisons each is a law unto itself. Some are lavish, some niggardly. Dr. Henderson very properly suggests as one of the most desirable reforms in administration of jails in the United States the establishment of a standard legal dietary with power lodged in a state board of supervision to see that it is enforced. As yet there is no approach to a common understanding on the subject. "The admirable studies of food published by the Department of Agriculture will ultimately assist in the preparation of a standard dietary suited to American conditions."

The criminal class naturally shows a strong tendency toward various neuroses and especially toward insanity. In some countries in the selection of prison physicians the preference is given to those who have had experience in hospitals for the insane. In Holland and Belgium provision is made for periodical inspection of prisons by expert alienists. Prisoners who become violently insane are removed to the state asylums, but the system of special asylums for criminal insane is apparently further advanced in America than in the continental countries. Sometimes special expert commissions are sent from the institutions for the insane to inspect the prisons at regular intervals or for special cases if necessary. The German states and Belgium have notably good regulations on these points. It is true that the details of punishment and discipline, the limited exercise and food, the scant provisions allowed for cleanliness, as set down in the various official regulations, indicate a rather inadequate fulfillment of the larger conception of the physical aim of the prison with which the author sets out. Yet there are points of great encouragement. For instance, it is indisputable that the Elmira Reformatory has furnished to the world the best and earliest practical example of a prison conducted on the basis Dr. Henderson describes. It has undergone many vicissitudes of management, but the principles on which it is conducted not only have for their basis the conviction that a healthy body is an essential condition of mental and moral sanity, but the practical carrying out of these principles has demonstrated their truth.

To the Italians we are, of course, indebted for those brilliant studies in criminal psychology which have given

a world-wide impetus to the understanding of the physical basis of moral disorder, and have brought the criminal class within the recognized field of medical science.

There is one point of great significance in this report, namely, the fact that in the European prisons the appointment of all officials and the entire control of the prisons is shown to be free from political influence. As we have had occasion to point out in discussing the public care of the insane, political control and scientific progress are eternal enemies. As soon as this incubus is removed the higher standard of living in this country, the simpler democratic attitude toward individuals, and, above all, the growing interest of the schools and universities in social science, give cause to believe that the American prison may become truly humanizing.

THE CURABILITY OF PULMONARY TUBERCULOSIS.

It is not without reason that pulmonary tuberculosis has been dubbed "the white scourge," "the captain of the men of death," and similar terms denoting its destructive effect on human life. It is probable that the knowledge of its great mortality has led both the laity and the profession to too pessimistic a view of the curability of this disease. When we consider some of the recent statistics, such as those of Naegeli and others, which show that practically everyone has some form of tuberculosis before death, one is led to the conclusion that tuberculosis is the most curable of the more chronic diseases.

In a recent article Blumer and Lartigau¹ give the results of an analysis of 500 consecutive autopsies with regard to the prevalence of healing or quiescence in pulmonary tuberculosis. They regard as evidence of healing the patches of cicatricial tissue found in the region of the apices, and also the calcareous nodules so frequently present in the lungs. Neither of these lesions can be definitely proved to be residua of tuberculosis, because inoculation experiments with them are negative, but in the case of the calcareous nodules there is little doubt, as all stages, from caseous to calcareous areas, can be traced, and in the case of the apical scars their situation, their frequent association with active lesions, and the fact that they may be the only findings in individuals who are known to have had tuberculosis during life makes their previous tuberculous nature practically certain. The writers point out that any area which contains caseous material can not be regarded as healed, inasmuch as inoculation experiments with caseous material are practically always positive; they, therefore, regard such areas, whether encapsulated or not, as merely quiescent.

Inasmuch as in previous articles the healed and quiescent cases are considered together, Blumer and Lartigau follow the same course with their cases. They show that the percentage of healed pulmonary tuberculosis reported varies from 4 per cent. to 100 per cent.,

their own cases showing 28.8 per cent. The great differences in the reported statistics are due, they think, to a variety of causes. In some instances routine autopsy records are used made by many observers, many of whom were doubtless not at all interested in healed tuberculosis and were not looking for it particularly. In other articles all cases of active tuberculosis were excluded in making up the statistics, this tending to make the percentage of healed cases higher. Another source of error lies in the fact that some statistics cover cases from hospitals with patients suffering from acute illnesses, others cases from hospitals for chronic disease, others almshouse cases, and still other deaths from violence or suicide. The most important factor regulating the per cent. of cures, and one which is not mentioned in many of the reports, is the age of the patient. The authors show that where a very high percentage of cure is reported the patients are practically always old people. The cases analyzed by Blumer and Lartigau were some of them hospital and some of them private cases, and were all particularly scrutinized for signs of healed lesions in the lungs. The figures obtained by these observers show that the signs of healing, as would be expected, corresponded to the areas in the lung most often the sites of active tuberculosis. Almost the same percentage of healing occurred in females as in males, the former showing 29.4 per cent. of healing to 28.4 per cent. on the part of the males. The analysis of the cases as regards age brought out the most interesting figures. In both males and females there was very little tendency to healing up to the age of 15, and no very marked tendency even to the age of 25; after this age, however, the active cases tended very strongly to decrease and the healed or quiescent cases to increase, and the tendency to healing grew more marked as age advanced. Curiously enough, the active cases reached their height in the females ten years before they did in the males, and healing cases began to be common in the females ten years before this was the case with the males.

The whole study tends to show the curability of pulmonary tuberculosis, but it also shows that the tendency to spontaneous cure can not be relied on to any great extent in childhood and early youth, and impresses on us forcibly that at these periods of life especially the diagnosis of the disease must be made early if successful treatment is to be hoped for.

GRAFT IN PUBLIC INSTITUTIONS.

Occasionally it happens that a physician of excellent professional standing is appointed to a public position, such as the superintendency of a state institution, and that thereafter the newspapers begin to teem with stories of mismanagement, of revolts, and of general turmoil in the institution. And then it is insinuated that doctors are not business men. The man on the inside knows better. The sweeping statement can be made that the majority of our public eleemosynary

1. California State Journal of Medicine, September, 1904.

institutions are the subject of more or less "graft." This "grafting," except on the pettiest scale, is difficult when a shrewd man is at the helm. Therefore, the "grafters" must have a superintendent who, at least, is complaisant.

In two different instances, each in a separate state, medical men possessing administrative ability to a marked degree have had trouble all through their administrations. At the beginning the old "grafters" had been found and decapitated. These joined forces with others who wished to have a part of the spoils, and a regular plan was formed to foment turmoil in the institutions. Subordinate employes have been incited to drink and to disorder, assistant physicians have been told false and damaging stories regarding their chiefs, the legislature has been influenced to curtail necessary appropriations, and everything possible done to keep the superintendent in hot water, in order to make a showing that he is a poor administrator. This process is extremely harassing, and few can stand it. So it comes that the higher class of medical men rarely seek these positions where they could do so great service to medicine and to the commonwealth.

Indeed, nowadays one may almost conclude that administrative peace in an institution, whose management is in the hands of those appointed by partisan politicians, means that the "grafters" are allowed free hand, either for a share of the plunder or because of a convenient lack of vision that is assumed as the price of peace and of continued tenure of office. The superintendent is safe, and is a "good fellow" if he neglects to see that his wards are getting renovated butter when the state is paying the market price of good butter; that the coal bill is increased by the inclusion of quantities of slate; that the beef bill is swelled by the steward sharing in "short weighing" of cattle, and that the foundation of a heavy new building is being made out of loose, unshaped stone held together only by poor mortar.

As a rule, it is a sign that a superintendent of good repute is manfully doing his duty if discharged employes and small political fry bring against him all manner of charges, and keep it up persistently month after month. At least, one such battle is now in progress, but the superintendent, fortunately, has at his back the organized profession of his state. He should win.

And here a suggestion is permissible. In every such case the medical profession has a chief interest not yet acknowledged by the politicians. If there is doubt as to the true state of affairs, the state association or the county society should appoint a committee of members of tried integrity to investigate the institution's affairs minutely and report publicly; we repeat, report publicly. In this way the medical profession can do what it ought to do—discourage institutional "grafting." In this way, too, it can demonstrate to the public and to the politicians that it has a real interest in institutions for the care of the sick, the infirm and the insane.

THE PROBLEM OF A SATISFACTORY MILK SUPPLY.

It is not always easy to determine the most effective method of improving the quality of town and city milk supplies. The matter, however, is, as the French express it, on the order of the day. It is well known that various more or less tentative efforts looking toward reform have been made by many communities. Some of these experiments have been crowned with a high degree of success, but it is an open secret that the campaign for pure milk has not been equally effective in all places.

Under the circumstances, the experience of one remarkably successful method is of value to other municipalities similarly situated. The persistent endeavor made by the town of Montclair, N. J. (population in 1904 about 17,000), for a pure milk supply has been based on the doctrine of thorough investigation followed by publicity, and the result of this mode of procedure is worthy of deliberate examination. The tenth annual report of the Board of Health of Montclair (1904) now before us, affords an interesting illustration of the actual practice. Detailed and candid statements are made concerning the condition of the twenty-one chief sources of milk supply; together with these are given the complete reports of chemical and bacterial analyses based on the examination of monthly samples. In each case the name of the proprietor of the milk route is printed in full, as well as the names of the farmers from whom the supply is obtained. The comments on the cleanliness of surroundings and on various important details of conducting the business are decidedly frank, and there seems to be no reason why any citizen of Montclair should not keep thoroughly informed regarding the character of the milk furnished his household.

Two examples of the outspoken method followed in the printed report are, perhaps, worth quoting: "Albert and Eug.—As predicted last year, this supply has proved unsatisfactory to Montclair, and gave up the ghost after a little struggle." "The Puritan Dairy.—W. H. and R. S. Francisco, owners of this dairy, have kept it in better condition than usual this year, but it is necessary that they make further effort to keep down the bacteria and the dirt." Other milkmen and proprietors are, respectively, admonished to remove manure heaps from the neighborhood of the dairy, to discontinue the use of straw and hay as litter, and to use more whitewash. The open and public character of these statements and warnings must, in a large measure, be responsible for the high degree of success attained by the Montclair method. That the success is a real one is evinced by the analyses included in this interesting report. In view of the general legal requirement in our cities of a butter-fat content of 3 per cent., it is noteworthy that only eight of the twenty-one Montclair supplies failed to maintain an average of upward of 4.5 per cent., and that the lowest average of all is 1.27 per cent. ! The number of bacteria found in nearly

all the samples of milk is remarkably low. The highly satisfactory condition prevailing in Montclair is no accident, but is the outcome of an organized and systematic campaign.

The following extract from the report just cited is suggestive reading for citizens of other communities in which at the present time conditions are less favorable: "After ten years of unremitting effort to secure a pure milk supply for Montclair, it is felt that in a large measure success has been attained. Most of the dairymen are thoroughly aware that it is impossible to market an unclean or impure milk in town for the simple reason that the public will not buy it. The successful dairymen have brought their plants to a high degree of perfection, and the others are compelled to follow their example by the mere force of competition. Nearly all the men keep their cows in stables, which are ceiled and which are cleaned twice daily. The use of straw and meadow hay for bedding has been given up by all of the best dairymen and by most of the others. The feed is carefully selected, and the cows are kept clean and in good condition."

BLOOD PRESSURE IN THE INSANE.

That certain conditions are attended more or less constantly with a blood-pressure that varies only within narrow limits might be inferred from *a priori* reasoning, but knowledge on this subject is as yet too scanty to permit of the formulation of definite conclusions. As a matter of fact, it is only within comparatively recent times that methods have been devised by means of which it is possible to measure the blood-pressure with the facility necessary to make such a method of clinical utility. An important step forward would, indeed, be made if the conditions under which blood-pressure is raised or lowered respectively were established, as it is probable that information of this character would constitute a most valuable therapeutic guide. While it seems likely that the blood-pressure is subject to considerable variations even under apparently like conditions, it may be found, nevertheless, that it pursues a certain curve that may prove more or less distinctive. Observations have already been made indicating that the blood-pressure is increased in connection with depressive mental states, such as melancholia, and decreased in the presence of mental disorders attended with excitement, such as acute mania. It has further been found that the blood-pressure varies in the course of the same affection; for example, circular insanity, accordingly as a state of excitement or one of depression prevails.

With the view of determining the value of blood-pressure observations in their bearing on the diagnosis and treatment of mental diseases, Dr. W. R. Duntont¹ undertook a study of the subject at the Sheppard and Enoch Pratt Hospital, the results of which, while not conclusive, are at least interesting and suggestive. At

first a series of single observations were made on a number of patients, but it was soon realized that accurate results could not be obtained by such a method, so that later the blood-pressure was regularly measured in several cases throughout the course of the mental disorder. The readings were taken in the ordinary way, just as observations of temperature, pulse and respiration are made, no attempt being made to isolate the patient from sights and sounds that might affect the reading, and the patient not being asked to lie down, if up and about.

It was found that the continuous taking of the blood-pressure is of little value in the majority of mental cases, and the plan was adopted of taking it for a limited period, then discontinuing the observation, and resuming it at another period, whenever a change in the motor or mental condition of the patient occurred. While no point could be observed where there was any change sufficiently marked to be noticed as corresponding with any mental change, and no constant ratio, direct or indirect, could be made out between the motor, mental and blood-pressure curves, nevertheless the average blood-pressure was found to be low in connection with motor restlessness or mental excitement and high in connection with depressive conditions or diminished mental activity. The influence of the motor condition on the blood-pressure was greater than that of the mental condition. A moist state of the skin was without especial influence on the blood-pressure, although it is thought active perspiration may have such an effect. The observations of others that the blood-pressure is lower in the evening than in the morning could not be confirmed.

THE DANGER FROM ARSENIC IN CLOTHING.

The Department of Agriculture has been investigating the amount of arsenic used in coloring wall papers and in preserving articles of clothing. Samples of wall paper were purchased in the open market in Washington and examined. Only four samples contained more than 0.1 grain to the square yard. This is the maximum quantity allowed by the law of Massachusetts, which is the only state in the Union having a law regulating the use of arsenic in wall paper and wearing apparel. Several samples of stockings were examined, and a number were found to be heavily charged with the poison. Black stockings seemed to contain a larger amount of the drug than colored stockings. Furs and fur rugs were found to contain from 20 to 1,700 times as much arsenic as would be allowed by the law of Massachusetts. Poisoning caused by wearing garments containing arsenic is a very real danger and menace to health, which is probably often overlooked. Many cases of arsenical poisoning of obscure origin, no doubt, might be traced to a small abrasion of the skin of the feet or neck being brought into contact with hosiery or furs containing arsenic. This is another factor in the etiology of disease, for which the practitioner must watch until the government shall control the matter.

1. American Journal of Insanity, vol. lxi, 1, p. 41.

LARGE FEE SECURED BY MORAL VIOLENCE.

A distinguished Paris surgeon, whose methods have come sometimes under the criticism of his confrères, is in trouble. It is reported that he demanded a fee of \$20,000 to cure a patient with an anticancer serum, after having begun the treatment and declared the case a curable one, and that he threatened to discontinue his services if it was not at once paid. The patient became worse and finally died, and her husband is now suing the physician for the sum paid, pleading "fraud and moral violence." The plaintiff in the case is an American, as in another recent case noted by us as occurring in Germany. The proper moral to be drawn from the facts is, do not go to those who claim too much, and be especially shy of those who have not the full confidence of their own professional confrères or who have come under their criticism generally for methods or acts deemed unethical. The moral that will probably be drawn by many Americans is not to go abroad for treatment, and such occurrences will be likely to diminish the profits of foreign physicians from American tourists.

VACCINATING UNDER RED LIGHT.

A Hungarian physician, Dr. Hugo Goldmann,¹ has been vaccinating children with the exclusion of the chemical light rays. He vaccinated forty children in a room like a photographer's "dark chamber," that is, lighted only by a red lantern. The arms were then dressed with red cloths applied to exclude the light. A slip of photographers' sensitized paper was placed under the dressings to serve as a test for the exclusion of the chemical rays, and also to learn whether the dressings were tampered with. In each instance the pustules, it is said, developed typically, but without the slightest inflammatory reaction. The scar was typical, although small, and there were no general symptoms of any kind. Subsequent inoculation was always negative. The other arm was vaccinated in the usual way on some of the children, with the result that it became swollen and painful, with more or less fever and general symptoms. In some instances the red dressings were removed the second, third or tenth day, and the course of the pustules seemed milder than those of the controls.

THE POSSIBILITIES OF THE MEDICAL DEPARTMENT OF AN ARMY.

The ideals seem almost attained in the roseate picture presented by Dr. Louis L. Seaman,² concerning the remarkable work of the Japanese army medical department. He states that the medical corps has here its rightful position, and has authority over such details as rightly belong to it. He describes—having just returned from Manchuria—the Japanese medical officers testing water supplies in the forefront of the advance guard, inspecting all forage and supplies, and searching every village that is approached by the vast army, lest some insanitary condition imperil the health of the

soldiers and thus weaken the fighting force. He calls attention to the result, a mortality due almost entirely to the actual results of combat. The medical work is carried out with skill and speed, details are not neglected, and the rate of recovery from wounds is remarkable. He makes the pertinent remark that the United States Army should improve on Japan's system or else meekly follow it. His words are well worth heeding. If here is an example of the possibilities of the sanitary, prophylactic and reparative aid of the medical profession in warfare, when free from the hindrance of being subordinated to other departments, it should be well studied.

CENTENARIANISM.

The secular press is at present, or has been recently, considerably taken up with discussions of methods of obtaining longevity, and one little item which has the alleged authority of Professor Metchnikoff has been widely copied. It is that sour milk as a diet is specially conducive to longevity, more so, in fact, than any other form of food. It is the common drink among the Bulgarians, and they are said to furnish the largest number of centenarians. Some one has suggested that it is the ignorant and indolent who live to a good old age: it is at least exceptional to find a man of science like Chevreul or persons of cultivation or those taking an active part in the life of the age reaching one hundred years or over. Extreme simplicity in the mode of life is conducive to longevity. If a person should follow all the advice given, assuming that all be good, and live under the strenuous conditions of modern civilization, he might increase the chances of living one hundred years by a minute percentage above the present figure of one chance in one hundred thousand. Inasmuch as the conditions usually suggested involve some inconveniences and self-denials—as, for instance, living on sour milk—most individuals would probably not think the game worth the candle. At present, and probably for a long time in the future, the continuance of life to one hundred years or over is a happy—or shall we say an unhappy—accident, and being a centenarian, with its physical infirmities, is at best a mighty lonesome condition.

RHEUMATOID ARTHRITIS AND NERVOUS DISEASE.

Rheumatoid arthritis has not generally been included in the nervous disorders, and only in one recent text-book—that of Pearce—we find it thus placed. Nevertheless, the conviction seems to be growing that it is at least closely allied to certain of these diseases. Attention has been called to these points by Spiller and Llewellyn Jones, who have pointed out apparent relationships with paralysis agitans, tetany, exophthalmic goiter and symmetric gangrene, and the latter author concludes that rheumatoid arthritis, like certain other toxemias, "tends to pass into that gloomy region of medicine consecrated to system diseases of the cord." There are many reasons for supposing that rheumatoid arthritis is even primarily associated with a neurotic predisposition, and that the toxemia is only an exciting factor. Such are the marked heredity in some cases,

1. Wiener klin. Woch., vol. xvii, No. 36, Sept. 8, 1904.

2. Before the International Congress of Military Surgeons. See Society Proceedings, page 1247.

its occurrence in neurotic families (which has been frequently noticed) and the fact that it is not exclusively aroused into existence by toxic agencies, but that traumatism, exposure and nervous and debilitating influences may also be its antecedents. Still more striking in this connection are the facts that in some cases the motor paresis may locally precede the sensory and arthritic symptoms, a fact difficult to explain on the reflex theory of the rheumatic paralyses. That it depends on any special microbe seems highly improbable. Its aggravation by almost any form of active infection is against this hypothesis. While it will probably be long included among the more obscurely known disorders, its proper place, it seems possible, will be found from the balance of evidence to be among the diseases of the nervous system. A thorough pathologic study of cases in all stages of the disease as occasion offers is highly desirable.

THE ADMINISTRATION OF NITROGLYCERIN.

When it is desired to lower an abnormally high blood pressure and to alleviate symptoms associated therewith, such as headache and giddiness in arterio-sclerosis, no drug yields better results, when judiciously employed, than nitroglycerin. Physicians are, however, greatly disappointed at times when they give this remedy, the expected effect not being obtained. It would appear that disappointment is most common when the nitroglycerin is administered in tablet form. An examination of nitroglycerin tablets has revealed the fact that their nitroglycerin content is very variable, and that many of them contain extraordinarily little of the substance. Binz of Bonn, in several instances, was unable to demonstrate any nitroglycerin at all. Von Noorden of Frankfort, in view of these facts, urges the use of an alcoholic solution of nitroglycerin of the strength of 5 per cent. He asserts that when sufficient doses of this are used, one is certain, in suitable cases, of obtaining wholly satisfactory results. He has used the alcoholic solution extensively in his wards during the last few years, and finds its action much more constant and much safer than when tablets are employed. He asserts that it is permissible to give much larger doses than has hitherto been thought warrantable. Thus, when one begins with small doses and gradually increases the amount, as much as 10 milligrams (gr. 1/6) or even 12 (gr. 1/5) of nitroglycerin may be given in twenty-four hours, without any untoward symptoms becoming noticeable. Von Noorden has often been able, in cases with a blood pressure of from 180 to 220, controlled by repeated preliminary measurements, to reduce the pressure by gradually increasing doses of nitroglycerin to 100 or 120, or even lower. He finds, further, that the pressure remains low, not only as long as the drug is being administered, but very often for a time after the medicine has been stopped; it may remain low, as in one case, for eight days after the last dose, in another for twelve days or for two or three weeks, after which nitroglycerin may be begun again. It is hoped that this suggestion may be helpful in removing one of the many uncertainties of pharmacotherapies.

THE ULTRAVIOLET MICROSCOPE.

It often occurs that, soon after the declaration has been made that progress in a certain direction has reached its ultimate limit, new and unexpected discoveries are made. Many had believed until recently that the compound microscope had reached its maximal development, not owing to inability to construct lenses of greater magnifying power, but on account of the supposed impossibility of further illumination. Then came the remarkable invention of the ultramicroscope, which has been repeatedly referred to in these columns, and which renders particles of molecular size, hitherto totally outside the range of sight, visible. Just recently the Zeiss foundation has made available another new instrument, known as the ultraviolet microscope, which represents a most important advance. In this instrument, too, it is the mode of illumination and the method of utilizing it that characterize the invention. The shortest wave-length of light not absorbable by the lenses of ordinary microscopes is 550. By the use of a microscope in which the lenses are made entirely of quartz, it is found that a wave-length of 275 can be employed. The source of light is from cadmium electrodes. Condenser, slide and cover-slip lenses, all are made of quartz. By the naked eye nothing is seen through such a microscope, but by using an ocular containing a fluorescent screen, the rays are converted and a picture of the object may be seen in green. This fluorescent screen is for focusing purposes only; the real results are gained by photography. Photographic plates are very sensitive to the rays sent out from the cadmium electrodes, and the detail obtainable with wave-lengths of 275 is remarkable as contrasted with the detail from light of a wave-length of 550. Indeed, the effects are in many respects totally different from those gotten by ordinary illumination, for, as with the *x*-rays, some structures are penetrable by the cadmium rays and others are not. A wholly new method of differentiating unstained histologic structures is thus afforded us. The photographs already made of cells undergoing karyokinesis, of nostoc and of yeast-cells are full of promise for the future application of the instrument.

Medical News.

CALIFORNIA.

Antitoxin for Football Team.—Because of the prevalence of diphtheria at Leland Stanford University, all the football team have received prophylactic injections of antitoxin.

Accidents.—Dr. William W. Kerr, San Francisco, was severely cut and bruised in a head-on automobile collision, October 3.

—Dr. Thomas E. Ellis, Elsinore, was thrown from his buggy in a runaway accident, September 29, and fractured his clavicle.

Cancer-Curer Has License Revoked.—The State Board of Medical Examiners in 1903 revoked the license of S. R. Chamley, San Francisco, who advertised a "cure-all" for cancer. Chamley carried the matter into the courts and on September 29 Judge Cook of the Superior Court decided that the board acted within its rights and refused to give the petitioner relief.

Hospital Notes.—The Pacific Electric Railway System is planning to erect a hospital at Los Angeles to cost \$100,000. —The German Hospital, Los Angeles, was formally opened October 2. —Work on the Merritt Hospital, Oakland, will probably begin this month, as the trustees after long litigation

are now ready to proceed with the execution of the trust. — Fabiola Hospital, Oakland, will erect a new addition to the nurses' home connected with the hospital, to cost \$11,700.

College Opens.—The twentieth annual session of the Medical College of the University of Southern California, Los Angeles, opened October 13 with an address by the dean, Dr. Walter Lindley. Among faculty additions are Dr. Luther M. Powers, hygiene and state medicine; Dr. Louis G. Vischer, diseases of stomach and intestines; Dr. Albert Soiland, electro-therapeutics and radiology; Dr. Francis M. Pottenger, pulmonary tuberculosis and climatology, and Dr. W. A. Edwards, diseases of children.

ILLINOIS.

Personal.—Dr. William E. McClelland, Beason, is reported to be seriously ill with appendicitis.—Dr. and Mrs. Rufus J. Coultas, Mattoon, have returned from their trip abroad.

Physician Wins.—In the suit instituted by William P. Buchanan against Dr. William O. Beam, Moline, for alleged malpractice in the treatment of a dislocated shoulder, the jury decided in favor of the defendant.

Smallpox.—On October 17 Dr. Baker of the State Board of Health reported that there were 56 cases in Belleville and 75 in East St. Louis. In the past few days four deaths from the disease have been reported. Joliet reports five new cases and Peru still has four cases.

Scalds or Disease?—The death of a patient at the Illinois Hospital for the Incurable Insane, Bartonville, has excited much comment. The coroner's jury alleged gross carelessness and negligence on the part of the management of the institution, but the assistant physician states that death was due to senile gangrene, and the attendant avers that the water in which the patient was alleged to have been scalded to death was only "milk-warm."

Chicago.

Twenty-Minute-Old Baby Vaccinated.—A smallpox patient at the Isolation Hospital gave birth to a boy baby October 10, and within twenty minutes of its birth the child had been vaccinated.

Unlicensed Practitioner Fined.—Mrs. Anna Lietz was found guilty of practicing medicine without a license October 14 and was fined \$100 and costs. The fine and costs were suspended. The prosecution was at the instance of the State Board of Health.

Alleged Abortionist Attempts Suicide.—Dr. Alois Rasmussen, charged with having caused the death of a woman by an unlawful operation, took morphin while in a cell in Chicago avenue police station October 14, but was revived after much difficulty and will probably recover.

Davis Memorial Service.—A service in memory of the late Dr. N. S. Davis will be held Sunday, October 23, in Powers' theater. The principal addresses will be made by Bishop S. M. Merrill of Chicago and the Right Reverend J. L. Spalding, bishop of Peoria. Beside music, there will be five or ten-minute addresses by Drs. Billings, Murphy and others. The committee announces that a cordial invitation is extended to all.

Deaths of the Week.—The 424 deaths from all causes reported during the week are 14 more than the total for the week previous. Consumption, 62, shows the greatest increase, 13, followed by bronchitis, 11 more, apoplexy, 9 more, Bright's disease and pneumonia, each 8 more. On the other hand, there were 15 fewer deaths from acute intestinal diseases and 4 fewer from typhoid fever. The deaths from consumption form 14.6 per cent. of the total mortality, but those from pneumonia are only 8.4 per cent. of the total.

INDIANA.

Hospital for Children Opens.—Eleanor Hospital, Indianapolis, devoted to the care of sick children, was opened September 22 by the Flower Mission.

Richmond Hospital Begun.—The cornerstone of the hospital given by Daniel G. Reid of New York City to the city of Richmond was laid September 27.

Accidents.—Dr. Nathaniel H. Manning, Elwood, was thrown from his buggy October 3 and painfully bruised.—Dr. Emil Schable, Lafayette, was knocked down by his horse October 1 and painfully injured.

Disease and Death in September.—The monthly bulletin of the State Board of Health for September says: "Sickness in

the state this September was less than in the same month last year, and was also less than in the preceding month. Diarrheal diseases were most prevalent, and then in regular order follow typhoid fever, rheumatism, tonsillitis, bronchitis, scarlet fever, erysipelas, malarial fever, pneumonia, diphtheria, influenza, whooping cough, measles, purpural fever and cerebro-spinal meningitis. Typhoid fever was reported present in all but 13 of the 92 counties. There were 137 deaths from the disease and 702 cases reported. The number of deaths is accurate. The number of cases is probably twice as great as here given. The total number of deaths was 2,658, or an annual rate per 1,000 of 12.2. In the corresponding month last year the deaths numbered 2,766, or 13.4 per 1,000. There were 287 deaths from consumption, 20 fewer than in the corresponding month last year. Diphtheria deaths were 12 as compared with 35 in September, 1903. Very little influenza was reported in the month and only one death occurred from this disease. Cancer claimed 115 deaths, violence 146 and smallpox 12. Of the 332 consumption deaths 132 were males and 200 females. One hundred and eighty-five, or 56 per cent., were between the ages of 15 and 40. Eighteen were fathers between the ages of 18 and 40 and they left 36 orphans under 12 years of age. Of the females 59 were mothers between the ages of 18 and 40, and they left 118 orphans under 12 years of age. This monthly havoc wrought by consumption could be reduced 50 per cent. in three years if the people would unite against the disease causing it. Of the 146 violent deaths 3 were murders, 27 suicides, and the remainder accidental, of which railroads killed 31, street cars 1, gunshot wounds 11, electricity 1, drowning 8, and burns and scalds 11. Smallpox is reported in 22 counties, 197 cases in all, with 12 deaths. All of the deaths occurred in Vigo County. At several points the disease appeared in virulent form. Several of the Vigo County deaths were from hemorrhagic smallpox. Cases of confluent and semi-confluent smallpox are now quite common and hemorrhagic smallpox is reported not infrequently. All of this shows that the disease is becoming more virulent, as has been predicted would be the case.

IOWA.

Physicians Purchase Ambulance.—The physicians of Des Moines have purchased and presented to the city a new \$1,000 ambulance.

State Medical Department Opens.—The State University of Iowa College of Medicine, Iowa City, opened for the year in its new buildings, September 29. Dr. Elmer F. Clapp delivered the opening address.

Reference Medical Library.—Medical men of Dubuque have combined and subscribed for 19 medical journals, which are to be placed on the shelves of the public library for the use of physicians, nurses and druggists and others at the discretion of the librarian.

"Cancer Doctor" Acquitted.—"Dr." F. L. Pond, who has been treating cancers in Osage for thirty years, and who was arrested for practicing medicine contrary to the state medical law, was acquitted October 3, his attorney claiming that as he treated cancer by plasters and used no medicine, he could not be said to be practicing medicine.

MARYLAND.

Accident.—Dr. W. W. L. Cissel, Highland, was severely injured in a runaway accident October 8.

Acquitted of Criminal Charge.—Dr. Harry N. Rickards, Ridgely, charged with performing a criminal operation, who was admitted to \$5,000 bail September 23, the bail being furnished by citizens of the town, was acquitted. No evidence was adduced to connect him with the crime. He was on his way to the St. Louis fair when arrested.

Baltimore.

Death Rate High.—There were 181 deaths last week, an annual rate per 1,000 of 16.44. This is higher than usual.

Personal.—Dr. Harry Taylor Marshall has been appointed by the mayor a member of the board of supervisors of city charities, vice Dr. Mactier Warfield, resigned.

N-Ray a Delusion.—Prof. R. W. Wood spoke before the Johns Hopkins Scientific Association on October 13 on "The N-Ray Delusion." Professor Wood has personally tested Blondlot's experiments in France and finds nothing in them.

Portrait of Benefactress Painted.—The trustees of the Johns Hopkins University and Hospital have had painted by John S.

Sargent a portrait of Miss Mary E. Garrett and have had it hung in the corridor of McCoys Hall at the university in honor of the generosity of Miss Garrett, to which the Johns Hopkins Medical School owes its existence.

MICHIGAN.

Information on Pneumonia and Typhoid.—The State Board of Health has ordered a new edition of 25,000 copies of the leaflet on the restriction and prevention of pneumonia, and also 11,000 copies of the amended pamphlet on the restriction and prevention of typhoid fever.

Society Elects Officers.—The Saginaw County Medical Society held its annual meeting at Saginaw October 11 and elected the following officers: President, Dr. William L. Dickinson; vice-president, Dr. Bert E. Rowe; secretary and treasurer, Dr. John N. Kemp, and trustees, Drs. Fletcher S. Smith, Sidney I. Small and James W. McMeekin, all of Saginaw.

September Mortality of Michigan.—There were 2,635 deaths registered during September, representing a death rate of 12.7 per 1,000. This shows a slight increase over the preceding month, which had a death rate of only 12.1, but is lower than the rate for September, 1903, which was 13.4 per 1,000. Important causes of death were as follows: Tuberculosis, 192; typhoid fever, 63; diphtheria, 36; scarlet fever, 6; measles, 4; whooping cough, 4; pneumonia, 74; diarrhea, 318; cancer, 163; accidents and violence, 158. Smallpox caused 3 deaths during the month and 2 deaths were reported from tetanus.

Disinfection and Isolation.—Secretary Baker of the State Board of Health, at its meeting October 4, presented results of compilations of the evidence in the special reports of health officers for several years, on the relative importance of disinfection and isolation in measles, and in whooping cough, which indicate that prompt isolation is of greater importance in the restriction of measles and also of whooping cough than is disinfection. This indicates that the germs of these two diseases do not maintain their vitality for such long periods of time as do the germs of diphtheria and scarlet fever. On the other hand, measles is spread directly from the patient in the early stage of the disease. Eighteen times as many cases occurred in those outbreaks of measles in which both isolation and disinfection were neglected as in the outbreaks in which they were both enforced. Although isolation was of most importance, there were 25 per cent. less cases where both isolation and disinfection were enforced than where only isolation alone was enforced. Although isolation proved to be of more importance than disinfection for the restriction of whooping cough, there was an average of nearly one case less per outbreak where both isolation and disinfection were enforced than where isolation alone was enforced.

NEW YORK.

The Amalgamation in New York Apparently Indefinitely Postponed.—The annual meeting of the New York State Medical Association was held this week. Our correspondent telegraphs that the council and fellows of the association, at its meeting on Monday last, received the report of the Committee on Amalgamation of the New York State Medical Association and of the Medical Society of the State of New York. The committee reported that before a legal union of the organizations could be effected certain changes in the by-laws of the association were necessary to make them conform to the corporation laws of the state of New York. Considerable discussion ensued, but it was evident that nothing could be legally accomplished until after the annual meeting in October, 1905. The report of the committee was accepted. A motion to continue the committee with power to act was defeated.

New York City.

Free Clinical Lectures.—The New York Skin and Cancer Hospital announces a sixth series of clinical lectures on diseases of the skin, to be given by Dr. L. Duncan Bulkley in the Out-Patient Hall of the hospital, on Wednesday afternoon at 4:15 o'clock, commencing November 2. The course will be free to the medical profession.

New Home for Crippled Children.—The New York Home for Destitute Crippled Children has completed negotiations for the property at West Sixty-first Street. It proposes to open the home in about three weeks with fitting dedicatory ceremonies. The dispensary is now at Lexington Avenue and Fiftieth Street.

Impure Milk Traffic.—Judge Hinsdale has declared in Special Sessions Court that unless the practice of selling impure

milk is stopped, the punishment hereafter will be imprisonment instead of fine. Despite this statement he had before him on the following day 50 grocers and others, most of whom were punished by the infliction of the maximum fine.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 8, 291 cases of tuberculosis, with 157 deaths; 248 cases of diphtheria, with 34 deaths; 136 cases of typhoid fever, with 26 deaths; 103 cases of scarlet fever, with 6 deaths; 44 cases of measles, with 3 deaths; 16 cases of variola, one death from smallpox and 10 deaths from cerebro-spinal meningitis.

Personal.—Dr. Alexander E. Macdonald retired from the superintendency of Manhattan State Hospital East, Ward's Island, October 1, and was succeeded by Dr. J. T. W. Rowe, who was appointed acting superintendent.—Drs. Seth D. Close and Charles H. Goeller, while driving, were struck by an electric car. Dr. Close is in a serious condition as the result of a fracture of the skull and internal injuries.

More Water Needed.—The danger of a water famine is no mere bugaboo of periodic re-urrence, but an actual menace that engineers declare to be too real. On several occasions within recent years, when the rainfall has been below normal for considerable periods of time, the city has been within a day or two of a water famine, but the public has not known it. Engineers are now surveying for the proposed Paterson and Cross River aqueduct, which will add about 50,000,000 gallons daily to the present supply.

Tent Life for Babies.—Last summer the experiment of putting babies under canvas was made at Bellevue Hospital, a tent similar to those used by consumptives being used. The mortality records for the first month showed 46 babies cared for, with 11 deaths, whereas the usual mortality is 60 per cent. The children were taken into the hospital recently during the cold weather, but the results were so unfavorable that it has been decided to make a few changes in the tent, to surround it with steam pipes, and to continue its use during the winter months.

Crusade Against Adulterated Liquors.—As a result of a large number of sudden deaths from drinking adulterated whisky in the Strikers' Farm district there promises to be a general crusade against adulterated liquors. It is probable that the law-making powers, both state and national, will be asked to pass more stringent laws against the adulteration of liquors and their sale in bottles which do not reveal their true contents. The results of analyses of the stomach contents of victims, so far as have been completed, show that those of at least three of the supposed victims contained sufficient wood alcohol to cause death, and wood alcohol was also found in the whisky, though there is evidence that this wood alcohol had been used only for the past four weeks.

Drug Fraud.—Seven prisoners in all have now been arrested on the charge of counterfeiting drugs and patent medicines, and are under \$2,000 bail each. Most of the drugs counterfeited were those prescribed for producing sleep, allaying fever and stimulating heart action. In addition to the alleged spurious drugs there was a large quantity of literature and merchandise handled which subject the dealers to criminal prosecution. The drugs have been sold under false labels to druggists all over the country in no less than 1,500 drug stores. The attorney for one drug firm, whose drugs have been counterfeited, states that \$100,000 has been spent during the past year in getting evidence against these "drug peddlers." It is expected that an investigation of drug stores in this city will lead to many more arrests.

New Appointments at the College of Physicians and Surgeons.—Dr. Gorham Bacon has been appointed professor of otology; Dr. Joseph A. Blake, professor of surgery; Dr. George E. Brewer, professor of clinical surgery; Dr. Frederick R. Bailey, adjunct professor of normal histology; Dr. James R. Hayden, professor of genito-urinary diseases; Dr. Samuel W. Lambert, professor of applied therapeutics; Dr. Arnold Knapp, professor of ophthalmology; Dr. Eugene Hydenpyl, adjunct professor of pathological anatomy; Dr. Harry McMahon Painter, professor of clinical obstetrics; Dr. Frederick Peterson, clinical professor of psychiatry; Dr. John S. Thacher, professor of clinical medicine; Dr. Francis Carter Wood, adjunct professor of clinical pathology, and Dr. Russell Burton-Opitz, adjunct professor of physiology.

OHIO.

Magnificent Donation.—Dr. Charles E. Slocum, Defiance, has given to the new city library of his home city his private

scientific, historic and reference library and museum, valued at \$25,000.

Mercy Hospital Open.—On October 19 the new Mercy Hospital, Hamilton, erected at a cost of nearly \$125,000, was formally thrown open to the medical profession. Drs. E. Gustav Zinke and David I. Wolfstein, Cincinnati, were the chief speakers.

Resolutions Regarding Dr. Hyndman.—The faculty of the Medical College of Ohio, Cincinnati, at a special meeting passed resolutions expressive of their grief in the death of Dr. James G. Hyndman, of their admiration for his high intelligence, skill and professional attainments, and of their appreciation of his goodness of heart, generosity of soul and sincerity of friendship.

Assistant Physicians Meet.—The Association of Assistant Physicians of the Ohio State Hospitals held its fourth session at Columbus, October 5 and 6. The dietary committee was enlarged so as to include one member from each state hospital, and Dr. Rudolph W. Holmes, Gallipolis, chairman of the special committee chosen to represent the association at the meeting of the Ohio State Medical Association, reported that the latter had passed a resolution indorsing the objects and work of the assistant physicians' organization.

PENNSYLVANIA.

Philadelphia.

Bequests.—By the will of John E. Garrett the Philadelphia Home for Incurables receives \$5,000, and St. Agnes' Hospital, St. Mary's Hospital and the Methodist Hospital \$100 each.

Personal.—Dr. William Pickett was appointed professor of neurology and mental diseases in the Medico-Chirurgical College, succeeding the late Dr. F. Savary Pearce.—Dr. August F. Muller is seriously ill at his home in Germantown.

Honor for Dr. Chapin.—A banquet will be given Dr. John B. Chapin, chief physician of the Pennsylvania Hospital for the Insane, in honor of the fiftieth anniversary of his work among the insane, early in November. He will also be presented with a portrait of himself.

Health Report.—The total number of deaths reported for the last week reached 414. This is an increase of 34 over those of last week and of 27 over the corresponding period of last year. Pneumonia and diseases of the lungs caused the greatest mortality. Acute affections of the lung caused 36 deaths and tuberculosis 45. There was an increase of 20 cases of diphtheria, but a decrease in the other contagious diseases. In all there were 211 cases of contagious disease, with 23 deaths, as compared with 210 cases and 17 deaths the preceding week. One case of smallpox was reported.

Pure Food Indictments.—Twenty indictments for alleged violation of the pure food laws, involving nineteen persons, were found by the grand jury. The offenses named in the indictments were the selling of adulterated meats and milk, and oleomargarin for butter. Efforts are being made by the manufacturers of oleomargarin to have the 10-cent tax rate per pound repealed at the coming session of Congress. Dr. Warren, dairy and food commissioner, asserts that he will endeavor to combat their efforts and have the bill stand. The bill imposes a national tax of 10 cents a pound on colored oleomargarin, much of which has been sold for pure butter.

Railroad Teaches First Aid to Injured.—The Pennsylvania railroad has instituted a system for giving first aid to the injured. The plan includes the equipping of all baggage, mail, express, work and wrecking cars, terminal stations, yard offices, shops and important stations, with stretchers. Locomotives, terminals and important stations will also be provided with medical boxes containing first-aid material. The order also requires all brakemen, conductors, engineers, firemen and station employes to attend lectures by members of the medical staff on first aid. These lectures will be given every week. Dr. E. C. Town began his series of lectures here and classes of 300 and 400 members were instructed. The medical box contains six sterilized packets, each packet containing 1 large triangular bandage, 1 ordinary roller bandage, 2 compresses and 2 safety pins. Lectures were also delivered by Dr. H. W. Pownall to the employes at Altoona October 12.

GENERAL.

Warning Concerning a Fraud.—A physician at Elroy, Wis., has been victimized by a person purporting to be an agent of Schering & Glatz, New York. This person obtained money on

the representation that the firm would send a formalin lamp as a free sample to any physician who would pay the transportation charges. The firm announces that none of their representatives ask for or accept money under any circumstances from the physicians on whom they call and that anyone claiming to be their agent who does so is a fraud.

Panama Sanitation.—In a recent report to the President the Isthmian Canal Commission stated that between 200 and 300 engineers and from 1,000 to 1,200 laborers are engaged in engineering and construction work, and on sewerage and water supply. This number is exclusive of the sanitary force, which numbers over 500 and which is employed in cleaning the isthmus and putting it in good sanitary condition and as nurses and attendants in the hospitals. A reservoir is being constructed in the valley of the upper Rio Grande, which will furnish a minimum supply of 2,000,000 gallons daily for the city of Panama.

Dermatologists to Meet in New York.—The Sixth International Dermatological Congress will meet in New York City in 1907, under the presidency of Dr. James C. White, Boston. The congress of 1904 has just been held in Berlin and the invitation to the congress was extended by committees representing the American Dermatological Association and the Section on Cutaneous Medicine and Surgery of the American Medical Association. The invitation was accepted without objection from anyone and a successful session is anticipated. The committee of the American Dermatological Association was Dr. J. N. Hyde, Chicago, chairman; Dr. H. A. Stelwagon, Philadelphia; Dr. Gilchrist, Baltimore; Dr. J. A. Fordyce, New York City.

CANADA.

Antisanitarium League at Kamloops, B. C.—The proposition to erect a sanitarium for the care and treatment of cases of tuberculosis at Kamloops has resulted in the organization of an antisanitarium league in that thriving British Columbia city. Recently a deputation from the league waited on the provincial secretary opposing the establishing of a sanitarium at Kamloops, with the result that the provincial secretary promised to have the matter brought to the attention of his colleagues.

Appointments.—Dr. R. W. Bruce Smith, assistant physician at the Brockville, Ont., Asylum for the Insane, has been appointed inspector of prisons and public charities in Ontario, succeeding Dr. T. F. Chamberlain, who has resigned owing to ill health.—Dr. J. C. Mitchell of the Toronto Asylum succeeds Dr. Smith at Brockville, and Dr. Harris, at present relieving officer for the public institutions, will succeed Dr. Mitchell.—Dr. J. B. McConnell, Montreal, vice-dean of Bishop's College Medical Faculty, has been elected second vice-president of the College of Physicians and Surgeons of Quebec.—Dr. J. V. Anglin, assistant superintendent at the Protestant Hospital for Insane, at Verdun, Quebec, has been appointed medical superintendent at the Provincial Hospital for Nervous Diseases at St. John, N. B.

FOREIGN.

Cholera at Port Arthur.—A recent cable report states that cholera has appeared at Port Arthur. Up to September 19 there were only a few cases, but fears are entertained that the disease may become epidemic.

Cholera in the Trans-Caspian District.—Several cases of cholera have been reported from Merv, Askhabad, Bokhara and other towns in that region. These places are markets from which large shipments of wool to the United States are made through the port of Batoum.

Cholera in Persia.—A Russian exchange states that 10 per cent. of the population of Teheran has succumbed to cholera. All the papers published there, even the official organ of the government, have suspended publication. Nearly a quarter of a million persons have died from cholera in Persia since the epidemic began.

Decrease in Population of Manila.—A recent report of the board of health of Manila shows that in May, 1904, the deaths outnumbered the births by 146. Fifty-three per cent. of all deaths occurred in children under 1 year of age. On account of the prevalence of smallpox all officers and employes of the civil government were vaccinated.

Honors for Gaffky.—Professor Gaffky, until recently of Giessen, has now assumed charge of the Berlin University Institute for Infectious Diseases, in which he succeeds Robert Koch, his former master and collaborator. The city of Giessen has con-

ferred honorary citizenship on Gafky in token of his services in public health matters during his residence there.

Clinography.—This is the term coined by Professor Pensuti of Rome to express his method of bedside annotations. It is an ingenious system of graphic exposition in a condensed form of the symptoms, temperature and all the pathologic manifestations presented by the patient. Its simplicity and accuracy commend it for general adoption as a saving of time, and Baccelli, Alessandri and other Italian clinicians are already using it.

A Medical Editor Summoned to the Seat of War.—Dr. Rudolf Wanach, the editor of the *St. Petersburger medicinische Wochenschrift*, has left for the far east, and his place has been taken by Dr. E. Blessig. The last number of the weekly contains an article from Dr. Zoega von Manteuffel, dated August 14, written at Liaoyang. Later advices state that he with his "flying column," the field hospital and the 1,400 severely wounded inmates, were obliged to flee before the bombardment not long after, trains being placed at his disposal. The hospital is now settled on the railroad line to the north of Mukden.

Suits Against Physicians in Germany.—The editor of a Frankfurt paper was sued by a physician whom he had accused of "a lack of human kindness." The defendant was acquitted, as the judge decreed that he had established the truth of his statement by proving that the physician had refused to treat a sick housemaid. Another physician, in Cologne, was sued by a "nature healer" on account of the epithet "charlatan" (*Kurpfuscher*), applied to the latter by the former. The judicial decision was to the effect that this term is not necessarily always an insult, but in the case in question there was no doubt that it was such, both subjectively and objectively.

International Congress of Ophthalmology.—The tenth international congress of ophthalmology was held at Lucerne, Switzerland, September 13 to 17. It was opened by the chief executive of the country, who is a physician, Dr. Deucher. He greeted the 500 members on behalf of the state and also of the medical profession. The question as to the amount of indemnity in industrial insurance for the loss of an eye was referred to committees to be appointed in each country, as the conditions vary so widely in different lands. The notation of visual acuity was another subject discussed with great interest, but no final decisions were adopted. The next congress will be held at Naples in 1909.

International Congress of Dermatology.—The fifth triennial international congress of dermatology was held as announced, September 12 to 17, at Berlin, with a large and brilliant attendance. Among the more novel communications was one from Rizzo and Cippolina of Genoa, describing what they believe to be successful serum treatment of syphilis. Twelve patients in the secondary stage, not otherwise treated, recovered under the serotherapy. One patient with a tertiary nasal affection was cured after a dozen injections of serum. The principal addresses are being published in the specialist journals and will be duly abstracted in our current literature department as they appear. The next congress will be held at New York in 1907.

Retirement of the Medical Director of the Berlin Charité.—After eleven years of indefatigable service Dr. Schaper has retired from the medical leadership of the great Berlin Charité. He was also president of the National Public Health Association and served on the boards of several other hospitals. The reconstruction of the Charité has been conducted under his administration and many innovations are due to him which have advanced the progress of medicine. He has been connected with the Charité in some capacity for thirty-three years, and has written its history. In the management of their cities and hospitals the Germans certainly represent an unattainable ideal for countries under the dominance of the ward politician.

Disinfection of Public Library Books.—In its paternal care of the public health in every respect, except in protecting the public against quacks, the Prussian government has been debating the question of disinfection of public library books. No case of the transmission of tuberculosis to healthy subjects from such books is known, and as authorities differ in respect to the danger of infection from this source, and as it is so difficult and expensive to disinfect books thoroughly, the authorities have decided not to attempt it. All worn and soiled books will be withdrawn from circulation as soon as possible, but no disinfecting measures will be used, although the tests at the Institute for Infectious Diseases showed virulent tubercle bacilli on many books in use over two years.

Finsen's Funeral.—From the remote, icebound solitude and poverty of Iceland and the Faroe Islands to a crowded funeral

at 43, in one of the capitals of Europe, at which the mourners were crowned heads and an army of grateful patients—Finsen's career reads like a romance. His funeral was an imposing public ceremony, attended by the kings of Denmark and Greece, the queen of England, Prince Henry of Prussia as the representative of Kaiser Wilhelm, and numerous other princes and their representatives. The king of England was duly represented and sent an autograph letter of condolence to Finsen's widow. Queen Alexandra attended in person. The entire cabinet attended in a body with other high dignitaries, and the delegates from medical and scientific societies could scarcely be numbered.

Discrimination Against Young Candidates for the German Sanatoriums.—We learn that the great model sanatorium at Beelitz has found it impossible to keep the younger inmates from flirting. In spite of the restrictions and the segregation of the sexes, the young men and women found opportunities to meet, and their frivolity not only interfered with their own progress toward recovery, but annoyed the other inmates. Consequently the officials announce that as the applicants always far outnumber the places at their disposal, in future all below a certain age will be rejected. They base this measure on the grounds that there is much greater probability of a cure for an older than for a young person. Another sanatorium has reserved a department for young subjects, but this by no means supplies the demand.

Luacy in New Zealand.—In the annual report of the inspector of hospitals and lunatic asylums it is stated that in 1903 one person in every 284 of the population, exclusive of Maoris, was registered as afflicted with luacy; while in 1900 only one person in every 288, exclusive of Maoris, was so registered. This increase is not so great as during any recently preceding same number of years. In the final quarter of the nineteenth century the insane rate of the colony increased from 20 to over 32 in each 10,000 of the population, fully 60 per cent. The New Zealand reports give side by side the records of Europeans and natives. It is thus shown that the Maori is much less subject to insanity than the European. The comparative immunity of the natives is sufficient to reduce the rate for the total population of 850,000, to one in 296. The total cost for each patient for a year averages £30 (£150); the cost, less receipts, is only £17 (\$85).

Yellow Fever in Brazil.—Yellow fever is endemic in Para, Brazil, but not a single case has occurred in the interior of the state, the disease being strictly limited to the city of Para. Foreigners and, in general, new arrivals in the city form the greater number of victims. This is attributed to the complete neglect on their part of the proper prophylactic and hygienic measures supplemented by such imprudences as exposure to drafts while perspiring freely and drinking large quantities of iced beer. The *Stegomyia fasciata*, or so-called yellow fever mosquito, bites in the daytime and is attracted by the odor of human perspiration. As the mosquitoes with which strangers are familiar usually bite at night, they are not prepared for the attack of the stegomyia and merely complain of the inconvenience. They object to the use of mosquito netting during the daily siesta in complete ignorance of the danger incurred by not using it.

International Congress of Otology.—The seventh international congress of otology was held at Bordeaux in August. Politzer, Gradenigo and Delsaux presented a committee report on a formula for acumatic notation, but the matter was finally referred to the next congress, which will be held at Budapest in 1908. The Lenval prize was divided between Gellé of Ypres and Alexander of Politzer's clinic at Vienna. Delie of Ypres reported a dozen cases of neurosis to show the evil effects of the abuse of tobacco on the auditory nerve. Lermoyez and Bellin described 2 cases of acute otogenic meningitis treated by craniotomy and lumbar punctures (See page 924). The improvement was marked and permanent under these measures. E. J. Moure of Bordeaux was the president of the congress, and a full report was promptly published in his *Revue Hebdomadaire de Laryngologie*, Nos. 34 to 37. A number of Americans took a prominent part in the proceedings, including Dench, Knapp and Snow.

Hygienic Measures in France.—When the children reassembled this fall in the schools of France they found that china tablets had been placed on the walls giving various hygienic rules, especially cautioning against spitting on the floor. In the upper grades each pupil is expected to be weighed every quarter and the height and chest measure taken. A health record chart is given to each child, the chart accompanying him

from class to class and year to year. Similar rules are now enforced in the army. The men are to be weighed at certain intervals and those showing stationary or declining weight are kept under supervision and appropriate measures instituted, being temporarily dismissed from the service on suspicion of tuberculosis. The postoffice authorities have abolished dry sweeping and dusting. The floors must be swept with damp sawdust daily and wiped with 2 per cent. lysol once a week. A German exchange comments on these various measures that France is certainly taking the lead in civilization.

First Congress of the International Surgical Association.—The first congress of this new organization is to be held at Brussels in September, 1905. Prof. T. Kocher of Berne will preside, and it is announced that the discussions will be restricted solely to the six questions on the order of the day. W. W. Keen makes the first address, with Sonnenburg of Berlin, de la Torre of Madrid and Depage of Brussels, on the theme: "Value of the Blood Count for Surgery." The second question is "Treatment of Hypertrophied Prostate," with addresses by R. Harrison, Rovsing of Copenhagen and v. Rydysgier of Lemberg. The third theme is "Surgical Intervention in Non-Cancerous Stomach Affections," with addresses by Mayo Robson, von Eiselsberg, Mattoli, Montprout of Angers, Rotgans of Amsterdam and Jonnesco of Bucharest. The fourth subject is "Treatment of Tuberculosis of the Joints," with addresses by Bier of Bonn, Broca of Paris, Bradford of Boston, Codivilla of Bologna, and Willems of Ghent. The "Treatment of Peritonitis" will be presented by Lemander of Upsala, Friedrich of Leipzig, Lejars of Paris, McCosh of New York, Krogius of Helsingfors and de Isla of Madrid. The final theme is "Diagnosis of Surgical Renal Affections," with addresses by Albarran of Paris, Kummel of Hamburg, Giordano of Venice and Lambotte of Brussels. All communications for the congress and inquiries should be addressed to Dr. C. Willems, 6 Place St. Michel, Ghent.

Lead Poisoning from Wall Paper.—Professor Lefour of Bordeaux had occasion to treat a pregnant woman for obstinate intestinal colics and constipation, with the death of the fetus just before the seventh month. The husband also presented intestinal symptoms. Both husband and wife were previously healthy, and occupied a house which had been recently renovated and papered, the papers selected in Paris, Bordeaux and London with great care. After the abortion they traveled for a few months, both in good health, but as soon as they settled down again at home the symptoms reappeared. The idea finally occurred to the physician that the golden yellow velours paper on the wall might be the source of the trouble, and, in fact, 1.5 gm. of lead were found in each square yard. The paper in the adjoining rooms contained about one-third of this proportion of lead. Tests of eleven other papers from the stores showed from 1.2 to 7.68 gm. of lead per square meter in nine of the papers and copper in the others. The largest proportion of lead was found in the velvety style of papers. He does not hesitate to ascribe the death of the fetus and the illness of the parents to lead poisoning, and is confident that it is much more frequent than generally supposed. As lead poisoning has such a pernicious action on a pregnancy, he publishes his report in the *Obstétrique* for September to call the attention of obstetricians to the matter.

LONDON LETTER.

Contamination of the Atmosphere of Rooms by the Saliva.

The report of the medical officer of the local government board, which has just been published, contains a report by Dr. Mervyn Gordon on the contamination of the atmosphere of inhabited rooms by coughing, sneezing, singing and speaking, by which drops of mucus and saliva, impregnated with the bacteria of the mouth and air passages, and occasionally pathogenic microbes, are disseminated. He first examined the saliva of healthy persons to ascertain what microbes are most abundant therein and whether any bacterium by its abundance and constancy is to be regarded as characteristic of human saliva. He found that streptococci of various descriptions are very abundant and that the streptococcus brevis is commonly present to the amount of at least 10,000,000 to the cubic centimeter, and is readily detectable by the changes of color it produces on culture media. He found that minute quantities of saliva can be recognized by the presence of this streptococcus, and applied these facts in ascertaining the effects of loud speaking in disseminating droplets of saliva. He ascertained by means of Petri dishes charged with nutrient broth and set about the room that before "oration" the air did not contain

the streptococcus brevis nor other salivary streptococci in suspension. Then by similar distribution of culture media during and immediately after "oration" by a series of speakers he showed that droplets of saliva were disseminated throughout the air to a distance of 40 feet from the speakers. In this method of identifying the droplets Dr. Gordon has discovered a gauge of air contamination by people which may ultimately prove to be of great practical importance and far more trustworthy than the tests of mere gaseous impurity or of excess of CO₂ which has hitherto been relied on.

Professor Osler's Appointment to the Chair of Medicine at Oxford.

Professor Osler's appointment is received on all sides with the greatest satisfaction. The Oxford Medical School had fallen into decadence, from which it has begun to recover. This was due principally through the untiring efforts of the late Professor Acland, a predecessor of Professor Osler in the chair of medicine. In recent years the school has made great progress. But the appointment of Professor Osler is recognized as an impulse to its development the extent of which is difficult to exaggerate and which could have been obtained in no other manner. His almost unique combination of the highest qualities of the clinician and the scholar, his literary ability and his merits as a teacher have long been appreciated in this country, and peculiarly fit him for the chair, rendering him a worthy rival of the professor of medicine in the sister university of Cambridge, Dr. Clifford Allbutt, whose literary powers stand quite alone amongst the physicians of this country. The universal verdict is that the appointment is our gain and America's loss.

Trypanosomiasis.

The Liverpool School of Tropical Medicine has just issued an important series of reports on trypanosomiasis. The discovery of trypanosomes in the cerebrospinal fluid of cases of sleeping sickness by the commission of the Royal Society has previously been reported in *THE JOURNAL*. In 1901 Dr. J. E. Dutton while working in Gambia on one of the many expeditions sent out by the Liverpool School of Tropical Medicine for the investigation of tropical diseases, discovered trypanosomes in the blood of a European. In consequence an expedition consisting of Drs. Todd and Dutton was sent in 1902 by the school to Senegambia to prosecute further researches in trypanosomiasis. A valuable report was published in 1903 and contained the pathogenic trypanosomata of man and animals, with a description of several new species. Before the return of this expedition the discovery of trypanosomes in the cerebrospinal fluid of cases of sleeping sickness in Uganda caused the subject to assume great importance. In the Congo Free State the native population has from time to time suffered from fatal epidemics of the disease. The king of the Belgians, therefore, in 1902 sent an invitation to the school to send an expedition to that country. Drs. Todd and Dutton were recalled from Senegambia and left for the Congo in 1903, where they were joined by Dr. Christy, who had previously served on the Royal Society's commission in Uganda. A special hospital was erected by the state and facilities given for the study of a large number of patients. The results of the investigations are incorporated in the volume now issued. They show the distribution of sleeping sickness, trypanosomiasis, the symptoms in all stages, in both Europeans and natives, and the relation of sleeping sickness to trypanosomiasis. At the same time the school resolved to continue in Liverpool the researches began by Drs. Dutton and Todd in Gambia. Dr. Thomas was appointed to conduct the work, with the assistance of Dr. Linton. The two groups of observers have throughout worked together, and in order that comparable data might be obtained selected cases of sleeping sickness were, by permission of the Congo authorities, sent to Liverpool. Numerous observations show that the parasite identified with sleeping sickness in Uganda and the Congo does not differ from that described by Dr. Dutton in Gambia. The therapeutics receives considerable attention and experiments are in progress with a view to finding a remedy which may be as efficient as quinin is in ague. A variety of drugs has been used with more or less success. So far arsenic and trypan red appear to be the most useful. Under their administration the parasite disappears from the blood for a time and the life of the animal is prolonged, but a cure has not been obtained. A combination of the two appears to give the best results. A large number of animals infected with different trypanosomes is under treatment. The report seems to show conclusively that sleeping sickness is trypanosomiasis, although there are

severe and fatal cases of the latter disease in which somnolence does not occur. The symptoms and danger appear to bear some relation to the greater or less abundance of the parasites and to become more serious when these have gained access to the cerebrospinal fluid. The parasites may be present in the blood of deeply-seated organs when they are not discoverable in that drawn from a surface puncture. Their frequent temporary disappearance from the surface blood renders it difficult to be sure of their absence from the system. One of the most curious results of the expedition is the discovery of a blood-sucking larvæ of nocturnal habits which is abundant in many parts of the Congo and during the day is concealed in the cracks of the native floors, from which it may be dug out full of bright red blood, showing the abundance of its previous night's meal. It is the larvæ of the *Glossina* fly, which appears to be harmless in the imago stage.

The Institute of Hygiene.

The Institute of Hygiene which has been founded is a new department. The object is to advance various branches of popular teaching in hygienic matters and the first step has been the establishment of a permanent exhibition of hygienic products and appliances. It is in charge of a physician, who explains the character of the various exhibits. It has been opened by Sir Joseph Fayrer, who stated that it had been founded under the auspices of a medical council and pointed out that the permanent exhibition of hygienic products and appliances will be of advantage to doctors and others interested in hygiene by demonstrating the progress made in the various departments of manufacture auxiliary to their work. The value of every exhibit is investigated by an examining board and only those of high standard are admitted. It is recognized that any exhibit passed by the board may be used and recommended by doctors. A certificate is granted to exhibitors which constitutes a valuable award of merit. The exhibition is intended, 1, to supply medical men with practical information so as to enable them to keep abreast of the times in regard to the value and progress made in the various manufactured products and articles which affect health; 2, to supply nurses with useful knowledge in regard to products and appliances required by invalids; 3, to supply the general public and especially the large and increasing number who are interested in dietetics, clothing, appliances and articles affecting the health of the person or home with authoritative information as to their value and use. The exhibition is situated in Devonshire Street, Harley Street, in the heart of the medical center of London.

Marriages.

E. S. FITZMAURICE, M.D., Mohall, N. D., to Miss Alice Bryant of Chicago.

D. C. MARTIN, M.D., to Miss Annie E. Payne, at Stewartstown, Pa., October 5.

JOHN COLLISON JOYCE, M.D., to Miss M. Amy Knight, at Baltimore, October 4.

JESSE E. HERBERT, M.D., to Miss Claudia Rice, at Berkeley Springs, W. Va., October 12.

HARRY NORBERT McDEVITT, M.D., to Miss Isabel Carey Smith, at Baltimore, October 10.

C. NAEMANN McCloud, M.D., to Miss Agatha De Lambert, both of St. Paul, Minn., October 18.

GEORGE W. LAUTERBACH, M.D., to Miss Mary Alberta Heckman, both of Baltimore, October 18.

ALBERT B. CRAIG, M.D., Philadelphia, to Miss Frances Boyd Foster of Newton, Mass., October 12.

WILLIAM T. KIRBY, M.D., Chicago, to Miss Margaret Loretta Durkin of Waukegan, Ill., October 19.

THOMAS EDWARD SAMPLE, M.D., Crete, Neb., to Miss Christine Tuckey of Omaha, Neb., October 5.

CLARENCE T. HUTCHINS, M.D., to Miss Annette Elizabeth Northam, at Solomons, Md., October 11.

MARSHALL B. WEST, M.D., Catonsville, Md., to Miss Anne Evans Breeze, at Baltimore, October 11.

W. BRUCE GLOTFELTY, M.D., Sharpsburg, Pa., to Miss Edna Anna Hay, at Hagerstown, Md., October 5.

JOSEPH COLES BRICK, M.D., Philadelphia, to Miss Laura Brooke Clingan of Birdsboro, Pa., October 1.

LYLBURN HALL BEWLEY, M.D., Atlantic City, N. J., to Miss Bertha Bellis of Philadelphia, Pa., October 6.

H. F. TAYLOR, M.D., Ridley Park, Pa., to Miss Katherine Grace Manly of West Chester, Pa., October 12.

NATHAN WINSLOW, M.D., Baltimore, to Miss Margaret Kable Massey, at Sandy Spring, Md., October 5.

CHARLES SELLMAN McCOLLUM, M.D., to Miss Marie Elizabeth Turlington, both of Baltimore, at Wilmington, Del., June 8.

Deaths.

Richard Henry Thomas, M.D. University of Maryland Medical Department, Baltimore, 1875, dean and professor of diseases of the throat, nose and chest of the Woman's Medical College, Baltimore, also a prominent minister of the orthodox Society of Friends, son of the late Prof. R. H. Thomas, M.D., of the University of Maryland, died at his home in Baltimore, October 3, from chronic valvular disease of the heart, after an illness of eight months, aged 51.

Edgar D. Carr, M.D. Rush Medical College, Chicago, 1887, a member of the American Medical Association, and of the Decatur Medical Society, one of the most prominent physicians of Macon County, Ill., was found dead in bed from heart disease at his home in Argenta, October 11.

Gerhard Heinrich Eiskamp, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1892, a member of the American Medical Association, formerly a lecturer in his alma mater, died at his home in Washington, Iowa, October 9, from Bright's disease, aged 49.

Edward J. Belt, M.D. Harvard University Medical School, Boston, 1900, while delirious after a prolonged spree, shot and seriously wounded two of his friends, and then committed suicide by taking carbolic acid in his rooms in Springfield, Mass., October 8, aged 29.

Albert E. Mallory, M.D. McGill University Medical Department, Montreal, 1872, registrar of East Northumberland for 16 years and member of Parliament for Northumberland, died at his home in Calborne, Ont., October 4, after an illness of three days.

Thomas Devereux Hogg, M.D. Jefferson Medical College, Philadelphia, 1847, one of the oldest and most respected physicians of Raleigh, N. C., was run over by a locomotive near his home, September 30, and instantly killed, aged 80.

Upton Heath Belt, M.D. University of Maryland, Baltimore, 1850, of a Baltimore family, but a resident abroad for a great many years, died at Leghorn, Italy, October 15.

William Bishop, M.D. Howard University Medical Department, Washington, D. C., 1875, died from consumption, October 6, at his home in Annapolis, Md., aged 60.

Charles E. Elliott, M.D. Charity Hospital Medical College, Cleveland, 1869, died at the home of his son in Wellington, Kan., October 8, from consumption, aged 70.

William Wilmot Estabrook, M.D. Pennsylvania Medical College, Philadelphia, 1847, clergyman and surgeon, died at his home in Chicago, October 10, aged 77.

Rabin A. Burge, M.D. Medical College of Georgia, Augusta, 1902, of Graves, Ga., died in Brooksville, Fla., October 6, from typho-malarial fever.

Robert H. Daintree, M.D. Pennsylvania, 1875, died at his home in Lewiston, Maine, October 3, after a short illness, aged 53.

Isaac Newton Hugg, M.D. Philadelphia, 1869, died at his home in Camden, N. J., from uremia, October 15, aged 64.

William Hunn, M.D. University of Louisville, Ky., 1856, died at his home in Hustonville, Ky., aged 73.

Edward G. Nelson, M.D., died at his home in Baltimore, October 6, aged 57.

Deaths Abroad.

T. Carbone, M.D., professor of pathologic anatomy at Pisa, succumbed September 7 to the effects of a scarlet fever received at the necropsy of a subject with Malta fever.

A. Gombault, M.D., died at Ivry, September 20, aged 60. Although the name of Gombault is scarcely known outside of France, yet to him science owes some of its most important advances in the last quarter century. He was a specialist in pathologic anatomy and histology, but remained all his life an

enthusiastic laboratory worker and teacher, publishing very little over his own name. To his researches Charcot, Hanot, Debove and others owed the scientific basis for most of their brilliant work.

Book Notices.

THE CLINICAL STUDY OF BLOOD PRESSURE. A Guide to the Use of the Sphygmomanometer in Medical, Surgical and Obstetrical Practice, with a Summary of the Experimental and Clinical Facts Relating to the Blood Pressure in Health and in Disease. By Theodore C. Janeway, M.D., Lecturer in Medical Diagnosis, University and Bellevue Hospital Medical College. Seventy-five illustrations in the Text in Many Colors. Cloth. Pp. 300. Price, \$3.00. New York and London: D. Appleton & Co. 1904.

Dr. Janeway's book on the clinical study of blood pressure is the first complete work on this subject. As the study of blood pressure outside the laboratory is rather new and the interest in it is rapidly increasing, this work is an important contribution to American medical literature. The book is divided into three parts: physiological, technical and clinical. In the first part the author discusses blood pressure in the normal man. He gives the general features of arterial circulation, the factors which determine blood pressure and the various elements influencing it. This chapter is especially valuable in showing how to recognize normal variations in blood pressure, a knowledge essential to the interpretation of blood pressure readings under pathologic conditions. In the chapter on technique, the author gives the development of the sphygmomanometer. He describes each of the modern instruments, giving the method of use, advantages, defects, maker and cost. Part three is devoted to the clinical side of the subject. The first chapter consists of a discussion of blood pressure in the normal man, followed by the blood pressure findings in diseases—medical, surgical and obstetric. Added clearness is given the subject by numerous cuts, diagrams, tracings and charts. The literature is carefully reviewed and all of the scattered facts on this subject are collected in a manner most convenient for reference. This book can not but impress one with the value of blood pressure determinations. It will doubtless be an incentive to the physician to make more use of the sphygmomanometer at the same time, as it will aid him to employ it in an intelligent manner.

MANUAL OF MATERIA MEDICA AND PHARMACY. Specially Designed for the Use of Practitioners and Medical, Pharmaceutical, Dental and Veterinary Students. By E. Stanton Mair, Ph.G., V.M.D., Instructor in Comparative Materia Medica and Pharmacy in the University of Pennsylvania. Third Edition, Revised and Enlarged. Cloth. Pp. 192. Price, \$2.00 net. Philadelphia: F. A. Davis Company.

This book is interled primarily for the use of students, and as such will serve a useful purpose, although it has too many shortcomings to make it useful for the general practitioner. The general considerations which precede the part on materia medica are so short and "general" that it would have been better to have omitted them entirely. In order to understand this portion of the book, it is necessary for the student to consult a larger work or to have a previous knowledge of the subject. The author speaks of materia medica as consisting of four distinct divisions—materia medica proper, pharmacy, pharmacology and therapeutics. No mention is made of pharmacognosy nor of pharmacodynamics. We believe that all these should be classed as subdivisions of pharmacology, the term materia medica being more or less obsolete as applied to the whole subject. The text of the book is brief and concise, such as one would expect to find in a quiz-compend, and not in a work which is intended to be used as a textbook. Part III, which comprises about one-third of the book, is devoted exclusively to pharmacy. The book is interleaved, a very commendable feature, and one which will be appreciated by the student. For purposes of review or for use in conjunction with a larger book, the book will be found satisfactory.

THE PURIN BODIES OF FOODSTUFFS AND THE RÔLE OF URIC ACID IN HEALTH AND DISEASE. By I. Walker Hall, M.D., Assistant Lecturer and Demonstrator in Pathology, the Owens College. Second Edition, Revised. Cloth. Pp. 201-xiii. Price, \$1.50 net. Philadelphia: F. Blakiston's Son & Co. 1904.

This work gives the results of a painstaking study of the exogenous and endogenous purin bodies. The material is pre-

sented in such a manner as to be directly useful to the physician, especially from the point of view of dietetics. Here are given tables showing the amount of purin bodies in many foodstuffs, so that it becomes possible to determine the amount of endogenous urinary purin in many diseases. To facilitate accurate work in this line, a purinometer is described. A chapter is devoted to the study of the effects of daily injections of purin bodies in rabbits whose growth was hindered thereby at the same time as changes occurred in the liver and kidney and in the cellular relations in the blood and marrow. The book may be recommended to all physicians who desire to know the plain facts, so far as they have been unearthed, in regard to the relation between uric acid and food.

BERI-BERI. Its Symptoms and Symptomatic Treatment. An Essay Printed by the Board of Trinity College, Dublin, for the Author. By Percy Netterville Gerrard, B.A., B.Ch., B.A.O., M.D., Dublin University. Cloth. Pp. 95. Price, \$1.00. London: J. & A. Churchill. Philadelphia: F. Blakiston's Son & Co. 1904.

This little book contains nothing new concerning beri-beri, unless it be the statistical proof that other forms of treatment than the purely symptomatic are prejudicial. Those cases recover most rapidly that receive no other treatment than such as may be given for special symptoms. The arrangement of the matter in the book is peculiar. The great personal experience of the author should guarantee a reliable and complete clinical description of the disease.

Miscellany.

Serum Treatment of Whooping Cough.—M. Manicattide of Jassy asserts that a bacillus which he isolated from 83 cases of whooping cough is the true causal germ. He calls it the Z bacillus, and states that it is agglutinated by serum from whooping-cough subjects. He announces further in the *Zeitschrift f. Hygiene*, XLV, No. 5, 1903, that serum treatment is proving effectual.

Employ the Councilor.—The *Journal of the Kansas Medical Society*, asks: "Is the feeling among the physicians in your town unsatisfactory? Is there underbidding? Slander? Do the newspapers print all sorts of fakir advertisements and despise their 'home doctors'?" It advises, in case such conditions prevail, that the councilor for the district be informed of the state of affairs and his aid asked.

Paraplague Bacilli.—R. O. Neumann has isolated from rats at Hamburg a bacillus which closely resembles the plague bacillus both in shape and behavior; the pathologic findings are also closely similar to those of true plague. He describes it in detail in the *Zeitschrift f. Hygiene*, XLV, No. 5, 1903. It differs from the plague bacillus in the vital points that it can be injected with impunity subcutaneously or into the peritoneum of rats, but the smallest scrap of infectious material aspirated into the lungs is fatal. Agglutination tests were negative. These bacteria are capable of causing much confusion in the diagnosis of the plague.

The Parboiling Baths of the Japanese.—The newspaper correspondents have had much to say of the way in which the Japanese take their daily baths—"at a certain hour every day the entire nation is parboiled." There are a number of hot springs which are great resorts. The *Gaz. Méd. de Paris* describes those of Kusatsu, where the mineral waters have a temperature of 123 F., but are cooled down to 119 F. in the tanks. At the approach of the bathing hour a trumpet call summons the bathers, and they flock to the tanks in groups of 15 or 20, each group under the supervision of a bathing master. Each bather wets his head before stepping into the water, and the bathing master starts a song, calling out the minutes from time to time, until he announces that time is up, when all hasten out of the hot water. At another resort the waters are still hotter and are utilized for steam baths. On emerging from the steam room the bathers run across the street and plunge into a tank of cold water. The daily hot bath is usually taken in water heated with a charcoal burner placed in the water. This, with the frequent drinking of tea and large amounts of

water, is assumed to be the reason why arthritis and gout are so rare in Japan. The Japanese are said to recognize a European or other foreigner by the odor alone. Their houses are not built for cold weather, and the small portable charcoal heaters used are not able to take the chill out of the rooms. But the people shiver and bear the cold with their characteristic equanimity, although outraged Nature often punishes them with respiratory affections. This helplessness in respect to cold is liable to prove an important factor in the campaign in Manchuria during the winter, as the climate is much severer than that of Japan.

Indexing of Current Medical Literature.—Professor Huchard of Paris writes to the editor of the now defunct *Bibliographia Medica* to the effect that an index exclusively of titles is of no earthly use, not even for research work, as no one is able to sift the valuable from the worthless by the titles of the articles alone. An expensive publication giving merely the titles will never succeed. "You can have confidence in my long experience as a medical journalist," he adds. "What is needed is a journal costing about \$5 to \$6 a year, which gives summaries of all the important articles and merely the titles of the others. *In hoc signo vinces.*" Prof. H. Huchard was the founder and editor of the *Revue Clinique et Thérapeutique* and of the *Journal des Praticiens*, both able French journals, and has recently been "medaled" by his friends, as mentioned on page 617. The occasion was the completion of his great work on the pathology of the heart, and his promotion in the Legion of Honor.

Massage Cure for Obesity.—Ziegelroth proclaims in the *Archiv f. physikalisch-diätetische Therapie*, vi, No. 1, 1904, (according to an abstract in the *Allg. Med. Ct.-Ztg.*), that obesity will vanish like snow in the March sunshine if treated by appropriate massage. He ascribes the painfulness in certain cases of adipositas to direct compression of the sensory nerves by the masses of fat, and also by the serous impregnation of the tissues. Every obese subject suffers from actual dropsy of the tissues. In all probability the lymphatics which should carry off the surplus serous fluids are mechanically occluded by the masses of fat. The passages become impermeable and the circulation is more or less completely arrested. Besides these factors the heart action is usually more or less compromised in abnormally fat persons. The best means of combating obesity, adipositas dolorosa and cardiac incompetency from this cause is energetic massage. The obesity subsides like magic under it, probably because the local dropsy is thus relieved. The best evidence of this is the increased secretion of urine. The massage has also direct action on the masses of fat which are generally more or less empty of blood. Energetic massage induces a copious supply of blood through them. The pallid, cool masses of fat become warm and pink under the massage, local metabolism is promoted and the fat disintegrates and is absorbed. Large folds of fat on the abdomen should be taken up and squeezed, crushed, kneaded and pounded, but all without injury to the organs beneath. The best way is to take up a large fold and pound it horizontally with the other hand, remembering always that the organs below must not be disturbed. Less caution is required in massaging the thighs, hips, etc. In massaging the face the cosmetic results must be borne in mind and the lost tonus of the subderma be stimulated to avoid formation of wrinkles. Daily stroking massage is preferable here and the autovibrator may be found useful, but for double chin and similar accumulations of fat energetic squeezing and kneading is more rapidly effective.

Habit Pains.—Physicians are sometimes consulted by patients on account of a pain which recurs at a given day and hour, or at variable intervals but for some given trivial inciting cause. In both cases the pain seems to have become a habit. The pain recurs as a habit at a certain hour or in connection with a certain act or sight. Brissaud presented a communication on the subject at a recent medical congress, relating seven cases from his own experience to show the peculiarities of these *douleurs d'habitude*, as he calls them. His article is reproduced in the *Progrès Méd.*, xix, No. 2. He believes that the

subjects are victims of an actual obsession, a hallucination of pain when in reality there is no pain. As it is a subjective phenomenon, physicians are apt to accuse the subjects of a habit of complaining rather than a habit of actual pain. As these habit pains may be the only symptoms of ignored hysteria or neurasthenia, the differential diagnosis of these two conditions is frequently difficult. When material phenomena, vomiting, vertigo, spasms or visceral congestion demonstrate the actuality of the attack the physician must not be misled into treating the supposed organic origin. The narcotics alone are effectual unless the evil is of long standing. If it is, then psychotherapy is the only resource, for these habit pains are a manifestation of mental pathology. In 3 of his cases the nightly periodicity of the pain was a striking feature, suggesting what he has previously described as "nocturnal paroxysmal anguish"; the anguish sensation usually accompanied the habit pains. One patient was cured by opium, another by an emotion, interrupting the rhythm of the habit. In one case the pain recurred at 2 a. m. every night, always in the left leg from the calf to the toes, and lasted an hour, without any cramp contracture. In other cases the pain was in the trunk, head or neck. In one instance writer's cramp recurred whenever the subject tried to write, and always with the anguish sensation which distinguishes these habit pains.

Medical Missionary Work in China.—The prospectus has been received of the medical college recently opened in Canton, South China, under the auspices of the Medical Missionary Society (undenominational) in connection with the hospital at that place. The Chinese language is the medium of instruction used, and before entering the college students must present evidence of a good Chinese education and must be physically sound. The course consists of didactic and clinical lectures, graded for a period of four years. Each student, during the course, must spend periods of time, aggregating not less than one year in active hospital work. Dr. John M. Swan, surgeon in charge, has sent the last yearly report of the Canton Hospital, which shows it to be well equipped for the performance of successful surgical work, including x-ray and other electrical appliances. During the year 1,374 operations were performed on men and 1,127 on women. The operations on women included the following obstetric procedures: Craniotomies, 20; forceps deliveries, 57; operations for retained placenta, 19; transverse presentations (version and forceps), 28; perineorrhaphies, 20. Seven ovarian cysts were removed and amputation of the breast, with removal of the axillary glands for carcinoma, was done 21 times. One man was operated on for appendicitis. Seventy eye operations of various kinds were performed on men and 252 on women. There were 72 deaths during the year, 55 men and 17 women. The society announces that two additional foreign physicians are urgently needed for the work of the college and hospital combined. Apparatus, furniture and appliances, costing approximately \$5,000 are needed at once. Scholarships, costing \$300, are necessary for worthy students, who can take the course only in this way. An additional building, to be used largely for dormitories and costing about \$15,000, is also needed.

CLIPPINGS FROM LAY EXCHANGES.

GLYCOHEMIA.

In an advertisement of a much-exploited patent medicine, the following testimonial appears:

"It is with pleasure that I write this testimonial in behalf of my daughter, Lillian, who was very sick. Our doctors said her blood had turned to sugar at the critical time of womanhood. She could not walk or stand, but had to lie in bed almost all day for five long months. Our doctor did all he could for her, but she got worse all along. I was anxious about her; in fact, all our family were almost crazy to think she would die so young.

"I had heard and read so much of Dr. —'s blood and nerve remedy that I went and got a bottle. On the second day I saw an improvement in her condition. I was overjoyed and kept on and got another bottle, and when the second bottle was used she apparently came back to life."

REMOVED INSIDE OF EYEBALL—WHAT AN ABSCESS MAY CAUSE.

"Drs. — and — removed the inside of the ball of the left eye of the little . . . son of Billy — and wife the same being caused by an abscess forming on the eye."—*Anderson (Ind.) Herald*, April 21, 1904.

WHAT MILLIONAIRES CAN HAVE—OIA-PED-ES.

"—, . . . worth several millions of dollars, . . . came here . . . to recover from an attack of diabetes in the right foot."—*Atlantic Review*, Atlantic City, N. J., June 10, 1904.

FOR FURTHER PARTICULARS CONSULT HANDBILLS.

"NOTICE.—Dr. —, Dentist, — building, — and — streets, has returned from the bedside of his mother, who was ill, and is again ready to attend to the wants of his patrons."—*Johnston Democrat*, advertising columns.

READERS MAY TAKE THEIR CHANCE.

"At an early hour this morning — was resting fairly well, but was very restless."—*Johnston Democrat*, Aug. 20, 1903.

CARRY A PAINFUL WITH YOU.

"—, medical superintendent of the — School of Psychology, . . . proceeds to say: ' . . . in the treatment of acute or chronic appendicitis, it is best to take [water] . . . in small quantities, but [it] . . . should be taken frequently—say a good mouthful every five or ten minutes during the day.'"—*Seattle (Wash.) Times*, July 31, 1904.

TOO MANY (PTOMAINE) JOLTS FOR THE MILK.

"MILK POISONED BY JOLT.—Dr. —, secretary of the — State Board of Health, has completed his investigation into the cause of the ptomaine poisoning of . . . thirty . . . persons. . . . Dr. — is . . . convinced that the jolting of the milk over the road before it had been cooled produced a chemical action which introduced the poisonous properties into the milk."—*Doylstown (Pa.) Republican*, Aug. 4, 1904.

WHICH AIR CELL?

"—, . . . suffered two broken ribs and punctured an air cell of one of his lungs in a collision. . . . The doctor said the rupture of the air-cell is likely to induce pneumonia."—*Stamford (Conn.) Advocate*, July 28, 1904.

APPENDICITIS IN THE BOWELS OF A SHIP.

"Ship's Surgeon —, . . . diagnosed the case as appendicitis. . . . With none of the modern appliances of a surgical operating room, on board an ocean liner, deep in the bowels of the ship . . . these three skilled and daring surgeons set about to relieve the sufferings of a poor workman. . . . Without doubt the past annals of surgery can not show a more unique and daring operation."—*Burlington (Vt.) Free Press*, Aug. 17, 1904.

The Public Service.**Army Changes.**

Memorandum of changes of stations and duties of medical officers, U. S. Army, for the week ending Oct. 15, 1904:

De Witt, W., asst.-surgeon, leave of absence extended fourteen days.

Held, Peter C., asst.-surgeon, leave of absence extended fifteen days.

Wakeman, W. J., surgeon, granted leave of absence for ten days.

Wilson, J. S., asst. surgeon, ordered to accompany Fifteenth Cavalry from Fort Myer, Va., to Fort Ethan Allen, Vt.

Hoff, John Van R., deputy surgeon general, left post Fort Leavenworth, Kan., on seven days' leave of absence.

Craig, C. F., asst.-surgeon, having reported to the military secretary is ordered to return to his proper station, Presidio of San Francisco.

Duval, D. E., asst.-surgeon, granted leave of absence for fifteen days.

Waddell, Ralph W., contract dental surgeon, granted leave of absence for three months from Fort Leavenworth, Kan.

Van Kirk, Harry H., contract surgeon, granted leave of absence for one month from Fort Sill, Okla.

Wythe, Stephen, contract surgeon, left the transport *Buford* October 10 on leave of absence for two months.

Jenkins, Frederick E., contract surgeon, granted leave of absence from Fort Barrancas, Fla., for two months.

Brown, Henry D., contract surgeon, granted leave of absence for two months from Fort Ward, Wash.

Burke, S., contract dental surgeon, ordered from Fort Hancock, N. J., to Fort Slooem, New York, for two months' duty.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Oct. 15, 1904:

Cole, H. W., Jr., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from Oct. 5, 1904.

Cowan, J., dentist, retired, ordered to the Naval Hospital, Fort Royal, S. C., for duty.

Smith, H. W., and Clifford, A. C., asst.-surgeons, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Oct. 12, 1904:

Stoner, G. W., surgeon, leave of absence for eight days from Sept. 19, 1904, under Paragraph 189 of the regulations, amended to read seven days only.

Wertenhaker, C. P., surgeon, granted leave of absence for one month from duty at receiving station at Ellis Island, New York.

Rosecan, M. J., P. A. surgeon, detailed to represent Service at meeting of the Committee on Antitoxin and Immunizing Sera of the Laboratory Section of the American Public Health Association at New York, October 7 and 8.

Sprague, E. K., P. A. surgeon, granted leave of absence for seven days from Oct. 11, 1904, under Paragraph 191 of the Regulations.

Foster, M. H., P. A. surgeon, relieved from duty at Port Townsend, Wash., and directed to proceed to San Diego, Cal., and assume command of the Service at that port, relieving temporary A. A. Surgeon B. V. Franklin.

Robinson, D. E., P. A. surgeon, relieved from duty at Port Townsend Quarantine, Washington, and directed to proceed to Port Townsend and assume command of the service at that port, relieving P. A. Surgeon M. H. Foster.

McClintic, T. B., P. A. surgeon, on being relieved at Tampico, Mexico, by P. A. Surgeon Joseph Goldberger, to proceed to Washington, D. C., and report at the Bureau for further orders.

Goldberger, Joseph, P. A. surgeon, relieved from duty at Monterey, Mexico, and directed to proceed to Tampico, Mexico, for duty, relieving P. A. Surgeon T. B. McClintic.

Amesse, J. W., asst. surgeon, to proceed to San Francisco and report on Oct. 21, 1904, to the chairman of board convened to determine the fitness of Asst.-Surgeon Amesse for promotion to the grade of P. A. surgeon.

Collins, G. L., asst.-surgeon, leave of absence for three days from Sept. 30, 1904, granted under Paragraph 191 of the Regulations, amended to read one day only.

Frick, John, A. A. surgeon, relieved from duty at Brownsville, Texas, and directed to proceed to Laredo, Texas, and report to the medical officer in command for duty.

Jackson, J. M., Jr., A. A. surgeon, granted leave of absence for 30 days from October 26.

LaGrange, J. V., pharmacist, granted extension of leave of absence for sixteen days from October 9.

APPOINTMENT.

John M. Bell, of Minnesota, appointed pharmacist of the third class.

BOARDS CONVENED.

Board convened to meet at the Purveying Depot, New York, Oct. 31, 1904, for the examination of such assistant surgeons as may present themselves to determine their fitness for promotion to the grade of P. A. surgeon. Detail for the board: Surgeon H. W. Sawtelle, chairman; Surgeon G. W. Stoner, P. A. Surgeon C. H. Lavinder, Recorder.

Board convened to meet at the Plague Laboratory, San Francisco, Cal., Oct. 31, 1904, for the examination of Asst.-Surgeon J. W. Amesse to determine his fitness for promotion to the grade of P. A. surgeon. Detail for the board: P. A. Surgeon Rupert Rhie, chairman; P. A. Surgeon H. S. Humbling; P. A. Surgeon D. H. Currie, recorder.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ending Oct. 15, 1904:

SMALLPOX—UNITED STATES.

Arkansas: Fort Smith, Aug. 20-27, 3 cases.

Illinois: Chicago, Oct. 1-8, 3 cases.

Indiana: Evansville, Oct. 10, 20 cases.

Massachusetts: North Adams, Oct. 1-8, 1 case.

Michigan: At 89 places, Sept. 24-Oct. 1, present.

Minnesota: Sept. 27-Oct. 3, Hennepin County, 23 cases; Washington County, 1 case.

Missouri: St. Louis, Sept. 24-Oct. 10, 20 cases, 1 death.

New York: Oct. 1-8, Buffalo, 1 case; New York City, 1 death.

Ohio: Cincinnati, Sept. 30-Oct. 7, 1 case; Toledo, Oct. 1-8, 1 case.

Tennessee: Nashville, Oct. 1-8, 3 cases.

Texas: San Antonio, Sept. 1-30, 1 case.

Wisconsin: Milwaukee, Oct. 1-8, 1 case.

SMALLPOX—INSULAR.

Philippine Islands: Manila, Aug. 13-20, 1 case, 2 deaths.

SMALLPOX—FOREIGN.

Africa: Cape Town, Aug. 20-27, 1 case.

Belgium: Brussels, Sept. 17-24, 1 death.

France: Paris, Sept. 17-24, 10 cases, 2 deaths.

Great Britain: Sept. 17-24, Bristol, 1 case; Manchester, 2 cases; Newcastle-on-Tyne, 3 cases; Nottingham, 4 cases; Glasgow, Sept. 23-30, 1 case; Leeds, Sept. 10-17, 5 cases.

India: Bombay, Sept. 6-13, 1 death; Karachi, Sept. 4-11, 1 death.

Italy: Catania, Sept. 23-29, 1 death; Palermo, Sept. 17-24, 9 cases, 2 deaths.
 Mexico: City of Mexico, Sept. 17-24, 2 cases.
 Russia: Sept. 10-17, Moscow, 6 cases, 1 death; St. Petersburg, 9 cases, 1 death; Warsaw, Sept. 13-20, 20 deaths.
 Turkey: Sept. 17-24, Alexandretta, present; Beirut, present; Constantinople, Sept. 18-24, 19 deaths.

YELLOW FEVER.

Mexico: Coahuacalcos, Sept. 17-24, 15 cases, 4 deaths; Sept. 25-Oct. 10, Merida, 1 case; Tehuantepec, 1 case, 1 death.

CHOLERA.

India: Bombay, Sept. 6-13, 4 deaths; Calcutta, Aug. 26 Sept. 10, 10 deaths.
 Russia: Transcaucasian territory and Central Asia, Askabad, Aug. 19, 1 case, 1 death; Balcum Ali, Aug. 14-17, 8 cases, 4 deaths; Khabka, Aug. 12-19, 12 cases, 5 deaths; Merv, Aug. 18-19, 29 cases, 16 deaths; New Bokhara, Aug. 16, 1 case, 1 death; Tadjik, Aug. 12, 1 case, 1 death; Trans-Caucasia, Baku, Sept. 11, 5 cases.

PLAGUE—INSULAR.

Philippine Islands: Manila, Aug. 13-20, 1 case, 1 death.

PLAGUE—FOREIGN.

Egypt: Sept. 3-9, Alexandria, 9 cases, 8 deaths; Tuhk, 6 cases, 4 deaths.
 India: Bombay, Sept. 6-13, 62 deaths; Calcutta, Aug. 26 Sept. 3, 7 deaths; Karachi, Sept. 4-11, 6 cases, 2 deaths.
 Japan: Formosa, Aug. 20-27, 7 cases, 9 deaths.

State Boards of Registration.

COMING EXAMINATIONS.

Board of Medical Examiners of the State of California, San Francisco, October 25, Secretary, Charles L. Tisdale, M.D., Alameda.
 Nebraska State Board of Health, November 9-10, State House, Lincoln. Secretary, George H. Brash, M.D., Beatrice.

Illinois July Report.—Dr. J. A. Egan, secretary of the State Board of Health of Illinois, reports the written examination held at Chicago, July 20-22, 1904. The number of subjects examined in was 11; total number of questions, 110; percentage required to pass, 75. The total number examined was 168, of whom 159 passed and 9 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Baltimore Medical College,	(1894) 85,	(1904) 87	
College of P. and S., Baltimore,	(1904) 87		
College of P. and S., Chicago, (1904) the grade of 77 was reached by one, 80 by one, 82 by one, 83 by three, 84 by three, 85 by three, 86 by two, 87 by four, 89 by one, 91 by two.			
Coll. of P. and S. Columbia University, New York, (1904)	83		
College of P. and S., St. Louis, (1904)	82		
Columbia University, Washington, D. C., (1903)	86		
Dearborn Medical College, Chicago, (1904) the grade of 76 was reached by two, 80 by one, 81 by one, 82 by three, 83 by two, 84 by two, 85 by two, 88 by one.			
Hahnemann Med. Coll. and Hosp., Chicago, (1904) 88, 88, 88, 86			
Harvey Medical College, Chicago, (1904) the grade of 80 was reached by one, 81 by two, 82 by one, 84 by four, 85 by four, 86 by one, 87 by one, 89 by one.			
Illinois Medical College, Chicago, (1904) 83, 82, 77, 83			
Jefferson Med. Coll., Philadelphia, (1880)	80		
Jenner Med. Coll., Chicago, (1904) 79, 81, 80, 82, 77, 85			
Johns Hopkins Med. School, Baltimore, (1904)	88, 87		
Kentucky Univ. Med. Dept., Louisville, (1904)	81, 82		
Louisville Medical College, (1904)	86		
Marion-Sims-Beaumont, St. Louis, (1897) 81, (1904)	82, 84		
McGill University, Montreal, (1904)	92		
Med. Coll. of Indiana, Indianapolis, (1904)	80		
Med. School, Harvard Univ., Boston, (1904)	86		
National Med. Univ., Chicago, (1904) the grade of 79 was reached by one, 80 by two, 81 by one, 82 by one, 86 by one, 87 by two, 89 by one, Athens, Greece, (1900) 81, (1902)	80		
Northwestern Univ. Med. School, Chicago, (1903) 86, (1904) the grade of 80 was reached by one, 82 by one, 83 by one, 85 by one, 86 by three, 87 by four, 88 by four, 89 by seven, 90 by one, 92 by one.			
Royal Univ. Vienna, Austria, (1898)	85		
Rush Medical College, Chicago, (1902) 89, (1903) 87, 91, 83, 83, (1904) the grade of 83 was reached by one, 84 by two, 85 by one, 86 by five, 87 by two, 88 by seven, 89 by five, 90 by four, 91 by one.			
Trinity Medical College, Ontario, (1894)	87		
Univ. of Michigan, Ann Arbor, (1903) 91, (1904)	86		
Univ. of Parma Italy, (1903)	79		
Univ. of Pennsylvania, Philadelphia, (1903) 91, (1904)	82		
Wisconsin College P. and S., Milwaukee, (1904)	86		

FAILED.

Chicago Homeo. Med. College, Chicago, (1903)	74
College of Med. and Surg., Chicago, (1904)	40, 72
Harvey Medical College, Chicago, (1904)	64
Louisville Medical College, (1891)	73
Miami Med. Coll., Cincinnati, (1904)	63
National Medical Univ., Chicago, (1904) 66, 69, 72	

The general average for all representatives of the College of Physicians and Surgeons, Chicago, who passed was 85; of Dearborn Medical College, 82.2; of Harvey, 84.1; of Jenner, 80.7; of National Medical University, 82.7; of Northwestern University, 86.7; of Rush, 86.2.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Hawaiian Territorial Medical Society, Honolulu, November 5.
 Oklahoma State Medical Association, Oklahoma City, November 9.

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Thirtieth Annual Meeting, held in the Hall of Congresses, St. Louis, Oct. 10-15, 1904.

Addresses of welcome were delivered by Governor Alexander M. Dockery, on behalf of the State of Missouri; by President David R. Francis, on behalf of the Louisiana Purchase Exposition, and by certain of the foreign delegates, after which Medical Director John Cropper Wise, U. S. Navy, delivered the presidential address, entitled "The Ideal Military Surgeon."

Organization of the Army Medical Department.

An abstract was submitted of the essay to which was awarded the Enno Sander prize, on "The Relation of the Medical Department to the Health of Armies." The plan contemplates the organization of the Army Medical Department on a new basis, recognizing the fact that medical officers, like other men, differ much in their capacity for performing properly the manifold duties which devolve on them, and that in their assignments their special abilities and experience should be taken into consideration. Few are or can become skilled operators, and few are or can become skilled sanitarians; hence the importance of putting these specially skilled men where they are most needed.

The Army Medical Reserve.

MAJOR AZEL AMES, U. S. V., reviewed the composition of the medical staff of the United States Army since 1846, in which the contingent fresh from civil practice has always necessarily been large and disproportionate. The acting assistant surgeon is a chief factor of this contingent, always of anomalous status; his very existence has been made impossible by the decisions of the Judge Advocate General and of the Secretary of War. As it is essential to supply his place with a commissioned competently trained officer, an adequate corps should be drawn from physicians in civil life. This corps should be made an adjunct of the Army, available on call, maintained at the minimum of expense and the maximum of efficiency, easily mobilized and always under training. To establish the means and standing of their instruction, Major Ames recommends the establishment of an army medical school, the adjunct and reserve medical corps being instructed and examined by the school, by means of the correspondence method now so successful in scientific educational institutions. Thus the unsatisfactory and anomalous position of the contract surgeon body would be taken by a homogeneous commissioned corps of competent medical men in civil practice, ready to take the field on call or to serve as needed in time of peace, viz., the Medical Reserve Corps of the United States Army.

The Russian-Japanese War.

MAJOR LOUIS L. SEAMAN, U. S. V., who has recently returned from the seat of war in Manchuria, declared that the United States is very far behind the Japanese in matters of military medical organization and sanitation. The Japanese are the first to recognize the true value of the army medical corps. As he saw the organization in operation, the care of the sick and wounded consumed but a small share of their time. The solution of the greater problem of preventing disease by the careful supervision of the smallest details of subsistence, clothing and shelter is their first and most important duty. Nothing is too small to escape their vigilance, nor too tedious to weary their patience, and everywhere, in the field with the scouts or in the base hospitals at home, the one great, prevailing idea is the prevention of disease. The medical offi-

cer will be found both in the front and in the rear. He is with the first screen of scouts, with his microscopes and chemicals, testing and labeling wells, so that the army which follows shall drink no contaminated water. When scouts reach a town, he immediately institutes a thorough examination of its sanitary condition, and if contagion or infection be found, he quarantines and places a guard around it. A medical officer accompanies foraging parties, and with the commissariat officers, samples the various food, fruit and vegetables sold by the natives before the arrival of the army. If the food be tainted, or the fruit overripe or the water require boiling, notice is posted to that effect. As a result of all this, the medical officer is not obliged to treat cases of dysentery and fevers that follow improper subsistence and neglected sanitation—diseases that have brought more campaigns to disastrous terminations than the strategy of opposing generals or the bullets of their followers. He stated that up to August 1, 9,802 patients had been received at the hospital at Hiroshima, of whom 6,636 were wounded, and that of the entire number only 34 had died.

Major Seaman also spoke of the contrast which he found on visiting the Russian lines, and told of the brutality, debauchery, apathy and criminal carelessness of the Russian officers.

(To be continued.)

CLEVELAND ACADEMY OF MEDICINE.

Eighteenth Regular Meeting of the Clinical and Pathological Section, held Oct. 7, 1904.

Dr. C. A. Hamann in the Chair.

Drs. W. T. Corlett and F. E. Bunts presented cases and Dr. J. J. Thomas showed a heart from a five-week-old child, in which the interventricular septum was incomplete, and the foramen ovale patent. The child showed slight cyanosis only at the conclusion of spasmodic attacks of dyspnea.

Albuminuria in Appendicitis and Hernia.

Dr. F. E. BUNTS reported 50 cases of appendicitis and 50 cases of hernia with reference to albuminuria. He contrasted the 50 cases of appendicitis as representing an intraperitoneal inflammatory condition, with the 50 cases of hernia, representing a non-inflammatory condition. The number of cases, though small, showed that in the inflammatory cases primary albuminuria was more frequent than in the non-inflammatory cases and that improvement or disappearance of albuminuria followed operation in 10 per cent. of the former and in but 4 per cent. of the latter. The statistics, being of but 100 cases, are meager, but suffice to emphasize observations made by Dr. John C. Munro that albuminuria is found in a large percentage of surgical cases, that it can not be considered on any ground yet established, that it is of itself a contraindication to operation; of the 100 patients reported, only two, both with acute suppurative appendicitis, having died.

Occlusion of the Bowel with Absorbent Cotton.

Dr. G. S. SMITH reported a case of pyrexia and reversed intestinal peristalsis, from mechanical irritation and temporary occlusion of the bowel, due to the presence of a large amount of absorbent cotton in the alimentary canal of a child aged 2½ years. For twelve hours after the cotton had been swallowed no symptoms appeared. Then suddenly signs of extreme prostration and drowsiness developed, with a temperature of 102. Tympanites was moderately pronounced over the epigastrium. In other respects physical examination was negative. The temperature steadily rose for twenty-one hours, finally reaching 105. At this time a large volume of bilious vomitus was thrown off, with no marked improvement. Later the colon was flushed and the cotton and a small amount of fecal matter removed. The symptoms of prostration and anorexia persisted for twenty-two hours longer, the temperature returning to normal by lysis. The recovery was finally as rapid as the onset had been nearly forty-eight hours previously.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-fourth Annual Meeting, held at Pittsburg, Sept. 26 to 29, 1904.

(Continued from page 1163.)

Tympanites.

Dr. J. C. O'DAY, Oil City, cited his unfortunate experience in his first case of obstinate tympanites in which operation was not done. While believing that needle puncture is unsurgical, he is convinced from an experience of two cases that the operation should be encouraged, because its dangers are nil, and many untrained in the use of the knife could resort to this simple procedure with successful result.

Autointoxication.

Dr. EDWIN W. MOORE, Franklin, said that the real cause of autointoxication is an unsolved mystery, and claimed that perverted nutrition and cell destruction afford sufficient cause to justify it a place as a causative factor in disease. He separated autointoxication from infection by giving to the infection theorists all conditions of exogenous origin, and to the autointoxication investigators those of endogenous origin. He admitted a large field of toxemias between these extremes as unclassified and of no known definite origin. He differentiated rheumatism, gout, many nervous diseases, jaundice from obstruction, Addison's disease and many gastroenteric conditions as autointoxications, and questions the right of investigators in claiming anemia as an infection.

Symptomatology and Treatment of Influenza.

Dr. SAMUEL WOLFE, Philadelphia, said that the history of influenza showed characteristic deviations from the clinical type, but that the affinity of the specific cause for mucous membranes and nervous structures is constantly demonstrated. There is reason to believe that certain symptoms are caused by the bacillus itself, and certain others by the toxin resulting from it, but strict differentiation is not yet practicable. The treatment aims at the control and mitigation of such conditions as fever, pain, catarrhal inflammations and central nervous derangements. Facilitating the elimination of the toxin must be regarded as important.

Pleurisy with Effusion.

Dr. J. E. RIGG, Wilkensburg, considered the frequency of pleurisy found at autopsies, the forms of pleurisy, tuberculosis as a predisposing cause, and cold, traumatism and infection as exciting causes. The value of blisters in the early stage was discussed, the optional use of the aspirator, with the positive signs for its prompt use. He also mentioned the value of tincture of aconite combined with belladonna.

Pneumonia.

Dr. JOHN R. MCCARTY, Fredonia, is at variance with those advocating the expectant treatment in pneumonia. From 32 years' experience, he considers spirit of chloroform a specific, when given early. Two cases were cited. The first, seen as soon as the patient emerged from a severe chill, received 20 minims every fifteen minutes for six doses, and every hour thereafter, and dismissed the next day. Case 2 was seen eight hours after the initial chill, and dismissed on the third day. The remedy is of no avail after bapuzation is established. He uses aconite in combination. Salicylic acid alone will cure and abort pneumonia by its antiseptic action. He gives it by absorption by dissolving it in gasoline and applying it externally. His mortality has been but 2 per cent.

Blood Analysis.

Dr. J. M. McNALL referred to the advantages of blood analysis, with its limitations and requirements. He defined leucocytosis, and gave its varieties, absolute and relative, and emphasized the importance of relative count and leucocyte curve.

Sea Bathing.

Dr. PHILIP MARVEL, Atlantic City, spoke of the great an-

tiquity of sea bathing as a curative of bodily ills. The influence of temperature, conditions of the atmosphere, the physical and mental condition of the individual, and the fact that the water is truly a mineral water, were facts not to be lost sight of. Observations were noted of the slowing or enfeeblement of the pulse of those submerged for hours in the sea and of those immersed for a time in water at a temperature higher than that of the body, with a lowering in the systemic resistance. He believes that sea bathing as practiced on the Atlantic coast is responsible for greater harm than good, and believes that physicians have been too long silent on the subject. They should impress on those under their care the advantages of a short exposure, not exceeding 30 minutes, and the necessity for prompt and positive reaction. Sea bathing is indicated in those weakened conditions where normal metabolism is inhibited or perverted nutrition exists, and is contraindicated where the arterial elasticity has been changed or lost, as in arteriosclerosis and capillary fibrosis; also in those cases in which the peripheral vessels have ceased to respond to reflex stimuli; in any condition in which the stimulation would favor internal hemorrhage; in cases of chronic heart disease, and in cases in which lowered resistance necessitates more than ordinary care of the patient's forces.

DISCUSSION.

DR. S. S. COHEN, Philadelphia, believed that sea bathing was abused, and that the responsibility for changing this lay with the physician.

Ulnar Palpation and Transmanual Auscultation.

DR. DAVID RIESMAN, Philadelphia, designated as ulnar palpation a method which he believes gives more satisfactory results than the one commonly employed. Dr. Riesman's method consists in applying the ulnar surface of the hand and little finger into each interspace, the hand being held perpendicularly to the chest. In the old method an area much larger than the seat of disease is often covered, and the fremitus of the diseased area is modified by that of the surrounding normal tissue. The method gives very accurate information and enables one to discover small shades of difference in the fremitus of contiguous interspaces or corresponding areas of the two sides. It also shows accurately the upper level of an effusion and the limits of a plastic exudate. It is of most value in examining the front of the chest, but may be also used for the back. After speaking of the difficulties of the method of timing heart murmurs, and of the unsatisfactory results generally given by timing murmurs by means of the carotid pulse, Dr. Riesman described a method which overcame some of the difficulties. It consists in auscultating with the binaural stethoscope through the hand placed over the apex beat. By this method the apex beat is felt and the murmur heard at the same point, and timing becomes easy. The best stethoscope for the purpose is one provided with a diaphragm. Not only is it possible to hear murmurs plainly through the hand, but almost as satisfactory results can be obtained by placing a finger flexed at a right angle on the apex beat, and then resting the stethoscope on the finger. The principal advantage of transmanual auscultation is found in the differentiation of presystolic from systolic murmurs. It is also of use in timing musical and other peculiar murmurs that are heard over the entire precordia, or perhaps the entire chest. The successful application of the method presupposes the existence of a palpable heart.

DISCUSSION.

DR. S. SOLIS-COLEN thought this method of transmanual auscultation one of the greatest advances made in physical diagnosis and urged it on the attention of the members.

Myocardial Degeneration.

DR. ALBERT E. ROUSSEL, Philadelphia, stated that if the statistics of Schott were accepted, it would be found that diseases of the myocardium were more frequent than those of the endocardium in the proportion of 505 to 245. He believed that arteriosclerosis must be accepted as an important factor in many cases of cardiac degeneration, and considered it worthy

of note that at least partial occlusion of the coronary arteries due to this cause may be compensated through the vessels of Thebesius with avoidance of the otherwise resulting damage. Parenchymatous degeneration, fatty heart and allied conditions were considered, with their etiology and treatment. The diagnosis of many cases of fatty degeneration he believes more difficult than that of a fibroid heart and is confident that often cases of this disease are not recognized even after a physical examination. This is because the size of the heart in simple fatty degeneration is little changed, and the area of dulness presents no alteration.

Practical Points Concerning Smallpox.

DR. WILLIAM M. DAVIS, Pittsburg, emphasized the importance of taking into consideration the entire symptom complex. Contrary to some opinions, he believes the primary fever to be very contagious. The varieties of smallpox in reference to diagnosis and prognosis were discussed.

The Test for Occult Blood in the Feces, and Its Clinical Significance.

DR. J. DUTTON STEELE, Philadelphia, said that by occult is meant an amount of blood so small that it can not be recognized by the naked eye or by the microscope. It has been found by certain German observers that the old guaiac test for hemoglobin can be so modified as to detect exceedingly small amounts of blood in the feces. This is of special value in the diagnosis of gastric carcinoma and gastric and duodenal ulcers. The blood is constantly present in the stools of carcinoma and is intermittently present in cases of gastric and duodenal ulcer, and organic but benign stricture of the pylorus. Dr. Steele reported seven cases in which the test had been applied and in which it appeared to be as valuable as is claimed. He is of the opinion that the method is a distinct advance in the diagnosis of gastrointestinal diseases and will soon rank with such symptoms as the absence of hydrochloric acid in cancer or hyperacidity in ulcer.

DISCUSSION.

DR. J. A. LICHTY, Pittsburg, said that his knowledge of the subject lay in what he had read in Boas' publications, but that he would employ the test, which he believed would be of special value in revealing the cause of many cases of so-called primary anemias.

Tuberculosis of the Gastrointestinal Tract.

DR. J. A. LICHTY, Pittsburg, reported a case having perforation and partial stenosis of the bowels. The modes of infection of the gastrointestinal tract were given as primary: *a*, by inspiration; *b*, by kissing; *c*, by dirty objects or contaminated hands which find access to the mouth; *d*, food from infected animals, or food which accidentally became infected; or secondary, that is, from the swallowing of sputum which is tuberculous.

The Diagnosis of Cirrhosis of the Liver.

DR. ALFRED STENGEL, Philadelphia, stated that cirrhosis of the liver is usually recognized when the disease has reached a practically incurable stage. This statement, however, Dr. Stengel said, needs some modification, for occasionally cases not recognized until ascites and other signs of portal obstruction have developed recover from these striking symptoms and survive, which is probably due to the fact that with the terminal cirrhotic change in the liver there is always a considerable amount of cellular infiltration which is removable. He referred to a certain train of symptoms met in the earlier stages of cases of cirrhosis as well as in other conditions, and then proceeded to a discussion of the differential diagnosis. With regard to the occurrence of enlargement in the early stage of cirrhosis, he stated that, contrary to the opinion of Leube, he had watched cases of cirrhosis from a stage when the liver was enlarged to the terminal contracted condition. The symptoms in congestion are practically those that usually are seen, but there is always found some adequate circulatory cause for the congestion, some form of cardiac or obstructive pulmonary disease which prevents the proper circulation of

the blood; the congestion is found to fluctuate with the fluctuations in the underlying condition. Dr. Stengel referred to the chemistry of cirrhosis and stated that the only test that had proved of any value, and this merely confirmative, is that for urobilin. Among the conditions causing the train of symptoms met with, cirrhosis is the only one which regularly produces urobilinuria. Finally, in referring to the physical examination for cirrhosis in its more advanced stages, he warned against a too ready acceptance of the results of percussion as an indication of decrease in the size of the spleen, and advocated a more general appreciation of the value of splenic enlargement in the diagnosis of cirrhosis of the liver.

DISCUSSION.

DR. DAVID L. EDSALL, Philadelphia, referred to alimentary leucosuria as one of the chemical methods used in the diagnosis of liver disease. Strauss administered 100 grams of levulose on an empty stomach and determined that levulose appeared in the urine in a large proportion of cases of liver disease, but in only a small proportion of cases of disease of other kinds. Dr. Edsall, from his own results and those of others, is skeptical as to the diagnostic value of this test. He emphasized the ease with which the test for urobilinuria may be carried out when the method of Hammerschlag is used. The determination of large amounts of phenol in the urine is a test which he is inclined to regard favorably. He thought it would be worth while to determine to what extent the products of putrefaction escape into the general circulation and then into the urine in liver disease, as a loss of the liver's function more or less complete might be indicated by their escape in abnormal quantity. Of the various substances that Dr. Edsall has investigated in this connection he found that phenol alone seemed to show reasonably characteristic changes. While this substance is variable in liver disease, it seems to him that a very large amount of phenol in the urine is strongly suggestive of liver disease when other evident reasons for its presence are absent.

The Home Modification of Milk.

DR. THEODORE J. ELTERICH, Allegheny, emphasized a few general truths regarding the home modification of cow's milk without attempting to cover the work already done in this direction or to criticize the various methods in use at the present time. The percentages of the proteids and fat, very low at first, are gradually increased until they approximate the averages required at the end of the first year. The quantity for each feeding depends on the age of the child and the table recommended by Heit is usually followed.

Observations on Food in Typhoid Fever.

DR. JAMES I. JOENSTON, Pittsburg, said that in the management of typhoid fever the attention should be directed primarily to the nursing, care of the patient, efficient hydrotherapeutic measures and to proper feeding; secondarily, to the employment of drugs, usually for the relief of symptoms. He discussed the question of food, about which there is diversity of opinion, and quoted the case of Dr. Stuart Patterson of Pittsburg, in which the patient had no food for twenty-one days—water only being given. The course of the disease was very favorable and the loss of flesh and strength no more marked than usual. While not agreeing entirely with those who would give no food during the period when desire for it is absent, Dr. Johnston has restricted his patients at this time of the disease very greatly, and in a study of some fifty cases he thinks he has seen some advantage, at least in comfort to the patients, when compared with fifty other cases treated immediately preceding this group. In the class of cases in which limited feeding was employed during the period of anorexia the cases were less toxic, were no more emaciated than other cases, and made a quicker convalescence. There were but three relapses, no perforations and few hemorrhages. All had flat abdomens, one only required treatment for tympanites and few any treatment for diarrhea other than stopping nourishment for a brief period.

(To be continued.)

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirtieth Annual Meeting, held in Cincinnati, Oct. 11-13, 1904.

The President, Dr. Hugh T. Patrick, Chicago, in the Chair.

The mayor of Cincinnati delivered an address of welcome, which was responded to by Dr. Dudley S. Reynolds of Louisville.

What Shall Be Done with the Criminal Insane?

DR. JOHN PUNTON, Kansas City, Mo., said that the conflict of authorities raging between law and medicine is responsible for much miscarriage of justice. A mutual conference to adjust differences of opinion and formulate conclusions relative to the medico-legal aspects of insanity in keeping with the more advanced state of medical knowledge, which can be used as a criterion in courts of law, is greatly to be desired.

DISCUSSION.

DR. A. RAVOGLI, Cincinnati, deprecated the tendency to generalize to much in discussing the criminal insane. He reported a case in which an epileptic committed several murders before his insanity was recognized.

DR. CHARLES W. HITCHCOCK, Detroit, said that this was a very delicate question for the medical profession to decide, and a case was reported showing that justice might miscarry, even where there was an institution provided for the incarceration of those not responsible under the law.

DR. G. FRANK LYDSTON, Chicago, said that the entire subject of criminology should be relegated to the medical profession, so far as the physical conditions and remedies therefor are concerned. Many irresponsible individuals are punished. Punishment for crime has proved a distinct failure. Both the sane and the insane criminals should be removed from our social system and isolated. The principle should be not punishment, but simply social self-defense. We have not yet come to the sterilization of these individuals, but we undoubtedly will.

DR. F. W. LANGDON, Cincinnati, said that the legal and medical professions have different points of view, and, therefore, their conclusions must vary. He agreed with Dr. Lydston as to the punishment of the sane and insane, and said that we should not arrogate to ourselves the fixing of the penalty that probably was never right.

DR. B. F. BEEBE, Cincinnati, stated that law has been coming to medicine on this question, because the prosecutors have been securing the assistance of medical men. Society must be protected, but the question is how and when and where to take care of the criminal insane. We must determine what constitutes responsibility or irresponsibility. While the laws of the various states do not agree, there is practical unanimity among those who have studied this subject from a medical standpoint.

DR. DUDLEY S. REYNOLDS, Louisville, spoke of the qualifications of the jury, requiring that they be not familiar with the facts and not opposed to capital punishment. Such qualifications do not require that the jury be really competent to decide these cases, and medical men are called in to testify as to the responsibility or irresponsibility of the defendant. Medical testimony is based not on an examination of the individual, as a rule, but on hypothetical questions constructed by the lawyers. The chief trouble is with the legislative conditions in the various states. Any person convicted of a felony should be unsexed rather than killed. No person in his right mind would commit a felony.

DR. SPRAGUE referred to the fact that the use of the asylum for the criminal insane is being rapidly extended throughout the country by the legal and medical professions. Often the attorneys for the prosecution and defense agree to rest the matter of commitment or trial with the medical commission of such an institution. Such a reference would be more frequent if there were more assurance that such a medical commission were composed of really expert medical men.

DR. LYDSTON in answer to a question stated that sterilization could be effected by obliteration of the fallopian tubes in the female, and by obliteration of the vas deferens in the male.

without any effect on the individual, save the arrest of the function of procreation.

Loss of Consciousness and Automatism in Inebriety.

Dr. THOMAS D. CROTHERS, Hartford, Conn., said that the claims of no recollection or consciousness of events by inebriates indicate a paralysis of certain brain sections during which the victim may act automatically and be without consciousness of the real condition. Histories of prominent cases confirm this fact, and many startling crimes have been committed in this condition. This new phase of irresponsibility has not been recognized by the courts and only recently has been studied by physicians. The defense of no recollection may be a reality in some cases, and should be recognized by physicians. Such persons are insane.

DISCUSSION.

Dr. B. F. BEEBE stated that the essential point is to prove the fact of the unconsciousness and the automatism. An idea can not exist if the brain cell is not in a condition to receive and retain an image. Whether unconsciousness is produced by alcohol or by any other poison, the result is the same.

Dr. JOHN PUNTON said that the medical profession ought to know the effects of alcohol on the nerve cells, but, when this question comes up in court there are as many opinions as there are physicians. It is not the individual's opinion the court asks for, but rather the consensus of opinion of the medical profession in reference to the question at issue.

Dr. HUGH T. PATRICK said that it is necessary to make a very fine distinction between alcoholic automatism and automatism in the alcoholic. In many degenerates or imperfects, there is a tendency to drink too much. The automatism and the drinking may be the result of a pre-existing condition.

Echinacea.

Dr. C. S. CHAMBERLIN, Cincinnati, made a plea for the recognition of echinacea as a valuable therapeutic agent. He gave a brief history and description of the drug, and protested against the suspicion with which the regular profession regards remedies introduced by irregular practitioners, and their reluctance to investigate the merits of the remedies. He cited brief reports of cases illustrating the therapeutic value of the drug as an alterative and antiseptic, and its range of application.

The Early Recognition of Important Eye Lesions by the Practitioner.

Dr. GEORGE F. SUKER, Akron, Ohio, pointed out the early diagnostic eye lesions in diabetes, chronic nephritis and locomotor ataxia. Reference was made to the diagnostic conjunctival spot in cases of measles. He spoke of the frequency in mistaking glaucoma for trifacial neuralgia; also the frequency with which simple, chronic glaucoma is confounded with cataract. He emphasized the need of recognizing the eye conditions as a factor in chorea, functional epilepsy, neurasthenia and hysteria. The relation between gastrointestinal derangements and certain eye lesions was pointed out, and the need of a thorough ophthalmic examination in the neurotic, chlorotic and patients of this character emphasized.

The Value of the X-Ray to the General Practitioner.

Dr. JAMES E. COLEMAN, Canton, Ill., stated that as the practice of medicine is still largely in the hands of the general practitioner, it makes it necessary for him to improve to the greatest extent his resources for diagnosing and combating disease. X-ray apparatus has become a necessary adjunct. To be satisfactory it must be first class. Every general practitioner should have one text-book on x-ray therapy. The mastery of the details and technic is not difficult when studied, but success depends on a knowledge of anatomy and proper interpretation of the screen and skiagraph.

Macular Atrophy of the Skin.

Dr. EDWARD H. SHIELDS, Cincinnati, said that this rare dis-

ease was first described by Jadassohn in 1892 and no other case has been reported. Dr. Shields presented the following history of a case: Eighteen months ago red macular lesions were found on the legs and thighs, with no subjective symptoms. Some weeks later the patches lost redness, became softer, depressed, and the skin over the diseased area became shriveled; atrophy continued for several weeks, when the atrophic spot became soft and pale. Owing to the marked irritability of the skin the atrophic lesions did not appear very pale immediately after the removal of the clothing, but after half an hour of absolute rest they became quite pale, resembling those of morphia. He stated that treatment was of little value, yet in due course of time the process was arrested.

Why So Many Errors in the Diagnosis of Exophthalmic Goiter?

Dr. J. H. STEALY, Freeport, Ill., showed what a remarkably large number of cases of this disease can be found if sought for. He discussed the percentage of symptoms, the diagnostic importance of each, and the symptomatology.

(To be continued.)

MEDICAL SOCIETY OF THE COUNTY OF NEW YORK.

Regular Meeting, held Sept. 26, 1901.

The President, Dr. Wendell C. Phillips, in the Chair

Summer Work of the Health Department.

Dr. JOHN J. CROXIN, assistant chief medical inspector, reviewed the work of this department since its inception in 1876. Pamphlets are now printed in several languages for distribution for mothers' instruction, with words of caution in regard to gastrointestinal diseases. There is house-to-house visitation, advice is given, and where sickness is severe a trained nurse is sent. When a child is found to be sick the store from which the milk was obtained with which it has been fed is inspected. Hot weather and ignorance are responsible for the high infant mortality. Flushing the streets after sundown would ameliorate the heat somewhat. One-third of the deaths occurred among children under two years of age, who were fed on condensed milk and prepared cereals during the month of August. The report of the inspectors during the past summer showed 215,997 families visited and the history card-numbering 35,187, all of children under one year of age.

Prevention of Spread of Disease in New York City Schools.

Dr. THOMAS DARLINGTON, commissioner of health of New York City, stated that the medical supervision of schools was undertaken in 1897. During the school year 1901-1902, 260,182 children attended and there were 9,703 exclusions. In September, 1902, the routine inspection of schools was begun by classes; the children passed by the inspector pulled down their own eyelids, etc., the inspector never touching a child. The inspectors found that many contagious diseases were not reported; during six months they found 561 cases of measles, 107 cases of German measles, 70 cases of scarlet fever, etc., unreported. The public libraries received daily lists of homes where contagious diseases existed. Eight trained nurses have been assigned the care of children suffering from skin and eye diseases. In 1903 there were cared for 156,186 cases of pediculosis, 106,257 cases of eye diseases, 3,307 of eczema, 3,498 of ringworm, 335 of scabies. It was recently discovered that 17 per cent. of the children were affected with trachoma.

Disinfection by the Health Department.

Dr. ROBERT J. WILSON, assistant bacteriologist of the New York City Department of Health, described the methods used in this work. During the past two or three years attempts have been made at bacteriologic control by placing in the room to be disinfected living bacilli (procyaneus) on threads. On the following day this was sent in for growth; if the cultures were positive the disinfection was well done. Sulphur dioxide and formaldehyd were the only two disinfectants allowed the Board of Health. In different parts of Greater New York there

were disinfectant stations where the germs which occupied the deeper parts of fabrics could be destroyed. Here a temperature of 225 degrees F. was employed for several hours.

Specific Treatment of Typhoid Fever.

DR. T. M. HACKETT, Champlain, N. Y., said that after fifteen years of experiment with blue mass and calomel in the treatment of typhoid fever he did not hesitate to make the statement that this remedy acted as a specific in the treatment of typhoid fever. As a result of his experience he has observed these facts: 1. In all cases of typhoid fever mercury is well borne by the system; it requires more mercury to get the constitutional symptoms of tenderness of the gums when typhoid fever was present than under any other circumstances. 2. In the administration of blue mass in typhoid fever gradually as the system is impregnated with mercury just so gradually are the bacilli disappearing from the system, so that by the time the mercury begins to affect the gums the bacilli are no longer active in the system. This is signified by a gradual reduction of temperature to normal and a rapid convalescence. 3. With the use of mercury the patient's blood is in a more healthful state; mercury maintains the red corpuscles and the system does not fall into that state of grave anemia so common to the disease. 4. The patient may begin taking solid food as soon as the temperature is normal without danger of relapse; this he attributed to the state of the blood consequent on the presence of mercury in the system. 5. A few days after the beginning of the administration of mercury in typhoid the tongue becomes moist, the breath becomes less fetid and there is a desire on the part of the patient to take the nourishment prescribed. The odor of the stools becomes less fetid. He has not had a dry tongue continue over three or four days after the treatment was begun. 6. The temperature of the patient thus treated did not go subnormal after the fever left. 7. It is unnecessary, unpardonable and unscientific to salivate a patient when using mercury in the treatment of typhoid. He has yet to observe any ill effects of the slightest nature from the use of mercury to the extent only of the soreness of the gums. He called attention to the temperature charts of several recent cases which were accompanied with certificates from the State Board of Health certifying that the Widal reaction was present. The charts showed that three weeks covered the whole period of illness and that the third week was a week of convalescence.

DISCUSSION.

DR. EGBERT LE FEVRE said that he had had some experience with the mercurial treatment of typhoid fever. He had noted that the temperatures were reduced, but the mortality was higher than under the present plan of treatment. He believed that any plan of treatment would offer results which varied according to the epidemics; in the later epidemics the disease ran a shorter course as a rule. He had endeavored to make the intestinal canal antiseptic and had failed, and he doubted if there was any agent which would place the blood in a condition to destroy the Eberth bacillus.

Travel Notes.

XIII.

THE MELBOURNE HOSPITALS.

NICHOLAS SENN, M.D.
CHICAGO.

FREMANTLE, AUSTRALIA, Aug. 15, 1904.

Man, the masterpiece of creation, the image of God, is subject to pain, disease and death wherever chance or circumstance may have fixed his abode in the world, as

"There is no mortal whom pain and disease does not reach." Cicero.

Primitive man has no, or at best only an imperfect, conception of the ways and means to protect himself against the disease-producing influences and he is powerless, or nearly so, when afflicted by accident or disease. For ages civilized man

has endeavored to ascertain the cause of diseases and to discover remedies for their prevention and successful treatment. In their primitive state the aborigines, living a natural life, are less exposed to injury and disease than civilized man living in luxury and intent on the accumulation of wealth or the gain of fame, for

"Increased means and increased luxuries are the two civilizers of man."—Disraeli.

Civilization and the conditions and circumstances attending and following it have bred the most destructive diseases unknown to the primitive races. Firearms, commerce, increase of travel and the various industries incident to civilization are productive of accidents from which the natives in their original state were almost exempt. On the other hand, civilization has always been concerned in establishing effective sanitary measures and in devising rational and more successful treatment of injuries and disease. The principal functions of every intelligent and humane government consists in protecting its citizens, so far as possible, against disease and in making ample provisions for its indigent sick. Australia has met these two duties in a most creditable manner, as is so well shown by its well-organized effective Boards of Health, the many excellent hospitals and other numerous charitable institutions. The public hospitals are managed and supported nearly in the same manner as the hospitals in England. It is an inflexible rule that none of these hospitals should provide for private patients. They are supported by donations, life and annual subscribers, by government appropriations and pay patients. The medical men give their services gratuitously; the internes and nurses receive small salaries. The churches of different denominations, societies and individuals in all the states contribute liberally toward the building and maintenance of hospitals. Protestant denominational hospitals are unknown.

Melbourne is the capital of the state of Victoria. It is a beautiful city, built on the undulating hills on both sides of Yarra river, with a population of nearly half a million. Its streets are well paved, clean and well lighted with electricity, and its system of cable trams affords an easy and rapid means of reaching all parts of the city and almost every public institution. The many well-kept public parks, botanical and zoological gardens, museum and library furnish ample proof of the public spirit of its citizens. Nearly all of the business buildings and residences are either solid stone or brick structures. There is no private residence without its garden ornamented with subtropical trees, flowering shrubs and flowers. The Australian takes as much pride in his garden as he does in his house, and this applies equally to rich and poor, large residences and small houses. The city in its general aspects bears a close resemblance to Belfast, Ireland. The water supply and sewerage are now in a satisfactory condition and have contributed much in reducing the former frequency of typhoid fever.

THE MELBOURNE HOSPITAL.

The Melbourne Hospital is the principal general hospital of the state. It is centrally located. It is a two-story sandstone building with a wide front and several pavilions, enclosing a square in the rear of the main building. Viewed from without it presents a somewhat stern, antique and very massive appearance. One of these pavilions is devoted to diphtheria cases and stands isolated from the remaining buildings. The hospital can accommodate 300 patients. It is in this hospital that the medical students of the University of Melbourne receive their clinical instruction. It has no gynecologic staff, all gynecologic cases being referred to the attending surgeons. The more legitimate specialties are well represented. The medical and surgical cases are under the care of four physicians and an equal number of surgeons, whose services are continuous throughout the year. The resident staff consists of a medical superintendent and eight internes. The latter are selected from the graduates of the university who have the highest standing; they remain for one year and serve in the different departments by being transferred every three months. The nursing is in charge of several sisters and 92 pupil nurses. The operating amphitheater is small but well lighted and on elevated seats

guarded by iron bars provides standing room for the medical students and visitors; it contains all the essential equipments for surgical asepsis and necessary instruments. I visited the hospital under the guidance of Mr. Fred. D. Bird, one of the attending physicians and professor of surgery in the university. He showed me many cases of great surgical interest, among them several cases of intestinal and gastric surgery and the usual number of appendix operations. I was shown a case in which Mr. Bird had excised a perforated gastric ulcer of the small curvature of the stomach, four years ago, near the pylorus, in a young woman. The patient made a satisfactory recovery, but returned recently to receive treatment for obscure digestive symptoms. In another case, a fourth operation for echinococcus of the omentum in a young woman had been successful a few days ago.

In all aseptic cases the wounds had healed or were healing by primary intention. All the wards were made comfortable and cheerful by fires in open grates and a liberal supply of flowers placed on the center tables and small bouquets for each bed, gifts of the Flower Mission. Cyanid gauze for dressing retains its reputation in this institution. Fine silk has almost entirely displaced the absorbable suture in the practice of Messrs. Bird and Syme. In the absence of contraindications chloroform is used as the routine anesthetic administered with an Esmarch mask. The great work this hospital is doing for the sick of Melbourne and the state of Victoria can be seen from the last report, 1903-1904. The total number of patients treated was 22,925, and of these 4,328 were received into the wards. The number of casualties treated in the out-patients' department was 7,544. In the infectious diseases department 338 cases were treated, of which 162 were diphtheria. Although the antitoxin treatment is in constant use, intubation was performed on 39 and tracheotomy on 14, for the relief of urgent symptoms, and only two of the tracheotomies succeeded in saving life. This unfavorable experience in the treatment of this disease was due to the fact that many of the children, when admitted, were in a condition beyond the curative power of the specific treatment. One hundred and seventy-one cases of typhoid fever were treated during the year, with a mortality of 18. Pneumonia appears to have been very virulent, as 63 out of 133 cases died, a mortality of nearly 50 per cent. The surgical showing of this hospital is excellent. Exploratory laparotomy was made 39 times without a death. Of 32 cases of hydatids of the liver operated on 4 died; of 11 cases of abdominal hydatids all recovered; of 15 cholecystotomies one died; of 102 cases of appendicitis subjected to operative treatment 15 died, and in 40 cases the disease was complicated by suppuration. Ovariectomy was performed 19 times without mortality. Of 10 cases of hysterectomy 3 died; 11 cases of tubal pregnancy with one death; 11 operations for pyosalpinx without a death; 99 operations for malignant tumors, 79 were relieved, 14 not benefited and 6 died; in 100 cases of radical operation for hernia, of which number 77 were inguinal, 2 died. Of 7 cases of prostatictomy 5 were relieved and 2 died. Two cases of perforated typhoid ulcer operated on died, and of 7 cases of perforated gastric ulcer operated on only one recovered. This hospital, the oldest and largest in the city, is always overcrowded and lacks many features of a modern institution, all of which should appeal strongly to the charitably disposed citizens and an appreciative generous government to provide it with ample means to carry out its humane intentions on a larger and more efficient scale in the future.

RADICAL CURE FOR INGUINAL HERNIA.

Australian surgeons, as a rule, prefer Bassini's method in operating for the radical cure of inguinal hernia. Professor Bird is in favor of a small incision parallel with and at least one inch above Poupart's ligament. He is careful not to injure the fibrous expansion of the superficial fascia and external oblique any more than is absolutely necessary to reach the hernial sac. Instead of using the knife freely, as is usually done, he makes liberal use of blunt dissection, thus separating instead of cutting resisting fibers. He never divides the external ring and insists that if we divide it, no suture, however deft, will make it nearly as strong as before; "we divide fibers

whose integrity we can never replace." He incises the external ring only in young subjects to procure room to carry out the necessary manipulations in the canal. He believes that the unnecessary division of the strong fibers of the external ring is responsible for many relapses. He is likewise cautious not to divide any of the muscular fibers of the internal oblique and cremasteric muscles, insisting that the integrity of all these structures should be respected. The infundibuliform fascia is torn through with a pair of dissecting forceps, and the sac, carefully isolated and separated from the cord, is then proceeded with, the isolation being commenced from above and behind. The sac must be cleared as far up as the deep epigastric artery. The sac is then tied with catgut at the point where it is continuous with the parietal peritoneum and excised below the ligature. He is of the opinion that when the operation is performed in this manner deep Bassini sutures are not only unnecessary, but actually harmful. Suture of the inguinal canal after excision of the sac he only resorts to when the hernia is old and large and when the obliquity of the inguinal canal is much impaired. The suggestions made by Professor Bird are based on anatomic facts and should receive the earnest attention of surgeons.

PROSTATECTOMY.

This operation has found much favor in Australia. The suprapubic and perineal routes have each their advocates. Mr. G.

Fig. 1.—Australian aborigines.

A. Syme, lecturer on anatomy in Melbourne University and one of the surgeons to the Melbourne Hospital, performed his first prostatectomy in September, 1897. He resorted to Freyer's method—suprapubic intravesical enucleation of the gland. Two vesical calculi were removed at the same time and the patient made a speedy and perfect recovery. In the next case he found enucleation impossible and he had to excise the projecting middle lobe with scissors. In his fourth case the enucleated mass weighed seven ounces and had to be fragmented to permit its removal through the vesical wound. In the fourth case previously operated on for enlarged prostate, he removed through the suprapubic route four phosphatic calculi and excised the projecting middle lobe. A third operation became necessary, and at this time another stone was removed and the entire gland enucleated. All these patients recovered with satisfactory functional results. He is a strong believer in the superiority of the suprapubic over the perineal route and quotes statistics from Melbourne Hospital to substantiate the correctness of his position. He advises operation in all cases in which the obstruction is caused by the adenomatous form of prostatic enlargement.

ALFRED HOSPITAL.

This hospital, somewhat remote from the center of the city, has a beautiful location and occupies the middle of ample grounds made attractive by trees, shrubs and flowers. It was

founded in 1874 and consists of two-story brick pavilions arranged around an open court. The wards are large, airy and well lighted and ventilated. The main operating room answers all modern requirements and has a small amphitheater for students, who receive here the benefit of extra mural clinical teaching. Three physicians and three surgeons constitute the attending staff. The consulting staff is made up of one physician and one surgeon. The surgeons attend to all gynecologic cases.

The surgeons on duty at the present time are: H. O'Hara, Esq., F.R.C.S., I. M., and L.R.Q.C. P. 1.; John Cook, Esq., M.R.C.S. Eng.; R. H. Russell, Esq., F.R.C.S. Eng. As in all Australian hospitals, the outdoor department has separate attending staffs and anesthetists, electrician, dentist, masseurs, masseuses, dispenser and pathologist, complete the list of regular hospital attendants. Three resident internes are appointed for two and a half years from the graduating class of the University of Melbourne, their merits being gauged by their class standing. The junior internes are paid \$250 a year, the senior internes \$500. The children's ward in this hospital is one of the finest I have ever seen. The upper part of the walls are frescoed, the pictures representing fairy tales, and at the foot of each bed is suspended from an erect curved wire a small conical tin cup which visiting relatives, friends and the Flower Mission supply regularly with fresh cut flowers. I was shown here a number of cases of liver hydatids recently operated on. It is the experience of surgeons that these cysts seldom rupture into the stomach and that, as a rule, they do not give rise to adhesions. Hydatid of the kidney is very rare. This hospital has an enviable record in the surgical treatment of perforating typhoid ulcer. During the last two years six cases were operated on and of these only one died. In about half of the cases this accident is initiated by a sudden fall of temperature. Chloroform is the anesthetic of choice. Silk, kangaroo tendon, catgut, silkworm-gut and horsehair are all in use, according to the indications presented by the wound under treatment. The government appropriation for this hospital amounts to from \$15,000 to \$25,000 a year and the subscriptions from \$10 to \$45,000. Patients who can pay are charged from 50 cents to \$7.50 per week, the latter figure being the maximum. This is one of the few hospitals in Australia supplied with a steam-heating apparatus. The training school for female nurses connected with this hospital has 50 pupils who serve for three years and have to pass two satisfactory and quite rigid examinations before they receive their certificate. In this connection it is worthy of notice that in each hospital the nurse's garb differs in color, all shades of blue, and gray and black, with white caps of the strangest designs, distinguish the nursing staffs of the different hospitals.

During the last year 1,910 patients were admitted to the wards and 4,750 out-patients with 2,058 casualties were cared for in the outdoor department. It is noteworthy in looking up the records of the hospital in reference to the religious convictions of the patients that out of 2,077 cases only one confessed that he had no religion, and only one placed his confidence in Confucius. Out of 122 cases of typhoid fever treated in the hospital during the last year 11 died, and of 90 cases of pneumonia 6 proved fatal. Aneurism appears to be much more common than in our country, as this hospital received 8 cases during one year. Abdominal hysterectomy has a doleful record in this hospital, as in 10 cases only 2 were discharged cured, 1 relieved, 3 remained in the hospital and 4 died.

MELBOURNE HOSPITAL FOR SICK CHILDREN.

The Melbourne Children's Hospital is an institution that reflects much credit on the state of Victoria and the city of Melbourne. The hospital is beautifully located and consists of a number of two-story brick pavilions. The wards are large, airy and flooded with an abundance of light. Flowers, palms and evergreen plants impart to all of them a cheerful appearance, which is greatly accentuated by the presence of tidy, smiling nurses. It receives substantial government appropriations and is well supported by voluntary contributions in the form of legacies, donations and subscriptions. It can accommodate 100

children. The medical and surgical staff is made up of ten members, with Charles S. Ryan, M.B., (Ch. Edin., M.B. Melb., L.M. Dublin), at the head. Mr. Ryan is also at the head of the medical department of the military forces of Victoria with the rank of colonel. The hospital has two internes and 45 nurses, who remain in training for three years. The convalescents are sent to the convalescent home for children, Brighton, in charge of Sister Danaher, a branch of this institution. I visited the hospital in company with Professor Bird, with Dr. W. H. Snammons, a member of the attending staff for the outdoor department, as chaperon. The operating room is perfect and supplied with all modern improvements and appliances. We found here Dr. Mackay operating for hydatid of the liver in a boy 13 years old who had been afflicted with this disease for five years. The cyst, the size of a man's fist, occupied the under surface of the liver in the region of the suspensory ligament. The incision was made vertically, from the border of the costal arch downward. The cyst was incised, opening of cyst drawn into the abdominal incision with the index finger, contents emptied and margins of cut sutured to the abdominal wall, after which the lining membrane was grasped with a broad blunt forceps and extracted with ease. Two drains and a small absorbent aseptic dressing finished the operation. I was somewhat surprised at the extent to which the Thomas splint is used here in the treatment of tubercular coxitis and spondylitis, as its usefulness can not be compared with the plaster-of-paris fixation splint in the former and the Rauchfuss sling in the latter. During the last year the hospital cared for 1,302 sick children and the outdoor department had attendances amounting to the astonishing number of 67,489, of which number 10,930 were new cases. Three cases of hydatid were operated on, 4 of the liver, 2 of the lung and one of the brain, all recovered. Of 78 cases of rheumatism 12 proved fatal from complications. One out of 2 cases of hemophilia died. Seventeen cases of cleft palate were operated on without a death, also 10 cases of congenital dislocation of the hip by the bloodless operation without mortality. In 27 cases of chorea one died of endocarditis. Of 33 cases of empyema, 6 died. Of 146 cases of pneumonia, 7 died, while the disease proved fatal 5 times in 24 cases of bronchopneumonia, and 5 times in 32 cases of endopericarditis and endocarditis, and no fatality in 6 cases of pericarditis. Twenty-two cases of appendicitis were operated on, with 4 deaths, among them one with perforation; and 6 radical operations for hernia, with 3 deaths. In 11 cases of intussusception, the operation failed to save life in 6. Of 2 cases of cirrhosis of the liver, both died. Of 50 cases of tuberculosis of spine and larger joints, one died. No mortality in 43 fractures of the limbs, and one death in 4 fractures of the skull.

ST. VINCENT'S HOSPITAL.

This is the only denominational hospital in Melbourne. It is conducted by the Sisters of Charity, a religious order, with the mother house at Dublin, Ireland. The present hospital is a private residence reconstructed for hospital use. It can accommodate 30 patients. Two surgeons, Mr. G. A. Syme and Dr. William Moore, and two physicians constitute the attending staff, to which must be added the different specialists, four anesthetists, the pathologist and the members of the outdoor department. Last year the Sisters received a government appropriation of \$3,500. The Catholic clergy are the most liberal subscribers. A small training school for nurses is connected with the hospital, in charge of the seven sisters. One interne answers for the resident staff. An elegant four-story brick building, with all modern improvements, and which will cost \$150,000, and which will accommodate 200 patients, is now in process of construction. The new building when completed will be the best hospital in Melbourne. Last year 10 cases of hydatid were operated on, all successful; 32 cases of appendicitis, with 2 deaths, in 8 the disease was complicated by suppuration; 25 cases of radical operation for hernia, without a death, and 6 cases of suprapubic cystotomy, with no mortality. The whole number of operations during the year amounted to 498, of which number 490 were relieved and only 3 died, a mortality of 1.6 per cent, a record which can not be surpassed and

which does great credit to the surgeons who performed the operations. I can not quit Melbourne without giving a brief description of a trip.

A TRIP TO THE GIANT EUCALYPTUS TREES.

On his arrival at Sydney the traveler's attention is attracted at once by two of the characteristic trees of the country, the wild fig tree and the eucalyptus tree. Two species of the former, the *Ficus australis* and the *Ficus macrophylla*, the Moreton-Bag Fig-tree, both of them indigenous through a great part of East Australia, the grandest of Australian avenue trees. They resemble each other very closely in appearance; the latter, however, is a larger tree and has broader leaves. The stems are short, the crowns broad and the roots wide-spreading. There is a dense foliage of evergreen leaves, which are oblong, with a deep green shiny upper and a pale green lower surface. The fruit is in the form of a miniature fig, with very small seeds, the favorite food of the wild pigeon. These trees are the principal shade trees in this and other Australian cities. The eucalyptus tree is the monarch of the Australian forests. It is found everywhere, on the coast, the plains, and invariably crowns every hill crest and all mountain peaks. It is an intolerant, jealous, selfish, anarchistic tree, its greatest virtue being its unconquerable patriotic sentiments. Diversity of climate and soil have succeeded in the course of thousands of years to break up the original family into nearly 400 species. Baron von Mueller has described 72. It is a strange tree. It never removes its green turban of pale green, long, narrow, pointed, aromatic leaves, but instead throws off its ragged garment of rough bark once a year, in order to exhibit its new, gay, grayish-white juvenile dress. I never lost sight of this tree during my 1,000 mile railway journey through the coast districts of Australia. The air everywhere was perfumed with the ethereal aromatic exhalations of this ubiquitous tree. I had heard much of the immense forests of giant eucalyptus trees of Australia, and was extremely anxious to satisfy my curiosity to see one of them. This desire was gratified Sunday, August 7. Accompanied by Professor Bird, his son, and Prof. G. A. Syme, we left Melbourne by rail at 11 a. m. and arrived at Healsville, 40 miles distant, two hours later. Healsville is at the foot of a range of mountains that rise to a height of from 2,500 to 3,000 feet above the level of the sea. The village is the terminal point of the railroad. The road passes through a prosperous agricultural and pasturage plain, from which the mountain ranges can be seen in the distance. The eucalyptus tree attains its largest size in the moist fertile ravines and summits of the mountains, where the rainfall is most abundant. A carriage awaited us at the depot, and we at once ascended the excellent zigzag road which leads over one of the mountain passes. From the very beginning we entered a forest of eucalyptus, with an almost impenetrable undergrowth of shrubs and bramble. Rabbits shot across the road with the speed of lightning, and the little Australian quail sought, slowly and thoughtfully, shelter in the inaccessible jungle. Magpies and the laughing jackass (Australian kingfisher) watched our progress and defied us in a language replete with mockery. It is a great treat to see a virgin forest of eucalyptus trees. As we ascended the steep, tortuous incline the trees became larger and larger, until we reached the highest elevation, when we were face to face with the patriarchs who were born centuries ago and had nearly reached the limits of their lives. Here were trees 250 feet in height and 33 feet in circumference. These veterans had not forgotten their customary habits: old and decrepit, they were engaged in throwing off their old clothing that had served them for fully a year. They began the divestment of their dilapidated clothing near the top of the evergreen crown, from where the rags were hanging down in streamers swayed to and fro by the mountain breeze, and many of them were lying in disorder at the foot of the rejuvenating veteran monarchs of the forest. They were not premature in changing their clothing. The bare parts of their bodies and limbs were already protected by a brand new coat and sleeves of a smooth silvery-white investment. The tree that lifted its head high above everything around it and reached

the greatest dimensions was the *Eucalyptus amadalina*, the giant gum tree. In some localities this tree attains a height of over 400 feet and a circumference of more than 60 feet. About the only other tree that is congenial to these anarchistic mountaineers is the fern tree. The pale green foliage and black, rough stem of the latter is in strong and pleasing contrast with the dark green crowns and white, smooth, bare trunks of the former. We found here three species of fern trees, the *Alsophila australis*, with a low, thick stem and a terminal scanty tuft of short cut leaves, the *Dicksonia antarctica* and the *Dicksonia davalliacea*, the high fern trees with a slender stem from 20 to 30 feet in height and an immense umbrella at its top made of fronds of enormous length. The *Dicksonia* in some localities is known to reach a height of 60 feet. The blue gum tree (*Eucalyptus globulus*), grows in abundance in Victoria. It attains exceptionally a height of 300 feet. It grows with unparalleled rapidity and yields a tough wood admirably adapted for shipbuilding and other purposes for which a durable and strong material is required. Shipbuilders can get keels of this timber 120 feet long. It is from this tree that eucalyptol and the various eucalyptus preparations are most profitably obtained. F. H. Faulding & Co., Adelaide, are the principal manufacturers of the eucalyptus preparations used as antiseptics in internal and external medicaments. We found in this forest a great number of one of the most beautiful of the ornamental trees of Australia—the golden wattle (*Acacia pyrenantha*), opening its blossoms of golden yellow in the form of long, drooping tassels. When in full bloom the evergreen leaves are almost obscured by this golden drapery. The tree attains a maximum height of about 30 feet; its long, slender trunk is branchless almost to its very top, and when, with the earliest indications of approaching spring, it decorates itself with a crown of gold, it presents a lovely sight even in the shadow of the giants of the eucalyptus race. The sight of a eucalyptus forest intermingled with the fern trees and the golden wattles and sprinkled with the fresh and brilliant early spring flowers is inspiring and leaves a pleasant impression which time can never erase from memory.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Insufficient Motility of Stomach.

Fulton, in the *N. Y. Med. Jour.*, gives the following treatment for this condition:

The diagnosis must be made of insufficiency due to atony or to obstruction. In both, stagnation of the stomach contents is to be prevented, and in both a diet must be given that spares the motor powers of the stomach. Aside from these common indications, different procedures must obtain in the atonic and in the obstructive forms. In the obstructive form early diagnosis indicates removal of the obstruction, this being practically the only method of treating such cases. In the atonic cases to improve the muscle tone and motor powers of the stomach is the indication.

DIET.

In those cases with reduced motor power a diet is selected on the basis of the more feeble the motility the more liquid the diet. Milk preparations, soft eggs, gruels, soups, and the various articles of concentrated food are to be chosen. A common error is to allow the patient too much liquid food at feeding. Liquids are both heavy and bulky, and if taken in this way add to the distension and discomfort. The feeding should be small and frequent. In cases of but slight motor insufficiency, if an

analysis reveals a fairly normal gastric juice solid foods, meats, purée of vegetables, toasts, etc., may be allowed. In these cases the best results are obtained by giving the patient but two meals a day. In weak, emaciated patients the stomach is usually unable to dispose of enough nourishment for the day on the two-meal plan; such patients do better on five or six smaller meals.

MEDICINAL TREATMENT.

The author states that relief for the distress of the patient is the chief result to be obtained by medicinal treatment. Strychnin gr. 1/24 should be given three times a day. The following prescription is of service in improving the peristalsis and fermentation after meals:

R. Creosoti	gr. ss-i	03-06
Puly, rhei		
Puly, saponis, aa	gr. i	06
M. Ft. pil. No. i. Sig.: One such pill after meals.		

Or:
 R. Bismuth. subicyclatis.....gr. x | 65
 M. Ft. chart No. i. Sig.: One such powder after meals.

Medicinal measures are also of value in correcting symptoms arising from abnormalities of the gastric juice. In all cases of this sort careful analysis of the state of the secretion is to be made, and the medical and dietetic efforts must be governed thereby. In the absence of HCl in gastric juice the dilute HCl given, freely diluted, in from 10 to 20 drop doses, through a glass tube, after meals, and repeated two or three times, is of decided value in some cases. If excessive acidity exists the following prescription is of value:

R. Magnesi levis		4
Sodij bicarbonatis, aa	ʒi	
M. Ft. chart No. i. Sig.: Give in one dose two hours after eating, and repeat if necessary to relieve the cardialgia.		

MECHANICAL MEASURES.

Lavage.—Lavage is indispensable in all cases in which there is abnormal retention of food. After food has lain in the stomach several hours longer than normal, and becomes thereby a decomposing, fermenting mass, its further retention and passage through the twenty feet of intestines can result only in further harm to the patient, by the absorption of toxins and disturbance of intestinal digestion. The author recommends washing the stomach daily, night or morning, in all those cases where food is found in the stomach before the morning meal. In less severe cases lavage may be practiced once or twice a week.

Results of Lavage.—1. Immediate relief from distress. 2. Improvement of the tone of both the secretory and motor mechanisms of the stomach. 3. Lavage should be controlled by the physician, otherwise its usefulness may become an abuse.

The author has used internal faradization of the stomach in fourteen atonic cases with undoubted improvement in all. He is uncertain, however, how much improvement may have been the result of the electricity, since the other measures mentioned above were also used.

Epilepsy.

Shoemaker, in the *Medical Bulletin*, outlines the treatment of this condition as follows:

TREATMENT OF THE ATTACK.

In cases preceded by an aura, a fit may sometimes be averted by encircling the limb with a moderately tight ligature. The patient may be instructed to carry with him constantly a girdle for this purpose. The inhalation of amyl nitrite may also do good at this stage. Pearls containing this agent can be provided by the patient and crushed in a handkerchief at the instant of warning of an impending attack. When the spasm is established the patient should be given an abundance of fresh air by keeping back the crowd, if the fit occurs in a public place, or opening the windows if it occurs indoors. The head should be raised, clothing loosened and measures taken to prevent him from hurting himself in his contortions. A piece of soft wood, rubber or roll of linen should be placed between the teeth to prevent biting the tongue. Allow the patient to sleep after the convulsion.

PREVENTION OF THE ATTACK.

Hygiene.—Fresh air, absolute cleanliness, a properly selected diet, moderate exercise in the open air (never carried to the point of exhaustion), moderate intellectual employment, avoid mental strain, strict temperance in all habits of life. Excesses of all kinds should be absolutely prohibited. Alcohol, tobacco, tea, coffee and condiments should be avoided. Constipation should be overcome.

Causative Treatment.—Each case should be studied to discover any exciting cause, and when such cause is found the next effort will be to remove it.

Medicinal Treatment.—Of the remedies used in this condition the author gives preference to the bromids and of these the potassium salt. All the other bromid salts have been tried, both alone and in various combinations. The following so-called Brown-Séguard antiepileptic mixture has found much favor:

R. Potassij iodidj	ʒi	4
Potassij bromidj	ʒiiss	30
Ammon. bromidj	ʒiiss	10
Potassij bicarbonatis	gr. xl	2 60
Spiriti chloroformi	ʒi	8
Infus. calumbe, q. s. ad	ʒvi	180

M. Sig.: Two teaspoonfuls morning and noon and three teaspoonfuls at night, diminishing the quantity after the convulsions cease, but continuing the remedy at intervals, especially at the time when the fits are liable to recur. If the patient be weak, the infusion of digitalis may be substituted for the calumbe.

When the bromids are prescribed for epilepsy it is best to begin with 10 or 15 gr. thrice daily and to increase the amount gradually until troublesome evidences of bromism supervene or until the daily dose necessary to hold the spasm under control has been found. The administration of Fowler's solution in 4 to 5 drop doses will often prevent the bromid eruption. Care should be taken to prevent, so far as possible, the disordered digestion, weakened heart action and impaired mentality which sometimes result from the long-continued use of the bromids. The oxid and valerianate of zinc are agents which may be employed in the treatment of epilepsy.

Borax has recently been proposed as a substitute for the bromids, and in some cases has given encouraging results. It is advised to be administered in doses of 10 grs. after meals, gradually increasing to a dram. Borax has the disadvantage of causing rashes on the skin, conjunctivitis and edema. The administration of the bromids must be carefully watched for both good and bad effects.

Bathing During the Menstrual Period.

At the recent meeting of the American Gynecological Society J. C. Edgar presented the following conclusions on this subject: 1. All forms of bathing during the menstrual period are largely a matter of habit, and usually can be acquired by caution and gentle progression, but not for every woman does this hold good, and surf bathing where the body surface remains chilled for some time should always be excepted. 2. A daily tepid sponge bath (85 to 92 degrees F.) during the menstrual period is not only a harmless proceeding, but is demanded by rules of hygiene. 3. In the majority of, if not all women tepid (85 to 92 degrees F.) sponge bathing after the establishing of the menstrual flow, namely, second or third day, is a perfectly safe practice. 4. Furthermore, in most women the habit of using the tepid shower or tub bath after the first day or two of the flow can with safety be acquired.

Medicolegal.

Sufficient Evidence of Employment of Physician.—The Supreme Court of California affirms, in the case of Scott vs. the Superior Sunset Oil Company, a judgment for \$1,200 for several surgical operations and some 61 days' attendance on an employe of the company who was shot through the knee and

through the lung while protecting its land against jumpers. A majority of the company's board of directors, including both a director who was its secretary and treasurer, and the vice-president, actively participated in employing the physician and consulting with him concerning the care and treatment of the patient, all of which was done avowedly on behalf of the company. This, it is held, was sufficient to charge the corporation. It was not necessary that the employment should be made or ratified by action of the board at a regular meeting. The separate assent of a majority of the board was all that ought to be required under the circumstances presented by the evidence. Furthermore, there was no error, it is held, in admitting evidence of the knowledge of the directors in regard to the employment of the physician by its secretary, acting for the company. Such evidence was clearly proper when coupled with evidence of the express assent to the employment by a majority of the board.

SOME 1904 IOWA LEGISLATION.

Against Bringing Certain Drugs into Certain Places.—Chapter 134 of the Laws of Iowa of 1904 provides that any person, not authorized by law, who shall bring or pass or cause to be brought into any penitentiary, reformatory or industrial school of the state, or the grounds thereof, or into any enclosure, building, quarry, farm, garden or other place used in connection with any such institution in which prisoners or other inmates are required or permitted to be, any opium, morphin, cocain or other narcotic, or any intoxicating liquor, etc., shall be punished by imprisonment in the penitentiary for a term not exceeding five years. An attempt to do any of the acts prohibited shall be subject to the same punishment as the completed act.

Provision for Bacteriologic Laboratory.—Chapter 101 of the Laws of Iowa for 1904 provides that the bacteriologic laboratory of the medical department of the State University at Iowa City is thereby established as a permanent part of the medical department of the university work, and it shall, in addition to its regular work, perform all scientific analyses and tests, chemical, microscopic or other scientific investigations which may be required by the State Board of Health, and it shall make prompt report of the results thereof, under such rules and regulations as the said State Board of Health may from time to time adopt. The professor of bacteriology of the medical department of the state university shall be the director of said laboratory and shall make, or cause to be made, all such analyses, tests and investigations as shall be required by the State Board of Health as above provided, causing the same to be made without delay and giving such analyses, tests or investigations the preference of the point of time over all other work, and shall make prompt report of the result thereof to the Board of Health, or to such person or persons as the Board of Health may by rule or designation designate.

Registration of Births and Deaths.—Chapter 100 of the Laws of Iowa of 1904 provides that, for the complete and proper registration of births and deaths for legal, sanitary and statistical purposes, the State Board of Health is constituted state registrar of vital statistics. Local registrars of vital statistics shall be the health officers of cities and the clerks of townships. Each local registrar shall at once, on his election or appointment, appoint a deputy, subject to the approval of the State Board of Health, and the State Board of Health may also appoint, as sub-registrars, the clerks of all incorporated villages and not more than three other persons in each township, to file certificates of births and deaths, transmit them to the township registrars, and to issue burial and removal permits. The undertaker or person in charge of the funeral shall cause a certificate of death to be filled out, and, with a statement of the cause of death by the attending physician, or, in his absence, by the health officer or coroner, and file it with the proper local registrar. A certificate of birth of the standard form adopted by the United States census shall be made out by the physician, midwife or other person attending the birth of every child born in Iowa, or in default of such person, by the parent, householder, superintendent of an institution, or other responsible person, and filed with the local registrar of vital statistics

within ten days after the birth. In case the child is not named, the registrar shall deliver a supplementary blank for report of given name to the person filing the certificate, to be filled out and returned as soon as the child shall be named. The Secretary of State shall furnish blank certificates of birth and death to physicians, undertakers and local registrars. Any physician, midwife or other person violating any of the provisions of this act, or failing to properly register a birth or death as herein required, shall, on conviction, be considered guilty of a misdemeanor, and shall be fined not less than \$5 and not more than \$100, or be imprisoned not more than 60 days, or be subjected to both such fine and imprisonment, at the discretion of the court. The State Board of Health shall endeavor to see that the act is uniformly and officially executed throughout the state.

Removal of Persons Sick with Infectious Diseases.—Chapter 99 of the Laws of Iowa of 1904 provides that no person known to be infected or sick with any contagious disease dangerous to the public health shall move or be removed from one city, town or township to another city, town or township except as therein provided and by written permission of the local board of health of the city, town or township to which such person is to be removed. If any person known to be infected or sick with smallpox or other contagious disease dangerous to the public health shall, with the knowledge or consent of any member of the local board of health of the city, town or township in which he resides, be removed from said city, town or township to another city, town or township, either with or without the permission of the local board of such city, town or township to which he is removed, all expense of quarantine or care of such person incurred by the city, town or township to which he is removed shall be paid by the city, town or township from which such person was so removed. If said person be so removed to another county, said expenses shall in the first instance be paid by such county and recovered from the county from which such person had been removed. When it is determined by any physician or health officer that any person is sick with smallpox or any other contagious disease dangerous to the public health while in any city, town or township other than the one in which he resides, provided the distance be not to exceed 15 miles from his place of residence, then and in that event, if the person so diseased elect to be moved to the city, town or township in which he resides, he may be so removed by private conveyance along the least frequented highways, under escort of a health officer, to his abode immediately on determining that he is so diseased; and every such vehicle shall carry as a signal of warning, conspicuously displayed, a yellow flag not less than two feet square. All expenses of removal, care and quarantine of such person shall be paid by the city, town or township to which he is removed. Any person who shall move, or any physician or any member of a local board of health who shall cause or assist any person known to be infected or sick with smallpox or any contagious disease dangerous to the public health, to be removed from one city, town or township to another city, town or township, contrary to the provision of this act or of any regulation of the State Board of Health, shall be guilty of a misdemeanor and be punished by a fine not exceeding \$100 or imprisonment not exceeding 30 days, or both, at the discretion of the court.

1. **Gastroptosis.**—Attention is called by Beyea to the operation of gastropexy practiced by him for the relief of gastroptosis. The principle of the operation is that by placing three rows of interrupted silk sutures from above downward and from right to left through the gastrophaptic and gastrophrenic ligaments, a single, broad transverse fold or plication is formed in the ligaments, shortening these ligamentary supports and elevating the stomach to its normal position without in the least disturbing the physiologic mobility of the organ. No abnormal adhesions are formed between other structures; there is no fixation of the stomach, and with the formation of a broad surface of adhesion between the surfaces plicated, sufficient strength is gained in the shortened ligaments to maintain the stomach permanently in normal position. That this is true Beyea has determined by the physical examination of one patient three and one-half years and another one and one-half years after operation. Eleven cases have thus far been operated on by this method—5 by the author, 2 by Martin and 4 by Bier. All had suffered for from five to fifteen years with the characteristic and very severe symptoms of gastroptosis. The convalescence in each case was normal and easy. The patients were kept in bed in the recumbent position for four weeks after operation and on a special diet. In every case the improvement in health has been most remarkable and the relief of symptoms complete: food of any character is taken without restriction. In no instance, regardless of the time which has elapsed since operation, has the stomach changed its position. The author concludes that the completeness of the relief, the simplicity of the operation and the fact that it is practically free from danger (the estimated danger being not greater than a fourth of 1 per cent.), strongly recommend this operation in every case of gastroptosis in which the suffering is great. It is well to note, however, that the patients thus far operated on represent but one class, those with gastroptosis and without relaxation of the abdominal walls or diastasis of the recti muscles.

3. **Mild and Incomplete Typhoid Fever.**—Briggs has made a careful study of cases in the literature and concludes therefrom that it is altogether probable that mild typhoid is affecting a large number of people every autumn and winter, and that it is certain that in the majority of instances the disease is not recognized. Very few of the patients present themselves for hospital treatment; while in private practice the absence of striking features in this type of the disease accounts for its attracting less attention than the much rarer fulminant, hemorrhagic and other extraordinarily severe forms. The paucity of symptoms makes thorough physical examinations and frequent collections of blood for Widal tests apparently unnecessary. Five cases are cited and the symptoms discussed in detail.

4. **Gunshot Wounds of the Abdomen.**—The value of timely surgery in the treatment of penetrating gunshot wounds of the abdomen is shown by Long, who operated on 5 cases, with 3 recoveries. In one case death occurred nine hours after operation, probably due to hemorrhage from the liver. In the other case the patient died on the fourth day, death probably being due to overlooked bladder perforations. As points worthy of consideration he mentions the following: 1. Consider all abdominal wounds as penetrating until the contrary is proved by exploration. 2. Consider all penetrating wounds as having injured the viscera, and operate. 3. Operate promptly at the first possible moment. 4. Inspect carefully every viscus that could possibly be injured. 5. Make a careful toilet of the peritoneum. 6. Use salt solution freely in the abdomen, under the skin and in the bowels.

- 13 *Castor Oil and Salts. Edward P. Carlton
- 14 Internal Antiseptics. J. X. Hall.

7. **Incidence of Gastric Ulcer.**—A careful study of the hospital records of cases of gastric ulcer with reference to their geographic distribution leads Howard to conclude that both clinically and pathologically gastric ulcer is less frequent in America than in London and on the continent. And, that both clinically and pathologically, ulcer is more common in the northeastern than in the more southern regions of America, with the exception of San Francisco.

8. **Blood and Urine in Gastric Ulcer.**—In the past fifteen years 77 cases of gastric ulcer and 5 cases of duodenal ulcer were admitted to the Johns Hopkins Hospital. Fitcher presents the blood and urinary findings of the cases in which such examinations were made. The red cells were counted in 44 cases. The highest count was 6,780,000; the lowest, 1,912,000; the average of 67 counts in these 44 cases was 4,071,000. The leucocytes were counted in 45 cases. The highest count was 40,000; the lowest, 1,100; the average of 263 counts was 7,500. The hemoglobin was estimated in 44 cases. The highest was 105 per cent.; the lowest, 12 per cent.; the average of 62 separate determinations was 58 per cent. The average color index was .72. The blood picture in the series was that of a secondary or chlorotic anemia. The alterations that may occur in the urine are neither striking nor constant, and may occasionally be accidental and due to some other cause. Albumin and casts were present in 14 cases; a trace of albumin alone in 7; in 55 the urine was negative so far as albumin and casts were concerned, and in 5 no record was made. If dilatation be considerable and the fermentations due to micro-organisms increase, the urine may contain an excess of ethereal sulphates and indican. Acetone and diacetic acid may occur in the urine in gastric ulcer.

9. **Pathologic Anatomy of Gastric Ulcer.**—Brooks believes that primarily gastric carcinoma frequently arises in the healing lesions. Two of his cases of gastric cancer showed this distinctly, both in their clinical history and from the subsequent anatomic findings.

10. **Complications and Sequelae of Gastric Ulcer.**—In 52 cases studied by Manges the following complications were noted: Hematemesis, 10; perforation, 4; perigastritis, 2; intestinal obstruction, 1; thrombosis of splenic vein, subphrenic abscess, gangrene of spleen, abscess of liver, and necrosis of lung, 1. The sequelae were, carcinoma, 4; pyloric stenosis, 6; recurrence, 2.

11. **Course of Gastric Ulcer.**—In Einhorn's experience the percentage of seemingly permanent recoveries from gastric ulcer is much larger than the figures quoted by others. He suggests that this may be due to the way the patients live after a cure has been obtained. Those leading a rational life, avoiding too coarse foods, and violent exercises, have a greater chance of remaining well than those who can not have the much desired care. The percentage of recurrence is greater in hospital patients than in private practice.

13. **Castor Oil and Salts.**—In order to overcome the repugnance to these two remedies Carlton prescribes them as follows:

R. Vanillin	xx	112
Oleol. menth. pip.	5j	4
Garantose (saccharin)	5jss	6
Alcohol	℥iij	100
Tinct. persicosis	5ss	16
Oleol. ricini, q.s. ad. one-half gallon		2000

Dissolve the vanillin, oil of peppermint and garantose in the alcohol. Add the tincture of eucubar to the oil and shake thoroughly. Finally mix the two mixtures. Carlton says that this mixture keeps well, looks nice, is pleasant to take,

does not leave a bad after-taste, and for all practical purposes is a disguised oil.

Medical Record, New York.

October 8.

R Magnesium sulphatis	℥ssiii	1000
Flint, cardamom, comp	ʒi	64
Vanillin	gr. xx	1 3
Garantose	ʒi-iv	8-16
Alcohol	ʒi	64
Glycerin	ʒi	64
Coffee, roasted and ground	ʒi	64
Aque q.s. ad. one-half gallon		2000

Stir the ground coffee in half a gallon of boiling-hot water and allow it to stand for from ten to twenty minutes. While still hot add enough of it to the magnesium sulphate to make about three and one-half pints. Dissolve the vanillin in the alcohol, add the glycerin and then the cardamom. When the first solution is cooled somewhat add the second mixture to it. After shaking thoroughly add the garantose and enough of the coffee infusion to make one-half gallon. Filter through a covered filter. An ounce of this solution contains half an ounce of magnesium sulphate. The solution is said to keep well, has a dark, whisky-like color, a nutty odor, and is easy to take, warm or cold. It should be taken with twice its volume of water.

15. Dupuytren's Contraction.—McWilliams reports a case which was operated on with the result that the patient had a hand which was as useful as it ever had been. The sensation was perfect in all the fingers except in an area the size of a lead pencil on the center of the palmar surface of the last phalanx of the little finger, where there was some numbness and insensibility. The principle of the operation was the excision of the fascial bands. It is described by McWilliams as follows:

Tourniquet about lower arm. Incision longitudinally along the palmar band continued on the first ring finger phalanx. Two incisions made from near the extremity of the first incision, one over the band going to the middle finger, the other to the little finger. Skin edges dissected away on both sides of the incision from the dense underlying fascia. Small cut flaps connecting the fascia and the skin had to be divided. The prominent longitudinal band was about two-fifths of an inch wide and of the consistency of cartilage. It could only be cut away piecemeal, as it was intimately adherent to the tendon sheath beneath, which latter was with difficulty recognized and was opened in one place by mistake. The digital nerves were not clearly identified until they were traced back into the palm from the sides of the fingers. After the palmar band had been excised, the fingers still resisted extension. This was found to be due to accessory bands extending to the sides of the fingers. It was impossible to dissect these all away, so that it was necessary to be content with transverse division of them, thereby running the risk of dividing the digital nerves. The fingers finally could be straightened after stretching the skin, which cracked slightly in one or two places. The opening in the tendon sheath was closed with catgut and the skin brought together with fine silk, an opening being left in the middle of the palm for a small gauze drain. The tourniquet was removed, a copious dressing applied, and the hand with the fingers perfectly straight bandaged to firm splints, anterior and posterior.

Careful post-operative treatment, says McWilliams, is highly essential. Splints should be applied until healing has taken place. At the end of two weeks they may be removed each day for gradually increasing periods, when massage and passive motions should be instituted. No greater degree of extension should be applied immediately than can be employed without too much tension being exerted on the wound for fear of gangrene. In bad cases it may be well to have the patient wear at night for some time some form of splint or retentive apparatus to hold the fingers in full extension.

16. A Vesical Calculus.—The stone in this case was found in the bladder of a boy aged 7 years and measured 2½ inches in length and 1 inch in thickness. It was composed of ammonium and magnesium phosphates and weighed 14.96 grams. The patient recovered.

- 27 Case of Supposed Primary Tuberculosis of the Pharyngeal Tonsil. D. M. Barstow.
- 28 *Diabetes in Two. Leonard Weber.

25. Treatment of Cirrhosis of the Liver.—After a brief discussion of the physiology of the liver and its relation to the etiology of cirrhosis, Richardson considers the treatment. He advises the following: Attention to gastrointestinal digestion, because if the food supply of the organism is perverted or reduced, it can not be expected to recuperate. The elimination of bile from the liver should be increased by the administration of sodium glycocholate with the addition of small doses of mercury. The ductility of the bile can be increased by the administration of alkaline mineral waters with sodium salicylate. Biniodid of mercury with iodid of potassium has a very beneficial effect in many cases of nephritis which are associated with hepatic insufficiency. Hepatic cirrhosis is the result of a toxemia and its treatment must, therefore, consist in the removal of the cause of the intoxication, with, at the same time, stimulation of the liver, so that it may do its part in the oxidation and elimination of the poisonous substances.

26. Strangulated Umbilical Hernia.—The case reported by Buchanan was complicated by gangrene of the abdominal wall overlying the hernia, and destruction of the free surface of the cecum, the ascending and transverse colon, with the distal border of the splenic flexure. After excision of the gangrenous portion of the bowel the ileum was implanted into an opening in the side of the sigmoid by simple continuous suture. The patient made an uneventful recovery.

28. Diabetes in Two.—Weber reports three instances of this kind where the husband became rather acutely affected with diabetes after the wife had been a sufferer from it for ten years or so. There was neither consanguinity nor similarity of constitution, disposition or temperament; indeed, the two partners were mentally and physically about as different as could be. Their domestic life, however, their habits and the kind of food consumed had been the same for many years. They had always slept together. Weber suggests that it is not desirable that a diabetic and a non-diabetic person should habitually sleep in the same bed. The acetone exhaled with the breath and the sweat of the diabetic might possibly, in the course of years, affect the physiologic functions of the liver and pancreas, with regard to dextrose, through the blood and nervous system. Then, too, the hopeless state of health of a beloved person might affect a sympathetic partner.

- 31 *A Comparison of Anesthetics: Results from Chlorotone. Theodore C. Beebe, Jr.
- 32 Examination of Pleural Fluids with Reference to Their Etiology and Diagnostic Value. (To be continued.) Percy Musgrave.
- 31. Comparison of Anesthetics.—Beebe presents the statistics obtained from 214 cases, in 65 of which gas and ether were used, in 34 ethyl chlorid and ether, in 110 anesthol and ether, and in 5 anesthol alone. He finds that there does not seem to be any class of cases in which ethyl chlorid has any advantage over either gas or anesthol, while its expense is a distinct disadvantage in a large clinic. Its record for safety has not proved equal to gas and anesthol. In a large clinic where speed is required gas is by far the more desirable. The absence of odor also tends to make gas the more popular. In alcoholic or powerful individuals who take gas poorly, or where there is some heart or lung complication, anesthol is a very efficient adjunct. Anesthol causes least disturbance of the pulse and

respiration rate, gas next, and ethyl chlorid most. Gas is the quickest to produce its effect, ethyl chlorid next, and anesthol last. On the other hand, profound anesthesia may be obtained with safety for a greater time with anesthol than with either of the other two drugs. During administration of the anesthetic there is the least struggling with anesthol, next with gas, and the most with ethyl chlorid. Beebe also noted the results obtained from the administration of chlorotone to prevent nausea and vomiting after anesthesia. Chlorotone, in amounts from 5 to 36 grains, given in 5-grain capsule, was used in 164 cases. The best results were obtained in adults with 10-grain doses given twenty to thirty minutes before starting the anesthetic. If given inside of twenty minutes the patient is liable to vomit soon after the anesthetic is started, thereby losing all benefit of the drug. While chlorotone has not always proved a reliable specific in preventing nausea and vomiting, it has been a great aid. The patients made a quicker recovery than when nothing was given. Vomiting, when present, usually took place before the return to consciousness, so that the patient had no distinct recollection of the occurrence. In more than half of the cases there was no conscious nausea or vomiting.

- 33 *Strontium Bromid. Joseph Eichberg.
34 The Discharging Eye. Mark D. Stevenson.

33. **Strontium Bromid.**—Eichberg advocates the use of strontium bromid in 10-grain doses three times daily as a diuretic, particularly in the nephritides. If necessary the dosage is steadily increased until the patient passes between three and four pints of urine; then the dose is reduced to 5 grains. Although strontium bromid is less serviceable than digitalis as a diuretic, there are many persons who bear digitalis badly or in whom the drug is contraindicated, and in such the strontium salt may render most valuable aid.

36. **Acute Leukemia in Early Life.**—Churchill cites 14 cases culled from the literature and adds one from his own practice. The patient, aged 4, always had good general health and did not have any of the acute diseases of childhood. The family history showed a tubercular taint. Illness began a few months before advice was sought, but the only symptoms were a loss of appetite and a gradually increasing waxy pallor. The blood count showed 3,500,000 red cells, 10,000 white cells; hemoglobin, 75 per cent. There were no signs of hemorrhage anywhere and no tenderness over the long bones. On the seventeenth day of the illness the spleen was felt one inch below the ribs. The pulse rose gradually to 134, but was strong and regular, except at night, when some irregularity was noted. Blood appeared in the stools on the twenty-seventh day, and continued to appear until death ensued on the twenty-ninth day. The bacteriologic examination of the blood revealed

streptococci. The day before death occurred the blood findings were: Red, 1,280,000; white, 8,000; hemoglobin, 15 per cent. A differential count was made of 1,000 white cells. Of these 98.2 per cent. were mononuclears, 1.55 per cent. polynuclears, .3 per cent. eosinophiles, 1 normoblast and 1 myelocyte (?). At the autopsy there was noted in the organs and tissues generally an infiltration with lymph adenoid cells, closely resembling the small mononuclear lymphocytes seen in the blood during life. The bone marrow was replaced by a reticulum filled with blood containing large numbers of nucleated red cells, but few giant cells were found. Churhill concludes that all cases of leukemia are myelogenous in origin and that the acute variety is more apt to be of the lymphocytic type. Although the disease is rare in early as well as in later life, it is probably more common than has been supposed, 22 cases of the acute or subacute variety having been recorded since 1898, while previous to that date only 7 cases are on record. The course of the disease in children differs from the adult type only in minor details; hemorrhages are fewer and less severe; the lymphocytosis is more apt to be of the small variety. The disease is always fatal.

40. **Chest in Pulmonary Tuberculosis.**—Brown and Pope have made a very careful study of the shape of the chest and its changes in disease, especially in pulmonary tuberculosis. They find that the measurements of the normal chest up to this time have not been determined with sufficient accuracy to allow of very positive conclusions. Race, age, occupation and altitude are factors that must be considered in determining the normal measures and relations. The chief impression they gained from their study is that the chest, which is subnormal in its diameters and normal or supernormal in its length, is the chest more subject to pulmonary tuberculosis, though whether in many cases the disease liability and the shape of the chest are not both results of the same conditions and not casually connected is an open question. Influences which tend to improve the development of the chest tend also to prevent consumption, and this may account for the relative immunity of the well-developed chest. The anteroposterior diameter of the chest in health may be stated to be about 20.5 cm. at the level of the nipples, the transverse diameter about 28 cm., giving an index of 73. In the early stages of pulmonary tuberculosis the anteroposterior diameter at the level of the fourth costal cartilage is about 19.5 cm., the transverse about 27, giving an index of 72. In advanced stages the figures are about 19 cm. and 25 cm. and the index 76. The chest index is readily changed within certain limits in the individual. The female chest shows a tendency to a lower index than the male. Pulmonary tuberculosis has a tendency to reduce the diameters of the chest, and it seems as if it also reduced length. The progress of the disease probably tends to increase the index, though further data are necessary before this can be confidently stated. The authors also found that there seems to be some tendency for the chest in pulmonary tuberculosis to acquire a larger or smaller index—that is, to divide into two types, one flat (index 68 to 70), and one deep and round (index 78 to 80), but both reduced in size. The relation of the diameters does not appear to have any prognostic value, as at either extreme there is no tendency in early cases of pulmonary tuberculosis to show an unduly large proportion of extreme indices. The change of index in pulmonary disease is probably not due to emaciation, but to change in bulk of the lungs. The chests of patients receiving sanitarium treatment showed that there is a marked increase in both expansion and respiratory movements, more striking in advanced than in incipient cases.

41. **Pulmonary Streptothricosis.**—Among the recently reported cases of human infection with streptothrices there stands out prominently a small but exceedingly interesting group of pulmonary cases presenting the clinical picture of tuberculosis, broncho-pneumonia or gangrene, but in which the infective agent appears to be some form of streptothrix differing from *Streptothrix bovis communis*. Warthin and Olney add to the casuistics of this subject one case. The patient, aged 45, a

farmer, has always been well, although not strong. His present trouble began with an attack of grip, after which a moderate cough and expectoration persisted. He became very much weakened and emaciated and finally was obliged to go to Colorado, a diagnosis of tuberculosis being made. Chest expansion was normal; there were no areas of dullness and no signs of cavities. Re-piration was labored. On auscultation, blowing breath sounds and dry crepitant râles were heard all over the chest. The sputum was muco-purulent in character, had no disagreeable odor, but was raised with difficulty. The temperature ranged from 102 to 103. The clinical picture suggested a chronic bronchitis or broncho-pneumonia of tubercular origin. The sputum contained great numbers of minute grayish granules, which proved to be masses of a filamentous organism closely interwoven and branching freely. With 25 per cent. sulphuric or nitric acids they were "as acid-fast as the tubercle bacillus," but gradually lost their stain when washed in 95 per cent. alcohol. A very thorough search was made for the tubercle bacillus, but none were found. With Gram's the branching threads stained beautifully. Streptococci and staphylococci were present in small numbers. The organism showed true branching and beading. The existence of such a condition as the one in the case cited is of great importance insofar as the question of the differential diagnosis of tuberculosis is concerned. It was impossible to make cultures in this case so that an absolute identification of the species of streptothrix is impossible. The authors believe, however, that it is the *Streptothrix eppingeri*, or a very closely related species.

42. **Tuberculosis and Heart Disease.**—Within the last year Norris examined all the postmortem records at three hospitals, aggregating a total of 7,040, and collected the data from all those which showed tuberculous lesions of the lungs, pleura, pericardium, heart and great vessels, with a view of studying their frequency and relationship. Of these autopsies, 1,764 were tuberculous cases. Norris also reviewed the literature, and had access to 1,276 clinical histories. Statistics have also been gathered from 57 successive cases of valvular heart disease which have come to autopsy. All this work was suggested by the teachings of Rokitsky that valvular disease of the heart, especially when affecting the mitral or aortic valves, as well as aneurisms of the large vessels, hydrothorax and even scoliosis lessen the tendency to pulmonary tuberculosis. Norris suggests that the increased resistance to tuberculosis in individuals with scoliosis probably exists not by reason of venous stasis, but because patients who have recovered from an attack of tubercular bone disease have usually developed an inhibitory capacity to tuberculosis of considerably greater potency than that possessed by an unaffected organism. In view of the frequency with which tuberculosis of the lungs has been found to be associated with valvular heart disease, Norris concludes that the latter exerts but very slight influence, if any, on the former, either as an inhibitive or curative influence, even if satisfactory compensation is maintained. Considering the relative frequency of valvular lesions in general, mitral stenosis does not seem to be less often coincident with tuberculous disease of the lungs than other varieties of heart lesions. Stenosis of the pulmonary orifice, however, seems to favor the development of tuberculosis of the lungs, and a very large proportion of these cases die of the latter disease. It is doubtful whether smallness of the heart predisposes to pulmonary tuberculosis to a greater degree than is explainable by the general systemic underdevelopment and lack of resistance which such individuals often exhibit. It is a fact, however, that small hearts, either as a result of wasting or hypoplasia, are commonly found at tuberculous autopsies, while large hearts are not often encountered in uncomplicated cases. Arterial and endocardial thickening is a common result of tuberculous intoxication, but it is doubtful whether this process attains a sufficient degree to produce valvular incompetency. Tuberculous endocarditis and myocarditis, particularly the former, occur with considerable rarity; but pericarditis, especially the chronic forms, very frequently

owes its existence to the presence of the tubercle bacillus. Tuberculosis of the aorta also is rare; the condition may result in the formation of an aneurism. The cardiac muscle undergoes various forms of degeneration in pulmonary tuberculosis, fatty and fibroid changes being very common, a fact which explains the signal failure of digitalis and certain other heart stimulants to benefit these cases. Uncomplicated cases of pulmonary tuberculosis often exhibit such striking differences in resisting power, and frequently evince such a remarkable tendency toward recovery, even in seemingly hopeless cases, that we should accept only the most absolute evidence as proof that either the coincidence of another pathologic condition or the administration of a special remedy has conferred a benefit on the patient.

47. **An Unusual Ovarian Condition.**—In the case reported by Schooler, an enlarged fallopian tube extended from the uterus to the enlarged and displaced spleen, and was so firmly attached as to admit of no displacement. The spleen was at least six times its normal size, black, and glistened like an old blood clot, but was firmer. The structures were divided between two ligatures and the abdomen closed. Obstruction of the bowels followed in nine weeks, and operation showed extensive adhesions almost the entire length of the descending colon. The patient recovered. Previous to the second operation, Schooler believed that this was a case of floating spleen, but the findings at the last operation caused him to abandon that theory. He offers no solution of these findings.

51. **Distribution and Prevention of Tuberculosis.**—Corbett gives a general review and cites the statistics taken from 84 cases of tuberculosis in Minneapolis, which are as follows: Tubercular history, no contact with tubercular members of family, 8; tubercular history and contact with tuberculous members of family, 20; no tubercular history and no contact with tuberculous members of family, 36; no tubercular history, contact with tuberculous members of family, 7; tubercular history and contact with tubercular associates, 3; no tubercular history and contact with tubercular associates, 7. The following rare and unusual methods of infection were discovered: 1. Infection from a coat. A Scandinavian mail carrier, previously healthy, developed tuberculosis soon after wearing a fur coat which had formerly been worn by a man who died from this disease. 2. Infection from husband apparently cured, to wife and brother. 3. Infection from house. Case 1 developed consumption and died. The rooms, with furnishings, were rented to Case 2, who also developed the disease and died. Case 3 rented the room, and after an attack of the disease went south and recovered completely. After the house had been thoroughly fumigated and cleaned, no new cases developed. 4. Infection following close on syphilis as general military tuberculosis. Developed in secondary stage. Three cases. 5. Infection following typhoid. At a postmortem examination lesions of typhoid and tuberculosis were found. 6. Infection of a family, father, mother, son and daughter, who had been in intimate contact. No disinfectants were used. 7. Infection of nurse, orderly, and scrubgirl. The prophylactic measures advocated by Corbett for the prevention of tuberculosis are those with which all physicians are familiar, and, therefore, need not be repeated at this time.

- 59 *Removal of the Lens in High Myopia. Henry D. Bruns.
60 *Silver Nitrate Injections in the Treatment of General Pyogenic Infections. Joseph Hume.

59. **Removal of Lens in High Myopia.**—Bruns says there are three classes of myopes for whose benefit this operation may be considered: 1. Extreme myopes of elderly or middle-age in whom the pathologic changes do not exceed the production of cones. In these the operation is unnecessary, except for particular reasons, such as the relief of recurring attacks of pain with injection of the eye, a condition that renders existence more or less miserable. They can usually be assured of useful vision, that will outlast the remainder of their lives, by properly adjusted glasses. As a rule, the danger of the extraction will outweigh the benefits conferred, for these persons will be least appreciative of the improved vision that may be obtained. 2. Extreme myopes of elderly or middle-age, in whose eyes extensive pathologic changes have taken place. Here the operation is virtually contraindicated, and only exceptional and imperative reasons should lead to its being undertaken. The dangers of extraction are very great. 3. Extreme myopes between the ages of 10 and 25. The prophylactic value of the operation is very high, for without it the patient is almost surely doomed to a purblind middle and old age. The operation can be very safely and painlessly done by cautiously repeated dissections. Vision is usually at once greatly improved as to kind and degree. Length of time is not to be considered in comparison with the horror of destroying a healthy, useful eye in an attempt to improve vision, or obviate a danger that the patient may never live to encounter. One eye only should be operated on at a time, and a long interval should elapse before the second eye is operated on, so that every opportunity may be afforded to judge of the degree and permanency of the result.

60. **Silver Nitrate Injections.**—Hume has utilized this treatment in 11 cases of pyogenic infection, with two deaths, one thirty-three days after the patient was reported doing well, and this death was due to an intercurrent affection. The other death was the result of embolism occurring in the course of malignant endocarditis. The silver injection was given 20 times, all the cases, with one exception, being *in extremis*. The injections were given as a last resort. In all the injections a characteristic reaction followed. In typhoid fever the leucocytes rose from about 5,000 to 20,000; the reds decreased about 800,000, and the hemoglobin fell about 10 per cent. In acute military tuberculosis the white cells before injecting numbered 4,000; they disappeared after the injection, and then reappeared and rose to 10,000. The solution was given over fifty times with no untoward results save a localized phlebitis twice, which Hume subsequently was able to avoid by handling the vein less. The injection has no influence on wound healing, nor does it interfere with kidney function. The urine is usually increased in amount, and in one case of acute nephritis of toxic origin the urine, which contained no casts, blood cells and albumin, became normal in quantity within forty-eight hours after the silver injection. Hume uses 1 cc. of a fresh 10 per cent. solution of silver nitrate in 1,000 cc. of sterile or sterile distilled water, each 100 cc. of the solution containing 10 milligrams of silver. As a rule, he injects 500 cc. at a time, although weaker and stronger solutions may be used. It is advisable to use only freshly made solutions at a temperature of 110 or 115, and they should be used rather slowly, so that 100 cc. are introduced into the vein every two or three minutes. Any superficial vein of sufficient size may be selected, but the median cephalic, or basilic, are the most suitable. The injection is made under the usual antiseptic precautions. Immediately after there is a rise in temperature, followed by a gradual decline, which is accompanied by the most profuse sweating which lasts for hours but does not weaken the patient. Within twelve hours the temperature is usually about normal, and the general condition of the patient is considerably improved.

65 Some Notes on the Symptoms and Diagnosis of Cholelithiasis. Stuart McFuire.

63. **Gelatin Treatment in Aneurism.**—An aneurism of the abdominal aorta was treated by this method by Williams, six injections being given in seven weeks, 90 cc. in all, of a solution containing 6.5 grams of gelatin and .4 of a gram of calcium chlorid. At this time the patient felt very well, was free from pain and was able to walk about with comparative ease. The aneurismal mass was firmer and the bruit less distinct and of a higher pitch. The injections of gelatin were continued through the following eight months at intervals of about two weeks, but larger injections were given, from 20 to 60 cc. of the solution. The patient died ten months after the beginning of the treatment, the injections failing to give relief from pain and discomfort toward the end. At the autopsy a dense laminated anemortem clot, crescent-shaped and thickest in the middle, was found to occupy the anterior wall of the sac, but did not appear to be closely adherent to the wall. Microscopic examination of the clot showed it to consist of a dense mass of fibrin, apparently deposited in layers at different times. The aneurism ruptured posteriorly. Another case was given three injections, 30 to 40 cc. of a solution containing 10 per cent. gelatin, but died within a month. Two other cases of suspected aneurism of the thoracic aorta were subjected to the same treatment, but without result, except that the patients believed that the pain was temporarily relieved. Williams urges that the treatment is one that should be given a thorough trial. It is practically painless, if given with due care, and so far it seems to be harmless, if the solution is properly sterilized. The gelatin undoubtedly increases the coagulative power of the blood, but its use is of value only in cases of sacular aneurism. Gelatin injections doubtless are of great value in many cases of hemorrhage and other conditions where a prompt increase in the coagulative power of the blood is desired.

74 Male Neurasthenia. E. Cutter.

66. **Treatment of Typhoid Fever.**—The routine treatment of typhoid fever is reviewed by Gordon, who, in closing, calls attention to certain mistakes which ought to be guarded against, such as friendly but damaging visits; too much or too frequently repeated feedings; feeding too often at night; too much temperature recording; too little water; disregard of antiseptics in the mouth, nose and pharynx; failure to examine the urine at intervals, and to see that the patient sleeps sufficiently.

69. **Flexible Rectal Tube.**—Earle refers to the use of the long, flexible rectal tube, which usually coils on itself in the lower portion of the rectum between the first of Houston's valves and the anal margin. In order to overcome this, he suggests the following procedure: With the patient placed in the knee-chest position, with the head and shoulders lowered (if the patient is too weak, then in Sim's position, with the hips elevated on a pillow), the high enema can be given with the most positive results by using the short rectal nozzle. Even in cases of impaction the water so introduced can be made to distend the bowel and to get beyond the point of obstruction by sufficiently elevating the bag containing the water. By using a large quantity of water, says Earle, it can be made to run round as far as the ascending colon, so that in every conceivable condition calling for the high enema this procedure is the most certain, simple means for accomplishing the desired end. Still another desirable object is obtained by this method, both in the use of high and nutrient enemata, and that

is, the water is not allowed to accumulate in and distend the lower portion of the rectum and thus bring on the expulsive efforts before the desired quantity of water has been introduced. In the case of nutrient enemata, they are retained more easily and are spread over a much larger surface for absorption.

4. **Aseptic Surgery.**—Cheyne's paper considers the destruction of bacteria by heat and chemical disinfectants, the disinfection of the skin, towels, instruments, sponges, ligatures, dressings, etc. The methods spoken of are those commonly employed for purposes of sterilization and disinfection.

5. **Cysts of the Neck.**—Edington cites a series of illustrative cases, giving in detail the operative measures employed, the histologic report, and subsequent history.

6. **Operation for Hernia in Young Children.**—The Bassini operation as a routine procedure in children is condemned by Stiles, who says that the indications in performing the radical cure in the young are to isolate and ligate the neck of the sac with the least possible damage to the inguinal canal. The operation he prefers is practically the one introduced for adults by Sir Mitchell Banks. After disinfecting the skin the day before the operation, a boracic poultice or a sterilized gauze dressing should be applied over night. Carbolic poultices should not be used, especially in children, as they are likely to produce severe general depression or even fatal collapse. The incision, which is made a little above and parallel to Poupart's ligament, should not extend down into the scrotum. After exposing the spermatic cord and the pillars of the external abdominal ring, the former, along with its coverings, is freed from the surrounding subcutaneous tissue. The coverings of the cord are caught up laterally at the lower part of the wound by two pairs of forceps, and are then divided longitudinally, layer by layer, with a sharp knife. By turning aside this fascia and grasping its cut edges with the catch-forceps, the pampiniform plexus of veins, covered by the thin fascia transversalis, can be seen on its lateral aspect. The peritoneum of the patent funicular process is exposed by incising the transversalis fascia parallel and just internal to the plexus of veins. This fascia, along with the veins, is stripped off the sac by means of a blunt dissector or by dissecting forceps. The vas deferens and its vessels are treated in the same way. The fascia transversalis is next stripped off the inner aspect of the funicular process, which is finally freed around its entire circumference. The separation of the above structures is continued downward until the fundus of the sac is isolated and drawn out of the wound. Should the sac extend well into the scrotum or be continuous with the tunica vaginalis testis, it may be cut across a little below the external ring. The sac is grasped with forceps and held on the stretch while the constituents of the cord are being separated from it in an upward direction as far as the internal abdominal ring. Except when the neck of the sac is unusually wide and the walls of the canal weak, it is unnecessary to fix the stump to the anterior abdominal wall; the ends of the ligature applied to the neck of the sac may be cut short, and the latter allowed to slip back up the canal. If the sac be properly freed at its neck and put well on the stretch the ligature will be applied high enough to avoid leaving a funnel-shaped depression at the level of the internal ring. The canal is closed by introducing a single catgut suture through the outer pillar close to Poupart's ligament, superficially to the cord, and then from within outward through the conjoined tendon and the inner pillar of the ring. By reducing the size of the external ring and including the conjoined tendon in the suture, the liability to the development

of an acquired hernia in after life is diminished. It is important to avoid the use of a drain in children. Hemorrhage must be carefully arrested. The space beneath the subcutaneous tissue of the somewhat undermined wound must be obliterated by the introduction of one or two buried catgut sutures or a single silkworm gut mattress suture through the skin and subcutaneous tissue. The skin wound is closed by horsehair stitches. The after-treatment which has given the best results in Stiles' hands is to smear the wound with iodoform out of a 1 in 1,000 sublimate solution, and dust with boracic acid powder, no further dressing being applied. The infant is kept in bed, flat on its back by means of a strap passed behind the shoulders and through the armholes of a flannel band passing across the front of the chest. A metal cage is placed over the child's body to keep the bedclothes from coming in contact with the wound. The nightdress is pinned up and covered with a binder so as to leave the lower part of the abdomen exposed. A piece of boracic lint is pinned around the lower edge of the folded-up gown. All that is necessary is to keep the wound thickly dusted with boracic acid, or, if preferred, with a mixture of boracic acid and iodoform. The average duration of the child's stay in the hospital after operation was rather less than a fortnight.

7. **Radical Cure of Oblique Inguinal Hernia.**—Kennedy gives the remote results obtained in 103 cases, most of which were operated on by a method practiced by him and which may be described briefly as follows: An incision is made over the inguinal canal in the usual way until the tendon of the external oblique muscle and the external ring are exposed. The contents of the scrotum are withdrawn, the sac isolated, and the testicle and cord returned to the scrotum. The sac is dealt with after Kocher's latest method, that is, it is invaginated into the abdomen and brought out through the abdominal wall, the peritoneal surface out, ligatured and cut off, and the internal oblique and transversalis stitched to the deep aspect of Poupart's ligament. The cord passes directly into the abdomen at a point opposite the external ring. The youngest patient on whom the operation was performed was six months old, a case of strangulated hernia, and the oldest was 74 years old, the operation being called for on account of the presence also of a large hydrocele. Both these patients are now well and free from recurrence, the older patient after four years. In 45.63 per cent. of the cases the hernia was due to non-obliteration of the funicular process. In six cases the contents of the sac consisted of the caput cecum and appendix. In one case, a girl of 8 years, the sac contained the ovary and tube. All the cases recovered except one child, who, some weeks after the operation, died of tuberculous meningitis. The operation in this case was undertaken on account of the large size of the hernia and the difficulty, and at times impossibility, of reducing it; strangulation being, therefore, feared. Of 70 cases operated on by the author's method 54 have been traced six years after the operation. Only one case recurred. Operated on by the Bassini method, 10 cases; number traced, 8; recurrences in 2. Operated on by Kocher's method, 3; traced, 3; recurred, none. Operated on by Macewen's method, 20; traced, 11; recurred, 2.

16. **Treatment of Deep-Seated Hemorrhage.**—Hare adds four cases of hemoptysis to those already published in which amyl nitrite caused immediate cessation of the hemorrhage. (See abstract in THE JOURNAL of September 10, [14, p. 761.]) Adding these four cases to those already published gives the following results: Of 13 attacks of hemoptysis (12 phthisical and 1 cardiac) treated by inhalations of amyl nitrite, all save one ceased within three minutes, the one referred to being delayed to ten minutes. Hare says that if amyl nitrite is unobtainable it would be rational to immerse the patient in a hot bath, thus producing vasodilation of the cutaneous area, a diminution of resistance in the aortic outflow, a fall of blood pressure in the left auricle, and a reduction in the pulmonary blood pressure. At the same time the mouth and nostrils should be protected from inhalation of the hot air. He believes that the deliberate provision of cold air for inhalation would aid in securing hemostasis.

17. **Constipation Treated by Injections of Olive Oil.**—According to Herschell, the methodical use of oil injections is one of the most useful procedures at our command for the treatment of muco-membranous colitis and constipation. In order to succeed, however, cases must be selected and injections given in the proper manner. The injection of olive oil as a matter of routine in all cases of constipation will prove disappointing and discredit the method. Gratifying results can be obtained in cases depending on chronic colitis; constipation associated with spasm of the bowel, such as is so frequently found in neurasthenia, and in atony of the intestines, used conjointly with the electrical treatment. The method consists in the injection of from 3 to 10 ounces of warm olive oil at bedtime. This is retained during the night and usually results in an evacuation after breakfast on the following day. The oil should be introduced slowly so as not to create an immediate desire to evacuate. The apparatus used by Herschell consists of a glass funnel provided with a metal loop, by which it can be suspended at a convenient height above the bed on which the patient lies while taking or receiving the injection. It is fitted with about 27 inches of rubber tube of large caliber and terminates in a nozzle of special construction. This nozzle has a large bore to allow the ready passage of the oil, and has the end of the bore well rounded so that even when roughly and unskillfully used it is impossible to damage the mucous membrane of the rectum, and from its shape it is self-retaining. The outflow of oil is controlled by a spring clip, which is so contrived that when opened it will remain so until a catch has been released. The measured quantity of oil is heated by standing the beaker containing it in a basin of hot water before it is injected. It is best to commence with five or six ounces and to reduce the dose daily until the smallest amount which will produce an action of the bowels is found. The effect may be then tried of using the oil on alternate nights, and so on, the intervals being lengthened gradually until the oil is no longer necessary.

20. **Cases of Skin Disease.**—The cases described by Saundby are one of acute pemphigus, an occupation rash caused by bichromate of potassium, and a case of orthostatic purpura (caused by assuming the upright position).

30. **Nerve Reactions in Genital Herpes.**—Ravaut and Darré report 27 cases of genital herpes, mostly of the neuralgic type. In another type the nervous symptoms are less pronounced, but still sufficiently marked. The pains are permanent, but remain localized without presenting the character of neuralgic pains. In both types the nervous troubles precede the appearance of the vesicles, and in both they are liable to vanish while the eruption is still at its height. In still another type the nervous symptoms are less evident and are usually restricted to pruritus. Lumbar puncture in 26 cases showed more than 20 figured elements in the cerebrospinal fluid to the field in 5 instances; from 7 to 20 in 10, and from 4 to 6 in 6. The patients showing the most marked reaction in this respect were always those with the severest nervous disturbances, exhibiting besides the genital pains, headache, rachialgia and neuralgias. The nervous system seems to react to the primary cause in the same way in both genital herpes and zona, although this primary cause is probably different for each. Every case of genital herpes with nervous symptoms was always accompanied by some modification of the cerebrospinal fluid.

33. **Radiotherapy of Alopecia Areata.**—Sabouraud's method of treating parasitic tinea by the x-rays was described in THE JOURNAL, page 983, of vol. xlii. The x-rays are of a strength equivalent to 4.5 to 5 Holzknicht units. This is followed in fifteen days by the falling out of the hair over the part. The hair grows again, and each hair is then healthy. It commences to grow in about ten weeks, and the growth is normal in ten weeks more. The contagiousness of the affection vanishes with the falling out of the last diseased hair, usually about twenty-five days at most after the exposure. In the last six months of 1903 57 children with cryptogamic tinea were cured by this treatment, and in the last six months 134 have been cured. The number includes 120 cases that had proved absolutely rebellious to all other measures. They required treatment of the entire scalp. As each exposure is only of a patch about 9 cm. in diameter, from 12 to 13 sittings were required in these extensive cases. They represent the dregs of the last four or five years of ordinary treatment, the cases left over, that had proved absolutely intractable. Two hospital schools were established in Paris some years ago exclusively for children with these affections. One of them has already been evacuated by the prompt curing of all the inmates. Radiotherapy is proving equally effectual for both favus and tinea tonsurans. During the entire number of 2,200 exposures only 6 cases of radiodermatitis were observed, and these occurred before the present mode of measuring the rays was adopted. The more penetrating rays, the greater their number, and hence the harder the tube the more penetrating its rays. When a radiodermatitis occurs it entails permanent baldness of the part, and hence the operator should carefully avoid anything of the sort. Permanent baldness is also entailed by repetition of the standard exposure after two or three weeks' interval. Consequently, it is of the utmost importance to have the first exposure complete in every respect. It is also extremely important in treating two separate patches not to allow the action of the rays in the second exposure to impinge on the part already treated in the first exposure, or permanent baldness is liable to result from the superposed action of the rays. The behavior of the tube varies from day to day with the electric tension of the atmosphere and other factors. The Holzknicht radiometer has certain disadvantages, which he enumerates. He has modified it to a certain extent, using instead of the Holzknicht pastilles slips of paper impregnated with an emulsion of barium platino-cyanid in an amyl acetate collodion—the prepared paper used for the spectroscope. It has the advantage of cheapness: the same slip can be used over and over again at need. The tint is modified only by the x-rays, and ceases to change as soon as the latter are withdrawn, and the tints are more distinct and more easily compared with the standard tint on the water color test card than the Holzknicht tints. The platino-cyanid paper loses its tint on exposure to the air, and it also requires to be placed at half the distance of the skin to be treated. By using it and keeping within the limits of the

proper tint there need be no fear of dermatitis, while the results of radiotherapy have amply demonstrated its great superiority to all other measures in the treatment of tinea and favus.

34. **X-Rays in Treatment of Cutaneous Affections.**—This extensive monograph issues from Brocq's laboratory at the Paris Broca-Pascal Hospital. A dozen pages are required for the bibliographic references alone. All the various skin affections that have been treated by the x-rays are reviewed in turn, with the particulars of the cases treated by Brocq or his assistants. The indications, technic and results attained are given in detail. Among the cases of cutaneous epithelioma 14 have been objectively cured and 6 nearly cured, while 8 are still under treatment, and 4 have abandoned treatment. The form most rapidly modified by the x-rays is always that with a central ulceration, surrounded by a hard border.

35. **Tuberculous Bacilæmia.**—Jousset comments on the exceptional character of the positive findings and the rarity of virulence of the blood in the course of spontaneous tuberculosis in animals and its transient character in induced experimental infection. His own research has established that positive results are reliable only when a large amount of blood is examined, and, whether the blood is tested by inocopy or by inoculation, the fibrinous clot is the part to be investigated. Subcutaneous inoculation of a guinea-pig with this clot, followed by the development of a specific adenopathy, even without generalization, are the only reliable proofs of tuberculous bacilæmia. He has studied the blood of 35 subjects and in only 11 could the tubercle bacillus be discovered, and these were mostly acute cases. Tuberculous bacilæmia is as rare in chronic tuberculosis as it is frequent in the acute forms. There do not seem to be any general manifestations of the bacilæmia except the fever. It generally coincided with a continuous and high fever, and was never found in connection with the remittent, hectic fever. Albuminuria is nearly constant in case of this bacilæmia. Whenever there were symptoms suggestive of typhoid fever in this bacilæmia, granulations were found in the intestines. He has encountered one case of the attenuated or gastric form. He has also observed cases in which the infection of the blood with the tubercle bacillus and arthralgias constituted the entire disease, the prelude to the "tuberculous rheumatism with granulations" described by Poncet. Dyspnea may likewise be the only manifestation of the specific septiciæmia. The dyspnea in one case coincided with the appearance of the bacilli in the blood and subsided as they were eliminated. At times the dyspnea assumed the character of true asthma. Fever and albuminuria accompanied the close of the periods of bacilæmia. The meningeal and cerebral forms of tuberculous bacilæmia have not yet been studied. Between the meningitis with actual granulations and toxic meningitis there is probably a phase of pure and simple bacillary infection of the nerve centers and their coverings. Two of the 3 cases of primary tuberculous bacilæmia terminated in recovery, and Sticker has observed a similar case. The bacilæmia is liable to terminate by elimination of the bacteria through the kidneys and complete recovery, or the bacilli may proliferate and granular implantation result. The bacilæmia is in these cases pregranular. The localizations of the lesions in bacilæmia may be legion, but the endocardium and the kidneys are the most frequent sites.

37. **Local Treatment of Rheumatic Joint Affections.**—San-

lini injects directly into the joint 3 to 5 c.c. of a 3 per cent solution of sodium salicylate. The pain is arrested and the joint can be moved without pain. The effusion is then gradually absorbed. In recent cases the absorption is complete in the course of the same day. The fever and other general symptoms are liable to persist somewhat longer. When they keep up unduly long endocarditis is probably present.

39. **Quinin and Salicylates in Puerperal Fever.**—Ovary mixes equal parts of quinin sulphate and sodium salicylate, and gives .6 gm. of the mixture every three hours. Three or four doses are generally sufficient to arrest the puerperal fever. In his experience with 28 cases thus treated there were 26 recoveries. He believes that the two drugs combine in the stomach to form nascent quinin salicylate, leaving sodium sulphate, which acts on the bowels.

43. **Isolated Inflammation of Bladder Diverticulum.**—Englisch has observed 6 cases of inflammation in a bladder diverticulum and its complications. Peritonitis is more apt to follow inflammation in the absence of a stone than with it. Palliative treatment by rinsing and draining is less successful than extirpation of the diverticulum. In case of a stone the diverticulum should be removed with the stone. He bases these conclusions on his own experience and an analysis of the literature. He has collected 250 cases of concrement formation in a diverticulum, and 57 cases of isolated inflammation without a stone. They include 17 in which the pocket was involved in a hernia.

45. **Access to Naso-Pharyngeal Cavity By Turning Back Jaw.**—Hertle adopted Kocher's technic, and found that it afforded remarkably fine access to a large fibroma growing in the naso-pharynx. The hemorrhage was readily controlled by tamponing. The temporary turning back of the entire upper jaw was preceded by tracheotomy and introduction of the tampon canula.

46. **Enteroanastomosis Without Opening the Gut.**—Sato's experimental research has already been mentioned in these columns. He found that freshened surfaces of mucosa approximated for a gastroenterostomy or enterocenterostomy, did not result in any perforation unless the approximated surfaces were cauterized with heat or silver nitrate. When this was done the communication between the two lumina was invariably established within two or three days in all his experiments on dogs and monkeys. Interesting illustrations accompany the article.

48. **Soap Spirits for Disinfection.**—Sikemeier's experiences confirm the value of soap spirits for disinfection of the skin. It was particularly effectual when the skin had been scrubbed with soap beforehand. He washes for five minutes with potassium soap under a stream of warm water, then scrubs for five minutes under the same, and then scrubs for five minutes with soap spirits, terminating with ether and sublimate.

49. **Temporary Nailing of Fractures.**—Niehans has treated several cases of supracondylar fracture of the humerus by temporarily nailing the stumps together. The olecranon is exposed through a side incision, detached at the base and turned back with all the muscles. This exposes the fracture, which is then reduced, and two long nails are driven through both stumps until their heads just project above the level of the skin. The flap is then replaced and the soft parts sutured. The nails were removed the fourth to the seventh day. He has also treated on the same principle fractures of the upper end of the humerus. The radiograms show the two nails inserted to form an acute angle, their points nearly touching. He uses nickel-plated steel nails with a four-sided point. He gives the details of 6 cases. In one the nails were 9.5 cm. long.

50. **Appendicitis in Inguinal Hernia.**—Wassiljew adds another to the 62 cases of appendicitis in inguinal hernia in men. Besides reviewing the literature he portrays the symptoms, diagnosis, prognosis, treatment, etc.

54. **Tuberculous Kidneys.**—Kronlein has operated in 51 cases of tuberculosis of the kidneys, which is about a third of all his surgical work on the kidneys. He performed nephrectomy in 34, and the results have convinced him that this is the operation to be preferred in such cases. The affection is much more common in women than in men. In 92 per cent. it was restricted to one kidney. The infection is always by way of the blood, never urogenic. The tuberculosis was solitary in the kidney in only 12 of his 34 cases; in the others the kidney affection was associated with a tuberculous process in the lungs in 9, in the bladder in 12, in a joint in 9, and in 4 the entire urogenital apparatus was invaded. Twenty-four of his 34 nephrectomized patients are still living. Eight died within eight months of the intervention. None died with indications of insufficiency of the remaining kidney. Nine of the 10 subjects who died were examined postmortem and nothing abnormal could be detected in the remaining kidney. He is getting up an atlas on renal tuberculosis, and has collected a quantity of valuable material. He distinguishes between the fluid and the solid form, the latter including the solid caseous and the diffuse solid varieties. There is also a tuberous form with unfavorable prognosis, as Israel has already proclaimed. The list concludes with the embolic form, of which he describes a typical example. The methods of functional diagnosis now in vogue can none of them be implicitly relied on. He regards extirpation of a tuberculous kidney as one of the most successful of all operations.

55. **Appendicitis.**—Jonnesco has collected and compares the published results of internal treatment of appendicitis with those of operation later, and proclaims that they are much better than the results of immediate operation. His own statistics confirm this view. He has had 44 per cent. mortality in his cases operated on early, and only 5.2 mortality in those treated by internal measures and surgical intervention later. He never resects the appendix unless it presents; he advises against searching for it. His rule now is to commence with internal treatment (opium, ice, no food, copious subcutaneous or intravenous saline infusion, lavage in case of excessive vom-

iting, no purgatives). When the signs of generalized peritonitis change to those of a circumscribed peritonitis, with adhesions or suppuration, usually about the eighth to the twelfth day, he proceeds to operate. An operation is indicated, of course, at any time if signs of aggravation are noted.

56. **To Enhance Resisting Power of Peritoneum Preliminary to Operations.**—Mikulicz's method of inducing high leucocytosis before attempting any gastrointestinal operation has been described in these columns, page 1242 of the last volume. He injects nucleic acid under the skin, using a 2 per cent. solution. He also advocates copious rinsing of the abdominal cavity with salt solution, having changed his views in this respect. The increased leucocytosis which follows is a valuable aid in enhancing the resistance of the parts. He has applied these procedures in 34 cases, and the leucocytosis increased by 17 to 45.2 per cent. in the various cases, as he describes in detail. The by-effects were trivial.

57. **Iodin Reaction of Leucocytes.**—Küttner does not ascribe much diagnostic importance to Ehrlich's iodine reaction. The only information to be derived from either the positive or negative findings, in his opinion, is that the prognosis generally proves bad when the iodine reaction is marked.

59. **Subcutaneous Artificial Feeding in Surgery.**—Friedrich's experiences were reviewed in these columns, page 1456 of the last volume.

60. **Prostatic Abscess.**—The points learned from a study of 35 cases are reviewed. In 76 per cent. the abscess was of gonorrhoeal origin. Three mild cases healed spontaneously after perforation into the urethra. Incision through the rectum is advisable only when perforation into the gut is impending. In all other cases the perineum is the preferable route.

61. **Soap Spirits for Disinfection of Skin.**—Falck has been making an extensive study of various modes of disinfection, and gives the preference over all others to soap spirits. For various reasons which he enumerates, it is better to have the soap spirits in a solid form. He mixes 15 parts sodium soap with 15 parts water and 70 parts alcohol. The soap is softened with a little water and rubbed into the skin in the air. It is then foamed up by putting the hands in water, the disinfection concluding with a solution of sublimate or lysol, applied after all the particles on the skin have been stirred up by the foaming soap spirits. Mechanical scrubbing is an important part of every disinfection.

66. **Resection of Tuberculous Knee.**—Blauer states that 343 out of the 400 patients operated on can be regarded as completely cured. In 17 a secondary operation was necessary. About 15 per cent. died later from general tuberculosis. The proportion of successful resections was 87.9 per cent., in striking contrast to the 45 per cent. reported in König's statistics as cured by conservative treatment of tuberculous knee affections (126 out of 288 cases). He urges that operative radical treatment should be accepted as the standard procedure for all severe cases in both children and adults, and also for the mild ones when good conservative treatment is not promptly beneficial or is impracticable for any reason.

67. **Etiology of Appendicitis.**—Brunn attributes the etiology of appendicitis to bacteria in the appendix, their numbers being in such contrast to the thinness of the wall of the appendix and its small size.

68. **Bladder Disturbances of Cerebral Origin.**—Goldmann's patient exhibited bladder disturbances which vanished permanently after evacuation of an epidural collection of pus compressing the cortex, due to tuberculous osteitis. The post-central convolution was the site of the lesion, which partly involved also the superior and inferior parietal lobe and the superior temporal convolution. There were no other motor disturbances. Psychic depression had existed for three months before the retention was noted. The desire to urinate was felt normally, and the retention was intermittent and not accompanied by any exaggeration of the psychic depression.

70. **Extensive Mobilization of Urethra.**—Goldmann asserts that defects in the urethra up to 8 cm., or even more, can be repaired by stretching the mobilized urethral stumps. The distal stump can be extensively mobilized, and the central stump is so elastic that it can be stretched to bridge the gap. The stretching is realized by extension of the legs, with traction at the ankles. He has treated 2 patients in this way, with excellent results. The stricture in the first case was the result of a cavalry accident, the resected portion measuring 3 cm. in length. In the second case, 6 cm. were resected to do away with an impassible gonorrhoeal stricture. The functions of the organ do not seem to be impaired in either instance.

95. **Diabetic Gangrene.**—Hildebrandt explains the occurrence of gangrene in diabetes as a secondary process induced by the arteriosclerosis entailed by the diabetes. The diabetic conditions favor the proliferation of bacteria; his experiments have demonstrated that media containing a certain proportion of sugar afford exceptionally favorable conditions for microbial growth. He has further established that the virulence of bacteria is enhanced when a solution of sugar is injected with them. In treatment of diabetic gangrene, dry aseptics should be the rule. König amputates according to the condition of the arteries. If there is pulsation in both tibialis arteries the leg can be safely amputated low down. A good pulse in the popliteal still allows ablatio cruris, but without these findings the thigh must be amputated. Of 5 patients whose legs were amputated, 2 died; and of 4 amputated at the thigh, 2 died.

98. **Treatment of Old Luxation of the Hip Joint.**—Brüning describes 3 cases and reviews 35 in the literature. The technique which he recommends is conservative attempts at reduction. If these fail, the anterior forward luxation should be transformed into a backward one, and this be operated on. The attempt at bloodless reposition should be followed by a few days of rest, with extension before the knife is used. The earlier the patient is seen and the younger he is, the better the chances for fine functional results. Brüning adds that what he calls "distension" luxations always give a worse prognosis than the traumatic.

103. **Bone and Joint Affections with Syringomyelia.**—Borchard practices at Posen, and has had occasion to treat 19 patients during the last seven years on account of bone and joint affections, the result of syringomyelia. He considers them of neuropathic origin, like the alterations in the joints of arthritis deformans and tabes. He describes the characteristics of the joint lesions and emphasizes the necessity for conservative treatment. In case even of panaritium a very small incision into the focus is all that is allowable. Phlegmons should be treated expectantly. In non-suppurating joint lesions he advises against operative intervention, and when there is pus, incision and drainage should be all that is attempted. In case of very severe changes in a joint he would prefer amputation to resection.

107. **Sanger Technic of Treating Prolapse.**—Scheib states that 141 cases of prolapse of vagina or uterus have been operated on according to the Sanger technic in the years 1899-1903 at the Prague gynecologic clinic. Of this number 65 have been examined after a long interval, and in 60 per cent. the cure was perfect. The advantages of this method are the readiness with which it can be adapted to individual conditions, the slight loss of blood and the easier avoidance of injury of the rectum. An existing slight retroversio-flexio is liable to entail recurrence unless corrected. When this is done, supplementary to the Sanger operation, the results will be even more favorable.
108. **Disinfection of the Hands.**—Schaeffer believes more in the mechanical than in the antiseptic part of hand disinfection. Alcohol and hot water are the main essentials. Alcohol is as destructive to germs as any other antiseptic during the short space of time it is used, while it loosens up and detaches all the detachable particles and germs and shrivels the skin so that the bacteria still lurking in the crevices are held and can not escape during the operation.

110. **Metastases of Bacteria, Tumor Cells and Dust in the Retroperitoneal Lymphatics.**—Tendelo has been studying the pathologic changes found in the retroperitoneal lymph glands. The importance of these changes has not been generally recognized. In case of processes in the lungs or pleura, he found almost constantly metastases in the lymphatics along the aorta. He frequently saw dust particles unmistakably derived from the lungs by way of the lymphatics. He cites his clinical experience and anatomic research in detail, and describes what he accepts as the mechanism of this retrograde metastasis by way of the lymph passages into the abdomen. It explains not only the occurrence of metastasis of a stomach or liver cancer in the para-aortic lymph glands, but also the metastasis of bacteria, cancer cells and dust particles from the thorax. Further study must be undertaken to determine which lymph vessels lead to certain organs in this region.

111. **Indications for Operative Gynecology.**—Sippel's principles may be summarized in the statement that he believes in operating in every case in which there is apparent danger to life, if the operation offers any prospect of success and the general condition does not forbid it; also in every chronic case in which conservative measures fail to cure and the operation is free from danger. He does not accept as a cure of a displacement a correction which requires the constant wearing of a pessary. He quotes Kocher's axiom: "It is not necessary for every practitioner to act surgically, but it is imperative that they should learn to think surgically," merely substituting the word "gynecologic" for "surgical." When the general practitioner learns to think gynecologically, then suffering woman-kind will derive the benefit it should receive from the advances in modern gynecology.

112. **Local Anesthesia in the Polyclinic.**—Aulhorn reviews the experiences at Perthes' polyclinic at Leipzig with local anesthesia in 763 cases. Of all the methods used, the combination of adrenalin with injection of .2 per cent. solution of cocaine along the course of the nerve proved the most convenient and effectual. All danger from the use of adrenalin can be avoided by injecting it at some distance from the wound. This is particularly necessary when there are flaps that are not very well nourished. In conclusion, he warns to refrain from employing local anesthesia in cases that are not suitable for it, as the excitement that follows its failure is a bad foundation for general narcosis, and lessens the confidence of the public in local anesthetics.

113. **X-Ray Examination of Stomach and Intestines on Living Subject.**—Rieder had large quantities of bismuth mixed with the food and given in enemas, and then examined the subjects with the x-ray screen. He gives a number of the facts thus learned, some of them contrary to the teachings of the text-books. The pylorus, for instance, when the stomach is full, may be found to the left of the median line. The full stomach lies vertical or diagonal, never horizontal. There is always an accumulation of gas to be noted in the upper part of the fundus during digestion in the stomach. Interesting facts in regard to the motor function of the stomach can also be learned in this way, as also of the various parts of the intestines.

114. **Complications of Articular Rheumatism.**—Harrass remarks that the majority of the 58 cases of acute articular rheumatism observed at Aix were in subjects from 16 to 20 years of age, and the affection recurred in nearly 40 per cent. About 43 per cent. of the patients recovered without complications of any kind, but 51.7 per cent. exhibited symptoms of endocarditis. The latter predominated in the younger sub-

jects. An alcoholic heredity seemed to afford a predisposition to these rheumatic heart affections. Other complications were erythema nodosum, pneumonia, chorea minor and a psychosis, one case of each, and 2 of nephritis.

115. **Large Doses of Ergot in Obstetric Practice.**—Burger reports no deaths and only a single case of slight temperature during 11 years of practice, with 8,700 births and 134 deliveries requiring some obstetric intervention. He attributes this fine record to his custom of giving large doses of ergot beforehand when he is contemplating such intervention, from .5 to 1.5 gm. ergotinum dialysatum per os, and, after delivery is concluded, an infusion of *secale cornutum*, 35 gm. in 180 gm. water, and 20 gm. syrup of raspberry, in tablespoon doses. The conditions were those of ordinary village and country practice.

116. **Hydrophobia and Trauma.**—Pfister describes a case of hydrophobia developing after an incubation of six months. He offers it as a contribution to the question of the influence of traumatism on internal affections. The patient was a healthy man of 33, whose father had committed suicide under some emotion. The subject was bitten in the thumb by a dog discovered later to be rabid. The wound was superficially disinfected, and four days later Pasteur treatment was commenced. Some other persons who had been bitten by the dog were treated at the same time, and all have remained healthy. The patient resumed his business, but four months after he had been bitten was hit on the head with a heavy chair in some business controversy. There was temporary unconsciousness, and after recovery the patient's character seemed to be altered; he became gloomy and aggressive, complained of headache, and by the sixth month developed a typical case of hydrophobia. Pfister also describes a typical case of false hydrophobia, a nervous affection following the bite of a healthy dog. In such cases a few days will generally witness the vanishing of the symptoms. One feature of this case was that the subject's symptoms, especially his inability to swallow, were reproduced in the spectators for a few days. In another case several persons were bitten by a rabid dog and took the Pasteur course. All have remained healthy except one man, who seven months later was attacked by a large healthy dog. Although he was not bitten, he was very much frightened, and the shock was followed by development of typical hydrophobia.

119. **Functional Kidney Tests.**—Kövesi has determined the functional capacity of the kidneys by various tests on 100 subjects. His experience has confirmed his opinion in regard to the necessity for leaving the catheter in the ureter for some time, as a reflex oliguria is likely to prove misleading at first.

He never observed polyuria, although it was carefully sought in his last 20 tests. He has never found the molecular concentration of the urine from the sound kidney less than that from the diseased one, with 2 exceptions, and even in these cases examination of the amount of urine indicated which organ was diseased. In regard to the "dilution test," he has found that the capacity of secreting a diluted urine is closely dependent on the condition of the kidney and character of the kidney affection. When the specific glandular element is destroyed the kidney is unable to dilute the urine, while in case of interstitial affections the diluting faculty may be retained unimpaired. The advantages of this test are that the procedure is a physiologic one, and that the elimination of water requires a specific activity on the part of the cells. In regard to the tests with stains, he thinks that they are usually indecisive in the early stages of a kidney affection, and that they can scarcely be regarded as affording much progress in functional diagnosis of the kidneys, although they may aid the novice to locate the months of the ureters.

123. **Operation for Torn-Out Tendon.**—When the parts were exposed after the traumatism, the tendon of the long head of the biceps was found completely torn out. The torn-out end of the tendon had become turned back on itself, forming a loop, the loose end of the tendon lower than its head in the muscle. This displacement of the stump must have occurred at the time the tendon was torn out, the elastic strain causing it to fly back. These findings demonstrate the impossibility of restoration of conditions to normal under such circumstances without surgical interference. Hofmann states that he has been able to find only 4 instances on record of operative treatment of this torn-out tendon. The functional results were all so good that he urges surgical intervention as soon as conservative measures fail to show improvement.

124. **Spinal Affection with Tabes.**—Frank reports the case of a man of 55, a cabinetmaker, previously healthy, no lues, who met with a slight accident affecting the sacral region in 1902. A year later symptoms of pronounced tabes developed, accompanied by an osteoarthropathy of the lumbar vertebrae. The latter corresponded in every particular with the descriptions of typical tabetic osteoarthropathy of the spine, and was undoubtedly due to the tabetic process. Comparison with other typical spinal affections shows the differences. The prognosis is favorable. Mercurial treatment should always be instituted in such cases and some mechanical support is advisable not only for its moral effect on the patient, but to relieve the affected vertebrae of weight-bearing. It thus aids in arresting the process or at least in rendering it milder and checking severe destructive changes. This effect may possibly be the reason, he adds, why a supporting corset has such an unmistakably favorable action in tabes.

125. **Operations on Maxillary Sinus Through Nose.**—Réthi has operated on 15 cases of maxillary sinusitis by resecting the anterior two-thirds of the inferior turbinal. At the point of its insertion he makes an opening into the maxillary sinus, extending toward the outer wall of the middle and lower nasal fosse, establishing a broad communication between the nose and the sinus. In 4 out of his first series of 5, the affection had resisted other measures for years, but was radically cured in one to four months. In the fifth case there is still slight secretion in the sinus. In the second series of 6 patients, 5 were cured and 1 much improved. Of 15 patients, 12 were completely cured and 3 much improved. He regards this technic as an improvement over the Caldwell operation, no external incision being necessary.

128. **Menstruatio Praecox and Ovarian Sarcoma.**—The patient was a girl of 6 who had menstruated regularly since her fourth year, and was precociously developed. A large round-celled sarcoma was removed from the left ovary. In 3 other cases of precocious menstruation on record, a tumor was found in one ovary. In the case described, no genital hemorrhage has been observed during the months since the ablation of the tumor, but the formation of another tumor, manifestly a recurrence of the sarcoma, is unmistakably evident.

131. **Pasteur Treatment of Hydrophobia.**—Nitsch presents arguments in favor of using fresh mixed virus, and in larger amounts than those hitherto adopted. It is convinced that the fresh, spinal cord virus, injected subcutaneously, is entirely harmless for man.

133. **Vaccination Under Red Light.**—See editorial.

134. **Cytology of Effusions.**—Lewkowicz analyzes the publications on this subject and classifies the findings as follows: Endotheliosis signifies a mechanical irritation (transudates in heart and kidney affections, mechanical irritation by the growth of some neof ormation or the result of traumatism). Mononucleosis indicates the presence of foreign cellular elements somewhere in some serous membrane. The organism is seeking to rid itself of these foreign elements by macrophagocytosis. Erythrocytosis signifies a hemorrhagic process, either hemorrhage from solution of continuity of the vessels or passage of the erythrocytes through the walls of the vessels in consequence of inflammatory changes in the walls. Lymphocytosis and polymucleosis indicate an inflammatory process, the former a serous, the latter a suppurative process. Cytologic examination is thus able to reveal a pathologic process in some serosa: meningitis can thus be differentiated from the cerebral symptoms accompanying an infectious disease; tuberculous meningitis can be differentiated from an intestinal affection with toxic brain symptoms; tabes and progressive paralysis can be differentiated from a neerosis. The cytologic findings may vary in the course of the same affection, as a serous may merge into a suppurative process. But experience shows that certain pathologic processes obey certain laws. For instance, in case of lymphocytosis of the region of the diaphragm or meninges, we must bear in mind that the majority of the affections in these regions are tuberculous. The lymphocyte formula in case of an exudate in the costal pleura may be regarded as suggestive evidence of tuberculosis, although it does not positively exclude pneumococcus, staphylococcus or influenza inflammations or neoplastic changes. In case of meningitis, this formula indicates tuberculosis or syphilis. The polymuclear formula does not exclude any of these processes, and may indicate more extensive tuberculous or gummatous foci, with necrotic changes. Scraps of endothelium speak against tuberculosis. The polymuclear formula is more liable to accompany probably some pyrogenic or allied process, or a rheumatic or hydrophobia process, heat stroke, or possibly malignant disease. In case of a transudate, it suggests an infarct in the lung. The finding of macrophages is testimony in favor of a pneumococcus or rheumatic exudation.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed to be a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

THE INVASION OF CARCINOMA CERVICIS UTERI INTO THE SURROUNDING TISSUES

AND ITS BEARING ON THE MORE RADICAL OPERATIONS
FOR THAT DISEASE.*

JOHN A. SAMPSON, M.D.

Resident Gynecologist, the Johns Hopkins Hospital; Instructor in
Gynecology, Johns Hopkins University.

BALTIMORE.

The invasion of carcinoma cervicis uteri into the surrounding tissue manifests itself clinically in the large percentage of the cases in which the disease is not recognized until after it has extended beyond operative treatment, and also in the still larger percentage of the cases in which the disease returns after operation, showing that at the time of the operation the surrounding tissues had already become involved, and on this account hysterectomy seldom cures the disease.

It is little wonder that the laity and even some physicians consider cancer of the cervix of the uterus an incurable disease, for over three-fifths of the patients admitted to this hospital with carcinoma cervicis uteri come too late for anything but palliative treatment, and probably over three-quarters of the patients operated on will die from cancer within five years of the operation. Our only hope of bettering this condition is in an earlier diagnosis, and also in doing the most radical operation possible, especially in the early cases, for in these there is the best chance for a cure.

The indications for the operative treatment of this condition must come, not only from a study of the results of operations which have been done, but especially from the microscopic study of the specimens removed by the more radical operations, in order to determine how and in what directions the growth invades the surrounding tissue and metastasizes to other parts. The justification of any course of treatment which may be suggested by pathologic studies must be tempered by the results of anatomic and physiologic studies of the parts involved, and finally by clinical experience, for the treatment suggested may be too severe or in other ways inapplicable to human beings. Clinical experience has shown that in a very high percentage of the cases the growth has already extended beyond the uterus at the time that the diagnosis is made, and a study of the specimens removed by the more radical operations shows how this extension occurs and why it is so difficult to remove the entire diseased area.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

A STUDY OF SPECIMENS INDICATING THE FREQUENCY OF INVASION OF THE SURROUNDING TISSUES.

Kundrat¹ has recently published the result of his studies of the parametrium in 80 of Wertheim's cases. An idea of the thoroughness of the work may be gained from his statement that he examined over 21,000 sections. In 44 of the cases the parametrium was found to be involved by the cancerous growth. He emphasizes the statement that the presence of cancer in the parametrium can only be diagnosed by the use of the microscope, for an infiltrated condition of the parametrium is not necessarily carcinomatous and a natural feeling parametrium does not exclude cancer, a point which has been previously emphasized by Wertheim.² Neither is there any relation between the size of the primary growth and the cancerous involvement of the parametrium, for the primary growth may be very large and yet the parametrium may be free from cancer; on the other hand, the primary growth may be very small and the parametrium may contain carcinoma. He calls attention to the frequency of metastases to the parametrial lymph nodes, as this occurred in fifteen instances.

Of great significance is the relation of the involvement of the parametrium to the involvement of the pelvic lymph nodes in these 80 cases. In 32 of the 80 cases both the parametrium and the pelvic lymph nodes were apparently free from cancer. In 22 cases the parametrium was found to be cancerous, while the pelvic nodes were uninvolved. In 18 cases both the parametrium and the pelvic lymph nodes were involved by cancer. In 4 cases the parametrium on both sides was free, but the pelvic lymph nodes of one side were cancerous, while in 3 other cases the parametrium of one side was cancerous and the lymph nodes of the opposite side, and in another instance only the parametrium on one side was cancerous, while the pelvic lymph nodes of both sides were involved.

This latter group showed that apparently in eight instances the growth was able to pass through the parametrium and reach the pelvic lymph nodes without the former becoming involved, while in 22 cases the parametrium was apparently able to prevent the further spread of the disease. In other words, in 22 out of 48 operable cases in which the disease had extended beyond the uterus (for in 32 cases it was apparently limited to the uterus), the parametrium was able apparently to check the further extension of the disease, and in addition, in 22 of the remaining 26 cases, the parametrium was involved as well as the pelvic lymph nodes, thus showing that the parametrium was involved

2. Wertheim: Zur Frage der Radical-operation beim Uteruskrebs, Archiv f. Gynäkologie, 1900, vol. lxi, No. 3, p. 662.

in 44 of the 48 operable cases in which the growth had extended beyond the uterus. In 26 of the 80 cases the pelvic lymph nodes were involved, and in 22 of these 26 cases the parametrium on one or both sides was also involved.

I have studied the specimens from 15 cases in which the more radical operation was done, and made an attempt to determine the exact relation between the primary growth and its invasion and metastases to other parts. The studies are unfinished and will be but briefly referred to here. A more elaborate description of the findings will appear later. In 12 of the 15 cases the growth was found to have extended beyond the uterus, and yet these cases were all the so-called operable ones. In 7 cases there was a direct extension of the growth from the cervix. There were metastases to the parametrial lymph nodes in four cases. Carcinoma as a metastasis was found in a parametrial lymph space at some distance from the cervix in only one case. In 12 cases in which the pelvic lymph nodes have been studied cancer has been found in six. As stated, these studies are incomplete, and further investigations of the same cases may show an even larger number in which the growth is not limited to the cervix.

A study of these cases shows that there is no relation between the size of the primary growth and the presence or absence of lymphatic involvement. Some of these cases showed very interesting features, as, for instance, the lymph nodes of the parametrium of one side would be involved and the pelvic lymph nodes would be free, while the lymph nodes of the parametrium of the opposite side were free, but the pelvic lymph nodes were involved. The cases are too few in number to be of any great statistical value, but a careful study of these cases shows how the growth invades the surrounding tissue and why hysterectomy alone so seldom cures this disease.

THE RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE URETERS.³

The relation between carcinoma cervicis uteri and the ureters manifests itself clinically:

First, in the renal insufficiency resulting from a compression of the ureters by the growth.

Secondly, in the frequency of accidental injury to the ureters occurring during operation for the removal of the growth, there having been in this hospital 19 cases of accidental injury to the ureter in 156 hysterectomies for carcinoma of the cervix, as compared with only 11 similar injuries in 4,513 other major gynecologic operations up to Jan. 1, 1904.

A study of the anatomic relation between the cervix and the ureters shows that this is altered by the position of the uterus in the pelvis and that it takes but very little involvement of the parametrium, either by direct invasion or by metastases, for the growth to reach or extend beyond the ureters. The ureters follow the curve of the pelvic wall and gradually approach each other so that at their orifices in the bladder they are but 1.5 to 3.5 cm. apart, the distance varying in individual cases and in the condition of the bladder, whether distended or contracted. One can see that in whichever side of the pelvis the cervix is that it is nearer the ureter of that side than the other, and also that the lower ends of the ureters are much nearer the cervix than portions of the ureters higher up.

It is evident that the ureters pass through tissue

which should be removed in every instance. The question arises, how can this best be done? Two ways present themselves; first, dissect the ureters free and remove all the tissue about them; second, resect the lower ends of the ureters and implant the renal ends into the bladder.

FREELING THE URETERS.⁴

When the lower ends of the ureters are freed in these operations it is usually necessary to shell them out of their sheath, which is derived from the tissue along or through which the ureter passes and serves as a channel in which the ureter may slide as it contracts and protects the ureter from the invasion of cancerous growths and inflammatory processes.

The effect of freeing the ureter from its sheath manifests itself in the opportunity for partial ureteral obstruction resulting from kinking or imbedding of the ureter in adhesions, and also in circulatory disturbances resulting from injury to the blood supply of the ureter, which vary according to the severity of these disturbances. The circulatory disturbances may be temporary and soon relieved by a compensatory hypertrophy of the vessels not injured.

On the other hand, necrosis of the ureter may occur, which may or may not lead to a rupture of the ureter, depending on the extent of the injury and whether or not the ureter becomes imbedded in the surrounding tissue before the necrosis has extended far enough to cause a rupture. The ureteral rupture is due to the extent of the necrosis and to the failure of the ureter to become imbedded in the surrounding tissue on account of gauze, exudates, infection or sloughing of surrounding tissues. Rupture of the ureter causes an extravasation of urine, which, if it becomes infected, may lead to renal or parametrial infections or other infectious processes. When the urine finds an outlet through the vagina or abdominal incision a ureteral fistula is formed, which is the usual manifestation of ureteral necrosis. Ureteral fistulae may heal spontaneously, but probably always with a stricture and frequently with renal infection, which may cause the death of the individual. Frequently they persist over long periods of time, with all the discomforts and dangers associated with this condition. In some cases they may close, with occlusion of the ureter and a loss of function of the kidney.

The most important etiologic factor in the causation of ureteral necrosis is injury to the periureteral arterial plexus from tearing or otherwise injuring the plexus, as may occur in dissecting the ureter free. Other etiologic factors must be considered, as the ligation of vessels supplying the plexus, exudates, infection, destruction of tissue about the ureter, as would result from the use of the cautery, foreign bodies against the ureter (as gauze), pressure on the ureter, stricture below the injury, and lowered general resistance.

RESECTION OF THE URETERS.

Removing all the tissue from pelvic wall to pelvic wall with the lower ends of the ureters offers the greatest chance for a cure and at the same time the ureteral sheath and periureteral arterial plexus may be preserved, for the portion of the ureter which is above the parametrium rest-against the peritoneum, so that when the peritoneum is freed the ureter with its sheath remains

4. Sampson: Complications Arising from Freeing the Ureters in the More Radical Operations for Carcinoma Cervicis Uteri, with Special Reference to Post-Operative Ureteral Necrosis, and the Efficiency of the Periureteral Arterial Plexus and the Importance of Its Preservation in the More Radical Operations for Carcinoma Cervicis Uteri, *Johns Hopkins Hospital Bulletin*, 1904, vol. xv, pp. 39-46 and 123-134.

attached to it and the peritoneal flap carrying the ureter with its sheath may be drawn down and sutured to the bladder. At the same time the bladder may be freed in order to help relieve the tension of the implantation. Against this procedure are the uncertainties of the uretero-vesical implantation and the dangers of ascending renal infection, for an implanted ureter is never so efficient as an intact one, and a most important accessory etiologic factor⁵ in the causation of ascending renal infection is stricture of the ureter. It can be seen that the operation which clinical experience and a study of the parametrium suggests as the one which will give the greatest percentage of cures is a very serious one and attended with uncertainties. In those cases in which one can determine that the growth has involved the ureteral sheath, it should be the operation of choice.

On the other hand, if the growth apparently has not extended out to the ureter the sheath may be opened from an incision made through its lateral surface and the ureters very carefully shelled out. If this is carefully done the dangers of ureteral necrosis is slight; on the other hand, if the bared ureter is roughly handled ureteral necrosis is apt to occur.

THE RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE BLADDER.⁶

The relation between carcinoma cervicis uteri and the bladder manifests itself clinically in the anterior extension of the disease, thus involving the bladder, and with the necrosis of the cancerous tissue a vesico-vaginal fistula is formed. Other clinical manifestations of this relation present themselves in the frequency of accidental injuries to the bladder in the operative treatment of this disease, there having been 17 such injuries in 156 hysterectomies for carcinoma cervicis uteri in this hospital, and also in the frequency of cystitis following these operations, suggesting that the operation must be considered an accessory etiologic factor in its origin. Cystitis has occurred in 12 out of 16 cases in which I have followed the bladder conditions after these operations.

The anterior surface of the cervix rests against the posterior surface of the bladder and the two organs are loosely attached to each other, so that they may be easily separated during operations unless there are some pathologic changes at this place. From a study of the anatomic relation between the two organs it becomes very evident that the bladder must soon become involved in a direct extension of the growth, either through the cervix or indirectly through the anterior vaginal wall. Whether or not the bladder becomes involved will depend on the origin of the growth, the direction of its invasion, and also its extent.

EFFECT OF THE MORE RADICAL OPERATIONS ON THE BLADDER.

In hysterectomy for carcinoma cervicis uteri, not only is the entire uterus removed, but also a portion of the vagina. The amount of the latter removed varies with the extent of the disease and also with the operator, some operators removing more than others. The posterior surface of the bladder is exposed and injured in freeing it from the cervix and vagina. The greater the difficulty in freeing the bladder, the greater chance for

injury to it, and also of leaving cancer attached to the bladder wall. The area of bladder thus exposed and injured varies with the amount of bladder attached to the cervix and also with the amount of vagina removed. It becomes evident that a large portion of the bladder is exposed and injured in these operations in such a manner that the function of the bladder is interfered with and that the bladder is predisposed to infection, the amount of injury varying with the area of the bladder exposed and the amount of trauma caused in freeing the bladder, which in turn would depend on whether the bladder was adherent or not. In freeing the bladder from the cervix and vagina not only are the vessels going to this portion of the bladder destroyed, but the larger vessels in the outer vesical wall are also injured, thus interfering with the nutrition of the bladder and impairing its function and predisposing it toward infection.

The blood supply of the bladder is frequently injured in other ways by the operation, i. e., in the ligation of large vessels, as the internal iliac or its anterior branch, from which arise the vesical arteries. I am unable to see any operative advantage to be gained in ligation of these vessels over the ligation of the uterine artery alone, and there is certainly this disadvantage, that the blood supply of these parts must be injured, thus making them less resistant to infection.

INJURY TO THE BLADDER AS A RESULT OF HYSTERECTOMY.

The 17 instances of accidental injury to the bladder in 156 hysterectomies for carcinoma cervicis uteri emphasize the close anatomic relation between the two organs and that the extension of the disease soon involves the bladder, so that the separation of the bladder from the growth results in injury to the bladder which may manifest itself in a vesical fistula, recognized either at the time or afterward.

The frequency of cystitis following these more radical operations is another indication of the close relation between carcinoma cervicis uteri and the bladder and indicates that as a result of the operation the bladder is left in a condition of lowered local resistance and this condition is responsible for the cystitis which may later develop. Krönig⁷ has carefully described the technic of closing the raw areas caused by these operations and emphasizes the importance of covering the posterior surface of the bladder by bringing down the utero-vesical peritoneal flap and suturing it to the anterior vaginal wall as a means of protecting the injured bladder and thus lessening the chance for cystitis.

Taussig⁸ has reviewed Wertheim's cases and demonstrated the importance of retention of urine as an etiologic factor in the causation of cystitis, and that in these more radical operations this is especially likely to occur. He calls attention to the fact that ganglia and nerves are found in the parametria of these cases and that their removal may interfere with the function of the bladder and so give rise to the retention of urine. Kolischer,⁹ in addition to the other views already mentioned, as injury to the bladder, blood supply, etc., adds another, i. e., in freeing the ureters certain trophoneurotic disturbances occur which predispose the bladder to cystitis.

Baisch¹⁰ has recently discussed this subject and con-

siders that there are two very important etiologic factors, namely, the injury to the nerve and blood supply of the bladder as a result of the operation, thus predisposing the organ to infection. He advocated frequent catheterization followed by bladder irrigation as prophylactic measures and quotes cases supporting these.

In order to make a positive diagnosis of cystitis two things must be done: first, a cystoscopic examination must be made and the inflamed bladder seen; secondly, cultures must be taken and the organism causing the infection obtained. These two steps are essential, for an inflamed appearing bladder may not be infected, and positive cultures obtained from the urine may come from an infected kidney and the bladder may be normal, or the organism may be excreted by the kidneys and appear in the urine without causing any harm to either kidney or bladder.

I have followed the bladder condition in 16 cases where hysterectomy for carcinoma cervicis uteri has been done. In 14 of these cases both cystoscopic examinations and urine cultures were taken, and in the other 2 cases the patients died, one on the ninth day and the other on the seventeenth day, and at autopsy the cause of death was found to be ascending renal infection. The ureters had been sacrificed in one, but not in the other, of these two cases.

In 10 of the 14 patients who lived, cystitis was found to be present, as determined by cystoscopic examination and taking cultures, and in three of the four cases in which the bladder apparently escaped infection an accidental vesicovaginal fistula was present, which apparently prevented a cystitis, for cultures taken in two of these three cases showed colon bacilli in large numbers. In 12 of the 16 cases cystitis occurred, resulting in ascending renal infection and death in two patients. In all the cases but one the raw areas were covered with peritoneum, and in that one case it was necessary to have on clamps and pack with gauze in order to control hemorrhage. In these cases the uterovesical peritoneal fold was sutured to the anterior vaginal wall and the entire denuded vesical wall was protected by peritoneum. In addition, the posterior vaginal wall was sutured to the recto-uterine peritoneal fold, thus covering in the raw tissue anterior to the rectum. The pelvis was drained by two small gauze drains extending under the peritoneum on each side and out through the vaginal opening. Yet these cases did not escape cystitis.

Realizing that retention of urine was an important etiologic factor in the causation of cystitis, I used a retention mushroom catheter in four cases. In all four cases cystitis developed, resulting in ascending renal infection and death in two, and in one of these there was a patchy membranous cystitis, the patches corresponding to the parts of the bladder which came in contact with the catheter when the bladder was collapsed. I think that the catheter was responsible for the severity of the cystitis, for it soon became covered with urinary salts, acting as a foreign body (stone) in the bladder. Another criticism against the retention catheter is that it is apt to become occluded or pushed too far in the bladder, and one can never tell whether or not it is doing what it is supposed to do—that is, keeping the bladder empty by draining the urine away as fast as it comes to the bladder.

I tried frequent catheterization, i. e., every three or four hours, in the next nine cases, following it by bladder irrigations in five cases; but cystitis developed in eight of the nine cases. Why does cystitis occur in these

cases? I have been unable to prevent it by covering the injured bladder with peritoneum, and also by preventing retention of urine by means of the retention catheter or frequent catheterizations.

The main accessory etiologic factors in the causation of the cystitis are as follows:

1. The large area of bladder exposed and injured in removing the cervix with parametrium and also a portion of the vagina.

2. Interference with the blood supply of the bladder, caused by ligating vessels giving rise to vesical arteries; freeing the bladder, thus cutting off vessels going to it, and the injury of the vessels in the bladder wall.

3. Interference with the function of the bladder, it having been injured in freeing it, its blood supply having been interfered with, some of its natural supports removed, and nerves and ganglia destroyed. This interference with its function may manifest itself in the inability to void urine. On the other hand, in one patient incontinence was present, there being no ureteral nor vesical fistula. In other cases the patient may micturate and there may still be a large amount of residual urine left in the bladder. In one of the above cases this was as great as 300 c.c.

Organisms may gain access to the bladder in various ways:

1. They may be present in the bladder at the time of the operation. They were present in one of the above cases, although there was no evidence of cystitis at the time.

2. They may pass through the injured bladder wall, through the fundus or trigonum, or along the bared ureters if dissected free or resected and implanted in the bladder.

3. In catheterizing the bladder organisms may be carried in.

4. They may be carried down from the kidneys or conveyed to the bladder by the circulating blood.

It becomes evident that the relation between carcinoma cervicis uteri and the bladder is a very important one on account of the invasion of the bladder by cancer, and also the likelihood of post-operative cystitis, with its accompanying danger of ascending renal infection.

THE SIGNIFICANCE OF VESICOVAGINAL FISTULE.

A study of specimens from the more radical operations emphasizes the importance of a wide excision of the primary growth, and the fact that the bladder anteriorly and the ureters laterally may soon be involved in the extension of the disease. A study of the bladder obtained at autopsy from those patients who have died after these more radical operations, as well as the clinical histories of those who survive, shows how frequently cystitis follows these operations and that danger of ascending renal infection is a very important consideration.

A very instructive feature associated with these cases is that an accidental vesicovaginal fistula was present in three or four cases in which cystitis apparently did not develop. The presence of a vesicovaginal fistula meant that intravesical tension was absent and that the injured bladder was put at rest and cystitis did not develop, or was less severe. We realize that the formation of a vesicovaginal fistula is the best means we have of treating severe cystitis. The best surgical treatment for infection in any part of the body is free incision and drainage, together with rest of the diseased part, and that is what a vesicovaginal fistula does for an infected bladder. Its significance here is most important. On

account of the proximity of the bladder to the uterus the growth does not have to extend far anteriorly to involve the bladder. The avoidance of injury to the bladder means in many instances a return of the growth and cystitis, with the danger of ascending renal infection. The wide excision of the growth, with any portion of the bladder adherent, means a higher percentage of cures and the probable avoidance or lessening of the severity of the cystitis.

In cases in which the bladder is not involved by the growth it is not necessary to sacrifice a portion of the bladder. In these cases all raw areas should be covered with peritoneum. The uterovesical peritoneal fold should be sutured to the anterior vaginal wall, and the recto-uterine to the posterior vaginal wall. Afterward the patient should be catheterized every three or four hours, followed by bladder irrigation, and at the first suggestion of cystitis, as seen by pus in the urine, the bladder should be examined, and if the cystitis is severe and does not yield to treatment, a vesicovaginal fistula should be formed.

A satisfactory cystoscopic examination may be made with the patient in the Sims position,¹¹ and if one decides to make a vesicovaginal fistula it can be done as follows: The handle of the cystoscope is pushed toward the symphysis so that the end of the cystoscope bulges the anterior vaginal wall at a point just posterior to the internal urethral orifice. This bulging place is opened with a knife and the incision enlarged posteriorly with scissors. The fistula may be made and afterward closed without even a local anesthetic, for the previous operation will have destroyed the sense of pain over this portion of the vagina and bladder.

THE RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE RECTUM.

The relation between carcinoma cervicis uteri and the rectum¹² manifests itself clinically in the posterior extension of the disease, involving the anterior wall of the rectum, and with the necrosis of the cancerous tissue a rectovaginal fistula is formed. Another manifestation of this relation is injury to the rectum in hysterectomy for the disease.

As the uterus under normal conditions is a relatively freely movable organ, it adapts itself to the space in the pelvis in which there is the most room, and its position in the pelvis is to a certain extent determined by the position and size of the rectum. So the relation between the two organs is dependent on the position of the uterus in the pelvis, whether in the right or left lateral positions, and also whether forward or in retroposition, and whether high in the pelvis or in descensus. The posterior surface of the uterus is covered by peritoneum, and the reflexion of this peritoneum over on to the uterus forms the bottom of the so-called cul-de-sac of Douglas. The bottom of this cul-de-sac is situated at a lower level than the lower portion of the cervix when the uterus is in its normal position, and, as is well known, the peritoneal cavity can easily be opened by an incision through the vaginal vault posterior to the cervix. While there is a relatively broad attachment between the bladder and cervix anteriorly, the cervix is separated from the rectum by the cul-de-sac, with its uterine and rectal peritoneal lining, and in descensus the pos-

terior vaginal wall is interposed between the two organs. In addition, there is adipose tissue between the anterior rectal wall and the vaginal and rectal peritoneal covering of the cul-de-sac. The amount of this adipose tissue varies in different cases.

A result of these anatomic studies shows that a direct invasion of the rectum by carcinoma cervicis uteri must extend either through the cul-de-sac, which may have become obliterated by adhesions, or indirectly through the vaginal wall, which may have become involved by the growth, or else through the parametrium of one side, which may be situated directly in front of the rectum.

THE RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE VAGINA.

The relation between carcinoma cervicis uteri and the vagina manifests itself in the involvement of the vagina by an extension of the growth and the so-called implantations on the vagina, which may be retrograde lymphatic metastases. The involvement of the bladder and rectum from the vagina has already been referred to. The first indication in the operative treatment of this condition is a wide excision of the primary growth. If the vagina is involved there should be a wide lateral excision of the vagina, and enough of the vagina removed to get below the growth. Against the unnecessary excisions of the entire or greater portion of the uninvolved vagina, it may be said that it prolongs the operation and weakens the bladder and rectum, and also leaves a raw area which is difficult to close.

The involvement of surrounding parts other than I have mentioned indicates a wide excision of these parts.

THE RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE PELVIC LYMPHATICS.

By the pelvic lymph nodes I refer to those along the sides of the pelvis exclusive of the parametrial lymphatics. As stated in this article, these were found to be involved in 6 of 12 cases operated on in which they had been studied. Kundrat found them involved in 26 of 80 cases studied. Apparently the pelvic lymph nodes are involved in from 30 to 50 per cent. of the cases operated on, and there is no relation between the size of the primary growth and the presence or absence of lymphatic involvement, for the primary growth may be small and the lymphatic involvement extensive, or the primary growth large and the pelvic lymphatics free from cancer. A large lymph node is not necessarily a cancerous one, and a small one may contain cancer. It becomes evident that there is just as much of an indication for the removal of the pelvic lymphatics in cancer of the cervix as there is for the removal of the axillary lymph nodes in cancer of the breast. And, as in the operative treatment of cancer of the breast, one should remove the lymphatics *en masse* with the growth and uterus. On the other hand, the first indication should be a wide excision of the primary growth and the removal of the pelvic lymph nodes should be of secondary importance, as will be discussed later.

(To be continued.)

Occupations for Inmates of Tuberculosis Sanatoria.—Elkan discusses this subject in the last issue of the *Zft. f. Tuberkulose*, V, 5. He admits that it is not an easy matter to find congenial occupations for tuberculous patients. Gardening seems to be the best adapted for them. Work should be optional, and he advises having a trained gardener to inspire them by his example and advice. No pecuniary inducement should be offered, but the physician and the personnel of the establishment should manifest an interest in the gardening.

TREATMENT OF COLD ABSCESSSES AND SINUSES IN TUBERCULOUS BONE LESIONS.*

V. P. GIBNEY, M.D.
NEW YORK CITY.

Paradoxical as it may appear, cold abscess and sinuses with all kinds of mixed infection furnish a fascination for me that years of experience in their treatment can not satisfy. Year after year, as requests from chairmen and secretaries come to present a paper for discussion, the topic chosen to-day comes first into mind, and because of its inexhaustibility it pleads for further discussion. To the practitioner remote from large cities, abscesses and sinuses appear insignificant, perhaps, because out-of-door life and good hygiene contribute so much to the storing up of vital resistance, and almost any surgical measure leads to satisfying results. In largely populated centers, however, where the tenement house plays so important a part, vital resistance is lowered and results are far from satisfactory.

My connection for nearly a third of a century with a hospital whose in- and out-patient service is second to none prompts me to insist on the importance of a further study of means for curing and preventing sinuses, because as yet no specific has been found.

By "cold abscesses" is meant the ordinary abscesses that appear in the course of a tuberculous osteitis involving the epiphysis of a long bone or the body of a vertebra, cancellous structure as distinguished from the compact tissue of bone. Acute or "hot abscesses" have no place in this paper, and a definition of sinus would waste time and be presumptuous.

A word as to the frequency of abscesses and sinuses may not be amiss as enhancing the importance of the subject. Without reference to statistics and percentages, it is well known that these complications of bone disease are sufficiently frequent to cause apprehension during the life of the patient. Long after a cure has been pronounced in a case where an abscess has not developed during the course of treatment, an abscess does develop, and it seems so simple that the physician can not resist the temptation to employ the scalpel, and sooner or later the infected sinus appears and refuses to heal.

Last winter a young man from one of the southern states came to New York because of a sinus. His history was as follows:

In early life, say at about 5 years of age, he developed tuberculous osteitis of the hip, common hip disease, was treated expectantly, and in a few years got well with ankylosed hip and a moderate amount of deformity, which gradually increased until it came under my care for correction. This was done by a subtrochanteric osteotomy, and he returned home with a strong hip, a reduced shortening, and went through college without further interruption. Eight or nine years after the osteotomy, and without apparent cause, a "bunch" appeared on the outer side of the thigh, just below the trochanter major. His local physician recognized fluctuation and incised, believing that a cure would soon follow. A sinus followed, the care of it was left to the patient, and mixed infection was the result. Tiring of its persistence and of rather frequent attacks of sepsis, he came, as above stated, to New York and again under my care. The sinus was enlarged, the lining cut away and the shaft of the bone near the trochanter "scraped." In fact, an attempt was made to remove the focus of the disease without resorting to a radical operation such as excision of the hip. He remained in the hospital six or

eight weeks, until he had become quite expert in keeping the sinus aseptic. He went home under the impression that in time the sinus would heal, and a letter to his physician urging asepsis and good drainage as better than a radical operation was deemed all sufficient. After a month or two a letter came telling of impaired health, profuse discharge and asepsis. He was ordered to the mountains and reports were more satisfactory.

This is not an isolated case, as my readers can testify, and we wish that the introduction of the scalpel had been postponed.

Many years ago a small boy with dorsolumbar Pott's disease came under treatment. A solid plaster-of-paris jacket was applied and immobilization without interruption was maintained for nearly two years. No exacerbation occurred during this period and a convalescing jacket was worn for another year. Resolution seemed complete, the deformity was trifling and he was discharged cured. Ten years later, during the past winter, he appeared again because of pain in his back and left hip. The deformity had not increased, but there seemed to be an exacerbation caused by a vigorous game of "leap-frog," he being the "frog." Local and simple treatment failed to give relief and a plaster-of-paris corset was employed. It was not long before deep fluctuation could be discovered in the left gluteal region and around the coccyx. Aspiration gave negative results. Pain and tenderness continued and it was fully four weeks before an exploring needle was deemed justifiable. One or two subsequent aspirations failed to evacuate the abscess because of thick pus and flakes, and as a burrowing sac about the rectum was feared, it was decided to incise aseptically, thoroughly evacuate and close. This was done under ether and an enormous sac extending pretty nearly over the entire posterior surface of the pelvis was thoroughly cleansed without the aid of chemicals. As the opening was ready for closing, a mural abscess was discovered near by, and this was treated as the large one. Both openings were closed with silk, a gauze drain inserted and removed in forty-eight hours. There was no reaction at the end of a week, the wounds were healed to all appearances, and the large sac had partially refilled. The next step was to aspirate remote from the wound, but as the sac filled so slowly this was postponed until a small amount leaked through the edges of the wound. Drainage was now inserted, and from day to day sepsis was kept at the minimum by aseptic cleansing and dressings. Nearly four months have elapsed and the patient is at the seashore slowly convalescing from a mild grade of sepsis, and the sinus is still open.

While this case is presented not to illustrate a mode of treatment, but to show how an abscess appears late in the day and how obstinate its management proves, it does show a failure in the treatment recommended in this paper. The skillful surgeon may say that if a free incision were made and all the parts exposed to view the result would have been different. Let the following illustrate: A few days ago, while visiting a desperate case on Long Island, a request was made that a young man near the station with spinal disease be examined.

He was 26 years of age, and had a focus of disease in the bodies of the ninth and tenth dorsal vertebrae, with very little deformity. He had been a brakeman on the railroad. A year and a half ago his disease was recognized by the local physician, but not treated. The course was slow, and the usual remissions and exacerbations made up a typical history. Last December a "bunch" appeared over the sacrum, left side, and this soon developed into a large-sized abscess. He was taken into the city, operated on in one of the large metropolitan hospitals by a surgeon whose fame is world-wide. The long cicatrix, nearly twelve inches, with a sinus about its lower end, showed that the operation was *secundum artem*. This was in February. The local physician is packing a long sinus every other day, and the condition of the patient and stiffening of the unprotected spine show that the case is not yet complete.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest, Willard, Charles A. Powers and J. E. Moore.

The general surgical dictum that, when pus is found, evacuate at once, has been so vigorously attacked within the past quarter of a century that it is not necessary to state that all surgeons adhere vigorously to this rule. Many there be whose experiences prompt them to dissent and exercise that surgical judgment which marks the man of conservatism. Still, it may be stated that the consensus of surgical teaching as set forth in the modern text-books on surgery is in favor of early incision and the establishment of drainage where a radical operation is impracticable. The ease with which aseptic dressings can be employed in hospital wards and in civil practice where trained nursing can be obtained leads surgeons to adopt the early incision, believing, too, as they do, that pus, although sterile for aught save the bacillus of tuberculosis, should be out of the body.

Some twenty years ago and more it was my privilege to refer cases of cold abscess in adult Pott's disease of the spine to my friends who held positions in the general hospitals in New York for treatment. The Hospital for the Ruptured and Crippled had no beds for adults, and the custom was to recommend out-patients, too old for admission to the hospital, and needing closer observation, to the other hospitals in the city. At first these surgical friends were profuse in thanks for cases so interesting. Later on they absolutely declined to accept them, and gave as reason that nearly all had either become permanent residents in the hospital, had died there, or had gone home to die. It is not my purpose to cite cases and names in proof of the statement just made, but if challenged these can be furnished later.

The details of so-called surgical treatment need not be rehearsed on this occasion. They are known to all. Among orthopedic surgeons methods differ, yet it may be stated as a general rule that abscesses are not interfered with unless they interfere with the protective treatment of the bone or joint whence they come. Belief is strong among orthopedic surgeons that rest and protection are essential to a cure, and that abscesses are complications that can be met at any time in case Nature does not come to the rescue. Bear in mind that many cold abscesses disappear not to return in a certain number of well-treated bones and joints. Those who cling to the mechanical treatment of tuberculous joints are presenting ever and anon cases where large psoas abscesses and large femoral abscesses have disappeared under the non-interference plan, and I am familiar with these cases, although not belonging to that class. Some of us, few in number though, lean to the early opening and drainage, insisting all the while on protection and fixation of the joint. These different methods may be stated as marking the course of orthopedic surgery during the past quarter of a century.

1. The "*Noli me tangere*." This means leaving the abscess to open spontaneously and soon develop into a sinus which may or may not persist indefinitely. This method was the one adopted at the Hospital for Ruptured and Crippled prior to 1888, and a thirteen years' residence enables me to speak of results. It is only fair to the advocates of this method believing also in joint protection, to state that during this period very inefficient, and, in many instances, no joint protection was afforded or even intended. A few abscesses would appear and soon, say within a few weeks, open, to close within as many weeks. A large number, say 50 per cent., would open, a sinus would follow, other sinuses would follow, preceded by "new abscesses," and soon the parts would be honeycombed with open sinuses. These

would "run" for an indefinite period, and one after another close, to scab over occasionally and "weep" a bit for a long time, years after leaving the hospital. A certain percentage of these, say 10 or 15 per cent., would continue until amyloid degeneration of the liver and kidneys would develop and death ensue after a long period of suffering. A smaller percentage would not develop amyloid changes, but the abscesses would multiply and the poor sufferer would die of exhaustion after prolonged suppuration. For sixteen years the spontaneous openings have not been permitted, and the results are better. Still, the percentage of poor results is too large, and how to reduce this to a minimum is a problem yet unsolved and full of interest.

2. A number of orthopedic surgeons, the majority, I believe, advocate aspiration early and often. A number of years ago a member of the staff, Dr. Matthew De Pass, collected statistics on this method of treatment and proved that 50 per cent. were permanently disposed of and the case went on to cure without any external suppuration. Since the collection of these statistics the general results obtained by this method have not been so good, yet this should be said by way of explanation, that other methods have come into vogue and the aspirations have not been so carefully performed. Incoming members of the house staff to whose care these details are entrusted differ in zeal, and discipline is not always carried to the point of lessening interest.

3. A method adopted by a limited number of orthopedic surgeons is that so ably advocated by a general surgeon of great fame, Dr. Nicholas Senn, viz., evacuation by trochar and introduction of iodoform, either in oil or in glycerin. This plan is still adhered to by many surgeons, and the wonder has been expressed why the majority of men in my own specialty have not found it of great value. The truth is, however, that with the majority of our guild it has not come up to expectations, and its use at the Hospital for Ruptured and Crippled has long since been abandoned.

4. The great goal to which all are looking forward, and which sometimes seems within reach, is the localization of the one or more foci feeding the abscess and the complete extirpation of the foci and abscess sac under rigid asepsis with immediate closure. The inability to reach this goal compels us to temporize, to treat expectantly, to attain the best possible results under existing circumstances. The plan advocated in this communication is based on the early recognition of the abscess and the well-known sterility of tuberculous abscesses.

A word about the early diagnosis may not be out of place. Those of us who have become by long experience familiar with the clinical history of tuberculous lesions involving the joints have come to know pretty accurately the symptoms attending the early formation of an abscess sac. When in the course of treatment of a given case we find the protection apparatus fails to protect, when an exacerbation comes on in spite of our most carefully applied apparatus, we begin to suspect, and pretty soon our suspicions are verified. The symptoms are increased tenderness, night cries, pain more or less persistent, unwillingness to move about, and sometimes an elevation of temperature. When to these is added a blood examination showing a leucocytosis, the diagnosis becomes comparatively easy. The explanation pathologically is this: The local bone lesion has increased in area, necrosis means exudates, and these are crowded against the periosteum, which must yield by a process of slow dissection. When this invasion is near muscular

attachments the pain is greater and muscular spasm becomes a feature that must be recognized. Reflex nervous symptoms must be present in many instances. This period varies from a week to two or three months. If a radiograph be taken at this time, while no pus or pus sac will show, a destruction of bone is so evident that one is perfectly justifiable in thrusting a tenotome or a scalpel into the joint to relieve the tension. Often within my experience the diagnosis has been established in this way, and the patient greatly relieved. This leads up to an important step in the management of the abscess.

Given a diagnosis, although no fluctuation can be made, fixation of the limb and joint in an immovable dressing, such, for instance, as plaster of paris, will sometimes arrest the active process and an abscess will be aborted. At other times, traction in the line of deformity, with an ice bag over the parts, will prove efficient. Let one avoid, however, attempts at correcting deformity in this stage. These are the instances men sometimes report as abscess induced by the trauma of forcible correction. When fixation and local applications fail to relieve the symptoms and the presence of a deep-seated abscess becomes more apparent, then is the time to resort to a very simple surgical procedure, viz., a small incision through the soft parts and down into the capsule; then squeeze out any pus or serum that may be present, and make a culture for examination. This incision, of course, is to be made with due regard to asepsis.

A case under treatment a year or two ago furnished an excellent illustration of the value of this procedure. It was one of hip disease, and for months night cries were most annoying. Complete immobilization and many pounds of traction failed to make any impression. After the incision relief was soon afforded, and the case went on to resolution. The pus was found to be small in quantity and absolutely sterile.

The plan recommended is to make a sterile aspiration and make a culture, supplemented by a microscopic examination. Continue the same protection as before and await the result of the examination. If, as usually is the case, the pus is sterile, let the treatment be further aspirations until the sac ceases to refill. If the contents are too thick for the needle of the aspirator, make a small incision and force out the contents, even if a curette be found necessary. Sew up the wound at once and apply a sterile dressing. Over all this apply a plaster-of-paris bandage, unless the splint can be adjusted so as to secure immobilization.

I wish to thank Dr. Fosdick Jones of the house staff at the Hospital for Ruptured and Crippled for cultures and microscopic examinations in twenty or more cases used to bear out the statements made in this paper. These cards he has filled out are of great assistance in the way of prognosis as well as future interference surgically.

L. G., female, age 5½ years, diagnosis osteitis of hip with deformity. Situated on the anterior and outer aspect of the right thigh is a large abscess, fluctuation marked, no local heat, no tenderness. Cultures taken May 19, 1904, media blood serum. On May 20, 1904, the culture was examined microscopically, no growth, sterile culture.

S. J., male, age 6 years. R. H. D. and C. S. D. Acute symptoms of hip disease, pain most marked over the great trochanter, no signs of abscess, no redness, no fluctuation, no local heat. On May 10, 1904, two ounces of pus were evacuated

from the right hip joint, scrapings from the head of the femur taken, and culture made with blood serum as media. On May 11 the culture was examined microscopically with negative results. Culture sterile. The scrapings microscopically show probable tuberculosis.

P. S., male, age 10 years, osteitis of right humerus with abscess; has also a lichen scrofulosum. Situated at the angles of the jaw, both sides, are two abscesses, size of a walnut. Fluctuation is marked, skin over abscess reddened, local heat. There is the appearance of mixed infection. On May 18, 1904, the abscess was incised and one ounce of pus was evacuated from each side. Cultures were taken and smears were made on sterile glass slides. On May 19 cultures were examined microscopically, staphylococci smears, pus cells, staphylococci, no tubercle bacilli.

These examinations are made after every aspiration or incision. And in some instances a disappearance of staphylococci takes places in those cases where there has been a mixed infection. These generally are the cases where free drainage has been established and where the parts have been thoroughly immobilized by means of bracketed splints secured above and below the joint by plaster-of-paris bandages.

Our examinations have been sufficiently numerous to prove the sterility of the pus from these cold abscesses, and it seems unfair to the patient to subject him to a mixed infection by the usual free incision and establishment of drainage. What harm can come so long as these collections of pus are sterile? If they must for any reason be evacuated, let the operation be done through a small opening and let the opening be closed at once. Suppose the sac does refill. Is it not better to open, evacuate and close many times than to take the risks of a sinus which must sooner or later become infected?

The plea to-day is for these simple procedures until one is ready to do a radical operation, which means the removal of diseased bone tissue as well as all the soft parts diseased. It will be admitted that failures sometimes come to the most careful, and yet these failures prove only a leakage in our technic. Did time permit, case after case could be presented in detail where failure has not been met with. A further plea is made for the protection of the joints involved before and after the abscess has been treated, regarding the latter as secondary, as only one phase of the disease.

The management of sinuses is far more difficult than that of the abscess which precedes. I regret that I have nothing new to offer as a specific. With the many antiseptics and chemicals of all kinds and caustics, I have had much to do. Operative procedures which obliterate the lining of the sinuses, free incisions and liberal dissections, all come in for a share in the general dissatisfaction. Cleanliness, frequent dressings with aseptic material, and, above all, protection to the parts, constitute the local treatment that yields the best results. Above all these, however, come nutrients, good hygiene, out-of-door life, and change of climate.

A few years ago great prominence was given in the hospital to an emulsion of mixed fats. All the details of this treatment were carried out by Dr. Arthur Cilley of New York, at that time house surgeon. We were able to report progress. Since that time this gentleman has continued this treatment in the out-patient service, and to him I am under many obligations for data bearing on this line or phase of the subject. He selects cases where improvement under ordinary local treatment has ceased. The skin is cleansed with a mildly antiseptic solution and sterile gauze is used for dressings. The feeding process is regulated according to the age and

1. Meningeal hip disease, right side and caries of the spine, dorsal.

weight of the patient. The object in general terms is to overfeed with fat in order to save nitrogenous waste, and this overfeeding can be carried far beyond the ordinary limit by the free use of cathartics.

He classifies as follows: 1. Children from 2 to 6 years of age, the plan is to give one teaspoonful of an emulsion of mixed fats in two or three ounces of hot water after breakfast and after supper. At the end of a week, two teaspoonfuls of the mixed fats in the same amount of water. In case of a rebellious stomach, it is presumed that the bulk of fluid and not the quality is the cause, and the hot water is diminished. Castor oil in doses of 2 drams is given one, two or three times a week, according to the general condition of the patient. Eggs are not usually indicated.

2. From 6 to 10 years of age, eggs are now added to the dietary; one in four ounces of milk to which a little salt is added twice or three times a day immediately after meals, while the mixed fats are given about an hour later. After three or four days, one egg is given after each meal in the same quantity of milk. It is rare to give more than six raw eggs a day. When these become distasteful, milk is pushed to two quarts per day. The details are the same as those for pulmonary tuberculosis, and one must expect all kinds of obstacles in forced feeding. Yet persistence will usually overcome these obstacles.

Of the out-patients, the following is of interest:

A. W., a boy about 5 years of age, had lumbar Potts' disease for about eighteen months when he came under observation in November, 1901. A gluteal abscess on the left side was aspirated several times, but unsuccessfully because of the thickness of the pus. Finally it opened spontaneously in January, 1902. The opening was enlarged and the dressings were done three times a week. In November, 1903, the feeding was begun and his weight was 39 pounds. During December of that year he took six raw eggs a day and two ounces of the mixed fats. Early in January he was obliged to omit the eggs for a week, but in February he was taking nine a day and his weight was 41 pounds. During the first half of March he was taking nine eggs a day. Then they were omitted for a week again, his weight dropping to 40 pounds. In April a lumbar abscess appeared, and in May it opened spontaneously. It was dressed daily for a week. During the summer of 1903 he was taking the full number of eggs, the dressings were three in a week, and by November his weight was 43 pounds. At this time he developed an attack of acute articular rheumatism involving all the joints, and yielded promptly to the withdrawal of the eggs, the employment of the salicylates and a milk diet. The physician believes firmly that the eggs caused the rheumatism. On December 27 his weight was 44½ pounds. Two small abscesses on either side of the sacrum were aspirated and finally discharged through the punctures. Since his recovery from rheumatism no eggs have been given, but he has taken two quarts of milk a day. In January of the present year his weight was 56 pounds and the lumbar abscess ceased to discharge. The gluteal abscess at the present writing "weeps" occasionally, and the dressings are made once a week. The weight on May 29 was 60 pounds.

A boy, the notes of whose case are not very full, had hip disease and four sinuses when treatment was begun. He took the fat emulsion in ounce doses twice a day and the eggs were given until he was taking eight a day. All sinuses closed in six months and have not reopened at the end of two years. He has had no treatment during that period and an examination made with Dr. Townsend on January 1 confirmed the reports.

Dr. Cilley has summed up in this manner: Three factors are of prime importance: 1, Fresh air; 2, fats; 3, cathartics. The emulsion of mixed fats, he believes, are the best fats at our command. Eggs should not be

increased beyond six a day in children from 6 to 10 years of age, and should not be continued at one time longer than two months. In children under 6 years of age, milk is better than eggs. Castor oil is preferable as a cathartic.

This report from a very efficient member of the out-patient staff of the Hospital for Ruptured and Crippled is given practically as it was presented, and while some may question the value of the method on the ground that results as good may attend any other plan of treatment carried out with the same care and persistence, this much must be said, that many plans have been tried by Dr. Cilley, and his experience is exceptionally large.

As stated in another part of the paper, there are no specifics for sinuses, and this statement is made with a full appreciation of the claims made for carbohc acid in solutions of all strengths, for enzymol, for frequent curettages, and for liberal sections connecting one with the other.

CONCLUSIONS.

Summing up, therefore, the claims made in this communication: 1. Early recognition of cold abscesses will enable one to dissipate or to nip them in the bud. 2. When they are present at the time the cases come under observation, treat them with indifference so long as they do not interfere with the proper adjustment of good protection apparatus. 3. If they are in the way, or if they show a disposition to burrow and encroach on parts that it is desirable to keep free from such invasion, resort to aspiration and make cultures in order to determine their virulence. 4. If aspiration fails, rely on incisions under rigid asepsis, large enough only to permit evacuation of the contents, and refrain from the introduction of chemicals. Close the wound by suture under the same rigid asepsis. 5. When the abscess lies directly over a bone focus that can be easily reached, make the incision large enough to remove the focus, and at the same time permit removal by curette or scissors of the lining of the sac and all necrotic tissue contiguous thereto. Then close aseptically, employing drainage for not over forty-eight hours. 6. If longer drainage is demanded, devise means by which asepsis in dressings may be continued indefinitely, and look on a mixed infection as a calamity. 7. Sinuses should be well drained, the foci on which they depend should be treated if involving joints by perfect and long-continued immobilization, with due regard to fresh air and a high state of nutrition.

HOW THE GENERAL PRACTITIONER SHOULD TREAT GONORRHEA.

FERD. C. VALENTINE, M.D.

AND

TERRY M. TOWNSEND, M.D.

NEW YORK CITY.

To the captions, the title of this paper may appear an arraignment of the brain and brawn of the medical profession. In a measure, it will so apply in some instances. It seems time to inveigh against the otherwise excellent practitioners who do not treat gonorrhœa. In refusing to give these cases the care needed, they not only neglect one of the physician's most precious privileges—the prevention of disease, but are derelict in the performance of a duty. Some practitioners base their

* Read at the fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

unwillingness to treat this disease on the ground of its danger to other patients. But even those much engaged in obstetric work, as a part of general practice, can very well protect their parturient patients against infection. The fact that no modern worker will attend a labor case without observing all minutiae of antiseptic and aseptic precautions, is in itself adequate protection for his non-infected patients.

The general practitioner, by declining to treat the gonorrhoeic, does him an injury so far-reaching as to affect the entire public. The average patient with a first infection knows nothing of gonorrhoea; the fact that the physician in whom he has confidence will not treat him, makes him apprehend that he has an ailment which is beneath the medical adviser's dignity to consider.

This inference readily leads to the conviction that gonorrhoea is a "shameful" disease. For a discussion of the correctness of this view, this is neither the time nor the place. So much, however, may be accepted—that the patient having gonorrhoea is entitled to treatment, as much at least as is the individual who has acquired a disease in consequence of drunkenness or of any other infraction of morals and ethics.

Some general practitioners defend their position of non-combattiveness as regards gonorrhoea, by the assertion that they prefer to place patients afflicted with gonorrhoea at once in the hands of a specialist. No attitude could be a more mistaken one. The layman can see no valid reason for being referred to a genitourinary specialist and being, incidentally, put to greater expense for what he may deem a trifling ailment. He leaves the office of a man whom he knows to be competent; for whom he has respect, and whom he has perhaps defended against aspersions of one or another ignorant individual who charged that "he does not know enough to cure even a clap." Recalling some of the instances in which his family physician undoubtedly saved life, he is disheartened at being sent to a stranger. The stranger, so his physician told him, is an able genitourinary specialist. But what does the patient know of specialists? He has seen advertisements of persons who call themselves most eminent specialists, quite properly classed together in the newspapers under "medical" with shameless abortionists and other criminals.

The patient may go to the man to whom he has been referred, but he does so with misgivings. Lacking confidence based on knowledge of the man, he is at best but a half-hearted coadjutor in the management of his case; it consequently may not respond to treatment as readily as otherwise. The specialist to whom the case has been sent may, because of the patient's mental attitude, fail to acquire over him that control which is essential in the relation of physician and patient. Without it, positive orders are violated, and the disease may drag on and perhaps become complicated. Not infrequently an opponent to scientific medicine is thus created.

It requires no great flight of imagination to appreciate the injury done the patient, when the family physician refuses to treat him for a simple, uncomplicated anterior gonorrhoea. Considering the vast number of physical and mental cripples produced by this disease, considering likewise its direct menaces to the family and the state, gonorrhoea merits concerted opposition by all medical men.

Its relegation to genitourinary specialists as a routine proceeding, however well intended, is an error. There are, of necessity, not even a sufficient number of specialists to treat all cases of chronic gonorrhoea.

The general practitioner can, if he will, thoroughly master the scientific management of acute cases. He can, moreover, better than anyone else, disseminate the knowledge that all gonorrhoeas require active attention from the very beginning. Failing to do this, he opens himself to moral responsibilities that certainly are grave.

Beside those sketched before, one reason of transcendental importance must be emphasized. It is that by refusing to treat his own patients when infected with gonorrhoea, the family physician neglects the only opportunity to abort the attack.

The preceding is intended to be merely suggestive. There will at once occur to the thoughtful general practitioner all the other reasons that make it obligatory on him to treat at least uncomplicated acute gonorrhoea, as he does all other diseases.

The only question that presents itself in this connection is whether he can afford the time necessary for personal attention to each patient. In the light of experience it is safe to say that fifteen minutes at the most are required to perform all that is necessary at each treatment. To demonstrate this, each step will be as minutely considered as is possible in a brief paper.

PREPARATION OF THE PHYSICIAN.

In view of the contagiousness of gonorrhoea, the physician should prepare himself as for any capital operation, to protect all subsequent patients and himself against infection. To this end his arms should be bared to above the elbows, and he should wear a gown or impervious apron, or preferably both. It will be well, also, to safeguard his eyes, even in emmetropic, with good-sized spectacles during the treatment of a gonorrhoeic.

PRELIMINARIES TO TREATMENT.

The record of occurrences since the previous visit should be fully written, before each treatment. The cardinal points to be noted are:

1. Was the patient obliged to arise from sleep to urinate during the night?
2. Quantity, consistency and color of the stain on the cotton he wore on the glans over night.
3. Amount, consistency and color of discharge from the meatus on arising.
4. Interval since the last urination.
5. Appearance of the cotton he wears and amount, color and consistency of the discharge from the meatus at examination.
6. Taking of a specimen for microscopic examination.
7. Causing the patient to urinate into two or three tubes and recording the quantity and transparency of the separate urines, as well as the kind and character of the "floaters" it contains.
8. Recording the relative amount of pain, if any, on urinating.

After these steps the physician is, in most uncomplicated cases, prepared to decide on what solution he will use for irrigation.

IRRIGATION OF THE ANTERIOR URETHRA.

1. In the preponderance of cases irrigations can best be performed with the patient on a firm chair. He sits far forward, his sacrum resting on the anterior margin of the chair, the tuberosities of his ischium projecting slightly beyond.
2. The trousers and drawers are dropped to beneath the knees and the shirt and undershirt folded upward to the level of the umbilicus.
3. A clean towel is placed on the patient's thighs, covering his testicles.

4. A clean enameled or tin basin is given the patient to hold while the penis is placed over its margin.

5. The operator standing at the patient's side takes the penis with his third, fourth and fifth fingers of the left hand and supports it against the thenar eminence of the same hand, keeping his thumb and index finger free for manipulation of the glans and prepuce.

6. With the other hand he takes the irrigator's stopcock and directs the nozzle against the preputial orifice.

7. By drawing back the flange of the stopcock he allows the escape of a stream of sufficient force to thoroughly cleanse the preputial orifice; subsequently the mucosa lining the preputial sac, the sulci at both sides of the frenum and finally the meatus urinarius externus. Then the nozzle is inserted into the meatus, and the force of the flow increased to successively irrigate all parts of the anterior urethra to the compressor.

8. After irrigation the meatus is covered with a bit of absorbent cotton wet with bichlorid solution 1 to 6,000, and the patient is instructed to apply fresh cotton after each urination.

IRRIGATION OF THE POSTERIOR URETHRA.

The sphincter vesicæ being but a feeble bundle of muscular fibers, irrigation of the posterior urethra inevitably becomes an intravesical irrigation.

For posterior irrigation each of the steps before mentioned is performed, and the following added thereto:

(a) After the anterior urethra has been cleansed, the nozzle is sunk into the meatus to a depth that precludes outflow of the irrigating fluid.

(b) The patient is instructed to breathe deeply and to make efforts at urination.

(c) The force of the flow is gradually increased until it suffices to overcome the compressor; this is appreciable to the left fingers, to whose tips resting on the urethra is communicated a purling sensation as the fluid enters the bladder.

(d) The rapidity and force of the inflow grows less as the bladder is being filled and ceases when maximum vesical distension is approached. The stopcock is then closed by thrusting forward its flange.

(e) The right hand then places the stopcock within the basin, with the thumb through the ring and the fingers holding the outside of the basin, while

(f) The left fingers take a glass urinal and hand it to the patient, who substitutes it for the basin as the physician removes the latter.

(g) The patient empties his bladder of the solution into the glass urinal.

CLEANLINESS OF IRRIGATIONS.

If deftly performed, no irrigation need soil the patient, his garments, the office furniture or floor, nor the physician, except when strong solutions are used and then only the tips of the physician's left fingers may be stained. When this happens with potassium permanganate it can be instantly removed with a little oxalic acid.

TIME CONSUMED BY IRRIGATIONS.

Intravesical irrigation necessarily consumes more time than does mere anterior irrigation. With the moments needed to note the history of the occurrences since the previous visit, to prepare the solution, to cleanse the articles used and wash the hands, ten or twelve minutes will be required. To avoid even the appearance of treating a subject so grave as gonorrhœa with undue haste, it will be well to allow fifteen minutes for each visit.

Even when two visits daily are required and five min-

utes more consumed for microscopic examination of the discharge, the total of time allowed each patient is not excessive in view of the importance of the disease.

INTERVALS BETWEEN IRRIGATIONS AND SOLUTIONS USED.

The ideal manner of treating gonorrhœa, on the days when one irrigation daily is needed, is in administering it twenty-four hours after its predecessor; when two irrigations daily are required, to perform them at an interval of twelve hours. The latter, however, is beyond the endurance of a physician practicing alone. When he has an associate or competent, reliable assistant, the two daily irrigations can well be made at the proper intervals. The better results will reward the more assiduous effort. Many practitioners, however, are not so situated that they can attend the same patient twice daily; they must then content themselves by performing irrigations within the hours at their disposal. In the table given below these facts are considered, but the hours mentioned for irrigation recommended only in case the practitioner can not observe the preferable twelve-hour interval.

The drugs employed as irrigating solutions must necessarily vary according to the practitioner's preference. Unprejudiced and careful tests of all that have been recommended lead to the conclusion that potassium permanganate is most satisfactory in the majority of cases. The proportions mentioned, therefore, refer to this drug.

The presentation of this scheme must naturally be coupled with the understanding that the intelligent practitioner will modify it to suit the exigencies of each case:

First day, first visit—Anterior irrigation, 1-3,000.
 First day, 7 p. m.—Anterior irrigation, 1-4,000.
 Second day, 9 a. m.—Anterior irrigation, 1-3,000.
 Second day, 7 p. m.—Anterior irrigation, 1-4,000.
 Third day, 9 a. m.—Intravesical irrigation, 1-6,000.
 Third day, 7 p. m.—Anterior irrigation, 1-5,000.
 Fourth day, 9 a. m.—Intravesical irrigation, 1-5,000.
 Fourth day, 7 p. m.—Intravesical irrigation, 1-5,000; anterior irrigation, 1-2,000.
 Fifth day, noon—Intravesical irrigation, 1-5,000.
 Sixth day, noon—Intravesical irrigation, 1-5,000.
 Seventh day, noon—Intravesical irrigation, 1-5,000.

 Tenth day, 7 p. m.—Intravesical irrigation, 1-5,000; anterior irrigation, 1-500.

When other solutions than those of potassium permanganate are used their concentrations are made in proportions relative to the local disturbance they would create.

If the objective manifestations (pain on urinating, discharge) do not subside markedly on the third day of treatment, or if microscopic examination of the discharge does not show a decided reduction in the number of gonococci, it is evident that reduced resistance has allowed the specific organisms to penetrate more deeply into the urethral tissues. This occurs most frequently when the practitioner has not had opportunity to treat the case from the beginning.

If, after a series of irrigations as above described, the discharge recurs, it will be well to recommence them immediately after ascertaining that the recurrence is not due to complications or sequelæ of the disease. When these are found to be the cause of the recurrence, they must be treated. In so doing irrigations will be of assistance in controlling the crass manifestations.

CONCLUSIONS.

The preceding is by no means offered as anything but a synopsis of the irrigation treatment of uncomplicated acute gonorrhœa, which elsewhere¹ has been exhaustively detailed. However, it is believed that enough has been said, at least in a suggestive way, to warrant offering the following conclusions:

1. Every general practitioner is perfectly competent to treat successfully uncomplicated anterior gonorrhœa, if he will devote as much attention to this as he does to any one other disease.

2. Every patient with gonorrhœa is entitled to the services of his family physician, just as much as if he had acquired any other disease in consequence of drunkenness or other violation of ethics or morals.

3. The general practitioner who declines to treat uncomplicated acute anterior gonorrhœa avoids one of his most sacred duties to the profession and to humanity.

4. The patient who, because of his gonorrhœa, is refused the services of his physician, is likely to become an opponent to scientific medicine, to the detriment of his health, that of his family and of the community.

5. The scientific treatment of at least acute anterior uncomplicated gonorrhœa, is perfectly within the power of the general practitioner.

6. The irrigation treatment of gonorrhœa is, as yet, the most effective method and most in accord with the modern scientific understanding of the disease.

OPERATIVE TREATMENT OF THE FAUCIAL TONSILS

WITH A VIEW TO THE PREVENTION OF CERVICAL ADENITIS.*

ROBERT C. MYLES.

NEW YORK CITY.

The recognition of the interdependence of the tonsils and pathologic conditions in other, sometimes remotely situated parts of the body, represents one of the important advances in medicine during recent decades. A variety of diseases have been traced to a primary involvement of the tonsils, and among them are rheumatism, septic infection, tuberculosis, and in a recent report¹ appendicitis and infectious jaundice.

The anatomic structure of the tonsil predisposes to the entrance of the bacilli, for the covering epithelium is always porous, owing to the constant migration of leucocytes, and may be absent over small areas. Microbes usually invade the tonsils through the crypts, which constitute good hiding places and breeding spots. The enlargement and the surface irregularities associated with chronic hypertrophy greatly favor infection, and the resistance of the tissues under these conditions is diminished by the accompanying catarrh and the loosening and casting off of the epithelium.

The pathologic condition which is most often referred to primary tonsillar infection is cervical adenitis, whether in the form of simple hyperplasia or tubercular lymphomata. Baumgarten experimentally produced tuberculosis of the tonsils and the adjacent cervical lymph nodes in animals by feeding them with tuber-

culous material. His demonstration that the tonsil was the nidus of infection in tuberculous adenitis was also confirmed by other investigators.

A number of extended autopsy records have been published which show the frequency of tuberculosis of the tonsils in consumptives when tuberculosis of the cervical glands was present.

The danger which diseased tonsils represent as a possible etiologic factor in the production of other lesions has led a number of observers to propose tonsillectomy as a prophylactic measure.

Semon,² in 1885, presented an elaborate report advocating the more frequent recourse to ablation of the tonsils in order to improve debilitated constitutional states, and recommended "a reduction in the size of the tonsils, if the chronic enlargement, though not very considerable, be attended by a tumefaction of the cervical lymph nodes.

Krückmann³ reports a number of cases where a close connection could be traced between these two conditions, tuberculosis of the tonsils and cervical lymph nodes, sufficient for him to warrant the statement that where tuberculosis of the cervical lymph nodes is operated on attention at the same time should be directed to the tonsils. In fact, where a scrofulous diathesis is suspected, it is always advisable to remove hypertrophied tonsils.

Ruge⁴ says that the tonsils form an important port of entry for the tubercle bacillus, leading to infection, among other organs, of the cervical lymph nodes, and he is inclined to recommend the ablation of hypertrophied tonsils to avoid infection and its consequences. Even when they are already involved, the operation may prevent other infection. In recent text-books and manuals of surgery, the writers often refer to tonsillectomy as a prophylactic measure.

After we admit the necessity for operative treatment, with a view to preventing cervical adenitis, the most important question to be considered is the best and most effective operative treatment for all cases. Ablation or extirpation of the greater part is the thing desired. Those who have given strict attention to the subject feel that the advice that is usually given with regard to tonsillectomy does not cover the ground sufficiently.

The ordinary operation for tonsillectomy with the guillotine is usually effective in removing the part that protrudes. Some method of dissection, clipping, snaring, curettage or gouging seems to be necessary to relieve those cases in which the tonsil is deeply submerged or hypertrophied in its obscure parts. And it is these obscure parts that convey the septic material in chronic cases to the lymphatic glands of the neck and general circulation. It is to these deeper parts of the crypts and the base of the tonsil that I wish specially to call attention. Anyone who has not had extensive experience can not appreciate the difficulties that are met with in a series of hundreds of cases. The tonsillar mass frequently extends from one-half to three-fourths of an inch, or even an inch outward into the walls of the throat and mouth with a large curtain composed of the opercular folds and the mucous membrane covering the anterior surface. The writer has spent much time and thought trying to devise serviceable instruments for this operation. He has used almost everything that has been

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

1. Forchheimer: Archives of Pediatrics, 1902, p. 656.

suggested by others, as well as those he has constructed. He finds that numerous instruments are needed for safe and proper removal of this tissue in the different cases that present so many individual features. If the tonsil is peculiarly situated and can be drawn out by engaging forceps, and the old Physick guillotine used after having been properly adjusted, the result is perfect. But this can apply to only a limited number of cases. Usually it is necessary to grasp the tonsil with a pair of forceps and carefully cut it loose from its capsular sheath, when, after traction with the forceps has been employed, the adjustment of a strong wire snare or a guillotine is made. Frequently bleeding, gagging, vomiting, pain or a terrorized condition of the patient will interfere with this method, then some form of the punch forceps can be effectively used through the above-mentioned interfering manifestations.

I have a tonsillar curette made of razor steel, well sharpened, which I have found most valuable for removing the masses at the bottom of the cavities, which have been left after using the guillotine snare and punch forceps. In many cases it is better to sacrifice the opercular fold and a part of the mucous membrane that covers the faucial tonsil anteriorly. This procedure frequently materially aids one in "biting" out the deeper masses with the punch forceps.

I have a self-threading and unthreading needle for drawing the tonsil out of its bed; in some cases it will be found more practical than the forceps, as it does not need readjusting in cases of bleeding or vomiting. In addition to a solution of 100 per cent. locally I use a limited amount of solution of cocaine, from 1 to 10 of 1 per cent. hypodermically, to be followed by free injections of sterilized water into the adjacent tissues. It is my custom to do the operation with or without general anesthesia. When it has to be done under general anesthesia I have found the most feasible position of the patient is on the side with the head hanging over the edge of a high table, so that the operator can remove the sunken part of the upper tonsil and let the blood flow out at the lower angle of the opposite side of the mouth. I have noticed that the tonsillar capsule can be involuted by traction, and that in this position the cauliflower-like masses can be rapidly removed with the biting forceps or the snare.

There are two points that I would like to emphasize: First, that the cervical lymph nodes can be read with our fingers and considered as an index to pathologic conditions in the faucial tonsils. Second, that we should not be contented with the old method of tonsillectomy with the guillotine only, but that we should employ the scissors, dissecting knives, traction forceps, thread passed through the tonsil for traction purposes, wire snare, punch forceps or curette, each or all, as careful analysis of the anatomico-pathologic conditions may indicate in each individual case.

In conclusion, I may say that I firmly and conscientiously believe that we owe to childhood the thorough removal of the bases of all tonsils associated with continued and decided cervical lymphoid enlargements.

DISCUSSION.

DR. J. A. STUCKY, Lexington, Ky.—The general profession does not appreciate the importance of tonsillectomy. It has been looked on as one of the simpler operations which anyone could do. To me it is one of the most important and frequently one of the most difficult operations. In following the method suggested by Dr. Myles, I have been surprised in cases where I was unable to get the tonsil entirely out, to find that in thirty

days atrophy of the remaining portion had taken place and there was no tonsillar tissue there. It is astonishing what Nature will do in these cases. I question the wisdom of attempting to do the radical operation in one of these deep pockets without the use of a general anesthetic. It seems to me that it would be very difficult to control the hemorrhage if that should occur. In all cases where we find these deep, submerged tonsils, I think it is safer to use a general anesthetic.

DR. E. PYNCHON, Chicago—The teaching of the paper is absolutely correct as to the thorough removal of a diseased tonsil. If the indication is to remove any part of the tonsil, then the indication is to remove it all. I do not use the biting forceps, but use different methods at different times; in my operations before classes I do this so that the students may observe the different instruments in use. My favorite method is with the electric point, with which I can remove any tonsil. It has the advantage that I am practically working in a bloodless field. In operating on the deep part of the wound, the supratornillar fossa, I am not operating in a deep hole, because I am all the time pulling the tonsil outward. By use of the electric point and working in this way, I remove the tonsil absolutely, and never have these rough points and holes remaining, which are seen after other methods. After the operation is finished the work is not done; there is a great deal in the after-treatment which is just as important as the operation, as by massage we rub off excessive granulations and stimulate the wound so as to make it heal up smoothly. The cavity between the pillars thus becomes healed and is covered over with a smooth membrane of cicatricial tissue which has the same appearance as that of the roof of the mouth.

DR. O. TYDINGS, Piqua, Ohio—The snare I use is a little different. The instrument maker whom I had make it for me stole the idea from me and has patented it. I have tried the cautery, and I remove the whole tonsil instead of half. In this I make a section and separate the tonsil from the pillars, draw it down with a vulsellum and dissect it out with knives. I use a blunt dissector and with these one can peel out the entire tonsil with very little hemorrhage and remove it absolutely with this snare. I have never seen a tonsil I could not draw through this snare. With these knives I have been able to operate on any tonsil and, except in cases of severe and acute inflammation, with very little hemorrhage.

DR. ROBERT E. MYLES—I admit there is one serious drawback in advocating this operation; it virtually destroys a large portion of the general practitioner's income. All those conditions which are due to sepsis are discontinued, and that is one weighty reason why these tonsils should be removed. One can decide in some doubtful cases whether or not a tonsil should be extirpated by pressing the tongue down, squeezing the tonsil and causing the discharge of an offensive debris from the crypts. I do not think a general anesthetic is necessary in all cases. I seldom use it in adults, but it is frequently necessary in operating on children. As to Dr. Pynchon's practice of removing all the tonsil, I have tried to do it for years in cases where these large masses are found, and my experience has been that it is impossible unless one takes away the circular sheath. We need a certain amount of tonsil and in my judgment should remove only the part which is diseased or abnormal. I appreciate very much Dr. Tyding's point about tearing loose the tissue. The Italians were using the method several hundred years ago.

Rigor Mortis in Stillborn Children.—Dr. C. H. W. Parkinson, in an article in the *British Medical Journal*, brings out a fact probably not generally known, that rigor mortis may and does occur in stillborn children. He reports three cases and states that in one case cadaveric rigidity had clearly obstructed labor and that after delivery the rigidity increased, the legs and arms being drawn up in the position they would have taken within the uterus. Dr. Parkinson calls attention to the importance of the subject from a medicolegal point of view.

HEMORRHAGE OF THE LARYNX.*

JOHN EDWIN RHODES, A.M., M.D.

Associate Professor of Diseases of Chest, Throat and Nose, Rush Medical College; Laryngologist, Cook County Hospital, St. Mary's of Nazareth Hospital and Home for Destitute Crippled Children.
CHICAGO.

Hemorrhage of the larynx may be classified as follows: 1, Those cases in which there is a loss of blood through the mucous membrane of the larynx, and in which the main symptom is hemoptysis; 2, those cases in which there is no spitting of blood, but in which the evidences of hemorrhage are found on a careful laryngoscopic examination of the larynx, in an extravasation of blood in the tissues beneath the mucous membrane.

Kyle¹ thinks a distinction should be made between those that are secondary to inflammation and those secondary to necrosis; in the one the term "hemorrhagic laryngitis" is applicable, and in the other the term "laryngeal hemorrhage" should be used. This terminology, suggested by Bosworth² and others, is generally accepted.

Bresgen³ says that hemorrhagic laryngitis is an exacerbation of the simple phlogistic process, brought about by mechanical influences; the capillary vessels of the inflamed and strongly hyperemic mucosa are liable to rupture on account of the venous stasis produced by frequent intense cough.

Stepanow⁴ thinks that a distinct clinical picture is furnished by such a catarrhal laryngitis, accompanied by hemorrhage.

Of the remaining conditions, accompanied with bleeding from the free surface of the mucous membrane, there are distinct varieties.

Garrel⁵ (1898) makes a clinical subdivision of these as "traumatic," "dyscrasic" and "organic."

Of those cases in which there is no spitting of blood, there are varieties in which there is a sufficient extravasation in the submucous tissues to cause sensible change in the vocal bands, or laryngeal structures, from the mechanical presence of the blood, or a more diffuse form in which there is neither noticeable swelling nor deformity from its presence. There are recorded cases which are distinctly of this latter character.

The importance of precision in diagnoses in these cases is apparent. It is a fact that the true causes of hemoptysis are often not appreciated by the laity or practitioners of medicine, and a diagnosis of pulmonary hemoptysis or hematemesis has been made when a more careful examination, with the laryngoscope, would have at once revealed the source of the bleeding and quieted apprehension and have made a favorable prognosis possible. Such errors of diagnosis were formerly more frequent than at the present time, when laryngoscopic examinations are more generally made in such cases.

ETIOLOGY.

Breaches of the mucous membrane may be caused by a simple traumatism. The laceration of the membrane may be the result of wounds of various sorts and of the passage of hard pieces of food, of the shells of nuts and

fish, of bone or other irregular particles, or from their impactation within the larynx. External violence applied to the neck over the larynx, as in choking, severe blows, wounds, etc., might also cause rupture of vessels.

In the inflammatory form will be found a marked congestion or inflammation of the vocal cords. In these cases the blood vessels are dilated and weakened by the inflammatory process, and yield to sudden and marked pressure such as would be caused by coughing, vomiting or unusual and severe vocal efforts, and hemorrhage occurs from the free surface or in the submucous tissues.

In cancerous, syphilitic or tubercular disease of the larynx it is not unusual to have hemorrhage, usually small in quantity, but sometimes so abundant as to cause death. In such cases there are, generally, other evidences of the disease than those located in the larynx. The hemorrhage is the result of necrosis of tissues perforating the vessel wall or so weakening it that rupture takes place from any unusual strain, such as might come from a severe cough.

There is a class of cases in which there is a derangement of the blood, and hemorrhages take place from other mucous surfaces. Such conditions are found in purpura hemorrhagica, variola hemorrhagica, hemophilia, scorbutus, anemia, pseudoleukemia, diabetes, pronounced albuminuria, hepatic cirrhosis, the passive congestions of heart disease, fibrosis of the lung, etc.

It is interesting to note that hemorrhages of the larynx occurred during pregnancy, possibly dependent on changes in the vessel walls, in cases reported by Frinkel,⁶ Strübing⁷ and La Sota y Lastra,⁸ and it was possibly venacious in Treitel's⁹ patient, being suspiciously dependent on cessation of menses.

And, finally, there is a class of cases in which hemorrhage from the larynx has occurred, and no assignable cause can be discovered. The individuals have seemed to be in perfect health, and the bleeding has been spontaneous.

The exciting causes seem to be, in a majority of cases, some unusual vocal efforts, as in the cases of singers who may or may not have had some catarrhal condition and impairment of the voice preceding the hemorrhage. In some, violent expiratory efforts, as coughing or vomiting, are the immediate cause of the attack. In others, special efforts in speaking in a large assemblage or using the voice in teaching in a larger assemblage than has been customary. In other instances the attack has come on while the patient has been reading in bed quietly, the presence of blood in the throat being the first evidence of the trouble. Violent sneezing, crying aloud suddenly, exercising the voice, have all been noted as causing hemorrhage of the larynx, on subsequent examination. It has also been found preceding an attack of hay fever, and, in one case, followed the simple act of drinking.

Hemorrhages from the larynx are not rare, many cases having been reported in literature. This was clearly brought out in correspondence by Gleitsman,¹⁰ who, in 1884, wrote an admirable article on the subject of "Laryngeal Hemorrhages," and gave brief abstracts of the cases on record and the bibliography up to that date. He wrote 57 letters to laryngologists, receiving 25 answers, of which number 12 had not seen

cases; 22 cases had been seen by the remaining 13, which had never been reported. However, in a study of the reported cases, it is evident that what may be termed "true laryngeal hemorrhage," that is, that which is not dependent on local conditions and which may not be classed as simply a symptom of such conditions, is quite rare.

Strübing⁷ says that in true laryngeal hemorrhage the hemorrhage plays the important rôle, and is responsible for most of the symptoms present.

A suffused laryngeal hemorrhage, such as my first case and those reported by Pleskoff,¹¹ Garrel⁵ and Schnitzler,¹² are exceedingly rare.

PATHOLOGY.

Newman¹³ calls attention to the free vascular supply of the larynx, and the fact that these blood vessels, if weakened by disease, when exposed to injury, are liable to rupture. The arterial supply of the larynx comes from two sources: mainly, the laryngeal branch of the superior thyroid, coming from the external carotid, and ramifying in the small muscles, glands and mucous membrane of the organ, and the inferior laryngeal branch of the inferior thyroid artery, coming from the subclavian and being distributed to the muscles and mucous membrane of the back of the larynx. These communicate freely with each other, and those of one side of the larynx with the corresponding arteries of the other side.

Hektoen, in a personal note to me, makes the pathologic distinctions in hemorrhages of the larynx as follows: They may occur, in the absence of ulceration, from dilated veins, in consequence of general circulatory obstruction; in asphyxia, in hemophilia; in scorbutus, and in various acute infections, such as ordinary sepsis of a violent character; also in diseases like smallpox. All forms of ulcers may lead to hemorrhage. Laryngeal hemorrhage, without ulceration, seems rare.

Gottstein explains some cases of hemorrhage as occurring in the separation of hardened secretion from the delicate mucous membrane, there being a condition of laryngitis sicca present. This is also mentioned by Richardson.¹⁴

The escape of blood may be confined to a single point, from which blood can be seen oozing. A favorite site for such bleeding is at the posterior end of a vocal cord, sometimes on other portions of the vocal cords, on the ventricular bands, and occasionally on the anterior surface of the arytenoids. There may be, at the time of examination, coagulæ of blood on the surface of the cords, or in the vestibule of the larynx, confined to the vicinity of the bleeding point; or there may be numerous coagulæ of blood scattered over the mucous membrane, or it may be covered with a liquid or semiliquid blood. A case has been reported by Stockton, in which a pulsating artery was seen in the larynx of an opera singer, the larynx being covered with blood. An examination will often show reddening of the laryngeal membrane in a marked degree, sometimes confined to the vocal cords. This coloration may be generally diffused or in patches. It may invade the whole larynx, however, and extend to the epiglottis. Swelling of one or both of the vocal cords may be present, and tumefactions of the mucosa are occasionally found.

Of cases of submucous hemorrhage there is an inter-

esting series given by Langmaid,¹⁵ in four of which there was found a globule of blood beneath the delicate mucous membrane of the vocal cords, well defined, and of a diameter nearly that of the transverse diameter of the cord. A vascular tumor, attached to the edge and upper surface of a vocal cord, evidently from an extravasation of blood beneath or in the mucous membrane, has been described by Dundas Grant.¹⁶ A hematoma from the same cause has been reported by Geyer.¹⁷

Garrel's⁵ four cases were of a different character. In two, the right, and in two, the left vocal cord presented a vivid red color. In one case it was accompanied by a uniform swelling of the cord in its entire length. Ives¹⁷ had a similar case, in which the left vocal cord was swollen uniformly and bright red. In one of my own cases this coloration was found in both cords unaccompanied by any appreciable swelling. Similar conditions appear in cases reported by Schnitzler,¹² and a case here reported, of Wippen's.

SYMPTOMATOLOGY.

In cases of hemorrhage from the free surface of the mucous membrane the principal symptom is hemoptysis. The blood is usually small in amount, consists of small, dark clots, and is generally easily expelled; sometimes the blood is bright red, streaking the sputum, though still small in amount. Such hemorrhages may have occurred a number of times, at varying intervals, but are often a daily occurrence. There can be no question that, while the expectoration of blood is usually small in amount, there have been cases in which it was possible to exclude pulmonary tuberculosis, both from the clinical findings and from the subsequent history of the patient, in which the hemorrhage was profuse. Such cases have been described by Luc,¹⁸ Hartman, Clinton Wagner,¹⁹ Straight²⁰ and others. While it is undoubtedly true that we should look with suspicion on an hemoptysis which is at all profuse, and that time would show that most of such cases were tubercular, we can not, certainly, accept the dictum of Lennox Browne²¹ that "a hemorrhage from the larynx is almost always indicative of serious disease." On the contrary, the reverse is true.

Among the symptoms, that of a sudden impairment or complete loss of voice has been common. This has come on in the course of some severe or unusual vocal effort. Many of the patients have been singers, and the accident has occurred while in the practice of their art, either in the singing of some trying rôle or in vocalizing in practice. Pain is not a common symptom, but is sometimes present. Cough is a usual accompaniment of the condition, both in the hemorrhage from the free surface and in the submucous variety, and is caused by the presence of the blood clots and the pathologic changes taking place from the presence of the blood in the tissues. Difficulty in deglutition has been rarely noted. Dyspnea has been noted, of a mild form in some instances, but of an alarming character in others, from the obstruction in the lumen of the larynx, caused by clots of blood, or tumefactions, or diffused swelling of the laryngeal structures. In other cases the symptoms

are very slight, consisting possibly of slight irritation, of a tendency to hawk and clear the throat, or of moderate hoarseness, and nothing more.

DIAGNOSIS.

With a knowledge of the causative factors and of the possibility of recognizing the condition with the laryngoscope, in many cases the diagnosis presents no great difficulties. It is so often impossible to view the actual oozing of blood from a vessel in which rhexis has occurred, that diagnosis must be doubtful until such condition is present at the time of examination. The suspicion that a case under observation is one of laryngeal hemorrhage should lead to an effort to get the patient to present himself for examination, if possible, at a time when bleeding is taking place. The recognition of the various dyscrasic factors in which it has been shown such hemorrhages might occur, should lead to careful investigation as to the presence of hemophilia, scorbutus, anemia, etc., and of the lungs, the heart, the kidneys, the liver and the blood, and also inquiries as to pregnancy, menstruation, etc. In fine, all conditions that may have played a rôle in the development of the disease should be investigated.

It should always be possible, in conjunction with a laryngoscopic examination, to determine the presence of cancer, syphilis or tuberculosis in the larynx, in which necrosis has caused the hemorrhage.

The recognition of the varied phenomena of tumor formation, coloration of the laryngeal membrane, blood clots on the surface, or submucous tumefaction and swelling, should be comparatively easy to one familiar with the use of the laryngoscope. In fact, on this instrument we must depend for primary or confirmatory diagnosis in every case.

Careful rhinoscopic examinations should always be made also that we may exclude the nose, nasopharynx and oral cavity, as the possible source of the bleeding.

The sudden onset of the hemorrhage during coughing, vomiting, or severe straining, or during or following vocal efforts in speaking or singing, may at once suggest the possible seat of the lesion and be confirmed by examination of the larynx.

I fancy, after all, that interest in this subject centers, largely, in the differential diagnosis of laryngeal and pulmonary hemorrhage. We should remember that most cases of profuse hemorrhage are from the lung, and that a free bleeding from mucous membranes of the throat or bronchi are very rare, but they do sometimes occur. Careful examination of the chest may reveal no signs of tubercular involvement there, but there may exist very small foci in the lungs, which may not be demonstrable by physical examination, and such areas have been found to be sites of copious hemorrhages. In such cases, if the bleeding point in the larynx has not been certainly located, the subsequent history may confirm a suspected pulmonary origin of the bleeding. Even in those cases in which blood clots are found covering the laryngeal membrane, if there has been spitting of fluid blood, it is well to remember that they may have been lodged there during hemorrhage which occurred below the larynx. The exciting cause of the hemorrhage, and the general condition of the patient, would be of importance in the study of such cases. The character of the blood in hemoptysis is well known, and should always be considered.

PROGNOSIS.

This is invariably good in cases of true laryngeal hemorrhage and no fatal case has been recorded.

TREATMENT.

Rest, so far as the use of the voice is concerned, is the most important item in the therapy for this condition, and too much stress can not be laid on the enforcement of this measure.

The avoidance of exciting cause, as in overstrain, overexercise of the voice, the application of a wrong method of singing, etc., should enter into the measures used for the prevention of subsequent attacks. Internal remedies may be indicated for the quieting of the cough, the allaying of irritation, or for general treatment of dyscrasiae causing the condition; and remedies like ergot, stypticin, etc., for the local effect on blood vessels.

Topically, the use of astringents is recommended. Some cases have been managed with the application of mild solutions of argentic nitrate, perchlorid of iron, alumol, the zinc salt, etc. I have found that one of the satisfactory remedies was adrenalin or a suprarenalin (1-1000) and its physiologic action has hastened absorption of exudates.

In every case, care should be taken that no harsh remedies are used, and only the mildest of applications need be made, as special stimulation is not required. Surgical measures need to be resorted to but rarely, but have, of necessity, been adopted in some cases. The incision of a hematoma, the removal of a small tumor formation, the cauterization of a bleeding point, have been found necessary in some cases.

CASE 1.—G. H., age 29, single, tenor in one of our visiting opera companies, consulted me in February, 1903, for a slight impairment of the voice, a diminished resonance, noticeable particularly in the upper register. He attributed the present condition to a severe vomiting spell of the evening before, caused by a disordered stomach.

History.—He was in perfect health otherwise, and had had no severe illness except an attack of pneumonia about twenty years before. He used alcoholics very moderately and tobacco not at all. He had always been subject to epistaxis, and although he had had only one attack thus far the present season, he had, in former years, repeated attacks, and the bleeding sometimes continued for several hours at a time. He had also noticed that a slight cut was often followed by prolonged bleeding. Whenever there was a slight contusion on any part of the body it was usually followed by a black and blue spot which remained for a day or so and then disappeared. Almost every day small blood blisters appeared, spontaneously, on the buccal surfaces of the cheeks and on the tongue. These he was accustomed to break open and they would disappear in a few hours. He had an attack of laryngeal trouble the preceding September, but it was much more severe than the present one and had continued for five weeks. During that time he was obliged to give his voice complete rest. Heredity was negative.

Examination.—He had accompanied the prima donna of the company to my office a day or so before, and had called my attention to the condition of the mouth and tongue, and I had looked at his larynx also. I had found that the vocal cords were quite red, but there was no swelling (a condition I have often seen in singers' larynges, when singing regularly and in good voice). At this time the voice was excellent, and he had been singing a heavy rôle three times a week during the season. When he consulted me later there were purpurae bullosa on the tongue and buccal mucous membrane, few in number and about the size of a small pea. The pharynx had several prominent blood vessels coursing over it, and these extended up into the nasopharynx. The larynx was diffusely congested, but the vocal cords were a brilliant crimson. There was no hemorrhage on the surface, and no bleeding vessels, but there seemed to be a suffusion of blood beneath the epithelium, uniform in its distribution. There was no swelling, and the muscular action of the cords appeared to be about perfect.

Treatment.—I applied as an astringent a 10 per cent. solu-

tion of alumnol, freely. He sang that evening, sparing his voice as much as possible, and improved so that he missed no performance, and in three or four days was in as good voice as ever, the larynx rapidly returning to its normal condition.

CASE 2.—S. A., aged 56, lawyer, came to me in the afternoon of March 22, complaining of hoarseness and irritation of the larynx, which had come on suddenly about noon of that day.

History.—He had not been using the voice unusually during the day, simply transacting business in his office with his clients. He had had some symptoms of a cold for a day or two, and said the mucous membrane of the nose and throat seemed dry. I had treated him for some years for chronic catarrhal inflammation.

Examination.—There was considerable viscid mucus clinging to the membrane of the pharyngeal wall and nasopharynx, and the nasal membrane was very dry. Congestion was not marked. On examination of the larynx the right cord was found normal in appearance. Coursing over the surface of the left cord, somewhat irregularly, from the inner edge, posteriorly, then externally, and separated from the edge about 1 mm. along its upper flat surface to the anterior insertion, was a band, vividly red, with well-defined demarkation, showing plainly extravasation of blood beneath the mucous membrane. This changed very little in twenty-four hours, then gradual absorption took place, and in a few days had disappeared.

Treatment.—The treatment consisted in an application daily of adrenalin solution (1 to 1,000), and at home the following spray was used two or three times a day:

B. Zinci sulphatis	gr. ii	11
Acidi borici	gr. viii	16
Menthol	gr. i	5
Aq. dest. q. s. ad.	ʒi	30

CASE 3.—F. E. J., male, married, whom I have known for a number of years, came to me in the early part of February with a history of an acute rhinitis about four weeks before his visit, and of becoming hoarse a few days afterward, after an evening of exposure while tobogganing, and he had been hoarse ever since.

Symptoms.—The throat felt dry and sore, and there was occasionally a feeling of intense dryness in the larynx, accompanied, at times, with a sharp but momentary pain. He had been having some bleeding from the nose nearly every day, small in amount, and caused by vigorous blowing and the dislodgment of small crusts of mucus. He had noticed also for the last week that he had coughed up small streaks of blood with his sputum every morning.

His brother had died a few months previously from a lingering tuberculosis, and I had treated him for a number of years for a chronic laryngeal catarrh before the pulmonary disease had developed. This knowledge of his brother's throat trouble and subsequent history made the patient very apprehensive. His general health was good, and he had gained forty pounds in the last year and a half.

Examination.—An examination of the chest was entirely negative. In an examination of the nose I found a slight abrasion on the cartilaginous septum on the right side; the pharynx was dry and congested, and the vocal cords were rather bright red and slightly swollen. I found no bleeding point then, but two days afterward he came to me early in the morning and I discovered one on the left vocal cord, near its posterior insertion and on its upper surface. From this point a small amount of blood coozed, and had flowed down over the edge of the cord, where it still remained as small coagula. Spraying the larynx dislodged these, but the bleeding point still remained. Within three days the spitting of blood ceased and the bleeding point disappeared. The treatment consisted of sprays of a 10 per cent. solution of alumnol and the following:

B. Adrenal.	ʒi	3 75
Acidi borici	grs. xvi	106
Aq. cinnamomi	ʒiv	15
Aq. camphoræ, hot.	ʒi	30
Aq. dest. q. s. ad.	ʒiii	60

Macerate for two hours; then filter.

Sig.: Spray the larynx two or three times daily.

The effect of this spray seemed quickly efficacious, his apprehensions as to pulmonary hemoptysis could be at once quieted, and he has had no return of the trouble.

CASE 4.—A. G. Wippen has kindly furnished me the notes of a case he has seen: Miss C., aged 22, a professional elocutionist, while imitating the shrill notes of a bird, suddenly lost her voice and could only speak in a whisper. She tried inhalations of steam, which had relieved her before when troubled with laryngitis, but without any benefit. The next day she was examined, and numerous little hemorrhagic spots were seen on both cords. The following day some of these spots had become confluent. The hemorrhage seemed to be confined to the two cords, and no blood was at any time coughed up, nor did the laryngeal applicator become tinged with blood. The use of steam inhalations, absolute rest of the voice, local applications of astringents and the administration of iodids effected the absorption of the hemorrhages within three weeks, when the patient resumed her occupation.

ABSTRACTS OF CASES.

The following are the brief abstracts of the cases recorded by the respective authors since 1884, which it has been possible for me to consult. A few reports have not been accessible to me. A report and a bibliography of those previous to that date have been given by Gleitsman.¹⁹

LENNOX BROWNE.²⁰ Girl, aged 18, seamstress, had complete loss of voice.

Examination.—There was a general anemia of the larynx, except the vocal cords, which were covered with moist blood, and, on removing it, the cords were found very hyperemic. There was general debility and amenorrhea. She had often spat and tasted blood in the morning, though only a little.

BUKOW.²² Female, aged 21. She was well built and strong and had never been sick. She had acute laryngitis, and had expectorated blood in four instances. The symptoms were cough, some anphny, bloody sputum, and no dyspnea.

Examination.—Laryngoscopic examination showed signs of laryngeal inflammation, particularly of the true and false cords. There were, here and there, some blood coagula, but no tumefaction of the mucosa. She recovered in two weeks.

DOBSON.²⁷ Robust man, aged 40. He spoke to an unusual degree at a public meeting the night before. The next morning he had symptoms of irritation in the larynx, with rawking, and could speak only in a hoarse whisper.

Examination.—The left vocal cord was found to be swollen to twice its normal size through its entire length and was bright red in color, the coloring being diffuse and even. Afterward a cystic growth appeared, and this was evidently opened and the voice cleared while he was coughing violently.

STREIBER.²⁵ Female, aged 34. Strong. She was pregnant, in the ninth month. She began to cough, after exposure, and fifteen days later expectorated blood. There was aphony, which was total for the higher notes, dyspnea, which occurred in paroxysms, but which was relieved with the ejection of small quantities of coagulated blood, after much cough. At times there was mucopurulent sputum with streaks of blood.

Examination.—This showed the laryngeal mucosa, and particularly that of the true cords, strongly reddened; the latter was literally wrapped all around with blood coagula, and the lumen of the larynx was much narrowed. The patient was cured in six weeks.

MOCH.²³ A patient developed a laryngitis as a sequence of pseudoleukæmia, with cough and bloody sputum. There was a dry catarrh of the nose and throat.

Examination.—This showed an extravasation of blood in the submucous tissues of a vocal cord and a crumpled crust on the laryngeal plaques, which he believed was due to decubitus. The patient recovered.

PLESKOFF.²⁴ Male, teacher, aged 41. Symptoms were pain in the larynx and slight hoarseness. He had been called to teach a larger class than usual and pain was worse while teaching it. He had had some cough and expectoration for years. Ten years before was hoarse for six weeks, two weeks before examination sputum was blood streaked, and four days before, this occurred again. The patient was healthy and robust.

Examination.—This revealed a diffuse but scarlet red coloration of both true cords like that of a catarrhal laryngitis, and a sharply outlined band, bright red, covered about half the breadth of the left vocal cord in the region of the processus vocalis, a submucous extravasation of blood. There was no ulceration, no cicatrization and no history of trauma. The author says this spontaneous laryngeal hemorrhage is very rare. Only two cases had been seen before this in the Heidelberg clinic in ten years.

PORTER.²¹ Case 1.—Miss K. She had had repeated bleedings from the larynx and had complained of hoarseness at times and some soreness in the chest region. She had a good family history. The site of the hemorrhage was a small ulcer on the right ventricular band. The bleeding was finally controlled, and had not returned in two years.

Case 2.—Mr. G., a government inspector of boats, aged 42, and robust. He was alarmed by expectorating blood. He was slightly hoarse. The bleeding point was found to be from the posterior end of the right vocal cord, which was red and swollen. This was controlled by an application of iron.

Case 3.—Miss L., aged 33. Delicate. No heredity known. The

larynx was red and the mucous membrane over the left arytenoid, the whole of the left side of the larynx and the vocal cords were swollen. At her third visit bleeding began while she was waiting, and a bleeding point was discovered near the posterior attachment of the left cord. In four months evidences were found of pulmonary congestion.

HARTMAN: Male, aged 28. The patient was strong and weighed 162 pounds. An hour after singing there was a sudden filling of the throat with two or three ounces of pure, bright blood. This was repeated the following morning.

Examination.—The nasal, oral and ear cavities were found normal. In the larynx was seen a ruptured blood vessel on the upper surface and middle of the left ventricular band. Blood was seen oozing from this, trickling down into the glottis and causing cough and spasms of dyspnea. Hearty coughing.

CLAYTON WAGNER: Dr. M., aged 28. Consulted him for hemoptysis. Patient of spare habit, but excellent health. Lungs were healthy. There was general hyperemia of the larynx. Minute drops of blood were seen oozing from the left ventricular band and ventricular wall one week later was a profuse hemorrhage. Drs. Flint and Lee thought this was bronchial. In this the author concurred, but believed it had its origin in the larynx. About four months later hemorrhage returned and afterward there were small clots expectorated after taking time on two occasions. On the occasion he had just two or three ounces of blood. He had several attacks, but there was no loss of weight or evidence of pulmonary disease.

MASSUCI: Man, aged 39. He was a singer, of robust health. There were suspicions of hereditary deafness, and he had had several times attacks of dyspnea. Hearty coughing. His symptoms were a sensation of a foreign body in the throat, a continuous and unrestrainable desire to cough, hoarseness and bloody expectoration. He had a dry pharyngitis.

Examination.—A transvasation was found on the arytenoids and under the mucous membrane of the cords, with a few hemorrhagic points in the trachea. He was well in 28 days.

LUC: Male, aged 35. Several months previous, while reading a paper in bed, he suddenly felt a liquid flowing down his throat. He expectorated blood, bright red in color. Three days after being seen, he was awakened about 3 a. m. by a desire to cough and expectorated a larger quantity of bright red blood, and this was done, in increased amount, on the next day. He was highly nervous and apprehensive of lung or heart disease.

Examination.—Nasal cavities were found normal. There was acute catarrh of the larynx, with general laryngeal congestion. There was a small erosion in the region of the cartilage of Santorini on the left side, the center of an irregular white spot of a violet color, the origin of the hemorrhage. Recovered in eight days.

TRETEL: Woman, aged 50. Healthy and of strong constitution. Married four years. Had no children and no abortion. Menstruation regular up to four months previous, when it ceased without known cause. There was no hemiplegia. In the middle of the previous December there was catarrh of the upper air passages. Two days later there was profuse menstruation. On the 18th of the month, coagula of blood were raised by persistent cough, and she became aphonic. Her voice was restored by relief by coughing up congealed blood, especially mornings.

Examination.—This revealed a slightly reddened epiglottis, the laryngeal walls markedly swollen and bright red. In the left middle portion was a blackish scab. The vocal cords were red in patches and swollen. The posterior pharyngeal wall was also swollen, and two coagula were removed from it by a brush, measuring 5 by 2 mm. each. The chest was normal. Patient cured in 20 days.

NOGARO: Male, aged 45. Family history negative. Had hyperemic catarrh of the larynx, due to edema, probably, and edema of the lower extremities. Two attacks of hemorrhoidal hemorrhages several months previous. Complained of hoarseness, aphonia, painful dryness of the throat and pain in deglutition, of about one month's duration, and a dry pharyngitis and acute catarrhal laryngitis. In eight days hemoptysis occurred.

Examination.—This showed the left vocal cord to be covered posteriorly, a hemorrhagic spot and small varicosities of the right vocal cord. The whole cord was markedly reddened and covered in places with congealed stry of blood, which could be easily removed with pincette. The condition was undoubtedly due to a passive pulmonary congestion, following the cirrhosis of the liver.

ROYLT: Two patients, singers at the opera, had hemorrhagic laryngitis several months previous, as a result of a hematoma. Another case of a patient with a vague history of hemiplegia in the family was cured.

DUNDAS GRANT: Woman, aged 24. Had aphonia and hoarseness at intervals for four years. The attacks were induced by sneezing or some vocal effort, and lasted a fortnight.

Examination.—M. This showed the left vocal cord to be covered by a loose layer of blood clot and projecting over the other cord, on phonation. This could not be removed, and was obviously submucous. When the tumor was removed, the hemorrhage seemed to arise from the anterior and middle third of the cord. Eight days later a hempsized tumor was discovered attached to the edge and upper surface of the cord. Baber reported in discussion that he had a similar case, and was understood to be correct.

GEVART: A lady cried loudly, and immediately was conscious of a sensation above the thyroid, accompanied by a change of voice, followed by aphony. There were no functional symptoms, save slight cough and expectoration of blood-streaked sputum.

Examination.—The right cord was found slightly congested, as was the whole laryngeal mucosa. The left cord was somewhat swollen, and of a deep ecythemic red color. The ecythymosis was completely absorbed in eight days.

SCHNITZLER: A singer, whose voice was good in the first act of a great opera, became completely aphonic after great vocal exertion. The following day, an examination showed the left cord relaxed and suffused with blood. Absorption took place gradually, and the voice was completely restored in a few days. A few months later the same mishap occurred under similar circumstances. Rest and astringents, locally applied, brought about a complete cure.

LANGMAD: He records five interesting cases in which there was sudden vocal disability. The lesion had a definite cause. Extravasation was found at the junction of the anterior and middle third of the vocal cord in each case; in one the hemorrhage was diffuse, in the other it consisted of a white mass of blood under the mucous membrane, with a diameter nearly that of the transverse diameter of the cord. Four of the patients were singers, and one an actor. The hemorrhage was caused by vocal strain in every case. There was no hemoptysis. All cases were cured.

SKRABOURG: Case 1.—Male, aged 37. Fourteen years previously had marked expectoration of blood, lasting two or three days, and for a few months subsequently occasionally expectorated small quantities. His general health was good. Seven years afterward he had a recurrence of the hemoptysis, with frequent repetitions during the succeeding four years. For three years before coming under observation the condition had been worse. At one time the bleeding had been very profuse for several days. For three weeks he had been spitting blood daily. The family history was excellent. There had been no catarrh nor general hemorrhages. The lungs were found normal.

Examination.—This showed general enlargement of the blood vessels of the larynx, epiglottis and base of the tongue. No bleeding point was detected. Singing in chorus was followed by marked bleeding the following morning. Improved at once under a spray of weak solution of argentic nitrate. The patient had had no recurrence in two months.

Case 2. Male, aged 35. Spat blood for sixteen years. The first, after running for a train. The intervals varied widely. They were after a profuse hemorrhage, but no decline in health. There were no abnormal lung findings. The family history was good. A bleeding point was found on the anterior third of the left cord. This was verified a number of times when bleeding was taking place. Treatment did not avail, and he died of tuberculosis, which he died from a profuse hemorrhage of the larynx. He had no symptoms of tuberculosis. Its possibility must be accepted.

GEYER: Case 1.—Mrs. K., aged 40. Menstruation regular, weakness marked, slight cough and hoarseness for about two days. She had had profuse hemoptysis for several weeks.

Examination.—This showed a hematoma, a collection of blood under the mucosa. This was removed, but reappeared and was again removed.

Case 2. Woman, aged 40. For ten years she had had frequent attacks of hoarseness, alternating with a sense of irritation in the throat.

Examination.—A small blood tumor was found in the larynx, which was removed and examined microscopically. It was found to consist of organized blood pigment, with some vascularization and a fibrous capsule, covered wholly by the mucosa.

GAUMER: Case 1.—Miss H., a singer. While exercising her voice, became suddenly hoarse.

Examination.—This showed the vocal cords to be of a vivid red color, as far down as the inferior surface.

Treatment and Result.—She was ordered to rest, and local astringents were applied. On the thirteenth day she intended to begin her vocal exercises, but on taking a hot inhalation of eucalyptus the voice again suddenly changed. It was found that the submucous hemorrhage had again appeared. Treatment was instituted for a longer period. A year later, having resumed her occupation, the same condition recurred, and the same ecythemic area was noted. Cough, as well as loss of voice, was present. Cure followed rest and the use of astringents.

Case 2.—The first baritone at the grand opera. He complained of inability to sing the high or low notes well, and of a gradual change of the voice. His right vocal cord was found reddened on its internal surface. Rest restored the voice.

Case 3.—M. C., architect. In 1855, while fearing the annual return of his hay fever, he suddenly lost his voice, preceding which he had a sensation of something breaking in the throat. There was no hemoptysis.

Examination.—This showed an intense redness of the left vocal cord, which appeared swollen in its entire length.

Case 4.—Mr. X, was of a nervous temperament. While taking a drink, a month previously, his voice suddenly changed.

Examination.—This showed uniform red injected appearance of the left vocal cord, contrasting markedly with the whiteness of the opposite cord. The hemorrhage was in a state of absorption.

LA SOTA Y LASTRA: A woman, aged 35, had suddenly a sensation of heat in the throat and difficulty of deglutition. She began coughing frequently. Four days before she began expectorating pure blood.

Examination.—This showed no abnormal condition of the chest or lesion of the blood vessels. Later, blood mixed with sputum and sometimes streaked with congeal. An examination of the larynx showed a congested and granular mucosa, with reddening of the velum and uvula, and the laryngeal mucosa in a tumefied condition, covered in some places with a semi-liquid blood, in others with coagula, particularly over the cords forming irregular dentations over the free border. The following day the coughing ceased, and there was dyspnea and aphonia, and the mucus was blood-streaked. A small dark conulum was found between the cords, which was removed and the dyspnea and aphonia disappeared.

100 State Street.

DISCUSSION.

DR. P. S. DONNELLAN, Philadelphia.—In my judgment the kernel of the question is whether the hemorrhage proceeds from the lungs or from the larynx, and whether the case is tubercular or non-tubercular. Whenever a case of this kind presents itself, we should always view it with suspicion and keep it under observation until we are able to exclude or include the possibility of tuberculosis. We should not only examine each case laryngologically, but all the secretions of the body should be carefully examined, especially the sputum. Re-

cently I had an opportunity to see an interesting case of spitting of blood in a boy of fourteen; three or four days previously he had slight sore throat and fever, followed by profuse hemorrhage, which was coughed up. Investigation showed that this was due to sudden suppression of a scarlatina rash. He had run out into the street where the atmospheric air had a temperature of about 50 from a room where the temperature was 82, and this hemorrhage immediately resulted. He also had hemorrhagic nephritis. I now have under my care a physician who has had three or four hemorrhages from the larynx and have decided that they are due to gouty diathesis. He has been under observation for a year and a half, and in that time he has lost no flesh and shows no tubercle bacilli. Insurance companies are very suspicious of laryngeal hemorrhage, and look on every case with such a history as one to be carefully watched; first-class conservative companies will not issue to them ordinary policies unless an interval of ten years has elapsed since the last hemorrhage. Many cases are seen in connection with syphilis, cancer, etc., and as an early accompaniment of arteriosclerosis. An interesting case recently was traced to the sudden stoppage through means of operation of a bleeding hemorrhoid which had lasted for a number of years. Some cases of hemorrhage from the larynx have been reported as occurring during epidemics of influenza. We are all familiar with post-operative hemorrhage. I do not recall whether Dr. Rhodes alluded to hemorrhage from the nose, trickling down into the larynx during the hours of sleep, with its origin in the nose. As to syphilis as a cause, while the hemorrhage does not come directly from the larynx, it may trickle from an ulcerative area back of the larynx. I remember reading in THE JOURNAL of two cases reported by Dr. Page of Indianapolis where the blood had trickled into the throat from a syphilitic ulceration; one case was thought to be ulcer of the stomach, and a surgeon operated, but failed to cure the hemorrhage. Further examination showed it to be due to a specific ulceration back of the tongue, and the patient recovered under antisyphilitic treatment. Some cases of hemorrhage may occur underneath the mucous membrane and give no external evidence. Such cases should be regarded as very serious because of the possibility of sudden edema of the larynx and consequent asphyxia. As to treatment, general medication must not be lost sight of; cold compresses are good, with mustard water footbaths. Ergot is not regarded as of very high value in all cases of hemorrhage, and is not to be used in these cases because it contracts the arterioles, and this may lead to disastrous results. Adrenalin is useful.

DR. W. E. CASSELLBERRY, Chicago.—The kernel of the subject is in distinguishing laryngeal hemorrhage from true tubercular, pulmonary hemorrhage. Supplementing Dr. Rhodes' report, I have seen two cases of hemorrhagic extravasation of the vocal cord, both of which were due to abuse of the voice. I have also seen a case of profuse hemorrhage from the larynx in a singer who had hemangioma of the vocal cord. Such angiomatous vessels may be ruptured by energetic use of the voice.

DR. G. V. WOOLLEN, Indianapolis.—It is very necessary to discover the source of the hemorrhage. I wish to call attention to a case illustrative of that point. A gentleman came to me with hemorrhage from the throat. He was badly frightened. On examination, I found at the base of the tongue a traumatism, a slit—anteroposteriorly—the size of a small shirt buttonhole, which had been caused by swallowing something sharp. I assured him that he had no hemorrhage from the lung. He would not believe it, therefore I placed the mirror where he could see the lesion himself, and irritated it with a probe so that it bled. He was the brother of a physician, and I had him and two other physicians see the case. He insisted then and ever afterward that he had pulmonary hemorrhage, and two years later died from pulmonary tuberculosis. At the time we examined his chest carefully and found no evidences of tuberculosis.

DR. D. ROY, Atlanta, Ga.—Have these cases been followed up so that we may know something as to the prognosis, whether tuberculosis is likely to follow as a result of these primary symptoms? I have had cases of severe hemorrhages from the

base of the arytenoid cartilage without the least apparent cause of exertion on part of the patient. One of these patients came up two or three months later for life insurance, but this case has not yet been acted on. I have not seen anything in the literature as to the prognosis in such cases or the attitude the laryngologist should assume when questioned by the agents of such insurance companies.

DR. J. E. RHODES.—My cases have not been followed up long enough to determine, but in reading the abstracts I have made of the cases Dr. Roy will find all there is in the literature on the subject. I have excluded angrisma from the paper in order to avoid complicating the subject. I have tried to confine the discussion to true laryngeal hemorrhage and not to all cases of blood in the larynx. We should be careful in diagnosis to exclude bleeding from the posterior nares and ulceration. I agree that the great importance of the subject lies in the exclusion of pulmonary tuberculosis.

POISONING BY WOOD ALCOHOL.

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS.

FRANK BULLER, M.D.

MONTREAL.

AND

CASEY A. WOOD, M.D.

CHICAGO.

(Concluded from page 1221.)

(A.) PUBLISHED CASES OF WOOD-ALCOHOL POISONING.

The following tables, prepared by Dr. Buller, are practically complete to June, 1904. As previously stated, they furnish characteristic accounts of intoxication from various methylated drinks, as well as from inhalation of the vapor of methyl alcohol. That only two of these cases occurred in Europe points the moral so often urged in these papers; wherever a government permits the sale of "deodorized" wood alcohol (as in the case of Columbian spirits in the United States and standard wood spirits in Canada), the only effective safeguard against the ingestion of the poison is removed and the annual sacrifice to death and blindness will certainly continue. Either the manufacture and sale of "deodorized" wood spirit should be absolutely prohibited, or, as in Germany and Great Britain, an un-taxed ethyl alcohol, rendered undrinkable by the addition of pyroligneous spirit, mineral oil, naphthalin or some other nauseous compound, should be employed in the arts in the place of Columbian spirits and similar dangerous preparations. Either enactment would prevent the use of Columbian spirits and other forms of "deodorized" wood alcohol in the adulteration of Jamaica ginger, lemon extract, bay rum, essence of lemon, whisky, witch hazel, cologne water, and innumerable other alcoholic mixtures now employed in the preparation of food and drink.

That this menace to the health of the community is an ever-present reality is evidenced by the recent death in New York within two days of seventeen persons from drinking whisky adulterated with wood alcohol. Commenting on this tragedy, Dr. H. W. Wiley, chief of the Government Bureau of Chemistry, expressed the opinion that "85 per cent. of the whisky sold in this country, in hotel restaurants, clubs and bars, is nothing less than a cheap imitation—an adulterated article distinctly injurious to the health."

A. METHYL ALCOHOL INTOXICATION. — PUBLISHED CASES.

NO.	REPORTER AND DATE	JOURNAL	AGE	SEX	OCCUPATION AND HABITS OF LIFE	MODE OF OCCURRENCE	PREPARATION AND QUANTITY OF SPIRITS CONSUMED	GENERAL EFFECT	VISUAL DISTURBANCES	RESULTS	REMARKS
1.	Viger and later by Meunier, 1878.	Revue Ophthalmologique, p. 669.	30	M	Washed out a varnish jar with two liters of alcohol and a half liter of the liquid.	As above stated.	An hour later in the evening, vomiting, headache, vomiting, and a sensation of pain and delirium; next day delirium gone.	Completely blind next day and remained so two years later. Improvement to such extent that he could see to get about.	Later on became entirely blind again and two years later, in 1881, he was cured. The optic nerves were not visible; vessels not markedly reduced in size. (Arch. Ophth., Medicale, June, 1877.)	This is said to be the first typical case of blindness from methyl alcohol poisoning reported by Viger in 1878. Medicinally, about fifteen minutes before death the conjunctiva became congested, and very much congested.	
2.	Dr. H. C. Kipp, 1888.	Baltimore Medical Journal.	28	M	Artistic painter; long to do some work occasionally.	At the end of a spree one Sunday, began to take twenty-four hours had taken a considerable quantity.	About a pint; the preparation was said to be 90 per cent pure alcohol and 10 per cent methyl alcohol.	When seen by Dr. Kipp on Aug. 6, eyes protruded widely dilated, pupils were of mild opisthotic position, respiration slow, mucous membrane of the throat, face, neck, headache, nausea and vomiting next day.	Masked by profound general effect.	Died in the course of a few hours from the time when first seen.	About fifteen minutes before death the conjunctiva became congested, and very much congested.
3.	Dr. A. G. Thompson, 1897.	Proc. of Philadelphia Academy of Nat. Sci., 1897, p. 472.	32	M	Sailor.	Drank about 20 ozs. of essence of Jamaica ginger in two days.	Essence of Jamaica ginger, 20 ozs.	Headache, nausea and vomiting next day.	Next day everything looked hazy; blindness complete by sixth day. Vision improved for four weeks and subsequent failure of vision.	Examination 3½ months subsequently showed V= counting fingers at 12 inches; optic nerves excruciatingly pale; lower outer quadrants completely of optic nerves.	Examination 3½ months subsequently showed V= counting fingers at 12 inches; optic nerves excruciatingly pale; lower outer quadrants completely of optic nerves.
4.	Dr. C. MacCoy and P. M. Michael, 1886.	Medical Record, Vol. 21, 1886, p. 472.	21	M	Attendant; habits good.	When convalescing from measles, drank about a quart of Jamaica ginger mixed with water and sugar, and repeated this dose in Christmas week, Dec. 1886.	Columbian spirits with water, 8 ozs.	After the first dose he experienced pleasant effects, and at first night exhibited symptoms of mild opisthotic position, awakening violent emesis and gastric pain.	Twenty-four hours after first dose, pupils widely dilated; vision = 0; double optic neuritis with congested retina.	Perception of light returned after 14 days but 12 months later was totally blind.	In this case the early symptoms were not observed and only imperfectly described.
5.	Dr. Hiram Woods, Jr., Baltimore, Md., Feb., 1899.	Medical Record, Chicago, 1899.	32	M	Bricklayer.	On an oyster boat, with a lot of men who drank Jamaica ginger mixed with water for five or six days, after this mixed with water.	Jamaica ginger, quantity not estimated.	No particular effect until early on Jan. 27, said to have frequent sharp lancinating pains in legs.	First noticed that vision after several hours after shells as they dropped into the water looked like drops of blood; vision then totally blind for four days; four weeks later could see to read.	After several weeks vision began failed on Feb. 7 could not see newspapers; headings; vision improved; optic nerves atrophied; contracted fields; absolute central scotomata.	After several weeks vision began failed on Feb. 7 could not see newspapers; headings; vision improved; optic nerves atrophied; contracted fields; absolute central scotomata.
6.	Dr. Hiram Woods, Jr., Baltimore, Md., 1899.	Medical Record, Chicago, 1899.	38	M	Workman in a mill; coffee drinker; took more gin and rum than usual on Saturdays.	During two days unsatisfactory hard work during a heavy snow, and then drank more gin and rum than usual on Saturdays.	Jamaica ginger mixed with water, also a little alcohol; quantity not known.	On Monday night 17 morphine taken with vomiting, diarrhoea, gastro-intestinal cramps, severe attacks occurred in the last of which "sight went quick as a flash."	After four days of vision returned, several times and then he became unresponsive on awakening Tuesday fully blind; afterwards vision partly returned.	After four days of vision returned, several times and then he became unresponsive on awakening Tuesday fully blind; afterwards vision partly returned.	After four days of vision returned, several times and then he became unresponsive on awakening Tuesday fully blind; afterwards vision partly returned.
7.	Dr. Hiram Woods, Jr., Baltimore, Md., Feb., 1899.	Medical Record, Chicago, 1899.	41	M	Stock breeder; heavy smoker; drank to excess.	Habitual inebriate and heavy smoker; had been in excess since 1895 or less for 3 years; the day before vision failed had taken 3 or 4 half bottles of whiskey besides other stimulants.	Ginger essence and other stimulants or that pint bottles.	On getting up next morning had a severe attack of nausea and vomiting. Sharp pains in the head.	Sudden blindness came on during this attack; vision returned slowly to some extent.	Vision reduced to counting fingers at about six inches; fields each limited to a small central scotomata.	Vision reduced to counting fingers at about six inches; fields each limited to a small central scotomata.
8.	Dr. Hiram Woods, Jr., Baltimore, Md., Feb., 1899.	Medical Record, Chicago, 1899.	50	M	Student in a law office.	In the habit of "going on" these, commencing with whiskey on "topping off" he drank during the week of the occurrence of Jamaica ginger.	As stated above.	No particular effect until four days later seen by Dr. Harlan, then pupils widely dilated, inextinguishable, optic nerves atrophied, optic chiasm and optic trunks prominent.	Five months later optic nerves atrophied, otherwise normal.	Five months later optic nerves atrophied, otherwise normal.	Five months later optic nerves atrophied, otherwise normal.
9.	Dr. Hiram Woods, Jr., Baltimore, Md., Feb., 1899.	Medical Record, Chicago, 1899.	32	M	Physicist; had taken 3 bottles of whiskey.	Drank 3 pints of whiskey on "topping off" with Jamaica ginger, took 6 or 7 bottles (1½ ozs. in each) be-	As stated above.	Next day felt indisposed, vomiting, diarrhoea, and abdominal pains; these continued through most of night.	On Sept. 28, "No light; these becoming clearly atrophic."	On Sept. 28, "No light; these becoming clearly atrophic."	On Sept. 28, "No light; these becoming clearly atrophic."

19.	Dr. R. S. Phillips, Chicago, Dec. 1889.	Ophthalmic Record, Chicago.	36	M	Painter	Shelling some beer vats, 10 days. Shellac mixed with Colophony spirits 87 88 p.c. alcohol, 3 coats applied to each vat. On 5th day, light-headedness, vertigo, slight headache, 18 inches square. Others drank wood alcohol.	Vapor from vats men- tioned above in- flicted on patient, temperature 70° F.	In four days discontinued work on account of nau- sea, dizziness and head- ache.	On 5th day sight was lost; 6th day, totally blind. On 7th day, vision gradually returned until able to go around, two weeks later, sight again failed.	R. E., fingers at three feet; disc bluish tint, vessels normal, constant; L. E., disc white, vessels slightly contracted.	Inhalation only.	
20.	Dr. R. S. Moulton, 1900.	Proc. Medical Assoc. Kansas, 1900, 285-292.	35	M	Painter	Oct. 8, 1897, with 30 or 40 others drank wood alcohol.	About eight ounces of wood alcohol.	Weakness, feeble pulse, no unconsciousness.	Twenty-four hours, sight dim, entirely lost in a few days.	months later condition unchanged; pupils dilated and hard; color perception absent, field contracted with absorption; normal anatomy; R. V. 20; P. 10; optic nerve and retina; arterioles much contracted; L. V. 20; P. 10; slight pinkish hue of papilla.	Recovery of normal vision, no impairment in fields.	At this time, patient sorted to early in this case.
21.	Dr. E. Sturten, Jan. 5, 1901.	Journal of American Medical Association, Chicago.	Adult	M	Not stated.	The drug was taken about noon when he fell asleep and on awakening about blind, was totally blind.	Quantity of consumption not definitely known.	Not stated.	Total blindness in three hours; partial return of vision three hours later; complete recovery in 14 days.			
22.	Dr. H. Harlan, Baltimore, Feb., 1901.	Ophthalmic Record, Chicago.	30	M		A hard drinker; when he could not get whiskey or remedy drank essence of lemon, lemon, etc.; on Saturday drank three bottles of essence of peppermint and one of a bottle of essence of lemon.	Three bottles of essence of peppermint and one of a bottle of essence of lemon.	Unimpaired, sick and stupid on Sunday, eyesight became dim and by evening had complete darkness.	Both neuroretinitis and optic atrophy. Vision was 3,200 in each eye.	After treatment of pilocarpin, strychnia, and later K. I., he became better and then returned to Dr. Harlan's clinic, Dr. V. Hawkins wrote me details of the death of patient, who drank 600 cc of essence of ginger put up by the same firm as Jamaica ginger.	The peppermint was prepared by the same firm as the Jamaica ginger, and the latter was made by Dr. V. Hawkins.	
23.	Dr. H. Harlan, Baltimore, Feb., 1901.	Ophthalmic Record, Chicago.	25	M	Not given.	On election day, Nov. 1, he had taken seven bottles of Jamaica ginger, washed down with beer, and then took seven more.	Fourteen bottles of Jamaica ginger in one day.	Very sick, unconscious for three days; awake, almost blind, and since then vision has been failing.	The optic nerve showed atrophy, a good deal of variation in the vision from day to day.	Little if any improvement in vision when he left hospital; later became entirely blind.	The patient remained in the hospital.	
24.	Dr. Edward Jackson, Denver, Colo., April, 1901.	Medical Times, Denver.	30	M	Colored	Drank a drink or two of wood alcohol.	Unconscious for 48 hours.	Blind in 18 hours, after 26, slight improvement, went to normal in 23 weeks again failed.	Blind in 18 hours, after 26, slight improvement, went to normal in 23 weeks again failed.	Complete blindness.		
25.	Dr. G. E. DeSchweini, Haz. June, 1901.	Ophthalmic Record, Chicago.	30	M	Painter; police-aid and alcohol moderate.	After using wood alcohol varnish for some time we would have dizziness and temporary haziness, but after using for two months continued at varnishing felt sick and chilly, and one unable to work.	Used wood alcohol in the camp and to wash hands and arms after working.	Chilliness and pain in the legs in morning; no headache, nausea and vomiting.	At night unable to see in the gas-light; blind in room; absolute blindness for two weeks; two weeks later could see through glasses, but three weeks more vision failed again.	Complete blindness.		
26.	Dr. Harold Gifford, 1901.	Medical Record, Philadelphia, 81, 308-309.	35	M		On Nov. 23, 1900, took 2 or 3 drinks of spirits, felt terrible, odor of methyl alcohol, also perhaps some the next day.	Quantity uncertain, probably less than one ounce, but the jar from which the spirits were taken was labeled Cologne.	Felt ill that evening and poorly on Nov. 21 and 25.	On the morning of Nov. 26, sight began to fail; on Nov. 28, Dr. Gifford was called, 0. after four days vision began slowly to return.	Recovery of nearly normal vision after two months, though the optic changes and the field was contracted below.	L. eye had shrunken and contracted, been blind many years—once of optic atrophy, but during perfect vision; Dr. Gifford points out why the lesion was contracted in the optic nerves.	

A. METHYL ALCOHOL INTOXICATION.—PUBLISHED CASES—Continued.

NO. REPORTER AND DATE	JOURNAL	AGE	OCCUPATION AND HABITS OF LIFE	MODE OF OCCURRENCE	PREPARATION AND QUANTITY OF SPIRITS CONSUMED	GENERAL EFFECT	VISUAL DISTURBANCES	RESULTS	REMARKS
34. Dr. H. W. Ring, New Haven, Conn., July, 1902.	Trans. Amer. Ophthalmological Society, 1902.	43 F	Housewife	Drank about 1 1/2 of a sweet wine and black coffee, each of a mixture containing about half a pint of each at night and next day took about the same quantity of the mixture.	A mixture, took probably about five ozs. of wood alcohol.	The first night there was nausea and vomiting and intelligence, coma and dilated pupils and with sickening respiration and gradually dilated pupils.	As above stated.	Died the same day.	The nature of this case was not suspected by the attending physician.
35. Dr. H. W. Ring, New Haven, Conn., July, 1902.	Trans. Amer. Ophthalmological Society, 1902.	F	Housewife	Between noon and 7 p. m. drank about 1/2 oz. glasses of a mixture composed of 1/2 oz. of cherry wine, coffee and water, well sweetened.	A mixture; took in all about three ozs. or less of wood alcohol.	Next forenoon was dizzy, nauseated and vomited, cold with clammy perspiration and deep sickening respiration.	General effect too profound to note.	Died at 6 p. m. the same day.	It is likely there was some mistake as to the actual quantity taken by this patient.
36. Dr. H. W. Ring, New Haven, Conn., July, 1902.	Trans. Amer. Ophthalmological Society, 1902.	M	Workman	Drank four glasses of the mixture, well sweetened, and next morning one glass more.	A mixture; took in all about five ozs. of wood alcohol.	Worked till 3 p. m., on that day, then became gradually blind with morning still dizzy, nauseated and vomiting.	Remained totally blind.		
37. Dr. H. W. Ring, New Haven, Conn., July, 1902.	Trans. Amer. Ophthalmological Society, 1902.	M	Workman	Drank 6 or 8 glasses of the same mixture as preceding four cases.	A mixture; took in all about four and one half ozs. of wood alcohol.	Woke heavily that night, awoke at 5 a. m., but could not get up on account of dizziness, vertigo and headache; slept until 1:30 p. m., grew worse; at 4 p. m. vision nearly delirious with partly delirious, with noted tremor, restlessness, faintness, gait unsteady and loss of appetite.	Blurred vision which seems to be growing dimmer.	Recovery partial and pupils complete.	Two other persons partaking in this dose, much to a less extent, became totally blind, but no cerebral symptoms.
38. Dr. E. L. Bell, North Woodstock, N. H., 1902.	Trans. of the New Hampshire Medical Society.	M	Prisoner	As in case No. 40.	Same as case No. 40, though quantity taken less than was taken by those who died.	At 11 days later there was noted tremor, restlessness, faintness, gait unsteady and loss of appetite.	Blurred vision which seems to be growing dimmer.	Recovery partial and pupils complete.	Par. case.
39. Dr. E. L. Bell, North Woodstock, N. H., 1902.	Trans. of the New Hampshire Medical Society.	M	Carpenter	Had at one time been a hard drinker, but had not been on a spree for some time; admitted his case shortly after he was taken a considerable quantity of wood alcohol.	Wood alcohol, quantity unknown.	Intense, agonizing pain, vomiting, delirium, faintness, small pulse, face pale, pupils dilated.	A few hours after he was first seen the vision became dim, all objects looked white to him.	He soon became delirious, then lapsed into coma and died about 10:30 a. m. on the following day.	This patient was seen by Dr. Bell on Aug. 29, 1896, and is therefore one of the first cases known in this country.
40. Dr. E. L. Bell, North Woodstock, N. H., 1902.	Trans. of the New Hampshire Medical Society.	M	Woodman	Drank freely of wood alcohol which had been sent them for "good" when they had ordered some, but some friends to the same.	Wood alcohol, quantity not stated.	Seen on the following day; one was already dead, the other delirious; severe abdominal pain, faintness, gait unsteady, inco-ordination, seen followed by coma and nausea and vomiting in the morning, later in the day headache and feeble movement of the eyes.	Effect too profound to admit of information on this point.	Death in both cases.	
41. Dr. E. L. Bell, North Woodstock, N. H., 1902.	Trans. New Hampshire Medical Society.	M		Drank some of the same stuff as taken by the ones who died; they were seen the same day.	Wood alcohol, quantity not stated.	Nausea and vomiting in the morning, later in the day headache and feeble movement of the eyes.	Dim vision, objects appeared as seen through a thick fog; pupils dilated, vision otherwise normal.	Recovery with some slight defect of vision of a permanent character.	
42. Dr. E. L. Bell, North Woodstock, N. H., 1902.	Trans. New Hampshire Medical Society.	M	Carpenter	Seven convicts obtained in quantity consumed by each, not known.	Columbian spirit; quantity consumed by each, not known.	Next morning at 6 o'clock, fainting at 8 a. m., very rapid, weak pulse, dilated pupils, white tongue, they soon became unconscious.	Masked by violence of general effect.	Two died the same morning, 2 p. m. the following day.	Par. cases

43.	Dr. J. W. Sherer, May 9, 1903.	Philadelphia Medical Journal.	32 M Farmer.	Four persons celebrating anniversary of their marriage, were drinking champagne containing cheap alcohol, water and other materials.	As stated above.	Next day very sick, nausea, headache, sweats, stiffness in limbs, lasting some three days.	Vision began to fail after 2 1/2 hours; absolute scotoma, field of vision what contracted; L. F. P. only, optic nerves dilated to more than normal.	The writer's description of the left vision field is somewhat inconsistent with his statement that it was contracted to more than normal.
44.	Dr. J. W. Sherer, May 9, 1903.	Philadelphia Medical Journal.	M Farmer, probably drunk probably occasionally.	Same as case No. 41, but drank less of the mixture.	Same as case No. 41.	Dizzy, nauseated, headache and vomiting.	Vision became very dim for a few days, then gradually returned to normal. 6/3. L. = 6/12.	Recovery.
45.	Dr. G. E. Barstow, South Manchester, N. H., May, 1903.	Charlotte (N. C.) Medical Journal.	36 M	Drank with four others 18 oz. bottles of lemon extract.	Patron's part of the methylated extract was drunk at 2:30 p. m.	Following night vomiting, headache, vertigo, tinnitus, and general aching about spine.	Eyesight began to fail in 2 1/2 hours; on 3rd day, double shadows; by 10 a. m. emia of retinal veins.	Patient slowly improved in 24 hours; on 5th day several months had been gained most of lost sight; field remained contracted.
46.	Dr. H. H. Main, Barry, Ill., Sept. 5, 1903.	American Medical News, Vol. 10, No. 10.	41 M Watchmaker.	Habitual inebriate, for several successive days being unable to obtain whiskey he had been drinking at a saloon on Feb. 17, sizzit began to fail and he stopped drinking.	Lemon extract, which contained methyl alcohol, quantity consumed had stated.	On Feb. 18, there was frontal headache, nausea, rapid pulse, labored breathing, the eyes were closed and he was restless and scared-looking but his mental faculties were but slightly affected.	Became rapidly worse with intense suffering, lapsed into coma and died in 24 hours. Death was caused by drinking lemon extract.	No ophthalmoscopic examination was made. A post-mortem examination of the lungs was caused by drinking lemon extract.
47.	Dr. M. E. Armstrong, Bridgetown, N. S., Oct., 1903.	Maritime Medical News, Halifax, N. S.	33 M Public-sterling and varnishing.	Living in a Scott (prohibition) town he drank whisky on Sunday and Monday evening between 7 p. m. and 12 he also drank about 7 ozs. of methylated spirits, diluted with water.	About a pint of hay run on each of two succeeding days. He was drunk and retained wood alcohol, h. o. l., finishing up with 7 ozs. of methylated spirits, diluted with water.	Vomiting, and a series of pains, during the evening, slight well, but next morning he was very anxious expression, great general distress, and at 3 p. m. became dull and later comatose.	Dim vision same evening, followed by double shadows; by 10 a. m. total blindness.	When seen by Dr. Armstrong at 1 p. m., the patient's pupils had been contracted in a dilator of spirit and the pulse was about normal, body with a normal temperature. On 11 a. m. patient with a subnormal temperature same as at 10 a. m. at 12 a. m. patient terminated in death.
48.	Dr. M. E. Armstrong, Bridgetown, N. S., Oct. 1903.	Maritime Medical News.	35 M Laborer.	Habitual inebriate after a drinking bout of several days, and by the time he had obtained from a hardware store.	Common methylated spirits, of which he had drunk a bottle with water, between 7 p. m. and midnight.	Before retiring had some vomiting, gastric pain, and next morning still had abdominal pains, which grew rapidly worse, at 1 p. m. the pupils were dilated and quite blind.	Total blindness, 13 hours after last dose of the spirit.	About 5 p. m. became very dull, then comatose, metacare, and died.
49.	Dr. F. Buller, Montreal, June, 1904.	Montreal Medical Journal.	34 F Dress-maker, habits strict, temperate.	Took by mistake Feb. 1902 a quantity of medicine used as a liniment for rheumatism, just after a vapor-bath.	About a wine glass = 3 or 4 ozs. of methyl alcohol containing wintergreen, introduced for external use only.	Some dull, next morning asleep and at the end of two hours awoke feeling very ill, with intense headache and quite blind.	Total blindness, lasted about two weeks then vision slowly returned to present condition.	Counts fingers at three feet, each eye, fields small, absolute scotomata, double shadows, metacare, by treatment except that peripheral field enlarged, showing effects from a single moderate dose; it is not likely to be regained in wintergreen increased the toxic effect of the alcohol.
50.	Dr. F. Buller, Montreal, June, 1904.	Montreal Medical Journal.	30 M Barber, always temperate.	Took by mistake on the 1903 a dose from a bottle which he supposed to be a simple tonic he had used at times for indigestion.	A wine glass of methylated spirits, perhaps 3 or 4 ozs.	None till next morning, then some dizziness, so that he could not see to do his work, was told he looked ill.	Varied for several days, became total blindness for 8 days; great improvement of 4 days about middle of April, but he could not work, then failed again.	Counts fingers at 3 feet, L. V. = fingers at 3 feet, field consisted of 4 small spots, the condition was permanent when some months later.

NO. REPORTER AND DATE	JOVENAL	SEX	OCCUPATION AND HABITS OF LIFE	MODE OF OCCURRENCE	PREPARATION AND QUANTITY OF SPIRITS CONSUMED	GENERAL EFFECT	VISCERAL DISTURBANCES	RESULTS	REMARKS
51. Dr. F. Bailew, Montreal, Jan. 1901.	42 M	M	Carpenter, habitually temperate.	Took a small wine glass of what was supposed to be ordinary apple brandy in the morning and evening for several days, and on the 8th, three glasses in all.	Beyond the statement that it contained methyl alcohol, no other facts are wanted.	No ill effects until Monday, Nov. 15, V. = fingers gradually improved under active treatment; at 2 foot each eye, pupils rather dilated and sluggish. On Dec. 7, V. = 2 in. On Dec. 22, V. = 2 in. fields narrowed, fundus crossed, dimness, a mild spasmodic headache; on Tuesday awoke entirely blind.	After several days of blindness, on the 11th morning outduly blind.	Gradually improved under active treatment; at 2 foot each eye, pupils rather dilated and sluggish. On Dec. 7, V. = 2 in. On Dec. 22, V. = 2 in. fields narrowed, fundus crossed, dimness, a mild spasmodic headache; on Tuesday awoke entirely blind.	A pure case showing effects of a moderate quantity of methyl alcohol on a healthy and temperate man; in chronic toxic, visual fields contracted, vision R. 6/15, L. 6/27. On Dec. 22, V. = 2 in. blindness came on, showed no changes; visual fields rather dilated.
52. Dr. W. E. Brewer, Cleveland, O., Feb. 1901.	47 M	M	Labourer.	After a seven days' spree with some strange liquor, he awoke on the 8th, with a white eye, called wood alcohol.	The wood alcohol was that used for burning in an alcohol lamp. He had consumed a pint of spirits was drunk a divided dose of some wood alcohol.	Prostration and vomiting; after several days with blurred vision.	After several days of blindness, on the 11th morning outduly blind.	At end of 49 months, R. = 20, V. = 2 in. nerves highly atrophic, visual fields rather small, visual fields much reduced.	Seen by Dr. Foucher some months after the accident, as he is said to have come to Montreal.
53. Dr. Foucher, Montreal, March, 1901.	22 M	M	Labourer.	Admitted to alcohol and tobacco; during a morning, presumably for the first time, drank a divided dose of some wood alcohol.	He then began to have nausea and dimness of vision. There was vomiting, headache and some vertigo.	At 2 p.m. could no longer stand, at 5 was found lying on the floor during the night awoke with nausea and vomiting in the morning was prostrated by action.	"Half blind" the day after taking the alcohol.	Seen by Dr. Foucher some months after the accident, as he is said to have come to Montreal.	
54. Dr. W. H. Wilder, Chicago, May 10, 1901.	33 M	M	China Doctor.	On Dec. 21, 1903, drank some of the methyl alcohol used in his work of drying colors.	About a pint of methyl alcohol between 8 a. m. and noon.	He then began to have nausea and dimness of vision. There was vomiting, headache and some vertigo.	By 6 p.m. he was seen by a physician and then was blind, fingers were numb, pupils dilated, on the morning, totally blind remained so 14 days; recovered in two weeks or more.	At end of two and a half months, R. = 20, V. = 2 in. nerves highly atrophic, visual fields rather small, visual fields much reduced.	At end of two and a half months, R. = 20, V. = 2 in. nerves highly atrophic, visual fields rather small, visual fields much reduced.

DEVIATIONS OF THE NASAL SEPTUM.
A REVIEW OF ONE HUNDRED OPERATIONS FOR CORRECTION.*

JOSEPH S. GIBB, M.D.

Professor of Laryngology, Philadelphia Polyclinic, PHILADELPHIA.

The 100 cases which form the basis for the observations on septal deviations have been selected from the case books of both hospital and private work.

Each case was one of more or less marked deviation. Care has been taken not to include in this list mere cartilaginous or osseous spurs, so that those cases tabulated under the head of "Spurs" represent cases in which these outgrowths were removed because it was thought that the physiologic function of the nasal chambers could be restored without recourse to the more formidable operative procedures.

In tabulating the result of the operations, a good result is noted when the object sought has been attained and does not mean that in each case recorded as "good" a perfectly straight septum has been secured, nor that each case has been entirely uneventful in its course.

Cases classified as "fair" were those which could not be considered successful either from an artistic or functional standpoint, but in which better breathing space and more comfort to the patient was secured.

The cases of failure require no comment, except to make an attempt to explain the cause.

In 100 cases there were 65 in which the Asch operation was resorted to—of these, in 47 the result is noted good. In 11 it was fair, 3 were failures and 3 failed to report after the operation, and the subsequent history is unknown.

In one case the Asch operation resulted in failure, but it was subsequently successfully corrected by a modified Watson-Gleason operation.

Taking these 65 cases of Asch operation, it is noted there were 48 in which the cartilaginous septum alone was deflected, and in these the Asch method was the sole operative measure employed. In the other 17 cases there were deviations of both osseous and cartilaginous portions of the septum with other complications such as synechiae, bands of cicatricial tissue, dislocation of the columar cartilage, etc., in which supplementary operative measures were employed. In most of these complicated cases, spurs were removed by the saw either at the time or subsequent to the operation. In 5 of the mixed cartilaginous and osseous deviations the Asch alone was performed.

Of the 48 uncomplicated cartilaginous deviations in which the Asch was done, in 37 a good result is recorded; in 6 the result was fair, while 3 failed to report, and the ultimate result is unknown.

Taking up the 17 complicated cases (mixed cartilaginous and osseous deviations): In 5 the Asch operation was relied on to correct the difficulty—of these 2 were only fairly successful, the other 3 were failures, one of these latter was subsequently successfully corrected by a modified Gleason-Watson operation.

Of the remaining 12 cases of this group, spurs, both cartilaginous and osseous, were removed either at the time or subsequent to the operation, and of these 11 were successful and 1 was fairly successful.

In 23 of the 100 cases the deviated septum was corrected by the Watson-Gleason method, supplemented

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

and modified to meet the exigencies of the case. Of these 23 cases, in 9 the deviation involved only the cartilaginous septum. The reason this operation was selected as the proper one, was that in each instance a condition existed making the Asch operation inadvisable. In most of the cases, the deviation was so pronounced as to entirely block the nasal chamber, making it impossible to introduce the Asch instruments. Fourteen of the cases were well marked examples of cartilago-osseous deviations, which experience had taught were not well adapted for correction by the Asch method.

Of the 9 cartilaginous deviations in 8 the result was good, in 1 it was fair.

Of the 14 mixed (cartilago-osseous) in 11 the result was good; 2 fair, and in 1 the result is unknown.

Many of the complicated deviations presented conditions which made adherence to the strict lines of the Watson-Gleason operation inadvisable. For instance: In 4 cases it was necessary to remove large bony spurs before any operation could hope to be successful. In 2 others a dislocated columnar cartilage was excised before the operation was feasible—and in 1 case, masses of cicatricial tissue and a synechia were dissected out before attempting the operation.

The last group of 12 cases were those in which a careful study of the case made it seem possible to correct the physiologic disturbance by removing a mass of redundant cartilaginous or osseous tissue, or both. In all of these, the result justifies the measure adopted, for in each case good breathing space was secured and the subjective symptoms resulting from the obstruction were relieved.

In one case only of this group was any untoward symptom or sequela presented. In this case an attack of influenza seemed to be responsible for a septic attack, during which healing was retarded, and a large perforation resulted. The ultimate result, however, was all that could be desired.

In the 100 cases here tabulated, perforations occurred in 5. Four of these were after the Asch and 1 in which a spur was removed. The fact that no perforations resulted in the group of 23 cases in which the Watson-Gleason method was used, does not indicate that they are less likely to occur after this than other methods for correction. It is merely a fortunate circumstance. In other years and with other groups of cases, I have had perforations after this method in about the same proportion as in others.

SUMMARY OF CASES.

The total number of Asch operations was 65; Watson-Gleason operations, 23; number of spurs removed, 12.

The number of Asch operations in which the result was good was 47; fair results, 11, and 3 cases were failures.

One case which resulted in failure by the Asch operation was subsequently successfully treated by the Watson-Gleason operation.

The number of Watson-Gleason operations in which the result was good was 19; fair results were obtained in 3 cases, and in one case the result was unknown.

Good results were obtained in all the spur operations.

CONCLUSIONS.

The conclusions reached from a careful study of these and other cases are:

1. There is no single operation suitable for all cases of deflection of the nasal septum.

2. Each case should be a study unto itself and the

judgment of the surgeon must determine the operative measure best suited to that particular case.

3. The Asch operation is eminently satisfactory in the large number of cases in which the cartilaginous septum is alone deflected.

4. Osseous deviation and cartilago-osseous deviations are not suitable for correction by the Asch method.

5. Deviations of both the cartilaginous and osseous septum offer the most difficult problem to solve, and no one operation meets every indication, but in many cases the Watson-Gleason operation, modified to suit the case, offers a good chance for success.

6. Careful observation will discover a fair proportion of cases in which the removal of spurs either cartilaginous or bony, or both, will accomplish the best result; and it is more desirable to attain the result by this method than by the more formidable division of the septum.

7. There are a certain number of cases which must be classed as inoperable.

8. Perforations occur in about the same number of cases in all operations in which an entire division of the tissues of the septum is effected.

REMARKS ON SEPTAL OPERATIONS.

Operations for the correction of deviated septa are undertaken for the purpose of restoring lost or diminished function to the nasal chamber. The disturbance of function is made manifest to the patient by difficulty or impossibility of nasal respiration, necessitating mouth breathing, with all the ills this latter condition entails. Among the lesser, though by no means unimportant, effect of deviated septa there may be interference with excretory ducts, e.g., the nasal duct and the orifices of the accessory sinuses, and pressure neuroses. Any one of these conditions justifies an attempt to relieve by correction of the deviated septum. On the other hand, the correction of a deviated septum in a case in which there are no disturbing symptoms, is open to criticism.

Septal deviations, except in recent cases, are rarely sharply defined; we find associated with the septal irregularity thickening of the tissues—cartilaginous, in those cases in which the cartilage alone is involved; bony, in those in which the bone is also deflected, so that we have in each case a septum pushed out of line, plus a redundancy of tissue composed of either cartilage or bone, depending on the portion of the septum involved. This redundancy of tissue is not confined to the nasal chamber toward which the septum is deflected—not infrequently the concavity is found filled with these thickened masses.

These, then, are the difficulties to be overcome in the operation for the correction of the trouble, and that operation will be most successful which overcomes these difficulties. It is of more importance to carefully study a case on these lines than to enter into an elaborate description of the character of a deviation as to its position in the nasal chamber. It matters little whether a deflection is along the horizontal or vertical axis or is sigmoid in its shape so long as we have a proper appreciation of the amount of deviation, and the concurrent thickening. Each case should be studied in itself and both nasal chambers should be thoroughly investigated, the extent of the deviation noted, and the amount of thickened tissue comprised within the deviated area carefully estimated.

It is apparent from the complicated nature of the

difficulties to be overcome, that no one operation will meet every indication in the correction of a deviated septum. With a careful study of each case, we are in a position to decide which operation or combination of operative procedures will meet the indications in the case before us.

The more simple the operation, the less damage done to the nasal tissues, the better the result, and the less discomfort to the patient. If our study leads us to the belief that by paring off here and there, we may obtain sufficient room to restore the function of the nasal chamber, and to take off pressure on sensitive areas, there seems no good reason to do the more formidable, lengthy and painful operation, or to be more explicit.

If in a given case the removal of an exostosis or eehondrosis gives sufficient space in the nasal chamber to ensure good respiration, and take off pressure, the accurate replacement of a septum to a straight line becomes an unnecessary, not to say painful, refinement.

The early methods employed for the correction of deviated septa had for their object the one idea of making the septum movable at its base, thus enabling the operator to push it over to the position he desired.

The Roberts operation consisted of an incision along the line of the greatest convexity; the septum was then pushed over to the desired position and a pin introduced through the tissues externally held the septum in the corrected position.

The Steele operation aimed to break up the septum at its base, thus making it movable, by means of specially designed punch forceps—after correction the septum was retained by means similar to that of Roberts. While these operations were successful in a certain proportion of cases, they failed in a much larger number because knowledge of the conditions to be overcome in the early days of rhinology was not well understood.

In the modern operations, the thought of the designer of an operation has been to provide both for the correction of the deviation and the redundancy of the tissues.

Of all the modern methods, the Asch operation has been in my hands the most satisfactory for the correction of purely cartilaginous deviations. The cases which would seem to make an exception are those in which the deviation is so pronounced as to leave no space for the introduction of instruments between the septum and the outer wall of the nasal chamber, but even in such, it is in many cases a simple matter to make an incision underneath the most prominent portion, and push the septum over sufficiently to give space for the forceps. However, as many of the cases of pronounced cartilaginous deviation are associated with osseous deformity, and as will be seen later, the Asch operation is not deemed suitable for such, it would seem better to employ some other method in these.

The advantages of the Asch in the class of cases to which reference has been made, is its simplicity and the rapidity with which it may be accomplished. The results may not be better than other methods, but they are generally good and it is easy of execution.

The use of splints causes some annoyance, it is true, but usually this lasts but a few days, and the sense of comfort which they give to the surgeon as to the permanency of the correction more than counterbalances the discomfort.

In most of my cases this operation has been done under cocaine anesthesia. Previous to the adoption of the Asch operation I had been accustomed to perform these septal operations under cocaine.

The Roberts, the Steele, and later the operation which has since become known as the Watson or Gleason operation were all done many times without the use of general anesthetics, and in the main were accomplished with ease and without severe distress to the patient. The Asch operation is, in my judgment, a much less formidable one than any of those enumerated and accomplished in a much shorter space of time. It is for these reasons I have never felt that it was necessary to change the general plan to which I had been accustomed in the management of these septal operations.

The Asch operation, while leaving little to be desired in simple cartilaginous deviations, can not be relied on alone in those cases in which there is great thickening of the deviated portion of the septum. In such it becomes necessary either to remove these thickenings prior to the operation, or at a subsequent period.

With the purely osseous or the cartilaginno-osseous deviations, the case is different. In these the Asch operation has in my hands not been successful and for such we must turn our attention to some other method.

Fortunately we have in the operation known variously as the Watson or the Gleason operation, one that is admirably suited for such cases. This method of correction aims to provide for the redundancy by forcing the thickened portions through the incisions in the septum over to the roomy nasal chamber from whence it may be subsequently removed should it be deemed necessary.

Of course, this same operation gives very excellent results in the purely cartilaginous deviations, but the Asch is preferred for reasons already given.

The Watson-Gleason operation, however, does not adequately provide for every osseous or cartilaginno-osseous deviation. There are cases in which the osseous thickenings are so great or the position they occupy in the nasal chamber such that they can not be included within the deviated flap which is thrust through the septal incision. In these, however, the removal may be accomplished by the saw, either prior or subsequent to the operation for correction.

One or the other of these operative procedures, with modifications and supplementary operations to suit the needs of the case, with the selection of certain appropriate cases for the removal of spurs as the sole method of correction, will meet, in my judgment, all indications in any operable case of deviation of the nasal septum.

A number of operations have been designed, one purpose of which is to preserve the mucous membrane of the septum. Some of these aim merely to preserve the membrane on the opposite side to the deviation; others are planned to save that on both sides of the septum.

Theoretically, the preservation of the mucous membrane of the septum with its rich blood supply is to be desired. Practically, however, few cases of deviated septa are observed in which the mucous membrane may be separated from the underlying cartilage save by tedious and prolonged dissection, and in the osseous portion of the septum, the anatomic position of the part with the limited amount of workable space renders such dissection practically impossible; but even if it should be possible to make a clean dissection, it is a question whether the benefit derived therefrom compensates for the tedious operation with its attendant fatigue to both operator and patient.

For a number of years I have ceased the attempt to preserve the mucous membrane of the septum on either side, and from the reports of operations so performed

as compared with my own in the matter of perforations, tardy healing and other postoperative embarrassments, I have seen no reasons to regret the step.

Krieg, Boennighaus, Krebs, and more recently Hajek, in Europe, and almost simultaneously Freer in this country, have described and warmly recommended what is known as the "window resection." In this operation the mucous membrane is dissected from the deviated portion of the septum and that portion of the septum which is included in the deviation is entirely removed, the mucous membrane alone remaining in the place formerly occupied by the cartilage. It is stated that ultimately the space resected becomes the seat of a thick fibrous tissue.

Hajek states that in 35 of the 100 cases in which this operation was performed, and which he was able to follow for from one to two years, the results were uniformly good, and that similar good results are not obtained by any of the usual methods. He further says: "I ought, it is true, to add at once that the method is complicated, technically difficult and of long duration (half an hour to one and a half hours), and that it requires much patience on the part of the patient and operator. For this reason the value of the method must not be gauged by the results of the first few cases on which anyone may operate, as quiet and circumspect working is only acquired after some time. To the difficulty just named the disadvantage was added of a large wounded surface on the convexity being left until cicatrization had taken place, and not rarely even afterwards formation of crusts becomes an increased source of subjective troubles for the patient. One could not help feeling sometimes that the price which the patient had to pay, in order to obtain in course of time a free passage through the nose, was rather too costly."

An endorsement of this sort from so high an authority and expert rhinologist as Hajek will not tend to popularize this operation; indeed, while so difficult and tedious an operation is a testimony of the technical skill of the operator it is for this reason not likely to be popular because few possess such skill; more than this, however, there are but a limited number of patients knowing the nature of the operation beforehand would be willing to undertake it to obtain, as Hajek observes, "a free passage through the nose."

American rhinologists must certainly take exception to the statement of Hajek's, that results are obtained by the window resection operation, not possible by other methods.

Operations designed by American rhinologists are little known abroad. In a noteworthy discussion on intranasal operations held during last winter before the London Laryngological Society, at which many of the most distinguished laryngologists of Great Britain were present, much was said of the French, German and English operations and little of the American.

The Asch operation was the only one even mentioned, and but one speaker made any claims to having practiced it, and this in only a few cases.

In an editorial in the *Journal of Laryngology* of January, 1904, devoted to the above meeting of the London Laryngological Society, the editor says: "The question of the preparation and after treatment in cases of intranasal operations is one to which no experienced rhinologist will refuse his earnest attention. To many such, it must be astounding to read the recommendations of energetic surgical treatment in the interior of this organ found in various articles, and notably those issuing on the other side of the Atlantic.

"There may be climatic conditions or other circumstances leading to immunity from postoperative embarrassments on which the practitioners in these islands cannot depend. None will deny that the noses with which we have here to deal, decline in many cases to recover from the operative interference in the kindly way to which many of our Transatlantic colleagues seem to be accustomed."

Passing by the sarcasm which is contained in this editorial, in the reference to American intranasal operations, it is evident from the editorial and the comments brought out in the above mentioned discussion, that the British rhinologist has many difficulties attending the postoperative period of his intranasal operations. It is also evident that methods introduced by American rhinologists have very little place.

No American rhinologist can truthfully say that all his intranasal surgical measures have an uneventful postoperative period, but we do not often see such distressing results as many of our London colleagues picture.

Almost every village in this land has a rhinologist who will show you good results from an Asch, a Watson, a Gleason or many other operations, and these are obtained for the most part without the horrible picture of septic complications and other disturbances which the editor draws. Nor is it necessary to invoke the aid of climate, for this vast land provides most any kind of climate.

As to "energetic surgery," can any of our American operations vie in energy with those of Krieg, Boennighaus, Hajek or Moure, and yet these are the operations that received most favorable mention at the London Laryngological Society.

With the many devices for the correction of deviated septa at our command, there are few cases which may not be relieved by one or the other method or combination of methods. Still there are cases in which it were better to stay our hand, and a few which may be called inoperable. Notably those in which syphilis or previous operative interference have left large cicatricial masses in each nasal chamber possibly coupled with a crumpled and crushed septum.

We have all seen these cases and some of us perhaps have learned from experience the wisdom of abstinence from active interference.

DISCUSSION.

DR. R. C. MYLES, New York City.—There is some lack of comprehension in many minds as to the methods pursued by different operators. I have had experience with each of the different methods and have seen failures resulting from the work of each of these men themselves. Asch insisted that the bony septum had nothing to do with this operation, and yet constant reference is made to the bony septum in speaking of the Asch operation. It may be that someone has since modified it in that particular. For the general surgeon, no other operation is equal to it, but while in some cases it may be our duty to do this operation, there are other methods which are better. The physician should ask himself whether he would personally submit to this operation. As to the triangular cartilage, that is a different proposition. In some cases it is better to take off part of the outgrowth and a little of the outer wall, and this I do in many of my cases. I find that is much better than extensive breaking up of the septum. As to the Watson-Gleason operation, it is excellent if the case is a suitable one, but if the septum is thin it is not applicable. The septum is not stiff enough to hold in position and some other operation will be found better. Perforation is one of the most serious propositions we encounter. They do not bother the

operation much because he does not see them. The anterior perforations are the only ones which give any trouble. I have seen them extend all the way from the sphenoid to the end of the septum.

DR. EMIL MAYER, New York City—The Asch operation deals only with the cartilaginous septum, and all the writings of Asch and also my own distinctly state that the cartilaginous septum is to be thus treated. The results obtained by Dr. Gibb in treating the cartilaginous deviations by the Asch operation are certainly very gratifying. I have no hesitation in indorsing that method to its fullest extent, and believe that for simplicity, rapidity of performance and ultimate results, it is the best method yet devised. No one method is good for all cases and no one should be welded to a single procedure. The operation is certainly best done under general anesthesia, and I recall a case that delayed operation for over a year because of the unwillingness of the patient to undergo the anesthesia. He finally consented to take ether, and was very grateful to me after for my insistence. The incisions should go through from the deflected side, and the segments broken through with the finger; the straightening forceps should not be twisted about but introduced in place, tightly closed, and held with all the firmness possible, but without rotary motion. Regarding the tubes, there is some complaint that the tubes irritate the tip of the nose and also that granulations form. Others favor the non-removal of the tube for a fortnight after operation. We are all ingenious enough to devise instruments to fit unusual conditions; why not fit the tubes to our patients? I can show tubes of all manner of shapes that have been fitted to various patients, and a perfectly fitting tube can not produce ulceration. Granulations are readily swept away. I remove the tube daily and I have fewer perforations than those who do not, and materially reduce the length of time of wearing the tube. Seven years ago I operated on a child of five years for deviation, doing an Asch operation. The septum was straight and a slight linear perforation resulted. Three months ago he fell on some stones, there was great ecchymosis and on its subsidence a deviation as bad as ever existed. I did here the Watson-Gleason operation, using the perforation for the posterior incision with most gratifying results. In conclusion I wish to reiterate that it behooves us to select such a method as will be best suited to the individual case.

DR. GEORGE L. RICHARDS, Fall River, Mass.—I would urge one operation which seems to me simpler, and, in many cases, better than the Asch operation or any of its modifications. Much of the difficulty in after-treatment arises from the fact that it is hard to keep the inferior segments in place. I make a horizontal incision on the convex side the full length of the convexity, cutting obliquely from below upwards and going clear through into the opposite nostril. Enough of the cartilage of the lower segment is then dissected out in the same manner as in the submucous operation to take care of the redundancy which occurs when the septum is brought into the vertical position. In order to maintain the lower segment in position the nasal saw is then taken and the lower segment sawed almost through at its base at the very floor of the nose. With the finger it is then easily straightened so as to be brought into the vertical position and in direct contact with the upper fragment. A loose-fitting hollow splint is maintained in position for a number of days until complete union in the new position has taken place. This operation can be done under cocaine and will result in a straight open nostril. It is limited entirely to operations on the cartilaginous septum.

DR. L. E. WHITE, Boston—I differ with Dr. Gibb, for I think there is one method of correcting all deviations. I have never seen one that I was not willing to attempt. The ordinary cartilaginous conditions in the anterior part are easily corrected by the resection method. The objection that it takes too long does not apply to these cases, for it can be done under cocaine anesthesia with the patient in the recumbent posture. In looking over my records I find that I have done 33 with the saw, 10 by the Watson-Gleason method and 5 Asch operations.

I have now abandoned all these and adopted the window resection method, of which I have done 27. The results following the last named are better than in all the others. It is true that I have had three perforations out of these 27, but they occurred in my first eight cases. I have had no perforations in the last 19. So I think these three were due to inexperience, the lack of proper instruments, and in one case to either pressure of the gauze or too much adrenalin, which caused sloughing. This operation is more accurate, since it is done under the eye and every part of the deflection can be seen as it is removed. We have a higher standard in window resection work, for we do not call a result good unless we get the septum in the median line. Splints do not have to be worn. They are a great source of annoyance to the patient. There is greater rapidity of recovery. The mucous membrane is frequently smooth at the end of three weeks, while the other methods require five or six. The patient can go to work two days after this method has been employed. There is also lack of pain, due to absence of traumatism and greater freedom from sepsis.

DR. W. S. ANDERSON, Detroit—I speak in favor of the window resection method. I have done the other operations a number of times, but feel that the window resection method is the most satisfactory. In my experience, cartilaginous deviations alone are not very common. My cases usually have some bony deviation as well, and the resection operation seems to give the best results. It takes longer to do the operation, but the shorter after-treatment compensates for this. Another advantage is that it can be done under cocaine. Patients are not confined to their bed or room and the after-treatment is such that a business man does not have to be away from his business more than a day or two. The operation on the cartilaginous septum alone can be done quickly, but the bony part takes a longer time. I have had a few perforations, but they were all in my earlier cases. I do not believe we can practice any operation without an occasional perforation.

DR. OTTO T. FREER, Chicago—I continue to correct all varieties of deflections of the nasal septum by the window resection or submucous method, for the principle of that operation, the absolute removal of the bent cartilage or bone, unlike the fracturing methods, makes complete and lasting relief from the nasal obstruction a positive certainty, no matter what be the size, shape or position of the deviation. The window resection needs no longer either defense or advocates. It needs, however, to be saved from such of its friends as are attempting to do the operation with an imperfect conception of its character and crude instruments; imperfect results due to work of this kind will injure its popularity. Both from publications and personal communications I have found that the idea prevails that the mucoperichondrium or mucoperiosteum covering the deviation should be pushed back by blunt or chisel-like instruments, much as the skin and periosteum are scraped off from the mastoid process. This notion is incorrect. The soft cartilage does not offer a good surface for scraping and, in addition, in almost every case, the mucoperichondrium, over the anterior one-third to three-fourths of the area of the cartilaginous deviation on both sides, is so firmly grown on to the cartilage that only sharp dissection with keen, thin-bladed knives of proper shape makes the separation of the mucous membrane from its attachment possible. Back of the vertical summit of the deflection on the convex side and above and behind the deepest hollow on the concave one the mucosa may usually be undermined, not pushed off, with dulled thin-bladed instruments; thicker chisel-shaped ones are not at all suited to the purpose. The multiplicity of my instruments for dissection has been criticised. The reason for their number is the necessity for many little blades attached at various angles to dissect parallel to the many planes offered by different deviations. In addition the knives must be suited to cut deep in the naris or far in front; some must be rounded and sharp on their front ends for places where the side of the blade can not be used; some blades must be dull and others have a razor edge. All these qualities necessarily multiply the instruments somewhat, but, their number enables the operator to always find the knife to

dissect most readily in a given place. All the blades were designed gradually as successive operations showed the need of peculiar shapes. In the average case not more than perhaps eight different blades will be used, but the odd ones will fill a need at some time. The shank and handle of the knives should be in a straight line. If they form a so-called nasal angle the sense of direction of the hand is interfered with and its motions are made complicated. The little cartilage knives are very important as they enable the operator to remove the entire cartilaginous deflection in one piece in most cases, thus saving a great deal of time and reducing the time of operation in cartilaginous deflections often to but thirty minutes. For forceps I still prefer the Grünwald punch. It reaches to the back of the nares and is not so large that it interferes with exact vision. A forceps that does not reach to the posterior border of the vomer in a large man is too short for use. The use of the chisel I confine to the base of the septum since Dr. Christian R. Holmes, at the Saratoga session in 1902, spoke warningly of its employment on the higher parts of the septum on account of the danger of shattering the delicate bone and creating far-reaching fissures. I operate now on all cases with the patient recumbent on a high operating chair. This avoids the faintness that often overcomes him when sitting, puts him at ease and the operator has more freedom of motion when he stands beside his patient than when he is sitting. To trim off remains of the deviation along the base of the septum I have the patient sit in a chair for a few minutes at the end of the operation. As a substitute for the expensive Kirschstein light a 50-candle power, pigtail filament, stereopticon, incandescent, Edison light, attached to a stand, may be used for reflection with the head mirror.

Dr. E. E. FOSTER, New Bedford, Mass.—The resection of the nasal septum mentioned by Dr. Gibb has not received in our country the proper amount of consideration and trial that it deserves. The Germans have for a long time resected the septum with much better results than we obtain from the Asch, the Gleason or any of the modifications of these or similar methods. Freer and White have been resecting the septum for the past two or three years and report good results. Their mucous incisions, however, are made in such a way that retraction, curling, perforations and granulations are more apt to occur than in the more simple operation of Killian, Jansen, Menzel, et al. Their operations are also complicated with many specially devised instruments. The submucous resection of the septum as done by Professor Killian consists of one straight incision through the mucous membrane over the cartilaginous part of the septum, about three-quarters of an inch long and nearly at right angles with the floor of the nose. The perichondrium and periosteum of this side of the septum are elevated from that part of the septum to be removed; then an incision is made through the cartilage, in line with the first mucous incision, to the perichondrium of the opposite side. Through this last incision the opposite mucous surface can easily be elevated from the septum. The two mucous surfaces thus elevated are separated with a long Killian speculum, leaving the cartilage between the blades. The septum can now be removed with scissors, Hartmann's concho-tome or Jansen-Middleton's forceps. In a few cases a chisel may be used to remove the lower part of the vomer, but should not be used until the overlying bone has been removed. The mucous incision can easily be closed with one or more sutures, but as a usual thing they are not required. The inferior meati are loosely packed with cotton, to be removed on the following day. I saw a large number of patients in Killian's clinic on whom this operation had been performed. All had a straight, smooth septum. In many of the older cases the septum was firm, there being a re-formation between the two mucous layers. I did not see a deformity of the nose as a result of the operation. The Killian long speculum and the elevator are the only instruments required that are not contained in a laryngologist's armamentarium.

Dr. H. H. BRIGGS, Asheville, N. C.—I have had experience with 11 cases of resection operation. The first two were done with the instruments used in ordinary nasal work, and

were successful in restoring the function of the nostril except that perforations resulted, one 3 mm. by 6 mm. and the other nearly twice as large. The remaining cases were done with the Freer instruments devised especially for the resection operation, and the results have been very gratifying. I have had some difficulty in maintaining the flaps in place, but have overcome this in the last few cases by inserting a suture through the corners of the flaps and through the mucous membrane immediately below, after which the packing can be done without fear that the flaps may be misplaced. I consider the resection operation the preferable one in the great majority of deflections. It is tedious and requires much time and patience, but you are amply repaid for this in the end.

Dr. KASPAR FISCHER, San Francisco—In all intranasal operations in which splints are not necessary we have to decide whether we should pack the nose or not. If we do not pack the nose we are liable to be called out at any time of the night on account of a secondary hemorrhage; if we do pack, the patient may pass a sleepless night from the discomfort of the packing. I would like to draw your attention to my method of using collodium as a dressing after nose operations, published in the *Archives of Otolaryngology*, 1902.

Dr. JOSEPH S. GIBB—I am glad that Dr. Myles and Dr. Mayer are, in the main, in accord with my views as to the indications for both the Asch operation and the Watson-Gleason. I fully coincide with Dr. Myles in that the Watson-Gleason does not meet every indication in bony deviations, and that it is necessary, in some cases, to do supplementary operative work. Dr. Mayer has given me too high a number of good results in the Asch when he states there were 47 cures in 48 cases. The figures were 47 cases in which the result was good, 11 in which the result was fair, and 3 failures. I have not followed the practice of Dr. Mayer to use general anesthesia in the Asch operation. Nearly all the cases reported were done under local anesthesia. This, I presume, is a matter of custom. I have been accustomed, for years past, of employing only local anesthetics in all the various methods for the correction of deviated septa, so that when I began to do the Asch, a much less formidable operation than many of its predecessors, I could see no reason to change my method. In the main the results have been good, and I never use general anesthesia in these operations unless requested by the patient. In reply to Drs. White, Anderson, Foster and Freer, who have spoken so favorably of the "window resection" method, I would say that the time limit did not permit me to reach this part of my subject, and that I have little to add to what is said in the body of the paper. While I have had little experience with this method, I still believe, as stated in the conclusions, that it will not meet every case. I am sure there are cases of marked cartilaginous and osseous deviations in narrow nares, complicated, as is so often the case, by largely hypertrophied turbinates, in which the mucous membrane is so "thinned out" over the deviated portion as to make anything like a clean dissection absolutely impossible.

TUBERCULAR LARYNGITIS; PROGNOSIS AND TREATMENT.*

THOMAS J. GALLAHER, A.M., M.D.
DENVER, COLO.

In considering the prognosis of tubercular laryngitis it is my desire to do so under three heads:

1. In regard to local lesions.
2. In regard to restoration of function.
3. In regard to life.

Irrespective of the character of the local lesions it is impossible to give an abstract prognosis concerning them.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

Most careful consideration must be given the pulmonary and general condition of the patient. With extensive and rapidly breaking down pulmonary areas the reparative process in the larynx may be *nil*, as it is in other parts of the body. With slight pulmonary involvement, general condition good, the prognosis is more favorable. Laryngeal manifestations seldom improve under any treatment unless the pulmonary and general conditions improve.

With increased activity of the pulmonary disease, further infection of the larynx is likely to occur through the lymphatics and vessels or by direct infection of the bacilli in the sputum; or, again, the laryngeal disease progresses owing to the general resistance being diminished. We must consider the location of the lesion, area and depth of the infection, and also if many distinct places are involved. If the entire larynx is affected, including the perichondrium and cartilages, the case is hopeless. Ulcerations in the commissure and on the epiglottis are, in my experience, most intractable. Those involving the true and false vocal cords seem to yield more quickly. Most prompt and energetic treatment is necessary to limit destruction of the vocal cords in order to save the voice. There is a direct relation between extent and depth of ulceration and cure. Deep infiltrations are followed by the most extensive ulcerations. The more superficial ulcerations are more amenable to treatment.

LESIONS IN LARYNX.

The lesions found in the larynx may be placed under the following heads:

1. Infiltration: Superficial and deep.
2. Ulceration: Superficial and deep.

Both conditions are associated with more or less edema, which is usually found in the parts with underlying loose connective tissue, as in the epiglottis and aryepiglottic folds.

Infiltrations, both superficial and deep, may remain quiescent indefinitely, depending on the blood supply and the change in the tubercles. The tubercles undergo the same change as in other parts of the body, viz.: *a*, softening; *b*, fibroid limitation (encapsulation); *c*, calcification. Ulceration follows softening; this in turn may be followed by cicatrization as a result of treatment. I have never seen a case of spontaneous cure of tubercular ulceration in the larynx. If fibroid change surround the tubercle, it may remain quiescent, but it is not destroyed. The term cure can only be applied to given laryngeal lesions which are replaced by scar tissue or to softened areas which have become impregnated with lime salts.

Restoration of voice will depend on the amount of muscular involvement and on the integrity of the vocal cords and freedom of the articulations. Laryngeal tuberculosis seldom if ever produces death *per se*.

INFLUENCE OF CLIMATE.

It is of the utmost importance that the pulmonary and general conditions be improved as rapidly as possible. The removal of the patient to a proper climate is imperative. The arrest of the pulmonary disease will lessen the probability of further laryngeal infection.

While good results have sometimes been obtained by laryngologists despite unfavorable climatic conditions, yet the prognosis in regard to life, as well as a cure of the laryngeal lesions, is much more favorable in a suitable climate.

PROGNOSIS.

To say that all cases of laryngeal tuberculosis are fa-

tal is erroneous; I have seen many cases in one stage or another recover; some who were apparently doomed, in which extensive involvement of the larynx had occurred, including considerable destruction of the epiglottis. I have had two cases in the last year where from one-fourth to one-third of the epiglottis was destroyed, and yet the patients recovered.

Many have recovered where the true and false cords and commissure were affected, either alone or in combination.

In every case it is our duty to give these patients the benefit of our best efforts as early and as thoroughly as possible.

Too often patients present themselves with a hopeless condition of the lungs as well as of the larynx, yet we must not be discouraged in our efforts to save those who have a possible chance for life.

TREATMENT.

In case active surgical procedures are deemed unwise, the treatment consists of thoroughly cleansing the larynx, followed by soothing applications and sprays. I have seen cases of infiltration remain quiescent from one to five years, and still the parts are intact; therefore, we can not deem it best to endeavor to remove this infiltrated area in all cases.

If surgical procedures are decided on, however, the infiltrated area should be very thoroughly removed, and the parts stimulated to promote cicatrization. When once ulceration has occurred, however, I have seen nothing but good follow a thorough curettement and the energetic application of strong germicidal remedies. If vegetations are engrafted on the ulcerated areas they should be removed before any other treatment is instituted, so that the remedies may be more effective. The treatment by electrolysis has not been widely used, nor has the influence of the x-rays or radium been sufficiently demonstrated to warrant their general use.

In the treatment of the ulcerations many remedies have been used, and I desire to again call attention to the value of formaldehyd. Since my report in regard to this remedy, read before this Section in Denver in 1898, I am still further convinced that it is a remedy of very great value. It is satisfactory as a germicide, tends to shrink the exuberant granulations and stimulates the healing process. It is probably more penetrating than any other remedy which we possess. The best results are to be obtained by the persistent use of formaldehyd. In addition to the office treatment, I direct my patients to spray the larynx several times daily with a formaldehyd solution (gtt. 1 to 3 to ounce). The local applications of formaldehyd are made with a stronger solution, 3 to 5 per cent. This I follow with insufflation of aristol and orthoform, and lastly, the intratracheal and laryngeal injection of oil containing menthol oil of cinnamon, etc. Formaldehyd should be thoroughly rubbed in.

Too much stress can not be laid on the proper use of this remedy, as many have failed to get its beneficial results owing to its too infrequent use. In addition to its influence on the ulcerated areas, it is a splendid prophylactic. My experience with formaldehyd extends over a period of ten years, and I have seen the most gratifying results from its use.

DISCUSSION.

DR. W. FREUDENTHAL, New York City.—It does not accord with my experience of tubercular laryngitis that the local manifestations seldom improve unless the general condition gets better. In laryngeal tuberculosis we may expect anything

and everything, and I have seen cases improve very much while the process in the lungs was getting worse rapidly. When we succeed in putting these ulcerations at rest by means of a narcotic, Nature will do the rest, and they often heal up while the process in the lungs is getting worse. Another method of treatment I have pursued has been the use of radium intralaryngeally. I have introduced it into the larynx and left it there for ten minutes at first, and then for half an hour, daily. The result was very interesting. Some of you remember the time when Koch's tuberculin was first injected and the changes that were produced in the larynx. The changes observed after the use of radium were almost identically the same. This patient had a large larynx, with ulceration of both vocal cords, but after a few sittings infiltration set up, edema appeared, and after the tenth day I had to stop treatment for a day. These infiltrations grew so that she could speak with some voice, and she was delighted. While I did not accomplish a great deal, it was an interesting experiment.

DR. W. S. ANDERSON, Detroit—The treatment of laryngeal tuberculosis with soothing applications gives better results than with those that are irritating. I also wish to indorse the value of intratracheal injections. I find them very efficacious in relieving the symptoms, allaying cough and improving the patient's general condition. I always use olive oil as a base, and such drugs as guaiacol, camphor, menthol, oil of thyme, oil of wintergreen and oil of eucalyptus, and have found them very helpful.

DR. W. E. CASSELLBERRY, Chicago—I welcome any new remedy for tuberculosis of the larynx in the hope of improved results, but confess in advance to skepticism. I have treated many cases in different ways, and the more I see of it the more I feel that local remedies have but little influence on the ultimate outcome of the disease, although often of incalculable value to relieve pain and distress. A few cases recover and some run a slow course, with periods of distinct betterment, but the definite improvements which I have observed have followed increasing the general resistance by correct mode of life rather than local medication. Concerning the surgical treatment, I am in accord with Dr. Gallaher, that one should hesitate before breaking up a mere infiltration. I have seen the use of the curette followed by a rapid aggravation of the condition. If, however, there is already an active ulceration, which is circumscribed and accessible, so that one can make a thorough curettement, I have seen the best results follow, especially if supplemented by the application of lactic acid. Therefore, I do not wish to disparage surgical treatment, but to plead for a wise selection of cases on which the curette is to be used. I differ somewhat as regards tuberculosis of the larynx going *pari passu* with the condition in the lungs. I have seen cases where death was practically dependent on the larynx, and I have also seen the reverse condition, where the larynx continued to improve while the lungs grew progressively worse. However, these cases may be exceptional. I would like to know how Dr. Gallaher manages to have the patient spray his own larynx. I have no apparatus by which a patient can spray his own larynx effectively with other than oily medicaments. In this connection, I would like to call attention to the spraying nozzle of Dr. Freer, which goes around the epiglottis and into the larynx, but it requires a physician to use it.

DR. KATE W. BALDWIN, Philadelphia—I want to mention the use of carbolic acid in these cases of tuberculosis of the larynx. After thorough cocaineization, the ulcer is touched with carbolic acid. I have seen a number of cases where the ulcer was absolutely cured in this way, especially where the treatment was instituted in connection with the x-rays.

DR. ROSS H. SKILLERN, Philadelphia—I agree with Dr. Freudenthal regarding the laryngeal and pulmonary lesions not being dependent on each other, so far as the general condition of the patient is concerned. I have often noted marked improvement in the local lesion, while the general systemic condition of the patient was growing steadily worse. The prognosis depends more on the general systemic condition than on the throat lesion and may be said to be favorable if the case is

seen at an early stage of its development and the tuberculous deposit in the larynx is localized. Extensive curettement should only be employed in those cases in which there is a fair chance of curing the disease. Regarding the preparation anesthetic, I have used it for some months, but fail to note any advantages over orthoform, although when the latter loses its effect anesthetic may be used as a very satisfactory substitute.

DR. OTTO T. FREER, Chicago—I think the galvanocautery should not pass unnoticed as a therapeutic measure in tubercular ulceration of the larynx. It produced complete recovery in one of my cases presenting epiglottic and interarytenoid superficial tubercular ulcers. The edematous infiltrations of tuberculosis are, of course, not suited for it. Recovery in any case of tubercular laryngitis, in my experience, is a rare event, and I was surprised at the rapidity with which thorough cauterization in this case arrested the disease. The good vitality of the patient and her moderate susceptibility to tuberculosis were aids in producing the recovery. If these conditions had not been present the treatment would doubtless merely have aggravated the disease.

DR. J. F. MCCONNELL, Las Cruces, N. M.—I have seen a great many of these cases which have come from high altitudes down to a low altitude in very bad condition. I have used a 2 per cent. solution of methylene blue in these cases with most gratifying results after all analgesics had failed. I apply it in the ordinary manner with the McKenzie forceps, in a 2 per cent. aqueous solution, taking care to get a good quality of methylene blue. The action is so prompt that in three or four hours all the annoying symptoms are relieved and the patient gets great benefit from this palliation. I know of no real effect on the course of the disease other than that due to climatic conditions, but it has a very decided palliative action, and is well worth trying.

DR. THOMAS J. GALLAHER—The method of spraying the larynx is not learned in a day, but these patients make repeated efforts and eventually yield to instruction. It is done with difficulty in a number of cases, but it does a great deal of good. It is simply a question of trial, and I am satisfied I can teach four out of ten to use the spray. After an experience of fifteen years with a large number of cases of laryngeal tuberculosis, I make the statement with a good deal of thought that the condition in the larynx does not often improve unless that of the lung improves also; but the converse of that I have not found to be true. While the larynx may be retrograding, the lung is often improved, this probably being due to the climatic effects on the pulmonary areas. In many cases nothing but breaking down of the larynx can result, though the lung may improve very rapidly. The curette must be used carefully, and we should always hesitate about breaking up a fibrous capsule. If it is once undertaken, it should be done with the idea of thorough removal, and it must not be attempted unless that can be done. After ulceration has begun, I do not know of any other treatment which compares with it. It is capable of producing much good, for the larynx is breaking down more and more; many of these cases will not improve without it. Methylene blue and intratracheal injections of various kinds all have their place. The influence of these on the cough is often quite marked and lasts for some time.

Black Penis from Dose of Antipyrin.—M. Malherbe of Nantes was consulted by a young man, recently infected with syphilis, on account of a large bluish-black patch which had suddenly appeared on the dorsum of the penis. He supposed that gangrene was imminent, but Malherbe reassured him on learning that he had taken 1.5 gm. of antipyrin six hours before to banish an attack of migraine. Aside from the discoloration the tissues were entirely normal, and there was no other discoloration elsewhere on the body. Fournier called attention more than five years ago to this possible action of antipyrin on the penis. Malherbe thinks that the phenomenon is due to an intense congestion entailing actual ecchymosis. The young man was in the habit of taking 1 to 2 gm. of antipyrin occasionally to cure migraine and had always found it answer the purpose, with no by-effects. The details are given in the *Gazette Méd. de Nantes* of June 18.

INTUBATION.

INCLUDING A REPORT OF SOME UNUSUAL CASES.*

BURT RUSSELL SHURLY, M.D.
DETROIT, MICH.

Notwithstanding the active opposition of many prominent British and continental specialists, the administration of large doses of antidiphtheritic serum and intubation have become generally recognized as among the most successful life-saving methods in the hands of the pediatrician or laryngologist. This treatment, however, of laryngeal diphtheria in private practice has not attained the wide field of usefulness which it deserves. The larger and earlier doses of antitoxin have developed new indications for the treatment of tube cases, and greatly reduced the mortality.

In an experience with over 350 intubations with antitoxins in private practice some peculiar difficulties have been encountered which I have not observed to have been recorded in our literature, except meagerly. The usual technic of intubation may be necessarily modified in a hurried introduction of the tube. When the handle of the introducer can not be pressed well down against the chest wall, the tube may be passed in a horizontal, lateral position into the pharynx, and then tipped to the vertical, engaging the left index finger when in position; or the index finger and the tube resting against it in proper position may be passed simultaneously to the opening of the larynx.

A study of the various modifications of the O'Dwyer instruments made by Collin, Baer, Tsakeris, Egide, Rabot, Bauer, Fisher, Trumpp, Bayeau and others is exceedingly interesting. We are led to the conclusion that the European surgeon is endeavoring to avoid the use of our perfect American instruments, but with more expensive results. Let us join with Waxham, Nicoll, McCollom, McNaughton and others in a plea for the ideal instruments and tubes of O'Dwyer. Let them remain in their perfection as a fitting monument to the genius of the master who presented them. Two or more sets of seven tubes are essential for careful work.

The operation should not be attempted without practice on the phantom, anesthetized dogs, or the cadaver. Traumatism, followed by superficial and deep ulceration, retained tubes, or the spasmodic ulcerous condition, characterized by frequent autoextubations, result in many cases when an ill-fitting tube is worn. The selection of a proper tube for each patient deserves the most careful consideration. The great value of experience in technic and the dangers and accidents of intubation have been pointed out by the numerous writers.

Variations in the size of the lumen of the larynx are found in different races. An Italian child of three years frequently requires a two-year tube, while those of Polish or Bohemian parentage, for example, will frequently wear a tube a size larger than the American subject. The presence of adenoids and other nasal obstructions so common in children who develop severe laryngeal diphtheria are also important factors in the development of malformations. These patients often require smaller tubes than the age would indicate. The peculiar abnormal topography of the larynx, as a high or low variety, may be noted as a family anomaly, where two or more intubations are required in the same household. The expert sense of touch alone can reveal the peculiar deviation from the normal larynx in the living child. A

plea is made for an accurate interpretation of abnormalities or pathologic conditions by digital examination of the larynx. This is not attained without considerable practice.

The laryngologist who is not an intubationist does not frequently resort to digital examination of the larynx. As the late Dr. O'Dwyer has said, little is known about malformation of the larynx in children. A considerable number of infants undoubtedly die of undetected congenital stenosis of the syphilitic, vestibular, web or pouch varieties. The diagnosis must be carefully made before operation. I have been called to intubate cases of asthma, pneumonia, acute laryngitis, laryngismus stridulus, retropharyngeal abscess, foreign body in the trachea, laryngitis of measles, and edema, which were mistaken for the stenosis of diphtheritic laryngitis.

Intubation is usually considered an easy operation, especially in a child from 3 to 4 years of age. In point of fact, it may be exceedingly difficult or impossible. Ingals and Abt of Chicago and Ranke of Munich report impossible cases. My experience will add one case to the list. Operation was attempted many times by my colleague, Dr. P. M. Hickey, and myself in a child 1½ years of age, suffering from laryngeal diphtheria until tracheotomy was necessary. The right arytenoid region was infiltrated and firm under the finger. The one-year tube was used and engaged the laryngeal opening perfectly. With gentle pressure it could be advanced about one-half inch, only to meet with a firm obstruction. Intubation was attempted after tracheotomy, with the same result. When the child died some days later of bronchopneumonia, a postmortem was refused. The patient apparently had a congenital stenosis just below the right arytenoid.

In endeavoring to teach students the proper technic serious difficulties are presented, which are given meager consideration in the various books on the subject. Some men never can learn to intubate. The prominent difficulties, briefly stated, are: Large or clumsy fingers, imperfect tactile sensibility, insufficient attention to detail, poor knowledge of the anatomy of the larynx and adjacent structures, the use of too much force or tendency to carry the tube too far posteriorly into the esophagus. A considerable number of cases have come under my observation recently where the former operator had failed to intubate. The causes of failure have been carefully studied. They are exceedingly interesting and instructive. An intubationist can not be considered an expert until he has performed the operation on at least 25 cases. The usual difficulties are then overcome and confidence is established.

CAUSES OF FAILURE TO INTUBATE.

The most common causes of failure are, first, the faulty position of the patient. With the head thrown well back, we have a direct route into the esophagus. With the patient "held as if hung from the head," the larynx is readily entered.

Second, proper technic is dependent on drawing the tongue well forward. We frequently note the effort of patients who have been previously intubated to resist the introduction of the tube by forcing the root of the tongue backward and holding the epiglottis well over the opening of the larynx.

Third, spasm of the glottis may cause the tube to slip over into the esophagus or engage the folds of mucous membrane on either side. This is easily prevented by holding the tube in place until the patient takes a deep inspiration.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolaryngology, and approved for publication by the Executive Committee: Drs. G. Hudson Makken, George L. Richards and John F. Barnhill.

Fourth, peculiarities of structure or conditions about the epiglottis may interfere with the operation. In children from 6 months to 2 years, the flexible epiglottis may curl downward and posteriorly under the index finger, making it difficult to restrain the normal function of the cartilage. Edema may make the operation difficult.

Fifth, the cause of failure is frequently due to the use of a larger tube than necessary.

Sixth, hypertrophy or edematous arytenoids, a large leathery diphtheritic exudate, a sharp lateral or anterior curve of the laryngeal bands or tumors greatly increase the difficulties.

Seventh, the use of force is only mentioned to be condemned.

The resulting hemorrhages, syncope, false passages and other traumatism are unnecessary.

Gentle, firm pressure may be required to force the tube through a subglottic obstruction into position after the obturator has been removed. A deep inspiration offers a favorable moment to exercise this steady pressure.

OBSTRUCTION OF TUBE WITH MEMBRANE.

The use of large doses of antitoxin has increased the so-called danger of pushing down the diphtheritic membrane ahead of the tube. The exudate separates more rapidly and easily from the mucous membrane under the action of the serum, and this accident occurs frequently. It is usually to the advantage of the patient, however. The sudden withdrawal of the tube immediately during the paroxysm of coughing may be attended by the expulsion of a cast of membrane. Where difficulty is experienced in dislodging the detached membrane from the larynx or trachea, mechanical emesis produced by placing the handle of a spoon against the base of the tongue and pharyngeal wall is usually sufficient. This may be followed by several teaspoonful doses of spts. frumenti until coughing is produced. Repeated intubations may succeed if these measures fail. Severe hemorrhage and syncope during a skillful operation are extremely rare.

Obstruction of the tube with loose membrane is much more frequent when antitoxin is given 12 to 24 hours before operation. Casts of the larynx and bronchi are frequently expelled as such in these cases at the time of intubation, or they may be pushed below the tube. When the familiar valve-like sound is heard with each expiration it denotes the danger of obstruction.

CARE AND EXTRACTION OF TUBE.

Large doses of antidiphtheritic serum have made possible a procedure that obviates the danger of sudden death from obstruction of the tube, facilitates the extraction, and in private practice has been found entirely practicable, especially among children over three years of age. Where this method has been followed of leaving the string fastened with adhesive plaster across the left cheek, no prolonged or retained tubes have been necessary. Where antitoxin has been given in large doses, 24 hours or more before the operation, the tube is usually worn from two to three days. It is possible during so brief a period to allow the string to remain in place. Under these conditions the nurse can easily remove the tube in case of danger, and the anxiety of the parents is greatly relieved when prepared for this emergency. In some cases among ungovernable children and unreliable parents this method is not a success. Leaving the string is obviously not necessary in hospital practice, where the services of a trained nurse and expert intubator are always on call; but in private city practice it is convenient, simple, practicable in older children, and also in

many selected cases under three years of age. The technique, accidents and dangers of extraction are eliminated. It is a well-known fact that edema of the tissues in the region of the epiglottis and arytenoids often follows the most careful manipulation, and a slight swelling about the entrance of the larynx may result in obstruction enough to require reintubation. Gentle removal of the tube with the string has been followed by no obstructive edema in my series of cases. In a few cases the string seemed to increase the difficulty in taking nourishment, but post-pharyngeal paralysis also existed in several as the explanation of the trouble. When genuine interference with swallowing is encountered, the string or tube may be removed.

A case which illustrates one of the unusual accidents of extraction came under my observation some months ago. A previously healthy child, 4½ years of age, was intubated with a three-year tube for the relief of stenosis due to laryngeal diphtheria of the descending type. Three thousand units of antitoxin as an initial dose were administered, and the child placed in an improvised croup tent. Although the sepsis was extensive from an infected area involving the tonsils, both pillars and a portion of the pharyngeal wall, the child made an uninterrupted recovery until the morning of the fourth day, when extraction was attempted. As the closed jaw of the extractor was resting against the head of the tube, with a deep inspiration the child raised up suddenly and the head of the tube was pressed below the cords. An effort to remove it by the method known as enucleation proved unsuccessful, as the cartilaginous rings of the trachea were exceedingly firm at this age. Five possible methods may be available in these cases. First, evulsion or enucleation; second, a specially modified slender extractor with a long curve and sharply pointed beak; third, the use of a general anesthetic and the extractor; fourth, the extractor and x-ray; fifth, tracheotomy as a last resort. In this case the special extractor was inserted below the cords, while the left hand held the larynx from the exterior. The instrument could be felt to come in contact with the head of the tube, and gentle pressure with a delicate side-to-side motion was sufficient to engage the proper opening and remove the tube.

INTUBATION FOR OTHER CONDITIONS.

Intubation for the relief of dyspnea due to multiple papillomata in children is successful as a measure of temporary relief. The theory of producing sufficient pressure by the tube to produce absorption of the growth has not received the practical verification expected. A case that illustrates the limitations of the operation in this condition came under my observation.

CASE 1.—H. L., a boy aged 4 years, was referred to me by Dr. E. L. Shurly. He was suffering from a slowly progressive difficulty in respiration, with complete aphonia.

Symptoms.—The dyspnea became so great at times that danger of asphyxia was imminent. The attacks of laryngeal spasm with great cyanosis increased and surgical interference was demanded.

Treatment and Result.—He was sent to Harper Hospital and intubation was performed with complete relief. The tube was worn for some months, during which time it was removed each week and reinserted after some hours of natural respiration. Persistent treatment by this method resulted in normal respiration without the tube for an interval of three to four days. The patient returned to his home in a neighboring city and instructed to have intubation performed at home. A week later he was returned in a serious condition, with the information that no physician in the city was able to intubate.

Subsequent Treatment.—Tracheotomy was performed and the

larynx put at rest for over a month. Subsequent operations were also performed by Dr. E. L. Shurly during my extended absence from the city, when portions of the papillomata were removed through the tracheotomy wound and finally a thyrotomy was performed, with almost complete restoration of voice.

Intubation for papillomata can be classified as a temporary measure of relief only, and when performed tracheotomy instruments should always be at hand. It is possible that gelatin alum or other astringents or medicaments, when applied as a coating about the tube, might be useful in these conditions.

INTUBATION IN THE ADULT.

Intubation in the adult for the relief of acute stenosis is not attended by the successful results obtained by the intubation of the child, although Casselberry reported six cases, with five recoveries. While operation with the use of a laryngoscopic mirror is the method generally indicated in chronic stenosis, cases of acute obstruction in private practice present conditions which demand hurried intubations with the index finger as a guide. The adult cases that require intubation for acute conditions are, fortunately, very rare. Three cases have come under my observation. They are two cases of acute secondary edema, both of which were fatal, and one of diphtheria, as follows:

CASE 2.—Mrs. F. B., age 29 years, was seen in consultation with Dr. Burgess Dec. 19, 1903, on the sixth day of the disease, and sent at once to Harper Hospital.

Examination.—Examination revealed a diphtheritic exudate over the tonsils, pillars, pharynx, uvula and epiglottis. Laryngoscopy showed the extension of the pseudo-membrane over the arytenoids and downward, apparently completely obstructing the lumen. Respirations were thirty and very labored.

Treatment.—Four thousand units of antitoxin were administered, and intubation, with the index finger as a guide, was performed at once. The tube was immediately expelled with a complete cast of the larynx, and the trachea beyond the bifurcation, followed by perfectly easy respiration. Three subsequent intubations were necessary (two performed by Dr. P. M. Hickey in my absence), and a thick leathery cast of the larynx was expelled at each operation, although 12,000 units of diphtheritic antitoxin and 20 c.c. of antistreptococcus serum were administered during the forty-eight-hour interval. Although the laryngeal dyspnea was entirely relieved, the patient died on the ninth day of anuria and septicaemia of the streptococcus and Klebs-Loeffler varieties. In this case it was unnecessary to leave the tube in place.

The adult larynx is extremely irritable in this condition, as reported by Dr. Casselberry in his paper, "Intubation in Acute Stenosis."

CONCLUSIONS.

1. O'Dwyer tubes and instruments are generally satisfactory. No cheap modifications or substitutes are required.
2. Digital exploration of structures about the entrance of the larynx are as relatively important in diagnosis as examination of the nasopharynx.
3. Failure to intubate is due to the operator, except in very rare cases, in which it is impossible to intubate.
4. Obstruction of the tube is more frequent after large doses of antitoxin. Therefore, the string should be left when indicated.
5. Early intubation is advocated in private practice and removal of the tube at the beginning of the fourth day.
6. Early removal of the tube and large doses of antitoxin before operation are in direct ratio.
7. Intubation is usually indicated as the primary operation in papillomata of children and acute stenosis in adults.

DISCUSSION.

DR. GEORGE F. COTT, Buffalo, N. Y.—We are all aware that intubation is becoming a lost art, now relegated to the surgeon. I have been wondering why laryngologists do not practice it more, and have been told it is because they are afraid of carrying infection from diphtheritic patients. I do not believe that, for these same men take care of tubercular and syphilitic throats. I have also been told that probably some of the younger men do not practice intubation because they are afraid of carrying the infection to their babies. I said that I did not believe that either. I have never had any trouble, nor have I taken any precautions except as to my hands. It is difficult to teach intubation. I have tried it on the adult cadaver in the dissecting room and found that a poor practice. It is difficult to get bodies of young children for intubation purposes. I mentioned these difficulties to a class, and one of the young physicians, taking a post-graduate course, offered himself as a volunteer, and I intubated him twice. He never volunteered again, however. Intubation puts the larynx into an irritated condition for from twenty-four to forty-eight hours. The young man wrote up his experience, and I read it to one of the societies. It is important to know when to intubate and what result to expect. Dr. Shurly has intubated 350 cases; I have intubated 109, and have had almost every accident except a false passage. I have been called to cases a number of times where the child was turning blue, the reflexes were abolished and it was gasping for breath, but pulse quite full and normal. The tube may be put in in half a second, and the child will live in every instance. Here you have a peculiar condition, want of oxygen, with a normal pulse. When you have poisoning from the Klebs-Loeffler bacillus you have a very rapid and compressible pulse, an indication of acute fatty degeneration. In that case the child will die every time, with or without intubation. It does not die from suffocation, but from the bacillary alkaloidal absorption. In the course of the next few years students will probably know very little of the art of intubation. Since the advent of antitoxin, it is almost impossible to get a good intubator. When you have a membrane in the throat and nose, it is also in the trachea, and the string must be left on the tube, or the child will be suffocated by the membrane occluding the tube. When you are sure the trachea, nose and throat are free of membrane, then you can take the string out. If a man is not expert enough to remove the tube, it is well to leave the string in and tie the child's hands so that it can not possibly pull out the tube. The tube may be left indefinitely. I have intubated one child as many as fifty or a hundred times in six months. It is as well to-day as ever and has a perfect voice. A healthy larynx can not stand much irritation, but a diseased larynx can stand anything.

DR. W. E. CASSELBERRY, Chicago—Intubation is becoming a lost art, not for the reasons mentioned, but because antitoxin cut short the stage of constriction of the larynx. When I heard Dr. Shurly refer to 350 cases of intubation since the introduction of antitoxin, I confess that I was surprised, and can only infer that for some reason, in certain districts in Detroit, the diagnosis of diphtheria is not made sufficiently early. I have had very few cases of intubation since the advent of antitoxin. This reason for the decline of intubation is supplemented by the other, that more physicians are capable to-day of making intubation than formerly. I have not found it difficult to teach intubation. I have taught one hundred men annually the initial steps, and many of these students subsequently perfected themselves in practice. The instruction is on young cadavers which are accumulated by the institution for this purpose. The class is divided into sections, and each member is compelled first to make a digital examination for study of the pharynx and larynx, then to make an intubation and extubation. Pediatricists and general surgeons also are conversant with the art. Fewer cases and more operators may mean diminished skill with which to meet complications, but the general good has been subserved. As to the absolute inability to make an intubation in any given case, the unexpected is especially liable to happen with this procedure. I recall a case of Dr. Plummer's which came to autopsy, at which it was demon-

strated that the inner caliber of the cricoid cartilage would not permit the passage of the smallest tube of the O'Dwyer set. In a case of my own, a partial ankylosis of the jaw precluded a proper manipulation of the instruments. A sphincter-like spasmodic closure of the larynx interrupting the passage of the tube is a real possibility. I have seen this happen in laryngeal diphtheria in a girl of twenty years of age on whom I was making intubation under laryngoscopic observation. With two phases of this subject I have been especially interested—the posture method of feeding, and intubation in the adult. Intubation in the adult is a good procedure when you can perform it under laryngoscopic observation, but I have warned the profession against it when the patient is moribund or recumbent, usually on a slouchy bed and unable to sit up, and when the diagnosis is not accurately made. In such emergency cases, usually of erysipelatous or infectuous edema of the larynx or those with an underlying syphilitic or tuberculous stenosis, tracheotomy is much the safer and more satisfactory operation. One's index finger is too short to guide the tube in most adults, and, moreover, the mere insertion of the finger into the throat when the patient is already in *extremis* may cause immediate death. The so-called posture method of feeding after intubation of the larynx, which originated, and which was instrumental in popularizing the operation by satisfying the distressing thirst of patients without the danger of "swallowing pneumonia," consists in feeding while the head and chest are inclined downward, at such an angle as to preclude liquids from gravitating through the tube into the lungs, the ability in this position to "swallow upward" being, of course, retained. I wish to report continued success and satisfaction with this method of feeding with the head and chest on a downwardly inclined plane.

DR. KATE W. BALDWIN, Philadelphia—I will say for the benefit of those teaching on the cadaver, that it is of advantage to do a preliminary tracheotomy and thereby control the tube with the finger from below. It adds very much to the facility with which the tube is introduced and also in the removal.

DR. B. R. SHURLY—I should like to see the day when we can have an expert intubator in every large city. There are a great many practitioners in our city who have returned from courses in the east without being able to do an intubation, and I can not agree with Dr. Casselberry that intubation is easily learned, even with courses of instruction. I have trained my students carefully with the phantom, the cadaver and on the dog, and by the time they were through they were able to perform the manipulations. Yet I am often called in by some of these very men for cases of not unusual difficulty. There are new indications which have developed since we began to use large doses of antitoxin. The tube can be removed much earlier, especially when the string is left on. The fact that I have had so many cases under my observation in Detroit is due to the large Polish settlement there. They are densely ignorant, live in unhygienic conditions, disease thrives among them, and they will not call in a physician until after the disease is under way three or four days. This makes intubation necessary in a great many cases.

Graduates of Medical Schools.—In THE JOURNAL, Aug. 13, 1904, we published a table showing the results of state board examinations in 1903 and remarked that many deductions might be made from the tabulated facts, but that we left it to others to make them. In a letter to the editor of the *New York Medical Journal* a correspondent has made certain deductions from the standpoint of a Philadelphian. He shows that graduates of the Philadelphia schools give a smaller percentage of failures than the graduates of schools in other cities and that the proportion of failures by graduates of Washington schools was more than three times that of the graduates from Philadelphia, and of those from Baltimore, Louisville, and St. Louis, respectively, it was over *four, five* and *six* times that of the Philadelphia candidates.

A CHIEF PREDISPOSING CAUSE OF APPENDICITIS.

A PRELIMINARY NOTE WITH A FEW LABORATORY EXPERIMENTS.*

GEORGE RUBIN, M.D.

[From the Pathological Laboratories, Rush Medical College, University of Chicago.]

CHICAGO.

One evening in the fall of last year I was called to the bedside of a man who had suddenly become ill with symptoms typical of acute appendicitis, viz., chills, nausea and vomiting, general abdominal pain and local tenderness over the ileocecal region. The patient's history was as follows:

An American, of German extraction, 40 years of age, unmarried, stenographer, almost a total abstainer, and of excellent habits in general. Family history excellent. He has always been well, with the exception of a diarrhea several months ago, of a few weeks' duration, from which he made a complete recovery. For a week or so preceding his last illness he was troubled with flatulency, though it caused him slight inconvenience.

After remaining in bed for ten days, and with appropriate medical treatment, the patient made an uneventful recovery from appendicitis.

In considering the case in all its bearings, but especially with regard to the intestinal flatus preceding his attack, the following questions arose: Why is appendicitis rare in infancy and early childhood and also in persons of advanced years? If, according to some authors, who claim that appendicitis is due principally and primarily to infection or to an extension of infection from the bowel, then the disease ought to be by far more common during the early years of childhood. The susceptibility at this time to infection in general, and especially to intestinal infection, is well known; at least there are no *a priori* reasons for believing that infection of the appendix from the bowel or through other channels, e. g., lymphatic or blood system, might not occur as readily in infants as in adults. We might assume from this that infection occurs at a later stage in the evolution of appendicitis.

The etiologic connection between appendicitis and fecal concretion, though not emphasized as much at present as formerly—in many text-books, however, still occupies a conspicuous position. If this were an important factor in the production of appendicitis, the disease would surely be more common in persons advanced in years, owing to their greater liability to formation of concretions and calculi generally. If the same conditions govern the development of concretions or calculi in various parts of the body, then we might also rightfully expect women to have appendicitis more frequently than is the case, judging from their marked predisposition to gall-stone disease.

Constipation is, according to a number of authors, a condition that favors the development of appendicitis. But such a view becomes untenable in considering the great disproportion of appendicitis in the sexes. If constipation really played an important rôle in predisposing to this disease, instead of having one female to about three males, the converse would surely be the case.

The occurrence of appendicitis in about three-fourths of all cases between the ages of 10 and 30, also appears enigmatic from the point of view of infection as the primary cause, considering the greater resistance possessed at such a time than by children under 10 years of age.

* Read before the Chicago Medical Society, May 11, 1904.

An explanation that would answer all the foregoing questions rationally is, I believe, the following: The accumulation of gases below the ileocecal valve and their voluntary retention;¹ the ensuing distension of the cecum and dilatation in various degrees of the ceco-appendicular orifice; the entrance into the appendix of larger fecal masses than are readily expelled; the interference with the vascular circulation and resulting erosion of the mucosa of the appendix with subsequent infection; these altogether give rise to a series of symptoms well known to you all.

Let us now see how this explanation will fit the several questions under consideration. First, regarding the rarity of appendicitis in infancy and early childhood; such individuals are not likely to retain gases voluntarily; as soon as there is a certain amount in the colon and rectum it is passed off automatically, hence no distension or overdistension of the cecum and no impaction in the appendix take place.

The same argument will hold good, I believe, regarding the rarity of appendicitis in anthropoid apes: Bland-Sutton² states, "In all the specimens of anthropoid apes which have come into my hands for dissection, I have always made a point of examining the appendix, and have never succeeded in detecting disease or even concretions."

J. H. Campbell, also quoted by the same author, has examined a large number of monkeys from the gardens of the Zoological Society of London, and also failed to find appendicular disease.

It will perhaps be well to mention a conversation I had with Dr. Hassin (now of this city), who had practiced medicine in Siberia for four years, a part of that time in the capacity of a military physician, where he says appendicitis is exceedingly rare, and the same he says is true among the moujiks (peasants) in Russia. Another conversation I had with Major Farrell of this city, who had had considerable experience (in the capacity of army surgeon and otherwise) with the natives of the Philippine Islands, South Africa, the West Indies, New Guinea and Borneo, has also shown that appendicitis is exceedingly rare among them.

It will also be interesting to consider in this connection the rarity of this disease in asylums and among imbeciles. One would expect a much larger proportion of cases in such individuals owing to the fact that their digestive organs are greatly overtaxed by excessive amounts of food as well as by all sorts of foreign substances and indigestible articles. If healthy persons should subject their digestive organs to similar treatment the outcome might be very different. It has often been observed that attacks of appendicitis follow indiscretions in diet. Such occurrences might be explained by the abnormal production of gases due to increased fermentation which, in consequence, under certain conditions, cause a distension of the cecum and hence favor an attack of appendicitis.

Now relative to the infrequency of the disease in elderly persons, we know that the latter lead, comparatively speaking, a more retired life: they stay at home the greater part of their time, and are mostly so situated that they are not obliged to retain their bowel contents—including gases—for hours at a time, as is often the case with younger persons. Another explanation might be the persistence of certain anatomic peculiarities, mode of

life or other conditions which helped them to escape the disease in their earlier years.

The occurrence of appendicitis in nearly three-fourths of the cases between the ages of 10 and 30, may be explained by the fact that these decades are spent principally in schools, colleges, universities and similar institutions. It is also the most propitious period of life for amusements of all sorts, e. g., theaters, receptions, balls, parties, etc., and especially is this true of the latter decade.

The great disproportion in the sexes can be largely explained on a numerical basis. It is a fact that there are more males in the various educational and professional institutions than females; furthermore, nearly all men spend their days in offices or other places of business where, owing to the urgency of their affairs, they very often have to forego certain natural demands for various lengths of time. Meetings of societies, clubs, lodges, directorial boards, juries, etc., where men remain closeted for hours at a time, ought also to be seriously considered. Traveling might be added to the above list.

In view of the foregoing arguments, all of which seem to corroborate the theory proposed, the following experiments were undertaken. The technic was as follows:

Portions of bowel about 50 cm. long, including cecum and appendix, were resected from subjects dead of diseases other than would affect that part of the intestinal tract. After cleansing the bowel the colonic end was ligated; shot ranging in size from 4 to 11 metric scale, peas and beans were introduced through the ileum end, and the bowel manipulated so as to imitate peristalsis more or less. The rolling of these bodies was often done with more vigor than normal peristalsis would effect. It was observed that none of the contents entered the appendiceal cavity, although the appendix was held at the most pendant point. Then the bowel, still containing those substances, was inflated, the same process of rolling repeated, with the result that in all the experiments with one exception (where only one small shot entered owing to an hypertrophied appendiceal wall and a constricted lumen) the appendix was filled with shot, and in two cases peas of medium size also gained entrance. Ten such experiments were carried out. It may be added here that the appendix was readily balloned during the process of inflation. It is reasonable to suppose that similar phenomena might occur in the living.

The amount of pressure employed in the experiments and that which might occur in the normal living subject is a matter of conjecture. It seems that much less gas would be required to dilate the ceco-appendicular orifice in the living than is the case with the laboratory experiments, owing to the pressure brought to bear on the cecum by the surrounding structures and especially by that of the abdominal wall.

Fitz recorded nineteen out of 257 cases of appendicitis that were supposed to be due to indirect violence. Such cases might be explained in the following manner, first the forcing of a larger mass of fecal matter through the ceco-appendicular opening than the appendix is able to expel, following that, trauma to the mucosa with subsequent infection taking place. It seems not improbable that heavy labor, such as lifting, may operate in a similar manner, i. e., owing to the increased intra-abdominal pressure produced by tension of the abdominal wall. Athletics might be considered in the same category. These considerations help us also to explain the marked disproportion in the sexes.

Regarding the size of the obstructing mass no definite

1. With some exceptions when it might be involuntary, i. e., obstruction anywhere between the cecum and anus.

2. A private communication to Kelynaek, from the latter's book, "The Pathology of the Vermiform Appendix," 1893, p. 5, London.

statement can be made. The calibers of appendices vary very much. What would be an insignificant particle for one might completely obstruct another. Likewise little can be said about the rôle the valve of Gerlach plays in preventing matter from entering the appendix. Of the several specimens of bowel that I have examined, in only one was there a lengthening of the mucosa that might have been called a valve.

Under ordinary circumstances the mucous lining itself is sufficient to act as such.

Van Zwahlenberg² has recently published several series of experiments in which he shows that obstruction is a chief factor in the production of appendicitis, but he considers the subsequent distension of the appendix with fluid, which impedes the circulation, to be the essential cause. That the circulation of the appendix might be more readily interfered with from an inflammation of the lymphoid tissue in which the appendix is especially rich, apparently escaped his notice.

Distension of the appendiceal cavity with fluid would take place rather gradually, and symptoms—if any were produced—would not come on so abruptly. Furthermore, cysts of the appendix are not very uncommon and they are seldom associated with inflammation of that organ. I found one in the course of the several experiments, where the distal half of the appendix contained a considerable amount of fluid with no other abnormal changes.

Importance has been attached by some authors to Clado's discovery of a special peritoneal fold connecting the ovary and appendix (appendeo-ovarian ligament). Its supposed extra blood supply is thought to explain the comparative infrequency of appendicitis in females. Even if Clado's ligament were a constant anatomic structure (which it is not), it would not explain the disproportion of the disease in the two sexes, or the rarity of the disease in male infants and young boys and in old men, since the main arterial supply is seldom primarily affected from the inflammatory process within the appendix wall.

Before this question will be definitely settled further experiments will, perhaps, be necessary.

In conclusion I wish to sincerely thank Professor Le Count for many suggestions and in supplying me with material. I am also greatly indebted to Drs. Bassoe and Stober for their kindness in providing me with desired specimens for the experiments.

Clinical Reports.

A CASE OF PRECOCIOUS MENSTRUATION.*

M. J. FORD, M. D.,
OMAHA.

Patient.—I was recently called to see a child who had swallowed a baby pin and was at once struck with the unusual development of the child. It was two years and four months of age, but had the body and limbs of a much older child.

History.—The child was born May 13, 1902, and the mother noticed soon after its birth that the external genitals were enlarged. She asked her attendant about it and was told that it was a little swelling, which would soon disappear. The child was fretful and cried practically all the time when awake till it was six months old. Its sleep had never been good, and it was always restless. When six months old the mother noticed that the child was bleeding as if menstruating. The flow became very free and the child sank into its first peaceful sleep. The flow continued for 3 or 4 days, just as

mother, but she did not consult her physician. After 28 days the flow again made its appearance and continued for the same time and in the same quantity. Since then the child has menstruated every 28 days regularly for the same number of days and showing the same quantity, soiling 2 napkins a day, except that on two occasions there was a little delay, corrected by warm drinks and foot baths.

Family History.—There is nothing abnormal to be found in the history of the grandparents or parents. The parents are Americans, aged 33 and 32. The mother began her menstrual life at 14, and it has been a normal one. The only peculiarity noticed was that she was unable to feel well and hearty in this pregnancy as in two previous ones. Nausea was not unduly prolonged in early pregnancy.

The mother reports that the child, though fretful and restless prior to the establishment of menstruation, has been perfectly well ever since. Other than the condition named as preceding the first menses, there has been no prodrome to the successive menstruations. The mother has seen nothing to indicate any attempt to masturbate. The child opposes exposure more than ordinary children of her age and shows decided modesty.

Examination Before the Society.—The child is of normal height and face for one of her age. The breasts are well developed and of good size, as are the nipples. The trunk and legs show the development of a much older child. The hips are broad and rounded, and the calves well developed. The mons veneris is large and covered with a good growth of long, silky hair, which is light in color but beginning to change to a darker shade. The labia are large and very prominent.

Comment.—So far as the literature in private and public libraries shows, there is but one recorded case of menstruation before the age of one year, and that showed the establishment of the menses just prior to that age. This case is unique in that the menses were established at apparently the earliest age on record.

FIBRO-ADENOMA OF THE LACHRYMAL GLAND.

LYMAN SKEEN, JR., M.D., PH.D.
OGDEN, UTAH.

Patient.—Mr. J. A. T., aged 82, came to me in July, 1904, with a tumor the size of a hazel nut at the outer canthus of left eye.

History.—A history of gradual development with no pain was obtained. The patient had been told that cancer existed and the sun glass and x-rays had been used as treatment. One operation on the under surface of the lid had been done before I saw the case.

Examination.—The tumor was pressing on the eyeball and interfered with its movement; a portion of the growth presented below the border of the upper eyelid. A clear fluid was discharged from a sinus near the outer edge of the orbit.

Diagnosis.—Benign tumor of the lachrymal gland.

Operation.—Under general anesthesia the entire mass was removed *en masse* through an incision along the eyebrow. On microscopic examination it proved to be a fibro-adenoma of the lachrymal gland. The wound healed without complications and with no tendency to recurrence.

I present this case not only because of the rare occurrence of tumors of this gland, but because of the excellent result obtained by this radical operation.

Mouth and Rectal Temperature.—Ostenfeld writes to the *Zift. f. Tuberculose*, V, 5, to extol the advantages of the rectum for determination of the temperature in tuberculosis. By careful comparison of the temperature findings in the mouth and in the rectum it is possible to determine the difference for each individual. When this is once ascertained the temperature can then be taken in the mouth thereafter, making allowance for the difference.

THE IRRITABLE BLADDER.

As the science of medicine grows older the use of such general terms as "irritable bladder" becomes less and less common on account of the fact that the pathologic conditions underlying such symptoms become gradually known, and the use of the symptom as a disease name ceases. At first sight irritable bladder as a symptom-complex seems to belong to the class of diseases which have disappeared in the manner above mentioned, but a recent study by Hirsch¹ shows that although in many instances this condition is merely a symptom of other diseases, there are cases in which it can not be explained in this way.

According to Hirsch cases which are described under the head of irritable bladder should have as their predominant symptoms frequency of urination with clear urine and a bladder which appears normal to the cystoscope. Hirsch admits that the number of such cases has been reduced since the cystoscope came into more general use, but he shows by a review of the literature that they still exist. The symptoms in these cases vary with the severity of the case. In the mild cases the predominant symptom is an increase in the frequency and the intensity of the desire to urinate. The patient may urinate as often as every fifteen minutes, or rarely as often as every five minutes. This urinary urgency may be present in the waking hours only, or may persist also during the sleeping hours. In more severe cases there is added an actual urinary distress, by which is meant an absolute necessity to pass urine when the desire appears. In some cases this results in wetting the clothes, in others there is a spasm of the sphincter with temporary suppression which may have to be relieved by the catheter. In the very severe cases actual pain, in the form of the so-called vesical colic, may be present, and may radiate from its original site in the bladder to the genitals or the intestines, or even to the abdominal wall in the neighborhood. Associated with the strictly vesical symptoms we find in the more severe cases symptoms referable to the intestines, and also symptoms on the part of the general system. The intestinal symptoms, readily explained by the nervous connection between the bladder and the intestines, take the form of a desire to pass feces coincident with the urinary desire, or of a nervous diarrhea or constipation. The general symptoms may occur during the attack in the form of cold

sweats, shivering, vomiting and pallor, or may persist the whole time and are then mental and take the form of mental depression or hypochondria. The sole objective symptom in the majority of these cases is a hyperesthesia of the bladder wall, which is especially apt to involve the fundus or the neck of the bladder. This hyperesthesia may occur merely as an increase in the normal sensibility to tension or as an abnormal sensibility to pressure; in the latter case this sensibility may be made manifest by the effects of hardened feces in the rectum, or may be first detected by the physical examination made by the physician.

The urine in this condition may in many instances show no abnormality, the reaction, quantity and physical and chemical characteristics being unchanged. In some cases characteristics are present which render the urine more irritating, such as hyperacidity, concentration, excess of phosphates or oxalates, or the presence of sugar. Some authors have claimed, too, that the consumption of alcoholic beverages, especially those which contain carbonic acid gas, may lead to the elimination of irritating substances. In long-continued cases of irritable bladder the quantity of urine may be demonstrably increased.

The main underlying condition in all cases, according to Hirsch, is hyperesthesia of the bladder wall, but just what leads to this hyperesthesia is by no means apparent. Numerous cystoscopic examinations, and a few autopsies, have shown that pathologically cases of this condition can be divided into two groups, those which show absolutely no pathologic change, and those which show local or general hyperemia of the bladder wall. The first group of cases is in all probability purely nervous in character. In the second group the hyperemia seems to belong with the so-called non-inflammatory hyperemias, or at any rate is not due to inflammatory changes which can be detected. As would be expected, the nervous form is much influenced by psychic disturbances, while the hyperemic form is influenced by any factor causing an increased blood supply to the pelvic organs. The prognosis of this condition is bad, especially in the more severe forms, and the fact that the treatment is unsatisfactory is well borne out by the two or three pages of remedies which Hirsch publishes. It seems likely that future work may bring out the true factor underlying this condition, but for the present it appears that we are still justified in classing certain cases as "irritable bladder."

CRUSADE AGAINST OVERCROWDING AND THE TENEMENT EVIL.

Buffalo has recently inaugurated a health crusade which is interesting and instructive in many ways. Since the first of last May a rigid tenement-house inspection, followed by enforced repairs, improvements and even condemnations, has been carried on, and now, at the end of five months only, an amount of work has

1. Centralblatt für die Grenzgebiete der Medizin u. Chirurgie, v. l. VIII, Nos. 13 and 14; THE JOURNAL, page 1093.

been accomplished which is a source of pride to the city itself and an example to other cities in this country. Buffalo's experience is especially valuable because it shows what is needed and what can be done in middle-sized cities. We are all so familiar with the enormous housing problems of our large cities, with squalid pictures of the dirt, darkness and overcrowding in which the "other half" of New York, Boston, Chicago, etc., are obliged to live, that we are apt to treat lightly the less spectacular conditions in smaller cities. Yet in many of these cities the evils of overcrowded, insanitary tenements do exist, though they are numbered by tens instead of hundreds, and it is these smaller cities which can really grapple with the evil and overcome it. The cities in Massachusetts and New York should find this task far easier than cities in many other states, for the excellent state tenement-house laws make in these two states the erection at the present time of insanitary houses almost impossible, and they have only to do away with the existing slum tenements to feel secure that they will never in the future be made to face the situation which confronts such cities as New York and London, and which has cost and must in the future cost millions of dollars before it can be regarded as satisfactorily settled.

Buffalo is fortunate in possessing a health officer of vigor, for, according to the existing statutes, a reform in the housing conditions depends largely on him. Landlords may be proceeded against through indictments by a grand jury, but this procedure is slow and cumbersome, while the health officer has authority to vacate, after a hearing, any building which is unfit for habitation. A description of some of the housing conditions of Buffalo, together with a sketch of the reform movement, is given in a recent number of *Charities*,¹ by G. W. Gillette, a member of the committee of physicians and public-spirited citizens who undertook the investigation on which the action of the Department of Health was based.

An unusually harmonious action on the part of public officials and private citizens facilitated the work. The co-operation of the district attorney's office and of the bureau of buildings was secured, the daily papers gave the movement their heartiest support, and the Charity Organization Society undertook to care for the evicted tenants. At the time of writing, Mr. Gillette states that forty of the worst tenements have either been vacated or put in order, and he believes that if one hundred and fifty are subjected to this treatment the city will be really cleaned up. A certain number of landlords, alarmed at the new activity of the department, have begun repairs without waiting for notifications.

The evils discovered in Buffalo were those which we may expect to find in many cities of its size—dark bedrooms, filthy, insanitary water-closets and absence of fire-escapes. The common plea of tenement landlords,

that the filthy habits of their foreign-born tenants make decent conditions impossible, was not justified by the Buffalo investigating committee, who found the tenants—mostly Italians—surprisingly clean, but the houses badly constructed and in worse repair.

It is to be hoped that the crusade thus begun will go on, and that the work will be directed not only to the abolition of existing insanitary tenements, but to the prevention of underhand violations of the law prohibiting the erection of such buildings. It is also to be hoped that other cities will follow Buffalo's example. The proper legal means for doing so are already in the hands of many other cities: it is almost certainly true that evils calling out for remedy exist in their midst, and the necessary vigor, courage and public spirit should not be lacking in any of them. Nor should the smaller cities think themselves secure. A city slum is a thing of insidious growth; a tall tenement springs up here, a rear building creeps in there, and suddenly the town realizes that it has a plague spot, a center of poverty and sickness which has grown, no one knows how, which will take time and money to eradicate, and which might have been prevented by a little knowledge gained from the sad experience of our large cities.

THE NEGRI BODIES.

About a year ago¹ Dr. A. Negri of the University of Pavia described certain bodies which he had observed in the nervous system of animals dead of hydrophobia. These bodies are found in the protoplasm of nerve cells and occasionally in the processes, but not in the nucleus, though they may be in contact with it. Their distribution in various parts of the nervous system is fairly constant. They are usually found in greatest abundance and are also, as a rule, larger in the hippocampus major, but also appear frequently in the Purkinje cells in the cerebellum, in the pyramidal cells of the cerebral cortex, and often in the pons, the spinal ganglia, the gasserian ganglia and in the spinal cord.

The bodies are round or oval in shape or may be oblong and somewhat irregular. They vary a great deal in size, depending on their location in the nervous system, the stage of the disease and also on the animal in which they are found. Forms occur in size from the smallest, which can just be seen with the highest power of the microscope, to those which measure as high as 25 microns in length. Usually they are from 4 to 10 microns in diameter. They may be stained with any of the ordinary stains used for tissue, and are shown very well in fresh tissues teased in a dilute acetic acid solution. Negri has found the bodies in dogs, cats, rabbits and human beings, and has observed them in experimental rabies, as well as in that acquired in the natural way, though they are larger in the experimental form. These bodies successfully resist putrefaction for several days, and are not destroyed by immersion in glycerin. In

1. *Charities*, Oct. 1, 1904, p. 31.

1. *Zeitschrift f. Hyg. u. Inf.*, vol. xlv, No. 3.

rabies produced by inoculation in the sciatic nerve, the bodies are chiefly found in the cord and spinal ganglia, and rarely in the brain; or if present, they are very small. He says that there is a difference in the symptoms corresponding to this distribution. They appear usually in the cells of the hippocampus major about the same time that the first symptoms occur, or a day or two earlier, and at this stage are very small.

In a second paper² Negri emphasizes the importance of the presence of these bodies in the diagnosis of rabies in suspected animals. In 75 animals, mostly dogs, the diagnosis of rabies was made by the inoculation method in 52, in 50 of which the bodies were found. Of the two remaining cases one animal was killed before the symptoms came on, and so too early for the bodies to appear. The failure to find the bodies in the other case was probably due to an exceptional localization of the parasite which sometimes occurs. The bodies were not found in any of the 25 remaining cases, which were negative to the inoculation test. He concludes that the bodies are constant in rabid animals, and are never found in any other conditions. He believes that these bodies are parasites—probably protozoa—and have an etiologic relationship to hydrophobia, though he frankly admits that such has not been proven.

Many other Italian investigators have confirmed the observations of Negri, among whom may be mentioned Bertarelli, Volpino, Daddi and Guarnieri. Guarnieri believes that he has observed distinct segmentation in the parasite. Volpino, in 40 cases, found the bodies present in all those in which the inoculation test was positive, and absent in those resulting negatively to the test. Bertarelli found the bodies in the hippocampus major in the human. Little work apparently has been done on these bodies outside of Italy.

These results certainly are of great importance if they do nothing more than furnish a reliable and rapid means of diagnosis; and such the observations, if reliable, seem to have established. One must admit also that Negri is justified in assuming as a working hypothesis that these bodies are parasites. Artefacts, degeneration forms and the like must, of course, be carefully excluded. The fact that the virus of hydrophobia will pass through a porcelain filter in no way contradicts the view that they are parasites, for it is possible for the organism to have different stages of development, in some of which ultramicroscopic forms may exist. In fact, Negri observed some of these bodies so small that they could barely be seen with the highest powers of the microscope.

THE PROTECTIVE AND CURATIVE VALUE OF ANTI-STREPTOCOCCUS SERUM.

With the preparation of the antitoxin of diphtheria and its successful therapeutic employment, it was

hoped that other forms of serum might be found to have a corresponding utility. This hope, however, has been realized only in small degree, and to the future must be left the determination of the causes for this relative disappointment. Streptococcus infection especially is so common and it appears in so many forms that it would be a boon indeed if a serum could be prepared capable of conferring immunity to such infection and of bringing about recovery from it. Past failure has been attributed to differences in the species of streptococci giving rise to the several infections. In the course of an investigation undertaken primarily to secure information as to the identity of the streptococci found in milk and those in the human organism in health and disease, Dr. D. H. Bergey¹ made some observations for the purpose of shedding light on the question of immunity to streptococcus infection. Goats and rabbits were treated at intervals of from a week to ten days for periods of from three to nine months with repeated and increasing doses of certain streptococci isolated from cows' milk and from human beings, and the sera of these animals were then tested as to their agglutinating, protective and curative properties. It was found that the serum of animals immunized with cultures of streptococci acquires an agglutinating power for all varieties of streptococci, although the agglutination occurs in somewhat higher dilutions for the homologous culture than for those derived from other animals. It was not possible to differentiate definitely between cultures of streptococci of human and those of animal origin. The serum of animals immunized with cultures of streptococci exhibited neither bactericidal activity with respect to the micro-organisms nor antitoxic effect with respect to the action of the filtrates of the cultures.

It would appear, therefore, that the immunity to streptococcus infection is of a somewhat more complex character than that to some other infections. In the case of the latter, antitoxins are formed in the body which neutralize the toxins generated by the causative bacteria, for example, the diphtheria bacillus and the tetanus bacillus; or the blood serum of the organism acquires a bactericidal power capable of destroying the specific bacteria themselves, as in typhoid fever, cholera, dysentery.

In view of the relatively small amount of toxin developed in streptococcus cultures, and the absence of evident bactericidal properties in the serum of animals treated with streptococci, it seems reasonable to conclude that phagocytosis is an important factor in the development of immunity to streptococcus infection. From the evidence, both clinical and experimental, thus far accumulated, it may be concluded that antistreptococcus sera as at present prepared have but slight protective and curative value.

THE ETIOLOGY OF DYSBASIA ANGIOSCLEROTICA.

The senior Erb, at the last Congress of Internal Medicine held at Leipsic, gave an epitome of his observations on this disease since the publication of his long article on the subject in 1898. In his earlier paper he showed the close relation of "intermittent lameness" (*intermittierendes Hinken*) to arteriosclerotic changes in the vessels of the leg and foot. His more recent studies are of great interest in connection with the etiology of the affection.

Since the disease is a form of arteriosclerosis, the same causes that are held responsible for arteriosclerosis in general may be assumed to play a part in its etiology, but certain peculiar facts seem worthy of emphasis. In the first place the disease is one of the upper classes rather than of the lower; of 45 cases studied by Erb only two were not within his clinic; the rest were private cases. Secondly, it is a disease of men rather than of women; an analysis of 127 cases showed 120 men and only 7 women. Thirdly, Jews seem especially predisposed, though not so predominantly as some authors have believed. Higier, Goldblam and Idelson reported 58 cases, of which 55 were Jews, but in Erb's recent experience he found only 14 Jews affected to 29 Christians. Fourthly, the disease is rare before the age of 40. Of 45 cases, 8 occurred under 40 (only one under 30) and 37 above the 40th year, the latter cases being tolerably evenly distributed through the fifth, sixth and seventh decades of life. Fifthly, it is noteworthy that a previous syphilitic infection was demonstrable in only 10 of 45 cases, i. e., in 22.77 per cent.; since, according to Erb's statistics based on a study of 10,000 patients of the better class, 21.5 per cent. have syphilis, the existence of any especial relation between intermittent lameness and lues may be denied. Sixthly, there is no evidence that the use of alcohol is an important etiologic factor. Thirty-two of the 45 patients were either total abstainers or had used alcohol in strict moderation; only 7 admitted drinking to excess. Eighthly, it seems very probable that the excessive use of tobacco is one of the causes of the affection. Of 38 cases in which habits regarding tobacco were carefully inquired into, only 13 did not smoke at all or smoked in strict moderation, while 10 had been "heavy smokers," and no less than 15 had used tobacco in enormous excess (forty to sixty cigarettes or ten, fifteen or more cigars daily). In 14 of the excessive smokers, the abuse of tobacco was the only discoverable factor which could be thought responsible, the patients being free from a history of syphilis, alcoholic excess, exposure to cold and diabetes. The extreme rarity of the disease in women is a striking fact in this connection. Ninthly, injury from cold, especially to the feet and legs, was noted in 12 instances; the patients referred to "many cold baths," "frozen feet," "much work in water," "standing in snow," etc. Finally, gout, diabetes, lead poisoning and neurotic taint do not appear prominently in the histories of the cases.

It is worthy of record that in Erb's cases he found very frequently a number of possible etiologic factors combined. For example, syphilis with excessive use of tobacco; syphilis with abuse of both alcohol and tobacco; exposure to cold with excessive smoking; abuse of tobacco and alcohol with cold, etc. In four cases absolutely none of these injurious influences could be detected.

Erb's conclusion of the whole study is that syphilis and alcohol are of doubtful influence or act relatively slightly; that exposure to cold, especially of the feet, is of greater significance, and that finally the abuse of tobacco is of very great importance in the etiology of the disease. It is, as he says, very difficult to understand, however, just why the arteries of the lower extremities should be picked out. Possibly some vasomotor influence, as yet not recognized, is concerned in the process.

WOOD ALCOHOL NOT FOR INTERNAL USE.

The investigations of Drs. Buller and Wood, which we have been publishing,¹ illustrate how many articles may be the means of blindness and death because of the wood alcohol which they contain. Agitation of the subject ought to result in many new laws on the statute books of the various states to provide for protection against the misuse of wood alcohol. In our Medicolegal Department this week we quote from the law of Maryland, which provides a penalty for the use of wood alcohol in any extract, essence or fluid used for flavoring articles of food and drink. This is good for Maryland. Now what about the rest of the country?

INORGANIC CONSTITUENTS OF TUMORS.

Now that the enthusiasm for finding an organism as the causal agent in malignant tumors has somewhat diminished, it will be noted with interest that the direction the investigation of new growths is taking is along chemical lines. This is fully in accord with the general trend of modern biology and medicine. Undoubtedly, the chemical side has been too much neglected, though the progress of investigation of the problem from this point of view is entirely dependent on the progress of general physiologic chemistry, and this we know is comparatively a new field. In recent years attention has been called in many ways to the importance of the inorganic constituents of the organism in promoting vital activities. Though these elements are all present in small quantities and some in even the minutest quantities, still their action appears to be specific and their presence indispensable to the organism. The presence of iodine in the thyroid is a familiar example. Potassium is an element found in greater abundance in a young, rapidly growing organism than in the older, mature organism. Calcium, sodium, magnesium and iron may be mentioned as other inorganic elements all playing important rôles in the body metabolism. Investigation of the inorganic constituents of tumors of various kinds has recently been

1. THE JOURNAL, October 1, 8, 15, 22 and 29.

undertaken by Beebe.¹ Only a few observations were made, and hence any conclusions drawn therefrom would be necessarily untrustworthy. While no striking results were obtained, Beebe calls attention to the relatively large amount of calcium and the small amount of potassium in the older and more degenerated tumors, while in the young and rapidly growing tumors the reverse is true. If this fact is found to be generally true, it conforms to the well-established idea that potassium in some way operates to bring forth cellular activity, and therefore may play an important part in the metabolism of new growths. Certainly the field is well chosen, and interesting results may be expected from further research in this line.

SEA BURIAL.

Notwithstanding the popular jocosity on the subject, there is no special friendship or alliance between the medical profession and the undertakers. The latter profit by our failures and their business suffers by our success. We can not, however, indifferently and complacently regard the recent proposal by the president of the New York State Embalmers' Association that a law be passed prohibiting burials at sea. The mercenary spirit of the proposition is evident, and its insanitary character is also sufficiently clear. The only possible objection to a sea burial, aside from personal and sentimental ones, is the loss to the soil of the fertilizing constituents of the human organism, and that is too utterly absurd to notice. On the other hand, the retention of bodies on a ship, often with very imperfect means of preservation, and especially in the case of death from certain diseases, might be extremely dangerous. Still, the passage of such laws is a possibility. Similar gems of commercial cupidity appear sometimes on our law books, but they usually have a sort of pseudo-sanitary or other claim for excuse, which is wanting for the above-mentioned proposition.

DUST IN CITY AIR.

An immense amount of dust is daily inhaled by those living in a great city. No additional evidence on the point is needed, but the reported experiments in a New York hotel are interesting. This hotel has a ventilating system by which fresh air is supplied to each room after having been filtered through fine cheesecloth screens. It is reported that a barrel of dust was thus filtered from the air in the course of a week. It is presumed that the air was secured from a point where the least dust already existed so that without doubt a far greater amount circulated at other places—for example, on the street level where traffic was passing by. In cleaning the hotel pneumatic suction appliances are used, and in sweeping the halls and rooms in this hygienic manner, two and a half barrels of dust, it is said, were collected during one week. The hotel advises that the windows should not be opened, as the air supplied by the ventilating system is purer than that which can be obtained from outside. This system of interior ventilation and purification of air, which has been estab-

lished in many public buildings, etc., marks a distinct advance, and may be expected to be one of the regular features of our buildings and homes in the not far distant future.

THE CURABILITY OF LEPROSY.

In his latest report, the Surgeon General of the Army gives an account of favorable results obtained in the case of a soldier who had contracted leprosy, and expresses a hope, if not a belief, that this disorder may become amenable to medical treatment. With the means afforded by modern science, especially the mysterious x-ray and other similar agencies, there does seem room for hope that some forms at least of the disorder may yet succumb to medical science. There is no reason to suppose that the leprosy bacillus, which has apparently so little vitality outside the human organism, is absolutely resistant to all medical treatment within the bodies of its victims. At least, we may hope to abate some of its symptoms and rob the disorder of some of its most repulsive features. Dr. O'Reilly's report gives us additional evidence to that received from other sources of the possibility of something being done to destroy this opprobrium of medicine. We can not hope to overcome disease in general, but there is no reason why any single disease should be always and invariably resistant to therapeutic measures, and leprosy need not be the exception.

THE BEGINNING OF ARTERIOSCLEROSIS.

A discussion of the subject is not proposed; only the recording of a note and a suggestion. The recent literature indicating some probability of the supreme etiologic rôle of hyperfunction of the adrenals in the production of arteriosclerosis has opened a wide field of physiologic and pathologic research. In addition to the experimental work necessary exactly to establish the causative relation of the adrenals to arterial disease, it is exceedingly desirable to have careful clinical observation of the early cases of arteriosclerosis. In no other line of work do physicians have the opportunity to observe the beginnings of any arterial disease as that which comes to the examiner for life insurance. He it is, almost solely, who every now and then has the chance carefully to examine arterial sclerosis in young men, and at its first stage. At this time it is usually overlooked by the examiner, because up to the present most physicians do not look for it except in those of advanced years. The observant examiner knows this to be a faulty practice, as it is by no means infrequent to find slight thickening of the radials and temporals in men under 35 years of age. Therefore, it is urged that examiners look more particularly for this condition, make all possible history and notes of the case, and then, if practicable, advise the applicant's physician of the existing condition, with the suggestion that the case be followed up and studied as closely as possible for a long period of time. Without doubt, the general adoption of this method by careful workers would add greatly to our knowledge of the early clinical course and associations of arteriosclerosis. In any event, the appearance of the adrenal hypothesis bids

fair rapidly to throw some real light on the thus far extremely dark problem of the etiology of vascular sclerosis. While we make this suggestion specifically to this disease, it should apply to many others. The physician who is an examiner for life insurance has a peculiar advantage over others; he has the opportunity of examining the well man, the man who is supposed to be healthy. The earnest student will often run across a case in which he may detect a possible beginning of a chronic disease, and by a hint to the family physician a continuous study of its development may be carried on.

THE VALUE OF TALLQVIST'S HEMOGLOBINOMETER.

Most of the laboratory procedures designed to aid the practitioner are so time consuming or so technical that they are neglected altogether or turned over to the specialist. Any instrument which is cheap, simple and reasonably reliable ought, therefore, to come into instant favor with the profession, especially if the technical operation consumes only one or two minutes. Such an instrument is the Tallqvist hemoglobinometer, an instrument which was introduced two or three years ago, but which does not seem to have received the wide use which it merits. The comparison of a drop of blood on filter paper with a graduated color scale is so simple that many physicians have probably considered it inaccurate. It is well to bear in mind that accuracy in such procedures as estimating the hemoglobin is only relative with the best machines, and it is certainly more desirable that a large number of examinations should be made with a relatively inaccurate instrument than that a very few should be made with one which is relatively accurate. This is particularly the case if the range of error of the less accurate machine is known and is not so great as to exclude its use. Recently Verth and Schumacher¹ have made a large number of estimations with the Tallqvist scale, comparing them with 100 estimations made with the Fleischl hemoglobinometer. They find that there is an average variation in the reading of the Tallqvist scale of 10 per cent. from the reading of the Fleischl hemoglobinometer. This is not a marked difference, inasmuch as almost as great a variation often results in the readings of two observers examining the same blood. Verth and Schumacher come to the conclusion that the Tallqvist scale is perfectly reliable for all practical purposes. Tallqvist himself, in a recent paper,² adds his testimony, and that of Cabot and others whom he quotes from the literature, as to the general usefulness of the method. He adds one or two points which will be of service. In severe anemias he states that on holding the filter paper up to the light a moist ring is seen about the blood spot. This does not appear, as a rule, in chlorosis, but is seldom absent in pernicious anemia. In leukemia it is to be noted that the drop of blood is taken up by the filter paper with difficulty, dries slowly and irregularly so that the blood spot has a mottled appearance, and differs in gloss from the comparison scale.

THE PURE FOOD BILL.

The agitation in favor of the Pure Food Bill, which has been relaxed since the adjournment of Congress, will be resumed next winter when Congress is again in session. The evidence presented to the committees of the House and of the Senate in the past has been sufficient to warrant the most radical legislation for the protection of the people against the adulteration of food, drugs, etc. But as time goes on, other evidence is developing. The showing made by Bulley and Wood in our columns, in the full report on the effects of wood alcohol, is of itself sufficient to warrant legislation to protect the people against this substitution. The adulteration of whisky with wood alcohol in New York, to which we referred last week, and which caused the deaths of over twenty persons, comes at an opportune time to emphasize this point as regards wood alcohol. But there are other things happening, and these should be noted by those who want arguments next winter. For example, Dr. H. W. Wiley of the Government Bureau of Chemistry states that about 85 per cent. of all the whisky sold throughout the country is adulterated. He comments further that if pure whisky, except in the most moderate quantities, is injurious to the human system, how much more so, then, must be this adulterated preparation. Another instance is the fact that only a few days ago the New York police arrested some men belonging to a gang who are said to have disposed of half a million dollars' worth of bogus drugs. Some of their substitution was of coal-tar products and some of "patent medicines." While we are not particularly interested in the latter, nevertheless the fact remains that the public should be protected from taking any worse concoctions than those which it intends to take. It behooves us to give wide publicity to all these facts, and to bring to hear, on our representatives in the National Legislature next winter all the legitimate arguments we can to bring about the passage of the bill. The influence of money and commercial enterprise on the other side of the question must be counteracted by the thorough education of the people. And here is a field in which we can work now and continuously, for if we educate the people to a realization of the widespread substitution in drugs, and to the many and varied ways in which the health and even the lives of the people are sacrificed for commercial interests, it will not be long before their representatives will act.

Medical News.

GEORGIA.

Journal Applies for Charter.—Drs. Miller B. Hutchins and Bernard Wolf, Atlanta, have filed application for a charter for the Atlanta Medical Journal Company, with a paid-up capital of \$5,000.

Physician Injured.—Dr. Charles E. Murphey, Atlanta, while riding in his automobile was thrown out, when the wheels ran into a defective place in the pavement, and was seriously bruised and sustained internal injuries.

To Fight Tuberculosis.—The Georgia State Commission on Tuberculosis met in Macon, October 19, and organized with Dr. Charles Hicks, Dublin, chairman, and Dr. Bernard Wolf,

1. Münchener med. Woch., No. 20, 1904.
2. Berliner klin. Woch., No. 35, 1904.

Atlanta, secretary. The most important action taken was the adoption of the following resolution:

Resolved, That the members of this commission endeavor to secure statistics on each point mentioned in the bill creating this commission by correspondence with such physicians in the districts as deemed best by the members, or by any other means, and that they report the result to the secretary of this commission by April 1, 1905.

The bill calls for the report of the number of cases, number contracted, number imported, and a report as to whether physicians of the state are in favor of taking measures for the prevention of the disease.

ILLINOIS.

Seriously Ill.—Dr. Charles S. Young, Geneseo, is seriously ill from septicæmia supposed to have been contracted in performing an operation.

Smallpox.—There are nine cases of smallpox in and near Irving, the infection coming from East St. Louis.—The situation at Chatsworth is improving and quarantine will soon be raised.—The patients at Peru are progressing satisfactorily toward recovery.

Langdon Not Indicted.—In the case of Dr. P. R. Langdon, Kankakee, who was brought back from Europe charged with causing the death of a woman by a criminal operation, the grand jury failed to return an indictment, the vote being 11 for and 12 against.

Chicago.

Money to Combat Smallpox.—The City Council, at its meeting October 24, approved Health Commissioner Reynolds' request for an appropriation of \$15,000 to be used in fighting smallpox.

Personal.—Dr. Raymond C. Turck will go to Alma, Mich., November 1 as medical director and business manager of the Alma Springs sanitarium.—Dr. Frederick F. Garrison has located at Grand Boulevard and Forty-seventh Street.

County Hospital Staff Must Stand Examination.—Under a recently promulgated rule of the Board of County Commissioners, all physicians, whatever their age, rank or professional standing, will be obliged to pass a strict examination before they can be placed on the attending staff of Cook County Hospital. The board also voted to reduce the staff from 113 to 65.

The Week's Deaths.—During the week ended October 22, 462 deaths were reported, equivalent to an annual rate of 12.50 per 1,000. Consumption caused 54 deaths; acute intestinal diseases, 48; Bright's disease, 43; violence, 42; heart diseases, 38; pneumonia, 31, and cancer, 28. The increase of 38 deaths during the week is due to 9 more from Bright's disease, 13 from cancer, 9 from diphtheria, 11 from heart diseases, 5 from nervous diseases and 16 from violence.

Davis Park.—At the memorial services for Dr. N. S. Davis, referred to elsewhere, a letter was read from the president of the park commissioners of Chicago, in which it was announced that on account "of Dr. Davis' services to the city of Chicago and because of the high esteem in which he was held by the citizens," the South Park commissioners had named one of the new parks "Davis Square," in honor of Dr. Davis. It is bounded by Forty-fourth Street, Forty-fifth Street, Marshfield and Hermitage Avenues, contains a little over ten acres, and in the park field house a tablet will be placed in memory of Dr. Davis.

Memorial Service for Dr. N. S. Davis.—The friends, associates, students and admirers of the late Nathan Smith Davis filled Powers' Theater, October 23, at a memorial service, held to bear tribute to his character and achievements. Dr. Frank Billings spoke of Dr. Davis as a constructive worker in his profession; Dr. John H. Hollister, a lifelong friend, gave reminiscences of Dr. Davis' career; Bishop Lancaster Spalding, Peoria, delivered one of the principal addresses, and Bishop Stephen M. Merrill of Chicago the other. Over 1,000 were in attendance. The addresses will be printed in book form for distribution.

A Significant Warning.—The Department of Health in the current issue of the *Bulletin* discusses the smallpox situation as follows:

In the absence of any demonstrable source or cause of the 30 separate smallpox infection centers discovered during the week, the probability is strengthened that they have one common origin, to-wit, infected bedding and clothing of undetected cases that occurred last winter and spring. Because these cases were undetected, no disinfection of their bedding and clothing was secured; with the advent of warm weather blankets, underwear, etc., were packed away until the abnormally cold weather of the first few days of October brought them into use in artificially heated and poorly ventilated rooms, favorable to the active growth and diffusion of the contagion.

The most searching investigation has failed to show any connection between the infection centers; they are widely separated; the families were unknown to one another and did not interchange visits. Some of the victims had been away from the city; they had nothing in common, except the coincident development of the disease at a period directly related to the cold weather of three weeks previous.

It is true, nevertheless, that the majority of the cases had one significant feature in common: Of the 30 victims 27 had never been vaccinated at all, and the three exceptions had never been re-vaccinated. These latter were 34, 39 and 42 years of age respectively and bore imperfect, non-typical marks of vaccination attempted in childhood.

The lesson is obvious: For parents, see that your children are properly vaccinated forthwith. For adults—if not effectively re-vaccinated within the last few years, have the operation performed at once.

For parents the lesson gains added significance from the fact that ten of the cases or one-third are of children under 6 years of age. Last year's figures showed that a population of 245,000 under 6 years of age furnished 89 cases, or one case to every 2,750 of this age group—130 per cent. more than in the population over 6 years of age. Out of these 89 cases there were 14 deaths—a mortality rate of 15.7 per cent., or 23.6 per cent. greater than the mortality rate among those over 6 years.

The younger the child the more severe and fatal is smallpox.

KANSAS.

Proposed Sanitary Law.—As boards of health of Kansas cities are now powerless to remove nuisances, charging the cost to property owners, the State Board of Health is having a bill prepared for introduction in the next legislature giving boards of health in all cities authority to abate nuisances and charge the cost to the property on which they exist.

State Hospital for Epileptics Open.—The first group of cottages in the female department of the Kansas State Hospital for Epileptics at Parsons was opened for patients October 17, when 88 patients were transferred from the state hospitals for the insane. The male epileptics were transferred at the opening of the institution last year. The entire epileptic population of the state hospitals for the insane has now been removed to Parsons. The hospital has at present 265 patients, with a total capacity of 400. It is built on the cottage plan and is designed to accommodate 800 to 1,000 patients when completed. The construction and arrangement of the buildings afford ample opportunity for classification. Both sane and insane epileptics are received for treatment.

MARYLAND.

Baltimore.

Applies for Pardon.—Application has been made to the Governor for the pardon of Dr. George C. Worthington, who was sentenced in May, 1899, to ten years' imprisonment for practicing criminal abortion.

Osler Memorial.—The movement for a memorial to Dr. William Osler is now taking the direction of a great medical and library building. A very high figure is set for the collections, which it is thought will be national—possibly international—in extent.

Elected Presidents.—The following were elected presidents of their respective societies for the year: Johns Hopkins Medical Society, Dr. Joseph C. Bloodgood; Johns Hopkins Hospital Historical Club, Dr. Thomas McCrae; Medical Journal Club, Dr. John Ruhrah, and University Hospital Medical Society, Dr. John C. Hemmeter.

Personal.—Dr. Henrietta M. Thomas, daughter of the late Dr. Richard H. Thomas, will spend the winter in England, where she has relatives.—Dr. Alice L. Ernst, who has charge of a large hospital at Jhansi, India, under direction of the Woman's Union Foreign Missionary Society of New York, is taking a post-graduate course in Johns Hopkins Medical School.

NEW YORK.

Gold Medal for the Craig Colony.—The Craig Colony for Epileptics, Sonyea, has been awarded a gold medal for its exhibit at the St. Louis Exposition. The exhibit consisted of models, in groups, of thirty-eight of the sixty-six buildings that comprise this institution.

Bogus Doctors Fined.—Attorney Lewis, representing the state medical association, prosecuted a number of persons for practicing as physicians without proper registration. Four were convicted and fined, the sums ranging from \$35 to \$150, with the alternative of from ten to sixty days in jail.

Smallpox.—A serious outbreak of smallpox has occurred in the French settlement of Malone. The early outbreak is stated to be due to the unusually cold weather, over 70 cases having been reported.—Five cases of smallpox have ap-

peared among the bricklayers of Croton Point. It is supposed to have been brought from Hackensack, N. J.

Vaccination Compulsory.—At a special term of the Supreme Court in Albany the decision in a case in which the plaintiff had attacked the law on the ground that it was a violation of that provision of the constitution which provided that every child in the state should be afforded the opportunity to have a common school education, upheld the law that a child could not attend a public school unless vaccinated.

Society Hampered by Lack of Funds.—The Medical Society of the County of New York, replying to the criticism of the small number of medical charlatans punished through its efforts, gives as a reason lack of funds. The society has curtailed its scientific features in order to devote its funds to the suppression of quacks. It is also hampered by the difficulty of getting victims to testify, by certain defects in the medical law, and by objectionable advertising.

County Society and Club Practice.—At a regular meeting of the Fulton County Medical Society, held at Johnstown, Oct. 13, 1904, the following amendment to the by-laws of the society was unanimously adopted:

On and after the first day of January, 1905, no member of this society shall accept the position of club, society or organization physician, or do or agree to do any medical or surgical work for any club, society or organization at a less rate than the regular customary charges for like services rendered by other physicians for patients not members of such club, society or organization.

Also, in no case shall any physician agree to attend the families of the members of such club, society or organization at half price or a less price than the regular rate.

Nothing in this section shall be construed as preventing any member from attending the worthy poor at a less rate or from giving free service to those who are too poor to pay anything, or from acting as city, county or town physician, health officer, or from serving under any political appointments.

Any violation of this by-law shall be considered unprofessional conduct and shall render the member guilty thereof liable to suspension or expulsion from this society, as the society may determine.

Buffalo.

Tuberculous Houses Disinfected.—About 100 houses in which tuberculosis has existed are to be disinfected by the Department of Health.

Must Be Vaccinated.—Now that the Court of Appeals has affirmed the right of the educational authorities to exclude from the public schools pupils who refuse to be vaccinated, those who refuse to submit to the operation will be denied the use of the public schools in Buffalo.

Daily Medical Inspection of Schools.—A complete system of medical inspection of the schools has been established. A physician is sent daily to every school and the scholars are inspected as to contagious or infectious diseases. Trained nurses are assigned to the schools in the poorer districts. Children are made to keep themselves clean and three nurses make home inspections. They show the parents the necessity of keeping the children clean and healthy.

Exclusion and Fumigation.—For the benefit of the public school teachers the Board of Education published the following: "The Board of Health requires that the children of the household in which the contagious disease exists be excluded from the school until the termination of the disease and fumigation of the premises by the Board of Health. This applies to all contagious diseases except smallpox, when all the children in the house in which the case exists are excluded."

September Deaths.—The monthly report of the Department of Health for September shows a death rate of 15.88 per 1,000. The principal causes of death were: Consumption, 41; cholera infantum, 26; diphtheria, 7; typhoid fever, 15; debility, 48; cancer, 24; apoplexy, 21; valvular disease of the heart, 31; pneumonia, 17; appendicitis, 6; enterocolitis, 15; gastroenteritis, 20; ileocolitis, 12; nephritis, 22, and violence, 31. The total deaths for September were 503, as compared to 454 for September, 1903.

New York City.

Diphtheria Epidemic.—Nearly fifty pupils in public schools at Bay Ridge and Fort Hamilton in Brooklyn have been stricken with diphtheria.

Widal-Ehrlich Tests Free.—New York City makes the Widal blood examination and the Ehrlich diazo reaction as well as blood examinations for malaria gratis. This is in addition to sputum analyses.

Free from Smallpox.—During the past four or five years the city has been remarkably free from smallpox. There have been so few cases that the smallpox quarters on North Brothers Island has been cleared out.

Charitable Bequests.—Under the will of the late Moritz Frankenthal, the Hebrew Infant Asylum, the Montefiore Home for Chronic Invalids, the Home for Aged and Infirm Hebrews, Mt. Sinai Hospital and other charities received \$1,000 each.

Health Department Gets Prize.—Dr. Darlington, of the Health Commission of New York, received word that the department's exhibit at the St. Louis fair had been awarded the grand prize, the highest honor that this class of exhibits can get.

Entertainment for Hospital.—The Garde Républicaine Band of France gave a concert for the benefit of the French Hospital, which realized about \$4,000. The French government has contributed \$20,000 toward the erection of this building, now nearing completion.

Teacher for Consumptives.—The Board of Education has granted the request made by the Association for Improving the Condition of the Poor, for a teacher at the Seaside tent camp, Coney Island. These children have tuberculosis of bones, and the board, therefore, thinks that there is no danger of contagion.

Croton Water Not Contaminated.—The health commissioner, after going over the Croton watershed and examining the supply, says that from a bacteriologic standpoint the water is perfectly safe, though he thought that the Italian colonies located in close proximity should be removed. This might require special state legislation.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 15, 320 cases of tuberculosis, with 157 deaths; 275 cases of diphtheria, with 26 deaths; 140 cases of typhoid fever, with 26 deaths; 109 cases of scarlet fever, with 8 deaths; 26 cases of varicella; 52 cases of measles, with 6 deaths, and 13 deaths from cerebrospinal meningitis.

Pneumonia Inquiry Begins.—The pneumonia commission has had its first meeting in the offices of the Board of Health. The subjects discussed here were the frequency and variation of the occurrence of pneumonia, evidence of its communicability, mouth infection, seasonable relations and the collection of statistics and geographical relations. Dr. Edward G. Janeway was chosen chairman of the commission and Dr. T. Mitchell Prudden was made secretary. The commission was subdivided into a clinical committee and a bacteriologic committee.

New Dean.—The deanship of the College of Physicians and Surgeons of Columbia University, which has been filled by Dr. John G. Curtis as acting dean since the resignation of Dr. McLane, in June, 1903, has been filled by the election for the statutory term of Dr. Samuel W. Lambert, professor of applied therapeutics. Dr. Lambert becomes ex-officio a member of the Columbia University Council, of the board of trustees of the Roosevelt Hospital, and of the boards of managers of the Sloane Maternity Hospital and of the Vanderbilt Clinic.

OHIO.

Valentine in Cincinnati.—Dr. A. Ravogli gave a reception at his home in Clifton, October 17, in honor of his guest, Dr. Ferd. C. Valentine of New York City, who delivered an address before the Cincinnati Academy of Medicine.

Appointments.—Dr. Charles B. Rogers, formerly assistant physician at the Massillon State Hospital, has been made resident physician at the Cincinnati Sanitarium, College Hill.—Dr. John B. Alcorn, Gallipolis, has been appointed second assistant physician at the state penitentiary, Columbus.

County Society Does Its Duty.—Through the efforts of the Columbiana County Medical Society, Charles D. Stevenson, a practitioner of magnetism and electro-therapeutics, was indicted for illegal practice of medicine, pleaded guilty, and was sentenced to pay a fine of \$25 and costs, and to stand committed until payment of the fine and costs.

PENNSYLVANIA.

Philadelphia.

Physicians' Offices Robbed.—During the past few weeks a woman has visited the offices of physicians throughout the city and has stolen office furniture and instruments.

Lectures to Teachers.—Arrangements are being made by the Department of Health and Charities for a series of lectures to school teachers on "The Detection of Contagious Diseases," by Jay F. Schamberg of the Municipal Hospital.

Births During 1902 and 1903.—During 1903 there were 15,031 male and 14,810 female births, making a total of 29,841.

In 1902, 13,796 males and 13,017 females were born, making a total of 26,813, thus showing an increase in 1903 of 3,028 or 11.3 per cent.

University Medical Council.—The following have been chosen members of the Council of the Department of Medicine in the University of Pennsylvania: Dr. Alfred Stengel, to represent the professors of clinical medicine; Dr. Edward Martin, the professors of clinical surgery; Dr. Charles K. Mills, the professors and clinical professors of specialties, and Dr. Howard Fussell, teachers below the rank of clinical professors.

Copper as an Antiseptic.—Dr. George T. Moore, chief of the laboratory of plant physiology of the Department of Agriculture, spoke in this city October 21 on copper, both the metal and sulphate, as a germicide. As a bactericide, he said it possessed three cardinal points, efficiency, harmlessness and cost, and cited scientific authorities as to the harmlessness of the solution. He asserted that reservoirs holding 80,000,000 gallons had been treated successfully at a cost not greater than \$50. (See THE JOURNAL, Oct. 15, 1904, page 1157.)

Health Report.—The total number of deaths for the week was 380, a decrease of 34 from the record of last week and a decrease of 10 as compared with the corresponding period of last year. Typhoid fever cases show a marked decrease, but the total number of contagious disease cases exceeds those of last week, owing to the prevalence of scarlet fever and diphtheria. Two hundred and thirty-three cases of contagious disease, with 22 deaths, were reported during the week, as compared with 211 cases and 22 deaths during the preceding week. Eighty-eight deaths were due to diseases of the lungs.

Meat Preservative Adulteration.—C. W. Spencer was convicted of having sold meat preserved by the use of sodium sulphite. This case has aroused much interest throughout the state, and testimony was given by Drs. James C. Wilson, Philadelphia; Victor C. Vaughan, Ann Arbor, Mich.; Adolph Koenig, Pittsburg, and also by Edward M. Chase, chemist in the Department of Agriculture, Washington, all of whom testified for the commonwealth. They all asserted that this agent was harmful and poisonous. Dr. Wilson stated that the material combined with the hydrochloric acid in the stomach and thus interfered with digestion. He also asserted that from its absorption it destroyed the blood and therefore was responsible for anemia. Drs. Hobart A. Hare, Robert G. Eccles, Robert N. Willson and Oscar Leibrich of Berlin testified for the defense.

Food Preservatives Discussed.—At the meeting of the Medical Jurisprudence Society in the College of Physicians, October 17, Dr. William S. Wadsworth, coroner's physician, and Dr. Solomon Solis-Cohen advocated the establishment of legislation to eliminate the use of drugs as preservatives. They stated that only prolonged experiments, made under every possible condition, should be accepted as proof that any preservative is harmless. Dr. Henry Leffmann, speaking on the legislation of the sale of foods, said: "The adoption of food laws is merely the beginning of the work of suppressing adulteration. It is necessary to institute investigations, obtain and analyze specimens, make results public and bring prosecution." He further said that analytical results should be obtained and reported quickly, and that all the prosecutions shall be brought not more than a month after the purchase of the sample, and that the formal trial should not be more than six months later. He also advocated a system of warning to dealers. The first offense, he said, should be met by written notice to the offender, that a second offense would be prosecuted. Dr. Thomas L. Coley read a paper on the results of experiments he had made with benzoic acid and sodium benzoate. Benzoic acid, he says, is not a poisonous drug, and he could find no deaths recorded from its use. He cited an instance where one man took 680 grains without any bad result. He found by experiment that it has no bad effects on digestion in the proportion of one to ten. In food preservatives he found that it was used only in the proportion of 1 to 1,000. Vinegar, he stated, was more powerful for harm than any of the acids used as food preservatives.

TENNESSEE.

Old Gallatin Physicians Ill.—Dr. Andrew J. Swaney is critically ill with heart disease, and Dr. Thomas M. Woodson with paralysis.

Recommend Isolation Hospital.—The Davidson County Board of Health at its quarterly session in Nashville, October 3, unanimously recommended the erection of an isolation hospital at a cost of \$6,000 or less.

Smallpox.—At the meeting of the State Board of Health, October 5, a tabular statement was presented showing the prevalence of smallpox in the state for the six months ended September 15. There were 2,486 cases reported from 64 counties, 1,374 white and 1,112 colored, with a total mortality of 59. On September 15 there were 58 cases in the state, 14 of which were in Cooke County and 9 in Marion County.

Medical Departments Open.—The Medical Department of Vanderbilt University, Nashville, opened October 3. Dr. William Litterer has been made adjunct professor of pathology, bacteriology and physiology, and Dr. Robert S. Doak, adjunct professor of ophthalmology. The Medical Department of the University of Tennessee, Nashville, was formally opened October 3. The Medical Department of the University of Nashville opened for its fall session, October 1. The Medical Department of Grant University, Chattanooga, opened informally October 3.

WISCONSIN.

Typhoid Epidemic.—In Port Washington, a town of 3,400 population, 72 cases of typhoid fever have been reported, with four deaths.

School Inspectors Chosen.—Drs. Max V. Beust and John A. L. Bradford have been selected as medical examiners for the La Crosse schools for the coming year.

Ill and Injured.—Dr. Solon Marks, Milwaukee, slipped and fell recently, fracturing his hip.—Dr. Alfred L. Buchan, Racine, recently sustained serious wounds and bruises by falling through a window.

Personal.—Dr. Adolph Sonntag has been appointed house physician of Emergency Hospital, Milwaukee, succeeding Dr. George Hughes, who has received an appointment as physician at the Devil's Lake Indian reservation, North Dakota.

GENERAL.

Yellow Fever Stamped Out.—Yellow fever seems to be practically stamped out in southwest Texas and on the Mexican border. The United States Public Health and Marine-Hospital Service has withdrawn the sanitary force which has been stationed in the border section of the state.

California Physicians' Directory.—A new edition of the Official Register and Directory of Physicians and Surgeons in the State of California has just been received. This edition includes the names of physicians in Oregon and Washington and a list of hospitals and trained nurses. It also contains a copy of the laws regulating the practice of medicine in the three states and gives a list of the California state and county medical societies with their officers.

Sanitation in Cuba.—It is reported that the sanitary conditions of the cities in the eastern part of Cuba are becoming worse. The minority members of the Senate special committee on the question of resumption of government aid for the sanitation of cities has submitted a bill appropriating \$2,000,000 for that purpose. Of this sum \$500,000 is apportioned to Havana, \$123,000 to Santiago and \$143,000 to Puerto Principe. The majority of the committee oppose the granting of so much assistance.

Warning Against Impostor.—One of THE JOURNAL correspondents states that the profession should be warned of an impostor representing himself as a German physician of Disseldorf, who was compelled to come to America because he killed an army officer in a duel. He speaks of von Bergmann, Koehler and other surgeons as his friends, and, being in straitened circumstances, solicits funds. He is poorly dressed, speaks German very well and uses many technical medical terms. It is said that he picked up these terms while acting as orderly in Bellevue Hospital, New York.

Principal Causes of Death in Manila.—The report of the Board of Health for the Philippine Islands for June, 1904, shows that during that month in the city of Manila there were 14 deaths from typhoid, 16 from intermittent fever and malarial cachexia, 11 from pneumonia, 10 from cerebral congestion and hemorrhage, 9 from tetanus, 9 from organic heart disease, 14 from nephritis, 9 from tuberculosis of the larynx, 7 from chronic rheumatism, 5 from leprosy, 5 from angina pectoris, 4 from variola, 275 from convulsions, 250 of which occurred in children under 1 year of age, and 387 from various other causes. Forty-eight per cent. of the deaths in Manila during June occurred among children under one year of age, as compared with 53 per cent. during May.

Annual Report of the Surgeon General of the Navy.—In his annual report, Surgeon General Rixey, referring to the great difficulty of securing qualified medical men for the Navy, says that the interest of the entire naval personnel, officers and enlisted, is too seriously involved in the success of the effort now being made to secure and maintain the highest state of professional efficiency in the medical corps for it to be wise to place it at a disadvantage, in comparison with the medical staff of the Army, by offering inferior inducements to civilian medical men who might be inclined to enter the naval service. The bureau renews its recommendation that Congress be asked for legislation changing the name of the different grades of the medical corps now existing, as follows:

In place of surgeon general, surgeon admiral; and in the other grades, medical director to become surgeon captain; medical inspector, surgeon commander; surgeon, surgeon lieutenant commander; passed assistant surgeon, surgeon lieutenant, and assistant surgeon, surgeon lieutenant (junior grade).

The report also states that the Naval Medical School in Washington, D. C., is in a more thorough condition of preparedness for all its work than in the initial session of last year, and is now on a firm footing. The completion of improvements in the museum building to meet the requirements of larger classes increased the facilities for instruction, and supplies adequate accommodations.

CANADA.

Causes of Typhoid in Winnipeg.—The medical commissioners appointed by Winnipeg to report the cause of the prevalence of typhoid fever assign the epidemic almost wholly to insanitary conditions prevailing in the city and to the more-than-usually abundant house flies.

To Enlarge Hamilton Hospital.—A new wing is to be built to the Hamilton General Hospital at a cost of \$40,000, and to accommodate 65 patients. At the coming municipal elections the citizens will be asked to vote on a by-law for the purpose of raising \$50,000 for hospital purposes.

Government Detention Hospital at St. John, N. B.—Dr. P. H. Bryce, Ottawa, chief medical officer of the department of the interior, is in St. John, N. B., to select a site for a government detention hospital for which the federal government has voted \$30,000. The hospital is expected to be ready for patients next season.

FOREIGN.

A Medical Charity.—Dr. Blöde has given the city of Nuremberg an endowment of \$2,500, the income to be applied to supplying nourishing food to poor convalescents.

The German Red Cross Society in the East.—The German Red Cross Society has decided to erect a hospital at Irkutsk, Siberia, and to provide it with an auxiliary ambulance train. Negotiations are in progress regarding a similar hospital for the Japanese.

Von Bergmann Invited to Address the French Congress of Surgery.—Prof. E. von Bergmann of Berlin has accepted an invitation to deliver an address before the French Congress of Surgery this month. It is the first time that an invitation of this kind has been sent across the Rhine.

Koch Returns to Africa.—There has been a rumor that Koch intended to settle in Paris, but he is merely visiting there on his leisurely way to German Africa to study the cattle diseases transmitted by the tick. His research this time is purely scientific and not directly practical, his attention now being devoted to the study of the important problems of general biology. As foreign associate he was welcomed in the scientific organizations of western Europe, and in an interview reported in the *Presse Médicale*, stated that the combination of sanatorium and tuberculin treatment apparently induced an actual immunization in tuberculosis. The results of sanatorium treatment alone are not lasting. He remarked that he leaves the study of tuberculosis now entirely to others.

Visit of the French Physicians to London.—About 150 French physicians and surgeons formed the party which spent three interesting days in London two weeks ago. They were received and entertained with great cordiality, nearly 400 sitting down to the banquet, where witty Frenchmen spoke English and Englishmen French without restraint. The *Lancet's* leading editorial was in French, "Welcome et au revoir," and the institutes, hospitals and leading members of the British medical profession vied with each other in hospitality. A very large local committee had the matter in charge, and subscriptions poured in for the entertainment of the guests.

Sixth International Congress of Physiology.—The International Congress of Physiology recently concluded its sessions

at Brussels, to convene again in 1907 at Heidelberg, when Professor Kossel will preside. Professor Heger of Brussels was president of the congress and inaugurated a movement to erect a monument to Marey, the inventor of the sphygmograph, etc. Athanasie of Paris described experiments with what he called chromostylography and chronophotography, that is, the making of permanent records of the findings of the various registering apparatus used in physiologic research. The reports of the observations made at the international observatory on Mont Rosa, about 10,000 feet high, under charge of Professor Mosso of Turin, proved important for the study of the influence of altitude on the physiologic processes.

LONDON LETTER.

The Middlesex Hospital Cancer Research Laboratories.

The third report from the cancer research laboratories of the Middlesex Hospital has been issued. It is edited by Dr. Lazarus-Barlow and contains 12 separate papers. Mr. W. S. Handley writes on the centrifugal spread of mammary cancer in the pareties and its bearing on operation. He contends that the chief plane of extension is the deep fascia and that the skin nodules are secondary upgrowths from this; that this has not been sufficiently recognized by surgeons, so that the deep fascia is insufficiently removed. He also holds that the secondary foci in bones takes place in the same centrifugal manner, the disease extending by the medium of fascial attachments. Dr. Lazarus-Barlow contributes a paper on 4 cases of endothelioma of the tongue—a condition that has not been previously described. The patients were all males of the ages of 42, 44, 51 and 61. There is a difficulty in distinguishing the growths from epithelioma originating in the malpighian layer in which the cells remain of the undifferentiated type characteristic of this layer. Considerable aid in the differentiation was obtained by the study of the metastases. There is an interesting paper on the statistics of the Mayo Hospital, Lahore, India, by Captain Sutherland, I.M.S., and a comparison between these and the statistics of the Middlesex Hospital. Carcinoma of the penis is very common in the Mayo Hospital and occurs almost exclusively in Hindus; the freedom of Mahomedans is ascribed to circumcision. Carcinoma of the skin in the Mayo series is 17.6 per cent. of the whole; in the Middlesex, only 3.8. As to age periods, the greatest incidence occurred ten years earlier in the former series. Multiple primary growths are discussed by Dr. R. A. Young and 8 cases are described. In 5 the growths were of different histologic character and in 3 they were of the same type, but in two of the latter the independence of the growths was somewhat doubtful.

Formalin in Milk.

The question whether the minute quantities of formalin used to preserve milk exercise any injurious effect has given rise to a good deal of discussion and contradictory views have been expressed by experts. A case in which milk contained only .001 per cent. of formalin has been decided against a milk vendor. For the defense it was alleged that some preservative was necessary when milk had to be brought a long distance and that the quantity used in this case could not possibly injure health. Dr. Rideal, a public analyst and authority on hygiene, said that he was the first to make experiments in this country with formalin, in 1894, and had never known it to be injurious to health. He had given his son twenty times the quantity in question. The royal commission recommended the prohibition of the use of formalin because it was impossible to ascertain the quantity used in milk. On the other hand, Dr. Harris, health officer for Lewisham, where the action was tried, said that after taking daily a pint of milk containing one part of formalin in 100,000 for ten days he felt much discomfort and nausea, and considered that it must be deleterious to young and delicate children. Dr. Toogood, superintendent of the Lewisham Infirmary, said that formalin was an irritant poison and he had no doubt that one part in 100,000 retarded digestion if taken for any period. A fine of \$25 and \$12 costs was imposed.

The Bombay Plague Research Laboratory.

Valuable work has been done in the Bombay plague research laboratory which was founded by Mr. Haffkine in 1896, at the time of the outbreak of the disease in India. It soon became evident that the ordinary methods of disinfection, isolation, segregation, etc., were not applicable to the epidemic. The activity of the laboratory was then concentrated on the manu-

facture and distribution of a serum for preventive inoculation introduced by Haffkine. During the period in which the laboratory has been in existence the number of doses issued has amounted to 5,750,000, of which 250,000 has been sent to countries outside of India. It is claimed that the death rate of the inoculated is only one-sixth of that of the non-inoculated. The number of attacks is less than a third of that in the non-inoculated and the proportion of deaths to attacks is less than 25 per cent., or less than one-half of that in the non-inoculated. These figures refer to the natives, whose susceptibility to plague is high. Among the inoculated Europeans no fatal cases have been observed. On the other hand, the use of curative serums, such as Yersin's and Lustig's have not been attended with any notable benefit. A large amount of research work has been done in the laboratory in connection with various tropical diseases.

The Increase of Insanity.

The fifty-eighth report of the commissioners in lunacy shows that on Jan. 1, 1903, there were in England and Wales 113,964 persons certified as insane, and on Jan. 1, 1904, 117,199, an increase of 3,235. This increase is less than that of the previous year, which was 3,251, but it exceeds the annual average increase in the preceding ten years by 321. The proportion of insane to the general population at the beginning of the present year was 34.71 per 10,000 or one for every 288. In 1859 the proportion of certified insane to population was only 18.67 per 10,000, and since then the increase has been steady. This increase has been practically confined to the pauper class. Thus since 1859 the proportion of private patients has risen from 2.38 only to 2.83 per 10,000, while that of pauper lunatics has risen from 15.95 to 31.62. The assigned causes of insanity do not differ materially from those in the last report for the years 1897-1901. Hereditary influence was ascertained in 18.6 per cent. of the males and 24.4 per cent. of the females. Alcoholism takes a chief place among the physical causes, being noted in 22.8 per cent. of the males and 9.5 per cent. of the females. Venereal disease is assigned as a cause in 3.6 per cent. of the males and .8 per cent. of the females. As to the forms of insanity, the statistics of institutions, excluding those for idiots, show that for 1899-1902 5.5 per cent. of the admissions were for congenital insanity, 41.7 per cent. for mania, 29.5 per cent. for melancholia, 4.1 per cent. for delusional insanity, 6.4 per cent. for general paralysis and 12.8 per cent. for dementia. Since 1899 there has been an increase of melancholic types and a decrease of mania. In 1903 8,299 persons were discharged recovered. The percentage recovery rate on admissions exclusive of readmissions was 37.35, which is slightly below that of the average of the preceding ten years (38.08).

The Treatment of Idiots and Epileptics.

A royal commission has been appointed to consider the existing methods of dealing with idiots and epileptics, and with imbecile, feeble-minded or defective persons not certified under the lunacy laws, and in view of the hardship or danger resulting from or to such persons and the community from insufficient provision for their care, training and control, to report as to the amendments in the law or other measures which should be adopted in the matter, due regard being had to the expense involved in any such proposals and to the best means of securing economy therein.

PARIS LETTER.

The Crocker-Doyen Controversy.

During the last two weeks the attention not only of the medical profession, but also of the general public, has been called to what is known as the Crocker-Doyen affair, in which the reputation of one of the best-known French surgeons is at stake. The daily papers have devoted much space to a recital of the opinions of the various medical men as to Dr. Doyen's actions in the case. Dr. Doyen is about 45 years old and his father was a physician, who practiced at Rheims. After passing his internate in the Paris hospitals, a position which he obtained in 1881, he set up a *maison de santé* or private surgical hospital in his native town, and was soon known for his clever operating as *Doyen de Rheims*. At that time he attracted attention by his method for operating on fibroids, in which he aimed at great rapidity, and by his angiostribe, a species of huge pincers for obliterating arteries by pressure. Not finding Rheims a sufficient field, he erected a costly *maison de santé* in the rue Piccini, a street leading off the avenue du Bois de Boulogne, and where he operated on patients of every class. It was in this hospital that he operated on Radica

and Doodiea, who were to have been operated on by Kirmisson, professor of infantile surgery, but who were removed from Dr. Kirmisson's wards at Trouseau by means which were not to the liking of the latter. Dr. Doyen's interference in the Labori case is well known to American readers as well as his striving after notoriety by having himself cinematographed while operating. In 1902 he claimed to have found a serum for carbuncles, boils and other ills due to the same category of microbes, and presented to the Academy of Sciences his treatment for cancer by a special serum, claiming to have cured a number of patients. At the Congress of Surgery, held in 1903, he described the results he had obtained and it was then that Professor Pozzi asked him why he had not published the composition of his serum and details of its mode of preparation. Dr. Pozzi remarked that it would be an injustice to Dr. Doyen to suppose that he desires to retain the monopoly of it, as that would constitute the employment of a secret remedy, a speculation that would certainly be far from the intentions of his honorable colleague. Dr. Doyen's answer was that he had always placed this serum at the disposal of his colleagues and that he had followed the example of the Pasteur Institute. Dr. Pozzi replied that so long as Dr. Doyen did not publish the methods employed in preparing his serum, it could not be considered otherwise than as a secret remedy. There is a law in France which punishes anyone selling a secret remedy, the composition of which has not been registered, by a fine of from 10 to 1,000 francs (\$2 to \$190), and Dr. Doyen is liable to this.

In connection with the tremendous fee which Dr. Doyen demanded from Mr. Crocker, the circumstances attending which having been reported in the daily papers, various French physicians have been interviewed and their opinions vary considerably. Dr. Ledetee, surgeon of the Necker Hospital, remarked that one always comes to an understanding with a patient when one is conscientious. Dr. Pinar, the chief of French accoucheurs, said that he had never asked for a fee and never would. Dr. Legond, the well-known gynecologist, said that fees were never exacted in advance. Dr. Leguen considered that the serum was worthless and, referring to the practice of exacting a fee in advance, remarked that it was not entirely regular. Dr. Max Nordan, the well-known author of "Degeneration" and kindred works, cited two cases where a similar sum, i. e., 100,000 francs (\$19,000), was paid to a physician. In one case Dr. Pajot, a celebrated accoucheur, went to Rio de Janeiro to treat the oldest daughter of Dom Pedro II. and spent three weeks on the road, and stopped ten days in Rio. The second was when Kussmaul, the professor of internal medicine at Heidelberg, was called to Paris by Baron Hirsch, to see his oldest son, who was ill with typhoid fever. The best practitioners in Paris had pronounced the case hopeless. Dr. Kussmaul could only agree with his French colleagues, but Baron Hirsch begged him to stay and, when after twenty-four hours the child was dead, he handed him a check for 100,000 francs. Dr. Charles Walther, who is perhaps the best general surgeon in Paris, refused to be interviewed, following in this the example of Professor Debove, the dean of the faculty. Professor Berger, one of the professors of clinical surgery, the best known surgeon in Paris for bone affections, remarked that he did not possess a sufficient number of the facts to give an opinion. Dr. Doyen has also been interviewed and said that he was a victim of the ill-will of his colleagues, and that he would make a communication to the Congress of Surgery October 18.

Correspondence.

Distribution of Medical College Graduates.

ST. LOUIS, Oct. 18, 1904.

To the Editor:—In your Educational Number, Aug. 13, 1904, is printed a "Table of State Board Examination Results" for the year 1903. The table is incomplete, as indicated by asterisks, as to the returns from Illinois, Kansas, Montana and Pennsylvania, and yet the statistical genius that got up this table proceeds to calculate "percentages of failures" from these faulty data. The Medical Department of Washington University is made a victim of this inaccuracy and misleading conclusion.

We are quoted as having had 13 men up for examination, viz.: 4 in California, 1 in Indiana, 1 in Iowa, 1 in Michigan, 1 in New York, 1 in North Carolina, 3 in Oklahoma, and 1 in Washington. Three failures are recorded, viz.: 2 in Califor-

nia and 1 in Oklahoma. And so we are charged with a failure of 23 per cent.

I have before me the official record of Dr. James A. Egan, secretary of the Illinois State Board of Health, to-wit: "In 1903 twenty-seven of your graduates appeared before this board for examination, and all of these candidates passed successfully."

It appears, therefore, that out of 40 applicants 3 failed, or 7.5 per cent. And even this figure is not a true indication. The men who failed in California and Oklahoma are graduates of long ago before the organization of the Medical Department of Washington University, which took place in 1891. These men have evidently not kept pace with the modern advances in medicine.

ROBERT LUEDEKING, M. D.,
Dean, Medical Department, Washington University.

[It is pleasing to note that our table is already doing good work. Criticisms such as the above were not unexpected, and we are glad to correct any wrong impressions conveyed thereby. It is to be hoped that other medical colleges will have as earnest a desire as the Medical Department of Washington University to have as good a showing as possible. The table referred to was as complete as could be prepared from the data obtained and on the basis of such data is accurate. It was based on reports of examining boards for the calendar year 1903, not pretending to be only for 1903 graduates. As was carefully stated in our editorial, which accompanied the table (page 473), the percentages of the medical colleges of certain states would have been different had the examining boards of those states sent us the reports of their examinations as they were repeatedly requested to do. For instance, if the Missouri State Examining Board had sent us reports that could be used, the percentage of the Medical Department of Washington University, as well as those of the other medical colleges of Missouri, would undoubtedly have been different.—EDITOR.]

Diagnosis of Cholecystitis and Cholelithiasis.

CINCINNATI, Oct. 21, 1904.

To the Editor.—The excellent contribution of Dr. Parker Syms with the above title, in THE JOURNAL for October 15, serves me as a text to say something that I have frequently felt prompted to say on the significance of pain and tenderness as symptoms of cholelithiasis. The question is one of importance for the reason that, as I have had frequent occasion to observe in late and complicated cases that have been referred to me for operation, the delay on the part of the practitioner in making the diagnosis has been due to the absence of what he has been taught to look on as a "characteristic pain." Dr. Syms says of this pain that its characteristic features "are its acute onset, its colicky nature, and, as described by Lambert, the patient experiences a sense of something boring through the abdomen to the vertebra." That there is such a pain, where sudden cessation is likewise one of its characteristics, is not denied any more than, when present, it indicates obstruction, generally due to gallstones, in some part of the gall tract. But there are many cases of cholelithiasis that never have an attack of this character. I recall a case, a comparatively recent one, from Ross, Ohio, a woman of 68, who, during eighteen years, had had repeated attacks of jaundice, often associated with epigastric discomfort, but who had never had an attack of "gallstone colic." Yet at the time of operation—which I am glad to say was successful—I found a very large monolith—a conglomerate, however, made up of a hundred or more original concretions—completely occupying the gall bladder, which had become infected and was beginning to suppurate through into the colon. Another case came to me some years ago from Huntsville, Ala., giving a history of repeated attacks of jaundice covering a period of twelve years, during all of which time, but without reference to the attacks of jaundice, she had had discomfort, but never a colicky seizure, in the right upper quadrant of the abdomen. She was choleric and I found a stone lodged in the ampulla of Vater. These examples might be multiplied, but the two cases that I have given are sufficient to show that the absence

of "gallstone colic" is no evidence that gallstones or other forms of obstruction do not exist in cases giving other features of gallstone history.

Then a word as to tenderness and its location. I have long looked on the discovery of the "McBurney point" and its acceptance by the profession as an essential symptom of appendicitis as a serious misfortune. For I am convinced that, by the absence of this sign, many cases have been permitted to develop fatal complications before their true character has been detected. And I am equally sure that if we are to have a "Mayo Robson point" for gallstones we shall have a correspondingly large number of blunders in diagnosis. Thus, within the last fortnight I did a posterior gastro-enterostomy for surgical ulcer of the stomach and duodenum ("chronic dyspepsia") which had been diagnosed, among numerous other things, as a case of gallstones, the diagnosis having been based on tenderness at what I assume is meant by the "Mayo Robson point," i. e., a point about midway along a line from the umbilicus to the ninth costal cartilage. But as to this I may be in error. What, then, is the "Mayo Robson point?" The only reference that I find to it is in Mr. Mayo Robson's book on the "Diseases of the Gall Bladder and Bile Ducts," page 230, as follows:

Just as in appendicitis there is tenderness over McBurney's point, so in gallstones, with very few exceptions, marked tenderness will be found on pressing the finger deeply over the region of the gall bladder, or over some point in a line from the ninth costal cartilage to the umbilicus.

Now as the gall bladder may occupy almost any part or all of the area between the costal cartilages and the crest of the ilium, and as the line from the umbilicus to the ninth costal cartilage is quite seven inches in length, it will be seen that the so-called "Mayo Robson point" is coextensive with at least the right upper quadrant of the abdomen. Or, in other words, we may felicitate ourselves, as I have no doubt that Mr. Mayo Robson will felicitate himself, that we have no such thing as a "Mayo Robson point." I am sure that the quoted words and the valuable diagnostic sign that they describe were never intended by their author to be accepted in the absolute and dogmatic sense implied by Dr. Parker Syms' use of them.

The tendency of "sure signs" is to increase reliance on them and to obscure the diagnostic significance of that *ensemble* of symptoms that go to make up the clinical picture, and that, in the present instance, are so graphically depicted in Dr. Syms' masterly contribution.

CHARLES A. L. REED.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

THE MOST EXTENSIVE BOWEL RESECTION.

ST. LOUIS, Oct. 5, 1904.

To the Editor.—Please inform me what is the longest piece of bowel removed entire from a patient with complete recovery. Dr. W. J. Doyle, of the City Hospital, has removed a piece of intestine 6 feet 2 inches in length, containing sixteen perforations. The patient recovered.

G. H. C.

ANSWER.—The question is one not so much of the amount of small intestine that can be removed with recovery, but of the amount of intestine remaining. The length of the small intestine, according to a series of several hundred measurements made by Paul Dreike (*Deutsch. Zeitsch. f. Chir.*, 1895, vol. xl, p. 43), varied in the adult male from 340 cm. (11+ ft.) to 998 cm. (33+ ft.), the average being 623.6 cm. (20.8+ ft.). A number of cases are on record in which extensive resections of the intestine have been made, see Kinkula (*Arch. f. klin. Chir.*, 1900, ix, p. 887), Barker (*London Lancet*, 1901, April 27) and Fayr (*Arch. f. klin. Chir.*, 1902, lxviii, p. 181). In the latter article there are several cases recorded in which from 200 cm. (6 2/3+ ft.), the amount mentioned in the query) to 330 cm. (11+ ft.) were removed with complete recovery of the patient. The most remarkable case of all, however, is one reported by Nigrisali (XVI Cong. Ital. di Chir., 1902), recorded in Hildebrandt's *Jahresbericht*, 1902, in which 520 cm. (or a little over 17 ft.) were removed and the patient recovered. From this it is apparent that the amount of intestine which can be successfully removed depends entirely on the length of the intestine in the particular patient, for it is very evident that 520 cm., or even 330 cm., could not have been removed from a

patient with only 340 cm. of small intestine, while possibly even more than 520 cm. might be successfully removed from a patient with 598 cm. The particular part of the small intestine which is removed also has a bearing on the subject, for the studies of Albu (*Zeit. klin. Woch.*, 1901, No. 50, p. 16), of digestion and absorption in patients from whom a considerable portion of small intestine had been removed, shows that the lower part of the ileum can be dispensed with better than the upper part of the small intestine. A certain length of small intestine is essential in order that sufficient food may be digested and absorbed to maintain the nutrition of the individual. This is apparently in the neighborhood of 350 cm. Hence the importance of knowing the length of the small intestine which remains rather than the amount which is removed.

CONTRACT PRACTICE.

LOGANSPORT, IND., Oct. 21, 1904.

To the Editor:—Certain physicians of this town have contracted with certain lodges (fraternal insurance organizations) to treat the members and their families for so much a year, and the price is two dollars a year for a family. 1. Is this fair to the other physicians? 2. Is it ethical?

ANSWER.—It is not fair to the other physicians in the town. Physicians, with few exceptions, are ready and willing to give their services to the poor, but it is neither charitable nor necessary to make professional visits for less than the usual fee to people who are in receipt of an average income, as is the case with those who belong to lodges. We have several times referred to the dangers to the profession of contract practice, and it is unnecessary to repeat the warnings already given. The evil has not assumed the proportion in this country which it has in Great Britain and Europe, but it is fast becoming a problem which will require the united efforts of the profession to solve. A physician who undertakes "club practice" not only lowers his own dignity, but also degrades the profession. 2. It is not ethical. The Principles of Ethics of the American Medical Association, in Article VI, states:

"By the members of no profession are eleemosynary services more liberally dispensed than by the medical, but justice requires that some limits should be placed to their performance. . . . Poverty, as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by the rich, or by societies for mutual benefit, for life insurance, or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege."

See New York State news this week.

CALOMEL AS AN INTESTINAL ANTISEPTIC.

TOLEDO, OHIO, Oct. 20, 1904.

To the Editor:—There is a theory that calomel is a good, if not the best, intestinal antiseptic, and the theory, or fact, whichever it may be, underlies the administration of the medicine in the larger number of instances where it is prescribed. I will be obliged if you will give the basis for the belief and practice. Is the antiseptics due to chemical or to changed physiologic process?

J. L. TRACY.

ANSWER.—The antiseptic power of calomel on the intestinal tract is indisputable. The cause of this action is undoubtedly chemical, metallic mercury and all of its compounds possessing marked germicidal properties. When calomel is taken internally, on account of its sparing solubility it passes, to a great extent, unchanged, into the intestines and is there, in part, slowly dissolved either as such or somewhat altered in its chemical composition and is an active destroyer of bacteria.

X-RAY THERAPY IN TUBERCULAR JOINTS.

LINCOLN, IOWA, Oct. 17, 1904.

To the Editor:—I have a patient with tuberculosis of the wrist joint who absolutely refuses all operative measures. I have wondered if x-ray treatment would be beneficial, but can find no literature on the subject. Can you inform me where I can find reports on this method of treatment?

C. B. C.

ANSWER.—In Pusey and Caldwell's work, "The Reagent Rays in Therapeutics and Diagnosis," pages 423-425, several cases of tubercular joints treated with x-rays are reported. Dr. Murphy reported a case of tuberculosis of the knee joint treated in this way. In the *Journal of Advanced Therapeutics*, 1902, xxi, p. 250. A case of tubercular arthritis is reported in the *Therapeutic Gazette*, 1902, xxvi, p. 650.

FERRIER'S SNUFF.

ZANESVILLE, OHIO, Oct. 30, 1904.

To the Editor:—Please publish the formula for Ferrier's snuff.

F. S. B.

ANSWER.—

- R. Morphinae hydrochloratis. ʒ part
- Aceciae pulvis 60 parts
- Bismuthi oxychloratis ʒ80 parts

From one to three drams to be used as a snuff in 24 hours. This (British) preparation is used in acute coryza. Powdered cubes may be added to the formula.

GERMAN SURGICAL JOURNALS.

WACO, TEXAS, Oct. 10, 1904.

To the Editor:—I desire to subscribe for a surgical journal in German. Kindly give the name, address and subscription price of the best surgical journals in the German language.

K. H. AYNESWORTH.

ANSWER.—*Archiv für klin. Chirurgie*, Berlin; *Beiträge zur klin. Chirurgie*, Tübingen, and *Deutsche Zeitschrift für Chirurgie*, Leipzig, are three of the best German surgical journals. The price of the first two varies from \$2.25 to \$3.25 a part. The parts appear irregularly, about eight are received a year. The price of the *Zeitschrift* is \$4.80 a volume, which consists of six parts. These also appear irregularly, from two to three volumes a year. It is the cheapest of the three.

REQUIREMENTS FOR PRACTICE IN WASHINGTON.

HALEYVILLE, I. T., Oct. 19, 1904.

To the Editor:—What are the requirements for the practice of medicine in the state of Washington? Is any diploma accepted or is there any reciprocity with Illinois or Missouri? W. H. HOARNE.

ANSWER.—Persons desiring to practice medicine in the state of Washington are required to file evidence of graduation from a duly authorized medical college and to pass an examination. A grade of 75 per cent. is required, but those who have practiced ten years or over will be accepted on an average of 70. Washington does not reciprocate with any state.

Marriages.

F. E. KEFLEY, M. D., Mount Sterling, Ill., in Peoria, Ill., October 3.

OTTO W. KONZELMAN, M.D., to Miss Marie Pedersen, both of Chicago, October 5.

CLARENCE P. ERKENBRACK, M.D., to Miss Teresa Rose, both of Baltimore, October 19.

OTTO R. SPIEGEL, M.D., Terre Haute, Ind., to Miss Adah McPheeters of Bedford, Ind.

CARLETON S. MYERS, M.D., to Miss Blanche Irwin Stevens, both of Chicago, October 11.

GUSTAVE A. HEDEL, M.D., to Miss Harriet Hunt, both of Muscatine, Iowa, October 12.

JEREMIAH H. STEALY, M.D., Freeport, Ill., to Miss Zara H. Anderson, at Chicago, October 5.

SILAS GILBERT ALLEN, M.D., Clarkson, Neb., to Miss Louise M. Beran of Ord, Neb., October 12.

FRANZ H. BRANT, M. D., Chicago, to Miss Pauline Woltmann of Rock Island, Ill., October 10.

CHARLES W. MACGURE, M.D., Toledo, Ohio, to Mrs. Gertrude Matt of Venice, Ohio, October 5.

RODNEY S. SMITH, M.D., Saegerstown, Pa., to Miss Bessie Mook, at Conneautville, Pa., October 5.

JOHN H. CROWE, M.D., Virginia, Minn., to Miss Elizabeth Belle Tucker, of Salem, Ind., October 26.

HILARY T. WILLIS, M.D., Luray, Va., to Miss Emma Elizabeth Willis, at Lignum, Va., October 15.

JOHN HOWARD B-YANT, M.D., Galesburg, Ill., to Miss Lillian H. Warfield of Princeton, Ill., October 26.

WILLIAM WALTER PRETTIS, M.D., Platteville, Wis., to Miss Anna Maddock of St. Joseph, Ill., October 19.

E. J. BUTZKE, M.D., Jackson, Wis., to Miss Effajean McCormack of West Bend, Wis., September 29.

WILLIAM FRANCIS BUSHNELL, M.D., Freeport, Ill., to Miss Sadie Agatha Hummer of Iowa City, Iowa, October 6.

GEORGE H. STEWART, M.D., of Baltimore, to Miss Virginia Irene Blakemore of Virginia, at Baltimore, October 19.

GORDON F. HARKNESS, M.D., Davenport, Iowa, to Miss Mabel Gunsols of San Jose, Cal., at Iowa City, Iowa, October 19.

THEODORE N. PEASE, M.D., U. S. Navy, Washington, D. C., to Miss Mary Armistead Marshall, at Alexandria, Va., October 20.

P. HEBERT, M.D., Iron Mountain, Mich., to Miss Hannah Wemer of Hassle Bösarp, Sweden, in New York City, October 19.

Deaths.

Theodore F. Prewitt, M.D. St. Louis Medical College, 1856, for many years a member of the American Medical Association, formerly president of the American Surgical Association, of the Medical Association of the State of Missouri and of the

St. Louis Medical Society; member of the St. Louis Surgical Society; professor of principles of surgery in the Medical Department of Washington University and the Missouri Medical College, St. Louis, died at his home in St. Louis, October 17, after an illness of one year, aged 70.

Shadrack Cate Morrill, M.D. Homeopathic Hospital College, Cleveland, 1864, a member of the American Medical Association and of the New Hampshire Medical Society, who took additional courses at Harvard University Medical School and the College of Physicians and Surgeons of New York; one of the founders of the Margaret Pillsbury Hospital, Concord, N. H., and a life member of its staff, died at his home in Concord, October 9, after a long illness, aged 63.

Thomas J. Prichard, M.D. Medical College of Ohio, Cincinnati, 1883, a member of the American Medical Association; West Virginia Medical Association, Tri-State Medical Association and Cabell County Medical Society; formerly a member of the State Board of Medical Examiners; one of the most beloved and best known practitioners of southern West Virginia, died at his home in Huntington, October 5, from septicemia after an illness of three weeks, aged 44.

George Purviance, M.D., assistant surgeon-general United States Public Health and Marine-Hospital Service, Jefferson Medical College, Philadelphia, 1867, of Washington, D. C., while under treatment for an acute disorder in the Orthopedic Hospital, Philadelphia, threw himself from a fourth-story window of the hospital October 20, and was instantly killed.

Richard Sweet, M.D., assistant surgeon in the One Hundred Twenty-third United States Infantry in the Civil War, and also surgeon during the Franco-Prussian war, died at the Soldiers' Home, Marshalltown, Iowa, from the effects of carbolic acid taken with suicidal intent, October 11, aged 69.

W. W. Allen, M.D., a member of the American Medical Association and of the Medical Association of the State of Missouri, of Fort Pierre, S. D., who fractured his leg in a runaway accident several months ago, died from septicemia in a hospital in Pierre, S. D., October 15.

Joel Cloud Kendrick, M.D. University of Nashville (Tenn.) Medical Department, 1852, for many years health officer, and once mayor of Greenville, Ala., a Confederate officer, died at his home in Greenville October 9, from pneumonia, after an illness of one week, aged 72.

James Warren Lowell, M.D. Medical School of Maine, at Bowdoin College, Brunswick, 1866, died at his home in South Portland, Maine, October 8, after an illness of ten weeks which began with an attack of pneumonia, aged 62.

Hamilton E. Smith, M.D. University of Buffalo, 1859, assistant surgeon of the Twenty-Seventh Michigan Volunteer Infantry throughout the Civil War, died suddenly at his home in Detroit, October 8, from heart disease, aged 64.

Gideon F. Lower, M.D. University of Wooster Medical Department, Cleveland, 1890, of Canal Dover, Ohio, died at his former home in Port Washington, Ohio, October 12, from consumption, after an illness of a year, aged 54.

Herman Schafer, M.D. Long Island College Hospital, Brooklyn, N. Y., 1866, of San Diego, Cal., surgeon during the Civil War, died in Monrovia, Cal., from lung disease resulting from a wound received in the Civil War, aged 72.

August Frederic Muller, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1868, chief of staff of the Germantown (Pa.) Hospital, died at his home in Germantown October 20, from cancer, aged 64.

Clarendon L. Willey, M.D. University of Vermont, Burlington, 1903, formerly house physician of the Lynn Hospital, committed suicide October 12, by inhaling illuminating gas, while despondent from illness, aged 28.

John J. Tobin, M.D. New Orleans School of Medicine, 1861, staff surgeon with Hood's Brigade during the Civil War, died at his home in Austin, Texas, October 12, after an operation for intestinal obstruction, aged 66.

James T. McCulluch, M.D. Jefferson Medical College, Philadelphia, 1877, a member of the Armstrong County and Allegheny Valley medical associations, died at his home in Freeport, Pa., October 13, aged 53.

John Wellner, M.D. Jefferson Medical College, Philadelphia, 1903, of Titusville, Pa., an interne in Mercy Hospital, Pittsburgh, died in that institution October 9, from typhoid fever, after a short illness, aged 22.

William White, M.D. Medical Department of Hampden Sidney College, Richmond, Va., 1841, of Abingdon, Va., died October 13, in Johns Hopkins Hospital, Baltimore, where he recently underwent operation.

Nathan S. Hatfield, M.D. University of Wooster Medical Department, Cleveland, 1879, died at his home in Bowling Green, Ohio, October 6, after a long illness, from cancer of the intestines, aged 59.

Samuel A. Wilson, M.D. Medical Institution of Yale College, New Haven, Conn., 1832, who retired from practice in 1884, died suddenly from apoplexy at his home in Windsor, Conn., October 9, aged 76.

Andrew Wolfe Lyons, M.D. Columbus (Ohio) Medical College, 1876, who had been in bad health for the past two years, died suddenly at his home in Bridgeport, Conn., October 8, aged 52.

Oscar S. Erskine, M.D. Medical School of Maine, at Bowdoin College, Brunswick, 1887, died at his home in Winterport, Maine, October 8, from consumption, after an illness of two years.

Benjamin F. Reynolds, M.D. Medical College of Ohio, Cincinnati, 1864, president of the Nicholas County (Ky.) Board of Health, died at his home in Carlisle, October 10, aged 68.

William L. Severance, M. D. University of Vermont, Burlington, 1884, died at his home in Greenfield, Mass., from tuberculosis, October 1, after an illness of two years, aged 46.

Clarendon B. Harrison, M.D. Columbus (Ohio) Medical College, 1884, died at his home in Wellston, Ohio, October 5, from consumption, after an illness of a year, aged 52.

Richard C. Lee, M.D. University of Maryland School of Medicine, Baltimore, 1859, formerly coroner of Baltimore County, died at his home in Baltimore, October 20, aged 71.

Eugene H. Meade, M.D. University of Michigan, Ann Arbor, died at his home in Winsted, Conn., October 6, from spinal disease, after an invalidism of ten years, aged 51.

Joseph N. Henry, M.D. major and surgeon, U. S. V., who served acceptably in Cuba and the Philippines, died near Devon, Pa., after a long illness, October 3.

George B. Cole, M.D. Charity Hospital Medical College, Cleveland, 1867, died at his home in Medford, Ore., September 28, after a long illness, aged about 65.

William T. Owsley, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1889, died at his home in Glasgow, Ky., October 14, after a lingering illness.

Calvin L. Klopp, M.D. Pennsylvania, 1887, died from intermittent fever at his home in Reading, Pa., October 8, after an illness of two months, aged 41.

Stephen B. Stovall, M.D. Department of Medicine University of Pennsylvania, Philadelphia, 1848, died at his home in Vienna, Ga., October 10, aged 77.

John F. Mehrmann, M.D. University of Jena, Germany, 1847, died suddenly at his home in Oakland, Cal., October 4, from valvular heart disease, aged 76.

Ralph D'Ary, M.D. Ohio, 1878, died at his home in Wartburg, Tenn., October 7, from locomotor ataxia, after an illness of several years, aged 60.

Francis B. Greenough, M.D. Harvard University Medical School, Boston, 1867, died at his home in Brookline, Mass., October 16, aged 67.

J. J. Thornton, M.D., a pioneer settler of Gulfport, Miss., died at his home in that city, October 16, after many years of invalidism, aged 71.

Austin Lord, M.D. Medical Institution of Yale College, New Haven, Conn., 1844, died at his home in North Haven, Conn., October 11, aged 83.

J. W. Cecil, M.D. Rush Medical College, Chicago, 1889, of Hiawatha, Kan., died from heart disease in St. Joseph, Mo., October 3, aged 45.

George A. Blose, M.D. Jefferson Medical College, Philadelphia, 1883, died suddenly at his home in Tarentum, Pa., October 15, aged 49.

Carthon Archer, M.D. Medical College of Virginia, Richmond, 1848, died at his home in Henrico County, Virginia, September 30, aged 80.

Franklin D. Wright, M.D., of Atlanta, Ga., died at the home of his brother in Leguinn, Ga., October 17, from heart disease, aged 50.

Charles Darion Shepard, M.D. University of Buffalo, died at his home in Peckskill, N. Y., from Bright's disease, October 7, aged 52.

David H. Yockey, M.D. Indiana, 1897, died suddenly at his home in Richmond, Ind., October 6, from heart disease, aged 51.

Adelin Gasser, M.D. University of Erlangen, Germany, 1889, died at his home in Hancock, Mich., October 10, aged 45.

Edward C. Sample, M.D., 1853, a surgeon in the Civil War, died at his home in Florin, Pa., September 27, aged 75.

Joseph Brandt Enos, M.D. Ohio, 1874, died from heart disease at his home in Charleroi, Pa., October 12, aged 51.

Joseph J. Alleman, M.D. Michigan, 1875, died suddenly at his home in Union Springs, N. Y., September 27.

M. Howard Harpel, M.D. Pennsylvania, 1867, died at his home in Shamokin, Pa., October 11, aged 66.

George Wentz, M.D., died at Catonsville, Md., October 19, from cancer of the stomach, aged 68.

Joseph T. Harris, M.D., 1876, died at his home in Gridley, Cal., September 22, from apoplexy.

James W. Cummings, M.D., died at his home in West Haven, Conn., October 13, aged 69.

Book Notices.

DISEASES OF THE INTESTINES. By Dr. I. Boas, Specialist for Gastrointestinal Diseases in Berlin. Second Revised and Enlarged American Edition, Translated by Permission from the German Edition, with Special Notations and Additions. By Seymour Basch, M.D., New York City. With 48 Illustrations. Cloth. Pp. 600. Price, \$5.00. New York and London: D. Appleton & Co. 1904.

New chapters have been added on dysentery, syphilis and actinomycosis of the intestines. The brevity of the chapter on actinomycosis hardly suffices to adequately discuss this disease. There is a tendency in this book to group different processes under the same heading. Thus "Intestinal Ulcers" includes distinct etiologic entities. Scientific exactness would demand that separate diseases be given separate discussion; otherwise there is danger that they may lose their individuality. Hyperplastic tuberculosis of the intestine does not receive enough attention.

A TEXT-BOOK OF HUMAN PHYSIOLOGY. By Albert P. Brubaker, A.M., M.D., Professor of Physiology and Hygiene in the Jefferson Medical College. With Colored Plates and 354 Illustrations. Cloth. Pp. 690. Price, \$4.00 net. Philadelphia: P. Blakiston's Son & Co. 1904.

The special object of this book is to help physicians and students of medicine to acquire the knowledge of physiology necessary to practice medicine. The author has taught physiology for twenty-five years and has been guided in the preparation of this work largely by his experience as a teacher. An examination of the book shows that the main facts of the older physiology are given clearly and succinctly, but we miss adequate references to and discussions of these newer facts of such fundamental importance to physiology that have come from the application to physiologic investigation of physical and chemical methods. The influence of inorganic salts and their ions, of osmotic pressure, of electrical charges, of catalysis in life phenomena is not given direct attention and yet these are factors of fundamental importance in physiology. The presence of lysins and other substances of great interest in normal blood does not appear to be mentioned. We miss from the index such important words as calcium, ferment, catalysis, osmotic pressure, lysin, etc. Evidently there has been omitted from this text-book of physiology much information that it seems essential that physicians of these times should have an opportunity to study if they are to be able to follow the development of scientific medicine, a development that is fraught with the greatest practical significance. Teachers of physiology should concern themselves especially with the matters of fundamental importance in their science, the matters that determine the direction in which physiology is developing because these matters are in the end of as great if not greater practical importance to the student of medicine as the well-established, familiar facts in regard to the more manifest workings of the circulatory, respiratory and other systems. Teachers of physiology must beware lest they in their efforts to be "practical" cease to

be scientific, and thus fail to instill in their students that scientific spirit and interest which physiology is sure to call forth when its study is properly conducted, namely, from the investigative rather than the dogmatic point of view. Physicians sink quickly into the slavery of routinism if not animated by a spirit of inquiry, of criticism, of independent judgment. And how are such qualities to grow in our medical students if they are to be denied the stimulus that comes from the study of the living, growing part of sciences of such fundamental import as physiology?

Miscellany.

Increase of Susceptibility by Depressing Circumstances.—An interesting series of researches is reported by von Stejskal in the *Zeitschrift f. Heilkunde*, XXV, No. 1. He administered potassium and deuto-albumoses to animals in small amounts, enough to cause mild but by no means fatal intoxication. He then administered a small amount of diphtheria toxin, neutralized with antitoxin so that it was unable to affect healthy animals; it rapidly killed the intoxicated animals, however, showing that the previous mild intoxication had so reduced the resisting powers that they were unable to cope with even a mild superimposed intoxication.

Tuberculosis Questions.—The *Revue Moderne de Méd. et de Chir.* sent out blank circulars asking for the opinion of medical authorities in Europe in regard to the present status of the question of tuberculosis. The replies show the trend of thought to be rather against sanatoria. The results they have to show scarcely repay the expense. Special dispensaries for tuberculosis seem to be accomplishing as much as the sanatoria in the way of educating the public, while they frequently allow the detection of the disease in its incipient stages. The *Gaz. Méd. Belge.*, commenting on the data obtained, urges that children should be taught in the primary grades the principles of the prophylaxis of tuberculosis. "What is the use of teaching them astronomy, botany, etc., when they are destined to die so soon of some tuberculous affection?" It also remarks: "Why should we wait until consumption is established before we learn to profit by fresh air and proper ventilation?"

Abuse of Nitroglycerin.—Dr. Lefevre, in the *Medical News*, makes the following remarks on the use of this drug in the treatment of typhoid fever: "Frequently in acute collapse, or when cardiac weakness has reached the point of causing the pulse to become dicrotic, nitroglycerin is given at frequent intervals with the idea of diminishing the work of the heart. In acute cardiac collapse Romberg has shown that there is already vasomotor paralysis, and that the failure is more vascular than cardiac, and nitroglycerin can not under these circumstances relieve the condition. In the later stages of the disease, when the pulse is dicrotic, the dicrotism is due to the relaxed condition of the arteries, and the giving of nitroglycerin does not relieve the heart, but on the other hand destroys the normal control of the circulatory system. Nitroglycerin should only be given when arterial tension is relatively too high for the cardiac power, and then only to carry the patient over the immediate danger. It is not a drug that should be given continuously for any length of time."

State Boards of Registration.

COMING EXAMINATIONS.

Board of Registration in Medicine of Massachusetts, State House, Boston, November 8-9. Secretary, Edwin B. Harvey, M.D., Boston.

Nebraska State Board of Health, November 9-10, State House, Lincoln. Secretary, George H. Brasch, M.D., Beatrice.

Connecticut State Board of Medical Examiners, November 5-9, City Hall, New Haven. Secretary, Charles A. Tuttle, M.D., New Haven.

Maine Board of Registration of Medicine, November 15, Augusta. Secretary, A. K. P. Meserve, M.D., Portland.

Credit in Examinations for Years of Practice.—At a meeting of the State Board of Health, held in Chicago, Oct. 22, 1904, the following resolution, offered by the secretary, Dr. J. A. Egan, was unanimously adopted:

Resolved, That the rules of the State Board of Health, adopted July 11, 1899, regarding the character of examinations, are hereby amended as follows: On and after Jan. 1, 1905, the Illinois State Board of Health will accept as an equivalent of a part of the examination required satisfactory evidence of five or more years of reputable practice of medicine and surgery since graduation, and will allow a credit of 5 per cent. on the required average of 75 per cent. for each period of five years of such practice on the part of a candidate for a certificate.

[Under the above resolution the rights of the old practitioner are properly conserved; he is given credit for his years of practice, and the longer the practice the greater the credit.—Ed.]

Vermont July Report.—Dr. S. W. Hammond, secretary of the Vermont State Board of Medical Censors, reports the written examination held at Burlington, July 12-13, 1904. The number of subjects examined in was 8; total questions asked, 80; percentage required to pass, 75. The total number examined was 41, of whom 39 passed and 2 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Univ. of Vermont Med. Dept., (1903) 78, 81: (1904) the grade of 75 was reached by three, 78 by one, 77 by seven, 78 by six, 79 by three, 80 by one, 81 by one, 82 by two, 83, 84, 85 and 87 by one each.			
Dartmouth Medical College.....(1904)			81
University of Edinburgh.....(1901)			85
College of P. and S., New York.....(1903)			79
University of Michigan.....(1903)			81
Johas Hopkins University.....(1904)			84
Woman's Med. Coll. of Pa.....(1904)			82
Baltimore Medical College.....(1903) 77, (1904) 81			84
Albany Medical College.....(1904)			83
FAILED.			
Baltimore Medical College.....(1902)			44

The general average for all representatives of the University of Vermont was 79.2. Another candidate who failed held a diploma from the Metropolitan Medical College of Chicago, the well-known diploma mill which was declared fraudulent some time ago.

North Dakota October Report.—Dr. H. M. Wheeler, secretary of the North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, Oct. 4, 1904. The number of subjects examined in was 13 and the percentage required to pass, 75. The total number examined was 19, of whom 13 passed and 6 failed. The following colleges were represented:

College.	PASSED.	Year Grad.	Per Cent.
Barnes Medical College, St. Louis.....(1903)			75
Coll. of P. and S., Minneapolis.....(1904)			77
Coll. of P. and S., Chicago.....(1904)			82
University of Minnesota (Homeo.).....(1904)			84
University of Minnesota.....(1904)			82
University of Michigan.....(1904)			82
Philadelphia Medical College.....(1904)			82
McGill University.....(1904)			85
Toronto.....(1904)			82
Northwestern University, Chicago.....(1897)			95
Rush Medical College, Chicago.....(1891)			75
Hamline University.....(1904)			86
Cornell University.....(1904)			83

Two graduates of the Ohio Medical College failed and one each from the College of Physicians and Surgeons, Chicago, Hamline University, Sioux City Medical College and the University of Washington.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, for the week ending Oct. 22, 1904:

Stephenson, W., surgeon, will proceed to Fort Snelling, not later than Oct. 30, 1904, to accompany the Twenty-first Infantry to San Francisco.

Craig, Chas. F., asst.-surgeon, granted ten days' leave of absence. Appel, D. M., deputy surgeon general, leave of absence extended to Nov. 30, 1904.

Williamson, L. L., asst.-surgeon, reports from sick in St. Luke's Hospital, St. Louis, to absent on fifteen days leave of absence. Meears, E. A., surgeon, arrived at San Francisco from Manila on the *Logan*.

Vedder, E. B., asst.-surgeon, ordered to proceed to San Francisco for transportation to Manila on the transport leaving that port on or about Dec. 1, 1904.

Ford, C. S., asst.-surgeon, granted seven days' leave of absence. Kierstead, H. S., asst.-surgeon, relieved from duty at Fort Myer, Va., and ordered to proceed to Fort Snelling, Minn., to accompany the Twenty-first Infantry to San Francisco. On completion of this duty to proceed to presidio of Monterey, Cal., for duty at that post.

Hull, Alva R., contract surgeon, ordered from his home at Oconomowoc, Wis., to duty at Fort D. A. Russell, Wyoming.

Book, S. J., contract dental surgeon, granted leave of absence for one month.

Shellenberger, James E., contract surgeon, left Jackson Barracks, La., October 18, on leave of absence for one month and fifteen days.

Navy Changes.

Changes in the medical corps of the U. S. Navy for the week ending Oct. 22, 1904:

Vickers, E. A., asst.-surgeon, appointed asst.-surgeon, with rank of lieutenant, junior grade, from Oct. 11, 1904.

Cole, H. W., asst.-surgeon, ordered to the Naval Museum of Hygiene and Medical School Washington, D. C., October 22.

Faulstich, A. M., P. A. surgeon, commissioned P. A. surgeon, with rank of lieutenant, from Sept. 28, 1904.

Holcomb, R. C., P. A. surgeon, detached from the *Mayflower* and ordered home to wait orders.

Public Health and Marine-Hospital Service.

Official list of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Oct. 19, 1904:

Cumming, H. S., P. A. surgeon, granted leave of absence for one month, or so much thereof as may be necessary, on account of sickness.

Rodman, J. C., A. A. surgeon, granted leave of absence for three days from October 17.

Saford, M. V., A. A. surgeon, granted leave of absence for three days from Oct. 11, 1904, under Paragraph 210 of the Regulations.

Walker, R. T., A. A. surgeon, granted leave of absence for twenty-two days from November 1.

Brook, G. H., pharmacist, on being relieved at St. Louis, by Pharmacist E. M. Bell, to proceed to San Francisco and report to the medical officer in command for duty and assignment to quarters.

Davis, H. E., pharmacist, granted leave of absence for fifteen days from October 14.

Holt, E. M., pharmacist, granted leave of absence for eighteen days from October 26.

Hall, L. P., pharmacist, granted leave of absence for thirty days from November 4.

Bell, J. M., pharmacist, to proceed to St. Louis and report to the medical officer in command for duty and assignment to quarters, relieving Pharmacist G. H. Brook.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., Oct. 14, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: Asst.-Surgeon-General W. J. Pettus, chairman; Asst.-Surgeon-General H. D. Goddings, recorder.

Board convened to meet at Stapleton, N. Y., Oct. 26, 1904, for the physical examination of an officer of the Revenue-Cutter Service. Detail for the board: P. A. Surgeon C. H. Lavinder, chairman; Asst.-Surgeon T. L. Berry, recorder.

Board convened to meet at Baltimore, Md., Oct. 26, 1904, for the physical examination of officers of the Revenue-Cutter Service. Detail for the board: Asst.-surgeon C. W. Wille, chairman; A. A. Surgeon G. H. Steuart, recorder.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Oct. 22, 1904:

SMALLPOX—UNITED STATES.

Illinois: Chicago, Oct. 1-15, 6 cases.
Massachusetts: North Adams, Oct. 1-15, 1 case.
Michigan: At 42 places, Oct. 1-8, present.
Minnesota: St. Paul, Oct. 3-10, 7 cases.
Missouri: St. Louis, Oct. 10-17, 7 cases, 3 deaths.
New York: New York City, Oct. 1-15, 1 case.
Pennsylvania: Philadelphia, Oct. 1-15, 1 case.

SMALLPOX—FOREIGN.

Africa: Cape Town, Aug. 27-Sept. 3, 1 case.
Austria-Hungary: Prague, Sept. 25-Oct. 2, 2 cases.
Brazil: Bahia, Sept. 3-24, 45 cases, 4 deaths; Rio de Janeiro, Aug. 28-Sept. 18, 297 cases, 434 deaths.
China: Shanghai, Sept. 10-17, 3 deaths.
France: Paris, Sept. 25-Oct. 1, 7 cases, 1 death.
Great Britain: Leeds, Sept. 25-Oct. 8, 5 cases; Sept. 25-Oct. 1, Manchester, 6 cases; Newcastle-on-Tyne, 3 cases; Nottingham, 3 cases.
India: Bombay, Sept. 13-20, 2 deaths.
Mexico: City of Mexico, Sept. 25-Oct. 1, 4 cases, 1 death.
Russia: Sept. 17-24, Moscow, 7 cases, 2 deaths; St. Petersburg, 3 cases, 3 deaths; Warsaw, Aug. 20-Sept. 10, 55 deaths.
Spain: Barcelona, Sept. 1-20, 6 deaths.
Turkey: Beirut, Sept. 25-Oct. 1, present; Constantinople, Sept. 26-Oct. 2, 19 deaths.
Venezuela: La Guaira, Oct. 1, present.

YELLOW FEVER.

Mexico: Coatzacoalcos, Sept. 25-Oct. 8, 16 cases, 5 deaths.
CHOLERA.
India: Bombay, Sept. 13-20, 13 deaths; Calcutta, Sept. 10-17, 3 deaths.
Persia: Resht, Sept. 17, epidemic.

PLAGUE.

Africa: Cape Colony, Sept. 3-10, 2 cases, 1 death.
Australia: Brisbane, Aug. 13-27, 5 cases, 2 deaths.
Brazil: Bahia, Sept. 3-24, 12 deaths; Rio de Janeiro, Aug. 28-Sept. 18, 53 cases, 14 deaths.
India: Bombay, Sept. 13-20, 51 deaths; Calcutta, Sept. 10-17, 2 deaths; Karachi, Sept. 11-18, 4 cases, 5 deaths; Madras, Sept. 10-16, 1 death.

Society Proceedings.

COMING MEETINGS.

AMERICAN MEDICAL ASSOCIATION, Portland, Ore., July 11-14, 1905.

Hawaiian Territorial Medical Society, Honolulu, November 5.
Oklahoma State Medical Association, Oklahoma City, November 9.
American Academy of Medicine, Chicago, November 7-8.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirtieth Annual Meeting, held in Cincinnati, Oct. 11-13, 1904.
(Continued from page 1251.)

The president's address, "The Choice and Use of Medical Literature," by Dr. Hugh T. Patrick, Chicago, and the address on surgery, "Surgical Tuberculosis in the Abdominal Cavity," by Dr. William J. Mayo, Rochester, Minn., will appear in full in THE JOURNAL.

Officers.

The following officers were elected for the ensuing year: President, Dr. Bransford Lewis, St. Louis; vice-presidents, Drs. Frank P. Norbury, Jacksonville, Ill., and J. Henry Carstens, Detroit; secretary, Dr. Henry Enos Tuley, Louisville, (re-elected); assistant secretary, Dr. John F. Barnhill, Indianapolis; treasurer, Dr. S. C. Stanton, Chicago.

Indianapolis was selected as the place for holding the next annual meeting, Oct. 10-12, 1905.

The *Cincinnati Lancet-Clinic* was selected as the official organ of the association.

A Plea for Wider Knowledge Concerning Diseases Which Affect the Joints.

DR. C. TRAVIS DRENNAN, Hot Springs, Ark., delivered the address in medicine and urged the necessity of greater care in every instance in which a joint is involved, no matter how insignificant such condition may appear. The usual cases of acute articular rheumatism, gout and tubercular disease can easily be recognized under ordinary conditions, but not so the early manifestations of arthritis deformans, so-called sub-acute articular rheumatism, and certain forms of gonorrhoeal arthritis. When the etiology of gout is written it will be shown to manifest itself primarily somewhere along the digestive tract. Perfect digestion will be followed by perfect assimilation and elimination. He believes that there is a nervous element in arthritis deformans.

Hospital Construction in American Cities and Towns.

DR. A. J. OCHSNER, Chicago, pointed out that the enormous number of new hospitals recently established have almost all been built on the principles which governed hospital construction thirty years ago, when the theories of contagion and infection were wrong. Recent knowledge about differences in purity of air at different levels, about the perfected elevator, and how to make high buildings fireproof at a reasonable cost, and other knowledge of the greatest importance, should change entirely the plans of hospital construction. Millions of dollars will soon be spent in the construction of hospitals and the subject should be thoroughly studied.

Radical Cure of Hernia.

DR. HAL C. WYMAN, Detroit, stated that the problem of hernia has been so fully worked out in the inguinal and umbilical regions that there is nothing to do now but to find the hernial opening and stitch it up so that the bowel will stay in the abdomen. In hernia the intra-abdominal space is usually not large enough and the abdominal walls insufficient to retain the abdominal contents. Surgical intervention should, therefore, reduce the volume of the abdominal contents and increase the size and strength of the abdominal walls. Masses of omentum and part of the intestines must sometimes be removed and flaps must sometimes be used to supplement the muscles and fascias. Suturing must be complete, absolute and without tension. Scrotal skin and fascia may be sutured into the large hernial openings with gratifying results by making an entirely new place for impingement of the intestines. Many patients with inguinal hernia may be permitted to get up when they feel able, with great advantage in educating the abdominal muscles to perform their offices.

The Typical Anatomic Operation for Oblique Inguinal Hernia.

DR. ALEXANDER HUGH FERGUSON, Chicago, described his method and said that approximately 2,200 cases have been permanently cured by it.

DISCUSSION.

DR. WILLIAM J. MAYO, Rochester, Minn., said that of 609 operations by the Ferguson method only three relapses have occurred, and he is uncertain as to whether these were really due to the Ferguson or Bassini operation.

DR. H. O. WALKER, Detroit, considers the Ferguson method rational and the results good. He has operated by this method over a hundred times and has had no recurrence.

DR. VAN BUREN KNOTT, Sioux City, has been employing the Ferguson operation for some time, with the happiest results. He has had no recurrences.

DR. EMIL RIES, Chicago, does not hesitate to let his patients get out of bed on the first or second day after operation, and has had no evil results therefrom. He has used the method of Kocher in a number of cases of inguinal hernia, the main point being inversion of the sac, and has had no recurrences.

DR. JOSEPH RILUS EASTMAN, Indianapolis, doubted the wisdom of allowing patients to get out of bed two or three days after operation on account of the great strain from pressure on the aponeurosis of the external oblique. He prefers to keep his patients in bed two or three weeks.

DR. JOHN YOUNG BROWN, St. Louis, prefers the Ferguson operation in inguinal hernia. Its results are not better than those obtained by the Bassini, but the Ferguson is simpler and inflicts less trauma. He has had no recurrences, but he thinks that in a small percentage of cases recurrence will take place.

DR. THOMAS H. MANLEY, New York, recommended the method advocated by Lucas-Championnière. The results following this method are satisfactory.

DR. A. J. OCHSNER, Chicago, said that the Ferguson operation contains the successful elements of a herniotomy. The operation should be done without traumatizing the tissues severely.

Two Successful Splenectomies.

DR. J. HENRY CARSTENS, Detroit, stated that splenectomy is indicated in selected cases of enlarged spleen, but not in all instances. He reported two splenectomies, one for cancer and one for splenic anemia. The latter case was reported in THE JOURNAL, Oct. 1, 1904, page 980.

Perineal Prostatectomy.

DR. JOSEPH RILUS EASTMAN, Indianapolis, said that if all prostatectomies are made as soon as the symptom of residual urine makes its appearance the mortality would be practically nil. Too often the reason for the Bottini method, perineal cauterization, or other palliative procedure is that a case has been permitted to drag along with the catheter until advanced age, general sclerosis or kidney complications forbid prostatectomy. The conservative operation of Hugh Young should be chosen, if applicable. Clinically the perineal operation has been proven to be the safest. In a large majority of cases prostatectomy may be completed through a perineal incision. If, however, it is discovered that the perineal distance is so great or the median intravesical growth so large as to make the suprapubic operation necessary, such an opening, except in exceptional cases, may be made at the same sitting. The perineal is the least bloody route, since it admits of a complete exposure of the prostate, thereby making it easier to shell out the gland in the essential line of cleavage. After perineal prostatectomy, the bladder is provided with low, level drainage instead of the uphill or siphon drainage of the suprapubic operation. The danger of wounding the ejaculatory duct in any conservative operation is lessened if the perineal operation be chosen.

Pathologic Changes Resulting from Prostatic Enlargement.

DR. CHARLES E. BARNETT, Fort Wayne, Ind., said that perverted function of the testicle and inflammation seem the most logical causes of prostatic enlargement. The former produces hyperplasia by a lack of orchoprostatic equilibrium.

Inflammation starts true adenomyoma, either by stimulating the embryologic matrix, or on account of the infected acini, or both, and there is a pathologic evolution tumor metamorphosis from a fibromyoadenoma to an adenomyofibroma. The pelvic fascia does not accommodate itself to the displacements that occur. The distorted neck of the bladder starts pathology which, in its progression, finally reaches the kidneys, and if not stopped by operative procedure on the prostate, will destroy them. The cases reported show the fallacy of operating on patients at that stage of pathology.

DISCUSSION.

DR. G. FRANK LYDSTON, Chicago, thinks the profession at large has accepted perineal prostatectomy as the operation of election. Many patients must be treated palliatively until one is positive that the tumor is not only increasing in size, but is causing urinary obstruction. A careful operation will not injure the ejaculatory ducts. In numerous cases the sexual function is not impaired.

DR. E. M. GILLIAM recommended keeping the patient after operation in the Fowler position.

DR. H. J. SCHERCK said that in old men whose bladders contain residual urine irrespective of the condition and size of the prostate, the condition seems to be more of an atonic state of the bladder walls than the effect of the enlarged prostate.

DR. BRANSFORD LEWIS, St. Louis, pointed out that there is no particular operation which fulfills all the indications in cases of hypertrophied prostate. He mentioned a man, 71 years of age, who, he believes, could not have withstood a prostatectomy at any time. Dr. Lewis did a suprapubic lithotomy, removed the stone, drained, and also performed a Bottini operation. The patient was relieved of a fistula that had existed, and completely recovered.

DR. F. F. LAWRENCE, Columbus, Ohio, said that if surgeons could convince the general profession that hypertrophy of the prostate is a surgical disease, the mortality now attending prostatectomy would immediately decrease, as it has done from operations on cases of appendicitis, ovariectomy and other surgical affections.

DR. H. O. WALKER, Detroit, prefers, wherever practicable, to do perineal prostatectomy.

Therapeutic Value of Radium.

DR. MYRON METZENBAUM, Cleveland, Ohio, discussed the physiologic action of radium of low activities on ulcerated areas and on the unbroken skin for thirty-five minutes; also the pathologic condition from placing radium of high activity on the unbroken skin for long periods of time. The therapeutic results from radium of low activity are as good as those from radium of high activity and great expense.

Two Cases of Pancreatic Cyst.

DR. VAN BUREN KNOTT, Sioux City, Iowa, discussed the method of treatment, made a comparison between incision and drainage and excision, and reported two cases, neither of which had the sallow, dry skin said to be characteristic of cysts of the pancreas.

Tenotomy of the Tendo-Achilles.

DR. J. P. WEBSTER, Chicago, drew the following conclusions: "1. After tenotomy of the tendo-Achilles (when the foot is kept at rest) the process of repair takes place and satisfactory functional use of the foot is the result. 2. It is much easier to maintain the foot in the exaggerated flexed position after the tenotomy of the tendo-Achilles than with any form of splint, anterior or posterior, metallic or plaster. 3. There is much less pain, as the foot and ankle joints are placed at absolute rest. 4. When the patient commences to walk, none of the resistance of the contracted heel cord is present, so that there is but a slight limp. 5. In oblique and comminuted fractures of the tibia there is much less danger of overriding of the fragments of bone after a tenotomy. This greatly simplifies the care of the leg and helps to prevent deformity."

The Mamma: Its Physiologic Purposes.

DR. THOMAS H. MAXLEY, New York, drew the following con-

clusions: "1. The mamma is a highly organized and structurally a most complex organ. 2. Its functions are manifold. It is an essential and integral part of the generative system. Intermittent in function, like the testes, total ablation, like double castration, makes its impress on the sensorium. 3. Very frequently degenerative or pathologic changes begin in a single isolated lobe, about twenty of which are in each breast. In all non-malignant affections radical measures should be limited so far as possible to the affected area or lobe. 4. It is only in malignant disease of the progressive type and life is imperiled, that total sacrifice of the breast is justifiable. 5. Inasmuch as the functions and purposes of the axillary lymph ganglia are yet imperfectly understood, and their removal quite invariably enhances the risks of operation, involves a wide mutilation of the chest walls, and always leaves more or less impediment in shoulder action, or even at times a painful tumefied limb, it is only as an extreme and exceptional measure that their complete extirpation should be practiced."

(To be continued.)

ASSOCIATION OF MILITARY SURGEONS OF THE UNITED STATES.

Thirteenth Annual Meeting, held in the Hall of Congresses, St. Louis, Oct. 10-15, 1904.

(Concluded from page 1248.)

Accidents to Divers.

LIEUTENANT COLONEL LUIGI ARBAMONDI, Royal Italian Navy, discussed in a very interesting manner the accidents incident to submarine investigations which have been carried on under the direction of the navy department of Italy. On every ship of the Italian navy a diver is carried with complete submarine equipment.

The Sanitary Sergeant.

BRIGADIER GENERAL OTIS H. MARION, Surgeon General, U. S. A., suggested that an extra sergeant be detailed in each military company to be known as the "sanitary sergeant," or as the "acting sanitary sergeant," who should receive special instruction in, and be put in charge of, the sanitation of the company and its surroundings. His duties should consist of care of the personal hygiene of the enlisted men of his company, the hygiene of the quarters, clothing, equipment and food, and the conduct of the sick or injured men of the company. He proposed that in each regiment a medical officer should give systematic instruction to the sanitary sergeants of the several companies in order fully to qualify them for their work. As cleanliness furnishes an atmosphere of self-respect, the enlisted men should gain some intelligent knowledge of hygiene from the sanitary sergeant.

Naval Medical School.

MEDICAL DIRECTOR ROBERT A. MARMION, U. S. N., urged the importance of broader education for the naval medical officer than could be imparted from professional and other standpoints at present. The naval medical officer should not only be a general practitioner, but should be a specialist in all specialties. He must be the custodian of the health of the community where he happens to be detailed, and on ship-board, unaided, he must meet and combat all contagious diseases and epidemics. The essayist gave a résumé of the attempts at such instruction which had been made in the past: a history of the Naval Medical School and its scope, and explained the various features of the school and its value in increasing the efficiency of the medical officer in the Navy in new fields.

Care of Wounded in Naval Warfare.

SURGEON CHARLES FRANCIS STOKES, U. S. N., reviewed the types of wounds requiring treatment in naval warfare, most of which are infected, and consequently require immediate treatment before the patient is transported from the ship in

action to the hospital ship. He described a first-aid packet which he had designed, of suitable size, for shell wounds, and also exhibited and explained the Stokes splint stretcher and the proper method of using it.

Camp Sanitation.

MAJOR HERBERT A. ARNOLD, Surgeon, N. G. Pa., detailed in methods employed by him in camp sanitation, which included the selection of the camp site, the water supply, the inspection and care of the rations, the care of the sick, the disposal of garbage by an improvised crematory, the policing of the camp, tent sanitation, personal cleanliness, frequent medical inspection, and prompt change of camp site when contagion, infection or soil pollution becomes manifest.

Standardizing the Recruit.

SURGEON HENRY D. BEYER, U. S. N., discussed the significance of physical examination in the selection of recruits and its bearing on the efficiency of the service. On account of the intimate correlation shown to exist between the physique of a boy and his mental qualifications, the author suggested a method of percental standardization whereby the records of measurements might be kept in such a form that they would show at once in graphic form the physical grade of the recruit as compared with other recruits.

Practical Hearing Tests.

MAJOR WILLIAM S. BRYANT, Surgeon U. S. V., contended that inadequacy, inexactness, unreliability and injustice attended the ordinary method of hearing tests in physical examination and that the need was for a voice-sound of known intensity. He suggested for this purpose the phonograph fitted with a sound-proof box, a graduated stopcock and a three-way valve, which would produce a voice-sound of constant volume and pitch, and would allow exact determination of the ability of the applicant to understand the human voice and would also determine absolutely the efficiency of each ear independent of mental bias.

Pneumonia in Chicago.

SURGEON CHARLES E. BANKS, U. S. P. H. & M. H. Service, Chicago, gave the statistical relations of pneumonia and tuberculosis, past and present, with comparisons of the increasing prevalence of pneumonia and the gradual decrease of tuberculosis. He mentioned the growth of pneumonia in the large cities of late years with especial reference to the type noticed in Chicago last winter. He gave a clinical description of a typical case, noted the unsatisfactory results from all forms of treatment, the slow convalescence, the great mortality and the undoubted contagious character of the disease. In conclusion, he urged the need of combined effort to develop a successful curative agency.

SURGEON CHARLES F. STOKES, U. S. N., in discussion, stated that many cases of pneumonia were derived from direct infection from drinking cups, and suggested that all drinking cups be submerged in a solution of formalin.

Altitude and Expansion.

SURGEON PAUL M. CARRINGTON, U. S. P. H. & M. H. Service, Fort Stanton, N. M., first defined altitude, then gave the significance of expansion and the reasons why expansion should guide in the determination of proper altitude in patients suffering from tuberculosis and gave statistics based on his experience at Fort Stanton supporting this contention. These two factors, he said, were of undoubted value in determining the question of what climate to advise for consumptives.

Radical Treatment of Varicocele.

A paper prepared by Lieut. Col. Agostino Aguirre, of the Mexican Army, in which he detailed his methods of treatment of varicocele, was read by Captain Stanton, of Illinois.

Gunshot Wounds of the Spheno-Maxillary Fossa.

PASSED-ASSISTANT SURGEON LOUIS S. PILCHER, U. S. N., described the difficulties in locating bullets lodged in the

deeper recesses of the framework of the skull, and bore testimony to the value of the x-ray as an aid in such localizations. He spoke of the technical difficulties in reaching and removing these deeply-lodged bullets even after accurate localization had been effected. He then described a recent case of gunshot wound of the face, the operation and after-treatment.

Gunshot Wounds of the Ureter.

ASSISTANT SURGEON-GENERAL GEORGE TULLY VAUGHAN, U. S. P. H. & M. H. Service, Washington, noted the extreme rarity of gunshot wounds of the ureter as compared with other wounds of this structure. He reported two similar cases which required uretero-vesical anastomosis, one of which was due to a gunshot wound of the ureter and the other to injury received in operation for malignant disease of the rectum.

International Congress of Military Surgeons.

SURGEON GENERAL NICHOLAS SENN, III, N. G., who had just returned from a trip around the world, presented an important paper on the needs and advantages of a permanent international congress of military surgeons. He considered first the advantage to the sick and wounded of a uniform method of medical assistance; second, the necessity under modern conditions of co-operation in aid to the disabled of the medical departments of both sides in active hostilities; third, the greater efficiency of service secured by mutual acquaintance among military medical officers of various nations; fourth, the peculiar usefulness of discussion and contact in professional convention, and, fifth, the desirability of securing this result by the institution of a periodically recurring International Congress of Military Surgeons. Colonel Senn believed that the military surgeon should be as well equipped as the surgeon in a civil hospital, and that since the standing army must be maintained to render justice, the soldier must still be cared for; that the surgeon is a human representative of modern warfare and it is his duty to save human life; that no restriction should be placed on his close association with military surgeons of other nations; that military sanitation, therapeutics and transportation are of interest to all military surgeons. In conclusion, the speaker suggested that an International Congress of Military Surgeons be held about every three years to promote discussion and contact in professional convention to secure greater efficiency among military medical officers, and to secure co-operation of medical departments of the belligerent forces during active hostilities.

A committee was appointed to consider this matter and report at the next meeting of the association.

Conferring of Decorations.

On October 13, the association through its secretary, Major James Evelyn Pilcher, U. S. V., conferred the badge of the association on the following foreign delegates:

Col. Eugene Flis, Director General, Canadian Army Medical Forces; R. W. Conplinger, Inspector General, Royal Navy; Col. Henry, of the Indian Medical Service; Don Juan Redondo y Goelno, Spanish Navy; Col. Marschal, of the French Army; Col. H. W. Murray, Royal Army Medical Corps; Don Joaquin Yela of Guatemala; Don Leonelito Romlerz Marieno, of Nicaragua; Don David Mattio, Peru; Col. Pietro Imbrigo, Italian Army, and Lieut. Col. Luigi Abbonardi of the Italian Navy.

Prizes.

The first prize for the Enno Sander Prize Essay (an abstract of which appeared in THE JOURNAL, October 22, page 1247) was awarded to Lieut.-Col. William Hall-Chine, Army Medical Staff (retired), and the second prize to Lieut.-Col. H. Hathaway, Royal Volunteer Medical Corps, India.

Major Louis L. Seaman, U. S. V., New York, offered a prize of \$500 for the best paper on "The Prevention of Disease in the Army."

Election of Officers and Place of Meeting.

The nominating committee reported the following list of officers, which was unanimously accepted by the association: President, Surgeon General Walter Wyman, U. S. P. H. & M. H. S.; first vice-president, Major Albert H. Briggs, Surgeon N. G., N. Y., Buffalo, N. Y.; second vice-president, Brigadier

General Robert M. O'Reilly, Surgeon General, U. S. Army; third vice-president, Surgeon General Presley M. Rixey, U. S. N., and treasurer, Major Herbert A. Arnold, Surgeon, N. G. Pa., Ardmore, Pa.

After discussion of the advantages of Portland, Ore., and other localities, to which the Association had been invited for the 1905 meeting, Detroit was selected, the exact time of meeting to be determined by the Executive Committee.

NEW YORK STATE MEDICAL ASSOCIATION.

Twenty-first Annual Meeting, held in New York City, Oct. 17 to 20, 1904.

The President, Dr. William H. Thornton, Buffalo, in the chair.

Treasurer's Report.

The total expenditure during the last year was \$11,717.20, and the balance on hand, \$4,073.16, which showed the financial condition of the association to be better than it has been for a number of years.

Report on Amalgamation.

The committee on conference, by Dr. E. Eliot Harris, chairman, outlined the history of the attempt at amalgamation of the New York State Medical Association and the Medical Society of the State of New York. They had started out with the idea of mandatory legislation, and an impartial lawyer had informed them that this was out of the question, but that a permissive act might be obtained. Several conferences followed at which the question of union was discussed. The state association stood mainly for clean medical literature, clean advertising and reliable data regarding physicians; these principles the association had worked and fought for, and would continue to struggle for, though they were willing to waive matters of sentiment. The plan for union was defeated because the by-laws of the state association contain no provision for the manner of giving notice of meetings so that it became necessary to accept the common law rule, according to which, when a meeting of any organization is to be held for the passage of resolutions affecting privileges or property rights the notice of such meetings must be served on each member personally and not through the mail. As no such notices were served for the meeting at which resolutions were adopted for a plan of union of the two societies they were illegal and not binding on any of the members. A modification of the by-laws is necessary before such a meeting could be held, and this would require time. After a great deal of heated argument it was moved, seconded and passed that the whole matter be laid on the table for another year. Those who have opposed the union think that they have made it impossible, while others believe that union is only a question of time.

DR. BERNHARD COHEN, Buffalo, spoke of the unfortunate delay in effecting a union of the New York State Medical Association and the Medical Society of the State of New York as not due to either body and as a disappointment to the association, and it was resolved that it was the unqualified desire of medical men that good-fellowship should prevail, and the association pledged itself to endeavor to secure a union of the two bodies.

Officers Elected.

President, Dr. J. Riddle Goffe, N. Y.; vice-president, Dr. Allen Arthur Jones, Buffalo; treasurer, Dr. F. A. Baldwin, New York City; secretary, Dr. Charles I. Redfield, Middletown.

Medical Fellowship.

DR. WILLIAM HARVEY THORNTON, Buffalo, delivered the president's address and after speaking of the benefits of co-operation and organization said that out of 1,800 members of the state association, 1,000 are members of the American Medical Association. The demand for unity by the profession in the state of New York is great, and he asked that continued efforts be made to bring the association nearer the ideal which they are striving to attain.

How and When to Use Antitoxin in Diphtheria.

DR. CHARLES GILMER KERLEY, New York, after referring to 66 cases that he had treated in private practice, emphasized the fact that this serum should be given in persistent laryngeal stenosis, and especially where there is any obstruction to inspiration and expiration. Patients who are seen on the second day of the disease should receive 3,000 units regardless of the age; after the third day the initial dose should be 5,000 units, to be repeated in twelve hours if improvement is not positive. The dosage must be determined by the severity of the infection when first seen.

DISCUSSION.

DR. EVERARD D. FERGUSON, Troy, said that before the introduction of antitoxin he had had 75 intubation cases without a single recovery; since then he had successfully treated 5 cases of primary laryngeal diphtheria.

DR. FRANCIS J. QUINLAN, New York, said that before the introduction of antitoxin he had done as many as 116 intubations in one year, but the timely use of antitoxin in the laryngeal and tracheal forms of the disease now seldom require the performance of this operation.

DR. LOUIS CURTIS AGER, Brooklyn, believes 3,000 units should be the minimum initial dose.

DR. BERNHARD COHEN, Buffalo, has given as high as 28,000 units in two days because of the decided cardiac weakness.

DR. LOUIS FRSCHER, New York, believes that the initial dose should be not less than from 5,000 to 10,000 units. In laryngeal cases 10,000 units should be the initial dose.

(To be continued.)

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

Fifty-fourth Annual Meeting, held at Pittsburg, Sept. 26 to 29, 1904.

(Concluded from page 1250.)

The Influence of Milk Infection on the Course of Acute Infectious Diseases in Adults.

DR. DAVID L. EDSALL, Philadelphia, reported a series of cases of typhoid fever occurring in one hospital ward and under entirely similar conditions, excepting for a difference in the care of the milk, in the two periods contrasted. When the service began a very large proportion of the cases had severe diarrhea and many had mild diarrhea, while abdominal symptoms were common. The milk was examined bacteriologically and showed excessive numbers of bacteria. The milk was pasteurized after this and in the following three and a half months of the service diarrhea was almost absent and abdominal symptoms were extremely slight. The milk supply was subsequently changed and is now under careful regulation, and it seems in all ways satisfactory. The great importance of determining definitely in both private and hospital practice that the milk used comes from an approved source and is properly cared for was emphasized, as well as the fact that such conditions are undoubtedly common in individual cases, and a bad milk probably exercises not uncommonly a very evil influence on the prognosis of acute infectious diseases. Milk infection of this kind is peculiar from a clinical standpoint in that it is observed in patients already ill. The milk infection is apt to be overlooked, because the symptoms may be attributed to the primary disease.

DISCUSSION.

DR. ADOLPH KOENIG, Pittsburg, said he believed that physicians should be guided largely in their efforts to cure disease by paying attention to the natural instincts of their patients. He believed that it was an established physiologic fact that there is no digestion of food possible when there is a temperature of 102 degrees F., although not in a position to verify it. He has withheld food, absolutely everything but a little whisky, for sixteen days with the most happy results. As soon as the patient manifests desire for food, he believes that milk is the best diet, and the best results are to be obtained by adding barley water.

DR. STENGEI, Philadelphia, considered the doctrine of over-feeding most pernicious and one in which he had seen the most disastrous consequences. While he could not withhold food, as Dr. Koenig suggested, during the period of anorexia, still he is convinced that in the first period of the disease nine out of ten are overfed.

Knee Ankylosis.

DR. DEFOREST WILLARD, Philadelphia, stated that this was a condition, the result of a disease and not a disease itself, and might result from many different pathologic conditions. He remarked that the discovery of the cause was all-important, as the treatment to be pursued after the joint has become fixed must depend, first, on the cause, and second, on present joint conditions as discovered by careful clinical examinations aided by x-rays. He outlined the appropriate treatment for ankylosis, following gonorrhoeal infection, septic infection, tubercular disease, or with suppuration, and cited as the accidents most liable to result from forcible straightening, fracture, posterior dislocation and aneurism.

A New Line for Defining the Relationship of the Femur to the Pelvis.

DR. STEWART L. MCCURDY, Pittsburg, stated that trans-pelvic lines crossing the pubic spines will cross the trochanteric eminences in children and above the same point in adults, and that when the trochanter is found above this line, displacement from some cause is always present. Disregarding the pubic spines, two lines may cross the pelvis, one through the anterior superior spines and a second through the trochanteric eminences. If these lines are not parallel, then the displacement exists on the side on which the lines converge or are closer. He demonstrated on a skeleton the inaccuracy of the usual method of estimating shortening of an extremity unless the femurs are placed at the same angles with the pelvis on the two sides.

Modern Methods for Combating Deformity in Spinal Curves.

DR. DAVID SILVER, Pittsburg, stated that the complicated nature of the spine rendered treatment of deformity difficult. Traction by suspension as a means for correcting the deformity and placing the spine in proper position for fixation is deficient: 1. It does not separate the diseased vertebral bodies and so does not abolish the traumatism from weight bearing and functional uses. 2. The force is largely expended on the secondary curves, the kyphosis being but slightly modified. 3. A large part of the good effect is lost unless traction is made continuously by means of a head support. Similar objections apply to recumbency on a flat surface. Hyperextension he considered the best method, and the best procedure for obtaining correction and for the routine application of the jacket was said to be a modification of the Metzger-Goldthwait frame.

Symposium on Rectal Diseases.

A paper on "The Treatment of Internal Hemorrhoids by Excision" was read by Dr. Ernest Laplace, Philadelphia, who described in detail a new method of operating. Dr. E. Montgomery, Philadelphia, said that the Downes angiotribe should be used only in the hands of an experienced operator, otherwise there is danger of injuring the surrounding tissues. Dr. Levi J. Hammond, Philadelphia, said that most of the discomfort following operations is due to imperfect dilatation of the sphincter.

A paper on "Anal Fissure" was read by Dr. William H. Beach, Pittsburg, who dwelt particularly on the danger of tearing the sphincter in overdilatation, and stated that equally good results could be obtained by simply cutting a few of the fibers.

A paper on "The Treatment of Internal Hemorrhoids by Injection" was read by Dr. Lewis H. Adler, Jr., Philadelphia.

Surgical Treatment of Retrodisplacement of the Uterus.

DR. HENRY D. BEYEA, Philadelphia, reported the results of 465 cases in which he had employed ventrosuspension, with but one death and no complications, although over forty labors occurred subsequent thereto.

The Disturbances of Menstruation and Their Significance.

DR. E. E. MONTGOMERY, Philadelphia, considered the disturbed conditions under amenorrhoea, which may be either congenital, constitutional or mechanical; dysmenorrhoea, which, owing to the present mode of dress is rapidly increasing; menorrhagia and metrorrhagia, and vicarious menstruation, a discharge periodically from some other surface than the uterine mucosa.

DISCUSSION.

DR. J. M. FISHER, Philadelphia, remarked on the interdependence of all the organs of the body and the necessity for the gynecologist being a thorough obstetrician, citing a case in which the patient did not know she was pregnant until she felt the fetal movements, menstruation having occurred at regular intervals up to that time.

Some of the Unsettled Questions of Extra-Uterine Pregnancy.

DR. MORDECAI PRICE, Philadelphia, thought that the presence of the amniotic sac was absolutely necessary for the child to go to term, and also remarked on the occurrence of hemorrhage during normal pregnancy simulating this condition, reporting two cases illustrative of the latter proposition.

DISCUSSION.

DR. J. M. FISHER, Philadelphia, said that the point as to the presence of the amniotic sac was well taken, and urged the better education of the general practitioner in regard to this condition.

DR. E. E. MONTGOMERY, Philadelphia, spoke of the cases in which grave hemorrhage occurred and yet no hemorrhage could be demonstrated into the sac.

DR. PRICE referred to a case which he had diagnosed as extrauterine pregnancy, which on operation proved to be a dermoid cyst, and another which proved to be appendicitis.

Overlapping of the Aponeuroses in the Closure of Abdominal Wounds.

DR. CHARLES P. NOBLE, Philadelphia, stated that he first used this procedure in 1894 for umbilical hernia and since 1897 had employed it in all incisions, in over 150 cases, and by overlapping the neuroses in this way one can secure firmer union than by any other method. He then described in detail the operation.

Paraffin as a Surgical Medium.

DR. M. DELMAR RITCHIE, Pittsburg, went in detail into the development of the use of this remedy, the indications for its use, technic, etc. He recommended the use of cold, solid paraffin, of a melting point of 110 degrees, injected by means of a lever injector. He also stated that the production of an embolus was impossible when cold, sterile paraffin was injected into the surgically cleansed tissue through the rounded needle point, and that there was no known danger to life in the correction of any deformity, however marked.

DISCUSSION.

DR. STEWART L. MCCURDY, Pittsburg, said that the employment of cold paraffin would be a great advance over the old method of employing the heated article, which had been followed in almost every instance by some complication such as ulceration or hyperemia.

DR. DILLINGER referred to a case of total blindness caused by the paraffin getting into the central artery of the retina, which he felt was probably due to semi-solid or hot paraffin being used, and that much of this objection would doubtless be removed by the method suggested by Dr. Ritchie.

DR. S. B. JACKSON, Pittsburg, stated that he had seen a case of embolism of the retinal artery following the employment of this remedy and believed it better to leave the work to those who had had considerable experience in it.

Cause and Cure of Catarrhal Deafness.

DR. LOUIS J. LAUTENBACH, Philadelphia, stated that catarrhal deafness is present in about 25 per cent. of all adults, and includes 75 per cent. of all cases of deafness, which is practically always caused by nose disease, and which is usually curable and easily controlled in the early stages and should be treated before the ear becomes affected, and, whether in the early or late

stages of the ear disease, the nose should be conjointly treated therewith.

DISCUSSION.

DR. HOWARD F. PYFFER, Norristown, said that there were many cases in which the disease had its inception in the ear.

DR. LAUTENBACH said that the origin of practically all cases of true catarrhal deafness could be traced to the nose, but that there were many cases caused by general diseases, which were too often confounded with catarrhal deafness in their diagnosis.

Convergent Strabismus.

DR. WENDELL REBER, Philadelphia, reported 36 private patients and 130 hospital cases, classified according to sex, age of onset, determining influence, degree of deviation, amblyopia, increase in vision, variety of squint and refraction. The treatment and the results obtained were carefully outlined. He believed heredity played an important rôle, and urged the early treatment of all cases occurring before puberty with properly adjusted glasses.

DISCUSSION.

DR. HOWARD F. PYFFER, Norristown, said that there was no doubt as to the improvement of this condition by properly adjusted glasses, and emphasized the necessity of constantly urging the parents to keep up the treatment.

DR. REBER stated that he did not believe operation should be done until after puberty, and that the amount of vision present in the respective eyes should determine the operation to be performed.

Carbolic Acid and Ammonia Burns of the Eye.

DR. EDWARD STIEREN, Pittsburg, commented on the meagerness of the ophthalmic literature on the action of ammonia on the tissues of the eye, and stated that eyes so affected are almost invariably rendered blind by the dense opacity of the cornea. Four cases of ammonia and three cases of carbolic acid burns of the eye were reported, the essayist remarking the great similarity of the ocular reaction for the first few days, while the ultimate outcome was very different, those burned by ammonia recovering very poor, if any, vision, while the carbolic acid burned cornea cleared up and in time recovered their former transparency.

DISCUSSION.

DR. WENDELL REBER, Philadelphia, mentioned a case coming under his observation at the Polyclinic Hospital, due to splashing of ammonia in the eye, and stated that when only the superficial tissues were affected the results were pretty good, but that occasionally there would be a case of deep penetration and infection of the whole eye, with resulting loss of sight.

DR. MICHAEL V. BALL, Warren, reported a case of limberburn of the eye, resulting in sloughing of the conjunctiva, followed by opacity of the cornea.

DR. STIEREN referred to the value of dinion as a lymphatic and circulatory remedy, and stated that he could see no reason why it would not be efficacious in lime burns.

Mastoiditis.

DR. FREMONT W. FRANKHAUSER, Reading, considered the condition with reference to the etiology, pathologic changes, symptoms, diagnosis, prognosis and treatment. He urged careful examination in all suspected cases, with operation, being sure to make the opening large enough, believing that if the operation was not complicated there was very little danger, and that it was better to sacrifice some parts to early operation than to allow the grave conditions to continue and thus run the chance of losing a valuable life.

DISCUSSION.

DR. BEVINGER, Pittsburg, reported a case of mastoiditis occurring in a man, following the use of a salt-water douche for acute rhinitis, with typhoid symptoms and delirium, pressure over the mastoid causing pain, with "prune juice" expectoration, and on opening the mastoid pure pneumococcus pus was found. The patient slowly recovered.

DR. HOWARD F. PYFFER, Norristown, said that in the acute cases conservative treatment might produce results, but that

in cases of any considerable duration the pus should be removed, and rest in bed, heat and atropin applied.

DR. LEVI J. HAMMOND, Philadelphia, divided the cases into acute and chronic, and recommended early operation in the former.

DR. FRANKHAUSER said that the most conservative plan of treatment was to open the mastoid and thus prevent destruction of the middle ear.

The Retarded Development of Speech in Young Children.

DR. G. HUNSON MAKUEN, Philadelphia, mentioned as some of the causes thereof, structural irregularities in the peripheral organs, obstructed nasal respiration, and parietic conditions of the nerves supplying the tongue, palate and lips, dwelling particularly on disturbed hearing as a causative factor, and the effects of faulty hearing and speech on mental development. Partial deafness in young children, or deafness for only a few sounds, is sufficient to interfere with the normal development of speech, and the child failing to understand gradually stops listening, the brain finally losing its power to comprehend the meaning of spoken language. He suggested, in addition to the usual and well-known methods for improving the peripheral auditory apparatus, a course of training for the development of the central perceptive faculties, and reported a case illustrating the various points in the paper, of a child who had been treated by this method.

The Removal of Cataract Without Iridectomy.

DR. JOSEPH E. WILLETS, Pittsburg, after reviewing the various steps in the formation of cataract, and considering the various operations which are and have been practiced for its removal, stated that the operation consisted essentially of three steps: 1, The making of a section whose dimensions vary according to the size and consistence of the cataract; 2, opening of the anterior capsule to allow the lens to escape from it; 3, the expulsion of the lens by pressure exerted on the eye. In conclusion, he stated that he felt simple extraction to be the ideal operation, as, if as good results could be obtained thereby, he felt it unscientific to subject the eye to unnecessary surgical procedure.

DISCUSSION.

DR. WENDELL REBER, Philadelphia, stated that he had in his early practice done some simple extractions of cataract, and when the healing was uneventful a very beautiful result was secured, but that the risk of complications was too great to warrant it being practiced as a routine procedure, a preliminary iridectomy being advised.

DR. WILLIAM H. DUDLEY, Easton, said that, while simple extraction might be the operation of choice for one who was doing much of this work, for the average man a preliminary iridectomy was the best procedure.

DR. WILLETS said that, while it was probably easier to do an operation on the eye having had a preliminary iridectomy, yet that it was just as hard to do the preliminary iridectomy as the simple extraction, in addition to subjecting the patient to two risks, which he felt to be unnecessary.

The Extract of Suprarenal Gland in Surgical Shock.

DR. ALEX. R. CRAIG, Columbia, reported two cases in which the drug was used. This was the first paper read Thursday afternoon at the general session. The first case was a compound fracture of the elbow caused by a gunshot wound six hours before his admission to the hospital, at which time he was pulseless, cold, cold sweat, pupils dilated and labored breathing. The injection of three pints of normal salt solution, in the first and third of which was one dram 1/100 degree solution of suprarenal extract, was followed by a very favorable reaction. The second case was a compound fracture of the skull in the right parietal region, caused by being thrown from a freight train, in which case similar results were obtained.

DISCUSSION.

DR. ALBERT E. ROUSSEL, Philadelphia, cited a case of typhoid fever with hemorrhage, in which this remedy had produced very good results, and expressed belief in its value in cases of di-

lated heart where digitalis has been used for a long time and is beginning to wane in its effect.

DR. JOHN B. ROBERTS said that it might be questioned whether it was the normal salt solution or the suprarenal extract that produced the result.

DR. CRAIG stated that he had never seen normal salt solution act in the prompt and efficient way this remedy did.

Boils.

DR. GEORGE W. GUTHRIE, Wilkesbarre, mentioned as the predisposing causes, coarse, unclean skins, large follicles, slight traumatism of the surface, anything that lowers the vitality, overwork, poor food, exhausting diseases, fever, albuminuria and diabetes, they being produced by infection of the skin follicles by pyogenic bacteria, and governed by the same developmental laws as control more serious infections. The remedial measures recommended were treatment tending to build up the general system, proper hygiene, rest, careful attention to the skin, and quinin. He believed abortive measures were of doubtful efficacy.

DISCUSSION.

DR. WILLIAM L. ESTES, South Bethlehem, said that boils on the upper lip and about the ale of the nose seemed to be more serious than elsewhere, and reported such a case resulting in embolism and death.

Treatment of Infected Wounds with a Phenol Product.

DR. C. B. LONGENECKER, Philadelphia, said that the mixture referred to was composed of two parts of camphor and one part of phenol, which, although known to the profession for a long time, had been but little used, its greatest value being in the treatment of infected wounds, and that its efficacy might be supplemented by the addition of ichthyol, tincture of iodine, etc. As a result of twelve years' experience in its use, he stated that if correctly applied it produces the best results in most cases, in many relieving the associated pain, without in any way producing a bad result.

A Case of Cesarean Section.

DR. G. W. WAGONER, Johnstown, reported a case in which cesarean section was done after failure to effect version in an impacted transverse presentation. The patient was a Slavish woman, aged 34, who when admitted to the hospital, after being several hours in labor and unsuccessful attempts had been made to deliver her, presented the following condition: All parts normal; os fully dilated, child presenting transversely, with the right shoulder impacted in the superior straight and the right arm prolapsed; pains frequent and excessively strong. After repeated unsuccessful attempts at version under complete anesthesia, rupture of the uterus seeming imminent, cesarean section was performed, following which the patient progressed favorably and was out of bed on the twenty-sixth day.

The Advantages of Performing Capital Operations in Certain Cases Without Anesthesia.

DR. J. J. BUCHANAN, Pittsburg, cited the following indication for this method: 1, Profound septic infection; 2, severe collapse from loss of blood and shock; 3, fecal vomiting, with liability to drowning during the operation, or aspiration pneumonia subsequently; 4, collapse or compression of the lung, with liability to respiratory failure; 5, obstruction of esophagus; 6, advanced kidney disease, with liability to anuria. He enumerated in detail the operations suitable for this procedure, and emphasized the slight pain and great tolerance and co-operation of the patients, stating that in an experience of ten years his results had been uniformly satisfactory.

DISCUSSION.

DR. H. E. WETHERILL, Philadelphia, referred to the impossibility of always employing anesthesia in military operations, and reported two cases, one of the extraction of a bullet from the lung and the other for removal of the superior maxillary bones, without anesthesia.

DRS. JOHN B. ROBERTS and JOSEPH W. HEARN, Philadelphia, emphasized the value of the suggestions contained in this pa-

per, and DR. EDMUND W. HOLMES, Philadelphia, while recognizing the value of such procedure in selected cases, believed the pain to be greater than the author supposed.

DR. BUCHANAN stated that, while it hurt the patient some, he did not believe it was nearly so much as some thought.

Professional Responsibility in Accident Cases Involving Litigation.

DR. JOHN B. ROBERTS, Philadelphia, stated that the duties of the medical attendant of the patient and the examining physician for the defendant are identical, to obtain a prompt return to health and a just settlement of damages. Careful and frequent examinations should be made, and he believed better results would be obtained by early settlement, too many examinations, conferences, etc., being productive of traumatic neurosis.

DISCUSSION.

DR. ERASMUS SWING, Coatesville, referred to the tendency to bring suits against corporations, whether the injury warranted it or not.

DR. LEVI J. HAMMOND, Philadelphia, suggested that possibly this would be lessened if all physicians would refuse to have anything to do with the case on a contingent basis.

DR. SPENCER M. FREE, DuBois, remarked on the necessity of care on the part of the consultants, as to the statements they make regarding the former treatment of the case.

DR. R. W. STEWART, Pittsburg, deprecated the practice of giving an expert opinion from an x-ray picture submitted.

Other Papers.

Among the other papers read at the meeting were the following:

"One Hundred Consecutive Abdominal Sections in Hospital Practice Without Mortality," by Dr. F. F. Simpson, Pittsburg. "Congenital Elongation of the Left Lobe of the Liver Presenting Symptoms of Tumor of the Spleen," Incision, Ventrofixation, Followed by Relief of Symptoms," by Dr. Levi J. Hammond, Philadelphia. "Twelve Years of Emergency Surgery," by Dr. E. E. Wible, Newhall. "A Study of Progress in the Treatment of Skin Diseases," by Dr. J. R. McCurdy, Pittsburg. "The Treatment of Skin and Glandular Diseases by the X-ray," by Dr. Russell H. Boggs, Pittsburg. "The Roentgen Ray and Radium Therapy," by Dr. Mirran K. Kassabian, Philadelphia. "The Treatment of Malignant Discharges of the Breast," by Dr. Charles Lester Leonard, Philadelphia. "The Inhibitory Action of X-ray on Malignant Growths," by Dr. George C. Johnson, Pittsburg. "Tubercular Adenitis Treated by the X-ray," by Dr. George E. Pfahler, Philadelphia. "The Post-operative Treatment of Malignant Disease," by Dr. R. W. Stewart, Pittsburg. "The Care of Fractures from the Standpoint of the General Practitioner," by Dr. William S. Newcomer, Philadelphia, recommending the employment of the x-ray, which he felt was particularly valuable in determining the existence of a fracture by chipping off a small portion of the bone near a joint. "Clinical Studies in Shock and Blood Pressure in Traumatic Surgery," by Dr. Jonathan M. Walnwright, Scranton. "Cranicectomy in Microcephaly," by Dr. W. D. Teazarden, Washington. "Acute Gastric Dilatation Following Surgical Operation and Accidents," by Dr. Theodore B. Appel, Lancaster. "The Cause of Death in Cases of Intestinal Perforation Occurring in Typhoid Fever which Had Been Operated On," by Dr. J. Hartley Anderson, Pittsburg. "Pernicious Vomiting Cured by Fixation of the Kidney," by Dr. George Erory Shoemaker, Philadelphia, reporting a case occurring in a woman 25 years of age in whom vomiting had been present for seven years previous to the operation, and who was completely relieved thereby. "The Diagnosis and Treatment of Tumors of the Ovarium and Cerebro-Pontil Angle," by Drs. Charles E. Mills and Charles H. Frazier, Philadelphia, describing in detail the symptoms and means of diagnosis and urging the necessity for early operation.

The secretary reported an attendance of 711 at this meeting, as compared with 355 at York last year; 337 at Allentown in 1902, and 602 at Philadelphia in 1901.

Travel Notes.

XIV.

THE ADELAIDE HOSPITALS.

NICHOLAS SENN, M.D.
CHICAGO.

S. S. CHINA, Aug. 24, 1904.

Adelaide is the capital of the state of Southern Australia. A railroad seven miles long connects it with the harbor, Port Adelaide. It is the intellectual as well as the business center of the state. The city is located in the midst of an extensive

fertile plain, with a range of tree-clad hills in the distance and the ocean in the opposite direction. Its streets are wide, well laid out, well paved and clean, but the electric lighting is conducted on an economic scale. Present population, 60,000. The hobtail horse trams remind one of the size of the city, while the substantial sandstone buildings in its main streets would do credit to any of our large cities. Australian cities have, fortunately, no need of sky scrapers which disfigure our large cities; buildings more than three stories high are the exception, and time-saving, muscle-weakening and lung-crippling elevators have as yet but a limited sphere of questionable usefulness. Adelaide has a young, prosperous university, splendid botanic and zoologic gardens, public library, art gallery, museum and a number of attractive parks. It is an ideal university city where students are given all conceivable opportunities to enrich their minds with object lessons in all the arts and sciences, and where they are free from the many temptations which lurk in such abundance in all of the large cities. Medical students are given here very thorough didactic teaching, and the clinical material is large enough for practical instruction in medicine, surgery and the different specialties. The hospitals of Adelaide receive patients from all parts of the state and furnish the medical department of the university with an abundance of material, which is utilized by the teachers to greatest advantage for bedside and amphitheater instruction. It is somewhat remarkable that none of the general hospitals of Australia makes any provision for maternity cases, but all medical schools have a large out-door obstetric department, where the students receive practical instruction at the bedside of the poor in this most important branch of the healing art. One of the rigid requirements for graduation in all of the medical schools is to the effect that the candidate must present evidence that he has attended a specified number of confinement cases.

THE ADELAIDE HOSPITAL.

The Adelaide Hospital is the largest and only public general hospital in the city and its medical affairs are controlled by the clinical staff of the university. It was founded fifty years ago and can accommodate 240 patients. The main building, of sandstone with brick corners, is two stories high. It is situated some distance back from the street in the rear of an open square which has been converted into a beautiful little park, with well laid out gravel drives and walks and shaded with a variety of trees and ornamented with shrubbery and flowers. The remaining two including sides of the park are occupied by one-story buildings, most of them of recent construction. The operating theater now in use is antique and the surgeons are anxiously awaiting the opening of the new one which is nearing completion and which has been well planned and will represent the most modern improvements in this, the most important part of any hospital. The wards in the old building are somewhat gloomy and not sufficiently lighted. The electric light has not as yet been introduced, and the scanty gas jets at night can be no improvement on the defective daylight. Heat is supplied by open coal fires. In one of the surgical wards the grates occupy the base of a beautifully frescoed square column, which contributes much to the cheerfulness of the otherwise somber room. As in all Australian hospitals, a profusion of flowers imparts to the sick rooms a homelike and cheerful appearance. Owing to a somewhat miserly government aid it is interesting to know the sources from which the additional funds are obtained to carry on the work of this deserving charity. For the purpose of stimulating the spirit of charity among the people the contributors are given certain privileges, a practice which it would be well for some of our hospitals to imitate. On this subject I will quote from the last annual report of the hospital:

"1. Every contributor of £2 annually shall have the privilege of recommending one indoor patient in the year; of £5 annually, three indoor patients in the year; of £10 annually, the privilege of having always one patient in the hospital.

"2. Contributors of £2 annually shall also have the privilege of recommending six out-door patients for relief from the dispensary; contributors of £5, twelve patients; contributors

of £10, fifteen patients. It is to be distinctly understood that these recommendations are only to be issued by the contributors to persons who can not pay for medical treatment elsewhere. . . .

"3. Life contributors to have the same privilege in proportion; their donations being estimated as annual contributions of one-tenth." The restriction placed on the issuing of recommendations on these terms is repeated once more in paragraph 5, regulating the admission of patients: "It is to be distinctly understood that these recommendations are only to be given to persons who, on account of their poverty, are proper subjects for hospital treatment." In paragraph 6 provision is made to exclude charity patients who are able to pay for medical service: "Applicants for admission to the hospital shall, unless possessed of means sufficient to pay for medical advice, make a declaration, on a form printed for that purpose, to the effect that they are unable to pay for medical advice, and stating whether they are entitled to medical attendance from any benefit society or lodge."

That these declarations are not always in accord with facts became evident to me in visiting the different hospitals. Many patients find their way into the hospitals who are abundantly able to pay the physicians a fair remuneration for their services. The abuse of charity is practiced here as well as elsewhere on a large scale. The people are fully aware of the fact that they can secure the very best medical and surgical talent in hospitals connected with medical schools, and are willing to declare and sign almost anything to avail themselves of the gratuitous services of the attending staff. The Adelaide Hospital cares for many such impostors. Adelaide and the surrounding agricultural and pastoral country are in a prosperous condition, and many who seek the shelter of this hospital rob it and the medical profession annually of a large amount of money which they have well earned and to which they are justly entitled. Such abuse of charity is difficult to remedy, more especially in the case of hospitals connected with medical schools.

Drs. E. C. Stirling and Archibald Watson are the consulting physicians and surgeons. Four physicians constitute the medical and three surgeons the surgical staff. The present surgical staff consists of Leonard W. Bickle, M.R.C.S. Eng., L.R.C.P. London, F.R.C.S. Edin.; William Anstey Giles, M.B., Ch.M. Edin.; Benjamin Poulton, M.D. Melb., M.R.C.S. Eng. Two gynecologists, two ophthalmologists, one surgeon for the ear and throat, a bacteriologist, a dentist and two pathologists complete the list of medical officers with the exception of the resident medical superintendent, Mr. F. J. Chaffee, six assistants and five internes. The internes are selected from the graduating class of the university on their college standing. One of these internes is a woman, who assists Mr. Giles in his surgical work. The women internes in this hospital have made an excellent record. The internes, as in all Australian hospitals, receive a small salary and serve for one year. The training school for female nurses connected with the hospital has fifty pupils, several sisters and a matron. The nurses remain in training for three years and receive annually from \$100 to \$200, according to the length of time of their service. The new laboratory is capacious, well lighted and is in charge of a graduate nurse, who does all the mechanical work and prepares the culture mediums. Patients suffering from tuberculosis of the lungs do not remain in the hospital for any length of time, as they are sent from here to a sanatorium in the mountains seventy miles from Adelaide, built specially for this purpose and managed by the same administration. Other infective diseases are not admitted to the hospital. Turpentine and biniodid of mercury solution are favorite antiseptics with many Australian surgeons in hand disinfection. Catgut and kangaroo tendon have been largely displaced by fine silk. On the whole, chloroform is used more frequently than ether as an anesthetic. Cyanid gauze as an inner dressing for wounds remains popular. I had the pleasure of seeing considerable of the surgical work of two of the clinical professors of surgery in the university, Dr. Poulton and Mr. Giles. The former I found operating on a case of prostatic hypertrophy in a

man 65 years of age, who had suffered from the obstruction for several years. The usual long suprapubic vertical incision was made, the peritoneal reflection pushed upward, and the bladder incised on the point of a sound previously introduced into the bladder and held in position by an assistant. Repeated efforts to enucleate the gland after incision of the mucosa failed. It was one of those cases in which the enlargement was not due to the growth of adenomata, but to a hypertrophy of the gland itself, hence the impossibility of removing it by intravesical enucleation. It is in such cases that the most experienced surgeon will fail in removing the obstruction by the suprapubic route. Suprapubic drainage of the bladder was established by the use of rubber tubing fixed in the lower angle of the wound with sutures and the balance of the wound carefully closed. The next operation was performed by one of his assistants. The patient was a man 72 years old, the subject of a tumor nearly the size of a fetal head occupying the right parotid and submaxillary regions. There could be no question as to the malignant nature of the tumor, as it had reached its present dimensions since last Christmas. As the labial branch of the facial nerve had lost its functions it was suspected that the tumor had its starting point in the parotid gland. The operation was a very difficult one, but was executed with care and precision. The operator from time to time availed himself of anatomic information furnished by Professor Watson, who stood by and watched every step with his eagle eyes. The lymphatic glands were not involved and the operation demonstrated that the tumor had its origin in the submaxillary salivary gland and was undoubtedly a sarcoma. One of the most interesting cases in Dr. Poulton's wards was a man in middle life who had recently been operated on for an obscure swelling in the region of the gall bladder and extending to the right lumbar region. Positive diagnosis could not be made, although it was suspected that it was connected either with the gall bladder or right kidney. It was first noticed a year ago. Urethral catheterization in the male, as a diagnostic aid, has so far not been practiced by any of the Australian surgeons so far as I was able to ascertain. The French separator, on the other hand, is frequently made use of. In this case a vertical incision was made from the eighth costal cartilage downward. On cutting through the abdominal wall the retro-peritoneal location of what now could be recognized as a cyst was ascertained without any difficulty, the ascending colon being displaced inward. Marsupialization was resorted to. This term is often employed by Australian surgeons to indicate the radical operation for echinococcus cysts and the treatment of other cysts by incision and drainage. This word was coined here and owes its origin to the many species of marsupial animals which inhabit Australia, animals which give birth to their offspring in the embryonic state and mature them in a pouch on the ventral side of the body, where the young have easy access to the milk-supplying breasts. After opening and stitching the sac to the abdominal incision, the dermoid character of the cyst was demonstrated by the escape of a large quantity of hair and sebaceous material. The patient was doing well, relieved of all subjective symptoms, and only a small quantity of a mucoid fluid was discharged daily through the drain which remained in the cyst. Such cases in this particular location are extremely rare, and it is to be hoped that a full report of the case will soon find its way into the current medical literature. The safety of the operation was enhanced in this case by previous firm adhesions between the two layers of the peritoneum, so that the marsupialization was practically extra-peritoneal. It has been observed in this, as well as in other hospitals of Australia, that the aborigines are more frequently affected with hydatids than the whites, as they are more exposed to infection, living with numerous dogs, and often obtaining their water supply from stagnant pools. Dr. Altmann of Bright has operated on many natives afflicted with this disease. All surgeons consider the natives good subjects for narcosis and capital operations. They are, however, very prone to homesickness and shorten their stay even in the best hospitals as much as their condition will permit. The surgical wards of the hospital contain 28 beds, and the new pavilions are perfect in

construction and appliances. The upper part of the walls are artistically frescoed, the pictures pleasing and well selected for the purpose for which they have been intended.

The next day, July 10, I visited the hospital again, this time with Mr. Giles, dean of the medical faculty and professor of clinical surgery, who had in his wards many very instructive cases. One case was of special interest to me, and had misled the surgeon, and would have misled anyone else, in making a correct ante-operation diagnosis. The history of the case pointed to appendicitis. The operation revealed a retrocecal subperitoneal suppurating hydatid of the right iliac fossa. The operation yielded the expected relief, suppuration has almost ceased, and the patient will soon be discharged, restored to perfect health. Within a very few weeks Mr. Giles had operated on three cases of undescended testicle, complicated by hernia. In all the results were excellent. Mr. Giles has the reputation of being one of the most conservative and successful surgeons of Southern Australia, and his clinical teaching is highly appreciated by his attentive classes. Appendicitis appears to be unusually prevalent in Southern Australia, as I was shown many cases recently operated on in the wards of both Dr. Poulton and Mr. Giles, and I have no reason to believe that either of these surgeons would resort to the use of the knife unless the indications were clear.

The great prevalence of hydatid in Adelaide and surrounding country is well shown by the records of this hospital. Last year 34 cases were operated on, of which number 3 died. Pneumonia appears to have been very virulent, as of 69 cases, 43 were cured, 4 relieved, and 22 died. Of 30 appendicitis operations, 26 were cured and 4 died; 2 deaths in 19 cases of ectopic pregnancy; 29 cases of pyosalpinx, with 21 cures, 1 relieved, 4 unrelieved, and 3 deaths; 16 cases of myofibromata, 12 cured, 2 unrelieved, and 2 died; 5 gastroenterostomies, with 2 deaths; 41 radical operations for inguinal and femoral hernia, without mortality; 10 cases of strangulated hernia, with 4 deaths; 5 cases of lithotrity, with 1 death; 4 cases of prostatectomy, with 3 cured and 1 relieved; 27 hysterectomies, 21 cured, 1 relieved and 5 died; 20 excisions of varicose veins, without mortality.

ADELAIDE CHILDREN'S HOSPITAL.

The foundation stone for this excellent institution for the care of sick children was laid June 20, 1878, for what is now known as the Way Buildings, and fourteen months later the first patient was admitted. The Way Building and a number of one-story pavilions since erected enclose an open square where the little patients can enjoy the sunshine and outdoor air and find ample room among the shade trees for their childish amusements. The hospital is located on a high ridge, from where a beautiful view can be obtained of the city and the distant mountain ranges. It has accommodations for 80 patients. All the buildings are of stone, and the wards are well lighted and cheerful. The diphtheria ward is never empty. One of the trained nurses administers the antitoxin under the direction of the attending physicians. The same nurse has also charge of the laboratory. The visiting medical officers are: W. M. Campbell, L.R.C.P., Edin.; Alfred E. Wing, M.D., Brux.; Alfred London, M.D., London; Harry Swift, B.A., M.D., Camb.; A. M. Morgan, M.B., B.S., Ad.; R. Brumrit, M.R.C.S. Two consulting medical officers, two consulting pathologists, and one oculist, two dentists, one aurist, seven anesthetists, one pathologist, one bacteriologist, one radiographer, one sanitary advisor, one registrar and one interne complete the long list of medical men who serve this institution. One matron and a staff of six sisters supervise the nursing and have charge of the training school, which has at present an attendance of 50 pupil nurses. The hospital is kept scrupulously clean, and the little patients receive the benefits of nursing of the highest order and the very best medical and surgical service. Electric lighting, complete equipments and appliances for diagnosis and all kinds of surgical work add much to the efficiency of the institution. Medical students are admitted to the clinics, and several members of the attending staff are clinical professors of the university. The wealth of flowers with which this hospital is kept supplied throughout the entire year is best seen in the picture illustrat-

ing the interior of one of the wards. The citizens of Adelaide take great interest in this hospital, and their liberal contributions enables the administration to carry out its humane intentions in the most satisfactory manner. I visited the hospital in company with Dr. Lendon, professor of obstetrics and diseases of children, who is familiar with all the details of its construction and management, and is one of the most influential members of its medical staff. During the last year 704 new patients were admitted. One hundred and two operations were performed on in-door patients and 364 on out-patients. Chloroform alone was used as an anesthetic 50 times; ether, 58; gas, 4; chloroform, followed by ether, 353; gas, followed by ether, 1. Appendicitis operation, only 1, and this patient died. Tuberculosis of the hip joint figures conspicuously in the list of surgical cases. Of 25 cases, only 2 were subjected to operative treatment, showing conclusively the conservatism which is observed in this hospital in the treatment of joint tuberculosis. Of 78 cases of diphtheria, the disease proved fatal in 3. Fifty cases of typhoid fever were treated without a death, certainly a remarkable record, and 27 cases of pneumonia, with only 4 deaths.

GALLSTONE IN ELEPHANTS.

During the last year three Indian elephants have died in the zoologic gardens of Australia, one in Melbourne, one in Queensland, and the last one in Adelaide. When I visited the museum

Fig. 1.—View on the grounds, Adelaide Children's Hospital.

of the university with Professor Watson the taxidermists were engaged in mounting the last victim. This elephant was of enormous size. He had been an inmate of the Adelaide zoologic garden for a long time, and was 30 years old. He was sick only a short time, and the postmortem, conducted by Professor Watson, revealed as the immediate cause of death an enormous abscess in the center of the liver, and in this abscess was found a gallstone that weighed 25 pounds. As the elephant has no gall bladder, this stone must have formed in one of the hepatic ducts. This rare and valuable specimen disappeared in a somewhat mysterious way before it could be taken to the museum, and it was ascertained later that it was purchased from the pilferous possessor by a Chinaman, who paid \$10 for it and considered it a great bargain, as he expected to realize a fortune from it by converting it into a cure-all medicine for his sick compatriots. The Melbourne elephant on postmortem was found to have died from the same disease, but the calculus was much larger, weighing more than 100 pounds. It is not definitely known, but it is surmised that the Queensland elephant met with a similar fate. It seems that all large animals from tropic regions, when brought into confinement, are subject to inflammatory affections of the bile ducts and subsequent gallstone formation. As elephants even in Australia command a price of \$2,000, what inducement there would have been to perform on these giant patients a life-saving hepatotomy!

POSTMORTEM ON A ZEBRA.

One evening, in visiting the zoologic garden in Adelaide in company with Professor Watson and the superintendent of the garden, a fine-looking, sleek, well nourished zebra came up close to the fence and seemed to enjoy my patting her forehead and well-rounded neck. The animal appeared to be in perfect health. It had been in the garden for twelve years and was old when it was brought there. The next morning I was informed by Professor Watson that the animal had died during the night. In the afternoon I attended the postmortem, which was made under the direction of Professor Watson. The abdomen was enormously distended, which seemed to indicate that the sudden death was due either to intestinal perforation or acute intestinal obstruction. On opening the abdomen the giant cecum, ascending and descending colon were found distended to their maximum limits. Large isolated sections of the liver were the seat of great dilatation of the bile ducts, many of them sacculated, and on slitting them open were seen to contain a thick, turbid mucus, the inflammatory accumulation of a chronic cholangitis. Numerous ascaris lumbricoides of prodigious size were found in the stomach, well filled with the remains of the last evening meal. The upper part of the lumen of the small intestines was almost entirely occluded by wriggling masses of the same parasite, and they were also numerous throughout the large intestine. The transverse colon was of normal size, cecum, ascending and descending colon impacted with dry fecal matter alive with worms. It is evident that the immediate cause of death was the result of mechanical obstruction, complicated, perhaps, by toxemia arising from the rapid decomposition of the impacted material. These parasites were undoubtedly likewise, at least indirectly, responsible for the chronic inflammation of the bile ducts, as this affection was not diffuse, but limited to circumscribed parts of the liver.

PRIVATE HOSPITALS IN AUSTRALIA.

As the general hospitals of Australia have made no provision for private patients, the surgeons are under the necessity to fill this gap by private hospitals in order to accommodate the patients who are able and willing to pay them for their services. All surgeons with a large private practice either own or patronize a private hospital. Many of these little hospitals are operated by trained nurses. Several nurses combine, rent a private residence in a desirable locality, convert it into a hospital and throw its doors wide open to medical men who wish to patronize them. I was informed that the nurses who risk their time and money in such enterprises usually make them a success financially. Surgeons with means, however, prefer, as a rule, to build, own and manage their own hospital.

TERRACE HOSPITAL.

One of the neatest and most attractive private hospitals I ever saw is the property of Professor MacCormick of Sydney. As its name implies, it is in a terraced tract of land, three acres in extent, which is bisected by a deep ravine, shaded by magnificent trees. The hospital, occupying the highest point of the romantic little park, is a two-story cottage brick building, with a grayish-white, rough coat of cement and a red tile roof. The finishing of the interior, the arrangement of rooms and wards, the heating, the ventilation, the operating room equipments and appliances are as complete as money and skill could make them. The building alone cost \$80,000. It can accommodate 40 beds. Ten graduate, salaried female nurses take care of the patients. The charge for board and nursing ranges between \$15 and \$35 a week. The large practice of Professor MacCormick fills the rooms and wards throughout the year, and the hospital is prospering financially. One of the redeeming features of these private undertakings is the fact that they do not undertake to educate female nurses for the purpose of cutting down the running expenses, as is done only too frequently by similar institutions in our country.

CLARETON HOSPITAL.

This is a new four-story brick building, erected and owned by Professor Bird of Melbourne. It is situated in one of the finest streets, almost opposite the House of Parliament, and faces a

picturesque park. The exterior of the building is pleasing in design and its interior is the last proof that the plans were well made to meet the requirements of a modern hospital. The cheery operating room is flooded with sunlight during the day and lighted by electric lamps at night, and the conveniences and appliances for asepsis are absolutely perfect. The upper part of the building contains the living rooms of the family, to which access is obtained by an elevator. The eight graduate nurses employed to take care of the 20 patients, the present capacity of the hospital, are well paid, and the two matrons receive \$500 each per year.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Drugs in Cardiac Affections.

Dr. S. Solis-Cohen, in the *Penn. Med. Jour.* for July, 1904, discusses some of the drugs which he has found useful in cardiac collapse. **Suprarenalin:** This drug may be given on the tongue or injected in any convenient solution under the skin. The effect is quick and likewise transient. Suprarenalin may be administered in doses of from 1/20 to 1/10 of a grain. **2. Camphor:** This drug may be injected hypodermically in a 10 per cent. solution in sterilized olive oil or in 10 per cent. solution of ether. The dose should be about 20 or 30 minims. The effect is prompt and lasts for some hours. **3. Musk:** Much of the musk sold in the shops is therapeutically inert. Real musk is expensive, but is therapeutically potent. The physician should provide himself with a small quantity of the good tincture in order to be prepared for emergencies. Five or ten drops of tincture of musk given hypodermically exerts a powerful influence in overcoming the tendency to cardiac collapse, and the action of musk is more sustained even than that of camphor. In cases in which a cardiac collapse is suspected to be impending, it is useful to administer five or ten drops of musk by the mouth two or three times a day, in anticipation, and often in successful prevention, of such an accident.

Acute Myocardial Insufficiency.

Forchheimer, in *Archives of Pediatrics*, discusses the occurrence of acute myocardial insufficiency in some infections in children and gives the following brief outline of his own method, used with good results in two cases: "Hypodermic injection of adrenalin: This drug has an elective effect on the blood vessels supplied by the splanchnic nerve. Its effects are very transitory; therefore, the injections have to be made every two hours. Saline transfusions are used in the beginning in order to keep up the heart's contractions. Ice bags are put on the abdomen, stimulating the splanchnic reflex. In one child, I was able to bring the pulse down from 140 to 60 by the use of these alone. After the most violent symptoms have passed over, then caffeine soda salicylate is given every two to four hours alternately with the adrenalin, which is gradually dropped." For uncomplicated myocardial insufficiency, the author recommends as the first principle of treatment absolute rest. "The digitalis group of drugs may be used; their efficacy depends largely on the amount of myocardium affected." (Jacobi, in discussing Forchheimer's paper, disagrees with him in regard to the use of digitalis. Jacobi dislikes to give it in the beginning of an acute myocarditis, believing that digitalis puts too much labor on the heart.) Stimulants will be required in most of the cases, alcohol, camphor, or ether, according to the severity of the case. The convalescence must be es-

pecially guarded, and for the purpose of strengthening the myocardium mechanical means are invaluable, such as Swedish movements, massage, vibratory methods. The diet is the same as in all myocardial affections. Laxatives that act violently should be avoided. Strychnia may be used for its general tonic effect; except in toxic doses, it has no effect on the heart nor vasomotors. Nitroglycerin or the nitrites should never be used unless there be anginous attacks. Jacobi, in further discussion, recommends the following treatment of myocarditis: "In chronic myocarditis I have found that strychnia makes the patient worse, and opium is better. In acute myocarditis, I rely on cold applications to the heart, the ice bag for a short time, not for a long time in young children. I also place much confidence in codein and in the iodids. I do not like the nitrites when the arteries are poorly filled. Absolute rest is enforced. In myocarditis with danger from overstrain, I should rather rely on some opiate, ioidid or nitrite. There is no better thing than rest in bed for some weeks and months. Place the patient in bed in a cool room, open the windows, and then absolute rest."

Irritability of the Bladder After Confinement.

Fothergill, in *Southern Med. and Surg.*, recommends the following formula:

R. Salol
Tr. hyoseyami, aa. ʒiii 8
Infus. buchu, q. s. ad. ʒvi 180

M. Sig.: Teaspoonful three times a day.

The following is also recommended for irritable bladder:

R. Tr. hyoseyami ʒi 30
Potass. citratis ʒss 15
Ext. buchu, fl. ʒss 15
Ext. tritici fl. ʒi 30
Aque dest., q. s. ad. ʒiv 120

M. Sig.: Teaspoonful in wineglass of water three times a day.

Diphtheria.

McMahon, in the *Canadian Practitioner and Review*, discusses the treatment of diphtheria in relation to the necessity of early diagnosis. He gives the following points in which the physician is usually remiss, and consequently effective treatment is delayed:

1. His attention is not specially directed to the throat, and he fails to look at it, and diagnoses something else. By the time he recognizes his error the case is hopeless. The golden rule is, "Always examine the throat of a sick child, no matter what the symptoms are." The physician who fails to diagnose diphtheria because he did not look at the throat ought to be prosecuted for malpractice.
2. He examines the throat and thinks he has a case of tonsillitis or coryza or croup to deal with, or that, even if it is diphtheria, it is so mild that the old-fashioned remedies are sufficient for its cure.
3. He fails to follow up a suspicious case, and finds too late that the patient is in a desperate condition.
4. He treats one among many children and fails to protect others exposed to contagion by a preventive injection.
5. He uses antitoxin, but is half-hearted and does not use enough.
6. In a case of laryngeal diphtheria he uses antitoxin—perhaps in large doses—but fails to make early resort to accessory remedies, such as calomel, fumigation and intubation.
7. He makes an early diagnosis, but puts off the injection of antitoxin until to-morrow or the day after.

The author's own conclusions are: 1. In every case in which there is a suspicion of diphtheria, give antitoxin at once and freely. 2. Get a report in every doubtful case, but do not wait for the report; inject at once. 3. If the bacteriologic examination shows the presence of diphtheria bacillus, give an injection to all children to prevent spread of the infection. (Other methods of preventing the spread of the infection must also be used.)

The objections to the use of prophylactic injection of antitoxin are, first, that it may be given in cases where it is not necessary; the answer to this is that there is no harm done.

Second objection, that of expense, is answered by the fact that it is actually cheaper to give a prophylactic dose of antitoxin than to care for a patient suffering from diphtheria.

ADMINISTRATION OF ANTITOXIN.

"One who recognizes the uncertainties and difficulties of diagnosis, and is prompt, bold and fearless in his treatment, will have a very low death rate, indeed."

"I believe that antitoxin is an absolutely certain specific remedy when given in sufficiently large doses early in the disease."

The author recommends for an ordinary case of pharyngeal diphtheria, without nasal or laryngeal involvement, a dose of 1,000 units, if given early. The very malignant cases, with laryngeal involvement, demand heroic treatment. The author quotes from a paper published by Louis Cairns in the *Lancet*, Dec. 20, 1902, on the intravenous injections of antitoxin: "There are a certain number of malignant cases which show no improvement after the subcutaneous injection of even large doses (20,000 to 30,000 units) of antitoxin." He suggests two causes for its failure:

1. A selective influence on the part of the glands in filtering out the active constituents of antitoxin.
2. There is definite chemical relation between toxin and antitoxin, and neutralization of the toxin goes on more quickly in contracted solutions than in diluted ones.

He recommends an initial dose of from 20,000 to 30,000 units injected in the median basilic vein, and the indications he gives for its employment in this way are:

1. Special malignancy of the disease.
2. Involvement of the lungs, especially if this complicates laryngeal involvement.
3. A moribund condition when first seen.
4. Marked toxic symptoms.

The author gives the following as the method pursued by him during the last ten years in the treatment of laryngeal diphtheria, with excellent results:

1. Inject antitoxin in full doses.
2. Fume calomel under a tent (30 grains an hour) until stenosis is relieved.
3. Intubate early, if symptoms demand it.

Medicolegal.

LEGISLATION OF THE YEAR IN MARYLAND.

Physicians to Be Appointed to Issue Burial Permits.—Chapter 384 of the Laws of Maryland of 1904 provides that the local boards of health and the county commissioners of the several counties where they exercise such powers shall appoint, in 1904, and on January 1 in each year thereafter, as sub-registers to issue burial permits, physicians residing in, attending on, or appointed to any college, academy, boarding school, hospital, retreat, asylum, sanitarium, or other like place in their respective counties. Such sub-registers shall be entitled to receive and to charge the sum of fifty cents for each permit so issued. They shall report to the local boards of health or to the county commissioners full lists of all information contained in such permits.

Against Use of Wood Alcohol in Flavoring Extracts.—Chapter 378 of the Laws of Maryland of 1904 provides, under penalty, that no person, firm or corporation engaged in making, compounding and selling extracts, essences or other fluids commonly used for flavoring articles of food or drink, shall use or permit to be used by employes in the manufacture of such extracts, etc., any methyl or wood alcohol; nor shall any person, etc., sell or offer for sale any such extract, etc., containing any methyl or wood alcohol.

Creates a Tuberculosis Commission.—Chapter 476 of the Laws of Maryland of 1904 provides for the appointment by the governor of five persons, three of whom shall be physicians, who shall constitute what is to be known as the Tuberculosis Commission, whose duty it shall be to investigate the pre-

valence, distribution and causes of human tuberculosis in Maryland, to determine its relation to the public health and welfare, and to devise means for restricting said disease, and to investigate and report on the proper construction, cost, equipment, maintenance and location of a sanatorium for the treatment of tuberculosis. They shall report the results of their investigations not later than January, 1906. All hospitals, dispensaries and other institutions having medical officers and supported in whole or in part by public funds of the state, or of any city or county in the state, shall cause to be made on blanks furnished by the tuberculosis commission records of such facts as may be available for the purposes of the commission concerning every case of tuberculosis coming under the care of such institution.

Anti-Tuberculosis Requirements.—Chapter 412 of the Laws of Maryland of 1904 provides that the state board of health shall keep a register of all persons in the state who are known to be afflicted with tuberculosis. The board shall have exclusive control of the register, and shall not permit inspection thereof nor disclose any of its personal particulars except to officials authorized under the laws of Maryland to receive such information. The superintendent or other person in charge or control of any hospital, dispensary, school, reformatory or other institution deriving the whole or any part of its support from the public funds of the state, or of any city, town or county thereof, having in charge or under care or custody any person or persons suffering with pulmonary or laryngeal tuberculosis, shall, within forty-eight hours after the recognition of such disease, make or cause to be made in the manner and form prescribed by the state board of health, record of the name, age, sex, color, occupation, social condition and residence of the person or persons so affected, together with such other information as may seem necessary or important. And all such records shall be delivered, under seal, to the state board of health, on Monday of the week immediately following that in which the records were made. Whenever any physician knows that any person under his professional care is afflicted with pulmonary or laryngeal tuberculosis, he shall transmit to the secretary of the state board of health, within seven days, and on blanks provided by the state board of health for that purpose, the name, age, sex, color, occupation, social condition and residence of such person. The apartment occupied by any consumptive shall be deemed infected, and when vacated by the death or removal of said consumptive shall be disinfected by the board of health of the city, town or county in which such apartments are situated. And it shall be the duty of the householder, physician or other person having knowledge of the facts, to notify the local board of health within forty-eight hours after the death or removal of a person affected with pulmonary or laryngeal tuberculosis. Any person who lets for hire or causes or permits any one to occupy apartments previously occupied by a consumptive, before such apartments shall have been disinfected by a board of health, shall be guilty of a misdemeanor.

To Protect from Communicable Diseases, Especially Tuberculosis.—Chapter 399 of the Laws of Maryland of 1904 provides that any person affected with any disease whose virus or infecting agent is contained in the sputum, saliva or other bodily secretion or excretion, who shall so dispose of his sputum, saliva, etc., as to cause offense or danger to any person occupying the same room, house or part of a house, shall, on complaint of said person or persons, be deemed guilty of a nuisance. And any persons subjected to such a nuisance may make complaint in person or writing to the local health officer of any city, town or county in Maryland where the nuisance exists. And it shall be the duty of the health officer receiving such complaint to investigate, and if it appears that the nuisance is such as to cause offense or danger, etc., he shall serve a notice on the person so complained of, reciting the alleged cause of offense, and requiring him to dispose of his sputum, excretion, etc., in such a manner as to remove all reasonable cause of offense or danger. And any person failing to comply with such orders shall be deemed guilty of a misdemeanor, and on conviction thereof shall be fined ten dollars;

provided, that the foregoing requirements shall apply only to pulmonary and laryngeal tuberculosis, pneumonia, influenza and such other diseases as the state board of health may from time to time determine to be communicable by means of sputum, saliva or other bodily secretion or excretion. It shall be the duty of the physician attending any case of pulmonary or laryngeal tuberculosis to provide for the safety of all individuals occupying the same house or apartment, and if no physician be attending such patient this duty shall devolve on the local health board, and all duties hereinafter made incumbent on the physician shall be performed by the local board of health in all cases of pulmonary or laryngeal tuberculosis not attended by a physician or when the physician is unwilling or unable to perform the duties specified. It shall be the duty of the local board of health to transmit to the physician reporting any case of pulmonary or laryngeal tuberculosis, a printed report, after the manner and form to be prepared and authorized by the state board of health, naming such procedures and precautions as in the opinion of the state board of health are necessary or desirable to be taken on the premises of the tuberculosis case. On receipt of the blank report the physician shall fill, sign and date the same and return it to the local board of health without delay: provided, that if the attending physician is unwilling or unable to undertake the procedures and precautions specified he shall so state on this report, and the duties herein prescribed shall then devolve on the local board of health. On receipt of this report the local board of health shall carefully examine the same, and if satisfied that the attending physician shall have taken all necessary and desirable precautions to insure the safety of all persons living in the house or apartments occupied by the consumptive, and to insure the safety of the people of the state of Maryland, the board shall issue an order on the state board of health in favor of the attending physician for \$1.50. If the precautions taken by the attending physician are, in the opinion of the board, not such as will remove all reasonable danger, etc., the board shall return to the attending physician the report blank with a letter specifying the additional precautions which they shall require him to take; and the physician shall immediately take the additional precautions specified and shall record and return the same on the original report blank to the board. It shall further be the duty of the local board of health to transmit to the physician reporting any case of pulmonary or laryngeal tuberculosis a printed requisition. On this requisition blank shall be named the materials kept on hand by the board for the prevention of the spread of the disease, and it shall be the duty of the state board of health to purchase such supplies as it may deem necessary, and to supply them to any local board of health on due requisition of the latter. Any physician may return a duly signed requisition to the local board of health for such of the specified materials and in such amount as he may deem necessary in preventing the spread of the disease, and all local boards of health shall honor, as far as possible, a requisition signed by the attending physician in such case. It shall be the duty of every local board of health to transmit to every physician reporting any case of pulmonary or laryngeal tuberculosis, or to the person reported as suffering from this disease, provided the latter has no attending physician, a circular of information prepared and printed by the state board of health, which shall inform the consumptive of the best methods of cure of his disease and of the precautions necessary to avoid transmitting the disease to others. Any physician or person practicing as a physician who shall fail to execute the duties prescribed by this act, or who shall knowingly report as affected with pulmonary or laryngeal tuberculosis any person who is not so affected, or who shall willfully make any false statement concerning the name, age, color, sex, address or occupation of any person reported as affected with pulmonary or laryngeal tuberculosis, or who shall certify falsely as to any of the precautions taken to prevent the spread of infection, shall be deemed guilty of fraud, and on conviction thereof shall be subject to a fine of \$100, or to imprisonment not exceeding six months, or both fine and imprisonment, in the discretion of the court.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

- 1 Relations of Laryngology, Rhinology and Otolaryngology with Other Arts and Sciences. Felix Semon.
- 2 *The Iodin Treatment of Suppuration. Winfield S. Pugh, Jr.
- 3 *The Molecular Concentration of the Blood and of the Urine, in Pregnancy, in the Puerperium and in Eclampsia. Ralph Waldo Lobenstein.
- 4 Research and Medicine. Robert G. Moody.

2. **Iodin in Suppuration.**—Pugh has made use of the iodine treatment advocated by Beek in scalp wounds, ulcers of the leg, inguinal adenitis, vaginitis, particularly the variety due to the gonococcus, and in the early stages of purpural sepsis, with excellent results. In the treatment of surgical tuberculosis, such as old tuberculous sinuses following tuberculous glands of the neck, and tuberculous joint affections, he finds iodine one of the very few remedies of value. Applied to venereal sores, such as chancre and chaneroid, it is useful. Particularly does it check the seriginous sores, and its use may be recommended for pus in the prineum following urinary extravasation. He strongly advises its trial in all cases of suppuration.

3. **Molecular Concentration of the Blood.**—Recourse to cryoscopy is taken by Lobenstein in order to ascertain whether or not the kidneys are primarily responsible for eclampsia. He finds that there is a marked diminution in the molecular concentration of the blood in pregnancy, the average Δ being $-.51$. There is likewise a diminution in the concentration of the blood in the puerperium, the average Δ being $-.53$, but a rise over that of pregnancy. In eclampsia the molecular concentration of the blood is not increased, the average Δ being $-.55$, the Δ of normal blood being $-.55$ to $-.57$. The urine shows no marked change in its freezing point, either in pregnancy, the puerperium, or in eclampsia. From his cryoscopic findings Lobenstein concludes that there is no evidence of renal inactivity nor of renal retention in eclampsia; that is, retention of the urinary products ordinarily supposed to be the cause of the disease, the products in question being crystalloid in shape. If there is renal retention it must be retention of either colloidal substances, which may come from either fetus or mother, or of crystalline substances too small in amount to affect the molecular concentration of the blood. Clinical facts and experimental research apparently show that eclampsia is an intoxication in which both mother and fetus have a share, the pathologic findings in both being due to the formation of multiple thrombi with subsequent necroses. What these substances are that give rise to the intoxication, and what part the symynton plays in their formation, Lobenstein is not prepared to say.

5. This article has appeared elsewhere. See THE JOURNAL, xlii, title 108, p. 699.

7. **Dilatation of the Esophagus.**—The authors report two cases of cardiospasm with diffuse dilatation of the esophagus in both of which pathologic conditions existed in the abdomen which might have been the cause of the reflex irritation. One patient had a floating kidney, and in the other the cessation of the menstrual function occurred simultaneously with the onset of the dysphagia. In making a diagnosis in such cases as these the authors state that the history of the patient is of paramount importance. The condition usually occurs in neu-

rotics from 20 to 40 years of age. The onset of the dysphasia is sudden and accompanied by a sensation of burning and stoppage posterior to the sternum. As the disease progresses the difficulty increases. At times no food can be swallowed; at other times certain articles of food pass into the stomach without any voluntary exertion. The symptoms may disappear entirely. Pain is a variable symptom and is dependent on the degree of secondary esophagitis. Regurgitation of food immediately or very shortly after eating is characteristic. In advanced cases with marked dilatation food may be retained for many hours without causing discomfort. Any food remaining in the esophagus will be regurgitated whenever the patient assumes the horizontal position, especially during sleep. The absence of true vomiting and the inability to raise flatus have been noted as symptoms of cardiospasm. The majority of patients are able to swallow food with exertion or by employing definite mechanical assistance. With a few, all that is necessary is to go through some gymnastic effort. A clinical examination establishes the diagnosis. The treatment of the condition depends on the character of the case. Lavage, systematic tubal feeding, rectal feeding, over-stretching of the cardia and gastro-tomy are some of the methods of treatment that suggest themselves. The rational treatment is repeated over-stretching of the cardia in order to destroy its tonicity. The prognosis as to complete restoration is bad, but the condition is not necessarily hopeless.

10. Bunions and Hallux Valgus.—When the painful symptoms of either of these conditions are present to such an extent as to occasion nearly continuous suffering, and to constitute a constant impediment to locomotion, Keller says that the demand for operative interference is imperative. He makes use of an operation which eliminates all interference with the tripod of the foot or its normal level. It is described as follows:

A longitudinal incision two inches in length is made along the inner side of the foot, exposing the first metatarsophalangeal articulation. The skin and tissues over the head of the metatarsal bone are retracted; the joint is then opened and opposing articular ends are separated; the articular covering over the lateral enlargement and adjoining part of bone are pushed back; and the osteosty with about one-eighth of an inch of the bone is removed by a rongeur forceps or, preferably, with a small saw. The tendon of the flexor longus hallucis is freed by blunt dissection from the under surface of the base of the first phalanx, sufficiently to pass a Gigli saw around the bone; the periosteum is pushed back, disarticulation accomplished, and the articular head of the first phalanx is removed. Particular care should be taken throughout the operation to protect the periosteum from needless destruction, and an effort should be made to preserve enough of it to cover the exposed surface of the bone. A small gauze drain is inserted between the head of the metatarsal bone and the sawed end of the phalanx (this drain is removed after forty-eight hours). The wound is carefully sutured; the toe being maintained at normal extension by a narrow internal lateral splint. Passive motion is begun on the fifth day.

- 14 Why Individuals and Similar Corporations Lose Their Damages Suits. John Punton.
- 15 *Acute Tetanus Cured by Intraneural Injections of Antitoxin. W. Scott Schley.

11. Prolapse of the Ovary.—The operation proposed by Barrows may be briefly described as follows: The abdomen is opened under the usual aseptic precautions, the patient being then preferably placed in the Trendelenburg position. An incision two inches in length ordinarily is sufficient. The intestines are held back from the field of operation by three aseptic bolsters, one being placed in the median line and one in each lateral fossa. The author finds these bolsters superior to gauze pads or rolls of gauze. All adhesions about the tubes and ovaries are broken up and any cysts that may exist in the ovaries are punctured, the wall being removed if the cysts have a definite cyst wall. If necessary, considerable portions of the ovary which have been destroyed by chronic cystic degeneration may be removed, the incision in the ovary being closed by interrupted sutures of fine catgut or silk. The round ligaments are then caught up and shortened, after the manner suggested by Wiley, two fine silk sutures being sufficient to

accomplish this result. If the uterus is markedly anteverted and the round ligaments not relaxed, this part of the procedure may be omitted. The infundibulopelvic ligament is caught up by forceps and a reef of one or two inches taken in it and secured by two or three sutures of fine silk. In the double peritoneal fold which stretches between the round ligament and the top of the broad ligament a small linear incision is made, half an inch long and the ovary, which lies beneath it, is brought through the opening and permitted to lie on the shelf thus provided for it. This procedure does not interfere with the relations of the fallopian tube to the ovary or of the blood supply to and from the ovary. In order to secure the ovary in its new situation, a suture is taken at either extremity of the gland, thus limiting the incision and securing the organ permanently in its new position. This procedure permits the ovary to rest comfortably on this top shelf of the pelvis, secure from any possible impact of the uterus, one of the causes of the intense suffering in prolapse of the ovary, and does not interfere with its functional activity. In the hands of the author the operation has proved an exceedingly satisfactory one, as is shown in the twelve cases cited.

12. The Rheumatic Process. Schreiber urges that the term muscular rheumatism should be dropped and the unqualified term "rheumatism" substituted for it. Rheumatism should be understood as meaning all the affections produced by rapid changes of temperature in the structures attached to the limbs, the periosteum, and in fibrous membranes. Those disposed to rheumatism do not need to dread uniform cold, even if intense, but rather warmth, especially that caused by muscular effort, suddenly followed by rest and cooling off. The most rapid and reliable remedy for recently acquired rheumatism is muscular exercise. Schreiber insists that the patient should boldly perform the movements that cause pain. Of course, articular rheumatism should be carefully excluded. Chronic rheumatism can be cured only by mechanico-therapeutics, in which active and passive movements play the chief rôle. He urges that the clergy, school teachers and foresters should add this simple doctrine concerning muscular rheumatism to their stock of hygienic lore in order that they may be able to instruct the people in regions without physicians and so preserve many from serious illness.

13. Specific Treatment of Typhoid Fever.—Hackett has evolved a treatment which he ventures to call specific. It consists of the administration of mercury in the form of blue mass and calomel. One or two grains of blue mass are given every three hours until the constitutional symptoms of mercurial saturation, such as soreness of the gums, are noted. An initial dose of 5 or 10 grains of calomel is also given, followed in a couple of hours by a seidlitz powder or 2 drams of Rochelle salts, unless hemorrhage or grave diarrhea are present. If constipation is the rule during the progress of the disease, 5 grains of calomel may be given once every day. Whether the bowels are constipated or loose, an alkaline cathartic is to be given every morning during the course of the fever, unless hemorrhage or some other complication contradicts its use. Opium should be given in one form or another, in sufficient amount to ensure good rest both day and night. In regard to the diet, Hackett prescribes milk and water in equal parts, a tumblerful every two hours, given ice cold. If this can not be borne by the stomach some light farinaceous gruel or peptonized milk may be substituted. He urges his patients to drink water as freely as possible during the course of the disease. Watermelons are allowed because he believes that they fill a long felt want in the diet treatment of typhoid. The treatment by mercury obviates the necessity of the cold bath.

15. Antitoxin in Tetanus.—Schley cites a case in evidence of the superior efficacy of the intraneural and intraspinal injection of antitoxin in the treatment of tetanus. He exposed the anterior crural and sciatic nerves for a distance of one and one-half inches and raised them on a flat probe. Injections were made with a fine hypodermic needle well up and down the nerve trunk, the needle being inserted several times in order to slightly wound the nerve filaments; 3 c.c. of antitoxin being

injected into each trunk. In order to facilitate reinjection of the nerves and to allow as much absorption of antitoxin as possible, the wounds were left open and lightly packed with sterile gauze strips saturated with antitoxin. Rubber tissue prevented absorption of the serum into the dressing. A lumbar puncture was made between the second and third lumbar vertebrae and after allowing a small amount of fluid to escape, 3 c.c. of antitoxin were injected. At the same time an attempt was made to scratch the nerves of the cauda equina. Ten c.c. of serum were injected subcutaneously. The patient received nearly 180 c.c. of antitoxin and was discharged cured on the twentieth day after admission to the hospital. Schley also noted that the effect of the chloroform given for the injections and for the relief of the more severe spasms seemed decidedly beneficial, and absence of spasm would be noted for some time after it had been given.

16. Early Signs of Tuberculosis.—Brown emphasizes the fact that absence of physical signs in the chest is no better proof that a patient has not pulmonary tuberculosis than absence of tubercle bacilli in the sputum. Auscultation is by far the most important method of physical exploration in incipient pulmonary tuberculosis. Inspection, including mensuration, and percussion, are of nearly equal importance. Palpation is of less value. Auscultation should be practiced, however, before the patient is made to breathe deeply, as otherwise fine crepitation may be overlooked. In many incipient cases little or no deformity of the chest exists. In most of these the chest is well developed, though possibly a trifle long, with a slight prominence of the clavicle on the affected side. Careful inspection showed a restriction of movement in 10 out of 18 cases; percussion of the bases revealed it in 13; radioscapy in 13. The vocal fremitus was normal in two-thirds of the cases examined (201), and was three times more apt to be increased on the affected than on the unaffected side. Some degree of dullness may occur without change in the auscultatory signs. Kroenig's method of percussion is of value in the examination of incipient cases. Radioscapy has a distinct advantage in determining the movement of the base of the lung in deep-seated lesions; percussion, possibly, in "pleuritic" cases. In 28 of the 201 cases percussion was negative, while auscultation revealed some pathologic sign. Prolonged expiration was present in 32 per cent.; wavy breathing at the site of the lesion in 11 per cent.; weakened breathing in 10 per cent.; puerile breathing in 12 per cent.; harsh breathing, with loss of vesicular murmur, in 8 per cent. Some deficiency in the vesicular murmur was present in 41 per cent. The vocal resonance was normal in 62 per cent.; increased at the site of the lesion in 38 per cent. Rales occurred in 70 per cent. in the following order of frequency: Fine, medium moist, rhonchi, mixed. Pleuritic friction occurred in 1 per cent. Tubercle bacilli were found in the sputum in 35 per cent. Fifty-eight per cent. of the cases did not apply for admission into the sanitarium within the first six months of illness. In the 201 cases the site of the primary lesion was most frequently above the clavicle, then in the suprascapular area and subclavicular fossa. Sixty-one per cent. occurred on the right side.
18. Mechanism of Exophthalmos.—MacCallum and Cornell conclude that obstruction to the outflow of blood from the veins of the orbit produces at once exophthalmos, which is relieved by the establishment of a collateral circulation. This process, however, is completed so slowly that in the meantime the orbital tissues as well as the tissue of the face become very edematous, thus adding to the exophthalmos. Entirely inde-

pendent of any circulatory changes is the exophthalmos produced directly by the stimulation of the cervical sympathetic nerve. This protrusion is due to the peristaltic contraction of the orbital muscle.

19. Erythromelalgia.—Voorhees' case is of interest because of the acute onset, the severe pain, the gradual progress and the long periods of intermission. The treatment was a total failure. Even morphin failed to control the pain. Local applications of antiplogistin were intolerable, causing much additional pain. Iodid of potassium afforded temporary relief. Fluid extract of ergot, in 30 minim doses, three times a day, gradually increased to a dram dose, lessened the pain within ten days, and the patient began to improve steadily. Six months after the beginning of treatment the patient had an apoplectic seizure, from which she died within twenty-two hours.

21. Silver Salts in Gonorrhoea.—Baum details the results of experiments carried on by him with a view to establishing the therapeutic worth of silver preparations. The cases selected for treatment were all first attacks. All the patients were instructed to first urinate, then to fill up the urethra with the injection so as to produce tension and to hold in the injected fluid for from three to five minutes; the injection to be repeated five times a day. The following solutions were employed for these experiments: Allbargin, gelatose silver, 1 to 1 per cent solution; argyrol, 2 to 10 per cent; argonin, casein of silver, 2 to 5 per cent.; argentamin, 1 to 3 per cent. solution; kargin, silver protalbin, $\frac{1}{4}$ to $\frac{1}{2}$ per cent.; protargol, protid of silver, $\frac{1}{4}$ to 5 per cent. Picrotol, $\frac{1}{4}$ to $1\frac{1}{2}$ per cent.; water; saline solution; permanganate solution, 1 to 4,000 to 1 to 500; boric acid solution, 1 per cent. In all the cases the discharge decreased quite rapidly. The cases in which the silver salts were employed suffered less in subjective symptoms and made the best recoveries. Those treated with argyrol were probably the most satisfactory. Baum believes that the organic silver salts owe their beneficial effects to the bactericidal effect produced on gonococci imbedded in the upper epithelial layer, which is being exfoliated, and in preventing reinfection, rather than to their penetrating power, which is very slight. The prolonged pressure of any fluid on the urethral mucosa causes temporary compression of the capillaries; the removal of this pressure is followed by dilatation of these capillaries, resulting in an increased leucocytosis through the walls of the vessels. The point of least resistance is the lumen of the urethra. This induces more rapid exfoliation of mucous membrane cells and literally carries out the infectious agent.

22. Adenectomy During Pneumonia.—Jarecki reports a case on which an adenoid operation was performed with marked benefit to the patient. So far as he knows this is the first case of the kind reported.

- 27 *Examination of Pleural Fluids with Reference to Their Etiology and Diagnostic Value. (Concluded.) Percy Musgrave.
26. Gastric Ulcer in Children.—Speaking of the treatment, Cutler advises that the patient should be kept quiet in bed for at least three weeks, and perhaps longer, according to the symptoms. When there is tenderness hot fomentations or poultices are advised during its continuance. Infants at the breast may be nursed a short time every hour if the milk agrees, but only a small amount of milk should be allowed at each nursing. With bottle-fed children, cow's milk, modified according to modern methods and diluted with barley or Vichy water, may be allowed with proper precautions; it may have to be peptonized. With older children, milk must be the chief article of diet, but soups, broths, meat extracts, raw or cooked meat juice, meat jellies, and white of egg may be alternated with it. As improvement advances the diet may be cautiously increased. Nutrient enemata may have to be given at times. For pain,

opium in some form is the safest and should be given by mouth in doses sufficient to meet the indication. Bismuth is advisable as in the adult. Small or single hemorrhages take care of themselves; when profuse or repeated, surgical consultation is obligatory, meanwhile suprarenal gland extract or saline infusions may be tried. A bland form of iron should be begun as soon as permissible, and later arsenic or cod liver oil should be added. The diet must be regulated for several months after apparent cure.

27. **Examination of Pleural Fluids.**—Musgrave concludes that routine and systematic examination of pleural fluids will aid greatly in diagnosis and in determining the etiology of pleurisy. Cytodiagnosis is the only method which can be employed easily; animal inoculation, inocopy and culture methods can only be used in the laboratory. Although cytodiagnosis is not absolutely accurate in every case, it is sufficiently accurate, especially when taken in conjunction with the history and bedside examination, and the physical and chemical properties of the fluid itself, to justify its use as a routine procedure. Routine examination of pleural fluids will also establish a basis on which accurate prognostic statistics can subsequently be based.

33. **Studies in Asepsis.**—Harrington has made what appear to be very thorough studies of the question of asepsis as carried out in the operating clinic. He calls attention to the fact that in some instances, as in the sterilization of ligatures and gauze, the methods employed, such as fractional sterilization, are unnecessary. On the other hand, no precautions are taken against the entering into the wound of salivary spray emitted by the surgeon while talking to the onlookers. For the sterilization of the hands, Harrington finds that a mixture consisting of commercial alcohol (94 per cent.), 640 c.c.; hydrochloric acid, 60 c.c.; corrosive sublimate, .8 gram, and water, 300 c.c., will sterilize the unwashed hands in two minutes. He has repeatedly soaked his hands, without any preliminary scrubbing, for two minutes, and then had plantings made from the material removed from about each nail and from scrapings from the skin of each finger and from the palm. Occasionally a growth followed, but, as a rule, every tube of bouillon remained clean and sterile. A young man, whose duties included the daily cleaning of cages in the animal room and whose hands were not the subject of much thought or care, soaked his hands after ordinary washing, on ten different occasions for from two to five minutes; and each time each nail and finger was tested. In 7 of the experiments there was entire absence of growths; in one, a growth was obtained from one fore finger, in one from one middle finger, and in one from one thumb. That is, of 100 plantings only 3 showed growths. The mixture causes no irritation beyond the same degree of biting that one notices on contact with peroxid of hydrogen.

34. **Adenoma of Sebaceous Glands.**—A case of this kind is reported by Clarke, who also presents a very complete résumé of the literature of the true adenomata of sebaceous glands, showing that these tumors, without associated lesions of the skin, do exist, and that they undergo fatty metamorphosis with formation of cysts. Tumors of this kind, however, are rare, especially the larger ones. On the other hand, a hyperplastic condition of the gland, secondary to or associated with hypertrophy of the skin, is not uncommon. True adenomata of the sebaceous glands may become calcified or carcinomatous. The stroma of the tumor may undergo hyalin degeneration. Giant cells may occur in them. The epithelial cells may undergo mucous degeneration and form cysts similar to those derived from the cell undergoing fat metamorphosis. In the case reported, occurring in a young girl, aged 11, dermoid cyst and simple inclusion cyst, or a cyst derived from a supereruptory mammary gland, or from a sweat gland, were positively excluded. Apparently, the growth was a true adenoma starting from the infundibula of the sebaceous glands and retaining the type of the secreting portion. It had all the characteristics of a steatadenoma or an adenoma of the sebaceous gland.

35.—See abstract in THE JOURNAL, xlij, p. 130.

36. **Post-Operative Intestinal Obstruction.**—Peck is of the opinion that postoperative intestinal obstruction is a condition, the frequency of which is hardly appreciated, and the gravity of which can not be over-estimated. He says, further, that the possibility of postoperative obstruction should be borne in mind in all abdominal operations, especially in conditions likely to result in extensive adhesions, such as appendicitis with peritonitis, and pyosalpingitis with pelvic peritonitis. All raw surfaces should be covered as much as possible with normal peritoneum, or, where this is not practicable, perhaps, with Cargile membrane, or carefully arranged omentum. Small incisions and the least possible manipulation and evisceration should be the rule. The cleansing of the peritoneum should be done rapidly and with the least possible trauma and handling of normal peritoneum. Flushing with hot saline solution is advisable where there is much foreign material to be removed. The smallest possible drains should be used, if any. Cigarette drains are preferable to gauze, as they are less irritating to the surrounding peritoneum; cases of pyosalpingitis or pelvic peritonitis rarely require drainage, and, when necessary, drainage through the cul-de-sac can usually be employed. Diet should be regulated and the bowels should be watched with the greatest care during the first few weeks of convalescence: the attacks of gaseous indigestion with colicky pain should be regarded with suspicion and treated promptly and vigorously. Determined efforts should be made to relieve early attacks of obstruction by enemata, position, gastric lavage, etc., and if successful, the patient should be kept on a scanty fluid diet for some time and watched most carefully for a possible recurrence of symptoms. If palliative measures are unsuccessful after a few hours' trial, operation should be promptly resorted to. In cases occurring later than four to six weeks, palliative measures are less likely to be effective and early operation is usually imperative. All patients who have been operated on for intra-abdominal inflammatory troubles, Peck warns of the possibility of the occurrence of obstruction, at the same time impressing them with the importance of avoiding indiscretions in diet and attacks of indigestion, and of seeking advice promptly if such attacks should occur. The operative procedure must be adapted to each individual case; the Wright-Kammerer incision for cases following appendicitis with complete healing is often useful; the median incision, as a rule, for other conditions. Resection and end-to-end anastomosis should be preferred to enterotomy in the majority of cases where gangrene or sloughing of the gut wall demands one or the other.

40. **Open Operation in Ununited Fractures of Femur.**—The value of the open operation for the union of the fracture fragments of the femoral neck is attested to by Freeman, who adds one case to the 13 hitherto published. The choice of cases for operation, he says, is of great importance. Advanced age is a contraindication, although, if the patient is not too

old and his general condition is exceptionally good, operative intervention might deserve serious consideration. The greatest field for the open operation lies among the young and middle-aged, where it is not only permissible, but strongly indicated. Chronic and acute derangements of various organs, particularly the kidneys and lungs, must be given due weight before recommending operation. A moderate limp, without pain or undue loss of function would hardly be sufficient ground for operation, especially as some degree of shortening would be almost sure to remain; if disability and suffering are pronounced, however, operation would be strongly indicated in favorable cases. Access to the joint is adequate; no muscles or other structures of importance need be divided or endangered. To affect this, the anterior incision, as devised by Jacobson, is the preferable one. The cut begins a short distance below and external to the anterior superior spinous process of the ileum and extends directly downward for three or four inches according to the thickness of the soft parts. It should lie just outside the sartorius muscle, which can be retracted inward while the fascia lata is drawn outward. Should the surgeon, during the course of the operation, conclude to remove the head of the bone instead of reuniting the fragments, he can do so through this incision quite as readily as through any other. All interposed connective tissue is removed with scissors, and the surfaces of the fragments are chipped away with a chisel or scraped off with a curette, care being taken to remove as little bone as possible in order to avoid shortening of the neck and, as a consequence, shortening of the entire limb, which is apt to be considerable in spite of all precautions. Troublesome oozing is checked by the use of pressure sponges wrung out of very hot water. Detached splinters of bone should be removed. The fragments are coaptated and made immobile by means of nails, screws, or bone or ivory pegs, the screws being preferable. They should remain, if possible, for several weeks until consolidation is well advanced, unless infection occurs, when they should be taken out at once. Temporary drainage of the wound is indicated. On the whole, the results have been encouraging. There always remains, however, some shortening arising from the absorption of bone, from loss by freshening the fragments and from imperfect adjustment; but is usually not great enough to become a large factor in the final result.

41. **Fracture of Patella.**—Hutchison records his experience in the treatment of fracture of the patella in 7 cases. One of these was treated by the non-operative plan by strapping, application of the posterior splint, elevation of the leg and massage; the other 6 were treated by the direct open method with wiring of the fragments. Of the 6 cases operated on all walk without lameness and are able to go up and down stairs without any noticeable difficulty. The one case that showed lameness, namely, that not operated on, was unable to step down from a chair, although the result of the treatment was what is commonly called a good one.

42. **The Hemolytic Action of Human Blood Serum.**—The contributions of various observers in this line of study are reviewed by Polk, and attention is directed to the lack of uniformity in the methods employed and in the results obtained. Polk obtained the serum in all cases by the same means and at about the same time of the day, and it was of like age when added to the test fluid. From 8 to 15 pathologic sera were ex-

amined at one time, and a control from a normal individual was always made whose serum in quantities of 50 millimeters had been shown to give a degree of hemolysis never varying below 5 or above 7.5 for a year. One solution of an .85 per cent. sodium chloride solution was used throughout all the experiments. Two rabbits were selected of the same weight and color, whose erythrocytes and hemoglobin were equal and whose blood, in 5 per cent. suspension in .85 per cent. sodium chloride solution, yielded hemoglobin to a degree equal to 5 on the scale when 50 millimeters of serum from the normal human control were added to 1 cm. of the suspension. Each time the rabbits were bled not more than 2 cm. of blood were removed and defibrinated. On each occasion the red cells and hemoglobin were determined, and a normal human serum control was made and found to correspond in all respects at each bleeding, save on the occasion of infection occurring in one rabbit. The serum was added to the test suspension between 2:30 and 3 o'clock, placed in an oven at 3, removed at 5 o'clock and placed on ice. The observations were made about 10 o'clock the following morning. In all cases 50 mm. of serum were added to 1 cm. of cell suspension; a complete solution of all the cells equaled 30. The most definite results of Polk's study are the low hemolytic action of the serum in severe anemia, the increase of the property in most infectious diseases and the striking increase in diabetes. In diabetes the hemolysis appeared to vary with the glycosuria, but with the other diseases there seemed to be little definite relation between hemolytic activity of the serum and the other features of the cases. Polk expresses the belief that the determination of the hemolytic property of the blood serum may find a considerable field of application in routine clinical work, and may be found to throw some new light on the nature of many morbid processes.

43. **Human and Bovine Tuberculin.**—Wolbach and Ernst have repeated the original experiments of Koch with tuberculin on tuberculous guinea-pigs, using for this purpose freshly isolated cultures and freshly prepared tuberculin of their own make. At the same time tests for differences in the specificity were made with tuberculins from both human and bovine tubercle bacilli. The cultures used by the authors were obtained directly from man and cattle, the human culture on human blood serum, the bovine culture on bovine blood serum. The human culture came from a tuberculous testis, the bovine culture from an isolated nodule in the lung of a cow with general tuberculosis. The virulence of the cultures was determined according to the method of Theobald Smith, and the strength of the tuberculin was determined according to the method of Doentz. Some of the guinea-pigs were inoculated with bovine culture and some with the human culture. One set of animals was treated with one tuberculin, while another similar set was being treated with the other tuberculin. The conclusions arrived at are: 1. That there is no difference in specificity between tuberculin made from human and bovine tubercle bacilli. 2. That the tuberculin treatment, on the whole, acts favorably on tuberculous guinea-pigs. 3. That there are no essential differences in the disease processes caused by the human and bovine tubercle bacilli.

47. **Etiology of Variola.**—The work of Councilman and his co-workers is confirmed by Howard and Perkins, who studied the material derived from 49 autopsies on cases of variola and from skin excised from 8 cases in various stages of the disease. They also confirm all of the cycle as made out by Calkins, except the invasion of nuclei by gemmules, there going through a stage leading to the formation of male gametocytes. They recognize a primary and a secondary cytoplasmic and a primary and a secondary intranuclear stage. The end forms of these stages are: (a) the gemmule; (b) large solid nucleated forms—the zygote—like body of Calkins; (c) small ring-like spores in both the intranuclear stages. The paper closes with the statement that: "The relation of these parasites to the skin lesions is of such a definite and intimate character as to lead to the conclusion that they are the cause of the disease."

74. Treatment of Complete Descent of the Uterus.—All operations based on the principles of the one devised by Stoltz for the treatment of this condition are condemned as unfit by Dudley. He says that an efficient operation on the vaginal walls should have for its object the restoration of the normal direction of the vagina so that the upper extremity, together with the cervix uteri, shall be in its normal location within an inch of the second and third sacral vertebrae, just where the uterosacral ligaments would hold it if their normal tonicity and integrity could be restored, and so that the lower extremity of the vagina shall be brought forward against the pubes. This will restore the normal obliquity of the vagina and will hold the cervix uteri so far back toward the sacrum that the corpus must be directed forward in its normal anterior position of mobile equilibrium. With these conditions, the uterus being at an acute angle with the vagina, and having little space posteriorly, can not retrovert and turn the necessary corner which would permit it to prolapse in the direction of the vaginal outlet. Operations designed to decrease the weight of the uterus are of questionable value. Alexander's operation and abdominal hysterorrhaphy belong to the surgical treatment of retroversion and retroflexion. Hysterorrhaphy may be indicated in cases of extreme relaxation of the uterine supports and greatly increased weight of the uterus, but the results will not be permanent in complete descent of the uterus unless it is supplemented by adequate surgery to the vagina. In order to accomplish the things mentioned by him, Dudley advises excision of the cystocele, together with perineorrhaphy and posterior colporrhaphy. Complete prolapse, being hernia, should be treated according to the established principles of herniotomy by reducing it and then excising the sac in such a way as to expose strong fascial edges which should be firmly united by sutures. The operation he urges is performed as follows: Split the vaginal plate of the vesico-vaginal septum by means of scissors from the cervix to the neck of the bladder; strip off the vaginal from the vesical layer and cut away the redundant part of the vaginal plate. Extend the incisions and remove the mucous and submucous structures to either side of the uterus, being sure to reach the fascial structures which are in direct connection with the lower margins of the broad ligaments, or, what is better, to reach the ligaments themselves. Introduce silkworm-gut or chronic catgut sutures so that when tied they will draw the loose vaginal tissues and the broad ligament structures on either side of the cervix in front of it so as to force the cervix back into the hollow of the sacrum. Additional interrupted sutures are introduced to unite the vaginal wound from side to side. This suturing is continued to a point near the urethra, when most of the redundant vaginal wall will have been taken up. The lower portion of the cystocele and, perhaps, some urethrocele can be taken up by uniting the remaining part of the wound in a transverse direction. Elytrorrhaphy is usually unnecessary and therefore contraindicated in descent of the first degree. The special province of the operation is in complete prolapse or procidentia when associated with cystocele. The operation further is contraindicated by tumors and adhesions which render replacement and retention impossible, and in disease of the uterus or its appendages which demand their removal. When such contraindications do not exist elytrorrhaphy and perineorrhaphy in a majority of cases are quite as effective, and therefore to be preferred to the more dangerous and mutilating operations of hysterectomy.

52. Gastric Ulcer.—Stewart advises that all cases of suspected gastric ulcer should first be submitted to thorough medical treatment along the lines of rest and suitable diet with the object of having the hemoglobin approximate the normal. Should the ulceration prove intractable or relapses occur, gastroenterostomy should be performed to secure the physiologic rest necessary to the repair of the ulcer. Repeated small hemorrhages, pyloric contraction with great dilatation of the stomach and serious impairment of health, with persistent anemia, call for surgical intervention. Perforation demands immediate operation.

64. Chronic Non-Suppurative Otitis Media.—The differential diagnosis of the chronic form of non-suppurative otitis media will be comparatively easy in most cases, says Ballenger, if we bear in mind that there should be but three clinical subdivisions of middle ear diseases; the moist or secreting type, the adhesive or sclerotic, and the spongy or rarefying osteitis of the bony capsule of the labyrinth. The latter is essentially a disease of the sound conduction apparatus and should, therefore, for purposes of clinical study, be classified with the middle ear diseases. In uncomplicated cases there are no objective signs of middle ear disease. The drumhead is normal in appearance and the eustachian tube is open. The functional tests of hearing give in a general way the same results as are obtained in other diseases of the conduction apparatus. When, therefore, the objective signs of middle ear and eustachian disease are absent, and the functional examination with the forks and whistles show the conduction apparatus to be affected, it is a fair presumption that the case is one of spongy or rarefying osteitis. When there is no apparent middle ear disease and the functional tests of hearing lead to the opposite conclusion, the case is one of spongy. The moist or secreting type of otitis media may readily be diagnosed by the presence of the serous or sero-mucous fluid as seen through the lusterless drumhead, or as shown by auscultation and paracentesis. Adhesive otitis media may be diagnosed by the presence of the fibrous bands seen through the thin, lusterless ground-glass drumhead, together with the calcareous deposits, irregular retraction of the drumhead and the slight or transient improvement of hearing after inflation.

6. Disseminated Croupous Pneumonia.—West calls attention to the fact that acute pneumococcal inflammation in children often occurs in a disseminated form. He finds, too, that many cases of bronchopneumonia in children occur without an antecedent bronchitis, beginning and ending just like the acute pneumonia of the adult. However, during life the physical signs show, and in fatal cases the postmortem examination demonstrates, not massive consolidation, but disseminated patches. Bacteriologic evidence shows that primary and secondary bronchopneumonia have a different bacteriology, and that the former is of pneumococcal origin, and almost as common in the child as in the adult. In other words, lobar pneumonia and primary bronchopneumonia are the same disease.

8. Human and Bovine Tuberculosis.—Raw has had under observation during the last few years over 3,000 cases of phthisis pulmonalis. He has been impressed with the fact that the tuberculous process is nearly always confined strictly to the lungs. Out of these cases he has seen the glands and joints affected in only 14 instances, and in the late stages, he says, the intestine and peritoneum may be involved. It is rare to see phthisis pulmonalis as a primary affection under the age of 12. On the other hand, strumous or tuberculous joints, enlarged glands, spinal disease and abdominal tuberculosis, with tabes mesenterica, are essentially diseases of infancy and childhood, and are only rarely seen in adult life. Furthermore, it is rare to see these young patients develop true phthisis pulmonalis. In fact, clinically they appear to be antagonistic to each other, attacking the body at quite different periods of life and exhibiting generally opposite symptoms. If one compares the appearances seen in cattle dying with tuberculosis with those of children dying of tabes mesenterica and abdominal tubercle, the almost exact counterpart is seen. Raw inclines to the belief that primary intestinal tuberculosis, tabes mesenterica and other tuberculous affections of the serous membranes in children are probably bovine tuberculosis conveyed by milk, and are not true human tuberculosis, although the bacillus of Koch is found in them all. Of nearly 300 cases of tabes mesenterica observed by him during the last twelve years not one has occurred in a child which has been fed strictly on the breast, the whole of them, without exception, having been reared on cow's milk for some considerable period. He concludes further that scrofulous glands in the neck are produced by the absorption of tubercle bacilli in the milk through the tonsils and pharynx, and, as a rule, the affection is a purely local one. This view is supported by feeding experiments on animals. Tuberculous meningitis in children Raw also considers as a bovine tuberculosis. He believes that when tuberculosis is stamped out from cattle surgical tuberculosis in children will to a great extent disappear with it. Further, that the human body is affected by two varieties of tubercle, one producing phthisis pulmonalis and generally attacking adults, the other bovine tuberculosis attacking children during the milk-drinking period, and producing bovine tuberculosis in children. Human and bovine tuberculosis are separate and distinct varieties of disease, but the human body is susceptible to both, and especially to bovine tuberculosis in the early periods of life. The two diseases are rarely seen together in the human organism. Raw is engaged at present in collecting the blood of animals killed for tuberculosis and securing the serum, which, after careful preparation, he proposes to use in the treatment of phthisis.

13. The Heart in Pregnancy.—Mackenzie finds the following changes, which, though in one sense abnormal, might in another sense be considered as incident to the pregnant state: (a) Limitation of the field of cardiac response, (b) Changes in rate and rhythm of the heart, (c) Dilatation of the right side of the heart, (d) Tendency to edema of the lungs. (e)

Tendency to overfilling of the veins of the legs. (f) The occurrence of marked pulsation in the veins of the neck. Systolic murmurs at the base and apex, of slight intensity, are extremely common both during pregnancy and the puerperium, and, apart from other evidence of heart failure, are of little importance, being due to slight and, as a rule, temporary dilatation of the heart. In regard to the question of pregnancy occurring in women with valvular disease Mackenzie draws the following conclusions: 1. When there is distinct evidence of failure of compensation, or when the patient is liable to frequent attacks of failure of compensation, pregnancy should be forbidden. 2. With fair compensation, if there should be paralysis of the auricle, as evidenced by the presence of a diastolic murmur, and the absence of a presystolic murmur, or of a continued irregularity of the pulse, or a jugular pulse, of the ventricular type, pregnancy should be forbidden. 3. With fair compensation, with a mitral murmur, systolic or presystolic in time, with the apex beat within the nipple line, and due to the left ventricle, the patient may undertake the burden of pregnancy. In all cases of valvular disease, when conception has taken place the patient should be kept under close observation. One feature of great prognostic significance is the presence or absence of symptoms of edema of the lung.

15. **Splenic Anemia.**—In two of the cases reported by Springthorpe, Stirling performed a splenectomy. Both patients are very much better in every way without their spleens than they were with them, although there are still vulnerable and not in a state of rugged health. So far there seems to have been no consecutive lymphatic enlargement, and apart from the blood (and even there not distinctively) there has been no evidence of substitutional action on the part of the bone marrow. Stirling, in his remarks, expresses a preference for an incision through the left of the median line because it permits of better handling of the spleen. It is well, too, he says, to begin below and work upward, having, of course, packed off the intestines well to the right. He does not leave saline solution in the abdominal cavity, as is usually advised, except in cases of ectopic gestation. Hemorrhage is controlled by forcipressure.

- 28 Notes on a Case of Infantlism. E. Cecil Williams.
21. **Systemic Infection in Acute Rheumatism.**—Williams concludes that acute rheumatism is an infective disease *sui generis*. That there is a true rheumatic pharyngitis and tonsillitis. That rheumatic pharyngitis or tonsillitis is a primary infectious disease. That rheumatic fever is a secondary infection, due either to the absorption of the products of the infective micro-organisms or to the growth of such micro-organisms in the tissues, and that the infection may manifest itself in arthritis, pericarditis, endocarditis, chorea, bronchitis, pleurisy, alone or in association. That in a large percentage of cases the portal of infection is in the fauces or pharynx or other region of the upper respiratory tract, but most frequently the oropharyngeal lymphoid ring. That there is no

proportion between the intensity of the primary local lesion and the appearance or severity of the secondary systemic complications.

26. **Chorea and Rheumatism.**—Lucas reports the case of a young girl, aged 14, with no history of acute rheumatism, having chorea in a severe form and showing post-mortem cardiac dilatation and mitral vegetations similar to those found in acute rheumatism. Cultures made from the brain substance and pia mater gave a pure growth of a diplococcus similar in most respects to Poynton's and Paine's rheumatic diplo-streptococcus. Bacteriologic evidence, so far as it goes, strongly supports the idea that chorea is rheumatic in origin, and Lucas believes that the presence of a diplococcus in the brain of his case is some additional confirmatory evidence of this. A culture made from the heart muscle, which was in a state of fatty degeneration, gave negative results, but one from the surface of the cardiac vegetations on the mitral valve gave a copious growth of staphylococcus associated with a few colonies of a diplococcus similar in every respect to those found in the brain. Microscopic sections were also made through the diseased valve, and these, when stained by Gram's method, showed a few diplococci similar in appearance to those found in the brain.

31. **Anatomic Study of Case of Chronic Tropical Diarrhea.**—Faber cites from fourteen authorities on the subject of psilosis or sprue, but does not mention any American works. He had occasion to observe a case in a European engineer, 44 years old, who had gone to China when he was 22. The description of the case is completed by the necropsy findings, which showed that the immediate cause of death had been diffuse peritonitis resulting from perforation of an ulcer in the small intestine. But this peritonitis was unmistakably recent and had caused scarcely any symptoms. The main affection, the chronic diarrhea, was explained by the changes found in the intestinal tract. In the large intestine there were only a few swollen follicles with surrounding hyperemia, but in the ileum 16 ulcers were found. They resembled somewhat the lesions of typhoid, but were of an unmistakably chronic type. They evidently had originated in Peyer's patches, which in time they destroyed. Some of the higher ulcers displayed a tendency to heal and some had quite healed. The mucosa had retracted, forming folds converging toward a center. The ulcers were larger and deeper in the vicinity of the ileocecal valve, some of them extending down into the muscularis, with necrotic tissue in the depths and perforation. There was no atrophy of the intestinal wall at any point. The microscope disclosed a diffuse inflammation of the mucosa throughout the entire intestinal tract, although the glands and superficial epithelium were everywhere normal, as were also the deeper strata of the intestinal walls. The differences between these findings and those of other observers are apparent. The enterocolitis had no specific features. In dysentery the lesions are deeper and restricted almost exclusively to the colon and rectum. A number of bacteria were cultivated from the stools, none resembling the Shiga-Kruse bacillus. Two predominated; one was the colon bacillus and the other a lanceolate pneumococcus. The latter was especially numerous in the mucosa and was the only micro-organism discovered in the clumps of mucus, which were scattered through the feces. In these clumps

of mucus little bunches were frequently found which proved to be agglomerations of these diplococci in pure cultures. He is inclined to attribute etiologic importance to these cocci, notwithstanding that they did not prove virulent for laboratory animals. The colon bacilli were exceptionally virulent. The stomach also presented evidences of inflammation, a round-celled infiltration throughout. The gastritis may have been secondary, as he has observed a case of hypochylia due to a foreign body in the colon, and another of achylia secondary to enteritis after appendicitis, and one of gastritis in a child with enteritis the consequence of a tuberculous stricture in the intestine. The pathogenesis in these cases was, of course, remote from that of chronic tropical diarrhea, but the latter has several points in common with infantile diarrhea. Bloch has shown that lesions of this kind in the stomach are almost certain to accompany diarrhea in infants. The acute inflammation in these cases is found in the lower ileum and upper colon, and also in the stomach, while the remainder of the ileum and the jejunum are intact. The similarity of the localizations in infantile diarrhea and in the case of sprue suggests that the pathogenesis in each may be identical. Faber is inclined to attribute the gastritis to the elimination of toxins through the stomach wall. He cites Alt and others to show, for example, that half of the dose of morphia injected subcutaneously is eliminated through the stomach, and by prompt lavage of this organ it is possible to prevent the toxic action of the drug. Other drugs, such as tartar emetic, antipyrin, caffeine and chloral, are eliminated in the stomach secretions in the same way. The stomach suffers from the elimination of toxic substances through its walls, as Panum has established. Albeck has shown that a powerful toxin is elaborated in a strangulated loop of intestine, and that this "putrid toxin" is probably the cause of the symptom-complex we call ileus. Injection of this poison into animals induces a hemorrhagic enteritis while the stomach is congested, with ecchymoses, and he found an ulceration in the stomach in one instance. These findings explain the efficacy of lavage of the stomach in ileus and similar conditions, and suggest that it is liable also to prove beneficial in cases of infectious enteritis. It will remove the toxins poured out into the stomach from the blood, which otherwise are liable to induce gastritis. Pernicious anemia is also in this category. Faber has shown that gastritis is nearly constant in this affection, while the intestine is not inflamed. The most plausible assumption in regard to this disease is that it is the result of the generation in the intestines of some toxin—especially in case of bothrioccephalus anemia—which has a destructive action on the blood and induces gastritis directly and also by its copious elimination in the stomach secretions. Faber suggests that a similar mechanism may possibly exist in regard to chronic tropical diarrhea. The article is fully illustrated. (See also title 80 below.)

32. Syphilitic Phlebitis in Secondary Stage.—Haslund reports 10 cases, all but 3 of the patients being men. In only one were there possible alcoholic antecedents. The syphilis was not particularly grave in any case with one exception. Overexertion and trauma could not be incriminated in the etiology in any case. None of the patients had varices. There seemed to be no reason in any of these cases why the syphilis should locate by preference in the superficial veins of the limbs. All with one exception were strong, healthy individuals, between 20 and 30, the infection averaging about nine months. The legs were the sole seat of the phlebitis in every case except one, in which the arms were also involved. The affection was not symmetrical in the majority. In one case a fresh syphilitic efflorescence was masked by gonorrheal symptoms and copaiaba exanthem. In 2 cases the phlebitis developed while the patient was in bed, the fifth or sixth day after entering the hospital to be treated for universal adenitis and an extensive maculo-papulous syphilitic, etc. The phlebitis healed promptly in every instance under mercurial injections, rest and warm applications. It is probably a frequent manifestation, but is liable to be overlooked and may display a tendency to heal spontaneously, but is liable to entail obliteration of the vein.

34. Boiled Formolized Catgut.—One of the results of the research described is that the catgut is liable to be imperfectly sterilized unless it is boiled for thirty minutes after it has been lying in 4 per cent. formaldehyde for twenty-four hours. Another fact noted in the experiments is that an infected catgut and a sterile catgut, under certain circumstances induce the same inflammation and the same pathologic anatomic changes.

37. Case of Erysipelas on Paralyzed Arm.—Kren's patient was paralyzed in consequence of a bullet injury of the spinal cord near the tenth thoracic vertebra. The erysipelas commenced about four months after the injury and rapidly extended downward, although above it remained nearly within the limits of the sensory paralysis. It invaded in less than three days the whole of the body below the wound, with only a few small islands of intact skin, and remained restricted to the paralyzed area.

38. Sarcoma and Carcinoma in Same Subject.—A spindle-celled sarcoma was removed from the epiglottis of the patient and eighteen months later an extensive carcinoma of the base of the tongue and epiglottis also required ablation.

40. Thymus Death Under Local Anesthesia.—The enlarged thyroid was removed under Scheich local anesthesia in a case of exophthalmic goiter in a woman of 31. She exhibited dyspnea during the operation and died fifteen minutes afterward. The thymus had not retrogressed and was unusually large.

The entire lymphatic apparatus showed great hyperplasia, especially the lymph follicles at the base of the tongue and in the spleen and intestines. Haberer reviews the scanty literature on the subject of the occurrence of multiple malignant neoplasms of different nature.

41. **Technic for Suture of Nerves.**—Foramiti finds the use of a protecting tube outside is a great aid in suturing a nerve. In his experimental studies he used for the tube the artery from a calf, either fresh or hardened in formalin after thorough boiling. He gives several illustrations to show the fine regeneration of the nerves attained by this technic. He passes a needle threaded with catgut through one of the stumps of the nerve. The needle and thread are then brought through the tube, and the nerve stump can then be readily drawn down into the tube or the latter slipped over the nerve. The one thread can be used for each stump and the tube thus slipped over their juncture. When a fresh artery is used it is taken aseptically from the animal and merely rinsed in salt solution.

44. **Bullet Wounds of the Stomach.**—In the case described the hole made by the bullet as it left the stomach could not be found, and yet it had unmistakably passed entirely through it. The patient recovered without mishap. Research on animals has also confirmed the fact that the hole made as the bullet passes out of the stomach is usually a tiny slit, difficult to be discovered. The entering hole is much larger and the stomach contents, if they escape at all, do so through this first opening. Consequently von Frisch advises when the entering hole is not more than 7 or 8 mm. in diameter, to abandon the search for the other opening if it does not readily present. The abdomen can be sutured with confidence, as the mucosa plugs the second opening. Fourteen figures are given in 3 colored plates to show the anatomic findings after the bullet had passed through the stomach (pigs). The bullet pushes the wall before it, stretching it taut, before it perforates it. This leaves a very small hole as the elastic wall contracts.

45. **Auto-intoxication in Ileus.**—Clairmont and Ranzi have been inducing ileus in animals and studying whether the fatal symptoms that followed were due to the action of toxins generated in the closed gut or to reflex action. The findings unhesitatingly sustain the former view. Sixty-three series of experiments are related, with control experiments. The results suggest the feasibility of serum treatment, although no positive success has yet been obtained.

47. **Remote Results of Colopexy.**—Weiss reports that von Eiselsberg has performed colopexy 17 times on 15 subjects. Four were entirely cured, but 7 presented relapses and no news has been obtained since of the 4 others. The results are better when the prolapse of the rectum is due to trouble in the sphincter than when it is the result of congenital low position of the Douglas. It might be advisable in some cases to combine the colopexy with fastening the Douglas in place. Relapses are most liable to occur after the Mikulicz technic of colopexy.

50. **Surgery of Tumors in Stomach.**—Nordmann reviews the operations done at the Urban Hospital in Berlin on account of gastric tumors, 126 in all. Of the 38 treated by resection 58 per cent. were cured. One of the cured patients had suffered from tuberculosis of the pylorus with stenosis, and was cured by the operation. Gastroenterostomy was done in 67 cases, with a mortality of 19.6 per cent. The vicious circle occurred in only a single instance. The Murphy button is not used.

52. **Micro-organisms in Small Intestine.**—Jundell has previously established that the mucosa of the trachea, conjunctiva and urethra is sterile under normal conditions. He now presents evidence to show that the same is true of the mucosa of the small intestine. He attributes this sterile condition to a bactericidal property possessed by the mucosa. It suggests the necessity for care of the mouth and of sterile foods after operations on the small intestine. It also suggests that the technic of laparotomy involving opening the small intestine might be modified. The patient should fast preliminary to the operation, so that the portion of the small intestine to be

opened will be found empty and sterile. It has also an important bearing on the prognosis of perforations of this part of the bowels.

59. **Varying Virulence of Contents of Digestive Tract at Different Points.**—Brunner has been making a study of the infectious character of the contents of the small intestine in comparison to the large. The contents of the upper part of the small intestine are less infectious than those of the lower part. The appendix has a special place apart in this respect. He found streptococci invariably present with the colon bacilli. He has operated on 7 patients to suture a perforated gastric ulcer. Two were saved. His experience and research have confirmed the assumption that acid stomach content is tolerated much better than the anacid. Rabbits tolerated injection of 20 c.c. of the former, while they succumbed after injection of 1 c.c. of the latter.

64. **Fate of Compresses Left in Abdomen.**—Riese reports a case of a simulated ovarian tumor which proved on operation to be a completely encysted compress, relic of some former surgical intervention. His experiments on animals confirmed the possibility that an overlooked sterile compress can be thus encysted, and also, further, that such a compress may work its way through into the gut and be spontaneously evacuated. He has found 41 cases on record of a compress having been left in the abdomen. In 9 the patient died soon after, with symptoms of peritonitis. In d'Antona's case the experts all testified that the peritonitis observed was not traceable to the compress which had been left in the abdomen at an exploratory laparotomy four weeks before death. Riese doubts whether a sterile compress could ever induce peritonitis. It is much more probable that the abdomen had become infected during the operation. In 11 cases the compress was eliminated in an abscess in the abdominal wall or through the vagina. In another case beside the one reported, the compress became encysted. In 11 cases the compress had worked its way into the bowel and had been evacuated per anum. Only in 7 out of the entire 41 did the compress cause intestinal occlusion, fatal in 2 instances.

80. Anatomic Study of a Case of Chronic Tropical Diarrhea.—Faber's article is summarized above, abstract 31.

81. Research on the Motor Function of the Stomach.—Pesthy's announcements in regard to the value of percussio-auscultation as a means of obtaining information in regard to the stomach conditions and functions were summarized on page 66 of the last volume of THE JOURNAL. The difference in the outline of the stomach as determined by this means before and during artificial inflation, indicate the degree of elasticity of the musculature. He found that a normally elastic stomach gives a difference of not more than 2 cm., while in case of ptosis, the difference may be 3 cm., and in case of atony or other muscular insufficiency the difference may reach 4 or even 6 cm. Further study of this subject on 10 subjects with normal stomachs confirmed the exactness of this standard difference of 2 cm. He determined the outlines of the stomach with percussio-auscultation, measuring both diameters and also the distance between the umbilicus and the upper and lower outlines of the organ. He then inflated the stomach with 5 gm. tartaric acid and 8 gm. sodium bicarbonate and repeated the above measurements, with special regard to the vertical diameter. As a further test he gave the subjects 2 gm. iodopin one-half to one hour after a light breakfast, and tested the saliva every five minutes with fuming nitric acid and chloroform. The standard difference in the outlines of a healthy stomach was 2 cm., and the iodopin reaction occurred not later than forty-five minutes. He tabulates the findings in 21 cases of atony of the stomach and in 14 of extreme motor insufficiency. The iodopin reaction occurred after an interval of 60 to 100 minutes in the first group, and of 55 to 150 minutes in the second. The difference in the outlines of the stomach before and during inflation ranged from 3 to 5 cm. in the first group, and from 4 to 9 in the second, with 2 exceptions. These 45 observations, added to the 95 on which his first communication was based, fully establish the diagnostic value of this difference as a test of the dynamic functional capacity of the stomach, more delicate than any other known to date. In all these pathologic cases, irrespective of their etiology, one common symptom is prominent, defective motor functioning, demonstrated by the iodopin test. The musculature of the stomach is incompetent, whether from simple atony or insufficiency of the second degree, that is, when remains of the food are found in the stomach the morning after a test dinner. Pesthy suggests that a good classification of stomach affections might be made by grouping them as class 1, relative insufficiency; the cases with a difference of 4 cm., iodopin test positive after 65 minutes, and stomach empty six hours after test dinner; class 2, relative insufficiency; difference 6 cm., iodopin test positive after 90 minutes, and 300 gm. of stomach content found six hours after test dinner; class 3, absolute insufficiency, difference 9 cm., iodopin test positive after 120 minutes, and remains of food morning after test dinner, with lactic acid. By specifying further in class 1 that ptosis and myasthenia exist also; in class 2, cicatricial stenosis of the pylorus, and in class 3, that a large tumor can be palpated near the pylorus, each of the symptom-complexes would be accurately defined in a few words and due stress placed on the important findings. He accepts Boas' restriction of the term "myasthenia" to cases with congenital weakness, and "atony" to the secondarily acquired weakness of the musculature, a degenerative process. By this classification of gastric insufficiency, treatment will be facilitated as in all of them the chief aim of therapeutics will be the restoration of the defective muscular function. In relative insufficiency appropriate diet and other measures will combat the insufficiency, while in the absolute form the results of the stagnation will have to be

combated also. The complaints of subjects with ptosis will not be lightly dismissed as the effects of nervous dyspepsia, but will be regarded as exclusively the consequences of the existing muscular insufficiency.

82. Occult Hemorrhages in Gastric Contents and Stools.—Clemm reviews the various sources for slight trickling of blood in the digestive tract, and the paramount diagnostic importance of its discovery. One of the latest important communications on the subject was reviewed on page 1525 of the last volume of THE JOURNAL. Clemm urges the importance of seeking for this premonitory occult bleeding as a means of warding off serious hemorrhage in certain affections, especially in tabes and paralysis. In typhoid, so long as a trace of blood can be detected in the feces, the patient should be spared even the slightest exertion. The premonitory occult bleeding in a case of hemorrhagic pancreatitis, reported by Joachim, was the clue to the nature of the affection. Positive findings would enable an operation to be done in time in this rare disease, of which Fiedler has collected 60 cases. In case of gastric ulcer, the coincidence of hyperchlorhydria with occult hemorrhages will confirm a dubious diagnosis, if Ewald's assertions in regard to the former are accepted. The diagnosis can be frequently confirmed by the blood findings in case of an ulcer in the esophagus, stomach and duodenum. They also serve to differentiate cancerous processes in the digestive tract from nervous affections, from simple inflammations and from ulcers, as only in case of cancer is the trickling of blood constant. Clemm mentions, by the way, the opening of a new field for research by Kobert's discovery that the blood from the human umbilical cord crystallizes in an entirely different manner from ordinary human blood, and that the crystals formed by blood from the cadaver are entirely different from both. It may prove to be possible to distinguish between blood from a suppurating cancer and blood of other origin by study of the crystallization, as blood exposed to putrefaction thus differs in this respect from fresh blood.

89. Roentgen Stereoscopic.—Becker describes and illustrates a simple, inexpensive box which answers the purpose of a stereoscope for Röntgen pictures. He also describes a simple device for taking radiograms for use in a stereoscope. It consists of a box open at both ends, with two wires crossing each other at right angles in the center of the outside. The plate is slipped inside the box and the part to be radiographed is placed at the intersection of the wires. The tube is moved about 7 cm. to one side for the second exposure, the part remaining in the same position.

90 Study of Acidity in Animal Fluids.—Moritz here presents the first part of an extensive study on the balance sheet of acids and bases in animal fluids. In this part he reports research on the determination of the acidity in fluids which contain alkaline earthy substances besides the phosphates. He gives the particulars of his technic, and of 50 tests of the gastric juice or urine or experiments with various chemicals to determine their value for tests in this line.

91 and 92. Photodynamic Action of Fluorescent Substances.—Protozoa and enzymes first treated with some fluorescent substance and then exposed to the action of light were much more rapidly destroyed than by the light alone. No substances except the fluorescent ones have been found to possess this photodynamic property. Its intensity does not depend on the amount of the fluorescence, but on the capacity of light absorption conferred by the fluorescent substance. This power of absorption increases and diminishes with the amount of fluorescence, but the destructive action is not due to the latter alone. It is not due to any chemical transformation of the photodynamic substance by the light, and neither is it a "sensitizing" process. Its nature is still a mystery; it is evidently an entirely new phenomenon. The effect observed suggests that part of the action of sunlight and electric light may be due to a photodynamic property possessed by some of the rays. Neither the Röntgen nor radium rays displayed any destructive action on paramedia and enzymes, not even when reinforced by fluorescent substances. The paramedia retained their motility after the exposures to the same extent as the controls.

93. Local Passive Congestion in Respect to the General Circulation.—Plaskuda found that loose constriction of the arm or leg or the application of a tight tourniquet or winding the limb from the extremity upward, was able to influence to a marked degree the conditions of the circulation in the trunk and head. It was possible by these means to withdraw from or supply to the trunk from nearly a pint to more than a quart of blood. Pronounced passive congestion in three extremities reduced the blood pressure 20 mm. Hg., as much as 14 per cent. In "nervous" subjects the findings are uncertain. In some instances the blood pressure dropped suddenly, sometimes to such an extent as to threaten collapse, but the symptoms rapidly subsided after removal of the constriction. The blood pressure can be increased by expelling the blood from a limb. He attributes this effect more to nervous than to mere mechanical factors, but in any event it justifies trial of this "autotransfusion," as it is called, as a therapeutic measure.

102. Study of Effects of Bloodless Reposition of Hip Dislocation.—Deutscher has been producing luxations in young cats and studying the effects of reposition. He found it an invariable rule that any disturbance in the mechanism of the joint entailed increased growth and development, instead of checking the development. When the joint capsule is extirpated the growth proceeds with abnormal intensity. His study of the condition in man shows that in case of luxation of the acetabulum the conditions are never those of rudimentary growth, but the contrary, the growth is exaggerated. These facts are of great importance for the treatment of hip dislocation. An anatomic cure of the trouble is possible only when the hypertrophied contents of the acetabulum can be forced to atrophy under the pressure of the head of the femur brought into contact with it. Anatomic cure is achieved by bloodless reposition only in about a third of the cases—that is, in unilateral luxation. In a fourth or fifth of all the cases there is sure to be some complication or actual failure as the result. About half the cases reported are qualified as improved, but no mention is made as to how long the improvement persisted. The failures in bloodless reduction should compel more extensive application of operative treatment. He tabulates the published results of over 1,000 cases from the literature. The failures amount to 27.8 per cent.

104. Fractures of the Leg from Standpoint of Industrial Insurance.—Out of 44 cases of these fractures 14 healed with permanent deformity, and 30 to 40 per cent. were incapacitated so that they were entitled to a pension.

105. Plastic Operations on Bladder.—Pedunculated flaps of serosa and muscle were sutured into the defect in the bladder in Brunn's experimental experiences. They all softened and became necrotic in a few days. Further experiments showed that when the pedunculated flap was cut from serosa and unstriated muscle it healed mostly in the defect and answered the desired purpose.

108. Advantages of Transverse Nephrotomy.—The principal result of Hermann's experiments on dogs was the discovery that the animals bore a transverse incision of the kidney much better than a lengthwise incision. After a longitudinal incision extensive infarcts formed and there was more or less interstitial inflammation. After transverse incision, the kidney tissue did not disappear by any means to the extent observed in case of a longitudinal incision. He suggests that a transverse incision might be better than the lengthwise for man.

110. Tropical Liver Abscess.—In 5 of the 6 cases reported there had been a history of dysentery. The abscess was located in the right lobe in every case. Two of the patients died. Exploratory puncture is an important help in diagnosing, and ample exposure and evacuation of the abscess are indispensable.

113. Hernia of the Ovary with Torsion.—In nearly every

case on record the hernia occurred in infants less than a year old. There is very little general disturbance. Gauzele describes a case.

114. **High Cancer in Rectum.**—At the surgical clinic at Kyoto 3 cases of rectal cancer located high or reaching up high, were removed by the abdominal-sacral routes. One patient recovered. In the 25 cases which the authors have found on record death occurred in 16.

115. **Tuberculous Osteomyelitis of Long Bones.** From 15 cases observed by Friedländer he finds that the *x* rays readily settle the diagnosis. There are three varieties, the cases with progressive infiltration, those with circumscribed infiltration with sequester formation, and the cases of central, caseous infiltration without macroscopic sequestrs. Demarcation of a large sequester without suppuration and before fistula formation, is an unconditional sign of tuberculous. It is characteristic of the caseous focus without sequester formation that the cavity is larger than the new-formed mass of bone, as can be ascertained by radioscapy. Operation is contraindicated in case of multiple foci in a long bone with progressive infiltration. Amputation is the only resource in such a case. The Moseley iodoforn filling is a great aid in treating tuberculous osteomyelitis of the long bones.

119. **Sensibility in Organs and Tissues in Respect to Local Anesthesia.**—THE JOURNAL has frequently quoted Lennander's views in regard to the lack of sensibility in certain organs and tissues, allowing them to be incised and handled without pain. He has continued his research on the subject, deeming it one of great importance for the use of local anesthesia. He proclaims now that all the organs which are exclusively innervated from the sympathetic or vagus system, below the inferior larynx, are lacking in nerves to convey pain sensations. Consequently there is no need for anesthesia in operating on them. The list of such organs includes the small and large intestine, the liver, spleen, pancreas, gall bladder, rectal and vaginal mucosa, uterus, ovaries, tubes and bone proper. The periosteum is sensitive. By observing certain precautions it is possible to operate in cases of hernia and appendicitis exclusively with local anesthesia and very little of this, and yet the patient knows no pain. He gives the details of more than 50 operations of various kinds in which the particulars in regard to the sensibility of the tissues were carefully noted. They include several amputations. It was noticed that after injection of cocaine into a nerve it was still painful when taut, but not painful when the nerve was relaxed. The periosteum could be incised without pain in an amputation for senile gangrene, for example, after local injection of 1.5 c.c. of 0.5 per cent. cocaine. The sawing of the femur caused no pain, nor the cutting of the bone marrow for 1.5 cm. above the cut surface. Even the application of the actual cautery to the stump was painless. Dry gauze was then applied to lessen the absorption of cocaine, and the operation concluded with no mishap. Another patient had his arm amputated without the slightest pain after the inflamed periosteum had been injected with a 0.25 per cent. cocaine solution, and turned back from the bone. (See abstract 108, page 344, in vol. xxxix of THE JOURNAL.)

121. **Myositis Ossificans.**—From further study of 5 more cases, Busse and Blecher reiterate that the process in this affection is both clinically and anatomically an inflammation. Under certain circumstances it is capable of retrogression. The neoformation of bone occurs exclusively in the muscles, not starting in the periosteum.

124. **Traumatic Chylothorax.**—In the month following a bullet wound of the breast, 27 liters of chylous fluid were evacuated by punctures. The patient recovered. Eight cases of traumatic chylothorax are on record and are reviewed. All but the present one were the result of contusions.

128. **Treatment of Leg Ulcer.**—Georgi reports very encouraging results from application of Wenzel's technic. This includes a circular incision between the middle and upper thirds of the thigh, and ligation of all the veins found above the fascia in the course of the incision, carefully avoiding the

nerves. This forces the blood to seek an outlet through the deeper veins and prevents recurrence. All of Wenzel's 26 patients were permanently cured.

129. **Alternating Roentgen and Daylight Operations.**—The radiologic operating table described allows the in-erposition of the fluorescent screen at any moment, a pedal arrangement turning on the Röntgen rays and excluding the daylight, while another touch to the pedal removes the screen and restores the daylight. The technic is described as practiced in 9 cases of extraction of a foreign body, which thus becomes a scientifically exact, simple and easy procedure. The apparatus is illustrated in detail.

134. **Successful Treatment of Senile Deafness.**—Akhsharumoff reports his experience with a method of checking the inroads of senile deafness in his own person. He noticed that his hearing varied with the weather. This suggested the idea that catarrhal conditions of the mucosa might obstruct the entrance of air, and thus interfere with the functional capacity of the ear. He sought to dilate the aural air passages by inflation with air, and found that it effectually relieved his deafness. He uses an ordinary double bulb spray apparatus with a nose douche tip. The latter is introduced into one nostril and both nostrils are closed air tight with the fingers. The mouth is held open and the subject breathes regularly all the time. The bulb is then squeezed with the other hand, the atomizer standing on a table on a level with the mouth. Air is thus pumped into the nose. The bulb must be rapidly compressed about 150 times to the minute or thereabouts, the pressure being moderate. This causes rhythmic vibration massage of the eustachian tube and of the ear drum. These exercises for a few minutes twice a day for several months restored his hearing and relieved him of the subjective acoustic phenomena which had previously annoyed him, especially when lecturing.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

TEXT-BOOK OF HUMAN HISTOLOGY, including Histology and Microscopical Anatomy, with Especial Reference to the Practice of Medicine. By Dr. L. Landis, Professor of Physiology and Director of the Physiological Institute in the University of Greifswald. Tenth Revised and Enlarged Edition. Edited by Albert P. Ribbaker, M.D., Professor of Physiology and Hygiene in the Jefferson Medical College. Translated by Augustus A. Eshner, M.D., Professor of Clinical Medicine in the Philadelphia Polyclinic. With 394 Illustrations. Cloth. Pp. 1027. Price, \$7.00. Philadelphia: P. Blakiston's Son & Co. 1904.

TOXICOLOGY. A Manual for Students and Practitioners. By Edwin Welles Dwight, M.D., Instructor in Legal Medicine, Harvard University. Series Edited by Victor Cox Pedersen, A.M., M.D., Instructor in Surgery and Anesthetist and Instructor in Alcesthesia at the New York Polyclinic Medical School and Hospital. Cloth. Pp. 298. Price, \$1.00. Philadelphia and New York: Lea Bros. & Co.

PRACTICAL PHYSIOLOGICAL CHEMISTRY. By J. A. Milroy, M.A., M.D., Demonstrator of Physiology, Queen's College, Belfast, and T. H. Milroy, M.D., B.Sc., F.R.S.E., Professor of Physiology, Queen's College, Belfast. Cloth. Pp. 200. Price, \$1.60 net. New York: Longmans, Green & Co. 1904.

PRIMARY CHORIO-EPITHELIOMA MALIGNUM OUTSIDE OF THE PLACENTAL SITE.

WITH REPORT OF A CASE.*

PALMER FINDLEY, M.D.

CHICAGO.

In spite of the enormous amount of literature lately evolved on this subject, little has been presented that throws light on the true character of the growth. This statement was recently made by W. Risel, and I think we must all agree with him.

Progress has been made in the study of the histology of these growths, and we have arrived at a more definite understanding of certain points in the histogenesis which were formerly much discussed.

The term deciduoma malignum, introduced by Sänger, has been abandoned, and it is generally conceded that this growth, composed as it is of Langhans' cells and syncytium, arises from the fetal ectoderm. But we seem to have been led into still greater confusion by the recent reports of cases of primary chorio-epitheliomatous growths arising outside of the placental site, and these not confined to the female, but found as well in the teratomata of the testicle.

During the past seven years 20 cases of primary chorio-epitheliomata arising in woman outside the placental site have been reported, and to this number I have added the report of a case that was primary in the uterine musculature.

The following is a brief résumé of the 20 reported cases:

CASE 1.—Reported by L. Pick² and Th. Landau, in 1897. Aged 22. Primipara; no abortions. There developed a hydatidiform mole, which was expelled spontaneously. While the mole was yet *in utero* a vaginal tumor the size of a walnut appeared in the anterior wall of the vagina. The surface of the tumor was slightly ulcerated, and bled freely. No blood came from the uterus. The tumor was removed, and three days later the mole was expelled spontaneously. Three and one-half years later there was a normal birth, and a second normal birth the following year. There has been no recurrence of the growth.

Histologic examination of the vaginal tumor showed villi re-

sembling those of a hydatidiform mole in the center of a large blood coagulum. Langhans' cells and syncytium were found in abundance. The overlying mucosa was necrotic.

CASE 2.—Reported by Schmorl,³ in 1897. Aged 35. Eighteen weeks after a normal labor a vaginal tumor appeared, which was followed by metastatic growths in the lungs, liver, kidney and intestine. The uterus, tubes and ovaries remained free. Death followed.

The histologic structure of the primary and secondary growths was that of a typical chorio-epithelioma malignum.

CASE 3.—Reported by Schlagenhauer,⁴ in 1899. Aged 38. IV-para. An incomplete abortion was followed in two or three months by hemorrhage from the vagina, and this recurred in six months. Ten months after the abortion a tumor the size of a large nut was found in the posterior wall of the vagina. It was round, of a dark red color, and on cross-section it appeared to the naked eye to be a blood coagulum. Microscopic examination showed the blood clot to be invaded by syncytial and Langhans' cells—a typical chorio-epithelioma. The overlying mucosa was broken through by the tumor mass, permitting blood fibrin and tumor cells to approach the surface. Twenty-one months after the vaginal tumor was removed the patient was reported well.

CASE 4.—Reported by von Guérard,⁵ in 1899. Aged 40. A hydatidiform mole of two or three months' development was artificially removed. There was nothing unusual seen in the histologic structure of the mole. Four weeks later a slight vaginal hemorrhage appeared, and continued to increase in amount. A tumor the size of a hazelnut was removed from the anterior lip of the cervix, two and one-half months after the removal of the mole. It was from this tumor that the bleeding occurred.

Microscopic examination of the tumor showed large quantities of syncytium. Two years after the removal of the mole the patient was reported to be in good health.

CASE 5.—Reported by H. Schmitz,⁶ in 1900. Aged 38. V-para. Three abortions; one hydatidiform mole.

Three months after the removal of the mole a dark red tumor, the size of a hen's egg, appeared in the anterior wall of the vagina, and a second tumor, the size of a hazelnut, appeared in the posterior wall of the vagina. There was no bleeding from the uterus. Vaginal tumors removed and uterus scraped, with negative findings.

Microscopic examination of the vaginal tumors: In a blood coagulum of the large tumor were chorionic villi, surrounded by large numbers of Langhans' cells and syncytium. No villi were present in the small tumor, but the arrangement of the cellular structures was not unlike that of the large tumor.

One and a half years after the removal of the vaginal tumors the patient was reported well.

CASE 6.—Reported by Fiedler,⁷ in 1900. (Schmorl's⁸ second observation.) Aged 35. 11-para. Severe hemorrhage occurred two months after a normal labor. Eight months later there developed severe abdominal pains and some swelling of the abdomen. Then followed vomiting, anorexia, and within a month (eleven months after labor) death occurred.

Postmortem examination revealed a soft dark red nodule, the size of a cherry stone, on the posterior wall of the fundus. Cysts the size of a child's head were in the ovaries; the tubes were normal. A soft reddish-gray tumor, the size of a child's head, was found in the liver. Similar but smaller growths were in the kidney, suprarenal glands and retroperitoneal lymph glands.

Microscopic examination: These tumors were largely composed of syncytium and blood coagulum. In the uterus was a decidua, 3 cm. thick.

CASE 7.—Reported by A. O. Lindfors,⁹ in 1901. Aged 22. 1-para; one abortion. Three weeks after labor there occurred a severe hemorrhage from the vagina, and a small tumor was found at the introitus vaginæ. In five weeks this tumor was the size of a cherry. Three weeks later a tumor, the size of a walnut, appeared above the urethra. It was pedunculated, dark red, and appeared to be composed of a blood coagulum. Scrapings from the uterus presented a normal mucosa.

Microscopic examination: The tumors contained large numbers of Langhans' cells and syncytium, which invaded the blood vessels of the vaginal mucosa. There were no villi. Nine months after the child-birth, or two months after the removal of the vaginal tumor, the patient succumbed to what was diagnosed as influenza, with an exudative pleurisy. Two hundred c.c. of bloody fluid were aspirated from the pleural cavity two days before death.

Postmortem examination: In the left lung was a large chorio-epithelioma, and smaller tumors of similar structure were found in the right lung, kidneys, brain, spleen, liver and intestine. The histologic structure resembled a typical chorio-epithelioma. Uterus and its appendages were free from tumor growths, as was also the vaginal scar.

CASE 8.—Reported by Schmit,¹⁰ in 1901. Aged 41. 0-para; two abortions. Last abortion was immediately followed by hemorrhage, which was checked by scraping away some retained placental tissue. Seven weeks later a tumor appeared in the vault of the vagina, which bled so freely that it required tamponing. This tumor was soft, of a bluish color, and the size of a hazelnut. No hemorrhage came from the uterus. Microscopic examination of the excised tumor revealed a large blood coagulum, within which were hydropic chorionic villi and a typical grouping of Langhans' cells and syncytium. Scrapings from the uterus showed normal mucosa. Eight months after operation patient was reported in good health.

CASE 9.—Reported by Marchand,¹¹ in 1901. One month after the artificial removal of a hydatidiform mole, brain symptoms developed, and death came speedily.

Postmortem examination revealed a malignant chorio-epithelioma in the right cerebrum; also numerous nodules in the lung and left kidney. The uterus was somewhat enlarged; there was a decided decidual formation in the uterus.

CASE 10.—Reported by Holzappel,¹² in 1901. Aged 37. Three years after an abortion a vaginal tumor appeared, which bled freely. The uterus was slightly enlarged. No blood came from the uterus. The vaginal tumor was excised and the uterus removed.

In the posterior wall of the uterus was a tumor, not connected with the mucosa. A third growth, the size of a walnut, was removed from a point above the urethra. The three growths presented the microscopic picture of a typical chorio-epithelioma. In the uterus was a decidual formation. Recovery followed.

CASE 11.—Reported by Pick¹³ and Th. Landau. Aged 20. Not married. An abortion occurred in the third month. Shortly afterward hemorrhage came from the vagina and lungs. The vaginal hemorrhage was seen to come from two small ulcerated nodules in the vaginal wall. These were excised, and their base curetted. The uterus was also scraped, with negative findings.

Microscopic examination of the excised nodules showed the presence of a few villi and a typical formation of a chorio-epithelioma. Hemorrhage ceased from the vagina and lungs. Seven months later she again aborted in the sixth week of pregnancy, and at the time of making the report she was three months pregnant. The author was of the opinion that the spitting of blood was due to a chorio-epitheliomatous growth in the lungs, which apparently healed.

CASE 12.—Reported by Wehle,¹⁴ in 1901. Aged 46. VII-para. Six months after the last normal child-birth a tumor appeared on the right labium. This was excised, and recurred in eight days, growing to the size of a mandarin. Death resulted in five weeks. The growth was a typical chorio-epithelioma.

CASE 13.—Reported by Wehle,¹⁴ in 1901. Aged 39. VI-para. Five weeks after the last labor there appeared a mucosanguineous discharge from the vagina. On examination there was found a tumor the size of a large orange on the posterior wall of the vagina. This was removed by curette and cautery. Ten days later the tumor recurred, when further surgical intervention was impossible. Death soon followed.

Microscopic examination: Typical chorio-epithelioma.

CASE 14.—Reported by H. Peters,¹⁵ in 1902. Aged 30. A normal labor was followed by a period of amenorrhœa, lasting from March to June. In June and July there were irregular hemorrhages. From July, 1900, to March, 1901, menses were again suspended. At this time a hydatidiform mole was expelled. Three days later bleeding recurred, and lasted six weeks. A tumor, the size of a pigeon's egg, was found in the vagina. It was bleeding profusely. The surface was ulcerated. The uterus was found normal, after an exploratory curettage. The vaginal tumor was removed, and healing was perfect. Oct. 20, 1901, a second tumor appeared near the cicatrix in the vagina, and grew rapidly to the size of a pigeon's egg. Death followed three days after the appearance of the second vaginal tumor, preceded by paralysis of left leg and forearm, and asphyxia. The vaginal tumor was composed of a typical chorio-epithelioma. There was no postmortem examination, but doubtless there were metastatic formations in the lungs and brain.

CASE 15.—Reported by Hugo Hübl,¹⁶ in 1902. Aged 36. VII-para. Four normal labors; one abortion at third month.

11. Marchand: Demonstration zweier Fälle von malignem Chorioepitheliom. Medizin. Gesellschaft zu Leipzig, 2. vii, 1901; Münchener med. Woch., 1901, No. 32, p. 1303.

and one hydatidiform mole. The last pregnancy terminated at the seventh month. Seven weeks later there was a vaginal hemorrhage, which rendered the patient very anemic in a few days. A tumor was then found in the posterior wall of the vagina, the size of a large nut, with an ulcerated surface. Scrapings from the uterus showed negative findings.

The vaginal tumor was extirpated and presented a typical chorio-epithelioma. Twenty days later it returned in the posterior wall of the vagina, to be shortly followed by the appearance of several similar growths in the vagina. Death occurred five months after the miscarriage, or thirteen weeks after the appearance of the vaginal tumor.

Postmortem examination: Secondary growths were found in the liver, lungs, base of bladder and ovary. All the tumors were identical in their histologic structure.

CASE 16.—Reported by Senarclaus, in 1902. Aged 38. I-para. In 1898 she had an early abortion. In November, 1901, there appeared a foul-smelling, bloody discharge from the vagina, together with severe abdominal pains. In February, 1902, an abdominal tumor was recognized and diagnosed as a swelling of the right adnexa.

Death occurred March 9, 1902, shortly after an abdominal section.

Postmortem examination: Multiple tumor growths were found in the lung, anterior mediastinum, the wall of the right ventricle of the heart, thyroid and suprarenal glands, and kidneys. The fallopian tubes, ovaries and uterus were negative.

Microscopic examination: An atypical chorio-epitheliomatous formation was found in all of these growths. Senarclaus was of the opinion that there had existed a tubal pregnancy.

CASE 17.—Reported by Busse,¹⁷ in 1902. Aged 40. Patient entered the hospital July 2, 1902, with hemiplegia of the right side. Postmortem examination revealed chorio-epitheliomatous growths in the lungs, liver, kidney, pia mater and intestine. The uterus and adnexa were negative. The primary growth was not recognized.

CASE 18.—Reported by Moltrecht,¹⁸ in 1902. An incomplete abortion was followed by curettage. There was no evidence of malignancy in the scrapings. Four months later a bleeding tumor was discovered on the posterior wall of the vagina. The uterus, adnexa and greater portion of the vagina were removed. The uterus and adnexa were normal.

Microscopic examination of the vaginal tumor showed a typical chorio-epithelioma. Recovery followed.

CASE 19.—Reported by Davis and Harris,¹⁹ in 1900. Aged 40. XIV-para. Uncontrollable vomiting occurred in the second month of her fifteenth pregnancy. Pregnancy was terminated and death soon followed.

Postmortem examination: Nine tumors were found in various portions of the brain; also similar growths in both lungs, left kidney, liver and thyroid gland. The tumor in the kidney was thought to be primary. The uterus and adnexa were negative.

Microscopic examination showed a typical chorio-epithelioma.

CASE 20.—Reported by G. Schmauch,²⁰ 1903. Aged 25. IV-para. Labors normal. Last birth Aug. 20, 1901. Entered clinic with severe postpartum hemorrhage. Placenta removed and reported normal; hemorrhage stopped, and patient apparently recovered. Three weeks later severe hemorrhage came from vagina, which was seen to come from a tumor in the vaginal wall; this was excised and the bleeding stopped for three weeks. The hemorrhage returned, and a second tumor was

found in the vagina. This was cauterized, and the uterus curetted. The bleeding was checked for a short time, and shortly returned, with vomiting. Four or five vaginal tumors were successively excised to control the hemorrhage. The pelvic connective tissue was invaded, and this, together with the anemic condition of the patient, made a radical operation impossible. Death followed ten weeks after the normal birth.

Postmortem examination: Typical chorio-epithelioma malignum of the vagina (primary), metastatic growths of similar structure in kidney, lungs, spleen, brain and pelvic connective tissue.

In addition to the previously reported 20 cases, I have the privilege of reporting a case, through the kindness of the operator, Dr. Karl Sandberg, Chicago:

CASE 21.—Mrs. M. L., aged 50. Danish; housewife. Father died at 84; mother at 80 years of age. No tuberculosis or malignancy in the family. Patient was never sick except from measles and whooping cough. Menstruation always regular in time and amount. Has had five children, the oldest 19 years and the youngest 5 years and 8 months of age. Labors not difficult. One miscarriage eleven years ago. No unusual hemorrhage, pain or fever followed the child-births or miscarriage. Has not been pregnant to her knowledge since the last child-birth, five years and eight months ago. She nursed this child two years, during which time, and the year following, she did not menstruate. In all, there was a period of amenorrhea lasting three years. The menses then appeared, were one week in duration, unusually copious and irregular. There was an associated headache and pain in the right side.

Present illness.—During the last fifteen months the pain has steadily increased, the flow has been gradually prolonged and increased in quantity, and intermenstrual hemorrhages were noted. These were brought on by physical exertion. An offensive leucorrhœal discharge also made its appearance. The flow appeared daily during the two months preceding the operation.

Examination.—Just prior to the operation the patient was found to be anemic and emaciated. A sanguinopurulent discharge flowed from the vagina. There was a nodular tumor the size of a hen's egg on the posterior wall of the vagina. It was of a dark red color. The overlying mucous membrane was intact and apparently not adherent to the tumor mass over the greater part of its circumference. It was of elastic consistency, and rather movable.

A bloody purulent discharge exuded from the cervix. There was nothing unusual in the appearance of the vaginal portion of the cervix. The body of the uterus was about the size of a three months' pregnant uterus, and inclined to the right side. Its mobility was restricted. The surface was nodular, the consistency elastic, and there was tenderness on pressure. The findings in the heart and lungs were negative.

Operation.—Dec. 15, 1903. A complete abdominal hysterectomy was performed, after separating extensive adhesions involving the body of the uterus. The patient made an uneventful recovery from the abdominal operation. Jan. 11, 1904, the vaginal tumor, which had continued to bleed, was removed.

The patient left the hospital January 31, and has continued to improve from that time to the present. A thorough physical examination, made April 15, four months after the operation, and nineteen months from the onset of the symptoms, failed to reveal any evidence of recurrence.

Microscopic Examination.—The uterus measured 18 cm. in length, 12 cm. from horn to horn, and 8 cm. in its greatest anteroposterior diameter.

It was dark red in color; the consistency was firm and elastic, and its surface smooth, with the exception of several nodules on the fundus, ranging in size to that of a hazelnut. Both appendages presented a normal appearance. The left appendage was elevated about 3 cm. above the right.

On cross-section it was seen that in the fundus, and inclining to the left, was a tumor apparently composed of a firm coagulum of blood. This was sharply circumscribed, and about 6 cm. in diameter. The upper surface of this tumor was immediately covered by peritoneum. At the sides, and separat-

ing the mass from the uterine cavity, was the musculature of the uterus, which ranged from 1 mm. to 1 cm. in thickness. There was no evident connection between the tumor and the uterine cavity.

Microscopic Examination.—We find in the center of a large coagulum of blood, varying amounts of syncytium and Langhans' cells, not unlike a typical primary chorio-epithelioma of the placental site. In a portion of the circumference of the tumor the serous covering of the uterus directly overlies the blood mass. In three places no serous covering was found, and the blood fibrin with invading syncytial cells presented at the surface.

The lateral muscular walls of the uterus became more and more in evidence from the fundus to about the level of the internal os, and from this point downward there was the usual structure of the cervix, without the presence of invading cell elements. Higher up in the musculature of the uterine body wandering syncytial cells were everywhere in evidence. Between the uterine cavity and the tumor there was not only an intact mucosa, but a distinct muscular wall containing numerous wandering syncytial cells. It is apparent, not only to the unaided eye, but under the microscope, that the growth had no direct connection with the endometrium, nor is it possible to account for its primary origin in the placental site.

The walls of blood vessels in the musculature were seen to be invaded by syncytium and Langhans' cells. No villi were found. In the blood coagulum were numerous large, irregular, branching, multinuclear masses of syncytium. Vacuoles were distributed in these masses, as well as in the isolated smaller syncytial elements, the so-called "wandering cells." In isolated fields and irregularly distributed throughout the tumor were the characteristic small polyhedral cells of Langhans.

Without entering into an extended description of the histology of the growth, suffice it to say that it corresponds with the "typical" chorio-epithelioma of Marchand.²¹

The metastatic growth in the vagina bore the same typical characteristics. There were negative findings in the tubes and ovaries.

In the above recorded 21 cases unmistakable chorio-epitheliomatous tumors have been observed in locations remote from the placental site of the uterus and fallopian tubes. In no case has it been possible to trace a direct anatomic connection between the placental site and the primary tumor.

In nearly all cases it has been possible to trace a direct clinical relation between pregnancy and the tumor formation. These tumors have arisen during the course of pregnancy, at varying intervals after the completion of normal pregnancy, following complete and incomplete abortions, while hydatidiform moles were *in situ*, and a variable time after their expulsion. In no instance has such a growth been recognized in a nullipara, though in one instance the appearance of the tumor followed the establishment of the menopause.

In primary chorio-epithelioma of the placental site the vagina is most often the seat of secondary invasion by metastasis. It is also true that primary extra-uterine chorio-epithelioma arises with greatest frequency in the vaginal walls. This is an exception to the rule that tissues which are a common seat of primary malignant growths are seldom a seat of secondary invasion by these growths. The following presents the topographical distribution of the chorio-epitheliomata in regions not connected with the placental site: Vagina, 14; lungs, 8; liver, 5; brain, 5; kidney, 5; uterine musculature, 3; intestine, 3, and 1 each in spleen, thyroid, suprarenal gland, retroperitoneal lymph glands, heart muscle, ovary, bladder, labium and mediastinum.

It was not always possible to identify the primary growth apart from the secondary metastatic growths. The vagina was believed to be the primary seat in eleven

cases, the uterine musculature in three cases, the cervix, brain, kidney and labium each in one case. In the remaining three cases it was not possible to identify the primary growth. The size was not found to be a safe guide in judging the priority of the growths. For example, in the case reported by Fiedler,⁷ the primary growth in the uterine musculature was the size of a cherry stone, while in the liver was a secondary growth the size of a child's head.

Undoubtedly small metastatic growths in various portions of the body are frequently overlooked, and subsequently disappear spontaneously. They are known to vary in size from that of a hazelnut to a child's head, and in number from one to a score or more. Multiple growths in the same organ or tissue have been repeatedly described, and in all cases there was an almost uniform appearance in the gross structure. In general, they have presented the macroscopic appearance of blood clots. As a rule, they were of firm consistency, bluish-red in color, and on cross-section presented a fibrinous-like character in the center of the blood coagulum.

In the vagina the overlying mucosa was frequently ulcerated, and through the defective covering blood escaped. Occasionally the hemorrhage was so great as to require tamponing or immediate operation.

In all cases of primary vaginal growths the hemorrhage was at first thought to come from the uterus, but direct inspection readily located the seat of hemorrhage in the vaginal tumor, and a subsequent exploratory curettage, with microscopic examination of the scrapings, excluded the presence of the growth in the uterus.

Krebs and E. Fränkel²¹ reported cases in which no hemorrhage occurred.

A case of Brault's, reported as "sarcoma angioplastique," was doubtless a chorio-epithelioma malignum, primary outside of the placental site.

In the liver was a tumor the size of an orange, and presented the appearance of a large red blood clot. Smaller ones of similar structure were found in the stomach, lungs and lymph glands. No lesion was found in the uterus and adnexa.

Histologically, the growth was composed of protoplasmic masses, which were rich in nuclei and very irregular in outline. These were vacuolated. Numerous smaller polyhedral cells, with single nuclei, resembling Langhans' cells, were intimately associated with the protoplasmic masses.

The decidual changes in the uterine mucosa in the cases of Schmorl,³ Fiedler⁷ and Holzapfel¹² are remarkable. The decidua was not unlike the decidua vera of normal pregnancy, and averaged $\frac{3}{4}$ cm. in thickness. We recognize here an analogy to the decidual formation of ectopic pregnancy.

HISTOGENESIS.

It is interesting to speculate on the genesis of these growths. We ask: Was the placental tissue malignant when *in utero*, and had metastatic invasion been instituted prior to a complete expulsion of the malignant placental tissue from the uterus? Can we conceive of a complete spontaneous expulsion of malignant placental tissue from the uterus, i. e., self-elimination of the original uterine tumor while the metastatic growths remain in distant portions of the body and continue to develop?

Is spontaneous involution of the original uterine

21. E. Fränkel (Breslau): Das Chorioepitheliom malignum (früher Deciduoma malignum). Sammlreferat. Deutsche med. Wech., 1899, No. 11, p. 177.

tumor possible? Is it possible that the primary growth at the placental site was removed by the curette or finger?

These are interesting and very important questions, which must remain for future investigations to answer.

It has been conclusively shown by Webster, Veit,²² Pick and later observers that not only chorionic epithelium, but the entire villus as well, is carried to distant parts of the body through the blood stream, and this under perfectly normal conditions.

May these deported elements proliferate to form tumor growths which may be benign in one case, malignant in another, and leave the uterus free from tumor formation?

With our present knowledge of the pathology of the placenta, we can not solve these problems. Macroscopic and microscopic examinations of the expelled placenta, of hydatidiform mole and of scrapings from the placental site afford no information, because we can not distinguish a malignant from a benign growth of the epithelial elements found in these structures.

Neumann's statement that malignancy is recognized by the epithelial invasion of the stroma of the villus has been disproven.

The atypical growth of syncytium with large and richly chromatic nuclei has been regarded by Gottschalk and others as indicative of malignancy, but this, too, has been disproven.

The proliferation of Langhans' cells and their atypical distribution was thought by Voigt to suggest malignancy, but subsequent investigations fail to substantiate his views.

Primary chorio-epitheliomatous growths outside of the placental site have developed where macroscopic examinations of the expelled mole or placenta showed none of these features (Pick,¹³ v. Guerard⁹).

The fact that syncytium under normal conditions is known to disappear spontaneously from uterine and other tissues leaves the question open as to the possibility of malignant chorio-epithelioma spontaneously disappearing from the uterus.

Under perfectly normal conditions we see the syncytium rapidly proliferating, destroying tissues as it advances, burrowing into blood vessels and carried to distant portions of the body. For all we are now able to judge, the difference in the behavior of normal syncytium and the malignant type is one of degree in its proliferating tendencies. It is probable, as Risel has suggested, that the difference between the benign and the malignant syncytial growth does not lie in these elements, but is dependent on the peculiar resistance of the tissues invaded. We find every possible gradation between the normal placenta, the hydatidiform mole and chorio-epithelioma malignum, and a transition from one to the other in the order named is possible.

Permanent healing has followed the removal of the growths, and even the partial removal, as in the case of Fleischmann,²³ in which a secondary vaginal tumor was removed, and only a portion of the primary uterine tumor was removed by the curette. Yet not only did the uterine tumor completely disappear, but there was subsequent child-bearing and complete recovery.

The microscopic examinations of the tissues scraped

from the uterus showed what appeared to be a typical chorio-epithelioma malignum.

We, therefore, are forced to the conclusion that we have no way of judging the malignancy of these growths save by the subsequent course of the case.

Schlagenhauser²⁴ and, about the same time, but independently, Wlassow²⁵ observed chorio-epitheliomatous growths in the testicle identical to those found in the female. These growths are regarded by the above observers to have the same histogenesis, i. e., that they arise from embryonic elements of the fetal ectoderm and contain both syncytium and Langhans' cells. Wlassow examined twelve teratomata of the testicle and found this peculiar cell structure in three.

L. Pick¹³ has since found a similar structure in ovarian tissue. Risel, Schmorl²⁶ and Steinhaus²⁷ have made further observations in cases of chorio-epithelioma malignum of the testicle. It is possible, though not yet proven, that such tumors may occur elsewhere in the male.

Breus (1878) recorded a testicular tumor with a secondary tumor in the heart, which Schlagenhauser regarded as a malignant hydatidiform mole in the male, and Breus later accepted his views as highly probable. In view of this case and the other testicular tumors reported by Schlagenhauser,²⁴ Risel, Schmorl,²⁶ Wlassow²⁵ and Steinhaus,²⁷ the question naturally arises, what light does this throw on the origin of teratomata, and on the chorio-epitheliomata in woman?²⁸ Certainly it establishes the theory of the fetal origin of these growths, as opposed to the theory of maternal origin. Furthermore, the epithelial covering of the villi must be regarded as being epiblastic in origin.

It is probable that in the antenatal period, when the fetus is little more than a segmentation sphere, one or more polar bodies or blastomeres become displaced and incorporated in the structures which go to make the tes-

ticle, and later develop into structures comprising all three layers of the blastoderm.

Why a complete embryo is not developed, and why the growth at times becomes malignant, are unsolved problems.

DIAGNOSIS.

From a study of these cases it is observed that the clinical diagnosis of primary chorio-epithelioma has only been made in the cases where the lesion could be directly inspected, i. e., in the vagina, labium and cervix. They were recognized by their characteristic rounded shape and bluish color, their tendency to bleed freely, and by the absence of uterine hemorrhage, together with negative findings in the uterus after exploring with the finger and curette.

The clinical diagnosis was at all times confirmed by microscopic examinations of portions of excised or curetted tissue. Without the microscope a positive diagnosis is not possible.

Tumors lying in hidden portions of the body, e. g., kidney, liver and lung, were not diagnosed with certainty without a postmortem examination.

Where the case did not end fatally, it was not possible to say that the growth was malignant, from the fact that the macroscopic and microscopic findings in these growths were in no way diagnostic of malignancy.

The ages at the time of operation were from 20 to 50 years. Twelve of the seventeen cases in which the age was recorded occurred between 35 and 41 years of age.

The following table presents the nature of the last pregnancy and the time of appearance of the symptoms and primary tumor, in relation to the last pregnancy:

- Case 1.—Hydatidiform mole *in utero*.
 - Case 2.—Eighteen weeks after normal labor.
 - Case 3.—Hemorrhage from vagina two or three months after an incomplete abortion. Tumor in vagina discovered ten months later.
 - Case 4.—Four weeks after artificial removal of hydatidiform mole.
 - Case 5.—Three months after artificial removal of hydatidiform mole.
 - Case 6.—Two months after normal labor.
 - Case 7.—Three weeks after normal labor.
 - Case 8.—Seven weeks after incomplete abortion.
 - Case 9.—One month after artificial removal of hydatidiform mole.
 - Case 10.—Three years after normal labor.
 - Case 11.—Shortly after abortion.
 - Case 12.—Six months after normal labor.
 - Case 13.—Five weeks after normal labor.
 - Case 14.—Few days after expulsion of hydatidiform mole.
 - Case 15.—Seven weeks after miscarriage at seventh month.
 - Case 16.—About three years after an early abortion.
 - Case 17.—Not known.
 - Case 18.—Four months after incomplete abortion.
 - Case 19.—Two months fetus *in utero*.
 - Case 20.—Three weeks after normal labor.
 - Case 21.—Five years and eight months after normal labor.
- Time of appearance of tumor not known; probably four years and five months after labor.

We find in this number that in one case a hydatidiform mole was *in utero* at the time of appearance of the symptoms and primary growth. In another case there was a two months' fetus *in utero*. In three cases the tumor followed incomplete abortions; in three others the abortions were complete, and in seven cases there were normal labors.

In all cases where there were vaginal or cervical tumors, hemorrhage was the symptom which led to the detection of the growth. In exceptional cases a foul-smelling vaginal discharge followed the appearance of the hemorrhage.

From the fact that these growths are so frequently located in the vagina, and that hemorrhage is an early and constant symptom, our suspicions should always be aroused by the occurrence of bleeding from the vagina

during the course of pregnancy, after the expulsion of a hydatidiform mole, an abortion or labor.

If, on inspection, such a tumor is found, it should be excised, and if on microscopic examination chorionic epithelium is found, an exploratory curettage of the uterus should be made. However, we have learned that we can not rely on the microscopic findings in the scrapings in determining the malignancy; hence, because of our present limitations, it would appear to be advisable to make a complete extirpation of the uterus when syncytial tissue is found in the scrapings. The cases which have recovered after the removal of the vaginal growth, and leaving the uterus, do not, in our present knowledge of these cases, justify us in leaving the uterus unless by an exploratory curettage the uterus is found free of all chorionic epithelium.

TREATMENT.

In view of our inability to accurately judge the character of these growths, a radical procedure of treatment should always be adopted. Vaginal growths should be excised. When the cervix is involved, a high amputation of the cervix or vaginal hysterectomy is demanded. Where, in the presence of a characteristic vaginal growth, nodules can be palpated on the surface of the uterus, or where the form of the uterus is irregular for an unaccountable reason, the possibility of a primary growth in the uterine musculature must be considered, and, though the uterine scrapings are negative, it would seem that a hysterectomy would be justifiable in the light of recorded cases in which the growths were primary in the uterine musculature.

If a characteristic chorio-epithelioma appears in the cervix or vagina during pregnancy, not only should the extrauterine growth be removed, but a total hysterectomy should be done.

It has been demonstrated that the emptying of the uterus and the examination of the fetal tissue will afford no reliable information as to the presence or absence of a malignant growth. An immediate removal of all tissues under question would, therefore, appear to be the only safe procedure.

From the fact that metastatic growths have been known to disappear spontaneously, the primary growth should be removed if possible, even in the presence of metastatic growths too remote for surgical interference. This is done in the hope that the metastatic growths may disappear spontaneously.

PROGNOSIS.

In view of the uncertainty as to the existence of metastatic growths and of the malignant intent of the growth, it is at all times necessary to give a guarded prognosis. Inasmuch as it is impossible to say that the growth is benign, and since metastatic growths may not make their appearance for an indefinite time, these cases demand careful attention for many years.

Doubtless the favorable prognosis of primary vaginal tumors, as compared with the primary growths located in less accessible regions, is accounted for by early recognition and prompt interference.

Of the twenty-one cases, twelve died and nine recovered after the removal of primary growths in the vagina, labium and cervix. In one instance recovery followed the removal of a primary growth in the vagina, and a probable secondary growth in the lung. In the fatal cases, death intervened in from a few days to eight months after the removal of the vaginal growth, and in all instances death appeared to be due to metastatic invasion of remote structures.

RESUME.

1. Twenty-one cases, including the above-recorded case, of unmistakable chorio-epitheliomatous tumors, have been observed in locations remote from the placental site. No direct anatomic connection between the tumor and the placental site was demonstrable.

2. These tumors have arisen while a fetus or hydatidiform mole was *in situ*, and at varying intervals of days and years following abortions, labors and the expulsion of hydatidiform moles.

3. The vagina was believed to be the primary seat of the tumor in 50 per cent. of the cases; the uterine musculature in 15 per cent.; the cervix, brain, kidney and labium, each 5 per cent. It was not always possible to identify the primary growth.

4. In all cases the growth presented the appearance of blood coagula, and were only identified with certainty by the aid of the microscope.

5. Nothing definite is known of the histogenesis. The degree of resistance of the invaded tissues probably determines the malignancy of these growths.

6. Microscopic examination of the tumor will demonstrate the presence of chorionic tissue, but will determine nothing as to the malignancy of the growth.

7. In primary vaginal and cervical growths it has been possible to make a highly probable diagnosis by a consideration of the history of the previous pregnancy, the occurrence of hemorrhage from the vagina, and by inspection of the tumor. The positive diagnosis was reserved for the microscope.

8. Sixty per cent. of the cases occurred between the ages of 30 and 41. The earliest was at 20 years of age, the oldest at 50.

9. Hemorrhage is the one constant symptom in the growths of the vagina and cervix, and should always arouse suspicion when occurring weeks, months or years after the termination of pregnancy, abortion or hydatidiform mole. The possibility of these growths occurring during the course of pregnancy must be borne in mind.

10. After the recognition of the primary growth outside of the placental site, an exploratory curettage is done and the scrapings examined by the microscope. If syncytial tissue is recognized, the uterus should be removed. Inasmuch as we are unable to judge the malignancy of the scrapings from the uterus in such cases, it would seem wise to anticipate the existence of a malignant growth by removing the uterus.

11. The malignancy of these growths can only be determined by the remote results. If the individual makes a permanent recovery after the removal of the primary growth, we are at a loss to know whether the growth was malignant.

12. It is necessary to give a guarded prognosis in all cases, because of the uncertainty as to the existence of metastatic growths, and the inability to differentiate a benign from a malignant growth.

100 State Street.

Health of Pilots.—The *Australasian Medical Gazette* states that the following regulation has been gazetted under the navigation act in New South Wales:

No person appointed as first class pilot shall be deemed eligible to continue to hold such position and discharge the duties thereof unless, in addition to compliance with other regulations relating to licensed pilots, at least once in each year he attends before a medical officer appointed by the treasurer, and obtains a certificate under his hand that he is in good health and not affected with any bodily or mental complaint or infirmity rendering him unfit to perform the duties of a pilot, particularly as to sight (vision and color), hearing and speech.

We understand that similar action is also being taken in Victoria.

THE DOWNES ELECTROTHERMIC CLAMPS.

FURTHER EXPERIENCE IN THEIR USE IN THE TREATMENT OF CANCER OF THE UTERUS.*

CHARLES P. NOBLE, M.D.

Surgeon-in-Chief Kensington Hospital for Women.

PHILADELPHIA.

The treatment of cancer of the uterus is one of the important questions of the day. Without treatment the disease is a hopeless one and usually causes death within two or three years.

The accepted treatment for cancer of the uterus at the present time is hysterectomy; and, without entering into details, it may be stated that cases thus operated on before the disease has apparently invaded the parametria have the following results: The primary mortality of the operation is from 5 to 10 per cent. Adenocarcinoma of the corpus uteri is cured by hysterectomy in about 75 per cent. of the cases. Epithelioma of the cervix uteri is cured in about 10 per cent. of the cases. Less than 10 per cent. of cases of adenocarcinoma of the cervix uteri are cured by hysterectomy.

Perhaps these figures would be more accurate if it were stated that this is the general average rather than the results secured by early operation. The results should be somewhat better in selected cases. My own results correspond with these figures. Taking all the cases of cancer of the uterus on which I have operated, about 20 per cent. of those subjected to hysterectomy have remained free from recurrence at the end of five years. This includes all three classes of cancer of the uterus, and the apparently high percentage of cures is due to the fact that the general average is raised by the proportion of cancers of the corpus uteri.

The alternative operation which has been practiced is amputation of the cervix in cases of cancer of the cervix uteri. The amputation has been practiced by removing the cervix with the knife and scissors, and also with the galvanocautery. The names of Sims and Schroeder are intimately associated with the first operation, and the name of Byrne with the second.

So far as statistics can determine the results of operations there is not much to choose between the results of amputation of the cervix and hysterectomy. As a matter of fact the results named by Byrne are better than those secured by hysterectomy. Every one, however, who has had large experience in dealing with statistical statements knows the difficulty of presenting statistics which will tell absolutely the truth about the subject.

The general results of operation for cancer in all portions of the body make it appear reasonable that hysterectomy should give better results than amputation of the cervix, because it is well known that, as a rule, cancer has invaded the tissues more widely than is apparent on clinical examination; and, therefore, in spite of the statistical evidence, most surgeons are convinced that hysterectomy should have the preference over amputation of the cervix in all cases in which hysterectomy is feasible. Nevertheless, it is true that no one has presented statistics so good as those of John Byrne of Brooklyn. This being true, when Dr. A. J. Downes of Philadelphia offered the profession a practical electrothermic clamp with which hysterectomy for cancer can be done without increasing the primary mortality of

HYSTERECTOMIES WITH "DOWNES CLAMPS."

Number.	Name and Date.	Marital Status or Widow.	Age at Operation.	Microscopical.	Diagnosis.	Condition of Patient Before Operation.	Operation.	Time.	Drainage.	Course.	Temp.	Subsequent History.
1	Mrs. H. 3-27-02.	W.	48	3	Squamous carcinoma of cervix.	Uterosacral ligaments invaded.	Celiotomy; pan-ophorosalpingo-lysis; clamps used first in vagina.	100 G a size in vagina.	Uterovag. fistula.	Febrile.	Died about 10 months after operation from cancer.	
2	Mrs. B. 10-5-02.	M.	50	2	Squamous carcinoma of cervix.	Parametria invaded.	Celiotomy; pan-ophorosalpingo-lysis; clamps not used first in vagina.	140 G a size in vagina.	Uterovag. fistula.	Febrile.	Died 10 months after operation from cancer.	
3	Mrs. B. 10-5-02.	M.	42	6	Papilloma of cervix.	Extensive involvement of cervix.	Celiotomy; pan-ophorosalpingo-lysis; clamps not used first in vagina.	67 G a size in vagina.	Left lobar pneumonia.	Febrile.	Unable to trace subsequent history.	
4	Mrs. C. 10-25-02.	M.	35	2	Squamous carcinoma of cervix.	Uterosacral ligaments invaded.	Celiotomy; uterovag. amputation above internal os; cervix removed from below.	115 None.	None.	Febrile.	Recurrence in seat in vagina, 9-11-03.	
5	Mrs. C. 10-27-02.	W.	33	0	Squamous carcinoma of cervix; uterosacral ligaments involved.	Uterosacral ligaments invaded.	Celiotomy; pan-ophorosalpingo-lysis; cervix removed from below.	80 G a size in vagina.	Uterovag. fistula.	Febrile.	Spontaneous healing in nine months.	
6	Mrs. M. C. 3-29-03.	M.	52	3	Squamous carcinoma of cervix.	Nephritis; parametria invaded.	Celiotomy; pan-ophorosalpingo-lysis.	80 G a size in vagina.	Uterovag. fistula.	Febrile.	Uterovag. fistula still open. Family physician reports recurrence.	
7	Mrs. K. 3-29-03.	M.	35	3	Squamous carcinoma of cervix.	Extensive involvement of cervix.	Celiotomy; pan-ophorosalpingo-lysis.	125 G a size in vagina.	Vesicovag. fistula.	Febrile.	Uterovag. fistula closed spontaneously a few weeks after operation.	
8	Mrs. C. 1-25-03.	M.	31	0	Squamous carcinoma of cervix; left hysterical flux.	Uterosacral space invaded. Prognosis doubtful.	Celiotomy; pan-ophorosalpingo-lysis.	120 G a size in vagina.	Vesicovag. fistula.	Febrile.	Uterovag. fistula apparently is closing; no involvement can be made out.	
9	Mrs. H. 11-4-03.	M.	41	3	Adenocarcinoma of cervix.	Parametria invaded; prognosis bad.	Celiotomy; pan-ophorosalpingo-lysis.	60 G a size in vagina.	Uterovag. fistula.	Febrile.	Uterovag. fistula closed spontaneously in 10 months.	
10	Mrs. H. 12-11-03.	M.	42	4	Adenocarcinoma of cervix; uterine intramural fibros-myoma.	Parametria invaded; prognosis bad.	Celiotomy; pan-ophorosalpingo-lysis.	125 G a size in vagina.	Uterovag. fistula.	Febrile.	Died five months after operation.	

the operation, it seemed to me a step in advance, and I was prepared to adopt this instrument for the treatment of cancer of the uterus, because it seemed to me that through the employment of this instrument we could secure the advantages of hysterectomy and also the advantages of the electrothermic cautery as employed by Byrne, and that, therefore, the results of hysterectomy performed by means of the electrothermic clamp should be still better than is true of hysterectomy performed in the usual manner, or the results secured by Byrne through amputation of the cervix with the galvanocautery knife together with the roasting of the adjacent parametrial tissues with the electrocautery.

At the meeting of the Southern Surgical and Gynecological Association in Cincinnati, Nov. 11, 1902,¹ I read a paper entitled "The Use of the Electric Cautery Clamp in the Treatment of Cancer of the Uterus." I reported four hysterectomies for cancer of the uterus. Three of the patients made typically good recoveries from the operation. The fourth case died mainly as the result of an accidental hemorrhage. I stated that this experience, while not large, was sufficient to convince me that the method has certain practical advantages. "It guards against oozing hemorrhage from numerous small vessels, which is so annoying in operations for cancer, and it leaves a dry field of operation to be buried under the peritoneal flaps. The special points in the method which appeal to me are: First, by its use less blood is lost during operation; second, the lymphatics are sealed up, thus lessening the risk of septic absorption and implantation of cancer; and third, more of the broad ligament is removed than by the usual operation. If the ligature is used, the needle must be passed to the uterine side of the ureter, and fear of including the ureter inevitably tends to make the ligature hug the uterus. Not only is this true, but the button which is left requires that the broad ligament tissues shall be cut directly against the cervix. With the cautery lamp, at least one-third of an inch of tissue is cooked outside of the uterus, and the tissues beyond are more or less heated. This is an absolute advantage, unless experience shows a certain percentage of ureteral fistulae from cooking this structure."

I wish to present the additional cases operated on since that date, together with the present condition of the cases already reported and those operated on since the date of my last communication.

In justice to the method it should be stated that the ten cases operated on by means of the electrocautery clamp were, without exception, advanced, or, rather, unfavorable cases. A number of them would have been refused operation by the ordinary methods. In the first case the uterosacral ligaments were involved. In the second case the parametria were invaded. In the third and fourth cases the cancer of the cervix was extensive. In the fifth case the uterosacral ligaments were invaded. In the sixth case the parametria were invaded and the patient had also a chronic nephritis. In the seventh case there was extensive involvement of the cervix and the prognosis was doubtful. In the eighth case the uterovesical space was invaded and the prognosis was doubtful. In the ninth case the parametria were invaded and the prognosis was bad. In this case the disease was far advanced and operation would not have been undertaken by the ordinary methods. In the tenth case the parametria were invaded, the prognosis

1. Am. Gynecology, December, 1902.

was bad and the operation would not have been undertaken by the ordinary methods.

This analysis of the cases shows that the results secured in this series of ten cases should not be taken as typical nor as representing what can be secured by the method in selected cases.

In discussing the advantages and disadvantages of the method in my previous communication, I stated that in my judgment an objection to the method, theoretically, seemed to be that it might well happen that a larger percentage of fistulæ would follow the use of the electrothermic clamp than the usual methods of operation. My experience has borne out this theoretical consideration, because of the nine cases there have been three ureterovaginal, and two vesicovaginal fistulæ. In one case of ureterovaginal fistulæ there was a vesicovaginal fistula in addition.

I have had the remarkable experience that of the three ureterovaginal fistulæ, two have healed spontaneously and one gives every appearance of spontaneous closure.

The first ureterovaginal fistula closed nine months after the operation. The second ureterovaginal fistula gives every appearance of closure five months after operation. The third ureterovaginal fistula closed ten weeks after operation. The first vesicovaginal fistula is still open thirteen months after operation, and the patient now has a recurrence. The second vesicovaginal fistula closed spontaneously within a few weeks after her discharge from the hospital.

This experience bears out the theoretical objection to the clamp that it would give a relatively high percentage of fistulæ. As to the ultimate results secured, the first patient died about ten months after operation. The second died about ten months after operation. The third patient has been lost sight of. The fourth patient died largely as the result of hemorrhage during the operation. The fifth patient, a very unfavorable one, is still alive, but undoubtedly will die from the disease, as there is an extensive growth. The sixth patient, a most unfavorable one, shows no evidence of recurrence thirteen months after the operation. The seventh patient, also an unfavorable case, has a recurrence. The eighth patient, also an unfavorable one, shows no evidence of recurrence one year after the operation. The ninth patient, a very unfavorable one, shows no evidence of recurrence. The tenth patient, a very unfavorable one, died five months after the operation.

It has always been my habit to present the unfavorable side of operations as well as the more pleasing side, and therefore I have made this supplementary report.

Those who oppose operation for cancer might conclude that their contention was supported by this experience. I do not feel at all that this is true, as this series of cases was a most unfavorable one, and undoubtedly the patients embraced in this series have suffered much less as a result of operation than they would have done without it. It seems to me that the true conclusion to be drawn from my experience with this series of cases is that the most pressing need in the treatment of cancer of the uterus is that the diagnosis of the disease shall be made early, in order that the patients may be submitted to early operation. In that case I feel confident that much better results can be secured.

So far as the electrocautery clamp is concerned, I believe that we should secure better results with it than with the ligature, knife and scissors, used after the

classical technic. Also, I am firmly convinced that hysterectomy can be performed with relative safety in a more advanced type of cases with the electrocautery clamp than is true of the classical technic. This is because a dry field is left after operation. On the other hand, I am satisfied in this class of cases that a definite percentage of ureteral and vesical fistulæ will be produced.

THE INVASION OF CARCINOMA CERVICIS UTERI INTO THE SURROUNDING TISSUES

AND ITS BEARING ON THE MORE RADICAL OPERATIONS FOR THAT DISEASE.

JOHN A. SAMPSON, M.D.

Resident Gynecologist, the Johns Hopkins Hospital; Instructor in Gynecology, Johns Hopkins University.

BALTIMORE.

(Concluded from p. 1275.)

OPERATIVE TREATMENT OF CARCINOMA CERVICIS UTERI¹³

It is evident that hysterectomy alone seldom cures this condition. As, for instance, in 12 of 15 cases in which the more radical operation has been done, the growth was found to have extended beyond the uterus, as has been mentioned in this paper. In the Johns Hopkins Hospital there have been 63 vaginal hysterectomies, with 5 deaths; 26 combined abdominal and vaginal hysterectomies, with 5 deaths, and 67 abdominal hysterectomies, with 16 deaths. The comparison of the percentage of cures and also the primary mortality in these three classes of cases is of no value, for the abdominal or combined abdominal and vaginal operation has in many instances been used instead of the vaginal operation, because the growth was too far advanced for the vaginal route. It can never be hoped that the abdominal operation will be attended with as low a primary mortality as the vaginal; on the other hand, by the vaginal route the wide excision of the parametrium and pelvic lymph nodes is impossible.

Whether one shall employ the vaginal route or the more radical abdominal operation in these cases can not be determined from statistics, for sufficient time has not elapsed since the use of the more radical abdominal operations to furnish enough cases to compare with those removed by the vaginal route.

Olshausen¹³ has recently endeavored to compare the results of the two methods of operating, and concludes that for the majority of cases he prefers the vaginal hysterectomy. He states that he has had 671 cases, of which 31.6 and 44 per cent. (two periods) were operable, with a primary mortality of 6 per cent.; 74 per cent. of the cases operated on were free from recurrence at the end of two years, and 38.8 per cent. at the end of five years. He compares these with Wertheim's 120 cases, of which 40.3 per cent. were operable, with a primary mortality of 20 per cent., and 77 per cent. free from recurrence at the end of two years. Five years have not elapsed since Wertheim's first cases were operated on, so one has no way of comparing the results at the end of this time. Our results, with less than 25 per cent. free from recurrence at the end of five years, as compared with Olshausen's 38.8 per cent., can only be explained on the ground that in the patients who were operated on by him the growth was limited to the uterus

¹³ Olshausen: Zum Vergleich der vaginalen und abdominalen Operationsmethode bei Carcinoma uteri, Zeitschrift f. Geburt. u. Gyn., 1903, vol. 1, No. 1, pp. 1-6.

in more instances than in our cases. The most ardent supporter of the vaginal route must admit that only those cases can be cured by a vaginal hysterectomy in which the growth is limited to the uterus. Even Ols-hausen states that it is advisable to use the abdominal route in those cases in which the parametrium is involved, so that the ureters may be the more safely dissected from the cancerous tissue.

Could one operate on cases before the growth had extended beyond the uterus, then the vaginal operation would be the operation of choice, as it is the one attended with the lowest primary mortality. In view of the fact that clinical experience can count for so little, the decision as to the choice of an operation must be based on a study of the parametrium and the pelvic lymph nodes in the so-called operable cases. The operation which should give the highest percentage of cures is one in which the lymphatics were removed from the sides of the pelvis, and *en masse* with them the growth and uterus, including all the tissue from pelvic wall to pelvic wall.

DESCRIPTION OF A MORE RADICAL OPERATION.

1. Building up of the patient before the operation, rest in bed, and treatment of anemia, if present, are all very essential if anything can be gained by it; on the other hand, some patients seem to lose by a too long preliminary preparation.

2. A preliminary curettage of the growth seems to me to be unnecessary, except in occasional instances, where it is the only way available to control the bleeding in order that the patient may be in a better condition to stand the operation. Theoretically, it would seem to be attended with danger of causing a spread of the disease. In one case in this hospital where the cervix was curetted the cervix and tissue about it became infected, probably from organisms present in the necrotic growth, causing an inflammatory condition about the cervix, and as a result the operation had to be postponed. The patient left the hospital, later refusing operation. In two other cases in which there was a preliminary curettage of the cervix, I painted the raw area with a gum acacia suspension of lamp black, thinking that it might get into the lymphatics and thus I would be able to study its distribution in the specimen removed later by operation. The operation in one case was five days and in the other one week after the curettage. The lamp black was found in the lymph spaces near the raw area caused by the curettage, but none in the parametrial or pelvic lymphatics. The danger of infection occurring during the operation is minimized by wiping the vagina out with gauze just before burning across it, and clamping it with two large right angle clamps, and burning between the two clamps with a Paquelin cautery. The uterus, with the vaginal cuff clamped below the growth, may thus be removed with very little danger of infecting the field of operation.

3. The preliminary catheterization of the ureters certainly aids during the operation, and should be done before the patient takes the anesthetic. I have operated with and without having the ureters catheterized, and in two cases have had only one catheterized, and find that the catheterized ureter is much easier to locate and is a very important landmark in controlling the vesicovaginal and uterovaginal plexuses of veins which are close to the ureter near its entrance into the bladder. The ureters can usually be catheterized with the patient in the Sims posture. This posture is not as generally satisfactory as the knee-chest, but is much easier for the pa-

tient, and unless she is very stout is usually just as satisfactory for the physician.

4. After the patient is anesthetized the passing of a rectal tube will frequently relieve any distension of the rectum, if gas is present, and this should be left in the rectum during the operation, for it keeps the rectum empty and can easily be palpated, and so serves as a means of locating the rectum, as the renal catheter does the catheterized ureter.

5. The patient is now placed in the high Trendelenburg position and an incision is made from the umbilicus to the symphysis down to the peritoneum, but not through it. The peritoneum is now pushed back from the anterior abdominal wall and a transverse incision is made through it just above the bladder. This gives rise to a peritoneal apron, which, after pushing back the intestines, is sutured to the posterior pelvic wall with catgut, thus shutting off the general peritoneal from the pelvic cavity and keeping the intestines from the field of operation, and doing away with bolsters and gauze pads in the general peritoneal cavity. This exposure, which was first described by Poter,¹⁴ is all that could be desired, especially if a self-retaining retractor is used and the sides of the abdominal incision are protected with gauze. It seems to me that the incisions proposed by Amann¹⁵ and Mackenrodt¹⁶ where the recti are cut, are unnecessary. I have used the Poter incision in twelve or fifteen of these more radical operations, and think it is much to be preferred to the older methods of packing back the intestines with gauze. It protects the abdominal cavity better and possibly also diminishes the shock of the operation, although I have seen patients at the close of an operation where this was used apparently as much shocked as in other cases where it has not been used. This peritoneal flap is released at the close of the operation, and the incision in the peritoneum is closed transversely.

6. After obtaining a satisfactory exposure, the high Trendelenburg position may be lowered if so desired. The ovary on the left side is now grasped by a pair of forceps and pulled outward and downward, thus making taut the ovarian vessels and the peritoneum covering the iliac vessels. The peritoneum is now split below the parallel to the ovarian vessels as high up as the iliac vessels. The ureter will lie with its sheath on the lower peritoneal flap and be out of harm's way. The ovarian vessels and the round ligaments are now cut. Beginning at the division of the common iliac artery (the apex of the pelvic axilla), dissect downward, removing the fat and lymphatic structures, including lymph nodes from along the iliac vessels, thus exposing the pelvic vessels and removing the tissue *en masse*. By using a blunt dissector or a small wad of gauze on a clamp, and always dissecting down along the vessels, hemorrhage may be avoided. The uterine artery is exposed and ligated at its origin. I do not think that there is any operative advantage to be gained in ligating either the internal iliac artery or its anterior branch over the ligation of the uterine artery alone, and there is this disadvantage, that the nutrition of the pelvis is interfered with, thus predisposing it to infection and possibly necrosis. The other side is treated in a similar manner. If difficulty is experienced in locating the uterine artery, first find

the obliterated hypogastric and follow that back, taking care not to injure its superior vesical branch, and this will lead one to the uterine vessel.

7. The tissue on either side is now dissected from the sides of the pelvis, thus freeing the bladder and uterus with all the tissue from pelvic wall to pelvic wall, including the lower portion of the ureters in one mass.

8. The uterus is now drawn upward, thus making the uterosacral ligaments taut; these are cut on each side, care being taken to avoid the ureter at this place; the vagina is now freed posteriorly from the rectum, care being taken to go well out toward the rectum and give the cervix and vagina a wide margin. This allows the uterus to be lifted further out of the pelvis.

9. The uterus should next be pulled upward toward the umbilicus and the bladder dissected free from the cervix down to the entrance of the ureters into that organ. If the bladder is adherent an opening should be made into it above the adherent portion, and with a finger in the bladder the exact area involved may be palpated and excised. This opening into the bladder aids in freeing the bladder in all cases in which there is any evidence of the growth being adherent to it.

10. The next step is a very important one, and that is to control the vaginal veins which go to form the vesicovaginal and uterovaginal plexuses of veins. These veins are situated for the most part lateral to the ureters at this level, and give rise to very troublesome bleeding unless properly controlled. The ureter should be freed just at its entrance into the bladder, and this is the one point in the operation where the catheter in the ureter is of the most value. The veins lateral to the ureter are now tied, and this will save much unnecessary bleeding and does away with the preliminary sutures described by me in previous publications.

11. The treatment of the ureters should occupy one's attention next. There is now situated in the pelvis a mass of tissue consisting of the uterus and all the tissue from pelvic wall to pelvic wall, through which the ureters pass. This tissue is held in the pelvis by the vagina; the ureters, which pass through it; the vesicovaginal and uterovaginal plexuses of veins; by the tissue uniting the vagina to the rectum posteriorly, and by similar tissue extending from the lower portion of the parametrium to the bottom of the pelvis. Whatever is done, the peri-ureteral arterial plexus must be guarded; otherwise there is liability of ureteral necrosis; and also, if possible, the ureteral sheath should be preserved, as it protects the ureter and its blood vessels, as has been explained.

(a) If the growth has apparently extended out to or beyond the ureters, and especially if there is any evidence of compression of the ureters by the growth, they should be cut off just within the parametrium and also at their entrance into the bladder.

(b) On the other hand, if the ureters are apparently free, it is probably best not to resect them, for an implanted ureter will not protect the patient from an ascending renal infection as well as one with a natural orifice, and we must realize that a most important accessory factor in the causation of ascending renal infection is a diseased ureteral orifice, and especially a strictured one. Unfortunately, a post-operative cystitis seems inevitable in these cases, and while the severity of this may apparently be lessened by making a vesicovaginal fistula, nevertheless the excision of the lower ends of the ureters in every case needs further clinical support. The following procedure seems best: Beginning at the entrance of the ureter into the parametrium,

an incision is made through the lateral wall of the sheath for its entire length, and the ureter is very carefully shelled out, taking care not to injure its peri-ureteral arterial plexus. In doing this one realizes the importance of having ligated the vaginal veins as has been described.

12. After having disposed of the ureters either by having resected their lower ends or else shelled them out of their sheath and gently drawn them to one side, the cervix must be freed all around posteriorly and laterally down to the vagina. This is difficult for there are always troublesome vessels here, the loss of control of which may give rise to very serious bleeding. This is the only place in the operation where I think the cauterizing clamp can be used with advantage, and I have tried it here, but prefer clamping with long artery clamps and cutting between, and then ligating with catgut, or else passing the catgut sutures first, with a large curved needle, well out toward the pelvic wall, and after tying, cutting internally to the ligature.

13. A wide excision of the upper portion of the vagina is very essential in these operations. On the other hand, I think that there are disadvantages in removing large portions of uninvolved vagina, for the bladder will lose the support afforded by the anterior vaginal wall. In order to determine how much of the vagina should be removed, I have found very serviceable the end of a spool which has been covered with gauze and grasped by a heavy pair of Jacobs' forceps. If this is inserted in the vagina, by palpation one can easily feel the rim of the spool and so determine how much of the vagina should be removed.

14. After dissecting the vagina free down to a point determined by palpating the end of the spool in the vagina, the vagina is first wiped dry from below, and then clamped with two right-angle clamps and burned across between the two clamps with a Paquelin cautery. The specimen, the vaginal end of which is closed by the upper right-angle clamp, is removed through the abdominal incision. The lower clamp is now released and the anterior and posterior vaginal walls are grasped with forceps, and a piece of gauze is forced through the vagina from above in order to remove all traces of necrotic material which may not have been removed when the vagina was wiped out before clamping and burning across it.

15. The ureterovesical implantation: The bladder should first be freed laterally and anteriorly so that the ureter may reach the bladder with as little tension as possible. The ureter in the lower peritoneal flap should be drawn down to the bladder. The opening into the bladder may be made in various ways. A long pair of forceps may be introduced into the bladder through the urethra and the bladder wall pushed out in a portion of the bladder as near the original ureteral orifices as possible, but at the same time in a portion of the bladder which has a good blood supply and which the ureter can reach without tension. An incision about 1 cm. long should be made in the bladder and the forceps pushed through. The end of the ureter may be split open for a distance of from 3 to 5 mm. and after freeing it from its sheath for 1.5 to 2 cm. it is grasped by the forceps and drawn into the bladder. Another way of drawing the ureter into the bladder is to grasp the bladder wall with two thumb forceps, at the place chosen, as stated above, in which the ureter is to be implanted. Now incise the bladder between the forceps, making an incision from 1 to 1.8 or 2 cm. long. The split ureter may now be drawn into the bladder by a suture armed with two

needles which is first passed through the end of the ureter and then into the bladder opening and out through the bladder wall, about 1 to 1.8 cm. beyond the incision. After having drawn the ureter into the bladder (by forceps or by the suture), the bladder wall should be sutured with mattress sutures of fine silk to the ureteral wall, the sutures including only the muscular coats of the bladder and ureter. Usually 2 or 3 sutures will be sufficient, taking care not to compress the ureter. If possible, have the ureter pass through the bladder wall in an oblique direction. Care should be taken that the ureter will not be kinked when the ureter and bladder are in the position they will assume at the close of the operation, and that the ureter is not compressed by the sutures, causing a stricture.

The most important feature of the implantation is that the ureteral sheath and peritoneal flap are now sutured to the bladder wall. This relieves to a great extent the tension of the implantation and the ureteral sheath is preserved and the blood supply of the ureter protected. If possible, fix the site of the implantation by suturing the bladder at this place to the side of the pelvis.

I have made 14 ureterovesical implantations in women for various causes, and 25 in dogs, and have tried the method previously reported by me,¹⁷ and also the Budinger¹⁸-Witzel¹⁹ implantation, but think that, while both of the latter have their advantages, the one described above will be the most successful in the greatest number of cases.

16. The vesico-uterine peritoneal fold should be sutured to the anterior vaginal wall and the recto-uterine fold to the posterior vaginal wall. A small gauze drain is now placed in each side of the pelvis and out through the vagina, taking care that they do not come in contact with the ureters. All raw areas are now covered with peritoneum.

I have done 15 of these more radical operations, resecting the trigonum of the bladder and reimplanting both ureters in one, resecting and reimplanting the lower ends of both ureters in another, and resecting the lower end of one ureter and reimplanting in the bladder in two cases. Three of the 15 cases have died, one on the fifth day from intestinal obstruction, and two from ascending renal infection, one dying on the ninth day and the other on the seventeenth. In the two cases dying from renal infection the ureters were resected in one but not in the other. Ureteral necrosis occurred in one case in which the ureters had been dissected free.

The post-operative treatment of these cases is most important, and especially so is the care of the bladder. Post-operative cystitis seems almost inevitable. It seems best that the patients should be catheterized every three hours with a two-way catheter and the bladder irrigated with salt solution after the catheterization. Urine cultures should be taken frequently and cystoscopic examinations made, and, if a severe cystitis develops, I think that the best treatment is to make a vesicovaginal fistula. This may be done without an anesthetic and closed without one.

It must be borne in mind that the object of the surgeon should be to cure as large a percentage as possible

17. Sampson: The Importance of a More Radical Operation in Carcinoma Cervicis Uteri, as Suggested by Pathologic Findings in the Parametrium. *Johns Hopkins Hospital Bulletin*, 1902, vol. XIII, pp. 299-307.

19. Witzel: Extraperitoneale Ureterocystostomie mit Schrägkanalbildung. *Cent. f. Gyn.*, 1896, vol. XX, pp. 289-293.

of all cases coming under his care. It is evident that the more radical operations extend the operability of cancer of the uterus, and possibly cases may be cured which previously would have been considered inoperable. On the other hand, we must not forget that the primary mortality is higher, and this must be taken into consideration in estimating the percentage of cures. The first demand is a wide excision of the primary growth and the removal of the pelvic lymph nodes is of secondary consideration, for they are probably not involved in over 50 per cent. of the operable cases, and in those cases in which they are involved we can not hope to remove all the involved lymph nodes in every instance.

For the above reasons we must consider two distinct classes of operable cases:

1. Patients where the uterus is freely movable and the growth apparently early.

2. Those in which the growth is apparently extensive and its removal difficult, the so-called "border-line cases."

In the first class of cases the patients are usually in good condition and the operation relatively easy. In these cases we should try to do as thorough an operation as possible. The lymphatics should be removed from the sides of the pelvis, the ureters freed and all tissue lateral to the cervix removed. We are thus able to improve the chances of a cure, and also, the patient being in excellent condition and the parts freely movable, the operation can be quickly accomplished, and with a low primary mortality.

In the second class of cases the patients are apt to be in poor condition and the extensive growth makes the operation very difficult. If the operation is indicated, the first demand is the removal of the primary growth. The removal of the lymphatics should be a secondary consideration and should be reserved for the last, and only removed if the condition of the patient warrants it, for we should expect them involved in only about from 50 to 60 per cent. of these cases. In these cases the operation is difficult and the primary mortality necessarily high, especially as the patients are apt to be in poor condition and unable to stand a severe operation. It seems that unless all can be removed, nothing should be tried, for severe operations are not justifiable for gaining very uncertain and temporary palliative results.

These are the cases in which excisions of the lower ends of the ureters and portions of the bladder are justifiable if indicated. By so doing I believe that we may hope to cure some of these cases, for the parametrium apparently is able to temporarily check the further advance of the disease, and by a wide excision of the entire growth we should expect to cure these cases, unless the disease has metastasized to parts which can not be removed.

CONCLUSIONS.

1. The invasion of carcinoma cervicis uteri into the surrounding tissue manifests itself clinically:

First, in the large per cent. of the cases (over 60 per cent. of the cases admitted to this hospital) in which the disease is not diagnosed until after it has extended beyond operative treatment.

Secondly, in the still larger per cent. of the cases (over 75 per cent. of the cases operated on in this hospital after a period of five years or more) in which the growth returns after the removal of the uterus for this disease, showing that at the time of the operation the cancer had already extended beyond the uterus, and on this account hysterectomy alone seldom cures this disease.

2. A careful study of the specimens removed by the

more radical operations (that is, where an attempt has been made to remove the lymphatics from the sides of the pelvis, and with them the uterus and growth, with all the tissue from pelvic wall to pelvic wall) has shown that in 12 out of 15 of the so-called "operable cases" the growth had extended beyond the uterus at the time of the operation, demonstrating that, at least in these 12 cases, hysterectomy alone would not have removed the entire diseased condition. In seven of these cases there was a direct extension of the disease from the cervix. There were metastases to the parametrial lymph nodes in four cases, while an apparent metastasis to a parametrial lymph space (at some distance from the cervix) was found in only one case. In 12 cases in which the pelvic lymph nodes have been studied, cancer has been found in 6. Further investigations of the same cases may show an even greater number in which the growth is not limited to the cervix. The study of these cases has shown that there is no relation between the size of a primary growth and the presence or absence of lymphatic involvement, and that only by the use of the microscope can we make a positive diagnosis of the presence or absence of metastases in the parametrium or pelvic lymphatics.

3. A study of the relation between the cervix and the neighboring parts shows that this is altered by the position of the uterus in the pelvis, i. e., whether in anteposition or retrorposition, high in the pelvis or in *descensus*, and especially the left and right lateral positions of the uterus. The position of the uterus in the pelvis must be considered a factor in determining what parts may first be involved in the extension of the disease.

4. The relation between carcinoma cervicis uteri and the ureters manifests itself clinically:

First, in renal insufficiency resulting from a compression of the ureters by the growth.

Second, in the frequency of accidental injury to the ureters occurring during operation for the removal of the growth, there having been in the Johns Hopkins Hospital 19 cases of accidental injury to the ureter in 156 hysterectomies for carcinoma of the cervix, as compared with only 11 similar injuries in 4,513 other major gynecologic operations, Jan. 1, 1904.

5. The anatomic relation between the ureters and the cervix shows that this relation is altered by the position of the uterus in the pelvis, and that the lower end of the cervix is very near the ureters, and that this distance may be less than 5 mm., especially in the lateral displacements of the cervix: so that it would take but very little extension of the growth either by direct invasion or by metastases for it to reach or extend beyond the ureters.

6. A study of the specimens removed in the more radical operations demonstrates the frequency of the involvement of the parametrium by a direct extension of the growth (in 7 out of 15 operable cases), and also by metastases, especially to the parametrial lymph nodes (in 4 out of 15 operable cases, and in 3 of the 4 cases the parametrial lymph nodes were involved without there being a direct extension of the growth into the parametrium), and for these reasons the ureters pass through tissue which should be removed.

7. Anatomic, experimental and clinical studies show that, while many liberties may be taken with the lower ends of the ureters, their blood supply must be preserved, otherwise necrosis will occur; and that the most important etiologic factor in the causation of ureteral necrosis is injury to the periureteral arterial plexus from

roughly handling the outer-perimuscular fibrous coat of the ureter, in which these blood vessels are imbedded. Other factors are also important in the causation of ureteral necrosis and should be guarded against, as exudates, especially if infected, gauze against the ureter, necrosis of the surrounding tissues, and general lowered resistance of the patient.

8. The relation between carcinoma cervicis uteri and the bladder manifests itself clinically:

First, the bladder wall may become involved in the anterior extension of the disease, and with the necrosis of the cancerous tissue a vesicovaginal fistula is formed.

Second, in the frequency of accidental injuries to the bladder in the operative treatment of this disease, there having been 17 such injuries in 156 hysterectomies for carcinoma cervicis uteri in the Johns Hopkins Hospital.

Third, in the frequency of cystitis following these more radical operations, suggesting that the operation must be considered an accessory etiologic factor in its origin. Cystitis has occurred in 12 out of 16 cases in which I have followed the bladder conditions after these operations, resulting in ascending renal infection and death in two cases. In 3 of 4 cases in which the bladder apparently escaped an accidental vesicovaginal fistula was present.

9. As a result of the removal of the uterus, with cervix and upper part of the vagina and parametrium on each side, a large area of the bladder loses its natural support, and in addition its blood and nerve supply is injured, so that it is unable to resist infection, and cystitis occurs.

10. The best surgical treatment for infection in any part of the body is incision and free drainage, together with rest of the part diseased, and apparently that is what a vesicovaginal fistula does for these cases.

11. The excision of portions of the bladder adherent to the growth improves the chances of a cure, and the presence of a vesicovaginal fistula apparently lessens the severity of a postoperative cystitis and the dangers of an ascending renal infection.

12. The relation between carcinoma cervicis uteri and the rectum manifests itself clinically in the rectovaginal fistulae resulting from the invasion of the rectum by the growth and by the accidental injuries to the rectum occurring during hysterectomy for the disease.

13. The relation between the cervix and the rectum is altered by the position of the uterus in the pelvis, and the invasion of the rectum by carcinoma cervicis uteri may occur by a direct extension of the growth either through the cul-de-sac, the surfaces of which may become adherent, or the posterior vaginal wall may become involved and the rectum secondarily invaded from the vagina, or in the lateral positions of the uterus the growth may extend across the obliterated cul-de-sac from the parametrium, which lies in front of the rectum, and which may have been invaded by the growth.

14. The relation between carcinoma cervicis uteri and the vagina manifests itself in the direct invasion of the vagina by the primary growth and in the so-called vaginal implantations. A wide excision of an involved vagina is most important; on the other hand, the removal of long portions of uninvolved vagina weakens the bladder and makes the closure of raw areas more difficult.

15. A study of the pelvic lymph nodes shows that they are involved in from 30 to 50 per cent. of the operable cases, and that there is no relation between the size of the primary growth and the presence or absence of metas-

tases to the pelvic lymph nodes. Furthermore, a large node is not necessarily cancerous and a small one may contain cancer. On this account the pelvic lymph nodes should be removed in every instance of the operative treatment of this condition, if the condition of the patient warrants it.

16. The importance of an early diagnosis can not be too strongly emphasized, for by it the operability and percentage of cures are increased and the primary mortality is lowered.

17. Past clinical experience and a study of the specimens removed by the more radical operations has taught us that hysterectomy alone seldom cures this disease, and that the operation which will give the highest percentage of cures is one in which the lymphatics are removed from the sides of the pelvis and *en masse* with them the growth and uterus and all the surrounding tissue from pelvic wall to pelvic wall. What shall be done with the lower ends of the ureters which pass through this tissue which should be removed? If the growth extends out to or involves the ureteral sheath, the lower ends of the ureters should be sacrificed and the renal ends implanted in the bladder, taking care to secure the ureteral sheath and the peritoneal flap on which the ureter with its sheath lies, to the bladder, in order to relieve the tension of the implantation and protect the ureter. If an attempt is made to dissect an adherent ureter free, the cancer is not only apt to return, but ureteral necrosis will probably result. Why not resect the lower ends of the ureters in every instance? Postoperative cystitis seems to be inevitable, and an implanted ureteral orifice is an injured one; and, while suturing the ureteral sheath and peritoneal flap to the bladder, which may be freed, relieves in a measure the tension of the implantation, nevertheless there must be some present on account of the amount of ureter resected, and a ureter implanted into the bladder under tension means a ureteral stricture. Animal experimentation and clinical experience show that an injured ureteral orifice, especially if a stricture is present, is very apt to lead to ascending renal infection in the presence of cystitis.

It would seem that with our present knowledge of the subject the resection of the ureters should be restricted to those cases in which there is apparently evidence of the growth having extended out to or beyond them. If the growth has apparently not invaded the ureteral sheath, then the ureteral sheath may be split open by means of an incision made through its lateral surface and the ureters very carefully shelled out. While there is danger of ureteral necrosis as a result of shelling the ureter from its sheath, if the outer coat of the ureter is handled very carefully this danger is reduced to a minimum, and in time the ureter will form a new sheath from the tissue in which it becomes imbedded.

If the bladder is adherent to the growth, the portion of the bladder adherent should be excised, for the first demand is a wide excision of the primary growth, and a vesicovaginal fistula apparently lessens the severity of cystitis and the dangers of ascending renal infection. After the operation in these cases in which the bladder is intact, frequent catheterizing of the bladder followed by irrigation is indicated, and if cystitis develops the formation of a vesicovaginal fistula apparently offers the best chance for a cure and lessens the danger of renal infection. The vesicovaginal fistula may be made and closed without the use of a local or general anesthetic.

18. Are these operations justifiable? I have done 15, resecting and implanting both ureters in one, resecting

the trigonum of the bladder and reimplanting both ureters in another, resecting and implanting one ureter in two. In the remaining 11 cases the ureters were dissected free and ureteral necrosis occurred in only one. Three have died, one on the fifth day from intestinal obstruction and two from ascending renal infection, one dying on the ninth and the other on the seventeenth day. In these last two cases the ureters were resected in one, but not in the other. So far, I have not lost any from immediate effects of the operation itself. The duration of the operation has varied with the difficulties of obtaining a satisfactory exposure, and also with the extent of the growth, that of the longest being four and a half hours and the shortest two hours and ten minutes. Several of these cases have been in a very critical condition at the close of the operation, emphasizing the narrow margin with which one has to work and the importance of an exact knowledge of the anatomy and pathology of the parts concerned, for any "nutting" will surely result in the loss of life, which is especially true in the so-called "border-line cases." The surgeon who is unwilling to learn thoroughly the retroperitoneal anatomy of the pelvis, and who is not in a position to recognize and meet the vesical and ureteral post-operative complications, should not attempt such an operation. The large percentage of recurrences in the so-called operable cases demands a more radical operation. Clinical experience shows that this operation is possible; but, on the other hand, that it is difficult unless one is thoroughly familiar with the anatomy of the parts concerned, and that the dangers of post-operative complications are great, thus requiring special training and a most careful attention to the details of the operation, which should not be learned entirely on patients.

A study of the specimens removed by these more radical operations shows that the disease has already extended beyond the cervix in a large percentage of the cases (12 out of 15 cases) at the time of operation, thus demonstrating why hysterectomy alone so seldom cures this disease. On the other hand, apparently the lymphatics of the parametrium and of the pelvis are able to arrest temporarily the progress of the disease, and if these are removed with the disease we should expect a cure in many instances in which the disease has extended beyond the uterus. Some claim that when the disease has extended beyond the cervix, either by direct extension or metastasis, that the case is hopeless. If it can be shown in from five and ten years from now that patients are living and free from cancer, in whom there was found to have been an extension of the disease from the cervix (as shown by the microscope) at the time of the operation, then these more radical operations are justifiable. On the other hand, we will never know whether or not they are justifiable unless they are done, and the specimens removed very carefully studied in order to form a basis from which to draw conclusions.

19. The object of the surgeon should be to cure as large a percentage as possible of all cases coming under his care, and, while the more radical operation not only increases the operability of cancer and also the percentage of cures, it is at the same time attended with a higher primary mortality, which is especially true in the so-called "border-line" cases, where the operation is difficult and the patients are usually in poor condition. For these reasons we must consider two distinct classes of operable cases:

(a) Those where the uterus is freely movable and the patient in excellent condition, thus permitting a thor-

operation, which can be quickly and easily accomplished and with a low primary mortality.

(b) The so-called "border-line" cases, where the growth is extensive and the patient is apt to be in poor condition. These patients usually will not stand a very severe operation, and on this account the first demand is a wide excision of the primary growth, and the removal of the pelvic lymphatics should be reserved for the last, and attempted only if the condition of the patient warrants it. The primary mortality will be high in the operative treatment of these cases. Still, we should hope to be able to save a few by a wide excision of the primary growth, even if the lymph nodes are not removed, for they are probably not involved in over 60 per cent. of these cases.

DISCUSSION

ON PAPERS BY DRs. FINDLEY, NOBLE AND SAMPSON.

DR. WILLIAM H. WATHEN, Louisville, Ky., said that a number of years ago a few of our progressive surgeons made a claim for a more radical operation for cancer of the uterus, especially when it had its origin in the cervix and that we found surgeons opening the abdomen and dissecting out the invaded tissues. The operation was prolonged and the immediate results were far more fatal than were those of previous methods. Dr. Wathen at that time took the position that this radical operation was not justifiable, and he has had no reason to recede from that position; nor has he seen statistics that justify a recession. The mortality is greatly increased, especially at the hands of inexperienced operators. It is impossible to dissect out all the infected glands. The larger glands may be dissected out, but what is the use when a large number of infected smaller glands that can not be discovered are left? Secondary invasion is bound to occur. Therefore, in his opinion, the operation mentioned is not justified. He said that we should go as far beyond the area of the cancer as possible, but should not prolong the operation unnecessarily. Furthermore, in these protracted cases, we never know when or how far the glands are invaded. Sometimes they are involved in the early stages, and sometimes not till later. The plan suggested by Dr. Noble would be a very good one if it could be applied in the proximity of the ureters without the danger of injury, which he has reported, for the reason that the method might destroy some of the cancerous tissue that otherwise would be left in the ligature or clamp and cause infection.

DR. JOHN G. CLARK, Philadelphia, said that notwithstanding the more radical means which have been instituted to permanently eradicate cancer, as yet there does not appear to have been a great decrease in the ultimate mortality further than the reduction due to more rigid and early examination and earlier operation. Therefore, hope lies in an early and radical operation. He said that the great merit of Dr. Sampson's work is that it does not rest on mere theory, but is based on the most careful histologic study of metastases to the pelvic lymph glands and their surrounding structures.

From 1894 to 1897, while Dr. Clark was engaged in the perfection of the radical operation described by Riess and himself, he was most enthusiastic as to its possibilities, and believed that if he could succeed in extirpating the pelvic lymph glands he would greatly enhance the curative value of the radical operative measure, but his experience since that time has led him to formulate the working hypothesis that if the glands are found after removal to be the seat of metastatic foci, the prognosis is bad. This opinion is further confirmed by Wertheim's statistics, which demonstrate from his careful study of the extirpated glands that in 33 per cent. of his cases operated on by the radical method, they are not the seat of metastasis. Dr. Clark said that when we consider that at the highest we can not hope for more than 30 per cent. of ultimate cures, he believed that these favorable results occur almost wholly among the 33 per cent. of cases in which there are no metastases. In Dr. Sampson's 15 cases there were three in

which there were no metastases, and while Dr. Sampson's series is not so large as Wertheim's, still the percentage in which there were no metastases is about the same. The work, therefore, of both Sampson and Wertheim, together with Dr. Clark's own practical experience, indicates that our recoveries depend on the absence of metastases.

Dr. Clark approved the extreme caution which Dr. Sampson exercises in advocating its extensive adoption, and said that no man should attempt this performance unless he is thoroughly skilled technically, and has the most accurate anatomic knowledge of the pelvic organs and the surrounding tissues. If it were possible to leave this matter in the hands of Dr. Sampson until he could prove definitely that the most radical measures are to be commended it would be much the wiser plan; but to increase the statistics through which it is only possible to prove its value, it will be necessary for other surgeons to adopt the method. With the electrocautery knife the tissues on both sides of the blade which come in contact with it are thoroughly burned; therefore, the frontier line of invasion is much more nearly destroyed than with the knife or scissors. It would seem, therefore, that the use of the electrocautery in all operations for carcinoma is preferable to any other means of removing the growth.

DR. G. B. MASSEY, Philadelphia, said that no one can be engaged in this work for any time without concluding that cancer is a parasitic disease, although that fact has not yet been proved. The victim of cancer is every moment liable to autoinfection in some other part of the body. It is difficult to transplant a germ from one animal to another, but the metastasis resulting from the uterine discharges of cancer coming in contact with the walls of the vagina and implanting cancer there, teaches that the individual is extremely prone to autoinfection. There is great danger in curetting, cutting and scraping operations, in causing autoinfection. A cancer of the breast invariably remains movable even when the ribs are infected. Remove it with the knife and when it recurs it is no longer movable. The lymph spaces have been opened by the cutting operation, and the germs have spread into the surrounding tissue. He compared this thorough knife operation that has been advocated to a man going to hoe a garden full of weeds that are ready to drop seed, with the result of a rapid growth in the disturbed portion. He emphasized the value of cauterization and said that since the subject was presented at the last session he had demonstrated in one case that cauterization by cataphoresis has the additional advantage of being capable of being given without ether, as the uterine cervix can stand 300 milliamperes. Held there for half an hour it will do considerable cauterization, if the zinc-mercury electrode is not large. If repeated daily it is a means of doing thorough work under the guidance of observation of the patient, with less danger than if done suddenly. In treating cancer of the cervix we are working in an extremely dangerous region. Any method of destroying the disease piecemeal, if it be effectual, would give us the advantage of checking the work as we go along.

DR. A. LAPHORNS SMITH, Montreal, Can., said that for several years he had dissected out the glands of the pelvis, and that so far there has been no practical result. He said that there is a great future for cancer of the uterus if the plan were adopted of operating so early that the pathologist is not sure that the disease is cancer. Since he has adopted this plan he has had better results than when he waited for the pathologist's diagnosis before operating. The time to operate is while the disease is in the precancerous stage. In many cases we know when to expect the development of a cancer, as in the case of a badly lacerated cervix in a woman over 40. In one of these cases he was clinically certain that the disease was cancer, but the pathologists reported month after month that it was not. Finally he operated and then the pathologist had no difficulty in diagnosing the removed specimen as cancer. He said that it is absolutely essential that the general practitioners throughout the country send these cases for operation just as soon as they suspect them to be cancer. By taking these uteri out and fighting about their cancerous na-

ture afterward we save the lives of the patients. The "wait-till-we-are-certain" plan has given 100 per cent. of ultimate deaths; it is time to change it.

DR. F. F. LAWRENCE, Columbus, Ohio, said that a number of years ago, to scrape out and cauterize deeply was not considered good practice. A little later high amputation was resigned in favor of vaginal hysterectomy. About sixteen years ago, in the Ohio State Medical Society, one of the most heated discussions was held on this very question, and in it one of the most distinguished and ablest men and one among the soundest in his pathologic ideas, voiced the opinion that high amputation and cautery was safer, so far as the ultimate result was concerned, than hysterectomy. Dr. Lawrence believes now that Dr. Reamy was right. In his experience for a number of years, early recurrence was the rule after hysterectomy for cancer, especially cancer of the cervix. A few years ago he found but one who had lived four years after the operation for removal of cancer of the uterus. In cases where he followed the teachings of Reamy and Lawson Tait, three or four cases had gone beyond six, seven or eight years. We must have something more than a logical argument because this does not hold in the majority of cases. We must accept those things that give us the results in the living patient for the longest time with the greatest comfort. No matter how much anatomy one knows, the best anatomist can not determine when there is infiltration of the pelvic tissues or whether he has gone beyond the cancerous area. These infiltrated tissues give the greatest trouble, and by deep cauterization the very best results are obtained.

DR. W. H. HUMISTON, Cleveland, Ohio, said that the work Dr. Sampson is doing is the foundation for future observations and results, and gives a very complete method not only for resection of the uterus and the structures of the pelvis, but also for keeping a close clinical history of cases and results. In these lengthy operations a certain number of cases succumb to the anesthetic. Dr. Humiston has found the submammary transfusion of saline solution of value and in all desperate cases he commences the injection at the beginning of the operation and continues it to the end. There is no shock and the patient leaves the table, in nine cases out of ten, in far better condition than before the operation, and the convalescence is undisturbed. He has used this method for two years with great satisfaction. That these cases are not sent to surgeons early by the general practitioner, he thinks is not their fault, as three-fourths of the cases do not present themselves to the physician until they have pain, hemorrhage and odorous discharge; and when these three symptoms are present there is a great spread of the carcinomatous disease and the results will be very bad. When a case has laceration of the cervix and eversion of the os with discharge, it is time to operate. The general practitioner should be thoroughly impressed with this idea of having these operations done immediately, and in that way many cases of cancer of the uterus will be saved.

DR. SWITWIN CHANDLER, Philadelphia, said that it was wise to examine the bladders before and after operation, particularly in the early stages of malignant disease, to learn the cause of the cystitis. Dr. Chandler said he thoroughly believed that it would have been impossible for us to advance to the point which we now occupy had it not been for the valuable assistance of the microscope and our studies in pathology. In many cases of the kind reported by Dr. Findley, it is impossible to tell whether or not the growth is malignant, except by the subsequent history of the case. In one case there was a condition in which even the pathologist thought it was malignant and advised operation, but the patient recovered after simple curettement. He said that there could be no question but that when we are sure and certain an operation should be performed in a case of malignant disease, it should be a radical operation.

DR. K. F. M. SANDBERG, Chicago, said that we look on the chorio-epithelioma a little differently from the way we looked on deciduoma malignum. We thought that these cases devel-

oped only immediately after a pregnancy, taking their origin from the decidual tissue. Now we know that they can develop years after a pregnancy and that they also may develop in the male. He said that we ought to furnish Dr. Findley and other men as much material of this kind as we can. Undoubtedly much of it is going to waste. Uteri are extirpated for cancer that may have been deciduomata. Dr. Sandberg said that the case he operated on was diagnosed as cancer, but the appearance of the tumor on exposing it made him change his diagnosis. It had a peculiar angiomatous appearance and perforated the uterus in four or five places and through the parietal peritoneal covering to the right of the rectum. There also was a tumor in the vagina and both were extirpated with good result. There was no evidence of recurrence four months after operation and the woman was in good health. It is evident that chorio-epithelioma is not so malignant as cancer.

DR. A. GOLDSPOHN, Chicago, said there are two important facts to which we subscribe: First, the extreme desirability of getting these cases at the very earliest possible moment, even, perhaps, running the chance of operating on a case where the microscope might not show the nature of the disease. Second, operating as far away from the disease focus as possible. The second proposition is open to a great deal of difference in procedure, according to the physical condition of the patient, and also as to where the recurrences of the malignant disease have been found to occur most frequently. These recurrences occur very largely in the upper part of the vagina and the connective tissues just above, indicating that the technic of the operation was defective, either in not removing enough of the tissue of the vagina at its insertion in the cervix, or that the carcinomatous elements were vaccinated into the wound at the time of extirpation. In view of the great difference in the mortality of the operation, it is far more important to remove, along with the uterus, a pretty good portion of the adjacent vagina than it is to do a somewhat risky and unwise extirpation of the glands and with it a difficult dissection of the ureters and cutting off of the circulation of the bladder with its evil effects, and a longer narcosis and higher mortality. The upper part of the vagina can be removed easily, and by a thorough procedure it will greatly improve our results.

Dr. Goldspohn said that the cautery clamp is one way of avoiding the danger of vaccination of carcinomatous elements and another is in the technic of removing the uterus. Naturally we should choose the abdominal route in the majority of cases. We should do reasonable work, and as thorough, in removal of glands, as possible, without greatly increasing the danger to the life of the patient. Then tuck the uterus into the still attached vagina and remove it from below by a process of evagination, having closed the pelvis from the abdominal cavity and also the abdominal wound, then removing the uterus easily from below with the adjacent portion of the vagina. By that method there will be the least opportunity of implantation of carcinomatous elements, and the best prospect of thorough work, without a much higher mortality. The forceps are valuable, particularly in vaginal hysterectomy for other reasons. After all cases of vaginal hysterectomy that do not positively demand drainage (as for pus tubes or extensive adhesions) the rule should be to close the abdominal cavity as after every other form of peritoneal section, at least closing the peritoneum and not leaving any drain or foreign body in contact with the peritoneum or intestines, which frequently invites adhesions of intestines, and sometimes leads to intestinal obstruction later on. In order to do this, no forceps should be left within the peritoneum, but the tying off of forceps requires heavy ligatures that are slow to be absorbed. Such infected ligatures sometimes lead to infection and breaking down of the thrombus, and consequently a late hemorrhage from the uterine artery. The electrothermic forceps avoids all this, as well as the difficult ligating high up in the vagina. In five cases he had removed the uterus by means of these forceps without any ligature at all, making it more simple and

making the possibility of closing the abdomen easy, and running practically no danger from infected ligatures.

DR. A. H. CORDIER, Kansas City, Mo., said that a few years ago he was very enthusiastic on removing as much of the tissue surrounding the uterus as possible, because he believed that that method would diminish the frequency of recurrence. After performing many operations, both with the clamp and with the ligatures, and finding that in from 95 to 98 per cent. the disease recurred and proved fatal, he abandoned the idea. Then he took up the use of the Paquelin cautery in advanced cases, where the disease had involved the vaginal wall, and his immediate mortality has been nothing so far as the operative procedure is concerned. These patients are alive as long as five or six years after the primary cauterization. He said that any operation that has a mortality of from 16 to 20 per cent. in the hands of skilled men, is a dangerous procedure. Any operation that requires two to four hours to perform will have a very high mortality, not only from the operation, but the anesthetic as well. We must not only think of the primary mortality, but also of the ultimate death rate, because that tends to discourage patients who could be operated on successfully. All these things must be taken into consideration. An operation that has no primary mortality and that prolongs life as long as can be expected, should be given the preference, hence he has been using the Paquelin cautery in these cases. It goes further into the tissue than ligature, forceps or knife; the heat destroys the diseased structures, producing an aseptic slough, and the wound heals kindly by granulation. The cancerous tissue is removed and the rapidity of recurrence is diminished. Many fail to recognize the importance of keeping down infection. It has much to do with the rapidity of the growth. Following the cauterization, Dr. Cordier said he packs usually packs the cavity with gauze to control any oozing which might occur, and at the end of three or four days he begins the use of carbide of calcium, first drying out the cavity thoroughly, then inserting the calcium and putting a piece of gauze over this. This generates acetylene gas, which has a predilection for cells of low vitality. At the end of 24 to 36 hours the dressing is removed and a solution of potassium permanganate is used. It keeps down the odor, diminishes the discharge, prevents infection, makes the patient comfortable and prolongs life.

DR. J. H. CARSTENS, Detroit, Mich., said that nothing is known about the anatomy of the lymphatics. One work on anatomy states that the lymphatics run one way, and another book says that they run somewhere else, and men who have operated do not know where they run, but pick out a few and remove them. Schauta, of Vienna, has had his assistants make a careful examination of cancer patients who die. He had 60 postmortems and every lymphatic gland was removed carefully from the pelvis, groin, above the promontory of the sacrum and the bifurcation of the aorta, up to the diaphragm. He placed these into four groups. One group comprised those in the pelvis that could be removed by abdominal hysterectomy, and he found that in 13 per cent. of these cases the lymphatics were limited to the pelvis and in 87 not; so that if one removes the lymphatics in the pelvis there are 13 per cent. to which the disease was limited. The question is whether one should operate on 87 per cent. where the lymphatics are elsewhere and can not be reached, simply for the sake of removing them in 13 per cent., and subject patients to such a serious operation. Schauta found lymphatics in the groin with cancer, and he found others in the pelvis absolutely free from cancer, and others over the sacrum and at the bifurcation of the aorta full of cancer; and cases where the second and first stages were free, but glands up near the diaphragm contained cancer cells. Now, what is the use of operating on the lymphatics in the pelvis and around the ureters and aorta when others that can not be reached are involved? Schauta had 160,000 sections made. Every gland was sectioned carefully. He found that the lymphatics did not only contain cancer cells, but the surrounding cellular tissue was full of cancer cells, and this, usually, is not removed. So what is the use of removing the glands? He also found that it is not necessary to remove these glands: that the cancer cells in them usually do no harm be-

cause the glands hold them and do not allow them to travel any further, and eventually they die there and that the recurrence of cancer takes its origin in the surrounding loose connective tissue. Dr. Carstens said that we know very little about cancer after all. If one can not remove a cancer by the vagina, one should leave it alone. Do a radical operation per vagina and do it early. Have every case of lacerated cervix and curettage examined carefully for cancer, and if it is found, that is the time to operate.

DR. A. J. DOWNES, Philadelphia, said that he had used the cautery clamp in 70 cases of cancer. In one the entire vagina had been removed, and in his efforts to get close to the bladder he scorched it and a fistula resulted, but healed within six months. The patient died 18 months afterward, but without any recurrence in the vagina. In another case he encircled the vagina from below, freed the cervix and found that the right broad ligament was very much involved, and the clamp must have got very close to the right ureter for a uretero-vaginal fistula resulted, but it healed nicely. He said that these accidents are not a discredit to the method, and did not argue against its further use, for as Dr. Noble said, in two of the cases one would do a very close vaginal operation and leave more tissue than we did in this case, but even in these very difficult cases it is possible to isolate the ureters. The operation for cancer as Dr. Downes performs it includes cauterization of the cervix. He encircles the cervix, beginning considerably below it, and dissects it out, follows up along vagina, and then opens the abdomen. It is a better operation than just cauterizing the cervix for the reason that we have already cauterized the cervix before we remove the balance of the uterus. He said that a careful dissection and using a sufficient amount of heat before cutting the base of the broad ligament without scorching the ureter, is enough; no dissection could go beyond that.

DR. FRANK CARY, Chicago, said that where there are two cases that come for operation, in one there is much involvement of tissue, as shown macroscopically and microscopically, it is operated on and does not recur for a long time. In another case there is little involvement of tissue, it is operated on and the patient succumbs to an early recurrence. Now is it not possible that in the first case the cellular connective tissue was in excess of the cancer cells, while in the latter case the cells developed excessively while the connective tissue developed very slowly? In his opinion the man with the knife is better able to tell where he is going than the man with the cautery. The only advantage of the cautery that he could see is that it leaves a large scar which, possibly, protects the tissues for a longer time against invasion by the cancer cells.

DR. C. O. THIENHAUS, Milwaukee, Wis., said that in looking over the large amount of literature on this question compiled within the last few years, he had been impressed with two facts: First, the primary mortality of these abdominal operations is much higher than in those cases performed by the vaginal route. Secondly, he failed to see that the ultimate results of the abdominal operations up to this time are better than those of Schuchard, who uses the vaginal route with the aid of what he calls a paravaginal incision. By this incision, extending from the cervix down on the left side of the rectum and anus to the os coccyx, the parametria are brought into such clear view that they can be resected at liberty even up to the pelvic border. His results have been 40 per cent. radically cured after five years, and his statistics are unquestionably reliable. So long, therefore, as the advocates of the abdominal route with extirpation of the glands can not show better results, we are justified, in order to avoid their primary high mortality, in using the vaginal route with the aid of the paravaginal incision. One other fact which has not been pointed out sufficiently has to be taken into consideration, and that is that a differentiation must be made, as well in regard to the histology of the different forms of cancer of the uterus and as in regard to their virulence. (Slow or rapid progress in growth locally and the possibility of early metastasis or metastasis in a very late period.) What shall we do with so-called

inoperable cases, taking it for granted that a case which has transgressed the boundary of the uterus and has formed metastatic growths in the parametrium should be classified as such? Schuchard and others have oftentimes attacked even such cases by radical operative procedures. Very interesting in this respect are recent statistics compiled by Lomer, in which he collected over 130 cases which had been treated by thorough curettement, followed by the use of the thermo-cautery, and which were still living after a period of five years. This shows that even for those cases we are enabled to do something, provided the form of cancer we have to deal with belongs to that class, which tends to grow slowly, and has no tendency to early metastasis.

Dr. J. A. SAMPSON said that this is a new field and there is much yet to be done. Probably none of us will live to see the work finished. Pathologic study and clinical experience show the importance of a more radical operation. Experience will prove whether it is justifiable. If cases are cured which would not have been cured by a less radical operation, then it is justifiable, otherwise not. A study of the parametrium and pelvic lymphatics shows that, apparently, they are able to check temporarily the further advance of the disease, so that if we can remove these with the primary growth we can hope to cure a certain number of cases where the disease has extended beyond the uterus. When long portions of the vagina are excised the bladder is weakened, and also large raw areas arise, which are difficult to close and less likely to resist infection. In regard to implantation and infection by the abdominal route: After the vagina is freed it is carefully wiped out with gauze and clamped with two right angle clamps and then burnt across between the two clamps with a Paquelin cautery, so that the only time that there is any chance for infection is when the cautery passes through the tissue.

Many think that cancer of the cervix is incurable. Out of 66 patients who have survived the operation and whom we have been able to hear from, over 20 per cent. are free from recurrence after five years and more, and in these patients the diagnosis was made not only from the clinical symptoms, but by the microscope as well. When we see patients free from recurrence, eight, ten and eleven years after operation, and in other cases are unable to find any evidence of cancer in the pelvis of patients dying after operation, we feel that cancer can be cured. Dr. Sampson said that in these cases urine cultures and cystoscopic examinations were made in fourteen after operation, and in two other patients, who died, an autopsy was made and the bladders carefully studied. A diagnosis of cystitis can not be made without such examinations because an apparently inflamed bladder may not yield anything on culture and organisms may be present in the bladder without causing cystitis. We have had cases in which an unfavorable prognosis was made at the time of the operation, but they are apparently cured five to ten years afterward, and in other cases we find just the opposite to be true. Some think that the more cellular the growth, the less the resistance of the surrounding tissues, and on this account the more malignant the disease; but this needs further study. He tried Dr. Downes' thermo-cautery, but preferred to operate without it. Future experience may show that the thermo-cautery has a field of usefulness. There is one place in which its use appeals to me, and that is after one has freed the lymphatics and ureters, ligated and cut the ovarian and uterine arteries and utero-sacral ligaments. The uterus is now held in place by the vagina and plexuses of veins, going out from the uterus laterally and posteriorly. The bleeding from the cutting of these veins is always difficult to control. It seems to me that the cautery clamp may be used with advantage in this step of the operation. He tried it in his last case, but it did not work very well. With regard to the post-operative uterine fistula, which close spontaneously, clinical and experimental studies show that usually a uterine stricture follows the above, frequently renal infection, and sometimes the ureter becomes occluded, for even if the ureter of a dog is cut completely across the fistula may close spontaneously, but the ureter becomes occluded and the kidney is thrown out of function.

Dr. CHARLES P. NOBLE said that the suggestion made by Dr. Sampson is a good one. The way to avoid trouble with the clamp is to operate according to his method and finish up the operation with the clamp. Aside from its possible value in sealing the lymphatics and thus preventing implantation during the operation, there is no doubt that the greatest practical value of the clamp is in sealing the numerous veins about the cervico-vaginal regions, thus leaving a dry wound.

Dr. PALMER FINDLEY said that he wished to challenge the statement that the microscope will not make a diagnosis prior to the appearance of clinical symptoms. He believes in the microscope in the early diagnosis of cancer because he has had no small amount of experience. It is not altogether improbable that the man who looks through the microscope may be unskilled in its use and in the interpretation of what he sees. In the hands of a capable man the microscopic diagnosis is perfect and may be relied on much more often than the clinical findings. There is not one symptom or group of symptoms which, in early cases of cancer, will make a diagnosis. Instead of operating on suspicion, I would do an exploratory curettage and excise a portion of the cervix and then make a microscopic diagnosis.

THE DIFFICULTIES AND DANGERS OF ACCOUCHEMENT FORCE.

A SIMPLE, SAFE AND SUCCESSFUL METHOD.*

HORACE G. WETHERILL, M.D.
DENVER.

That we may reason from a foundation of established basic principles, let us assume that it is generally agreed: 1, That absolute sterilization of the hands from all pathogenic bacteria and spores is impracticable; 2, that the parturient canal is usually free from pathogenic organisms, and that when they are present it is fair to assume that they have been introduced from without; 3, that frequent and prolonged manipulations within the genital canal, and the lacerations and abrasions they produce, vastly increase the dangers of and from infection.

All manual operations for the rapid dilatation of the cervical canal and extraction of the fetus are dangerous, beside being slow and exhausting. The routine use of rubber gloves reduces the risk of infection to a great degree, but they operate somewhat against facility and certainty in the work. Present instrumental methods are also slow and dangerous and demand expensive special instruments, which are often unavailable when most urgently needed.

When the employment of accouchement forcé becomes necessary, it is always for the relief of some serious complication of pregnancy which demands, or at least warrants, the operation and the known risks incident to it. We are confronted with a necessity to make a choice of alternatives, of which the operation, with its attendant dangers, is believed to be the better one.

In making this choice, however, we assume the responsibilities that go with it; and it is incumbent on us to so select and conduct the operative procedure as to reduce the known dangers to the minimum. In the regular course of events these dangers are rupture and laceration of the uterus and vagina, hemorrhage and infection for the mother, and injury and death for the infant.

Immediate success and good ultimate results depend on the simplicity, rapidity and cleanliness of the operation and on the use of the necessary force in exactly the

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee—Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

best way to avoid injury to the soft parts, hemorrhage, and accidents to the child.

INSTRUMENTS.

It is not the purpose of this paper to consider further the well-known manual methods of accouchement forcé, the advantages, disadvantages and limitations of which are familiar to all.

With regard to instrumental methods with various hydrostatic bags, branched metallic dilators, and graduated bougies, I believe it will be conceded that they are slow, cumbersome and unsatisfactory.

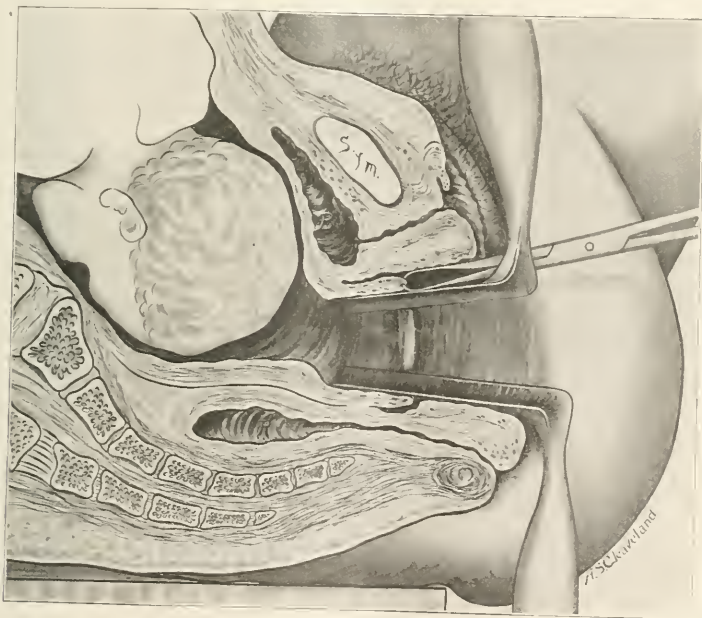

The huge, many-branched dilators, like that of Bossi, are expensive, unwieldy and seldom at hand when most needed. Monstrous instruments of this type are, furthermore, offensive to the artistic sense of the skilled surgeon, who associates them in his mind with veterinary practice. It is also unquestionably true that it is not

literated, packing with gauze or the use of the hydrostatic bag or some metallic branched dilator of the type of Goodell, Wathen or Starling may be demanded.

When, however, the internal os is dilated or dilatable, and the vaginal portion of the cervix is ready to yield to force such as may be safely and appropriately applied, we have in our armamentarium for this purpose one of the oldest and best instruments known to the gynecologist and obstetrician; one that will apply this force better and more efficiently than any other, an instrument bearing the name of a pioneer of modern gynecology, whom we all delight to honor. I refer to J. Marion Sims and his duck bill speculum.

TECHNIC.

The method I submit for your consideration, subsequent trial, and, I trust, approval, may not be universally applicable; but I am very sure it will be found

easy to estimate the force employed with them, nor are they so perfectly under the control of the operator as they should be.

Such appliances are too suggestive of the crowbar and jackscrew to have a permanent place in modern American gynecologic surgery. It is easy to predict that they will soon find repose in some remote corner where already rest the trephine perforator, the cranioclast and cephalotribe, and to which more recently has been consigned the ceraseur, Tuffier's angiotribe, the 10 and 12 inch hemostatic clamps, and various big vulsellum forceps of horse power hayfork design. American gynecology and obstetrics have passed beyond the stage when such huge instruments are necessary or even tolerable, and the resourceful and dexterous surgeon does not need to employ them. Others should not.

Instruments are necessary in making rapid dilatation of the cervix for immediate delivery; and when the supravaginal portion of the cervix has not been ob-

adaptable to a large proportion of the cases in which accouchement forcé is necessary.

In case the supravaginal cervix has not dilated and the external os is still rigid, it will be necessary to employ some instrument as a pilot for the Sims speculum used as a dilator. For this purpose, if time and the nature of the case permit, the gauze packing or hydrostatic bag is preferred; but if not, the Wathen or Starling type of metallic dilators is better.

The cervix being dilated to the diameter of the smallest Sims speculum or retractor available, the farther dilatation is readily, safely and rapidly completed with these instruments. For this operation the patient is fully anesthetized and drawn well down over the edge of the table, in the lithotomy position.

I employ Sims' specula of varying widths and lengths, with flat, shallow blades, the smallest a half inch and the largest two inches broad, and from three to four inches in length. With the exception of the narrowest

one, they are regular stock instruments. Sometimes I have employed for the upper lip of the cervix a long, narrow Eastman or Jackson retractor. Two stout double tenaculum forceps that will not lacerate and tear out of the cervical tissue are also necessary.

The *modus operandi* is as follows: The cervix is caught on either side in its upper outer quadrant with the tenaculum forceps, which are then handed to an assistant. The narrow speculum or retractor, as the case may be, is then slipped into the cervical canal between the tenaculum forceps, and with it the anterior lip of the cervix is drawn forward and upward under the symphysis pubis and held there by a second assistant. Now a Sims speculum with the broadest blade that can be introduced is crowded into the cervical canal, and with it the posterior lip of the cervix is drawn steadily downward and backward, the anterior lip being held forward and upward. Then the operator, grasping the lower end and shaft of the posterior speculum with both hands, presses firmly and steadily downward and backward and rocks the instrument from side to side. In this way he gently but surely and quickly irons out, dilates and paralyzes the cervix under the guidance of his hand and eye, and uses as much or as little force as may be actually required. He need not lacerate or damage the tissues if he proceeds with ordinary care; and in case he should do so he at once knows the extent of the injury.

After both specula are well placed inside the cervix the point of the blade of the upper one should be raised and the point of the lower one depressed to prevent them from slipping out, and the tenaculum forceps must now be removed. The diverging blades of the specula within the cervix will serve to hold it well down in the pelvis, and the strongly held upper one must allow plenty of room for the lower to be moved from side to side through the cervix and over the perineum, which is undergoing dilatation at the same time.

As dilatation progresses, rock the posterior blade well up on the sides of the cervix and have the position of the anterior blade slightly changed to better oppose the force exerted by the posterior. Thus the force is applied always from the center toward the circumference and at a right angle to the axis of the circular muscular fibers of the cervix, while the rocking motion of the broad blade distributes it to advantage.

If there be much hemorrhage the cervix may be tamponed between the blades, or constant irrigation may be employed during the operation.

Technically the method is ideal, but, as suggested, there may be cases to which it can not be applied during the first stages of dilatation. My obstetric practice is limited, and I have not had opportunities for trying the method fully under all conditions; but in the cases in which it has been employed it has worked admirably, and with such facility, safety and speed as to form a delightful contrast to all former methods.

The plan has to commend it the use of only such instruments as may be found in the armamentarium of every physician, uncomplicated instruments, too, and capable of absolute sterilization by boiling. Best of all, they are instruments with broad, smooth bearings for contact with the tissues, which are consequently not exposed to lacerations and abrasions through their use.

During one week of September last it was my fortune to have at the Denver Maternity and Woman's Hospital two very similar cases on which the method was used, one proving so easy and satisfactory as to be astonishing in the facility with which results were attained, and the

other presenting difficulties from a rigid and undilated supravaginal cervix and internal os, which served to demonstrate the value of the method under adverse circumstances. Permit me to quote these cases as examples.

Both were multipara. Each of them was found to have her urine loaded with albumin, and the quantity for twenty-four hours was reduced to a very few ounces. The urine of each was highly colored, of high specific gravity, and hyaline and granular casts and renal epithelium were abundant. Partial blindness and other pronounced symptoms of profound toxemia were present in both, though neither had had convulsions. Ophthalmoscopic examination showed well developed albuminuric retinitis, with small hemorrhages in one eye of each patient, and vision was much impaired in both eyes.

The first was at the end of the eighth month of pregnancy, and the second was at eight and one-half months. The fetal hearts were heard to beat strongly and fetal movements were active. No pains or other signs of labor were present, the heads were high in the pelvis and the ora were undilated, just admitting the tip of the index finger. In the first case, however, the supravaginal cervix was obliterated, the cervix was soft and the os dilatable. In the second these conditions did not exist. Immediate delivery by accoucheement forcé was determined on for each and was undertaken by the method here outlined.

The first patient was put under full surgical anesthesia, dilatation made, high forceps applied, and a living child was delivered, the record showing the time of anesthesia to have been but twenty minutes.

The second patient was similarly treated, but owing to the unobliterated supravaginal cervix and rigid external os much difficulty was encountered in the preliminary dilatation. When, however, the retractor and Sims' speculum could be introduced the hard cervix yielded readily to the ironing process and was rapidly dilated and paralyzed. High forceps were then used and a living child extracted. Time of anesthesia, one hour.

Both mothers made good recoveries. The child of the second died of uremic toxemia in thirty-six hours, the other being alive and well at this writing. Vision was restored to both women after the lapse of time, but is still somewhat impaired in the worse eye in each instance.

You must take these cases for what they are worth, but I believe that you will grant that, for their kind, they yielded to the peculiar treatment employed with rather more facility and rapidity than could have been hoped for from any other known method. The results, at least, were beyond criticism.

This method has not been sufficiently tried. I submit it for your consideration and use, and for such alterations and improvements as may suggest themselves to you.

Let me beg, merely, that the simple instruments employed be not evolved into one of those gynecologic engines with which our art has been peculiarly cursed.

If I were permitted to take any credit to myself in the formulation and presentation of this subject, it would be for having spared you the infliction of a huge new device to bear my name to the peaceful oblivion of your instrumental scrap heap.

DISCUSSION.

DR. J. H. CARSTENS, Detroit.—The question of accoucheement forcé is an important one. If a woman has albuminuria and has no convulsions, but there is a probability of convulsions

setting in later on, there is no need of accouchement forcé. That is an ordinary case in which you can bring on labor by introducing the catheter without the exhibition of force, delivering the woman slowly and deliberately in the course of ten or twelve hours. In such a case there is no need to use the Sims retractor, or the Bossi instrument, or anything else of that kind. If you have a case of placenta previa so far advanced in labor that you can introduce a Sims speculum, that woman will die; she would die before you got the os dilated sufficiently to introduce forceps and deliver the head. The use of such a method is a perfect absurdity, especially when the os is dilated so that you can introduce a finger, grasp a foot and pull it down. We should not let this paper go out as being the right thing to do in placenta previa. If the woman has convulsions then you must deliver quickly, unless the convulsion is slight, when the woman recovers from it in a few minutes. Then use the catheter and take your time. But if the convulsions are profound, deliver quickly or she will die. Do not depend on the Sims speculum or the use of any other instrument to dilate the os. Deliver in five minutes, and the only thing to do is vaginal cesarean section, a rapid, simple, yet efficient operation without any disastrous after-effects. In five minutes more you can repair the damage done to the uterus. Anybody can do it in fifteen minutes. That is the kind of accouchement forcé to do.

DR. RUDOLPH W. HOLMES, Chicago—Unfortunately, we have not as yet an ideal instrument for dilating the os in late pregnancy and labor. An instrument which will satisfy all conditions would be received gladly. The instrumental method advocated by Dr. Wetherill requires three conditions: First, there must be a material dilatation of the os. As a rule, in those cases demanding rapid dilatation, the os is closed. Second, the head must be high up. If the woman is a primipara at term, this condition ordinarily is not present; in multiparæ it usually exists. Third, the cervix must be so lax that it can be pulled down; if the cervix is high up and can not be pulled down, the ordinary Sims specula are not long enough to reach within the internal os. Furthermore, even if the Sims specula were in place, and vulsella held the cervix, there would be great danger of pulling out the vulsella, thereby producing lacerations of the cervix. For the general practitioner there must be a contrivance which is cheap and which all may possess; this, one may say, is a practical impossibility. The hand is always available, and at the present time is the least dangerous if properly used, method of dilating the parturient os. Of course we all know there is not any method used in dilating, even the hand, which has not its disadvantages and dangers, but with all the shortcomings, the methods of Harris and Edgar-Bonnaire are the most preferable. A competent assistant may relieve the operator whenever his hands become tired, thus permitting him to become rested before the delivery occurs. In placenta previa this method will be particularly contraindicated, because the tips of the specula will surely separate the placenta and cause an increased hemorrhage. I believe rapid, bloody dilatation of the os is contraindicated in placenta previa. Dr. Carstens is not exactly in the right position, for there are times when a woman is in such a precarious condition that it becomes necessary to deliver rapidly, and in such cases rapid means of dilatation are of inestimable value. I object to the strictures against craniotomy instruments. There always will be use for these instruments. I consider it exceedingly unscientific and little short of malpractice for a doctor to make prolonged and unduly forcible tractions in a vain attempt to deliver a dead baby intact, producing grave lacerations in the mother; or, as too often happens, finally delivering a much mutilated head. A scientific craniotomy is less horrible and offers less liability of producing maternal injuries.

DR. C. S. BACON, Chicago—There is need of methods for dilating the cervix in conditions other than eclampsia, but that, of course, is the chief indication for removing the child. The vaginal cesarean section, as advocated by Dr. Carstens, undoubtedly is preferable to any method of rapid dilatation of the cervix, provided you have the facilities for doing the opera-

tion. In the majority of cases these facilities are not at hand, hence arises the necessity for rapid dilatation to be followed by removal of the child, in certain cases. The question is whether the method proposed by Dr. Wetherill is better than the method that we now chiefly employ, manual dilatation. The instrument of Bossi has never been in favor in this country, and is now losing favor in Europe on account of the tears made by it. The method of manual dilatation as described by Harris and Edgar in this country, and Bonnaire in France, unquestionably is the best at the present time. Now, is Dr. Wetherill's method better than manual dilatation? One would suppose that there was risk of injury to the tissues by grasping the cervix with a tenaculum forceps and pulling it up against the symphysis, followed by pressure made with the speculum from behind. That danger would not be present in the use of the hand. Now, is it any cleaner? The hand may be made clean, if one has the time, or gloves may be worn. The greatest danger is the introduction of contamination from outside, and that is the chief danger of the Edgar method. But the same danger applies here; the manipulation with the speculum posteriorly must be involved with considerable contamination from the anal region. That is where the chief danger lies, and it is quite as great in the Edgar method, and much more dangerous than the use of the one hand, the method of Harris. So that I doubt that this method possesses any real advantage over the others.

DR. CHARLES J. HASTINGS, Toronto, Canada—We are not quite so fond of instruments in Canada as they are in some other places. I feel that there is no other method to compare with digital dilatation, as suggested by Harris with gloved hands, for the safety of the mother; and the means by which it is accomplished is always at hand. In my opinion the only condition demanding "accouchement forcé" is severe concealed accidental hemorrhage, in which case the uterus must be emptied as rapidly as possible or we will lose our patient. With regard to eclampsia, I can not agree with Dr. Carstens as to rapid emptying of the uterus, even in the eclamptic seizure. I prefer to control the convulsions with morphin and chloroform and when the patient is under the influence of these drugs, empty the uterus. Operative interference before this is done only intensifies the seizure. In placenta previa, in my opinion, accouchement forcé is positively contraindicated. How very easily we could produce a fatal issue from an uncontrollable hemorrhage by producing even a slight laceration, owing to the changed condition of the parts, the enormously enlarged vessels at the placental site. While some of the more rapid methods of dilatation may possibly diminish the infant mortality yet, for the aforesaid reasons, I should be afraid to adopt them.

DR. HENRY D. FRY, Washington, D. C.—Two weeks ago, in Boston, at the meeting of the American Gynecological Society, Dr. Harris presented an instrument for rapid dilatation of the cervix. I mention this merely to show that Dr. Harris, whose method of manual dilatation is so popular, has seen fit to get up this ingenious instrument to take the place of his manual method. We all have in mind only one single method, to the exclusion of all others. That is wrong. We should not attempt to use one method in all cases. In dilatation, the most difficult part is to start it, and here the difference is great between multipara and primipara. Dr. Wetherill's cases were multiparæ, and, as a rule, the multiparous cervix is dilated easily, either manually or instrumentally. I believe that there are some cases of multiparæ in which this is an efficient and simple method, far better than the use of any instrument. In primiparæ the hard part is starting dilatation, and here Dr. Wetherill's instruments would not be of much use to us. I agree with what has been said in regard to not using any of these methods for dilatation in placenta previa. The mortality of that condition has been brought down so far by bipolar version, that it would be retrogression to go back to any of the older methods. The maternal mortality will be higher, although we may save more children. Each method is applicable to certain cases, but in the majority of cases I prefer to use the manual dilatation.

DR. H. G. WETHERILL—It is not possible to listen to a paper of this kind without having some misapprehension as to the exact field it proposes to cover. That has occurred, apparently, in the mind of almost every one who has discussed this one. Dr. Carstens seems to have lost sight of the fact altogether that the two cases reported were operated on for retinal hemorrhages and albuminuric retinitis, which are accepted as a justification for immediate delivery by every obstetric authority. In regard to the degree of dilatation that is necessary: The ordinary Bossi instrument measures $1\frac{1}{2}$ inch across the end which is introduced, and it is circular, so that its circumference is something more than three inches. If, then, it is possible to use the Bossi dilator in any case, it is also possible to use the Sims specula, as I have advocated their use on this occasion. As to the hand: We all acknowledge that absolute sterilization of the hand is impossible, and that there is always a residuum of infection that goes with the hand into the vagina and which the tissues and secretions must take care of. We know how impossible it is to cleanse the hands and keep them clean throughout an entire obstetric operation, notwithstanding the fact that these cases often are seen in the hospital, under the most favorable circumstances, so that the hand always carries with it a certain danger, which is not carried by smooth, polished instruments. Dr. Bacon also had a misapprehension in regard to a very specific direction given in the paper. I did not say that a vulsellum forceps should be used to grasp the anterior lip. I said that the upper outer quadrants of the cervix should be grasped with forceps and drawn down until the specula could be introduced, and then the forceps be taken off, thus avoiding the possibility of a laceration of the cervix. It is very easy to listen to a paper of this kind, which presents only simple methods, and offer theoretical objections. I say simply this: Here is a method which has served me admirably: it may serve some of you a good turn at some time, and I am glad to suggest it to you, so that if opportunity occurs you may try it. It must be remembered that the obstetric and gynecologic specialist is not the only person to be considered. General practitioners often require methods which Dr. Carstens or Dr. Bacon might not think of using, and while this method may not appeal to Dr. Carstens, it may find a field of usefulness in the hands of some other practitioner, who may save a life with it. Perhaps I may be permitted to remind the Section that Dr. Oliver Wendell Holmes once wrote an essay on the congeniousness of puerperal fever. The rather conservative body of medical men whom we now represent were a generation in grasping and accepting the opinions which Dr. Holmes promulgated in 1844. It was more than fifty years before his views were practically applied. That is a sufficient commentary on your tendency to criticize severely certain things, while, on the other hand, you grasp at others, principally operative measures, with great avidity.

ANEURISM OF THE INNOMINATE ARTERY.*

ALBERT P. FRANCINE, A.M., M.D.

Instructor in Medicine, University of Pennsylvania; Fellow of the College of Physicians of Philadelphia, Etc.
PHILADELPHIA.

My interest in aneurism of the innominate artery was stimulated by a case which came under my observation in the medical dispensary of the University Hospital in December, 1901. After studying the symptoms and physical signs of this case for several months, I presented the patient before the medical society of the University of Pennsylvania, and my diagnosis was very generally concurred in.

It must be admitted, however, that "experience is fallacious and judgment difficult," and that in the last

analysis we must go to the post-mortem room for confirmation of such diagnoses. I, therefore, proceeded with the study of my subject there, and was able to collect eight cases.¹ In but one instance in this series, and in that case only tentatively, had the correct diagnosis been made, and the question naturally presented itself as to whether there existed in these cases such clinical obscurity as to warrant this apparent difficulty in diagnosis.

Proceeding, therefore, further in my study with the idea of at least satisfying myself on this point, I had recourse to the literature of the subject; and after collecting and analyzing in all 147 cases of these interesting morbid growths, where, in many instances, the correct diagnosis had been made clinically, a more definite clinical picture formulated itself which I have the honor to present herewith.

ANATOMY.

Before taking up the subject proper of this paper it will, perhaps, be well to review briefly the anatomic features involved. The accompanying chart (Fig. 1) shows well the relation of the arch and its great vessels to the chest wall. It will be seen that the arch² of the aorta begins from the upper part of the left ventricle opposite the lower border of the third costal cartilage, behind the left half of the sternum, and passes obliquely upward, forward and to the right, in the direction of the heart's axis, as high as the upper border of the second right costal cartilage. This is the ascending portion of the aorta, and is covered by the pericardium. From this point the aorta passes backward and to the left, to the left side of the lower border of the fourth dorsal vertebra. This is the transverse portion or arch and it is from this portion that the innominate artery and the left common carotid and subclavian are given off. The aorta from this point passes downward, lying in close proximity to, and to the left of, the spinal column, to the aortic opening in the diaphragm in front of the last dorsal vertebra (descending portion), where it becomes the abdominal aorta.

The innominate artery, its axis and position being well shown in the chart, is the largest of the three vessels arising from the arch. It arises from the lower portion of the arch, opposite the first intercostal space behind the left half of the sternum in front, or the fourth dorsal vertebra behind. It ascends obliquely to the right sternoclavicular articulation, where it divides into the right common carotid and right subclavian arteries. It varies from one and a half to two inches in length. The axis of this vessel is approximately that of the heart, and follows a line from the middle of the sternum opposite the lower border of the third costal cartilage to the right sternoclavicular articulation.

In front it is separated from the first bone of the sternum by the sternohyoid muscles, the remains of the thymus gland, the left innominate and right inferior thyroid veins which cross its root, and sometimes the inferior cervical cardiac branch of the right pneumogastric. Behind, it lies on the trachea, which it crosses obliquely. On the right side is the right innominate vein, right pneumogastric nerve, and the pleura; and on the left side, the remains of the thymus gland, the origin of the left carotid artery, the left inferior thyroid vein and the trachea.

2. For a masterful and complete description of the anatomic relation of the aorta and its branches, together with a full account of anomalous conditions, see Kruse's article in Henle's Anatomy, vol. iii, p. 203.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee: Drs. J. M. Anders, Frank Jones and W. S. Thayer.

The innominate artery does not usually give off any branches, but occasionally a small branch, the middle thyroid, is given off from this vessel. It also sometimes gives off a thymic or bronchial branch.

When the bifurcation of the innominate varies from the point above mentioned, it sometimes ascends a considerable distance above the sternal end of the clavicle; less frequently it divides below it. In the former class of cases its length may exceed two inches, and in the latter be reduced to an inch or less. When the aorta branches over to the right side, the innominate is directed to the left side of the neck instead of the right.³

PHYSICAL SIGNS AND SYMPTOMS.

The position of these aneurisms is, perhaps, their most striking clinical feature. Corresponding to the position and axis of the innominate artery, these growths are situated at the root of the neck, more on the right side than on the left, and frequently extending above the right clavicle and suprasternal notch. They point behind the right sternoclavicular articulation, to the inner side of the sternocleidomastoid muscle, often dislocating the sternal end of the clavicle where their pulsation can be distinctly felt. For an aneurism of the aorta to reach so high, it must have attained great size, or else there must be an anomalous position of the arch itself. In either event there is wanting another distinctive sign of aneurism of the innominate, namely, an angle of re-entry on the external and inferior aspect of the growth, in or above the second interspace. This angle of re-entry, to which attention has not been previously called, separates aneurism of the innominate artery from those of the ascending or transverse arch which so frequently point in the second interspace to the right. When the aneurism is so large as to involve the arch itself, this angle of re-entry is not an available sign. It is not common, however, for these growths to attain such size as to involve the arch in their growth, unless they originally spring therefrom. They usually are not larger than a lemon, though they may be as large as an orange and reach to the cricoid cartilage, or even attain still greater dimensions as in a case reported to the Philadelphia Pathological Society by Dr. Robertson,⁴ in which the aneurism was as large as a fetal head.

These aneurisms vary in size from time to time, increasing and diminishing quite remarkably. They nearly always dislocate, to a greater or less extent, the sternal end of the right clavicle, which is elevated by each pulsation of the tumor. They are more superficially placed than aneurisms of the arch, and consequently the evidence of their aneurismal nature is, as a rule, readily demonstrated. They can always be palpated above the right sternoclavicular articulation and in the suprasternal notch. In this latter situation the expansile character of the pulsation, as well as a thrill, diastolic shock and bruit, may be easily appreciated; while often they are accompanied by a marked tracheal tug, being usually adherent to the trachea.

In fully one-half the reported cases the trachea was compressed, producing cough. This may be dry, brassy and frequent, or paroxysmal and associated with hoarseness and aphonia. In a majority of the cases there was a mucopurulent expectoration and sometimes traces of blood.

Dyspnea in nearly all cases is a marked symptom. It is usually for this, or pulsation and pain at the root of the neck, that these patients seek medical advice. The pain complained of may be dull and aching, and confined to the sac itself, or sharp and lancing like an angina pectoris, but referred entirely or almost wholly so to the right side of the neck and shoulder. These patients may be free from pain much of the time, and they frequently have very good days, when the size of the tumor is reduced and the dyspnea and pain have almost disappeared. Again, they may suffer greatly, the pain and dyspnea being made worse by emotion, bodily exertion or temporary ill health.

Edema, particularly affecting the right side of the face and neck, may be a symptom. The right side may be colder than the left, and rarely, numbness and even paralysis in the right arm supervenes from pressure. The right external jugular vein often stands out turgid and prominent, and a slightly darker hue is noted over the right side of the neck from venous stasis.

Fig. 1.—Chart showing relation of the arch of the aorta and the great vessels to the chest wall.

Dysphagia is not a frequent nor a marked symptom, having been noted in not more than a quarter of the cases. Curiously enough, as the aneurism increases in size, this symptom, if present at first, is apt to grow less or even disappear, because the tumor in its growth extends upward and outward, pushing the clavicle before it and freeing itself from the resistance offered by the sternum.

Inequality in the radial pulse is usually readily demonstrable, the right being the weaker. Pulsation in the subclavian, axillary, brachial, carotid and temporal arteries on the right is less marked than in the corresponding arteries on the left, or it may be altogether absent. The latter is particularly apt to be the case in

3. The above anatomic description is taken principally from Gray. The chart is original.

4. Trans. Phila. Path. Soc., N. S., vol. ii, p. 269; vol. xviii, p. 220.

the right temporal artery, which seems, in many cases, to be more affected than even the right radial. There may be noted in some cases a lengthened interval between the heart's systole and the stroke of the pulse in the right radial, which is very suggestive; and in my own case I noted a peculiar regurgitant quality in the right pulse at the wrist which was absent in the left. This difference was well shown in a sphygmogram, and was very suggestive. It might possibly be due to the position of the aneurismal sac, which, not being continuously distended with blood, may act in a measure like or be considered analogous to a diminutive heart with incompetent valves. If this quality of the pulse is present in aneurism of the arch, it is apt to be felt in both radials.

Fig. 2.—Philadelphia Hospital case. Aneurism of arch of the aorta.

The auscultatory signs over these aneurisms, except in their higher position, are not distinctive. There may be a systolic murmur of variable intensity transmitted into the vessels on the right side and accompanied by a thrill. More rarely a double murmur is heard, usually associated with disease of the aortic valves.

There are certain respiratory signs, to which I wish to call attention, which have not been heretofore described in this connection. These result briefly from the compression exerted by the aneurism on the apex of the right lung, and consist in an area of impaired resonance with increased tactile fremitus, and diminished or distant breath sounds, immediately adjoining the tumor;

while adjacent to this area of compressed lung is an area of hyper-resonance with diminished tactile fremitus due, no doubt, to vesicular relaxation.

DIFFERENTIAL DIAGNOSIS.

Some of the more striking differences between aneurism of the innominate artery and aneurism of the arch may thus be briefly summarized: In nearly all cases of aneurism of the innominate there is a more or less pronounced external tumor on account of the more superficial position of the growth. The higher position of this tumor in innominate aneurism is significant, reaching into or above the suprasternal notch and behind or above the sternal end of the right clavicle. The latter is usually dislocated and pulsates with each beat of the heart. The larynx or trachea is more apt to be dislocated or compressed in aneurism of the innominate than in aneurism of the arch, but the esophagus is not so often compressed in the former as in the latter condition. Venous congestion, if present, is more apt to be general in aneurism of the arch, while involving the right side in innominate aneurism. The dyspnea is greater and the alterations in voice apt to be more marked in innominate aneurism.

The pain in aneurism of the arch is lower down, over the middle or lower sternum, and transmitted to the left or bilaterally like an angina pectoris. In innominate aneurism it is referred to a region higher up, corresponding to the aneurismal sac, and transmitted to the neck, shoulder and arm on the right side. Edema or impaired sensation, numbness or loss of power confined to the right arm is very suggestive of innominate aneurism. It is more apt to be general in aneurism of the arch. Pressure symptoms from involvement of the right sympathetic or right recurrent laryngeal nerves, while not rarely present in innominate aneurism, are not in themselves distinctive.

Rarely both signs and symptoms are remarkably indefinite, especially where the growth is small, or occasionally when the aneurism springs from the arch, as in a case reported to the London Pathological Society by Christopher Heath,⁵ in which the "inner end of the right clavicle was thrust forward and the interclavicular notch obscured and the aneurism had perforated the sternum close to the sternoclavicular joint." In the belief that it was an aneurism of the innominate artery, the right subclavian and right common carotid were ligated. The aneurism subsequently ruptured and the innominate artery was found healthy; the sac of the aneurism sprang from the ascending arch of the aorta.

When these aneurisms involve the arch, or in those rare instances where both the arch and the subclavian artery is involved,⁶ the clinical picture of uncomplicated innominate aneurism is not presented.

In conclusion, it may be said that a delayed and weakened beat in the right radial, absence of pulsation in the right temporal, a turgid external jugular, in association with paroxysmal attacks of dyspnea and pain at the root of the neck, or referred to the right side, are all very suggestive of innominate aneurism. The two signs to which I would like to call special attention, and which, so far as I am aware, have not been described before in this connection, are the regurgitant quality in the right radial pulse and the angle of re-entry in the second interspace. The presence of these

5. Trans. London Path. Soc., vol. xxi, p. 132; vol. xxv, p. 117.
6. Trans. London Path. Soc., vol. xlii, 80.

in association with the signs of aneurism in the supra-sternal notch and behind the right sternoclavicular articulation are pathognomonic of innominate aneurism.

PROGNOSIS AND TREATMENT.

As a rule, unless relieved by operative measures, these aneurisms sooner or later rupture. A very rare occurrence is spontaneous organization of the clot.⁷

Operative measures are not unattended by danger,

particularly valuable on account of the dangers attending operation *per se*, while later statistics seem to show that it has been attended by recovery and cure in more than three-quarters of the cases.

The operation consists in distal ligation of the right common carotid and subclavian, one or both, either consecutively, if it should prove necessary, or at the same time. This procedure was first suggested orally by Brasdor of Paris, but the operation itself was never performed by him, so that it has come to be associated with the name of Wardrop of London, who performed it in several cases of innominate aneurism.

Fig. 3.—Episcopal Hospital case. Aneurism of the arch of the aorta.

Fig. 4.—Pennsylvania Hospital case. Aneurism of the arch of the aorta.

which has been much reduced since the introduction of asepsis and modern surgical methods. It is always well to try palliative treatment at first, consisting in measures directed to reduce blood pressure and favor coagulability of the blood, aided by distal pressure. The earlier statistics of distal ligation for these growths are not

In uncomplicated cases it has proved highly successful, the sac becoming speedily obliterated by organized clot. When the aneurism is more extensive and involves the arch of the aorta, this operation is not unattended by danger from the extension of the coagulum into the lumen of the aorta, thus blocking off the circulation. This accident happened in a case reported to

7. Trans. London Path. Soc., vol. ix, pp. 95, 167.

the London Pathological Society, death ensuing on the sixth day after the operation.

In regard to the literature, reference must be made to Holland's Monograph⁹ on "Aneurism of the Arteria Innominata," in which he collected a series of 46 cases from a review of the literature to date. Since that time several statistical papers have appeared on the subject, notably that of Wyeth,¹⁰ in 1881, and of Rosenstern,¹¹ in 1886. Winslow¹² followed in 1893 with an extensive paper dealing with the symptomatology of these growths and their operative treatment. He made use of Wyeth's and Rosenstern's statistics, and collected in all 83 cases, 10 of which were included in Holland's paper, which seems to have escaped him.

I found 11 cases in the Transactions of the London Pathological Society, 4 in the Philadelphia Society, 2 in the New York Society, and 2 additional cases referred to by Ashhurst¹³ in his Surgery, and not included in any of the above series. Hirschman¹⁴ of Detroit also reports a case. The above cases, with my own series of 8, make a total of 147 cases.

Except in isolated instances, no attempt was made to review the pathologic and surgical literature in German, French and Italian, as this seemed to little purpose. The collection of a more or less complete list of the reported cases would have been interesting, but not necessary to my purpose of deducing from the clinical notes, the symptoms and physical signs. The above series of cases was already sufficiently large and detailed both for that purpose, and also to give in a general way some idea of the frequency of these aneurisms.¹⁵

NECROSIS OF THE BONES OF THE FACE.*

STEWART L. MCCURDY, M.D.

Professor of Orthopedic and Clinical Surgery, West Pennsylvania Medical College; Professor of Anatomy, Oral and General Surgery, Pittsburg Dental College; Orthopedic Surgeon, Presbyterian Hospital; Surgeon P. C. C. & St. L. Railway.
PITTSBURG, PA.

Pathologic changes about the tissues of the face resulting in death of bone are most common. It is quite usual for the dentist to remove portions of bone during the management of pyorrhea alveolaris and other suppurative conditions about the teeth. A cardinal symptom suggestive of beginning destruction of bone is swelling that pits on pressure, or what is known as edema. When this is found either on the alveolar process or tibia, a careful study of associated symptoms should be made, since it is on the proper and early management of such cases that the subsequent history depends.

When the existence of a periostitis is fully deter-

mined a free incision should be made down to the bone, for just so soon as the colony of bacteria that is causing the trouble is reached and disconcerted, their activity ceases and repair begins. When, however, myriads of bacteria are permitted to go on and multiply and destroy living cells, destruction is relatively great. The early treatment would appear to be applications of iodine and heat or ice, to be followed by incision in two or three days when no improvement is obtained from these remedies.

Syphilis as an etiologic factor should always be thought of, for in these cases radical operation should never be made, but instead, specific medication should be instituted.

To further emphasize the course of treatment and results in these conditions, a few typical cases are appended:

CASE 1.—H. H., male, aged 30, presented himself with a mouth converted into a pus basin. This putrescent condition had existed for many months. He had had a chancre four years before, but this history had apparently been overlooked, for specific medication had not been administered. An examination revealed a denuded left mandible from symphysis to condyle.

FIG. 1.—Outside of half of bone removed.

Operation.—There was nothing to be done but to operate. The first step required the removal of the entire left body. It was with some difficulty that the tissues were dissected back from the bone so as to permit its removal. Owing to the advanced process of decay the body was broken in three pieces. The angle and ramus were found also to be detached, but were included in the tissues, so that they could not be removed until a dissection was made from the position of the last molar upward, toward the coronoid process. This was done through the mouth with a pair of Cryer upper universal tooth forceps; the ramus was removed without great difficulty, the bone coming away in two fragments. It included the entire body, with the ramus coronoid process, sigmoid notch and the neck of the condyle, the condyle alone remaining on the left side. That portion of the symphysis not included in the specimen had disintegrated and was removed by curettement (Fig. 1).

Results.—Hemorrhage was extensive but this was controlled by packing, which was allowed to remain for forty-eight hours. Careful packing was required for several weeks, so as to keep the remaining half of the bone in as near a normal position as possible until reproduction of new bone has so far advanced as to bridge the chasm from the remaining condyle to the symphysis.

The ultimate result may be seen by studying Figure 2. Articulation between the teeth in the remaining half of the mandible and those in the corresponding maxilla is as near perfect as is possible. The wound itself repaired without incident under specific medication.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Stomatology, and approved for publication by the Executive Committee: Drs. E. A. Bogue, Alice M. Steeves and M. L. Rhein.

This case illustrated that many extensive incisions are made through the tissues of the face for operations on the mandible and bones of the face that could be done through the mouth. Figure 3 shows that no deformity of the face is present either from unnecessary incisions through the face or from loss of bone.

Figure 2.

Figure 3.

CASE 2.—G. W., aged 40, had a history of chancre eight years before the beginning of the present trouble, with an intermission of perfect health. The exciting cause of the present trouble was a suppurative peridontitis.

Operation.—I examined him and decided on an operation on the following day. After carefully dissecting back the flaps

of soft tissue, including the periosteum, requiring incisions in two or three directions, the left maxilla was removed. This included the antrum and lateral nasal wall. Further curettements removed fragments representing practically the entire right bone below the floor of the orbit, making the cavity for merely occupied by the right maxilla continuous with the right nasal cavity and the mouth. The hemorrhage was quite extensive, but was controlled with gauze packing.

Results.—Under specific medication the wound entirely repaired in three months. Packing was necessary all this time.

Figure 4.

and took the place of the roof of the mouth so well that there was little defect of speech; indeed, so little that his family never knew that he had undergone an operation. The operation was done through the mouth. The patient left the hospital on the fourth day. An artificial denture restored the voice perfectly, and, but for the nasal secretions falling into the

Figure 5.

mouth, he suffers no inconvenience. Medication was continued for one year. Figure 4 shows the case after complete recovery.

CASE 3.—H. M., aged 29, had a chancre eight years ago without usual history and no tertiary symptoms until two years ago, when he had beginning destructive disease of the nasal septum, which gradually extended to the nasal bones and roof of

the mouth. In spite of what it is reasonable to suppose was good treatment, the destruction continued and would, no doubt, have destroyed the entire maxilla had not treatment been faithfully carried out. The destruction ceased and repair of the ulcerative surfaces was complete in one year. The case presented a most extensive destruction. The bones in the roof of the mouth and nasal cavity were so destroyed as to freely expose the base of the skull. The ethmoid cells were destroyed well up to the cribriform plate. At no time, however, were there any cerebral symptoms (Fig. 5). A vulcanite prosthetic appliance attached to a set of teeth enabled the man to talk well.

CASE 4.—A woman, aged 50, had a severe supposed toothache in her left lower third molar. A competent dentist made an examination and decided to extract. This was done, but was not followed by relief from pain. The case came to me three weeks later, the patient suffering most intensely. A thorough examination with a probe showed that the external surface of the mandible from the second molar to the angle, and for a space of a square inch, was completely denuded of periosteum. The disease had also extended over the process to the internal surface of the bone, about half way down. The suffering, while quite severe at all times, was more intense at night. I had treated a so-called tubercular bone disease in another member of this family that made a most satisfactory improvement under systemic medication, so it was concluded that a systemic taint was the principal factor in the case under treatment. After opening up, through the mouth, the entire diseased areas were removed and the portion of the process that was denuded on both sides chilled away; the sinuses were curetted and flushed with pure tincture of iodine and packed. Mixed treatment was pushed vigorously and the wound dressed daily. Some small fragments of bone were removed during the following month. Pain disappeared in about one week after the operation. The wound healed in two months, and there has been no recurrence. The medication was continued, however, for eight months.

DISCUSSION.

DR. EUGENE S. TALBOT, Chicago—Has Dr. McCurdy noticed in his cases that the maxillary bones and the bones of the face and nose are more often involved in syphilis than other bones of the body, and if so, can he give a reason?

DR. M. L. RHEIN, New York City—I have heard that in one dental society it is the duty of a dentist never to attend a syphilitic case. Of course, we as stomatologists can not for one moment do anything but condemn any such outrageous doctrine as this. Dr. McCurdy has spoken about the non-surgical interference, but there are cases in which minor surgery becomes necessary for the perfect restoration of the health of the mouth, and this very question of sterilization of the mouth means a removal of the debris. This necessarily becomes surgical work, and it is in this position that the stomatologist so often places himself in a position not only of endangering himself by infection, but others, if sterilization is not thoroughly carried out. In all suspected cases my practice has been to use carefully on the patient, not only a mouth wash prior to operation, but also a spray of bichlorid of mercury. I do not believe that anything short of this agent is at all available in these cases. From memory I would say that in the last year I have had at least 20 cases with well-defined syphilitic history.

DR. McCURDY—In answer to Dr. Talbot, I think that in diseased conditions and operations about the teeth there are more chances for mixed infection to occur because the majority of people do not take proper care of their teeth. I observe this especially because my practice includes general as well as oral surgical cases. Students in infirmary work at college frequently refuse to operate on cases with facial eruptions, and especially those with tertiary syphilis, because they fear that they may become infected.

DR. RHEIN—The cases I referred to were in the secondary stage, where the treatment was about ended. I only want to draw the line of distinction.

DR. McCURDY—This matter has been definitely settled. In the third stage of syphilis it is impossible to become inoculated unless the destructive stage begins before the second stage ends. As you understand, there is, as a rule, an intermission of perfect health between the second and third stage, and it would be a rare condition for the second stage to extend over into the tertiary or destructive stage. For this reason the operator has very little chance of becoming inoculated in operating on destructive bone diseases of syphilitic origin, even when rubber gloves are used.

PROSTATIC OBSTRUCTION TO URINATION.

WHEN TO OPERATE AND HOW TO OPERATE.*

PARKER SYMS, M.D.

NEW YORK.

After fifty years of age one man in every nine is the subject of pronounced prostatic hypertrophy. About 20 per cent. of these show symptoms more or less marked.

Hypertrophy of the prostate, producing obstruction to urination, is the cause of the greatest suffering which men are called on to bear. In a typical case where cystitis is established the agonies endured by the patient are often beyond description. It is a fact to be recognized that prostatic obstruction of the severer type is surely, though often slowly, a fatal disease. Fortunately, the attention which surgeons have given to this subject in the last few years has resulted in the evolution of its treatment, so that to-day we can offer to these sufferers a safe and sure plan of treatment which results not only in the relief of the painful condition, but in its actual cure and in permanent correction of the anatomic condition which was the cause of the symptoms.

In this paper I shall not enter into consideration of the etiology of prostatic hypertrophy, nor shall I touch on the pathic conditions more than is necessary to explain their practical importance, and also to show the rationale of the treatment which has been found to be the best.

SYMPTOMS.

When obstruction to the outflow of urine by an enlarged prostate has reached a certain stage, changes take place in the structures of the bladder and in its function which lead up to the period when the patient's real suffering and danger become pronounced. During the earlier period, when there is mere impediment to the outflow of urine, compensatory hypertrophy of the bladder muscle takes place, which for a time may apparently overcome or counterbalance the obstruction to the outflow. Later the hypertrophied muscle degenerates and atony supervenes, giving place to dilatation of the bladder in many cases. It is then that the bladder becomes unable to completely empty itself, and a certain amount of urine is retained in the bladder, that is to say, a certain amount of residual urine, and this becomes one of the chief aids to infection which is liable to take place in every case. Of course, the presence of residual urine does not always depend on atony or dilatation of the bladder, but it will be found in any bladder when the obstruction to the outflow is sufficient to impede the effectual emptying of the bladder. In certain cases there is rather sudden complete obstruction to the outflow of urine as the first indication of this trouble. In many cases the obstruction and the impediment are manifested slowly, so that there is a retarded and, therefore, a pro-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Dr. DeForest Willard, Charles A. Powers and J. E. Moore.

longed act of urination. As the emptying of the bladder becomes more and more impeded, the act is necessarily oft repeated, and we have that very prominent symptom of prostatic obstruction, namely, frequency. I wish here to speak not too fully of the symptoms, but to describe what are, in my opinion, the indications calling for surgical relief, and later to describe what is, in my opinion, the best means of affording this relief to the patient.

DIAGNOSIS.

The diagnosis of prostatic obstruction should be made in the simplest possible manner. In a patient fifty years or more of age any pronounced change in the act of urination should lead one to suspect prostatic obstruction. A carefully taken history of the case will put one entirely in possession of the subjective conditions, and no examination should be made beyond palpation of the prostate through the rectum and the very

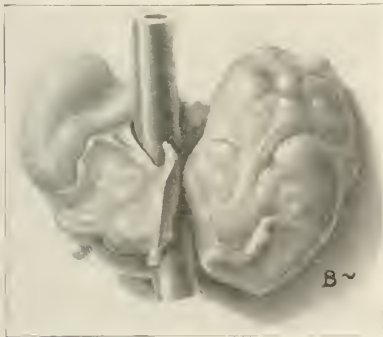

Fig. 1.—Actual size. Showing lateral lobe enlargement.

Fig. 2.—Actual size. Showing lateral lobe enlargement with median bar.

careful introduction of a flexible catheter into the bladder, after the patient has urinated, for the purpose of determining the amount of residual urine and the quality of the same.

CYSTOSCOPE.

I can not speak too strongly against the employment of the cystoscope in these cases. I regard a cystoscopic examination of a prostatic patient who is suffering from more or less severe cystitis as a thoroughly unwarranted procedure, and as far more dangerous than a properly performed removal of the prostate through the perineum.

As an example of this I would quote a patient who was examined by the cystoscope, and as a result lay at death's door for fourteen weeks. Last fall his prostate was removed, affording him complete relief from his

prostatic obstruction. He was up and walking about at the end of forty-eight hours and was never in a condition of danger.

METAL CATHETERS.

Again, I can not speak too strongly against the employment of metal catheters either for examination or for the purpose of withdrawing urine from these patients. More lives have been sacrificed to the silver catheter in cases of prostatic hypertrophy than can be computed. It is an instrument which never should be used. Before operation, the introduction of a metal instrument into one of these bladders is dangerous. When one can not succeed in introducing a soft catheter a Mercier catheter should be used, and if this can not be introduced without undue difficulty, it would be safer to do a perineal section on the patient at once rather than to subject him to prolonged manipulation which, if unsuccessful, would result in more or less damage, and to a risk of extravasation and all its disastrous consequences.

All that is needed in these cases is a sufficient working diagnosis, and the surgeon should abstain from attempting to make a too minute diagnosis by an unneces-

Fig. 3.—Actual size. Three lobe and isthmus type.

sarily extensive examination: for instance, if it be determined that a patient has prostatic obstruction which is doing damage to the bladder, or which has resulted in marked cystitis, and if stone be suspected, it is unwise to introduce even a searcher to accurately determine its presence or absence, for we already have sufficient indication for operation, and if there be a stone it can be readily found at the time of operation and at once removed by the aid of crushing, if it be large, or simply with forceps, if it be small.

WHEN TO OPERATE.

Frequency.—When a patient is suffering from obstruction which necessitates very frequent urination to a degree which entails exhaustion, he requires relief.

Catheter.—When the obstruction requires the habitual use of the catheter the patient is safer to have a radical operation performed than to enter on or to continue in the so-called catheter life.

Cystitis.—When the patient suffers from repeated attacks of acute cystitis, or when he suffers from a marked degree of chronic cystitis, he will be safer if radically operated on.

Stone. When bladder stone is caused by prostatic obstruction, I feel that the patient should have a radical prostatic operation performed, because if mere crushing of the stone is resorted to, stone will reform unless the obstruction to the outflow of urine is removed, and because the radical operation, to be later described, is so safe that it adds little or nothing to the risk which a patient runs before the danger of the anesthetic.

Hemorrhage.—When frequently repeated hemorrhage

Fig. 4.—Actual size. Lateral and median lobe enlargement.

is part of the history of prostatic obstruction, the radical operation should be performed, for the condition giving rise to hemorrhage may in that way be removed before the patient's strength has been badly depleted.

Pain.—If pain is a prominent symptom of prostatic obstruction, leading to an undermining of the patient's health from its consequent exhaustion, he should be relieved by radical operation.

To sum up, the indications for operation are: Frequency, pain, cystitis, hemorrhages, catheter life, stone, residual urine (extreme), dilated bladder, contracted bladder.

HOW NOT TO OPERATE.

Bottini Operation.—I have always inveighed against the Bottini operation, and I have been charged as improperly inveighing against this operation because I have not had experience in it. I gladly accept this charge because I feel that the Bottini operation can be condemned on its own demerits without any necessity arising for each surgeon to subject his patient to a procedure which is so contrary to well-established surgical principles. There is no law of surgery more clearly defined and more fully recognized than that which is applied to the treatment of laceration or rupture of the deep urethra. For this condition there is but one recognized mode of treatment, and that is immediate perineal section down to the site of the laceration, with drainage of the bladder. The Bottini operation is one which produces laceration of the deep urethra, and except as modified by Chetwood, does not meet this clearly de-

finer indication of external drainage. It has been claimed by its advocates that though it were often merely a palliative operation and frequently failed to effect a cure, that simply because it is not a cutting operation it is safer than one of the radical procedures. This is contrary to theory and contrary to fact, for every advocate of the Bottini method has shown a large mortality in his recorded cases.

Suprapubic Route.—I have always inveighed against the suprapubic route for operations on the prostate. The reasons for this are manifest and manifold. The prostate lies beneath and in front of the bladder, actually in the perineum; it does not lie above the bladder and it does not lie within the bladder, and to reach it by the suprapubic route is as irrational as it would be to operate on the tonsil by going through the occiput.

Suprapubic Prostatectomy.—I have always maintained that suprapubic prostatectomy entails an unnecessary danger to the patient, and statistics bear me out in this fact. Convalescence is tedious and protracted, infection of the prevesical space is of frequent occurrence, the uphill drainage of the bladder can not be compared with the perineal drainage in the line of gravitation, and prostatectomy performed through the upper route necessitates a double wounding of the bladder: that is to say, through its upper wall and through its lower or posterior wall. It leaves a thoroughly unsurgical wound, while prostatectomy performed

Fig. 5.—Actual size. Extreme lateral lobe enlargement.

by the perineal route, if properly done, does not involve the bladder at all; the bladder is uninjured, the drainage of the bladder and the drainage of the prostatic sheath are separate and distinct, convalescence is short and safe, the patients may be up on their feet at periods varying from one to five days after the operation, the least number of tissues are involved in the operation, with the smallest amount of mutilation. If properly performed, the operation is so simple and so safe that it may well be regulated to the realm of minor surgery.

HOW TO OPERATE.

A few years ago we all regarded prostatectomy as a dangerous procedure, and one which should not be undertaken unless there were grave indications for its employment, but to-day statistics have shown that in the hands of skilled and experienced operators perineal prostatectomy has been rendered so safe that it may be considered as the procedure which entails the least danger.

Fig. 6.—(a) Parker Syms prostate tractor collapsed. (b) Prostate tractor dilated to 2½ inches.

Perineal Route.—I have always maintained that operation should be done entirely through the perineum, and further experience, as well as the experience of surgeons at large, both those who hold this view and those who oppose it, has only tended to confirm me in this view.

I feel that the proper method of removing a prostate is the one which can be done the most expeditiously and

Fig. 7.—Extreme lithotomy position with hips raised. This is a great aid in bringing the prostate within reach.

at the same time involve the smallest amount of cutting and mutilation of parts, and the one that entails the least risk to the patient. I am persuaded that perineal prostatectomy performed through a small median perineal incision is the one that meets these requirements better than any other. The French operation described by Albarran, Proust and others, and which has been presented to us in a modified form by Young of Balti-

more, involves an unnecessarily elaborate dissection of the perineum which requires an unnecessary amount of time and entails an unnecessary amount of hemorrhage. Every hypertrophied prostate can be removed through a simple straight median incision of the perineum; the cut may be made by practically one sweep of the knife down to the membranous urethra, which should be opened on the lithotomy staff; the rest of the operation is done simply by stretching and pushing the tissues with the finger, and enucleation of the prostate may be rapidly and easily accomplished by the single finger of the operator. Goodfellow of San Francisco accomplishes this with the greatest success without the aid of any retractor.

I have found a great aid to this operation in the rubber retractor (Fig. 6) which I first presented to the profession at the session of the American Medical Association in 1900, and which continued experience has prompted me to again tender to you with increased confidence. I feel that this instrument is in many ways superior to the metal retractor of the French, which, how-

Fig. 8.—Showing simple median incision in perineum. There is no dissection and but a single sweep of the knife.

ever, as modified by Young, is a very good instrument. My rubber retractor is soft and yielding, is harmless to the interior of the bladder, is absolutely out of the way of the operator, and is an excellent hemostatic, closing the space and stopping the oozing as soon as a lobe of the prostate has been removed. Since I presented this method of operating to the American Medical Association in 1900, I have hardly modified it, but increased experience has taught me that I can accomplish the object in a very brief time, and can work through a smaller incision than formerly. I have also found that the after-treatment can be materially modified to the advantage of the patient, as the period of convalescence has been made much shorter and much more comfortable than was the case with the earlier operation.

The method of operation is as follows: The patient, anesthetized with chloroform or ether, or with spinal cocainization, is placed on a short inclined plane, so as to be in a very extreme lithotomy position (Fig. 7). A Syms staff is introduced in the bladder and a single incision is made, opening the perineum down to the

membranous urethra (Fig. 8), the knife is passed into the groove of the staff and the membranous urethra opened throughout its length (Fig. 9). A probe or curved director is passed to the groove of the sound and thence into the bladder as a guide; then the staff is removed and the index finger is pushed into and through the prostatic urethra, fully dilating it into the neck of the bladder. The bladder is then thoroughly irrigated

line of cleavage be found, this may be rapidly and almost bloodlessly accomplished. As soon as the prostate is removed, a large perineal drainage tube is introduced into the bladder through the prostatic urethra, and the wound and the space from which the prostate was removed are packed with iodoform gauze. This packing is made tight and firm in proportion to the amount of oozing encountered. The wound is temporarily sutured over the gauze and the operation is complete. Patients are usually in bed within half an hour from the time the operation is commenced. Concerning preservation of the ejaculatory ducts, we would say that certain prostates produce their obstruction entirely on account of anatomic changes which take place in the isthmus or so-called middle lobe. In the majority of

Fig. 9.—Shows knife entering the lithotomy staff preparatory to the division of the membranous urethra.

Fig. 11. Tractor in situ. Incision in sheath of prostate is shown, ready for enucleation.

Fig. 10.—Shows tractor dilated within the bladder pulling the prostate toward the surface.

with sterile water, the rubber retractor is introduced into the bladder and fully dilated and clamped (Fig 10). Sufficient traction is now made on it, the wound is dilated with the finger, the tissues being pushed posteriorly and to one side so that the sheath of the prostate is exposed (Fig. 11), and a free vertical opening is made with scissors. The prostate is then rapidly enucleated by the index finger. If the proper

cases the obstruction is due to the lateral lobes which distort or compress the bladder orifice. In certain cases it would be impossible to remove the obstruction without removing the portion of prostate which contains the ejaculatory ducts, but in no cases is it necessary to remove any material portion from this region. As to the ultimate preservation of these ducts, and as to the ultimate preservation of the sexual function, we say that this whole question must be more or less problematic. In a number of cases epididymitis has ensued as a post-operative complication, usually occurring when healing was nearly complete, sometimes occurring after complete healing. This would certainly show that infection had taken place from the urethra through the natural channels to the epididymis, and, therefore, that these ducts must have remained patent. In elderly patients, and, in fact, in the majority of prostatitis, it

would be difficult to arrive at a satisfactory conclusion regarding the preservation of the sexual function.

Most of my recent patients have been up and about at the end of forty-eight hours, the gauze packing having been removed twelve to twenty-four hours after the operation, and the drainage tube usually at the end of forty-eight hours. From then on I consider the patient better out of bed than in. The normal bladder function has been speedily reproduced in all of these later cases.

As to mortality, I have now operated on 34 cases. I did the first 23 without a death; I lost the twenty-fourth and twenty-sixth cases. They were each very feeble old men, who apparently died as the result of the anesthetic. Hemorrhage was not present in either case, nor was there any infection nor suppression of urine; they simply went rapidly to pieces and died. These are the only two deaths, so that I have thus far lost two patients out of thirty-four. Goodfellow operates in the same simple manner. He has been longer in the field than any of us, and I believe he can report over seventy cases without a death, showing that perineal prostatectomy performed by a simple medium incision is certainly a very safe procedure.

NOTE.—The discussion on the papers of Drs. Syms, Goodfellow and Fuller will follow the last two papers next week.

HYDRASTIS.

SOME OF ITS THERAPEUTIC USES.*

W. BLAIR STEWART, A.M., M.D.
ATLANTIC CITY, N. J.

Many years ago, no one can say how many, the Indian tribes that roved over what is now our United States well knew the physical properties, the curative and medicinal virtues of a beautiful yellow, juicy, perennial root that grew in the rich shady woodland east of the Rocky Mountains. This root, when beaten up alone or with a little water, yielded a beautiful yellow fluid that would dye their clothing varying shades of yellow, according to concentration and mixture with other plant juices. They also knew that an infusion of this yellow root would cure many cases of ophthalmia and chronic leg ulcers. Indeed, the Cherokees were reported to cure cancers by it, but our present knowledge of the drug and disease practically disproves this idea. Like many of our medicinal preparations, what was then used empirically is now known practically to us as *hydrastis canadensis*.

Hydrastis canadensis has been used in almost every form from the infusion, powdered root, tincture, and active principles to the proprietary preparations, the composition of which is unknown to the profession and to be necessarily avoided if we would prescribe intelligently. Briefly stated, we have berberin and hydrastin as the two active principles, and from the latter we obtain hydrastinin. The fluid extract, tincture and glycerinum are the official preparations most used. *Hydrastis* is best recognized by its peculiar narcotic bitter taste and yellow color. The fluid extract probably represents the purest and most reliable preparation, and none but assayed preparations should be used. Many impure forms of *hydrastis* are on the market, but will not give the results that can be obtained from the pure drug.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pharmacology, and approved for publication by the Executive Committee: Drs. G. F. Butler, Solomon Solis-Cohen and O. T. Osborne.

PHYSIOLOGIC ACTION.

Hydrastis seems to be most active on mucous membrane, particularly so on diseased mucous membrane. Its first effect is to stimulate glandular activity by virtue of its bitter taste and its slight local irritation of the gland moutais. When they are diseased and oversecretive in their action, it will restore tone, decrease the mucous secretion, and rapidly assist in restoring their physiologic processes. It improves the innervation to the gland, and by virtue of its systemic effects reduces the blood supply by contraction of the tissues surrounding the arterioles of the part. It is mildly antiseptic in type, and temporarily prevents the development of some of the lower forms of germ activity. It is slightly astringent, but should not strictly be classed as such. It acts mildly on a torpid liver, and stimulates a freer secretion of bile, and in large doses causes free watery evacuations of the bowels. By virtue of its action on contractile muscular tissue, it will often produce abortion in the pregnant uterus if not used with discretion. *Hydrastinin* is most active in this direction, but the pure drug must be used with care in pregnancy. With these few notes on some of its physiologic activities, it is easy to apply *hydrastis* in the treatment of diseased conditions.

THERAPEUTIC USES.

It has been my privilege to watch the action of *hydrastis* (the fluid extract) on many cases of chronic catarrhal conditions of the stomach and bowels, and particularly those forms of catarrh due to the effects of alcohol. The fluid extract was given alone and in combination. It is best to begin with one or two drops in water every two to four hours, and increase gradually to ten or fifteen drops at each dose according to the results. In those cases where a large quantity of mucus is vomited and expectorated and there is anorexia, there was a gradual reduction in symptoms in almost every case if a strict course of dietetics was enforced. One case of alcoholic catarrh and almost drug addiction occurs to me as worthy of report in this connection:

Patient.—Man, aged about 45, ordinarily sober and not addicted to the regular use of liquors.

History.—Digestion is normal until he overtaxes himself by prolonged mental work and worry. Under these conditions it was his custom to use that much-advertised and overestimated alcoholic catarrh remedy known as "Peruna." (It is mentioned only to be condemned.) This always excited his latent desire for drink and he used as much as one bottle in each twenty-four hours for about two days, when he developed the worst form of delirium tremens, accompanied by great mucous gastric catarrh, vomiting and inability to control himself.

Treatment.—The preliminary treatment was a hypodermic injection of three-quarters of a grain of morphin sulphate and atropin sulphate gr. 1 150 and in two or three hours 10 grains of calomel and soda, followed in six hours by Hunyadi Janos and effervescent Vichy. When the opiate effect began to wear away he was given:

R.	Ext. <i>hydrastis</i> can. fld.	m. iis	18
	Bismuthi subgallatis	gr. iis	18
	Glycerini acidi carbonici	m. ss	03
	Spiritus chloroformi	m. iv	24
	Elix. lactopeptin. q. s.	ʒi	4

M.

This dose was repeated every one-half to two hours. In addition he was given strychnia sulph. gr. 1 60 every two hours. His stimulant was cut off absolutely. In the first attack in which he called me no *hydrastis* was used and hypodermics had to be frequently repeated with very poor effect. At the suggestion of a fellow-practitioner *hydrastis* was used as above with the most remarkable results.

Result.—The mucus vomiting was reduced at the first dose and the desire for stimulant seemed to be controlled—in fact, stimulants were abhorred. If the hydrastis were withdrawn too soon the old appetite returned. Whenever he feels the least inclination for a drink or a return of the catarrhal condition he resumes his mixture of hydrastis with immediate benefit.

This is only one case in a number where it works well, but every person will not respond so quickly. If pushed and persisted in results may be expected in many cases, particularly the old catarrhal cases. It is quite noticeable that if pushed in large doses the bowels move very often for a few days, but this condition soon subsides for one of comparative regularity.

Many patients will come complaining of a poor appetite, slight nausea, sometimes vomiting catarrhal mucus and subacute indigestion. A proper counsel on diet and hygienic rules is of first importance; then give from one to six drops of fluid extract of hydrastis in water one hour before each meal and at bedtime. If there is no organic impairment of the mucous membrane decided results will follow. If a case of enterocolitis refuses to yield to ordinary treatment try small doses of hydrastis or hydrastinin at frequent intervals until results are obtained. It can be combined with other remedies.

For local use the glyceritum hydrastis is probably the best preparation. It is productive of excellent results in vaginitis and some forms of leucorrhœal discharges, but not in the real acute stages. It acts best in subacute or chronic conditions. Chronic or prolonged specific urethritis will benefit greatly by diluted solutions in injection or by direct application. A spray of the glyceritum hydrastis in three or four parts of water greatly reduces chronic nasal catarrh if systematically used. In fact, it is a remedy that, while not infallible, is too much neglected, and should not be overlooked for the newer materia medica. Most authorities recommend much larger doses of the various preparations than have been indicated in this paper, but my experience shows better results with small doses at frequent intervals. Large doses are liable to produce nausea, vomiting, abdominal discomfort or diarrhœa.

Hydrastininæ hydrochloras in doses of from one-fourth to one grain is an excellent remedy to control menorrhagia, but is slow in its first effects. It has a more prolonged effect than ergot. It is also recommended in epistaxis, hemoptysis, hematemesis and hematuria. It is a remedy that promises much for the future, and as reports of its use are published positive facts may be deduced. Do not use it in pregnant women except with the greatest caution, as it is liable to induce abortion.

Some prefer the use of hydrastin as representing the effective virtue of the drug. The impure hydrastin may do so, but the chemically pure hydrastin will not give the same effects as those obtained from the fluid extract. Pure hydrastin is given in doses of from one-eighth to one-third grain. While hydrastis is among the oldest remedies, it is probably too little used, too little understood, and is neglected. If this paper will serve to give an incentive to its further investigation and report it will accomplish the object of its production.

DISCUSSION.

DR. W. R. WHITE, Providence, R. I.—A number of years ago, when I was intern at the Rhode Island Hospital, an older physician, for whose opinion I had profound respect, told me that he was sure that hydrastis as a remedy was not sufficiently

appreciated by the profession. He said that in his own observation it had a certain influence on the mucous membrane that no other remedy had. I recalled what Dr. Wiggin had said when I listened to the recommendation of its use by Dr. Stewart. I would like to hear his experience with it in colitis and in subacute catarrhal conditions of the large intestine. I would also suggest its local use by injection in these cases. It is very valuable in the diseases of children. Of course its bitterness is an obstacle to its administration to young children. Can this be overcome by a suitable vehicle for administration?

DR. WILLIAM F. WAUGH, Chicago—*The Chemist and Druggist* called attention to the very inferior quality of the hydrastis that was coming to market. Owing to its collection by ignorant persons the drug supplied was almost entirely destitute of active principle. The editorial comment was that "this does not interest the manufacturers of galenics." This was an English paper and apparently no joke was intended. Hydrastin is a contractor of blood vessels and especially the small vessels, while berberin contracts the connective tissue. Where there is a relaxed condition of the uterine supports, it is interesting to observe its effects on the tissues; they remain contracted so that after several weeks instrumental support would not be needed. Dilated stomachs also will be contracted by the same remedy. This property also explains its value in proctitis and colitis. In very many mucous conditions we find relaxation of connective tissue for which we have a remedy in berberin.

DR. CLEMENT B. LOWE, Philadelphia—This is a case where we do not get the same results from an active principle as from the drug itself. Hydrastis has two principles, hydrastin and berberin; hydrastin is always white, its crystals are colorless, as also its salts. Berberin is yellow and its presence gives color to the e-lectic preparation hydrastin, which consists both of hydrastin and berberin. Dr. Stewart says that he got better results from a good extract of the drug than he got from hydrastin. The purer the hydrastin the less it represents the fluid extract. This is an illustration which takes the ground from under the feet of those who claim that we can always get as good results from the active principles as from the drug itself. Morphin does not take the place of opium in practice, because there are a number of other active principles present in the drug that have decided physiologic effects.

DR. HEINRICH STERN, New York City—I wish to call attention to the cumulative effect of hydrastis canadensis. I have not seen an account of this in the works on materia medica and pharmacology which I have consulted. My observations are based on a very large number of cases of manifold pathology for which hydrastis canadensis, in the form of the fluid extract, had been prescribed. The elimination of hydrastis is quite rapid as a general rule, the kidney being the chief excreting organ. In case the latter is chronically affected, especially in cases of chronic interstitial nephritis, the elimination of hydrastis does not occur in the normal ratio and it accumulates to a greater or less extent in the organism. In cases of chronic parenchymatous nephritis its elimination is not materially interfered with, but other medicines, for instance rheum, tend to accumulate when the kidney is of the large white variety. The symptoms of hydrastis accumulation in contracted kidney are headache, vertigo, blurred vision, nausea, constipation, insensibility of terminal nerve filaments and convulsive disorders. I have come to the conclusion that every individual exhibiting a pronounced idiosyncrasy for hydrastis possesses contracted kidneys, even if this is but in the very first incipient stages. In this respect it may serve as a valuable diagnostic remedy. I consider it even diagnostic in cases where kidney epithelia in large amounts, casts and albumin are for long periods not detectable in the urine. The usual doses of ten and more drops of the fluid extract are much too large in the general run of cases, especially when treatment is started. It is not for us to determine how much of a medicine a patient can stand before toxic symptoms develop, but how little of it will relieve his pathologic symptoms. I usually

start the patient on from two to three drops of the fluid extract, increasing it slowly if the desired results are not obtained in this dose. I hardly ever administer more than five drops three or four times a day.

DR. W. B. STEWART—In the treatment of diseases of the stomach the administration of hydrastis, or the alkaloidal forms of it, has probably more of a contractile effect on the connective tissue, and particularly on the relaxed glands of these parts. I have had no experience with the local application, but can see no reason why, in case of ulcer of the rectum for instance, it should not have a good effect. It certainly acts well in catarrhal conditions of other parts, and it would do no harm to try it. Another question was about the administration of hydrastis. The bitterness is covered up to a certain extent by verba santa and similar preparations, but if you combine it with much of these to make it palatable, you will get more harm from the excipients than you will get good from the hydrastis. I generally prefer to give it in capsule. In the case of very young children capsules would be entirely impracticable. When listening to Dr. Waugh, who is my old teacher at college, I recalled a statement by him in 1883 to the class, when lecturing on catarrhal conditions. He said: "Remember, gentlemen, in catarrhal conditions, hydrastis is the sheet anchor." In reply to Dr. Lowe I would state that I have not used the impure preparation of hydrastin, but in all cases have used the chemically pure alkaloid, and was very glad to hear Dr. Stern state that there are cumulative effects, and that in interstitial nephritis there is special danger of cumulative action, which adds to our stock of knowledge of this drug. I agree with the recommendation to use small doses at first and gradually increase them, watching the effect. If you do not get good effects you may suspect some trouble in the kidney. Has Dr. Boardman Reed had any experience in the use of hydrastin in diseases of the stomach?

DR. BOARDMAN REED, Philadelphia—I have had no personal experience with hydrastis in treating diseases of the stomach. When I pursued my special studies of stomach diseases in Germany they did not use it there for this purpose, and my attention was not directed to it. In my former general practice I found hydrastinin very satisfactory in treating uterine hemorrhage. In other conditions I have used hydrastis in small doses without any decided results. In testing any such remedy in stomach cases test meals should be given from time to time and the contents examined to determine the effects. In the future, when I see cases of gastric catarrh that are difficult to control, I shall bear hydrastis in mind and make trials of it under exact conditions. If gastric catarrh can be greatly relieved by small doses of hydrastis, it will be a very good thing to know.

HOW TO PRODUCE MILK FOR INFANT

FEEDING.*

EDWARD F. BRUSH, M.D.
MOUNT VERNON, N. Y.

Many infants must be nourished artificially. The reasons for this are plain. Sometimes the mother is overworked, insufficiently nourished, harassed by a vicious husband and many other children, often incompetent by her own unfortunate temper or a vicious appetite and indulgence or a vagrant desire for amusements, sometimes by an inability to secrete milk. The business of properly nourishing an infant is a serious one, and to be properly accomplished must be attended to with an intense sense of duty. The mother must be healthy, love her child, and not nurse it when she is seriously disturbed, either mentally or physically.

I was called to see an infant in a severe convulsion.

I found that the mother was very solicitous and affectionate. She had been so careful of her child that she did not even allow it to have a drink of water, feeling confident that she herself could fulfill all these requirements. So I said, "Have you any trouble in the family?" She answered, "No." "Well," said I, "surely if you have told me the truth about your feeding the baby, you are not truthful about everything being right in the house." Then, in a fit of crying, she said: "My husband's brother has been here disputing two days about a mortgage." So I said: "Stop nursing your baby until the mortgage business is settled." She did so, and the child recovered promptly. After the brother went away, the mother resumed nursing her child, and there was no further trouble to my knowledge.

It would be a long study to ascertain what effect butter and cheese from diseased cows, improperly fed, housed or cared for, has on the human being consuming these articles of diet. These foods are mixed with many other articles, and it would be difficult to say which was the cause when one's food disagrees with them, but I think with a bottle-fed baby using only milk and water, a search for the source of offense when the baby's stomach or bowels are affected, is very simple.

It is easier to control cows than women. Human mothers are often emotional, excitable, indiscreet, sometimes hysterical, and not always able to control themselves. A dairyman understanding that these conditions can affect milk, must also understand the necessity of controlling his cows. When a cow is in heat or otherwise gets disturbed or hurt, the milk can be thrown away and the excited cow can be kept from influencing the other members of the herd. From years of experience and observation, I feel safe in affirming that the accountable party to the individual in the cradle is the man who is responsible for the production of the milk when the foot that rocks the cradle is not the mater who furnishes the nourishment for the baby. And, therefore, dairymen who are supplying milk for infants' food are assuming a terrible responsibility. There are thousands of infants dying yearly from stomach and intestinal troubles who are fed on the milk sent to the cities and villages by dairymen surrounding the urban and interurban communities, and I am sure that the milkmen supplying these artificially fed infants are responsible for a large percentage of the deaths, and that these infants are killed by carelessness on the part of the dairymen supplying them with their daily food.

In the year 1882 I had charge of the country home of the New York Infant Asylum, and during that year I had 518 inmates, with only 26 deaths, for the entire year. Of these deaths, 5 were artificially fed infants, and 13 were breast fed; the others were weaned. There was not a single case of acute intestinal disturbance. I think that this percentage, a fraction above 5 per cent. of a death rate in an infant institution, is remarkable, and the low mortality was simply due to the fact that I had charge of the cows furnishing the milk for the artificially fed. It seems to me that we will never reach the proper stage of producing milk for infants until we separate the infant food dairy from the commercial dairy. The agricultural colleges and journals devoted to dairying interests are teaching how to raise an abundance of milk at the cheapest possible outlay on the part of the dairymen. The percentage of fats

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClaughan and John C. Cook.

and solids in good milk used for infant feeding is a very insignificant item, while in the cheese and butter factories the fats and solids are the only real value of the milk, and on these percentages the dairyman properly gets his returns. There are many factors at the present time working against the production of proper cow's milk for infant feeding, and the first is breeding.

That the bovine race is notoriously prone to tuberculosis and other forms of chronic disease is admitted, and the better the breed from the dairyman's point of view the more numerously are they afflicted by chronic diseases; therefore, the first and most important consideration, in reforming the methods of supplying milk for infant's food should begin with breeding.

The cow supplying milk for infants' food should be bred from rugged animals not closely related; she should be quiet in disposition, perfectly sound in health, comparatively well nourished, that is, neither excessively fat nor emaciated, and this variety of cow could not possibly be a large yielder of milk.

There has been for generations a tendency to breed the dairy cow to a wrong standard to get good milk for babies. The scrofulous form in all dairy animals is usually an abundant milker, and so from a commercial aspect she is the best cow. And for this reason she is the ideal standard for many breeders; hence the intense in and in breeding, which is necessary to produce this form, and we see in the Jersey herds this mistaken food form of the ideal butter cow. We all know how many of the fancy herds have been condemned by the health authorities, all of them yielding excessively fatty milk. I believe the first reform in infant feeding must begin with another cow.

We must separate the commercial butter and cheese cow from the animal supplying the baby's food. Dairy herds must be established for baby's milk especially; in fact, these will, of necessity, make a separate class of dairymen and dairy cattle with entirely separate methods of feeding, breeding and handling the milk. When these proper conditions are established, the dairy for butter and cheese and the dairy producing milk for food will be separate institutions, and the state control of fat and solid percentages will not be insisted on for the milk food supply.

The cow is man's forager and nurse, and if he attends to her properly she is the best of all his food producers; but she will surely furnish poison for him as easily as good food if he himself does not understand how to prevent her from doing so. She sometimes eats poisonous weeds with impunity to herself. It is said on good authority that the milking cow can eat poisonous weeds that would kill her if she was not giving milk, but the poison reaches the milk consumer, whether it is her own calf or somebody's baby.

I have in mind an animal I have been watching for some years. She is a Jersey, very handsome, fawn colored, large eyes, delicate limbs, a typical aristocratic Jersey cow. Three years ago at springtime a baby sickened and died while getting milk from this cow. I examined the cow very carefully at the time, but could find nothing definite ailing her except that she was a nervous and excitable animal. She was sold, and about a year later, in the spring, another baby getting her milk died, and there was considerable ugly talk about this affair, so the second owner sold her. Last spring she had a calf, and the calf sickened while sucking in the springtime. This owner asked me to examine the cow. I could find no definite disease, but told him

the history of the cow and advised him to kill her. He said he would, but I see her now nearly every day on the lawn, and the owner tells me that he makes butter from her rich milk. This is undoubtedly a good butter cow. She is a splendid lawn decoration, and for folks who do not want her milk for children she is all right. Her present owner has no children, and I do not believe now that there is any danger of any child getting her milk.

I believe the wealthy amateur dairyman does as much harm, if not more, than the careless, poor owner of dairy cows. Dirt that is not pathogenic is far less killing than milk from perturbed or nervous cows. The periodical injection of tuberculin must be disturbing. The effort to maintain a herd of aristocratic, highly bred Jerseys may do very well for a butter herd, but I am sure they are dangerous to supply milk to feed babies.

MODIFIED MILK.

A baby is a good milk analyzer, and when there is nothing added to the milk it gets its method of analysis is sure and simple. If the baby dies from intestinal disturbance when it has no other food than milk and sterilized water, the man furnishing the milk should be held responsible, but when physicians imagine that they can take milk fresh from the milk train and by some novel method of modifying make it equal to mother's milk, then no one can tell whether the trouble originated in the laboratory or from milk sugar, or any of the other causes that may arise with old milk and other old things.

While physicians are trying to construct plans to make bad milk good and persuade parents that sterilizing, peptonizing, pancreatizing, modifying with cream from equally bad milk and indefinite milk sugar, or making gruel, either from barley or other cereals, with the idea that this is the best that can be done, they will still have the problem unsolved, of how to nourish the baby who can not get good milk from his own mother's breast.

A few weeks ago a physician telephoned me that the milk I was sending to him went wrong. On inquiry I ascertained that he was adding milk sugar and lime water. I told him to stop the addition, and he was surprised to hear me say that milk could be fed without modifying. After three weeks his wife telephoned me asking if she could not add sugar. She said the baby was thriving, bowels normal, but she still had the idea that something must be added. No man living to-day can prepare good food for infants from bad milk. He may modify it as he pleases, but the baby will not receive it kindly. Still, on insistence, he often takes it and dies. I know that milk can not be improved, even by the most learned chemist that ever lived.

Good cow's milk will nourish an infant without intervention of the chemist, while bad milk will kill in spite of the man who knows how to modify milk according to the most approved method.

CARE OF THE COWS.

A properly bred cow should not have her first calf until after she is 2 years old. She should always be fed in the stable while giving milk, summer and winter; she should have clean stable and careful currying; her abode should be thoroughly ventilated during summer by exhaust fans, and in winter with properly constructed ventilators. Cows must receive a perfectly balanced ration, that is, a sufficient quantity of nitrogen-

ized and non-nitrogenized food, to balance the amount of the same element that they excrete in the milk and use up for their own nutrition. The grain and oats should be ground fresh daily. Good clean hay, bright oat straw, and properly housed ensilage during the winter months, and in the summer time green fodder, freshly cut and mixed with the hay and grain. None of the waste material from breweries, starch factories, cider mills, beet-sugar refuse, should be given; in fact, the only by-products that are good food for cows are wheat-bran, linseed meal cake, or cottonseed oil meal.

It is a curious fact that the greater part of dairy diet known as cow feed is the refuse from factories that can be put to no other use.

Milking.—Certainly the care of milk and the time that elapses from between its extraction from the cow and its introduction to the stomach are very necessary considerations. The care and attention to milking is also important. The milker should be a good-natured man. When a milker is kind and has a crooning way with the cow, there is a wonderful difference in the milk.

I have seen milk disagree with babies because of the presence of a cross man in the stable. When the cow is afraid of the man who milks her, the mental nervousness affects the milk perniciously. I have seen milk disturbed by the milker having long finger-nails, and thus hurting the dugs. Also, I have noticed a milker using his thumb double, thus using the hard joint to press the teat, causing pain and disturbing the quality of the milk. It is very important that the men milking cows should not have hard, callous or deformed hands, but clean soft hands and a gentle manner. I never allow my men to wet the teats or udder, simply brush the udder and belly clean before milking. I have seen many a chapping of the teats, especially in the winter time, from the wetting and washing before milking. The first squirt from each dug should be caught in a small pail and thrown away. In almost every dairy one will find many cows with either warts, small ulcers or other sores on the dugs of the milking cows. Many of them must be painful to the cow while being milked, and some of them are specific, i. e., cow-pox, or some form of disease from the milker's infected hand.*

CONCLUSION.

Dairymen should be held responsible for the stomach and intestinal condition of otherwise healthy infants fed on milk that they furnish, providing that nothing is added, except sterilized water, cane sugar or cream that comes from the cows under their control. Certainly, the milk must be carefully guarded, kept cold, below 50 F., and away from contaminating influences, or the addition of milk sugar, lime water, pepsin, pancreates or any other articles except as above specified.

The surest test that milk is good food for the baby is the baby itself. The percentages of fat, the proportions of proteids, and all the other chemical data amount to nothing, if the baby is thriving the milk is good.

Swimming as Part of a School Curriculum.—The *Medical Press* urges the desirability of making swimming a compulsory part of all school training, and deprecates the fact that many children are absolutely devoid of any knowledge of this most useful attainment. It advises, in the interests of the physical development of the people, and as a wise prophylactic measure for the safeguarding of human lives, that swimming be made a compulsory element in every public school education.

THE INITIAL CONTAMINATION OF MILK*

RICHARD COLE NEWTON, M.D.

MONTECLAIR, N. J.

There has been considerable advance in the study of lactology since the time when the old lady desired just enough milk in her tea to make it "taste a little bit cowy." And while there is still very much to be learned, there is no question that in both lay and professional circles the interest in milk as a food and as a means of contagion steadily increases. Among other influences, the great activity of the manufacturers and vendors of proprietary baby foods, it would seem, must have led people to inquire more strictly into the great question of how infants really ought to be fed, and the very gratifying decrease in the mortality of artificially nourished infants demonstrates the great utility of the steps already taken to properly nourish them, and, at the same time, to avoid communicating disease to them in their food.

It is not necessary to enumerate the names of a large number of physicians and scientists, many of them still young men and women, who have conferred an incalculable benefit on humanity by their labors in this

It has hitherto been supposed that milk while in the cow's udder is sterile, and that the bacterial content of market milk could be reduced to zero if infection of the milk after it leaves the udder could be prevented.

Conn and others, however, have been unable to produce sterile milk, although every possible precaution has been taken in milking and in handling the milk.

Conn¹ describes a process by which he produced what he calls aseptic milk, as follows: "The cow's tail was tied to the leg on the farther side, and the flank and side and the udder were then washed with a 3 per cent. solution of boracic acid and wiped with a sterilized cloth; the milker then washed his hands with the boracic-acid solution and wiped them on a sterilized cloth. About half the milk was milked out and the udder and surrounding parts were again washed in boracic acid and wiped with a sterilized cloth. Once more the milker washed his hands, and then drew the remaining milk into a sterilized covered pail through four thicknesses of sterilized cheesecloth and a layer of absorbent cotton. This milk we call aseptic milk." Of nine samples of this milk, when freshly drawn, the average bacterial content was 342 per cubic centimeter.

If the precautions just enumerated will not produce sterile milk, it would seem as though its production is impracticable. Nothing further apparently could have been done, unless it were to actually shave the cow. Freeman² says: "We have no dairy routine that is at the present time practicable that will give us milk free from bacteria"

Admitting, then, that sterile market milk can not be produced, let us look into some of the advantages which will accrue if milk can be marketed that shall be on the average practically as free from bacteria as the nine samples produced by Professor Conn.

From time immemorial milk has been subjected to a process of straining sooner or later after the conclusion of the milking, and for many years metallic strainers made of wire netting or perforated tin have been used.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

2. Albany Med. Annals, March, 1904, pp. 279, 280.

It has been demonstrated, however, that milk strained through such strainers undergoes little improvement, except that it is freed from pieces of hay, straw, hair and such large objects, but its keeping qualities or its bacterial content are not improved. Generally speaking, however, much visible dirt is left in milk strained in the ordinary way. Of this dirt a large portion is cow dung, and how important this source of contamination of milk is, the following quotation from Harrington will show: "A very small amount of fecal filth per quart of milk makes a very great increase in the number of bacteria per cubic centimeter." Thus it has been shown that with one-tenth grain of stable dirt per quart, one may expect about three and one-third millions of bacteria per cubic centimeter; with one-third grain the number rises to more than 7,000,000, and with a little more than a half grain it rises to nearly 13,000,000.

The average bacterial content of sewage is stated to be from 1,000,000 to 4,000,000 per cubic centimeter, hence we observe that a contamination of one-tenth grain of manure, an almost invisible quantity to the unaided eye, per quart of milk gives a bacterial content equal to that of ordinary sewage.

But this appalling statement is no more startling than another made by the same author, that from quantitative determinations of the amount of stable dirt in many samples of milk it has been estimated that Berlin drinks every day in the milk supply of the city no less than 300 pounds of cow manure, and what is true of Berlin must be true of New York and other cities, so that in the metropolis of the United States probably 500 or 600 pounds of cow manure are drunk every day with the milk.

Pure milk has no odor and a very delicate taste, so that the so-called "cow taste" and smell of ordinary milk are caused by cow manure, and this is too painfully apparent to a discriminating nose and palate in any but the cleanest milk.

That cow manure is very soluble in warm milk, so that a considerable portion of that finding its way into the milk is quickly dissolved and can not be removed by subsequent straining, Conn and others have proved. Belcher³ speaks of this property of milk, and says that no reliance can be placed on the strainer's ability to make up for previous careless handling of the milk.

Conn carried out a series of experiments to ascertain the effect of straining milk, at the conclusion of the process of milking, on its bacterial content, and found that in twenty samples there was little difference between strained and unstrained milk in the number of bacteria nor in the time of curdling.

He says: "It is something of a surprise that no larger benefit is shown (from straining) for as has been indicated by previous experiments, the amount of dirt which is removed by the straining is about 40 per cent." "It has been found by Weil⁴ that filtering milk through filters frequently increases the apparent number of bacteria present. This author, however, concluded that the cause of the apparent increase was that the filter was not sterilized and contained bacteria, which were washed through by the filtering. This does not apply to our experiments, inasmuch as the filter being simply cheesecloth was thoroughly sterilized before each experiment."

Another writer⁵ says: "The liquid impurities (of milk) can not be detected by the microscope. No pasteurizing process can cure or cover up the evil results of nastiness in milking. The particles of manure conveyed to the milk the digestive ferments from the bowels of the cow. They set up that class of fermentation that gives to milk a slimy physical condition and decidedly unpleasant odor."

This odor is so apparent to a susceptible nose that one large milk-dealing establishment employs a man who accepts or rejects the milk offered by the various producers, judging it solely by its odor.

The thorough aeration of cow's milk so commonly prescribed to remove its alleged natural odor would be entirely unnecessary if the manure could be kept out of the milk. In fact, a large part of the battle for clean and wholesome milk would be won if the initial contamination could be prevented. I refer to the avoidable contamination from sources external to the cow's udder.

The importance of preventing the initial contamination of the milk from dust and germs in the atmosphere does not seem to be generally appreciated. It is true that various devices have at times been adopted to accomplish this purpose, and some of them are still in vogue. Metal strainers have, however, been largely discarded, and justly so, since milking through them, as we have seen, tends to increase the bacterial content. Milking through absorbent cotton is effective, but is a troublesome method and requires for its successful use a rather complicated milk pail, with a number of pieces which makes the apparatus hard to keep sterile and rather too intricate, perhaps, for the average dairyman to manage.

In one of the best known of modern dairies, after experimenting with various devices and finding that the ordinary wire milk strainer was worse than none, the milk is now drawn into an open pail and strained after the process is completed, in the old-fashioned way. No doubt the managers of this dairy, whose name is synonymous with clean and scientific dairying, are now looking for a satisfactory device which shall arrest the air-borne and other impurities which are carried into the milk pail by the process of milking. Naturally, various attempts have been made to milk through strainers and even into bottles. One dairyman thought that he could strain the milk through its own froth, collected on a wire or other strainer. Covered pails of various sorts have from time to time been introduced, but have not yet come into general use.

Dr. Freeman⁶ advocates an ordinary eight- or ten-quart pail, with a hood over the top so that perpendicular droppings, dust and contamination from the cow's body, the milker's clothes, breath and so on shall be excluded.

Professor Conn,⁷ after pointing out that milk drawn by a milking machine has been experimentally proved to be rather more contaminated by bacteria than milk drawn in the ordinary way, describes a pail with a cover and with gauze or cheesecloth stretched over a small opening in the cover. This pail answers its purposes very well. By its use Professor Conn and his colleagues at the Storrs Experiment Station were able to exclude 66 per cent. of the initial contamination of milk by dirt, with very great improvement in its character and

keeping qualities, as will be described presently. The pail is an ordinary milk pail, with a well-fitting cover with a handle. In one side of this cover is sunk a circular cup or funnel-shaped rim surrounding an orifice about four inches in diameter, and into this can be fitted a funnel-shaped bottomless cup several inches high. One or more thicknesses of sterile cheesecloth are stretched across the opening of the cover and held in place by the upper cup being firmly driven into the lower.

The strainer of a second pail is somewhat less complicated in construction. The pail itself is shaped like an ordinary chamber slop-pail, with a cover, one-half of the upper portion of which has been cut away. The sterile cloth diaphragm is stretched across the top of the pail and the cover fitted snugly over it. A spout in the side of the pail, fitted with a metallic strainer, enables the milker to empty the pail without taking off the cover or disturbing the diaphragm—a doubtful advantage.

A cover consisting of one piece is easy to handle, to sterilize and to keep sterile. In one of these pails there is the objection advanced by Dr. Freeman⁶ that the opening looks perpendicularly upward and is, therefore, more liable to catch the droppings from the atmosphere and those which come off from the cow's body and from the milker's hands, clothes, breath, etc., and which are the initial contamination of the milk. Furthermore, there is always some spattering in milking, and the droplets of milk scattered around on the edges of the pail and the milker's hands and the cow's udder become contaminated and some of them will be subsequently washed into the pail; the spout in the side of the pail with the strainer over the end will surely catch some bacteria from outside, and will tempt a careless milker to empty his pail without renewing his diaphragm of sterile cheesecloth at the conclusion of each milking, as he should do.

A pail has recently been devised, and is now used in several dairies. This pail is made out of a single piece of steel, and has no seams to catch and hold bacteria or minute particles of curd or other fermenting substance. It is the size of an ordinary milk pail, and has a close-fitting, dome-shaped cover, also made of one piece of steel, with a circular orifice in the top $3\frac{1}{2}$ inches in diameter, which is the size of the plates on which the milk bacteria are grown. Two thicknesses of sterile cheesecloth are stretched over the top of the pail and the cover fitted on. The hole in the top of the cover is nearly six inches above the cloth diaphragm. This almost completely prevents spattering, which is bound to occur when the sterile cloth is stretched over a wire sieve or when the cloth is part of the cover itself and on a level with the top of the pail.

Owing to the comparatively small size of the opening in the cover and the slanting position in which the pail is held during milking, the perpendicular droppings into the pail during the process are largely prevented, whether they come from the milker's breath or hands, or the cow's body or the surrounding atmosphere.

There are only three pieces to the entire mechanism—the pail, the cover and the sterile cheesecloth—and each of them is of the simplest possible construction.

As to the efficiency of covered pails, there may be some room for discussion, and inasmuch as the matter is of such paramount importance, it may be well to follow it out somewhat in detail.

As already stated, Professor Conn found that when he used a covered pail and milked through four thicknesses of sterile cheesecloth and a layer of absorbent cotton, he reduced the number of bacteria in the milk to 342 per cubic centimeter in one set of experiments and 267 in another. And he also found that when the numbers of bacteria in fresh milk vary from 2,000 to 40,000 per cubic centimeter, and are from both external and internal sources of contamination, no parallel can be drawn between the number of bacteria present at any later stage and the number present at the outset. This does not hold true when the numbers are still further reduced. By aseptic milking, the bacteria have been reduced to about 300 per cubic centimeter, and this has a very striking effect on the numbers present in the milk at later stages, whether it has been preserved at 50 F. or 70 F.

These observations led Professor Conn to the important discovery that the bacteria which get into milk from other sources than the milk ducts grow more readily under ordinary conditions and ordinary temperatures than do those that come from the milk ducts.

In other words, by cutting off the supply of manure, dust, etc., which ordinarily defiles milk, we get a much better-keeping milk, because the rapidly growing bacteria which are brought in with the stable dirt and dust are excluded. It is also fair to assume that the pathogenic bacteria which might come from the milker's breath or his hands will also be excluded by the covered pail.

A number of analyses of milk drawn into a covered pail give an average bacterial count for nine samples (Table A) taken during September and December, 1904, of 628 per c.c., and of 70 analyses made later (Table E), the average was 449, which is not much higher than that of Professor Conn's aseptic milk, already cited, produced as we have seen with the utmost possible pains and being taken from the latter half of the milking, whereas the counts in the last-named experiments were made from the samples taken out of the market milk and milked under the same conditions as the rest of the milk in a regular milking room.

Of the milk twenty-four hours old, the showing is remarkable. Of fifty-three observations made during four months (Table B), the average bacterial content was 447 per cubic centimeter.

The temperature had been maintained at 45 F., whereas in Professor Conn's Table 10 the average bacterial content in eight samples of aseptic milk kept twenty-four hours at 50 degrees was 5,991. It seems only fair, however, to omit one sample from Professor Conn's table, which showed the extraordinary count of 45,416 per cubic centimeter. The table with this omission gives an average of 358, which is somewhat smaller than those just given, but showing remarkably little variation from the latter when we consider the differences observed in producing the milk already spoken of. Gratifying as the above showing is, it is not the most remarkable result obtained by using the covered pail nor the one of the greatest interest to milk consumers and producers alike.

Stocking, the assistant bacteriologist to the Storrs Experiment Station, says: "It has already been pointed out that these tests were made in a dairy where the conditions of cleanliness were good. The amount of filth, such as dirt, hair, etc., that is frequently removed by a separator from milk of ordinary dairies as delivered in cities, is appalling. It would be interesting to test the

efficiency of the covered pail in dairies where the sanitary conditions are not so good as they were in these tests."

A series of such tests have been, in fact, carried out (Tables C and E), in which fresh milk and milk twenty-four hours old were "counted." This milk had been produced "in old dusty barns with no precautions whatever, except that the covered pail with the sterile cheesecloth diaphragm was used, and the cloth was changed for every two cows." From these experiments, we get the remarkable showing that the average bacterial content of 74 samples of fresh milk drawn into the closed pail in a dusty barn (Table E) was 3,041; and of twenty-one samples of milk twenty-four hours old which had been drawn under the same conditions (Table C) kept at 45 F., the average count was 193.

Comparing these figures with those in Tables D and E, in which the "counts" are given of milk drawn into old-fashioned open pails in old dusty barns, of the fresh milk the average bacterial count was 2,269 and 3,041, second series. Of the milk twenty-four hours old, the average was 5,712. As stated in the note to Table D, the weather at the time of these observations was very cold and unfavorable to the growth of bacteria or the differences might have been considerably larger.

If these experiments, a summary of which will be found in Tables E and F, shall be confirmed by others, and I might say that they have already been measurably confirmed by two sets of experiments made entirely independently of each other, a great step will have been taken toward the production on any farm of a safe, wholesome, well-keeping milk, fully up to the standard of the "certified" and "standard milks" now on the market.

The poor farmer, with his three or four cows, will no longer labor under insurmountable obstacles when competing with the elaborate and richly stocked dairies.

Dr. Herold of the Newark Board of Health relates an instance in which a farmer, merely by tying a piece of clean cloth on an ordinary pail with a string, was able to produce better and cleaner milk than any one in the neighborhood of certain large summer hotels. Any farmer can buy an Arnold sterilizer, a few bolts of cheesecloth and one or more covered pails, and by using a sufficient amount of ice, can send milk to market with a bacterial content of less than 30,000 per cubic centimeter. No soap of any kind should be used in washing the cheesecloth, which should be boiled with ordinary soda or some alkaline powder.

If any one doubts the efficiency of the sterile cheesecloth diaphragm, let him observe the quantity of dirt which will collect on it from one milking, even in the cleanest milking room; and if the milk contains mucus, pus, blood or stringy matter the quantity of detritus filtered out will be appalling.

If the careful and painstaking experiments just cited are not entirely fallacious, the conclusion is obvious that a general dairy law that no milk shall be offered for sale with a bacterial content above 30,000 per cubic centimeter, would be justifiable and comparatively easy of enforcement.

As already mentioned, if milk is drawn into the covered pail the use of aeration is superfluous, for the so-called cow taste and odor are not present and do not have to be gotten rid of. Thus dangerous and troublesome manipulation and agitation of the milk, not to mention prolonged exposure to the atmosphere, are avoided. In one dairy milk drawn into one of these

pails in a clean milking room, is put immediately into bottles, and these are put in ice water, and in a fraction of a minute the necessary reduction of temperature is begun. These bottles are sealed up with an inner and an outer seal, and a guarantee is placed between the seals that the bacterial content of the milk shall not exceed 5,500 per cubic centimeter when delivered.

Any other dairy can be conducted on similar lines, and can achieve as good results as those already detailed.

As said above, the production of certified milk is no longer beyond the reach of any poor farmer or small dairyman. The consideration that the simple devices described in this paper are likely to revolutionize modern dairying and ought to be of incalculable benefit to humanity, affords, I believe, sufficient excuse for having taken up the time of the Section in describing them.

It is curious that the exhaustive work of Swithinbank and Newman,⁸ published last October, says nothing about covered milk pails, although the bacteriologic work therein described is highly confirmatory of much of that done at the Storrs Experiment Station. It must be borne in mind, however, that all really great improvements in human industries are in the direction of simplicity and common sense, and that is the direction in which the covered milk pail points.

TABLE A.

Bacterial Count of Fresh Certified Milk.—The analyses were made by taking samples from bottling machine and planting them immediately after milking. This milk was produced under best conditions, new milking barn, etc.

Nov. 30	395	Dec. 15	1,027
		Dec. 16	852
Dec. 1	385		
Dec. 2	463	Average	793

Two samples of this same milk were tested when "fresh" and gave results as follows:

Dec. 14	575	Dec. 15	930
		Average	752

TABLE D.

Counts of bacteria in milk milked in old-fashioned "open pail" in old dusty barn and with no special sanitary precautions. The milk tested was, some of it, bottled and cooled immediately after milking and tested when twenty-four hours old. Other samples were tested "fresh." These averages are very low for milk produced under above conditions. The weather was very cold and unfavorable to the growth of bacteria. Also, these samples were tested under most favorable conditions, i. e., when "fresh" and after proper cooling, the bottled milk being kept below 45 F. for twenty-four hours.

FRESH MILK.	MILK 24 HOURS OLD.		
Dec. 2	675	Dec. 3	6,525
Dec. 3	2,725	Dec. 4	7,000
Dec. 4	2,285	Dec. 6	16,895
Dec. 7	7,175	Dec. 9	3,465
Dec. 8	570	Dec. 10	1,825
Dec. 9	2,075	Dec. 13	6,750
Dec. 11	1,755	Dec. 14	1,223
Dec. 12	715	Dec. 16	2,485
Dec. 15	2,835		
Dec. 17	1,900	Average	5,772
Average	2,269		

TABLE E.

Milkings in Sanitary Stables.	The Closed Pail.	Old-Fashioned Open Pail.
Bacteria per c.c.	449	3,569
Highest count made in any single analysis	(Avg. 70 anal.) 1,525	(Avg. 58 anal.) 16,895
Lowest count made in any single analysis	5	290

The number of bacteria in milk from the closed pail is 12 1/2 per cent. of the number in the open pail. Therefore, the closed pail keeps out 87 1/2 per cent.

Milkings in Old Barns.	The Closed Pail.	Old Fashioned Pail.
Bacteria per c.c.	3,041	11,129
Highest count made in any one analysis...	9,000	100,800
Lowest count made in any one analysis...	330	350

The percentage kept out by covered pail was, therefore, 73.

TABLE F.

TOTAL AVERAGES.

Average "fresh certified" milk, average of 70 analyses	449

DISCUSSION

ON PAPERS BY DRs. BRUSH AND NEWTON.

DR. J. P. CROZER GRIFFITH, Philadelphia, said that sterilization and pasteurization, good as they are, are not the things we want. The one thing is to get pure milk. Sterilization and pasteurization may kill the germs present in the milk, but they do not destroy the poisonous products already introduced. We sterilize or pasteurize the milk only when we can not do anything better. We have been accustomed to believe that a really pure milk can only be produced at a greatly increased cost. When we consider the very small amount of money that the farmer receives for his milk, it can scarcely be expected that he will take great pains with it. The ordinary milk that reaches a large city goes through several hands before it gets to the consumer, and the farmer receives a very small amount as his share. If Dr. Newton's records can be proved to hold good, as seems to be the case, then there is no reason why we should not impose a decidedly smaller bacterial limit than is now done. This subject has been frequently discussed in Philadelphia, and Dr. Griffith believes that eventually a certain bacterial count will be decided on. The milk commission of the Philadelphia Pediatric Society is now supervising a number of dairies which agree to furnish milk with a bacterial count of not over 10,000 to the c.c., and for this milk they receive certificates. Of course, the milk is investigated in other respects as well, and the dairies are systematically visited by the veterinarian of the milk committee.

DR. F. L. SMITH, Bridgeport, Conn., said that his first year's practice was in the country, and he learned much about milk and its effect on children. A baby that was fed on cow's milk developed cholera infantum. On investigation it was found that the cows supplying the milk had broken into a cornfield and made a hearty meal of fresh corn. Jersey cows are more easily affected by what they eat than any other breed. On his father's farm the cows were once turned into an orchard. They fed freely on the decomposed apples that had been left there, and five became so drunk that they could not stand up. Imagine the effect of that condition on the milk. Some cows were fed on oat straw that contained a little wild mustard, and as a result mustard could be smelled in the milk and tasted in the butter. Turnip tips or turnips, if fed to cows, will impart a strong taste of turnips to the milk. We might, to advantage, use our influence on the farmers and see if we can not educate them in some way, so that they will be taught to produce a better product for us from the infant-feeding standpoint.

DR. LOUIS C. AGER, Brooklyn, N. Y., stated that the milk commission in Brooklyn has been grappling with this question in various ways and in trying to eliminate every possible source of contamination the most recent move is in the direction of having the milk bottled at the farm and not at the creamery. It is a self-evident fact that each handling of the milk makes a difference, and they have found that by using the milk from certain farms, and having it bottled and sealed there, the bacterial count is lowered. This proves the statement made by Dr. Newton that expensive apparatus is not necessary in order to secure comparatively pure milk. If the farm is clean, and those who handle the milk are clean, and the milk is bottled early, we get pretty clean milk.

DR. W. B. ULRICH, Chester, Pa., emphasized Dr. Smith's suggestion as to the importance of teaching mothers how to feed their children. If the profession would pay as much attention to the quantity of the food as to the quality, infants would be better protected. Physicians lose sight of the fact that the purest milk or food will make a child sick if it is overfed. Dr. Ulrich looks on overfeeding as the most fruitful source of digestive disturbance and malnutrition.

DR. THOMAS S. SOUTHWORTH, New York City, disagreed with Dr. Brush in regard to his condemnation of milk sugar and sees no reason why we could not sterilize a milk sugar solution as well as one of cane sugar. Dr. Southworth thinks that we understand the gross chemistry of milk, but the finer point, the nicer adjustment of the milk to the child, has not yet been

worked out. We have passed the day when we considered that we could make cow's milk the equivalent of breast milk. Breast milk is a fluid that is formed by the human mother for the human child, while cow's milk is formed for the calf. That fact should not be lost sight of, and when a child is removed from the breast and artificially fed, it is no longer as Nature intended it, and it is not too strong a statement if we say that the condition is a pathologic one. Dr. Southworth thinks that it is inconceivable that the growth of millions of bacteria in each cubic centimeter of milk should not consume important nutritious elements in the milk, but if we have to deal with old milk, or milk that has been polluted, we must do something to check the vast increase of the bacteria, and that is done by pasteurization. If the milk is pure to start with, pasteurization is unnecessary and undesirable, because it checks the development of lactic acid forming germs and to that extent opens the way to the putrefactive bacteria, which are held in check by the lactic acid.

DR. W. D. SCHWARTZ, Portland, Ind., considers that the danger incident to using large pint bottles with about three feet of rubber tubing attached for nursing bottles should not be lost sight of. Just so long as those bottles and long tubes are manufactured and sold under the name of nursing bottles, just so long will lazy mothers buy them and feed their babies from them. He thinks that the less delay there is in getting the milk from the cow to the infant, the better.

DR. JOHN L. MORSE, Boston, thinks that there is no doubt that the purity of the milk is of the first importance in infant feeding. This fact, however, does not diminish the value of the modification of milk. We can not make a good food for babies out of bad milk, but most babies will not thrive on cow's milk, unmodified, even if it is pure. Milk sugar is a different thing, chemically, from cane sugar, and yeast does not ferment milk sugar.

DR. LOUIS FISCHER, New York City, said that in his experience the further we get away from breast milk, the more trouble we encounter. Hence, his advice is to stick to breast milk. If it is deficient in quantity, supply the balance by using cow's milk. Properly modified raw milk should be advised. Sterilization, because of its well-known bad effects on the milk itself, should be avoided, as prolonged use induces rickets. The raw milk is received from the dairy in a clean state, and the principles of asepsis should be applied to the cow itself, its udder, the milk pail and everything and everybody that comes in contact with the milk before it reaches the consumer. When milk has once been contaminated the pathogenic bacteria or saprophytes may be killed, but the toxins are not destroyed. Dr. Fischer stated that raw milk possesses certain nutritive properties, and the chemical changes induced by even an ordinary temperature of 160 or 170 certainly destroys something that is required for the living baby. More attention should be paid to the little details that pertain to the cleanliness of the stable, the cow and the milker's hands.

DR. SAMUEL MCC. HAMILL, Philadelphia, stated that one of the largest dairies in Philadelphia keeps a very careful account of the cost of the product, and the average cost per quart for delivery in the city is 7½ cents. These figures were obtained by a very capable man, and in communicating with him he made the statement that the average price of milk was much lower than it should be. The average farmer never takes into consideration the price of his cow, the wear and tear, the equipment, etc., and simply figures the cost of labor and transportation. In Philadelphia the hospitals are now using the very worst milk supplied in Philadelphia, and at a recent meeting of the hospital association it was advocated to establish a bacterial standard of 250,000 per c. Dr. Hamill was anxious to have it reduced to 100,000, and thinks that it is just as easy to reach one as the other. Where an initial contamination takes place it is very difficult to limit the number of bacteria.

DR. J. H. CLAIBORNE, New York City, said that when he was very young, like all the rest of us, he was addicted to milk, but since he has been old enough to appreciate the senses of smell and taste he has had an intolerable disgust for milk, which persists to this day. When he came to New York, where

the milk is purer than in the part of the country where he was brought up, he first appreciated the cause of his disgust. He corroborated what Dr. Smith said of the effect of cow's food on the milk. On the farm there was one particular field where wild onions were very abundant, and when the cows had pastured there no one could drink the milk.

DR. R. B. GILBERT, Louisville, said that the milk from certain dairies is nothing better than a culture medium and he fails to understand why they do not make use of it in the laboratory instead of bouillon. It is well known that mental anxiety in the mother affects the quality of the milk, and the same is no doubt true of the cow, as, for example, when she is deprived of her calf. In the artificial feeding of infants with cow's milk he has for the past three years adopted the simple procedure of sending the child out to the country where good milk can be obtained from clean and healthy cows. The milk is milked directly into a wide-mouthed pint bottle, and after the nurse has ascertained that its specific gravity is satisfactory, it is fed to the baby immediately, while it still holds its animal heat. Dr. Gilbert has seen wonderful results from this method in cases of scorbutus. The infant should not be over-fed. One or two ounces of milk every three hours is enough, and no milk should be given after 8 o'clock at night; nothing after that excepting sterilized clean water.

DR. C. F. WAHNER, Fort Madison, Iowa, suggested that the more important facts be put in suitable shape and published in the lay press, so that the mothers of this country can become acquainted with them. The laity and many of the profession do not read medical journals. We must educate them through the daily papers. He is not in favor of publishing the papers of individual physicians, as that would favor advertising, but would publish a reasonable abstract of the transactions of a certain Section on a given symposium, such as infant feeding, tuberculosis, etc., so that the public will get it right and not as they now do, in a reporter's garbled and sensational write-up.

DR. EDWARD F. BRUSH said that the position he takes regarding milk for infant feeding differs somewhat from the prevailing fashion. For many years he has had a large herd of dairy cows, and also for many years the care of a number of infants, in institutions and homes, and some of his own. With this experience he has been able to bring together the two prominent factors, and the paper he read is the result of his experience. If he were to choose between a dairy in charge of a cross or brutal man, whose habits were perfectly clean, and another herd, in care of a dirty man, kind and merciful, he would prefer the milk from the latter (if there were no contagious disease in either). Certainly the plan of having the milk perfectly clean is one of the advances excellently presented, but sterilization and pasteurization, which we all thought were going to solve the entire problem, is only one of the phases. Clean milk is only one of the many necessary results to perfect milk. We may be able to get certified milk from a farmer whose child is sick with diphtheria or some of the other contagious diseases of childhood. Young children and infants should never be permitted on a farm from which milk is supplied for infant feeding. Some years ago Dr. Brush made a special investigation of the milk-sugar phase of infant feeding. In his experiments he made a weak solution of milk sugar, added yeast, and kept this solution in a warm temperature for four months and, at the end of that time, found that the so-called milk sugar was unchanged; thus it seems that this commercial compound can not be destroyed by fermentation. He fed it to guinea-pigs and recovered a large quantity of it from their urine. Milk sugar of commerce is largely made in Switzerland and is one of the by-products of the cheese factory. After the milk and the more or less purid rennet has been added, the resulting whey is allowed to evaporate in the open air, and when it becomes thick enough, is put into bags. It is poured in these receptacles with a lot of pine sticks, and when it has become perfectly dry these sticks are taken out covered with crystals, and this is the milk sugar of commerce. Dr. Brush affirms that no living man can guess what is obtained from this process, and it is reasonable to say that milk sugar is about as inert as ground cork, if it

does not contain pathogenic germs or dangerous ptomaines. If a child can get perfectly good milk, he does not advocate the use of sugar at all in infant feeding, except when the baby is constipated, and then cane sugar is altogether the best, because we know what we are using. When babies get only the milk he sends them, and are disturbed in their stomachs or bowels, he feels that he is responsible, and never fails to find the trouble, either in his cows or dairy help. Dr. Brush believes that milk good enough to give the baby is worth not less than 15 cents nor more than 20 cents a quart, because the man who distributes it must exercise such vigilance that there will be no rise of temperature from the finishing of the cooling process on the farm, that is, 60 degrees F., and no addition of any older milk.

Dr. R. C. NEWTON believes that there is no doubt about the exquisite sensitiveness of milk to various sources of contamination. It has been shown that the presence of a single fly in a milk pail will enormously increase the number of bacteria. The lactic acid bacteria are not in the milk when it is drawn, but come in probably from the air. The lactic acid bacteria hold in check the putrefactive bacteria, and to that extent their presence is actually beneficial. Conn makes the statement that the most important problems in connection with the chemistry and bacteriology of milk are still unsolved, and that their solution will probably be found in the study of what we now consider the unimportant bacteria. It has been shown that white mice fed on sterilized milk died within twenty days. Sterilization evidently destroys something the nature of which we do not fully understand, but which is necessary to life and growth. That child will thrive best that is nursed by a mother whose milk is mixed with love. In Dr. Brush's dairy love is evidently an important factor. Every one of his cows is treated just like a lady, which is the only way to treat her; more especially, she should be kept scrupulously clean, like a lady. Milking directly into bottles, to which method Dr. Gilbert referred, has been tried and has failed, because milk differs so much in composition according to the stage of the milking. The first few squirts of milk should be rejected because they always contain bacteria. The first third of the milk is little better than skimmed milk, because the cream has risen to the top of the udder, probably just as it does in a milk-pan after it has been drawn. The best plan yet devised is to milk into a covered pail, and to transfer the milk directly into sterilized bottles, which are immediately cooled. Thus we get the minimum of agitation and of exposure to the air, two great desiderata in handling milk.

THE USE OF NITROGLYCERIN IN THE TREATMENT OF ERYSIPELAS.

J. W. WHERRY, M.D.

Assistant Physician Clarinda State Hospital.

CLARINDA, IOWA.

While many diseases have a more or less specific treatment, which, with slight variation to meet individual peculiarities, will apply to nearly all cases, erysipelas has remained in the uncertain class for which many drugs are used, but for which few, if any, prove very effective.

It is very doubtful if any good results need be expected from local applications, although many methods are recommended. In treating facial erysipelas in this institution each physician has his own favorite topical application which he uses on all occasions. No two of these applications are alike, and the surprising thing about it is that all get equally good results—that is, the same results, in all probability, that they would get without any local treatment. Any application is indicated that will soften the skin and relieve the tension, thus adding to the patient's comfort.

This criticism of local applications will not apply, however, to internal treatment. I believe that the course

and symptoms of erysipelas can be very markedly modified by drugs properly used. For several years I used the various drugs recommended in publications on this subject, and, while I obtained variable results, there was always a conviction that the same results would have followed without treatment.

Last spring I had an opportunity to do some experimental work in the treatment of erysipelas, and the unusual and almost unexpected results obtained from the use of nitroglycerin lead me to give the facts to the profession for consideration and verification.

In three of the cases the erysipelas originated on the face; in the fourth case it had its origin near the ankle. Abbreviated records follow:

CASE 1.—Woman, aged 57. March 3, 1904. Patient admitted to ward with facial erysipelas. Inflammation originated in left ala nasi and spread rapidly. Temperature 103.4 degrees, pulse 104. Ordered calomel, grs. 3, given in 1-gr. doses every half-hour, and nitroglycerin, gr. 1/100, every three hours. Ichthyol and oxid of zinc ointment applied locally.

March 4, 1904. Inflammation involved entire left side of face and right cheek. Left eye closed. Temperature 99.6 degrees, pulse 90. Nitroglycerin, gr. 1/100, every four hours.

March 5, 1904. Entire right side of face involved. Inflammation disappearing from left side. Temperature 99 degrees, pulse 90. Patient eating well and appears comfortable. Nitroglycerin given every four hours during the day; none given at night.

March 6, 1904. Inflammation has disappeared from left side of face and scarcely perceptible on right side. Temperature normal, pulse 78.

March 7, 1904. Inflammation has disappeared. Temperature normal, pulse 74.

CASE 2.—Woman, aged 72. March 10, 1904. Patient admitted to ward with erysipelas of left leg having its origin in a slight abrasion about four inches above the ankle. Portion involved is about four by six inches in extent. Temperature 102 degrees, pulse 101. Patient very much prostrated. Ordered calomel, grs. 2, giving one grain every half-hour, and nitroglycerin, gr. 1/100, every three hours. Ichthyol and oxid of zinc ointment applied locally.

March 11, 1904. Inflammation extended to and involving the ankle. Temperature 99 degrees, pulse 94. Much less prostration. Nitroglycerin continued.

March 12, 1904. Inflammation has disappeared. Temperature normal, pulse 82. Appetite good. Medicine discontinued. Made good recovery.

CASE 3.—Woman, aged 49. April 4, 1904. Patient admitted to ward with erysipelas involving two-thirds of the face. Temperature 103 degrees, pulse 110. Calomel, grs. 3, was ordered given in divided doses, and nitroglycerin, gr. 1/100, every three hours. Ichthyol and oxid of zinc ointment applied locally.

April 5, 1904. Entire face involved. Temperature 99.4 degrees, pulse 96. No prostration, appetite good. Nitroglycerin continued.

April 6, 1904. Inflammation limited to the face and slowly clearing up. Temperature 99 degrees, pulse 90. Nitroglycerin, gr. 1/100, every four hours during the day; none given at night.

April 8, 1904. Inflammation has practically disappeared excepting on right ear. Temperature 98.8 degrees, pulse 82.

April 10, 1904. Patient made a good recovery.

CASE 4.—Woman, aged 65. April 6, 1904. Patient admitted to ward with erysipelas involving the nose, left eye and left cheek. Temperature 101.6 degrees, pulse 94. Ordered calomel, grs. 3, in divided doses, and nitroglycerin, 1/100, every three hours. Ichthyol and oxid of zinc ointment applied locally.

April 7, 1904. Inflammation clearing up on nose, but involves the left ear. Temperature 99 degrees, pulse 88 and intermittent. Appetite good.

April 9, 1904. Erysipelas has disappeared except on left

ear. Temperature 98.8 degrees, pulse 80. Nitroglycerin every four hours during the day only.

April 11, 1904. Inflammation has disappeared. Temperature normal, pulse 74, full and regular.

Two years ago this same patient had an attack of facial erysipelas which not only involved the whole face, but spread to the neck and gradually extended down the back, stopping only at the buttocks. The remedies relied on at that time were quinin and the tincture of the chlorid of iron.

I ascribe no virtue to the ichthylol and zinc oxid ointment used locally except its soothing effect on the skin, and in one instance it did not even produce this effect, for the patient would rub it off as fast as it was put on. All these cases presented several features in common as the result of this internal treatment, viz., a reduction of temperature, moist skin, good appetite, steady pulse after the first day, absence of prostration, general feeling of comfort and a fairly rapid disappearance of the inflammatory process.

In view of the above facts I believe I am safe in concluding, either that nitroglycerin is a *sine qua non* in erysipelas, or that I had a marvelous and phenomenal run of good luck. To be sure, four cases are insufficient to establish a positive conclusion, but as the results were so uniform in every case where nitroglycerin was used I feel that I can conscientiously recommend it to the profession without further comment.

New Appliances.

A SANITARY POCKET CUSPIDOR.

J. W. TRASK, M.D.
CHICAGO.

The cup I am about to describe was gotten up especially for use at the United States Public Health and Marine-Hospital Service Sanatorium for Consumptives at Fort Stanton, New Mexico. Many styles of cups had been in use at different times, but none was found very satisfactory. The hand cups were serviceable at the bedside, but the patients found them too clumsy for carrying about. They seemed to dislike the idea of always carrying a cup in the hand. The pocket flasks in use held so little that but a limited number of patients were able to use them and in addition they were continually getting out of order. Nor was there to be found on the market a cup or flask that seemed to meet the requirements any better than those already in use. What was needed was a cup that would go into the pocket and at the same time hold a large amount of sputum, a cup with a destructible filler which, when filled, could be pulled out and burned; a cup cheap in cost and with no small parts such as clamps, springs and hinges to become broken or lost. With these points in mind the following cup was devised:

The cup consists of a metal case, Figure 1—those in use were made of tin—into which a paper filler fits. The sputum is contained in the filler and does not come into contact with the metal. The cup consists of a body and a mouthpiece. The outside dimensions of the body are 3¼ inches high, 3¼ inches wide and 1½ inches thick. The cup is as large as it can be made and still slip into an ordinary coat pocket. It was made this size so that it might contain the largest possible amount of sputum for a pocket cup and thus be used by a larger number of patients, by those expectorating large amounts as well as by those raising less. Smaller sizes could, of course, be made for use by those expectorating but little. The cup is made up of three pieces, the bottom, Figure 2, into which the paper filler, Figure 8, fits, the top, Figure 3, which telescopes over the bottom and its contained filler to within half an inch of the extreme base, and of a cap, Figure 4, which fits over the neck projecting from the top.

The bottom of the cup, Figure 2, is 2½ inches deep, 3¼ inches long and 1½ inches thick at base. There is a half-inch wide strip of tin soldered around the base, so that the top will slip down to it and no farther, and so that when the cup is together the outside will be smooth.

The top, Figure 3, is 2¾ inches high, 3¼ inches long and 1½ inches thick. It telescopes over the bottom down to the strip of tin. From the top of it extends a neck, which is tapered on its inner surface. This is best shown in sectional drawings, Figures 5 and 6. The top fits well over the bottom and the two are held firmly together by the adhesion of their metallic surfaces.

The cap, Figure 4, is a simple affair and fits over the neck of the top.

Paper Filler extended Dotted lines folding lines

Sputum Cup (About one fourth size)

The paper filler consists of a filler proper and a paper funnel. The filler consists of a piece of water-proof paper cut and stamped as shown in Figure 7. It folds at the dotted lines. The corner squares A and C fold in and up against the side B. The corner squares D and F fold in and up against the side E. The flaps G, H and I then fold down, and flap I clinches flaps G and H at the small notches in their corners, thus holding the folded corner squares A, C, D and F up against the sides B and E. The filler is then inserted into the metallic bottom and the flap J is folded over the top of the filler and the side flaps K, L and M, which are an inch wide, are folded over the dotted lines as shown in Figure 8, and extend down inside of the cup bottom for one-fourth of an inch, thus holding the paper filler top in place. The filler folded is shown in Figure 8. N is a circular hole in the top of the filler.

The paper funnel, Figure 9, has the shape of the frustum of a hollow cone. It fits into the inside of the neck of the metallic top and its smaller end, which is its lower part when inserted, passes down into the paper filler through the circular hole X, into which it fits snugly. It has a flange at the top which flares over the top of the neck of the cup.

The patient carries the cup in the pocket. To use it he removes the metal cap and expectorates into the paper funnel, through which the sputum passes down into the paper filler proper. When the cup is filled, or better, partly filled, the metal cap is removed, the paper funnel removed and burned, the top of the cup is then removed and the filler extracted and burned, and a new filler and funnel inserted.

This cup will not become soiled with ordinary usage any more than will a patient's clothing or articles handled by him, such as coins, pocket knives and tools, and it can be much more easily washed or boiled, or both, than any of these. Then, too, one of its very important features, considering its efficiency, is its extreme cheapness of manufacture.

A description of this cup is offered in the belief that it possesses many valuable features not contained in any cup now manufactured.

I desire to thank Surgeon-General Walter Wyman and Dr. P. M. Carrington for placing at my disposal the facilities of the sanatorium for the making of models, and the latter also for suggestions regarding same.

A NEW TENACULUM FORCEPS.

OLIVER C. SMITH, M.D.
HARTFORD, CONN.

While in Paris last summer, I saw an instrument made by Collin, which struck me at once as being an excellent substitute for the pressure forceps, where this is used to grasp and hold the margins of delicate tissues, as the peritoneum, the pleura, the incised walls of viscera, the bladder, stomach, intestines, etc. The instrument was a delicately made straight tenaculum forceps, similar to the Croenlein forceps, with five interdigitating teeth; two on one jaw, three on the other, and provided with French lock and ratchet clasp.

I brought some of them home, but found on using that the teeth projected and scratched the tissues. This led me to modify the instrument by providing it with two diverging teeth, $1\frac{3}{4}$ mm. in length on the upper jaw, and with a flat ovoid platform with two perforations on the under jaw. I also gave the instrument a slight curve with the concavity on the under side, which allows it to lie more closely to the abdomen or chest, thereby being less in one's way.

The advantages claimed for these forceps are:

First: The avoidance of crushing the tissues. The appearance of the margins of serous, mucous or muscular tissue after a few moments' application of the ordinary pressure forceps is that of bruised, bloodless and flattened tissue, which certainly invites sloughing and offers a tempting field for infection. This crushing is what we desire when we pinch a blood vessel, and does no harm when grasping tissue which is later to

be excised, such as the margins of a hernial sac, but not so when dealing with tissues that are to be placed in apposition for union.

This injury of the tissues is almost entirely avoided by the use of the marginal tenaculum forceps, which makes two harmless punctures.

Second: The lower and projecting jaw of the instrument, being blunt, can not possibly injure an intestine, so that it can be carried fearlessly to the bottom of an abdominal incision to bring up the peritoneum.

Third: As before mentioned, the slight curve of the instrument makes it less in the operator's way.

Fourth: It holds the margins of any tissue securely; it does not tear out with considerable traction, and can be allowed to remain on during the entire operation without danger of injuring the structures.

The muscle is compressed to a wafer-like thickness, the color is entirely expressed, and the tissue is made transparent where it has been held by the hemostats, while two tiny punctures mark the spot held by the tenaculum forceps. After several months of almost daily use I can safely testify to the decided merit of this instrument.

IMPROVED URINE TEST GLASSES AND HOLDER.

E. G. BALLENGER, M.D.
ATLANTA, GA.

The value of having the urine passed in two or three glasses, with or without washing the anterior urethra, is too well known to need emphasis. The glasses recommended allow the urine to be collected in several portions without being spilled; the importance of this is evident to every physician making many examinations daily, where offices or dispensaries soon have the urinous odor so offensive both to physician and patient. Those who come needing urinary examinations for shreds, pus, etc., frequently do not have micturition well under their control, and when the stream is once started it is stopped

with some difficulty and pain, or not at all until the bladder is emptied, and so the two-glass or three-glass test is obtained at the expense of a "broken technic" with the urine spilled.

This is obviated by the use of the glasses recommended, which are of a pyramidal shape and on a small base, to be passed into a grooved block to hold them together (See illustration). Their rims being square, allow close apposition and the patient can change the urinary stream from one glass to another without stopping or spilling it. Either two or three glasses may be used as desired, and the urine examined without transferring it to a cylindrical glass, as is necessary with Gerson's, which has a flat bottom instead of a pointed one, and, so far as I am aware, is the only other one obtainable. Another advantage of the glasses recommended is the flat surface, which does not magnify and distort the shreds, etc.

SATURDAY, NOVEMBER 5, 1904.

SYPHILITIC AORTITIS AND ANEURISM.

The probability of there being some relationship between syphilis and aneurism has long been recognized. In 1886 Flint wrote in his *Practice of Medicine* (sixth edition): "As bearing on the diagnosis, it may be here stated that aortic aneurism is a rare event under 40 years of age, and that syphilis is often a remote cause." Since then we have learned that aortic aneurism under 40 is not an especially rare event, relatively speaking, and that syphilis may maintain a much closer relation to aortic aneurism than that of a remote cause. Among the various facts that have served to direct and fasten attention to the relationship between syphilis and aneurism may be mentioned especially the occurrence of aortic aneurism in notorious syphilitics at a relatively early age—25 to 45—which, of course, does not harmonize perfectly with the generally accepted views as to the rôle of ordinary arteriosclerosis in the production of aneurism.

Already in 1875 F. H. Welch noted severe aortic disease in 60.7 per cent. and aneurism in 32 per cent. of 56 cases of fatal syphilis; and a high frequency of syphilis among patients with aortic aneurism has been brought out in numerous statistical studies. The percentage varies greatly in the different series, being as high as 85 per cent. in Heller's and as low as 18.75 per cent. in von Hansemann's. In most series, however, the percentage exceeds 50; generally the figures are based on the facts secured as to a history of syphilis in the patient. Lichtenstern based his calculations on postmortem findings, and gives a percentage of 39. It will be noted that this average percentage greatly exceeds the average percentage of syphilis in all classes of people in this and European countries.

Von Hansemann insisted that a more trustworthy idea as to the relation between syphilis and aneurism could be gotten by learning how many syphilitics became victims of aneurism. His own figures—3.43 per cent. of 350 syphilitics—he regarded as very small, but Heller, the champion of syphilitic aneurism, points out that after death only a small percentage of those once infected with syphilis present definite syphilitic lesions. In 400 syphilitics Heller found aneurism in 3 per cent., cerebral syphilis in 2 per cent., cardiac syphilis in 2 per cent., pulmonary syphilis in 1 per cent. In 8,669 post-mortems Emmerich found aneurism only in 0.5 per cent., and in 745 tuberculous Heller found only 0.13 per cent. to have aneurism. Hence von Hansemann's

reversed statistics also show a probable relation between lues and aneurism.

While clinical experience and statistics unquestionably point to a close relationship between syphilis and aortic aneurism, the crucial point whether syphilis may cause aortic changes that stand in direct causal connection with aneurism can be solved only by the help of pathologic anatomy. Here certain difficulties confront us. The syphilitic nature of many chronic inflammatory and sclerotic processes has long been urged, but in many cases this view has met with doubt and more or less opposition, largely because it was not possible to prove unequivocally the syphilitic nature of the lesions in question. This has been and probably will continue to be, at least to some extent, the case with syphilis as the basis of acute aneurism. In most cases aneurisms are studied anatomically so late in their development that the specifically characteristic features possibly present in the fundamental lesion of the aortic wall long since have passed away. The results of recent investigations show, however, that much may be learned by thorough study of material everywhere readily available. Indeed, in view of recent developments, there seems to be little doubt but that our knowledge concerning the influence of syphilis in aortic disease and aortic aneurism has been materially delayed because the question was not seriously and systematically considered either by clinicians or pathologists. Every day pathologists looked at sclerotic and degenerated aortas without seeing any reason to in any way modify the usual off-hand diagnosis of arteriosclerosis or endarteritis chronica deformans, the manifold forms of which undoubtedly include various processes of distinct etiology.

Years ago a peculiar form of mesoarteritis was recognized (Wagner, 1866; Helmstedter, 1873), which Heiberger in 1877 was the first to interpret as syphilitic; he based his interpretation on the presence of miliary gummas. Shortly afterward, but entirely independently, Laveran in France reached the same result. Subsequently this mesoarteritis was studied more fully by Heller and his pupils, who speak of it as syphilitic aortitis, by Straub, and most recently by Chiari and also by Benda. This mesoarteritis is essentially a productive process, located principally in the ascending aorta. When uncomplicated by other forms of sclerosis the intima shows no increase in thickness, but furrows, small depressions and pits that correspond to scars in the media, which also may contain foci of granulation tissue. Occasionally occur areas of necrosis with giant cells, partly of the type of the Langhans' cells, partly of the type of the foreign body giant cell. The adventitia is usually involved, and productive endovasculitis is practically always present here as well as in the media. Chiari came to the conclusion that the mesoarteritis may be caused by syphilis, because he found it in one-half of the syphilitics and general paralytics examined. Straub claims to have noted this form of

aortitis in 82 per cent. of 84 general paralytics. Aneurisms were present in many cases in both these series. While the rôle of other infections can not be wholly excluded in the genesis of this fibrous form of meso-aortitis, especially as the lesion in its later stages does not present any absolutely diagnostic morphologic appearances, yet it seems that pathologists in general are willing to accept it as syphilitic in the majority of the cases, even though it may be impossible to trace its evolution from definite gummatous productions. Benda, however, has had the good fortune to obtain cases giving the complete picture of aortic gummas—miliary as well as macroscopic—passing into sclerosis or fibrous meso-aortitis. The larger gummas were situated on the border of the adventitia and the media; they were irregular in size and in shape, and consisted of a yellow material in the midst of a scar. Benda also found gummas of this kind in the margins of aneurisms; only four or five of such instances having been recorded previously, the most recent by Fabris. Whether productive meso-aortitis always represents cicatricial termination of aortic gummas, gross or microscopic, as Benda seems to think is the case, can probably not be determined from the material now at hand, as already indicated, but there is no longer any doubt that syphilis of the aorta, just as syphilis of the heart, may be the basis of aneurisms. Much work requiring the co-operation of clinician and pathologist must be done before all the facts may be learned in regard to syphilitic aneurism of the aorta as distinguished from other forms of aortic aneurism, which, of course, also may occur in syphilitics. Pathologists must study diseased aortas more carefully than in the past and also walls of aneurisms, especially when the latter are multiple. When it was learned that potassium iodid occasionally cures aneurisms, it was first thought that this was due to its antilucetic effect, but before long the coagulative influence of the iodid was accepted as giving the more plausible explanation. May it not be possible, after all, that in certain cases specific treatment promotes removal of gummas in the walls of aneurisms? Certainly the present trend of belief in regard to aneurism and syphilis will stimulate to most careful antisyphilitic treatment in all cases of suspected aortic disease in the young and the syphilitic.¹

WINTER BEDDING AND INFECTION.

The advent of cold weather, almost every year, is marked by a series of outbreaks of epidemic diseases, for which no definite cause can be found. All the cases in a locality may be traced to one or two original ones, but the origin of these primary cases, as a rule, is unknown. The Chicago Board of Health has suggested one source of contagion which deserves careful investigation. As the cold weather commences, bedding that

has been put away during the summer is brought out for use again. It is at least a curious coincidence that contagious diseases, such as measles, scarlet fever, whooping cough, and even the more serious, smallpox, are apt to become epidemic at this time of the year.

The Chicago Board of Health has found during the present year some thirty separate smallpox infection centers, the cause for which would seem to be the infected bedding and the clothing of the undetected cases that occurred late last winter and in the spring. To quote the report: "Because these cases were undetected, no disinfection of their bedding and clothing was secured; with the advent of warm weather, blankets, underwear, etc., were packed away until the abnormally cool weather of the first few days of October brought them into use in artificially heated and poorly ventilated rooms, favorable to the active growth and diffusion of the contagion." The report then goes on to state that it is impossible otherwise to explain the recent outbreak. The families were unknown to each other and did not exchange visits. None of the smallpox patients had been away from the city recently, and they had nothing in common except the development of the disease coincident with the cool weather, which necessitated the use of last winter's heavy clothing.

It is well known that the *materies morbi* of such diseases as measles and scarlet fever, especially the latter, may remain virulent in fomites for long periods, and there are at times surprising proofs of this fact. After a year, clothing that had been in contact with a scarlet fever patient has been known to produce the disease in others, though carefully packed away in camphor or tobacco in the meantime. Letters sent from an infected house, before the disease was recognized as scarlet fever, have been known to convey the disease long distances, proving infective many weeks after they had been sent.

The possibility of infections from this source suggests the necessity for at least domestic disinfection of such articles before they are used in a subsequent winter. Unfortunately, quilts are so made that the ordinary washing and boiling process is out of the question, and blankets shrink and lose their appearance and softness unless very carefully handled; thus household articles that greatly need occasional boiling are not cleansed in any way.

Such bed clothing as will not wash should be submitted at least once a year to the disinfecting influence of dry heat, or to the vapor of some powerful antiseptic, like formaldehyd. If this is not done, such articles are likely to become receptacles for such forms of virulent micro-organisms, as *Staphylococcus aureus*, in some of the organic material in which they are placed, a favorable culture medium for which they may, in the dark, warm closets usually packed away in them, and which resemble nothing so much as a "nest" for bacteria. A little disinfection of such articles at the beginning of the winter season would do so much

1. The literature on syphilitic aortitis in relation to aneurism may be found in connection with Chiari's and Benda's reports in *Ver. d. deutsch. path. Gesellschaft*, 1904, vi.

confirmatory evidence of this fact that next spring people will realize the necessity for disinfection of bed clothing before putting it away for the summer.

TUBERCULOSIS OF THE PLACENTA.

Many of the problems connected with the transmission of tuberculosis have been restudied as a result of the papers of Koch and von Behring. The former discussed the relation between human and bovine tuberculosis, the latter, the milk transmission of the disease, and both departed so radically from accepted beliefs that their declarations have led to attacks on many cognate aspects of the problem. The paper of von Behring necessitated, among other things, a belief in the old view of von Baumgarten that tubercle bacilli may remain latent in the body for years and subsequently give rise to tuberculosis. This view primarily arose from the fact that the supporters of the inheritance of the germ theory were constantly confronted with the small number of cases of congenital tuberculosis, which rendered a belief in the latency of the germ a logical necessity for them. Notwithstanding the fact that so few cases of congenital tuberculosis have been reported, there have always been those who held that a direct transmission of the germ from mother to child is probably much more frequent than is generally supposed, and among these observers Birch-Hirschfeld and his pupils, and particularly Schmorl, have been prominent.

In a recent paper Schmorl and Geipel¹ once more assert that transmission of the tubercle bacillus from mother to child is much more common than is generally supposed, this belief being based on the results obtained by the study of twenty placenta obtained from women in various stages of tuberculosis. The authors mention the two possible ways of obtaining evidence of hereditary transmission of tubercle bacilli, namely, examination of the fetus, and examination of the placenta. For obvious reasons the examination of the fetus is not possible, and, furthermore, Schmorl has shown that where the placenta is tuberculous the bacilli are always transmitted to the fetus, which would be expected from the modern view that the placenta is essentially a fetal organ. The authors, therefore, decided to study placental tuberculosis, of which condition up to the present only ten cases have been reported, and of these seven have been recorded by Schmorl or his pupils.

The present report of Schmorl and Geipel covers twenty cases. Of these, eleven were cases of advanced pulmonary tuberculosis, four cases of moderately advanced pulmonary tuberculosis, and three cases of the early stage. There was one case of acute miliary tuberculosis, and one case of tuberculous meningitis. In eighteen of these cases delivery took place at or near the normal time, and in eight of these there was positive evidence of tuberculosis of the placenta. The remaining three were delivered at the seventh and eighth months, respectively, and in the seven

months' placenta tuberculosis was present. Of the nine placenta showing tuberculosis, five came from cases with advanced pulmonary tuberculosis, one each from cases of early and moderately advanced pulmonary tuberculosis and one each from cases of acute miliary tuberculosis and tuberculous meningitis.

The pathologic features of these cases are of interest, and show how easily tuberculous lesions in the placenta may be overlooked. In only three of the nine tuberculous placenta was it possible to make a naked-eye diagnosis of the lesion, though in these three cases it was very apparent. In the other cases the microscope had to be depended on, and the difficulty with which the lesions were detected in some instances is shown by the fact that two thousand sections of some of the placenta were examined before the lesion was found. Schmorl describes at length the forms which the infection takes, but it is only necessary here to briefly state them. Generally the tubercles develop on the surface of the villi or in the intervillous spaces; in the early stages they may not present the typical lesions of tuberculosis, but these are, as a rule, to be found as the lesion progresses. Rarer forms are those in which the tubercles first develop inside the villi, in the layer of canalized fibrin or in the ectodermic layer of the chorion. The histologic evidence points to the fact that any part of the placenta may be attacked, and that the lesion may occur months before the birth of the child. This latter observation disproves the theory, which has been advanced by some observers, that where tubercle bacilli are found in the fetus they probably are transmitted during labor or on the death of the mother as a result of traumatic changes in the placenta due to the uterine contractions which occur at these times. The source of infection in the great majority of cases is undoubtedly the blood of the mother, though it is possible that in a few instances a local tuberculosis of the uterus is present and that the germs are transmitted from this.

These cases seem to show that tuberculosis of the placenta is far from being uncommon, that infection may occur not only in the late stages of pulmonary tuberculosis or in acute miliary tuberculosis, but also in incipient pulmonary tuberculosis, and that infection of the placenta means infection to the child. It seems unlikely that the child develops tuberculosis in all instances; indeed, Schmorl and Geipel think that if only a few bacilli are transmitted they are in all probability destroyed. If many are transmitted the child probably develops tuberculosis, generally during the first few years of life, the authors think. They do not deny the possibility of the bacilli remaining latent for years, as von Baumgarten claims they do, but they think such an event improbable. These studies are important. It must be remembered that nearly all the reports of cases of placental tuberculosis have been made by Schmorl and his students, and while they are reliable observers, their work should be confirmed before all their conclusions are accepted.

1. *Münchener m. Z.*

THE FUNCTION OF THE THYROID AND THE PARATHYROIDS.

It is well known that total extirpation of the thyroid, as for the relief of goiter, is followed by a peculiar symptom-complex which is called cachexia strumipriva. The symptoms resemble those of myxedema, in which disease there is a great increase of connective tissue in and beneath the skin. The skin becomes thick and dry and the hair falls off. The features are swollen and heavy and the movements clumsy and trembling. The mental powers also gradually deteriorate, and the patient becomes slow and stupid and finally imbecile. In carnivorous animals, as cats and dogs, more acute symptoms are seen after total removal of the thyroid, and the animal usually dies within the first month after the operation. The first symptoms generally are tetanic spasms and more or less severe convulsions. These convulsions may appear as early as the end of the first day, and may last for weeks, but do not always end in death.

We see, therefore, that three very different results may follow the removal of the thyroid in different animals: 1, Cachexia strumipriva; 2, tetanic convulsions leading to rapid death; and 3, tetanic convulsions, from which the animal recovers. The questions have now been raised as to what is the exact function of this gland, and how it is possible that its removal may be followed by such very different symptoms in different animals. The last question has been answered by several investigators by assuming that the parathyroids have a definite function, distinct from that of the thyroid, and that the removal of the thyroid alone gives rise to a chronic disease known as cachexia strumipriva, while the removal of the parathyroids, either with or without the thyroid, gives rise to the acute symptoms which may or may not end in death. It might be assumed, then, that in the operation for goiter the parathyroids were left in place, and no acute symptoms followed the operation, while in the thyroidectomies practiced on cats and dogs they are generally removed, and this explains the acute symptoms seen in these animals. This view is, however, no longer tenable, because it has been shown by Kishi¹ that extirpation of the thyroid in cats and dogs is followed by tetanic convulsions, even if all of the parathyroids are left behind.

Kishi made a careful study of the changes in the parathyroids after removal of the thyroid, and came to the conclusion that they are composed of embryonic thyroid tissue, which may, under special conditions (as after removal of the thyroid), be transformed into normal thyroid tissue. So long as the thyroid is normal, the parathyroids do not functionate, but when the former is diseased or removed, the latter take on the function of the thyroid, and in some instances replace it so completely that the animal does not die, but regains its normal health after a short illness, during which period

it may have frequent convulsions. This picture is frequently seen in dogs, while it is unusual in cats, because the latter require more thyroid tissue to maintain life than do dogs; and, therefore, cats nearly always die after total removal of this gland, even if the parathyroids are left behind. Dogs and monkeys more often recover after an acute illness of short duration. Kishi also made a careful study of the blood of animals after thyroidectomy, and found that the red corpuscles rapidly decrease in number, and may fall as low as 1,800,000, while the leucocytes increase in number up to 38,000. He also found degenerative changes in the vessel walls and in some of the organ cells around the blood vessels, and concluded that there is a toxic substance in the blood which, under normal conditions, is destroyed by the thyroid. Kishi further showed by quantitative studies of the constituents of the urine that there are marked nutritional disturbances. This toxic substance he believes to be of the nature of a nucleoprotein which arises from the nuclei of the cells of the meat that is ingested. The cells of the thyroid have the power of taking up the iodine that gets into the system with various articles of food, and they produce with it an iodine-containing globulin. This substance may have an attraction for the toxic nucleoprotein, and combines with it to form a substance which Kishi calls thyreotoxin. This thyreotoxin is now decomposed in the thyroid to form two harmless substances which constitute the colloidal substance of the thyroid. The colloidal substance slowly passes out of the follicles into the lymph spaces and blood vessels, but as it passes out the cells of the thyroid take out most of the iodine contained in it and again utilize it in producing the iodine-containing globulin.

This theory, which is based on a large number of experimental facts and postmortem findings, explains very well why thyroidectomy in carnivorous animals is followed by acute symptoms and often rapid death, while in man and the herbivorous animals it gives rise only to a chronic condition. Animals living on a meat diet ingest more nucleoprotein, which, according to this theory, gives rise to the toxic material responsible for the symptoms and which is destroyed by the thyroid under normal conditions. When the thyroid is removed from carnivorous animals the system is soon overwhelmed with this toxic material, and there are produced very acute symptoms, such as tetanic convulsions, and later death. In the herbivorous animals, however, only a small quantity of this poison is formed, and there is a very slow poisoning, which gives rise to the condition known as cachexia strumipriva.

THE SERUM-TREATMENT OF EXOPHTHALMIC GOITER.

That the secretion of the thyroid gland plays an important part in the maintenance of the metabolic equilibrium of the body would seem demonstrated by the effects resulting, on the one hand, from its pro-

1. Virchow's Archiv, 1904, vol. cxxvi, p. 260.

duction in excess, as, for example, in cases of exophthalmic goiter, and, on the other hand, from its deficiency, as in cases of myxedema and cretinism. The deficiency in secretion can be, in some measure at least, compensated for by the employment, in one form or other, of the gland or of preparations made from it. This has been done, and with no small degree of success, in cases of myxedema and cretinism especially. The only means at present known of combating an excess of the secretion consists in surgical removal of a portion of the gland, although some of the effects on the circulation can be counteracted by the employment of such agents as adrenal preparations, digitalis, strophanthus, ergot and the like.* Partial thyroidectomy is, however, not a simple operation, and its results are not always permanently satisfactory, while the other measures mentioned can not be relied on in the treatment of exophthalmic goiter. Accordingly, the suggestion has been made that a serum might be prepared that would be capable of neutralizing the untoward effects of the excessive activity of the thyroid gland under such circumstances.

Attempts have been made to produce cytotoxins having a specific action on the thyroid and parathyroid glands by the introduction of thyroid gland into lower animals and obtaining the blood-serum from the latter. Also the blood-serum and the milk from thyroidectomized animals have been employed with the same object.

Dr. George Murray,¹ whose name is identified with the successful treatment of myxedema and cretinism with thyroid preparations, proposes the use of serum in which the formation of antibodies has been induced by treating animals with gradually increasing doses of thyroid extract, a method that has also been pursued by Lepine. The latter fed a goat on gradually increasing amounts of thyroid gland from sheep or other goats on successive days, and obtained the blood-serum after the lapse of several months. Murray administered thyroid extract to rabbits by the mouth, and obtained the blood serum after about a month. This he was able to inject subcutaneously into a rabbit without ill effect, and accordingly he felt at liberty to employ it clinically. Two patients were thus treated, but the results were not conclusive. Nevertheless, it is considered possible that if larger animals were employed and larger doses of thyroid extract were given a serum might be obtained that could be used hypodermically in acute cases, or be administered by the mouth in chronic cases in which prolonged treatment would be required.

PROPOSED MIDWIFE ACT IN NEW ZEALAND.

The question of depopulation has stirred up the New Zealanders, and the premier of that country sees an important factor in the excessive infant mortality that exists at the present time. The reform he proposes

consists in the education of qualified midwives, none others being allowed to practice, the erection of maternity homes and foundling hospitals under state control or inspection and gratuitous nursing for the very poor supplied by the state. The nurses and midwives should be educated in hospitals under state supervision. Crèches and infant nursing hospitals are also to be provided.

THE CONVEYANCE OF SMALLPOX BY VAGRANTS.

The danger of transmission of smallpox and other diseases by the roving element of society, known as "tramps," is one which it is impossible wholly to prevent and difficult to restrict. The danger is a very real one in the experience of health officers. Emphasis is given to the need of proper restrictions by a report from Dr. Armstrong, health officer of Newcastle-on-Tyne, England, who investigated the subject by sending inquiries to 126 provincial health officers. Replies showed that smallpox was introduced by vagrants in 57 out of 111 districts (with a population of 20,000 and upward, where an epidemic had prevailed), and that in 25 of these 57 districts, spread of the infection occurred from vagrants. The importance of the matter has been appreciated by the London County Council, which has asked for a convention of the sanitary authorities of England and Wales to consider the subject and to endeavor to provide a remedy. We can not go back to the days of walled cities and passports, but there remains vital need for the restriction of the freedom of the tramp.

THE CURABILITY OF PULMONARY TUBERCULOSIS UNDER SANITARIUM TREATMENT.

Within the last few years numerous reliable statistics have been published bearing on the curability of pulmonary tuberculosis. In the majority of these it is to be noted that although the patients were traced, the ultimate condition of their lungs was not reported on by a physician, and, further, that the term "well" or "recovered" used in connection with such patients does not usually denote whether the patient is well enough to work at his ordinary vocation, or whether he is merely free from symptoms of the disease. In his recent report¹ of the last three years' work of the Friedrichsheim Sanitarium, Rumpf was able to follow nearly all his patients (over 97 per cent.) for from three to four years after their discharge, and was able to have the report of a physician as to their pulmonary condition. The real criterion of cure Rumpf considers to be the ability to perform daily work. Of the patients who entered the sanitarium in the first stage of the disease, it was found that 70 per cent. were able to work three to four years after discharge, while of those who entered in the third stage the percentage of deaths increased each year after discharge. The patients who commenced treatment in the second stage of the disease held a middle place, a fair number recovered, but not a few died. Summing up the results, Rumpf states that of those entering in the first stage, 70 per cent. are able

1. Lancet, Aug. 27, 1904, p. 553.

1. Münchener med. Wochenschrift, II, No. 33.

to work at the end of three or four years; of those entering in the second stage, 55 per cent.; of those entering in the third stage, 23 per cent. Such results place the prognosis of pulmonary tuberculosis in a rather more favorable light than many of the recent statistics would lead us to expect; they serve to emphasize the fact, which can not be too often stated, that the percentage of cures is in direct ratio to the number of early diagnoses.

UNUSUAL COMPLICATIONS OF MEASLES.

The micro-organism of measles is yet to be isolated and the effects of its biologic activity await demonstration. The symptoms of the disease are dependent largely on the localization of the morbid process to the mucous membrane of the respiratory tract, and complications of toxic origin are of rather uncommon occurrence, although a considerable number of cases in which cerebral and spinal disorders developed in the course or sequence of measles have been placed on record. For this reason the occurrence of polymyositis and polyneuritis in connection with measles would seem to be worthy of note. In a joint communication Dr. W. Jesen¹ reports a case of the former complication and Dr. E. Edens one of the latter. The first occurred in a woman, 32 years old, in whom the rash of measles appeared on the sixth day of an illness, and symptoms suggestive of articular and muscular rheumatism on the sixteenth day. When the patient came under observation, she presented edema of one foot and tenderness of the corresponding lower extremity. Active movements were restricted and attended with muscular pain. Later pain appeared also in the opposite lower extremity, together with edema and thickening and induration of the musculature, while the overlying skin became tense and glistening. The symptoms persisted for about a month and then subsided gradually, recovery eventually taking place. There was no doubt as to the diagnosis of measles, the mother of the patient after attending the latter also being attacked by the disease. The second case occurred in a girl, 16 years old, in whom symptoms of polyneuritis developed in the course of a severe attack of measles complicated by bronchopneumonia and otitis media. The two cases cited teach, in conformity with an abundant clinical experience, that the exanthemata are not to be ignored, but they must always, in mild as well as in severe cases, be considered as possible factors in the development of even serious complications.

Medical News.

CALIFORNIA.

Hospital Incorporated.—The Good Samaritan Hospital of San Francisco has been incorporated with a capital stock of \$100,000.

Personal.—Dr. Hiram N. Rucker, Merced, has been appointed superintendent of the Masonic Widows' and Orphans' Home, at Decoto, and assumed charge November 1.

Decision in Re Osteopaths.—The secretary of the State Board of Health states that an osteopath can not sign a death certificate and gives as his authority Attorney-General Webb, who

cited with his approval the decision of former Attorney-General Tiry L. Ford, who said:

I conclude that an osteopathist is not a physician within the meaning of Section 3084 of the Political Code, or the municipal corporation act, so called, hereinabove referred to, and that he can not, therefore, sign a death certificate as a physician as the word is used in the statutes.

ILLINOIS.

Board Awarded Medal.—The State Board of Health has been awarded a gold medal for its exhibit in the section of hygiene at the Louisiana Purchase Exposition.

Provides Hospital in Persia.—Mrs. Simon Reed, Lake Forest, has donated \$7,000 to the Presbyterian Board of Missions, to be used for the erection of a hospital at Oroomiah, Persia.

Diphtheria.—It is reported that there are 8 or 10 cases of diphtheria in East Peoria, and closure of the schools is proposed.—Diphtheria is prevalent near Shibley, and schools are being closed through fear of a general epidemic.

Personal.—Dr. Aurelius T. Bartlett, Virden, has moved to St. Louis.—Dr. Daniel Lichty, Rockford, has succeeded the late Dr. Edward P. Catlin as a member of the local board of pension examiners.—Dr. James D. Whitley, Petersburg, has resumed practice after a long and severe illness.

Smallpox Warning.—The State Board of Health has issued a circular to local health authorities throughout the state, calling attention to the prevalence of smallpox, the too common carelessness as to vaccination and other precautions; the present virulent nature of the disease and the necessity of taking immediate measures to safeguard the people of the state against the disease.

Chicago.

Home Again.—Dr. Nicholas Senn has returned from his trip around the world and has resumed practice.—Dr. and Mrs. Ferdinand C. Hotz have returned from Europe.—Dr. Thomas J. Jackson and family have returned from Europe.

A Low Mortality.—The deaths for the week ended October 29 numbered 412, equivalent to an annual death rate of 11.14 per 1,000. Consumption was the chief cause of death with 54; violence caused 39 deaths; acute intestinal diseases, 34; pneumonia and Bright's disease, each 32; heart diseases, 30; diphtheria, 10, and typhoid fever, 7.

Vaccination and Smallpox.—Upward of 270,000 vaccinations have been performed in the city since the first of the month—more than 40,000 by officers of the department and the remainder by private physicians. Twelve new cases of smallpox were discovered during the week, but no new center of infection; they are all traceable to the previous cases. Of the 12, only 2 had ever had vaccination even attempted; these two, 31 and 55 years of age respectively, exhibit old, imperfect scars made in childhood.

Drainage Canal and Typhoid.—A dozen years ago Chicago had the highest typhoid death rate of any large city in the civilized world. To-day its rate is among the lowest. During the four years 1889-1892 inclusive there were 4,747 deaths recorded from typhoid fever—an average rate of 10.86 in every 10,000 of population. In the four years since the opening of the Drainage Canal there have been 2,235 such deaths—an average of 3.09 in every 10,000 of population. These figures show a reduction of nearly three-quarters (74.8 per cent.) in the typhoid mortality rate.

INDIANA.

Typhoid at Carmel.—There have been 11 cases of typhoid fever in Carmel, all of school children in the public school. The school well is suspected.

Diphtheria in Institution.—There were 68 cases of diphtheria, with 3 deaths, the first week in October at the Miami County Orphans' Home at Mexico. The first cases were, as usual, diagnosed as tonsillitis.

Hidden Scarlet Fever.—The county health officer discovered 5 unreported cases of scarlet fever, October 25, in Woodruff Place, a suburb of Indianapolis. All the cases were attended by well-known physicians. It is probable that prosecutions will be made.

Impure Water.—The Indianapolis Water Company, which has often been openly accused of furnishing polluted water, threatens to ask for an injunction against the new United States Army post if the effluent from the septic tank and sewage filter beds is allowed to run into Fall Creek. This, we are informed, is likely to lose the post to Indianapolis.

1. Berliner klin. Woch., Aug. 8, 1904, p. 847. Abstract in THE JOURNAL, page 922.

The Terre Haute Epidemic.—In the smallpox epidemic at Terre Haute, which ended October 18, 114 cases were reported and 12 deaths. Most of the cases were very severe, and there were three cases of hemorrhagic smallpox, with three dying. Two deaths from hemorrhagic smallpox also occurred in a farmer's family in Warren County the last week in September.

Banquet in Honor of McCormack.—The societies which comprise the Thirteenth Council District gave a banquet at the Oliver Hotel, South Bend, October 20, in honor of Dr. J. N. McCormack, national organizer of the American Medical Association, at which Dr. James B. Greene, Mishawaka, responded to the toast of "The Pioneer Doctor"; Dr. Richard B. Dugdale, South Bend, to "The President of the County Medical Society and His Troubles"; Dr. William H. Thompson, Winamac, to "The General Practitioner"; Dr. John C. Fleming, Elkhart, responded for "Our Absent Sisters"; Dr. Charles A. Daugherty, South Bend, explained "Why Every Physician Should Be a Member of His County Medical Society"; Dr. James W. Milligan showed how "Others See Us"; Dr. Charles J. Loring, Rochester, responded for "The Country Doctor"; Dr. T. A. Burr, South Bend, described "The Clinician of To-Day and Yesterday," and Dr. McCormack gave some "Professional Reminiscences of Dixie." Dr. John B. Berteling, South Bend, was toastmaster.

KANSAS.

Epidemic at Wellington.—It is reported that there are 30 cases of typhoid fever and several of diphtheria in Wellington. The typhoid infection has been traced to ice cream served at a wedding feast.

Infectious Diseases.—During the last month there were in Topeka 31 cases each of diphtheria and scarlet fever, with 5 and 3 deaths respectively, 9 cases of smallpox, 2 of measles and 3 of chicken-pox, and 13 deaths from consumption.—Three district schools south of Emporia have been closed on account of epidemic diphtheria.

Extension of School for Feeble-Minded.—The State Board of Charities has confirmed the recommendations contained in the last report of Dr. C. S. Newlon, superintendent of the State School for Feeble-Minded Youths, which provide for a new four-story dormitory to cost \$40,000, an engine house, residence for superintendent, etc.

MARYLAND.

Personal.—Dr. L. Gillis Owings, Ellicott City, is at the University Hospital, Baltimore, suffering with typhoid fever.

Convicted for Abortion.—Dr. Joseph C. Orlandorff, tried at Upper Marlboro, on the charge of manslaughter in causing the death of Margaret Hall at his institute there by malpractice, was convicted October 27.

Protest Against Pardon.—The State Department has been flooded with protests against the pardon of Dr. George C. Worthington, a convicted abortionist, now serving his term in the penitentiary, and it is said in view of these protests the governor will not interfere.

State Board of Health Reports.—The annual reports of the State Board of Health for 1902 and 1903 are just issued, the delay being due to the fire last February. In the report for 1903 the secretary criticises some of the county officials for alleged indolence and indifference. St. Mary's and Garrett, he says, are the worst offenders in this regard, and but for their shortcomings Maryland would now be admitted to the group of registration states. More care in keeping birth and death records and better organization are strongly urged. The secretary recommends the establishment of an annual school or institute which all health officers shall be compelled to attend.

Baltimore.

Personal.—Dr. Charlotte S. Murdock sailed for Liverpool October 22.—Dr. John C. Schofield was painfully injured by being thrown from his buggy, October 20.

Medical Men Officers of War Society.—The Society of the War of 1812 elected the following among other officers, October 25: President, Dr. Albert K. Hadel; vice-president, Dr. James D. Iglehart; members of executive council, Drs. Charles E. Sadtler and Nicholas L. Dashiell.

MASSACHUSETTS.

Malden Isolation Hospital.—The council of Malden has recommended an appropriation of \$15,000 for the construction of a hospital for contagious diseases on the land of the poor farm, to accommodate 24 patients.

Diphtheria on the Increase.—There were 67 cases of diphtheria, 5 of which were fatal, reported to the Boston Board of Health for the week ended October 29. This is an increase of 60 per cent. and would be alarming except that most of the cases so far reported are mild.

Personal.—Dr. Robert A. Blood, Charlestown, formerly surgeon general, has moved to Brookline.—Dr. John B. Beebe, Great Barrington, has been appointed medical examiner of the fourth Berkshire district, vice Dr. Whitemell P. Small, resigned.—Dr. Roscoe D. Perley, Melrose, has been appointed medical examiner of Middlesex County, vice Dr. Ernest S. Jack, resigned.—Dr. John B. Tyler, Billerica, sails for home from Italy early this month.—Dr. Elisha S. Lewis, Springfield, sails for Europe early this month.

Free Issue of Vaccine Virus.—The Massachusetts State Board of Health has begun to issue free vaccine virus in accordance with the act of the legislature in 1903. This is produced and distributed in the same way as the diphtheria antitoxin, which has largely replaced the product of private manufacturers throughout the state. Both the antitoxin and vaccine virus are prepared under the close supervision of Prof. Theobald Smith, and the total expense is but a few thousand dollars per year. The lymph is issued in the glycerinated form in sealed tubes, and also in vials containing 25 or more doses, according to the desire of the physicians who use it. The circular sent out by the board urges the vaccination of all children before they are one year old and again at the age of 10, with careful inspection to determine success or failure. Careful observance of these rules with the easy access to free vaccine of the best quality, it is expected, will prevent the recurrence of the smallpox epidemics of the past few years.

MICHIGAN.

Personal.—Dr. Horace H. Phillips, Cassopolis, has been elected county physician of Cass County, to succeed himself.

Dr. Arthur D. Holmes and family, Detroit, returned October 22 after an absence of a year in Europe.

Postgraduate School for Detroit.—Plans are in progress to establish and maintain a postgraduate school of medicine and an additional hospital in Detroit. The following committee has been appointed to devise more definite plans: Drs. Lewis E. Maire, Frank D. Summers and Leo Breischler.

Another Anti-Vaccination Lie Nailed.—A circular issued by the State Board of Health says:

An item has been going the rounds of the press relative to the death of William Taylor, a child at Port Huron, alleging that "The parents believe that his death was caused by vaccination." But an official report to the secretary of the State Board of Health clearly proves that the alleged belief had no foundation in fact. The report says that a short time after vaccination the child was taken sick with bowel trouble and had no medical attendance, the parents being "Christian Scientists." After the death of the child the coroner called in a reputable physician and found the vaccinated arm, aside from a small scar, was exactly the same as the other, and showed no sign of having been inflamed. The physician and the coroner came to the conclusion that the child had died of "enterocolitis"—inflammation of the bowels. It appears that the parents belong to a sect whose members do not believe in vaccination, nor in calling a physician, and undoubtedly would have been pleased to have had the death recorded as due to vaccination, especially as otherwise there is a suspicion as to the effect of the lack of proper medical attendance for the relief of the inflammation of the bowels.

NEW JERSEY.

A Merited Honor.—Dr. Archibald Mercer, who recently retired after long service as an active member of the surgical staff of the City Hospital, was unanimously elected by the trustees surgeon emeritus of the hospital.

Physician Automoblists to Organize.—Physicians of New Jersey are planning a national organization of automobilists. A meeting will be held in Camden in January, when the Physicians' Automobile Club of New Jersey will hold its annual meeting.

Diphtheria in Salem.—Some of the public schools of Salem, Petersburg, Beasley's Point and Palermo have been closed on account of the prevalence of diphtheria. Camden is also suffering from a similar outbreak. The disease seems to be extremely virulent; 18 cases were reported in three days in Camden.

Physicians Ill.—Dr. Walter Steadman, Hoboken, who has been ill for three months with typhoid fever, is now convalescent.—Dr. Robert C. Riblans, Newark, has been seriously ill with septicæmia arising from an operation wound on the finger.—Dr. Rufus B. Whitehead, Elizabeth, who has been threatened with phthisis, has gone south for the winter.

Loving-Cup Presented.—The medical profession of Atlantic City, on October 17, presented Dr. Byrou Cook Pennington with a handsome silver loving-cup, suitably inscribed, in token of their appreciation of the sterling worth and faithful work of Dr. Pennington during his 24 years of practice in Atlantic City. Dr. Pennington sailed, October 22, for Bermuda, where he will spend the winter.

NEW YORK.

Personal.—Dr. Floyd S. Crego, Buffalo, is in Europe.—Dr. Montgomery Crockett leaves Buffalo for a year. He will first go to Asheville, N. C., and in the spring will go to Europe, remaining until the fall of 1905.

Another Drug Crusade.—The first step in a crusade which the New York State Medical Association has declared against druggists who sell impure drugs and traffic unlawfully in poisons, was taken when the agent of the association's attorney made a sampling tour among druggists. The samples will be sent to the health board for analysis and, if evidence of adulteration is found, the association will take drastic measures. The State Board of Pharmacy has inspectors out constantly endeavoring to obtain evidence of impure drugs.

Proposed Consumptive Sanitarium Impossible.—Despite the protest of the medical fraternity and philanthropists generally, the Goodsell-Bedell bill has been passed, prohibiting the establishment of a hospital for consumptives without the consent of the board of supervisors of the county, and of the town board of the town, in which the hospital or camp is sought to be located. A previous law provided that the consent of both the local and the state board of health must be obtained before such a hospital could be established. This will make it impossible, without further legislation, to establish the sanitarium for poor consumptives in an isolated part of Orange County which the health authorities of New York City had intended to be used for this purpose.

New York City.

Subway Contributes to Hospitals.—It was announced that the subway company would give to the hospitals of the city all the money collected from the sale of tickets on the opening day, October 27. It was ascertained that this sum would be in the neighborhood of \$5,600.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended October 22, 57 cases of measles, with 3 deaths; 317 cases of diphtheria, with 30 deaths; 123 cases of scarlet fever, with 7 deaths; 41 cases of chicken-pox; 337 cases of tuberculosis, with 143 deaths; 125 cases of typhoid fever, with 17 deaths, and 18 deaths from cerebrospinal meningitis.

Pneumonia Investigation.—At the request of this commission Dr. Darlington has prepared two large charts, which show the increase of pneumonia since 1870. The pneumonia charts show that the pneumonia deaths have increased nearly 50 per cent. in thirty-three years. The highest death rate was in 1892 and 1893, when there was an increase of from 75 per cent. to 85 per cent. over that of 1870, these being the years of the influenza epidemic. Another chart gives the comparison between the death rate from pneumonia and that from pulmonary tuberculosis from 1870 to 1893. For the first twenty years of this period tuberculosis was far more deadly. In 1891 the pneumonia rate exceeded that of tuberculosis and only once since then has the pneumonia rate been lower.

PENNSYLVANIA.

Personal.—Dr. Addison M. Rothrock, West Chester, has assumed his duties as resident physician of the Mount Alta Sanitarium for Consumptives.

Health Officers Close School.—On account of the existence of a great deal of contagious disease among the children attending St. Nicholas' German Catholic school, Wilkes-barre, the health officers have ordered the school closed for an indefinite period.

Philadelphia.

Personal.—Dr. Richard H. Harte has resigned his position as attending surgeon to the Episcopal Hospital. The vacancy on the surgical staff will be filled by the board of managers at its meeting, November 24.

Eminent Japanese Visitors.—A party of four distinguished professors from the Imperial University at Tokio visited Philadelphia, October 25. All are graduates of Berlin University. They were Dr. L. Sato, professor of surgery; Dr. K. Tamba, professor of pharmacy, and Profs. T. Yssisaka and A. Nissimura.

Uncinariasis.—The *Uncinariasis americana*, or hookworm, was discovered in a patient by Dr. M. H. Fussell in the University Hospital. The patient has been an inmate of the institution since August last. The true character of his ailment was totally obscure until the parasite was found. Dr. Fussell presented a paper on this subject and exhibited specimens at the last meeting of the College of Physicians.

Equips Medical Laboratories.—The University of Pennsylvania has just completed, at the cost of \$7,000, the equipment of the new medical laboratories. The laboratories were used for the first time, October 31. The donation provides the laboratory of pathologic histology, neuro-pathology and gynecologic pathology, with 50 microscopes each, also one dissecting microscope, 40 1 1/2 oil immersion lenses, 1 hydraulic press, 1 centrifuge, 1 thermostat, 1 spectroscope and 1 complete outfit for photomicrography. It also provides the 4 lecture rooms with projectoscopes, 2 for lantern slides and 2 for microscopic sections.

Health Report.—Diphtheria is widely prevalent throughout the city and is increasing with marked virulence, as 18 deaths resulted from the disease during the week, an increase of 10 over those of last week. The new cases numbered 98, an increase of 2 over the preceding week. The disease prevails generally throughout the city, and many schools have been compelled to close. The disease is also more or less prevalent throughout the state, and also in the near-by towns of New Jersey. The total death rate for the week shows an increase, numbering in all 407. This is an increase of 27 over those of last week, and a decrease of 59 over the corresponding period of last year. In all there were 244 cases of contagious disease, with 25 deaths reported, as compared with 233 cases and 22 deaths for the previous seven days.

TEXAS.

Personal.—Dr. Henry I. Hilliard, Marshall, was thrown from his buggy, October 11, and seriously injured.

Diphtheria Closes Schools.—Public schools at Mason, Ennis and Hallettsville have been closed on account of the prevalence of diphtheria.

Quarantine Removed.—On recommendation of the state health officer, the governor, on October 24, issued his annual quarantine proclamation raising the embargo against ports in tropical countries, recognized as infected during the summer months.

State Pasteur Institute Open.—The new Pasteur Institute, for the establishment of which an appropriation of \$5,000 was made by the last legislature, was opened at Austin for the reception of patients October 1. Dr. Benjamin M. Worsbam is in charge of the institute.

Openings of Colleges.—Dallas Medical College opened for its fifth annual session, September 20.—The fourteenth annual session of the Texas Medical College and Hospital, Galveston, was opened with an address by Prof. Alfred E. Thayer, October 3.—Fort Worth Medical College began its eleventh annual session October 3.

GENERAL NEWS.

Western Surgical Association.—The next annual meeting of the Western Surgical and Gynecological Association will be held in Milwaukee, Dec. 28-29, 1904.

Laryngologists at Pan-American Medical Congress.—Dr. G. Hudson Makuen is secretary of the section on laryngology and rhinology of this congress and asks those who wish to contribute papers to send titles to him at 252 South Sixteenth Street, Philadelphia.

American Public Health Association.—The thirty-second annual meeting of this body will be held at Havana, Cuba, Jan. 9-13, 1905, and, as noted in the Correspondence column, arrangements are made whereby one may attend the Pan-American Medical Congress and then go to Havana on the way back to the United States. The secretary of the health association is Dr. Charles O. Probst, Columbus, Ohio.

American Surgeons at the Seat of War.—The general staff has decided to send American surgeons as attachés to the Russian and Japanese armies provided the consent of these two nations can be secured. The military observers now in the field have reported so many interesting details regarding the medical departments of the two armies that it is evident to the general staff that there has been a revolution in the field hospital methods and they regard it as desirable that the American medical department should have an opportunity of profiting thereby.

A New Forgery Scheme.—The profession should be warned concerning a clever forger who has been cashing bad checks in Minneapolis. The man's scheme is novel and so far has proved successful. He writes a prescription and signs some well-known physician's name to it. This he takes to a drug store to be filled. In payment he tenders a check, usually for a small amount, and is usually given the change in cash. The man secured the blanks by telling a downtown druggist that he was a physician recently admitted to practice. His manners and appearance are good and few would take him for a crook. The Minneapolis police have been warned against a gang of forgers and confidence men that have recently left St. Louis and they think the present operator is one of these.

Medical Directory of New York, New Jersey and Connecticut.—The sixth edition of the Medical Directory of New York, New Jersey and Connecticut, compiled under the auspices of the New York State Medical Association, which has just been received, follows the same general order as the editions which preceded it, and is accordingly practical, neat and valuable. The total number of physicians noted in New York state is 11,746; in New Jersey, 2,176, and in Connecticut, 1,282. Polk's directory for 1904 gives the figures as New York state, 13,638; New Jersey, 2,360, and Connecticut, 1,434, and the Standard Directory for 1903-1904 states that there are 12,995 physicians in New York state; 2,245 in New Jersey, and 1,288 in Connecticut. Of the 11,746 physicians in New York state, 4,215 are credited to Manhattan and Bronx, 1,506 to Brooklyn, 121 to Queens, and 65 to Richmond, which makes a total for Greater New York of 5,907 and for the remainder of the state of 5,839.

FOREIGN.

Stabbed by an Insane Patient.—Dr. Vallon was stabbed in the back by an insane inmate in making his rounds at the Sainte-Anne asylum, Paris. The physician was paralyzed on one side at first, but seems to be recovering. The injury was inflicted with a kitchen knife which the patient had secured.

New Hygienic Measure at Rome.—The municipality of Rome has distributed cards to the various drug stores, each printed with the following:

The undersigned wishes to announce to the Board of Public Health that at No. of street, there exists cause for injuring the public health in overcrowding of sleeping rooms, filth, defects in the gas, pavements, cesspools, etc.; suspicion of adulteration of foods or beverages. N. B.—Underline the nuisance or defect complained of. No attention will be paid to unsigned communications.

The denouncer signs this card and returns it to the pharmacist, receiving a receipt therefore. It is turned over to the Board of Health and suitable measures are taken. The Italian medical journals regard this innovation as promising good results.

The First German Academy for Practical Medicine.—The first of the new German academies for practical medicine was formally inaugurated at Cologne October 10, with much ceremony. Bardenheuer was mainly instrumental in its organization, and he was decorated on the occasion. He has published a *Festschrift* in honor of the inauguration, with articles from his own pen and by his numerous pupils, including Sonnenschein, Graesser, Bayer and others. These new academies are designed to serve as centers for postgraduate study in places without a medical college and to train fledgling physicians and others wishing to take up some specialty. The profession at large regards this innovation with dubious approval.

Correspondence.

Fourth Pan-American Medical Congress.

NEW YORK CITY, Oct. 25, 1904.

To the Editor.—To attend the fourth Pan-American Medical Congress, which will be held in Panama, Jan. 2-6, 1905, will involve a most delightful midwinter trip. The delegates will leave this country by the Atlantic, Pacific and Gulf coasts the last week in December and will return by the same or other routes. The American Public Health Association will meet the following week in Havana, and those who desire to attend both meetings can do so. There are two routes for the physicians from Panama to Havana. The first is by way of Jamaica to Santiago de Cuba by boat and over-

land by rail to Havana. The second is by water from Panama to Vera Cruz and from there to Havana. The former will probably be the most pleasant.

From Havana, the return trip can be made directly north to New York by water or via Miami or Tampa, Fla., or New Orleans. The connections and dates of sailing are now being arranged.

The Panama government has appropriated \$25,000 for the scientific session and the entertainments. The afternoons will be devoted to the scientific sessions and the mornings and evenings to trips and social functions. So far as can be learned, the program in Panama will be a reception on the first day by President Amador of the Panama republic, and the formal opening session of the congress the same evening. On the second day an excursion to the canal in the morning, meeting of the various sections in the afternoon, and a banquet in the evening; on the third day an excursion down the bay to Taboga Island, where a Panama breakfast will be served, scientific sessions in the afternoon and a ball in the evening. On the fourth day an excursion to the United States Army barracks in the morning, section meetings in the afternoon and the formal closing session in the evening. On the fifth day an excursion to the plantation of the United Fruit Company, and in the afternoon those who go to Cuba will sail for Jamaica, while those who intend going to Cuba by way of Vera Cruz, or returning home by way of New Orleans or New York, will remain until the following Tuesday.

The secretaries of the sections of the congress for the United States are:

Dr. A. H. Doty, New York, Hygiene and Quarantine.
Dr. Judson Daland, Philadelphia, Medicine.
Dr. R. Maass, New Orleans, General Surgery.
Dr. H. Bert Ellis, Los Angeles, Eye.
Dr. Judson Makuen, Philadelphia, Throat.
Dr. Frederick Jack, Boston, Ear.
Dr. C. H. Hughes, St. Louis, Nervous Diseases.
Dr. Geo. Goodfellow, San Francisco, Military Surgery.
Dr. John Ridton, Chicago, Orthopedic Surgery.
Dr. D. W. Montgomery, San Francisco, Dermatology.
Dr. C. G. Kerley, New York, Pediatrics.
Dr. Noble F. Barnes, Washington, Therapeutics.
Dr. Walter Chase, Boston, Pathology.

Communications from physicians in the United States can be sent directly to these secretaries. Delegates intending to attend the congress, desirous of obtaining information, should communicate with the secretary of the international executive committee in the United States. DR. RAMON GUTIERAS,

75 West Fifty-fifth Street, New York City.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

VIBRATION THERAPY.

To the Editor.—I have lately been brought into contact with the promoters and their literature of the "Vibration Therapy" method of treatment. Their literature reads well, and if founded on scientific observations that can be substantiated, is worth attention. I know of no unbiased literature concerning this method—that is, papers written by those not interested commercially, in the exploiting of some particular appliance. Are there any reports or works on this subject by scientific or accredited authorities published that do not bear the earmarks of some commercial interest? Is the "vibration therapy" of sufficient value to the physician to warrant him in spending his time in studying it and the expense of installing the apparatus? Is it a better or more easily applicable form of treatment for certain conditions, such as lumbago, paralysis, neuralgia, neurasthenic conditions, nutritional disturbances, than other well-known remedies that are the universal property of the medical profession, or is it only a "fad," adapted to the purposes of a certain class of practitioners?

N. B. B.

ANSWER.—In Rockwell's work on Medical and Surgical Electricity, Chapter V, pages 635-641, is devoted to vibratory therapeutics. The following articles on this subject have appeared in medical journals: "Vibration Massage in the Treatment of Chronic Prostatitis," by Dr. Louis E. Schmidt, *St. Louis Courier of Medicine*, August, 1903; abstracted in *The Journal*, Sept. 12, 1903. "Mechanical Vibration, Its Theory and Application in the Treatment of Disease," by Maurice F. Pilgrim, *Boston Medical and Surg-*

ical Journal, Sept. 10, 1903 "Vibration Massage," by Werneck Machado, *Brasil Medico*, August, 1902. "A Consideration of the Scientific Application of Mechanical Vibratory Stimulation in the Treatment of Disease," by Maurice F. Pilgrim, *Medical Notes*, New York, Jan. 24, 1903. "Vibration Massage in the Expulsion of Kidney Stone," by G. Klemperer, *Therapie der Gegenwart*, Berlin, October, 1902; abstracted in *THE JOURNAL*, Dec. 6, 1902, page 1492. Vibration therapy, like massage, which it resembles, seems to have a definite place in the treatment of disease, but like some other methods, it has been used indiscriminately in many conditions for which it was very unsuited.

STATES THAT DO NOT REQUIRE EXAMINATION FOR LICENSE.

PHILADELPHIA, Oct. 15, 1904.

To the Editor:—What states do not require an examination for license to practice medicine? H. W.

ANSWER.—Colorado, Wyoming, Indian Territory, Nevada and New Mexico, issue licenses to practice medicine on registration of diploma. Colorado and Wyoming, however, do so only in the case of graduates holding diplomas from colleges having the standard laid down by their boards.

EUROPEAN MEDICAL SUMMARIES.

EL PASO, TEXAS, Oct. 29, 1904.

To the Editor:—1. Is there published in the English language something similar to "Progressive Medicine" or "International Clinics," but covering a field in one or more of the European countries? If so, give price, etc. 2. Is "Braithwaite's Retrospect" still published? E. J. M.

ANSWER.—1. No. 2. No.

Marriages.

JOSEPH GILBERT BEMIS, M.D., to Miss Sarah C. De Yoe, both of Chicago.

JOHN Z. PARKER, M.D., to Miss Mary Elizabeth Rea, both of Pattonsburg, Mo.

CHARLES LONG, M.D., to Miss Helen E. Miller, both of Toledo, Ohio, October 19.

C. T. HELMEY, M.D., to Miss Clara Hahn, both of Humboldt, S. D., October 15.

JOSEPH T. EDWARD, M.D., to Miss Alice Mary Reid, both of Chicago, October 25.

HARRIS G. MINTER, M.D., to Miss Alma Reddick, both of Jakin, Ga., October 19.

HERBERT E. LARROQUE, M.D., to Miss Mabel Britton, both of Baltimore, October 25.

S. LEE MAGNESS, M.D., to Miss Stella F. McConnell, both of Baltimore, October 20.

JOHN F. MACKAY, M.D., Odessa, Mo., to Miss Nellie McVeigh Hopkins of Breckenridge, Mo.

JAMES A. MANXON, M.D., Sherrard, Ill., to Miss Frances Edgar of Cable, Ill., October 19.

JOHN F. CROWLEY, M.D., La Salle, Ill., to Miss Margaret Hensler of Chicago, October 19.

J. HENRY MCNEEL, M.D., to Miss Lynnette Leininger, both of Foud du Lac, Wis., October 20.

Z. M. STORY, M.D., Thomson, Ga., to Miss Willie Spence Jones, of Gainesville, Ga., October 19.

WILLIAM W. MILLIGAN, M.D., to Miss Minerva M. Rankin, both of Burlington, Iowa, October 26.

EDWARD V. MILHOHLAND, M.D., to Miss Mary Katherine Clark, both of Baltimore, October 26.

AUGUST R. ANNEBERG, M.D., Templeton, Iowa, to Miss Bertha Kvits of Des Moines, Iowa, October 25.

WILLIAM EDWARD MACK, M.D., Paradise, Cal., to Mrs. Eva A. Chinn of Los Gatos, Cal., October 15.

ERNEST McCUE THRIFT, M.D., Madison, Va., to Miss Minnie Merle Giles at Raphine, Va., October 26.

THOMAS K. PROCTOR, M.D., to Mrs. Hallie H. Robertson, both of Sulphur Springs, Texas, September 15.

NEIL DUNCAN GRAHAM, M.D., of Washington, D. C., to Miss Elizabeth Farrow, at Baltimore, October 24.

WILLIAM R. BALL, M.D., Mitchell, S. D., to Miss Helen Beckwith Jones of Prospect, N. Y., September 21.

RICHARD BOOTH, M.D., Lynchburg, Va., to Miss Louise Harris Zimmerman, at Buena Vista, Va., October 26.

FRANK HILTON McLEOD, M.D., Florence, S. C., to Miss Caroline Goodwyn Nelson of Statesburg, S. C., October 5.

Deaths.

Samuel Warren Abbott, M.D. Harvard University Medical School, Boston, 1862, a member of the American Medical Association, American Public Health Association, American Statistical Association and Royal Statistical Society of Great Britain; for 18 years the efficient and painstaking secretary of the Massachusetts State Board of Health; an authority on vital statistics, author of "The Past and Present Condition of Public Hygiene and State Medicine in the United States," assistant surgeon in the Navy and in the First Massachusetts Volunteer Cavalry during the Civil War, coroner of Middlesex County

DR. SAMUEL W. ABBOTT.

from 1872 to 1877 and for seven years thereafter medical examiner for the same county, was found dead in bed at his home in Newton Highland, Mass., October 22, at the age of 67. Modest about his attainments and never seeking publicity, Dr. Abbott was recognized as being one of the most careful statisticians on medical matters in this country. His state reports have been regarded as models, and their style has been copied in many other states. He had the respect of the entire medical profession of the state. The *Boston Advertiser* pays the following editorial tribute to Dr. Abbott:

To most people around the state hence Dr. Abbott was merely a quiet, hard working secretary to the state board of health. To scientific authorities abroad his name was probably better known than that of any other American, with the possible exception of Dr. Weir Mitchell of Philadelphia. Dr. Abbott's name was signed to the Massachusetts reports, which are the highest possible authority of the kind on many subjects, such as typhoid epidemics, that interest scientists all over the world. It is worth remembering that when the much-heralded "copper treatment" for the Americans in the Panama Canal strip was to be tested it went to the Massachusetts board of health.

William Wotkins Seymour, M.D. Harvard University Medical School, Boston, 1878, a member of the American Medical Association, British Medical Association, American Association of Obstetricians and Gynecologists, New York State Medical Association and New York State Medical Society; professor of midwifery and gynecology in the University of Vermont for several years, trustee and chief surgeon of Samaritan Hospital, Troy, N. Y.; a pioneer investigator in gallstone disease and one of the first surgeons in the United States successfully to operate in this field; the translator of Kehr's classical treatise on "The Diagnosis of Gallstone Disease," died at his home in Troy, N. Y., October 18, after an illness of several weeks, from heart disease, aged 51.

Mordecai Price, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1869, died suddenly at his home in Philadelphia from apoplexy, October 29, aged 60. Dr. Price was one of the most eminent abdominal surgeons and gynecologists of Philadelphia and an operator of national reputation. He was born in Rockingham County, Virginia, in 1844, and came to Philadelphia when a boy. He was associated in his work with his brother, Dr. Joseph Price. He was a member of the Philadelphia County Society, the Medical Society

of the State of Pennsylvania and the American Medical Association. He was a frequent contributor to medical literature.

Samuel W. Woodhouse, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1847, surgeon and naturalist on the boundary survey expedition between the Creek and Cherokee Indians; surgeon of the topographical engineer corps on the Sitgreaves-Zuni expedition in New Mexico, in 1852, and to Central America in 1853; surgeon at Fort Delaware in 1854; surgeon to the Washington Grays, and surgeon on Cope's packets, famous in the early days of steamships, died suddenly at his home, Philadelphia, October 23, aged 83.

Albion K. P. Meserve, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1859, a member of the American Medical Association; formerly president of the Maine Medical Association and chairman of the Portland Board of Health; secretary of the State Board of Registration in Medicine; member of the National Confederation of State Examining and Licensing Boards, died at his home in Portland, September 15.

Christopher C. Cook, M.D. St. Joseph (Mo.) Medical College, a member of the American Medical Association and the Greeley County Medical Society; for more than thirty years a practitioner of Nebraska, and since 1895 a resident of Scotia, died at the home of his daughter in Kansas City, Mo., September 30, from tuberculosis of the intestines, after an illness of eight months, aged 59.

Daniel A. Thompson, M.D. Medical College of Indiana, Indianapolis, 1883, a member of the American Medical Association; professor of diseases of the eye in Medical College of Indiana; one of the best-known specialists on the eye in Indiana, died at his home in Indianapolis, October 22, from malarial fever and abscess of the liver, after an illness of three weeks.

Montefiore Levi Maduro, M.D. College of Physicians and Surgeons in the City of New York, 1895, visiting physician at Mt. Sinai Hospital, member of the American Medical Association and of the New York State Medical Association, died at his home in New York City, October 23, from the effect of injuries received in a bicycle accident in 1898.

William Caldwell Flowers, M.D. Harvard University Medical School, Boston, 1861, for eleven years acting assistant surgeon in the Army, a member of the Massachusetts Medical Society and the Middlesex Medical Association, died at his home in Cambridge, Mass., October 20, after a lingering illness, aged 72.

Van Telburg Hofman, M.D. Medical College of Virginia, Richmond, 1897, a member of the American Medical Association, after a quarrel with his wife, committed suicide by shooting himself through the head, at his home in Sumter, S. C., October 24, aged 38.

Frederick A. Adams, M.D. Jefferson Medical College, Philadelphia, 1867, for 40 years a practitioner of Pocomoke City, Md., died at the University Hospital, Baltimore, October 28, from blood poisoning contracted during an operation, aged 65.

Jesse B. Blocher, Jr., M.D. University of Louisville, 1902, of Blocher, Ind., coroner of Scott County, died suddenly from valvular heart disease, and his body was found in Smith's Ford of Fourteen-Mile Creek, October 23, aged 24.

Campbell Sheridan, M.D. Jefferson Medical College, Philadelphia, 1849, of Johnston, Pa., the oldest member of the Cambria County Medical Society, died at his home in Sheridan Station, Pa., October 18, aged 85.

Joseph P. Cessna, M.D., 1859, surgeon of a Michigan regiment during the Civil War, who retired from practice in 1882, died at his home in Canfield, Ohio, October 9, from kidney disease, after a long illness, aged 79.

Henry Lott McIlhenny, M.D. Missouri Medical College, St. Louis, 1884, of Kingman, Kan., was instantly killed in a train wreck on the Missouri Pacific Railway while en route to St. Louis, October 10, aged 47.

William Pannill, M.D. Texas Medical College and Hospital, Galveston, 1878, formerly physician to the Texas State Orphans' Home, died at his home in Corsicana, Texas, October 21, after a long illness.

Jacob Eugene Mohr, M.D. Jefferson Medical College, Philadelphia, 1888, formerly of Quakerstown, Pa., died from hemorrhage caused by tuberculosis, at his home in Las Vegas, N. M., October 19, aged 39.

George C. Schiem, M.D. Jefferson Medical College, Philadelphia, 1887, of Saginaw, Mich., died at the Johns Hopkins Hospital, Baltimore, October 20, from anemia, after an illness of two years, aged 41.

Alice P. Howes, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1882, formerly of Detroit, died in the Eastern Michigan Asylum, October 11, after a long illness.

Frederick C. Hennessy, M.D. Bellevue Hospital Medical College, New York, 1897, died at his home in Madison, Ind., October 17, from heart disease after a long illness, aged 31.

James M. Jennings, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1884, of Tyrone, Ky., died at St. Joseph's Infirmary, Louisville, from intestinal obstruction.

Lewis Royer, M.D. Department of Medicine University of Pennsylvania, Philadelphia, 1845, died from apoplexy at his home in Trappe, Pa., October 27, aged 82.

Stephen H. Brittain, M.D. Cincinnati College of Medicine and Surgery, 1859, died at his home in Loogootee, Ind., October 21, after a long period of invalidism, aged 72.

Henry C. Dixon, M.D. Louisville Medical College, 1872, of Tunnelton, Ind., died at Fort Ritner, Ind., October 15, from paralysis, after a long illness, aged 61.

Lewis J. Corey, M.D. Medical College of Ohio, Cincinnati, 1875, died at his home in Van Buren, Ind., October 25, after a short illness from apoplexy, aged 54.

Noah L. Eastman, M.D. Albany (N. Y.) Medical College, 1886, died at his home in Albany, N. Y., October 21, after a long illness, from Bright's disease, aged 46.

W. Bruce Collins, M.D. Vanderbilt University Medical Department, Nashville, 1893, died from paresis at his home near Oakfield, Tenn., October 9, aged 40.

J. Murray Wilcox, M.D. New York, 1893, of Barstow, Cal., died from pulmonary hemorrhage at his parents' home in St. Louis, October 19, aged 32.

William J. Moore, M.D. Illinois, 1902, died in Woodlawn, Birmingham, Ala., October 14, from typhoid fever after an illness of two weeks, aged 28.

Oliver Soper, M.D. New York, 1877, died at his home in Upper Montclair, N. J., October 22, from apoplexy, after an illness of a few hours, aged 61.

James S. Cabanne, M.D. Jefferson Medical College, Philadelphia, 1866, died in the City Hospital, St. Louis, October 19, from apoplexy, aged 71.

George A. Bentley, M.D. Georgetown University Medical Department, Washington, died at his home in Washington, October 21, aged 64.

J. Randolph Latimore, M.D. University of Maryland School of Medicine, 1881, died at his home in McAdenville, N. C., October 18.

Eleanor Louise Rundio, M.D. New York, 1902, died at her home in New York City, October 24, from typhoid fever aged 26.

Mary Alice Avery, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1879, of Portland, Maine, died recently.

Lydia A. Strowbridge, M.D. New York, 1861, died from cancer, at her home in Cortland, N. Y., October 4, aged 74.

Daniel J. Stowe, M.D. Illinois, 1878, died at his home in Belvidere, Ill., and was buried October 21, aged 73.

Miscellany.

The Portland Session.—The members of the profession of Portland are evidently appreciating their responsibilities regarding the session of the American Medical Association next July, and realize fully that unless preparations are made Portland will be uncomfortably overcrowded during the week of the session. The *Medical Sentinel* for October says that while it has recognized from the first "the gigantic nature of the task which Portland has undertaken in entertaining the A. M. A. in 1905, and has constantly frankly stated and discussed all the difficulties which confront us, this has been solely for the purpose of emphasizing the fact that Portland was fully aware of the magnitude of the task, and of predicting confidently that her public spirit and enterprise would meet it and rise superior to it. One after another our prophecies have been justified, and each month sees another of the difficulties of the problem triumphantly solved. First was the securing of building or auditorium on the grounds of the ex-

position, but opening from the street outside. This has been secured and will seat at least 2,500 to 3,000 people, and negotiations are on foot for its arrangement so that it can be subdivided into meeting places for some of the sections. Other sections can be accommodated in other rooms about the grounds and in school buildings in the neighborhood, so that if desired it seems quite feasible to hold the entire session meetings on and about the grounds themselves. And now to solve another great crux in the problem comes the news that the same syndicate which constructed and managed the Inside Inn at the World's Fair at St. Louis has made application for similar concessions here to the Lewis and Clark Fair Board. And this was not the only string to Portland's bow, as it was, immediately on the announcement of this plan, given out by a body of her leading business men and capitalists, that they had looked over the situation thoroughly, and while they preferred to let the St. Louis syndicate erect the hotel if it would, yet if its terms did not meet with the approval of the fair board, they would themselves erect a similar structure with home capital. So that an Inside Inn, with at least a thousand rooms, and capacity for 1,500 guests, is absolutely assured. . . . From the comparative lateness in the summer of the date of the meeting a considerable majority of the wealthier citizens of Portland will have left for their vacations, so that a large number of elegant rooms and suites in private houses can be secured for those who desire them, and there need not be any fear on the part of those who intend to come to the American Medical Association next year but that there will be an abundance of comfortable accommodations, in the finest summer climate in the world."

State Boards of Registration.

COMING EXAMINATIONS.

Board of Registration in Medicine of Massachusetts, State House, Boston, November 8-9. Secretary, Edwin B. Harvey, M.D., Boston.
Nebraska State Board of Health, November 9-10, State House, Lincoln. Secretary, George H. Brash, M.D., Beatrice.
Connecticut State Board of Medical Examiners, November 8-9, City Hall, New Haven. Secretary, Charles A. Tuttle, M.D., New Haven.

Maine Board of Registration of Medicine, November 15, Augusta. Secretary, A. K. P. Meserve, M.D., Portland.

Progress in the Movement for Reciprocity in Licensure.—In 1902 the American Confederation of Reciprocoating Examining and Licensing Medical Boards, representing fourteen states and since increased to seventeen, formulated the following declaration of purposes and qualifications as a desirable working basis of reciprocity:

PURPOSES OF THE CONFEDERATION.

The object of this confederation shall be to establish reciprocal relations between the medical examining and licensing boards of the states, territories, districts and provinces of the United States, the purpose of which being that thoroughly worthy and well-qualified physicians and surgeons, who have been legally authorized to practice under the laws of one of said states, territories, districts or provinces, may be given legal authority and be admitted to practice in any state, territory, district or province represented in this confederation, without a repetition of the tests and qualification to which such practitioner has submitted.

QUALIFICATION 1.

A certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent. was awarded, the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought, may be accepted, in lieu of examination, as evidence of qualification, provided that in case the scope of said examination was less than that prescribed by the state in which registration is sought, the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

QUALIFICATION 2.

A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for reciprocal registration in any other state, provided, that the holder of such certificate has been engaged in the reputable practice of medicine in such state at least one year; and also provided, that the holder thereof was, at the time of such registration, the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought, and that the date of such diploma was prior to the legal requirement of the legal examination test in such state.

In proposing these qualifications the importance of practically uniform standards in the various reciprocating states was recognized, and steps were taken to secure them through the work of proper committees.

When these propositions came to be discussed in the boards represented in the confederation a natural fear soon developed that the charlatans of the country, who are probably little less dangerous to the public because able to pass an examination, and who are notoriously migrating characters, would systematically secure license in every state where it was made possible for them and, when exposed or convicted in one place, be prepared to move elsewhere and continue their nefarious practices.

As a seemingly effective safeguard against such abuse of the privilege of reciprocity by the unworthy, without hardship to those who have been in practice long enough to establish a professional character, at a meeting of the confederation held at St. Louis, Oct. 25, 1904, the committee on qualifications reported the following, and asked, on account of its great importance, that it lie over one year:

QUALIFICATION 3.

As evidence of moral and professional character after graduation and licensure, each applicant shall present, from his former home, to the state board in which registration is sought, satisfactory evidence that he has been, for at least one year, a member in good standing of the county, state and national medical organizations of the school or system of practice to which he belongs, and a certificate of recommendation issued to him by vote, at a regular meeting of the society in which his membership originated, that he is worthy of the benefits of registration anywhere, and such certificate shall be treated as a part of such application, and considered in connection with the other evidence presented.

In the discussion the report met with such favor as to indicate that it is only a question of time until the main features of the above three qualifications will form the basis for a real, practical and safe reciprocity between a majority of the states of the Union.

Schedule of Questions for Examination.—The following resolution was unanimously adopted by the Illinois State Board of Health Oct. 22, 1904:

RESOLVED, That all persons desiring to practice medicine and surgery in the State of Illinois shall, in addition to other requirements already imposed, be required to pass a written examination, consisting of one hundred questions, in the following subjects: Anatomy, including histology and embryology, 10 questions; general surgery, 10 questions; materia medica and therapeutics, 10 questions; medicine, 10 questions; obstetrics, 10 questions; pathology and bacteriology, 10 questions; chemistry, 5 questions; cytology and hygiene, 5 questions; physiology, 7 questions; neurology, 3 questions; gynecology, 6 questions; laryngology and rhinology, 2 questions; medical jurisprudence, 2 questions; physical diagnosis, 5 questions; ophthalmology and otology, 3 questions; pediatrics, 2 questions; and be it further

RESOLVED, That an average of at least 75 per cent. of correct answers shall be required from each candidate.

A similar schedule of questions for examination was unanimously adopted by the American Confederation of Reciprocoating Examining and Licensing Medical Boards at its meeting in St. Louis October 25 on the recommendation of the committee appointed at a previous meeting to decide on uniformity as to scope and character of examinations by state medical boards.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers and of establishment and discontinuance of military posts, U. S. Army, for the week ending Oct. 29, 1904:

Teff, W. H., asst.-surgeon, ordered to proceed from Fort Snelling, Minn., to Fort Lincoln, N. D., to accompany the Third Battalion Twenty-first Infantry, to Presidio of San Francisco.

Usher, P. H. C., asst.-surgeon, leave of absence extended fourteen days.

Widmanson, L. P., asst.-surgeon, granted leave of absence for fifteen days.

Metcalfe, N. F., asst. surgeon, reports his departure from U. S. General Hospital, Presidio of San Francisco, on leave of absence for one month.

Lyster, W. J. L., asst.-surgeon, leave of absence extended fifteen days.

Wadhams, G. H., asst.-surgeon, left transport *Logan* on one month's leave of absence.

Dewey, Frederick S., contract surgeon, granted leave of absence for fifteen days from Oklahoma City, Okla.

McCown, Thomas B., contract surgeon, granted sick leave for three months from the Philippine Division with permission to visit China and Japan.

Warwick, Clarence A., contract surgeon, granted leave of absence for two months from the Philippine Division, with permission to visit Cochinchina and Siam.

McMillan, Clemens W., contract surgeon, granted leave of ab-

senes for twenty days, to take effect after his arrival at Fort Myer, Va., to which he has been ordered from Fort Hamilton, N. Y. Hayes, Melville A., contractor surgeon, arrived at San Francisco, October 17, from the Philippines, for treatment at the General Hospital, San Francisco.

Navy Changes.

Changes in the Medical Corps, United States Navy, for the week ending Oct. 29, 1904:

Curtis, L. W., surgeon, ordered to the *Pensacola* and to additional duty at the Naval Training Station, San Francisco.
Asserson, F. A., P. A. surgeon, ordered to the Navy Yard, New York.

Officers issued by the Commander-in-Chief of Asiatic Fleet): Tolfee, H. M., asst.-surgeon, detached from the *Wilmingon* and ordered home. Pachmann, R. A., asst.-surgeon, detached from the Naval Station, Cavite, P. I., and ordered to the *Wilmingon*.
Vickery, E. A., asst.-surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington, D. C.

Scott, S. L., asst.-surgeon, detached from the *Massachusetts* November 28 and ordered home; resignation accepted, to take effect December 1.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ending Oct. 26, 1904:

Brooks, S. D., surgeon, relieved from duty at Savannah, Ga. McIntosh, W. P., surgeon, granted leave of absence for twenty-five days from November 8.

Smith, A. C., P. A. surgeon, to proceed to New York City and report to chairman of board of examiners for examination to determine his fitness for promotion to the grade of surgeon.
Schereschewsky, J. W., asst.-surgeon, to proceed to New York City and report to chairman of board of examiners for examination to determine his fitness for promotion to the grade of P. A. surgeon.

Wille, C. W., asst.-surgeon, to proceed to New York City and report to chairman of board of examiners for examination to determine his fitness for promotion to the grade of P. A. surgeon.
Wilson, R. L., asst.-surgeon, to proceed to New York City and report to chairman of board of examiners for examination to determine his fitness for promotion to the grade of P. A. surgeon.

Trask, J. W., asst.-surgeon, granted leave of absence for one month from October 22.
Hanzrich, F. K., pharmacist, granted leave of absence for thirty days from September 26.

Gibson, F. L., pharmacist, granted leave of absence for thirty days from Dec. 2, 1904, and thirty days from Jan. 1, 1905.

RESIGNATION.

Mcckall, B. McV., A. A. surgeon, resigned, to take effect Oct. 10, 1904.

CASUALTY.

Purviance, George, asst.-surgeon general, died, result of accident at Philadelphia, Oct. 20, 1904.

Health Report.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ending Oct. 29, 1904:

SMALLPOX—UNITED STATES.

Illinois: Chicago, Oct. 15-22, 30 cases, 2 deaths.
Michigan: At 42 places, Oct. 8-15, present.
Missouri: St. Louis, Oct. 15-22, 30 cases, 6 deaths.
Ohio: Cincinnati, Oct. 7-21, 3 cases.
Pennsylvania: Oct. 15-22, Philadelphia, 1 death; Steelton, 1 case.
South Carolina: Greenville, Sept. 25-Oct. 1, 3 cases.
Wisconsin: Milwaukee, Oct. 8-22, 12 cases.

SMALLPOX—FOREIGN.

Brazil: Pernambuco, Sept. 1-15, 25 deaths; Rio de Janeiro, Sept. 18-Oct. 2, 655 cases, 247 deaths.
China: Shanghai, Sept. 3-10, 1 death.
France: Paris, Oct. 1-8, 8 cases.
Great Britain: Oct. 1-8, Edinburgh, 1 case; London, 1 case; Newcastle-on-Tyne, 8 cases; Nottingham, 1 case; South Shields, Sept. 18-24, 1 case.
India: Bombay, Sept. 20-27, 2 deaths.
Italy: Catania, Sept. 28-Oct. 6, 1 death; Palermo, Sept. 25-Oct. 8, 14 cases, 5 deaths.
Malta: Sept. 25-Oct. 1, 1 case.
Russia: Moscow, Sept. 25-Oct. 1, 7 cases, 2 deaths.
Spain: Barcelona, Oct. 1-10, 7 deaths.

YELLOW FEVER.

Costa Rica: Limon, Oct. 8-15, 1 case imported from Sequires.
China: Santiago, Oct. 24, 1 case imported from Puntasal.
Mexico: Oct. 1-2, Oaxaca, 3 cases, 2 deaths; Merida, 1 case, 1 death; Tehuantepec, Oct. 2-15, 4 cases, 2 deaths.

CHOLERA.

India: Bombay, Sept. 20-27, 9 deaths; Calcutta, Sept. 17-24, 2 deaths.
Turkey: Bagdad and vicinity, Aug. 20-Sept. 3, 585 cases, 405 deaths.

PLAGUE—INDIAN.

Philippine Islands: Manila, Sept. 3-10, 1 case, 1 death.

PLAGUE—FOREIGN.

Africa: Cape Colony, Sept. 10-17, 3 cases; Johannesburg, March 26-July 9, 156 cases, 95 deaths.
Brazil: Rio de Janeiro, Sept. 18-Oct. 2, 56 cases, 24 deaths.
China: Hongkong, Aug. 27-Sept. 10, 6 cases, 6 deaths.
India: Bombay, Sept. 20-27, 11 cases, 85 deaths; Calcutta, Sept. 17-24, 3 deaths; Karachi, Sept. 18-25, 11 cases, 7 deaths.
Japan: Formosa, Aug. 1-31, 34 cases, 28 deaths.
Strait Settlements: Singapore, Oct. 2, present.

Medical Organization.

Good Work in Oklahoma.—From the announcement of the next meeting of the Oklahoma State Medical Association, which takes place in Oklahoma City next Tuesday and Wednesday, we clip the following: "At the last meeting of the association it was unanimously decided to reorganize the association so as to have it conform to the plans of the American Medical Association. Accordingly the 'constitution and By-Laws prepared for State Associations' were adopted, and the territory divided into five council districts. The fact that every county in the territory, with the exception of Beaver, where it seemed impractical to organize a county society, has been organized, shows that the councilors have done their work well. The house of delegates and councilors will meet on the evening of November 8 to grant charters to county societies and to transact such other business as may come before them."

Society Proceedings.

MISSISSIPPI VALLEY MEDICAL ASSOCIATION.

Thirtieth Annual Meeting, held in Cincinnati, Oct. 11-13, 1904.

(Continued from page 1327.)

Intestinal Surgery, with Remarks on Technic.

DR. JOHN YOUNG BROWN, St. Louis, said that there is a class of abdominal cases which may justly be considered acute, because the indications for immediate surgery are mandatory, and in which the mortality largely depends on the time of operation and the technic of the work. He discussed, first, penetrating gunshot and stab wounds of the abdomen; second, severe abdominal contusions associated with rupture of the intestines or other visceral injuries; third, strangulated hernia.

Gastroenterostomy.

DR. WILLIAM H. WATSON, Louisville, described the pathologic conditions indicating the necessity for stomach drainage. He said that pyloric divulsion has proven unsatisfactory, seldom gives permanent results, and sometimes commits a traumatism that increases the trouble. Pyloroplasty and its modifications have given better results, but the operation is seldom indicated and is practically obsolete. Gastroduodenostomy is theoretically ideal, and in properly selected cases gives excellent results, but it is often impractical because of adhesions or tumors, while gastroenterostomy may be performed as easily, as quickly, and with a mortality as low, and is applicable in nearly all cases. Roux' method of cutting the intestine across, implanting the distal end into the stomach, and the proximal end into the side of the distal end is theoretically ideal, and avoids regurgitant vomiting, but it is difficult and prolonged, and if universally accepted would have a mortality that would be prohibitory. Gastroenterostomy by the surface-to-surface anastomosis of the stomach and jejunum is applicable to the greatest number of cases, and may be performed in nearly any condition requiring stomach drainage. Anterior gastroenterostomy as an operation of election must soon become obsolete, and will finally be accepted only where an operation is necessary to give temporary relief, or where the posterior operation is contraindicated. The ideal operation of election must eliminate the intestinal loop, and this may be done by the posterior method, by attaching the jejunum very near its origin under the transverse mesocolon; the bowel incision may then be made longitudinally or transversely, but is usually made in a longitudinal direction. This method is preferable if the opening into the bowel can be made large enough to permit of continued unimpeded drainage. Posterior gastroenterostomy is now an accepted method with no higher mortality than the anterior method, with nearly an absence of regurgitant vomiting and other immediate complications, and with ultimate excellent results in drainage, the gastrojejunic opening seldom contracting enough to induce pathologic condition. The McGraw ligature in the anterior method gives good immediate results, but we can not judge correctly of the ultimate results in the patency of the gastrojejunic

opening, and the ligature has probably not been tested in the posterior method.

The Indications and Limitations of Various Operations on the Gall Bladder.

DR. CHARLES A. L. REED, Cincinnati, reviewed the various operations for the relief of surgical conditions of the gall tract, summarizing them under the heads of cholecystotomy, cholecystectomy, cholecystenterostomy and choledochotomy. He said that cholecystotomy ought not to be done in cases in which prolonged drainage is required, or in which there is a demonstrable permanent obstruction in the common duct, or in which such obstruction might develop. He insisted that the gall bladder be not removed without adequate cause, such as conditions of atrophy and malignant degeneration of the gall bladder and cases in which benign neoplasms cause practical obstruction of that viscus. He said that cholecystenterostomy should be the operation of choice in all cases in which the gall bladder and a desirable segment of the intestinal tract, preferably the duodenum, the ileum or the jejunum, in the order mentioned, should be approximated, and in which drainage is demanded for accumulations within the gall bladder of whatever character; for occlusion of the common duct or following operations on it; for cholecystitis in which the gall bladder can be safely left *in situ*, and in all chronic fistule of the gall bladder.

Ectopic Pregnancy.

DR. F. F. LAWRENCE, Columbus, Ohio, said that in ectopic pregnancy the death rate should be lower than in appendicitis, providing the surgeon got the cases before rupture. The diagnosis of tubal pregnancy before rupture should be made with as much or greater certainty than could a normal pregnancy before the third month. The fact that a tubal pregnancy is allowed to go on to rupture is a reproach to obstetric practice. In unruptured cases the tube can be more safely removed through abdominal incision. In ruptured cases it is often unwise to attempt to remove a patient to a hospital. The chances of infection in her home can be more readily overcome than the danger of increasing hemorrhage by handling. In all cases of extrauterine pregnancy, tubal disease, which is bilateral, seems well established. The danger of a catastrophe in case the unaffected tube is left is, therefore, great, unless that tube be safely obliterated. Absorbable ligature is not a safe material to use for obliteration. Silk of large size only should be used. The better practice is to remove both tubes, retaining the ovary, if possible.

The Transverse Fascial Incision for Operations in the Pelvis.

DR. EMLI RIES, Chicago, said that in order to gain reliable fascial protection for incisions for pelvic work it is desirable not to incise the fascia in the median line.

Suppuration of Nasal Accessory Sinuses.

DR. J. A. STUCKY, Lexington, Ky., pointed out the importance of early recognition of suppuration of nasal accessory sinuses. Frequent peculiar anatomic inter-relationship of the different sinuses renders the symptoms obscure and misleading. Suppurative products may exist in latent form and eventually result in systemic infection. The sequelae of chronic suppuration of any accessory sinuses are frequently due to some form of neurasthenia, migraine, la grippe, pneumonia, and strenuous indoor life. The treatment is the same as for pus formation in any other part of the body. The middle turbinate most frequently causes obstruction of natural openings or a hindrance to free drainage, and he advocated its early removal.

Strictures of the Urethra.

DR. A. RAVOGLI, Cincinnati, said that the symptoms of urethral strictures are mostly local, but at times may be general and neurasthenic. Strictures are somewhat diminishing in their frequency, and this must be credited to the recent method of treatment of gonorrhoea. A great deal of benefit may be expected from systematic dilatation and from remedial applications, but in very serious cases external urethrotomy is imperative.

The Perilous Calms of Appendicitis.

DR. ROBERT WALLACE HARDON, Chicago, presented these conclusions: "1. Defervescence of symptoms and apparent better condition of the patient do not always mean recovery, but may precede a dangerous condition. 2. As there is no specific for the disease, no matter what treatment is used, the one who procrastinates should shoulder the responsibility for the death. 3. When a clear diagnosis is made only one treatment should be advised, operation as soon as possible, or the opportunity may be gone. 4. The physician who does not explain the great dangers of delay and the small comparative danger of operation, is doing his patient a serious injustice which often leads to fatal results. 5. Operation at the proper time usually greatly shortens convalescence, and eliminates all danger from this cause thereafter. 6. Procrastination is the greatest cause of surgical death, operation often being performed as a last resort when little hope of recovery exists."

(To be continued.)

NEW YORK STATE MEDICAL ASSOCIATION.

Twenty-first Annual Meeting, held in New York City, Oct. 17 to 20, 1904.

(Concluded from page 1329.)

Conservatism Versus Early Intervention in Simple Dystocia.

DR. WILLIAM J. MEYER, White Plains, believed that there is too much conservatism in uterine inertia, or cervical rigidity, and that the condition may exist for days because a physician does not use forceps. During the past five years he has used forceps in 186 cases of simple dystocia, and has had neither laceration of the perineum nor postpartum hemorrhage. He is convinced of the wisdom of manual dilatation in rigidity of the os, and never permitted patients to remain in labor longer than seven hours without interference.

DISCUSSION.

DR. EVERARD D. FERGUSON, Troy, strongly objected to mechanical metal dilators. With proper cleanliness the risks of manual interference are reduced to a minimum. He never uses any instrument but his hand in placenta previa or other conditions requiring interference.

DR. BERNARD COHEN, Buffalo, approves of manual dilatation of the rigid cervix; one of the advantages being that it gives information as to why the condition exists. He recommends morphin and quinin as an oxytotic. He emphasized the importance of proper judgment as to the right time to apply forceps. He has found that in 2,500 cases he has torn one out of every seven perineums, and one out of every five cervixes.

DR. JOSEPH B. COOKE, New York, invariably uses his fingers to dilate the cervix until it is completely dilated or paralyzed. His patients are always thoroughly anesthetized before the application of forceps, which should not be removed, but allowed to fall off after the expulsion of the head.

DR. BENJAMIN W. STEARNS, Binghamton, recommended the administration of six grains of chloral hydrate, one-half a dram of viburnum compound, and two grains of quinin every twenty minutes to relax a rigid cervix. Chloral does not interfere with the use of chloroform later.

Asthma and Its Relation to Environment.

DR. GEORGE N. JACK, Buffalo, said that the asthmatic is a human thermometer and barometer; some environments will explode this pathologically charged machine into an asthmatic manifestation, while others will retard the explosion or quell it. To one or the other of these classes belong every factor, climatic, thermic, actinic, motion and quiet, dust and fumes, and the asthmatic hourly responds to each.

An Old Specialty.

DR. JANE LINCOLN GHEELEY, Jamestown, said that others may render more conspicuous service, but the family physician stands nearest the daily life of the people. His work begins

with the beginning of the family. He looks to the sanitary condition of the house and the vicinity. He should be a public-spirited man, for the interests of the family are the interests of the community. He should have a good general education and should be interested in educational problems, in labor and in diversions. His work calls for a study of human nature, but the absolute requirement is character.

An Atypical Case of Appendicitis Presenting Some Unusual Features Found at Operation.

DR. W. B. REID, Rome, reported this case. The patient was 49 years of age, and was first seen after being thrown from a sleigh. Pulse, 110; temperature, 101; respiration, 24. There was tenderness over McBurney's point and general tympanitis. The bowels had not moved for three days, and the urine showed pus cells and granular and hyaline casts. The diagnosis was traumatic appendicitis. Operation three weeks later revealed a case of appendicitis of long standing, the traumatism being a coincidence; the acute attack was followed by the invasion of the colon bacillus and abscess formation. The acute nephritis was caused by an infectious toxemia, as postoperative examination of the urine showed that the associated diabetic condition furnished a sufficient amount of sugar in the abscess cavity for the production of gas formation. The question suggested was whether this was a double infection by the *Bacillus coli communis* and the *Bacillus lactis aerogenes* or the infection by the coli communis alone which had produced what is ordinarily called "involution forms" resulting in gas formation.

Nephropoiesis; Its Gynecologic Importance.

DR. AUGUSTINE H. GOELET, New York, said that the prolapse of the kidney is very often overlooked as a factor in producing and maintaining congestion of the pelvic organs. The kidney, when prolapsed, overlaps and compresses the ovarian vein, thus obstructing the return circulation from the pelvis when the waist is constricted even sufficiently to support the clothing. The intestinal distention is an important factor in forcing the kidney back against the spine. The colon, being attached to the kidney, when distended drags on it and holds it in position at the waist line, thus, as there is no room for the bowel above the waist line, it becomes displaced below. Compression and obstruction of the ovarian vein may also be caused by the vein being in front and the ureter behind the kidney where they cross, when the kidney descends the ureter becomes bent on and drags on the vein. Distention of the ureter will also cause pressure on this vein. Prolapse of the kidney may cause or maintain such conditions as leucorrhœa, endometritis, uterine displacements, ovaritis, salpingitis, hemorrhages into the pelvis, and even cystitis. Examination of patients who have consulted him for this condition showed that 75 per cent. suffered from existing inflammation of the pelvis or urinary tubules. In 197 consecutive nephropoieses, in 47 of which both kidneys were fixed, he has had no mortality, consequently the operation can not be considered a serious one.

Transillumination of the Stomach as an Aid to Diagnosis.

DR. ROBERT COLEMAN KEMP, New York, said that transillumination is an aid in investigating mucus colic and has enabled him to demonstrate gastropoiesis as a factor in this condition, which is due to abnormal positions, and not to inflammations. Transillumination is an aid in differentiating dilatation of the stomach and gastropoiesis, and also in indicating the degree of dilatation and the prognosis. It is of value in exploration of the anterior wall and the greater curvature of the stomach, of tumors and of thickenings and in explorations at or beneath the costal arch. It can be used in differentiating carcinoma or other tumors in various parts of the gastrointestinal tract. Gall-bladder diseases can be differentiated from diseases of the stomach, and it is also of value in determining the position of adhesions.

A Substitute for Rubber Gloves in Surgery.

DR. FREDERICK H. WIGGIN, New York, said that the following substitute for rubber gloves has given him the greatest

satisfaction: 49½ ounces alcohol (96 per cent.), 49½ ounces of ether, ½ ounce of colloidin and 1 ounce of castor oil. The operator dips his hands in this solution after having sterilized them. This gives a coating which does not crack and is not soluble in water or ordinary alcohol, and which equal parts of alcohol and ether will remove.

Salivary Calculi.

DR. HERMAN JARECKY, New York, reported three cases, in two of which the calculi were situated in the submaxillary ducts, while in the other case one calculus was in Wharton's duct and one in Blandin's gland. The point of interest is that two calculi could occur in two different glands. He has been able to find but two such cases in literature.

DISCUSSION.

DR. WOLFF FREUDENTHAL, New York, does not think that these calculi are rare, and said that it is remarkable how many people can stand the presence of large calculi without noticing them.

DR. G. LENOX CURTIS, New York, said that he has operated on at least twenty similar cases and does not consider the condition rare.

Radical Operation for Carcinoma of the Breast.

DR. WILLY MEYER, New York, said that in his ten years' experience with his operation he has only once had to give intravenous injections during the operation. Eighty patients have been operated on and only two of these have died from conditions connected with the operation. One of these was diabetic and the other had a recurrence of the carcinoma. The total removal of the pectoralis major does not interfere with the free movement of the arm. His statistics are as yet incomplete, owing to the difficulty of keeping track of patients in a large city.

Prolonged Fasting in Treatment of Acute Alimentary Diseases.

DR. NORTON JEROME SANDS, Port Chester, said that in acute diseases in general especially of the alimentary canal, food should be withheld, as the assimilative powers are impaired. Food should not be administered until the temperature is normal, the bowels regular and the tongue clean. It is possible to fast three or four weeks without pronounced weakness.

DISCUSSION.

DR. FREDERICK H. WIGGIN, New York, said that he relies on castor oil and glycerin by the mouth in surgical sepsis, and saline solutions by the bowels, two or three quarts daily until the temperature recedes.

The Suppression of the Acetone Bodies in Diabetics.

DR. HEINRICH STERN, New York, said that in diabetes the acetone substances always indicate a state of undernutrition. He does not consider that oatmeal is any better tolerated by diabetics exhibiting acetonaemia than other amyloid substances. If we wish to successfully combat acidosis without aggravating the diabetic condition, we can neither add carbohydrates to the diet for any length of time, nor can we augment the amount of protein ingesta. The only fatty article of food which he has found useful in the diabetic during acidosis is yolk of egg. Raw or semi-raw eggs may be consumed in almost any quantity. The yolk cure is based on four factors: 1. Palmatin, stearin and olein, the fatty substances of the yolk, yield little or no butyric acid. 2. The large amount of lecithin restores the nerve force and ameliorates the wasting condition. 3. The diastatic ferment in the yolk aids in starch conversion. 4. The yolks exert a stimulating action on the gastric secretion. This treatment consists in the consumption of from ten to forty yolks daily, with a small amount of proteids and some carbohydrates.

Twenty-five Cases of Pernicious Anemia.

DR. A. E. WOERNERT, Buffalo, reported cases in which blood drawn from the finger was less viscid and dark than normal, and when much impoverished looked more like water. A marked feature was that the red cells were increased in di-

ameter. The erythrocytes varied from 628,000 to 2,440,000 to the c.m. The leucocytes varied from 2,400 to 12,344. A differential count of the white cells showed, on the average, polynuclears 61 per cent., lymphocytes 33 per cent., large mononuclears 4 per cent., and eosinophiles 2 per cent. Specific gravity in 11 cases was from 1.037 to 1.051. Hemoglobin ranged from 23 per cent. to 65 per cent. The hemoglobin index was high, being about 122 per cent. Macrocytosis was the rule. Many of the cells had lost their concavity, and in some the nucleus took a light stain and was separated from the rest of the cell by a zone.

DISCUSSION.

DR. J. J. WALSH, New York, said that pernicious anemia is much more frequent than was formerly supposed. Anti-streptococcal serum in pernicious anemia has been disappointing.

DR. W. B. STEARNS, Binghamton, thought that as in malignant growths the malignant cells take the place of normal cells, so in pernicious anemia the abnormal cells may take the place of the normal.

Some Occupations and So-Called Rheumatic Pains.

DR. JAMES J. WALSH, New York, stated that patients frequently complain of pains which they believe to be rheumatic. In recent years there has been a decided reaction in regard to the so-called uric acid diathesis, and at present very few scientific men consider uric acid of etiologic importance, except, perhaps, in gout. Such pains seem caused by overworking certain muscles in various occupations, as in a motor-man, who was troubled with pains in the shoulders. In such cases a neuritis had probably been set up for which no satisfactory reason can be given.

DISCUSSION.

DR. WILLIAM W. BEMIS, Jamestown, has found that proper support to the instep has relieved many cases of cramps in the feet and legs. He had seen cases of general neurasthenia due to pains in the back, which were probably due to some pressure on the nerve low down. This condition can be relieved by supporting the upper part of the body.

The Alexander Operation; Its Results Immediate and Remote.

DR. JAMES E. KING, Buffalo, said that successful results are only possible when the indications have been carefully considered. The only indication is simple uncomplicated retroversion. Where relapses occurred they are due to suppurative or small ligaments. Great care should be taken in handling the ilio-inguinal nerve. In two cases that he reported the symptoms were due to a relaxing of the uterosacral ligament and prompt relief was afforded by operation. The operation has no influence on pregnancy or labor.

DISCUSSION.

DR. HENRY O. MARCY, Boston, has now ceased to do the operation. It has a limited field, but far less than formerly was thought.

DR. J. RIDDLE GOFFE, New York, has discontinued doing the operation, and has found that 80 per cent. of cases of retroversion are complicated by disease of the uterus or appendages and this limits the field to 20 per cent. The round ligaments are not designed to support the uterus, but, during gestation, to keep the fundus against the anterior abdominal wall. The uterosacral ligaments are the proper supports of the uterus and in proclitidia shortening these ligaments has given satisfactory results.

Scarlet Fever with Reference to the Heart and Other Complications.

DR. LOUIS FISCHER, New York, said that in this disease more attention should be paid to the heart and less to the temperature. A moderate rise in temperature often occurs in the most malignant forms of the disease, and, on the other hand, the mildest forms of scarlet fever begin sometimes with a very high temperature; therefore, one can not say that a very high fever is any guide to the severity of the case. Fever does not invariably indicate disease, and the temperature curve is

given far more credit during convalescence than it deserves. A drop of several degrees does not indicate improvement in all cases. The greatest attention should be bestowed on the condition of the heart. The pulse, its character, frequency and tension are the most important guides in determining a favorable or unfavorable termination. High mortality is largely due to the fact that the children are not kept in bed long enough; every case of scarlet fever should be kept in bed at least four weeks. The diet should be liquid, and the emunctories should be stimulated. A hot saline, colon flushing, one or two quarts, at a temperature of from 115 to 120 degrees F. should be given once a day after the first week, regardless of the necessity of the same; it stimulates diuresis, cleanses the bowel and nourishes the blood.

Other papers read and discussed were as follows: "Iodine in the Treatment of Postoperative Sepsis," by Dr. James H. Burtenshaw, New York; "The Result of 1,400 Operations for the Radical Cure of Hernia in Children," by Drs. William T. Bull and William B. Coley, New York; "The Brief Story of a Smallpox Epidemic," by Dr. Edward Munson, Medina; "Ocular Reflexes and Their Influences on General Health," by Dr. S. W. S. Toms, Nyack; "Infant Mortality in New York City," by Dr. Louis Curtis Ager, Brooklyn; and "Prostectomy in Emergency Cases," by Dr. John F. Erdmann, New York.

VERMONT STATE MEDICAL SOCIETY.

Ninety-first Annual Meeting, held at Rutland, Oct. 13 and 14, 1904.

The president, Dr. William N. Bryant, Ludlow, in the chair. DR. PATRICK M. MCSWEENEY, Burlington, the vice-president, made an earnest appeal for early operation in all cases of ectopic gestation.

DR. DONLY C. HAWLEY, Burlington, demanded pure milk and fresh air for children as being more important factors than medicine.

Surgery of the Stomach.

DR. JOHN C. MUNRO, Boston, a guest of the society, detailed in his address the great advancement that had been made in the last two years in surgery of the stomach, and the rapid decrease in mortality following operations on that viscus.

Prevention of Ear Infection.

DR. FRANCIS P. EMERSON, Boston, also a guest of the society, in a paper entitled "What Can Preventive Medicine Do to Safeguard the Middle Ear Against Acute and Chronic Infection," clearly demonstrated that in order to prevent infection of the ear it was necessary properly to treat all discharges and malformations of the nasal passages and pharynx.

President's Address.

DR. WILLIAM N. BRYANT, Ludlow, selected for his theme, "Epidemic Influenza in the Etiology of Certain Diseases," and by means of charts and statistics showed most clearly that influenza has a marked effect in the production of other disorders.

Mercury in Typhoid.

DR. J. MORRIS HACKETT, Champlain, N. Y., read a paper on "The Specific Treatment of Typhoid," which evoked considerable discussion, as the author alleged that, after fifteen years' experience, he had clearly demonstrated that mercury in the form of blue mass and calomel is a specific in typhoid fever.

Election of Officers.

The report of the house of delegates, read by the clerk, Dr. Lyman Allen, Burlington, named the following officers, committees and delegates, all of whom were declared elected: President, Dr. Patrick E. McSweeney, Burlington; vice-president, Dr. Myron L. Chandler, Barre; secretary, Dr. George H. Gorham, Bellows Falls; treasurer, Dr. Bingham H. Stone, Burlington; auditor, Dr. John H. Blodgett, Saxtons River. Executive committee, the president, secretary and Dr. Donly C. Hawley, Burlington. Publication committee, Drs. George H. Gorham, Bellows Falls; George R. Anderson, Brattleboro; Edward R. Campbell, Bellows Falls. Necrology committee, Drs. Merritt H. Eddy, Middlebury; Columbus S. Scofield, Richford, and C. W. Howard, Shoreham. Legislation com-

mittee, Drs. Sumner E. Darling, Hardwick; Henry D. Holton, Brattleboro, and Edward R. Campbell, Bellows Falls. License censors, Drs. Henry James, Waterbury; Schuyler W. Hammond, Rutland, and J. Sutcliffe Hill, Bellows Falls. Anniversary chairman, Dr. Charles W. Peck, Brandon. Delegates—To American Medical Association, Dr. Henry D. Holton, Brattleboro; to Massachusetts Medical Society, Drs. John H. Blodgett, Saxtons River, and Frederick R. Stoddard, Shelbourne; to Dartmouth Medical Society, Drs. Lester W. Burbank, Cabot, and Orville C. Baker, Brandon; to University of Vermont, Drs. Michael F. McGuire, Montpelier, and Clayton W. Bartlett, North Bennington; to Maine Medical Society, Drs. Edwin M. Nichols, Barton, and Frederick S. Gray, Troy; to Rhode Island Medical Society, Drs. Ansel I. Miller, Brattleboro, and William W. Townsend, Rutland; to New Hampshire Medical Society, Drs. Anson C. Bailey, Randolph, and Frederick C. Liddle, Dorset; to Connecticut Medical Society, Drs. Fred T. Kidder, Woodstock, and John W. Estabrooke, Brandon; to New York Medical Society, Drs. Edward D. Ellis, Pouttney, and C. Lyman Hodgkins, Castleton, and to White River Junction Medical Association, Drs. Frederick L. Osgood, Saxtons River, and A. Lawrence Miner, Bellows Falls.

The society adjourned to meet in Burlington in 1905.

Travel Notes.

XV.

MEDICAL EDUCATION IN AUSTRALIA.

NICHOLAS SENN, M.D.
CHICAGO.

COLOMBO, CEYLON, Aug. 25, 1904.

The number and character of the educational institutions of a country furnish the most reliable gauge with which to estimate the degree of intelligence of its people and the virtues of its government. Measured by this scale young Australia compares well with America and the countries of the old world. New countries, like new cities, have the great advantage of profiting by the experience of the past, placing them in a position to select what has been found most useful and practical and to eliminate what has been proved objectionable by the test of experience. The educational institutions of the old world and some of our own have been undergoing constant changes in the construction of buildings and methods of teaching, in order to keep pace with the rapid strides of progress and spirit of investigation and original research which characterize the present age. Scrutinized in the light of the beginning of the twentieth century, many of the famous, venerable, moss-covered universities of the old as well as of the new world appear like a patched garment when contrasted with the new, vigorous institutions of learning founded, organized and managed in accordance with the most recent requirements. Viewed from an educational standpoint, Australia has reason to take pride in what she has accomplished. The government of this country has been liberal in responding to the educational needs of its slowly growing and now almost stationary population. Its public schools are within easy reach of every child, not only in its cities and villages, but wherever a small settlement is found in the mountain forests and arid plains. It has its grammar and high schools, colleges and universities, which meet all the necessities of a higher and professional education. It is a great mistake for any young Australian man or woman to leave their native soil in search of better opportunities to qualify themselves for any position in life, as the choicest and best lies at their very door. An Oxford or Cambridge degree will be of no more use to a professional man or woman in Australia or anywhere else than a degree from any of the three universities of the island continent, as the requirements for graduation of the latter are equally, if not more, stringent than of the former. This southwestern part of the world is fully aware of what is going on in the way of scientific progress and

has already to some extent contributed its share to the common fund of knowledge, and is now in a position to become a more liberal contributor. We as physicians are more especially interested in the advantages offered by the Australian universities for its medical students. It is in this branch of university education that the greatest changes in the methods of teaching have been witnessed during the last quarter of a century. In writing this communication I have made liberal use of two addresses delivered by Prof. T. P. A. Stuart, the distinguished physiologist of the Sydney University ("A Review of University Life in Australia, Etc.," and "The Majority of the Medical School," the latter on the occasion of the University of Sydney celebrations), and the last calendars of the three universities. The three Australian universities are located at Sydney, Melbourne and Adelaide, and were founded in the order in which these names appear. Each university has its own medical department. Fortunately for the new country and its medical profession, private medical schools are out of the question. The requirements for entrance and graduation are about the same in all of the three schools and I quote here from the last catalogue of the University of Adelaide:

"No person shall be permitted to commence the medical course until he shall have completed his sixteenth year and have produced evidence of the fact to the satisfaction of the council. Before entering on the medical course the intending student must satisfy the examiners at the senior public examinations in the following subjects: 1, English literature and English history and geography; 2, Latin; 3, arithmetic and algebra; 4, geometry; 5, one of the following—a, Greek; b, French; c, German."

The medical course is five years. The examinations are held annually in November and supplementary examinations may be held, should occasion arise, in March. The students are not pestered with so many examinations as in some of our medical colleges and their time is spent in steady, uninterrupted work instead of one-fourth of it being spent in cramming for the frequent examinations, as is the case with some of our schools.

The first examination includes: 1, Elementary anatomy and dissection; 2, elementary biology, theoretical and practical; 3, inorganic chemistry, theoretical and practical; 4, elements of physics.

The second includes: 1, Anatomy, general and descriptive, with dissections; 2, physiology, including practical physiology, histology and physiologic chemistry; 3, organic chemistry, theoretical and practical, with special reference to physiology and medicine; the chemistry of poisons, organic and inorganic, with special reference to their detection.

The third includes: 1, Principles and practice of medicine; 2, principles and practice of surgery; 3, regional and surgical anatomy; 4, materia medica.

The fourth includes: 1, Principles and practice of medicine, including clinical medicine; 2, principles and practice of surgery, including surgical anatomy and clinical surgery; 3, obstetrics; 4, forensic medicine, including insanity; 5, pathology.

The fifth and last includes: 1, Medicine, all branches; 2, surgery, all branches, including anatomy and operative surgery; 3, gynecology; 4, ophthalmology; 5, otology; 6, elements of hygiene; 7, therapeutics.

It seems to me that the order of subjects in these examinations is excellent, leading the students from the elementary branches up a gradual incline to the most complicated practical subjects. Anatomy is taught in England better and more thoroughly than in any other country. The English surgeon is invariably a good anatomist. The Australian schools, conducted as they are largely by men who obtained their education in the United Kingdom, place the same stress on this the most important of all the primary branches, and when their students graduate they know their anatomy. No time is spent in making skeletons of clay. Gray's Anatomy and Heath's Dissector are their text-books and the cadaver their object lesson. Professor Watson of the Adelaide University has little confidence in lectures as a means of teaching anatomy and spends most of his time in the dissecting room with his students, supervising, demonstrating and directing their work.

Some of the dissections I examined were sufficient proof of the students' interest and diligence in acquiring their knowledge of anatomy and the efficiency of the methods of teaching employed.

The only fault I could find with the methods of teaching employed in the Australian medical schools is that too much weight is still given to didactic lectures and too little attention is paid to recitation courses. There are, however, indications that gradual changes will soon reverse this order of things. The attendance at the medical schools is necessarily small; the teaching force, on the other hand, in each school is large, conditions most favorable for systematic, theoretic teaching by the use of reliable text-books, recitations, remarks and demonstrations. Each of the three medical schools has the practical control over a hospital of 200 and more beds, where the main clinical teaching is done. In Sydney it is the Royal Prince Albert Hospital; in Melbourne, the Melbourne Hospital, and in Adelaide, the Adelaide hospitals. In all of these cities the students have also access to a children's and other hospitals, the former always directly or indirectly connected with the

and the obtaining of it involves another and not inconsiderable expense, most of the practitioners enter on their life work without applying for it. Many physicians and surgeons prefer the plain title of Mr. to Doctor. All the professors receive a salary of from \$800 to \$4,500 a year; in one or two of the universities they receive a pension of \$2,000 a year on retirement after twenty years' service.

SYDNEY UNIVERSITY AND MEDICAL SCHOOL.

The Sydney University commenced its first matriculation on Oct. 4, 1857. Its courses of lectures were at first restricted to those required for the Arts degree; the medical school and the school of engineering were opened in 1883, and the law school was opened in 1890. The teaching staff of the university has gradually increased from three professors and two lecturers in 1854 to 14 professors and 34 lecturers in 1899, having under their care 519 students. The university owes a great deal to private benefactions. The total sum from this source at the close of 1899 was over \$2,000,000.

The university building is a magnificent solid stone structure in Gothic style, occupying the summit of a high hill and

Medical School, University of Sidney.

medical school, the latter being available for extra mural clinical teaching. Not much weight is placed, however, on the importance or value of extra mural teaching in any of the schools. On the other hand, the greatest attention is given to laboratory work, and all of the schools have excellent laboratories with all modern equipments and appliances. No other medical schools in the world can offer better inducements for their graduates to obtain an internship in a hospital than those of Australia. Thus, of the 218 graduates of the Sydney University no less than 184 held office as resident medical officers in some hospital, and growing hospital facilities will only increase the number of internes in the future. The fees for the whole course of five years, including fees charged for examination, is about \$575.

The universities confer three medical degrees—Bachelor of Medicine, Bachelor of Surgery and Doctor of Medicine. To obtain the last degree a Bachelor of Medicine or Surgery makes application one or two years after graduation, writes a thesis or passes another examination and, if satisfactory, receives the degree of M.D. As this degree is more honorary than useful

surrounded by 132 acres of land. The Prince Alfred Hospital is located on the same grounds. A large, fine brick building for the library is now in process of construction. The present chancellor of the university is Sir Normand MacLaurin, a distinguished Sydney practitioner of medicine. I will always remember with pleasure and gratitude the hours I spent with the chancellor in visiting the university, inspecting its great hall, library, rich museum and the medical school. Sir Normand has shown great tact and executive ability in the management of this young but vigorous institution, but has not lost his interest in medicine and he takes a just pride in the medical school on which he showers his fostering care. The university has now an attendance of about 700, of whom 250 are medical students. Professor Stuart is the heart and soul of the medical school and its present dean.

The medical school is the gem among all the university buildings. It owes its origin largely to the indefatigable efforts of Dr. H. G. Douglass. Sir Charles Nicholson, Mr. Wentworth, Professor John Smith and Dr. Richard Greemp. The first medical school commenced its work in 1883 in a four-room

cottage. The palatial new college building was completed in 1890 at a cost of \$400,000, one of the finest buildings of its kind in the world. It is a massive stone building in imitation of the university building, with tile floors throughout and inner finishing seldom seen in a medical college. Statuary and stained glass windows make one forget one is in a medical college. One imagines he is in a cathedral or a palace. The stained glass windows do not immortalize saints, but the men in our profession whose work has made medicine and surgery what they are to-day. The inner architecture corresponds with the beauty of its external appearance. The lecture rooms and laboratories leave nothing to be desired. What a pleasure it must be to work in such a building!

MELBOURNE UNIVERSITY AND MEDICAL SCHOOL.

The Melbourne University is indebted for its foundation to the public enterprise of the late and well-known English statesman, Mr. Hugh Childers, formerly an inspector of schools in the state of Victoria, and to Mr. Latrobe, its first governor. The former introduced a bill into the legislative council for incorporating and endowing the University of Melbourne in 1853. The bill met with little opposition and was passed the same year. The university commenced work with three professors and 16 students in April, 1855. At the annual examinations of students in 1899, 341 passed. Its present attendance is from 700 to 800, of which number about 250 are medical students. It receives an annual endowment of \$45,000 from the government which, with the gifts, bequests and fees, suffice to meet the current expenses and leave a sufficient residue for making improvements as needed. The buildings are not so expensive as those of the Sydney University. The whole university plant consists of a group of buildings, each of which is devoted to the department for which it is intended. For instance, the medical school is made up of a number of separate one-story stone or brick buildings, representing as many departments. Melbourne Hospital and the Children's Hospital furnish the clinical material. Professor Allen is dean of the medical faculty and professor of anatomy and pathology. He is a remarkable man. He is a graduate of the university and has acquired his professional knowledge of anatomy and pathology by the hardest kind of work within the shadows of his beloved alma mater. The choicest fruit of his ceaseless labor has been a pathologic museum containing thousands of the most interesting specimens, which he has prepared and labeled with his own hands. Besides this, he keeps a record of all the findings of the postmortem examinations at the Melbourne Hospital and has also filed away the clinical history of each case. I believe he could walk through the great museum hall and pick out any particular specimen blindfolded; not only this, but he could give the astonished visitor a minute description of them all. He showed and demonstrated to me scores of the rarest and most interesting specimens. He has one of the finest collections illustrative of the pathologic anatomy of hydatid, actinomycosis and bone disease. He relies on wood alcohol in the preparation and preservation of the specimens. The specimen jars are covered with heavy tin foil, which can be removed and replaced with the utmost ease, and the tin foil cover properly applied over the mouths of the jars effectually prevents the evaporation of the liquid, the loss during a year from this source being insignificant. Professor Allen has become satisfied from his immense experience that malignant disease among the aborigines is extremely rare; on the other hand, syphilis is very common. Everything in his museum shows system and order, a beautiful and rich workshop for anyone who seeks information in this branch of medical study and teaching. Professor Allen knows how to get the best work from his students. He has published a little inter-leaved book, "Pathological and Histological Methods of Sections," for the junior students, in which a brief description is given of the mechanical part of the work and the blank pages are filled in by the students with notes and drawings. A somewhat similar plan is followed in the bacteriologic laboratory.

ADELAIDE UNIVERSITY AND MEDICAL SCHOOL.

The University of Adelaide, the youngest and smallest of

the Australian universities, was incorporated in 1874. It commenced work two years later with the Arts course. Other schools were gradually added until the university was able to give its students, besides degrees in arts, degrees in law, medicine, science, music, agriculture and engineering. It receives a substantial government aid and has been endowed by a number of handsome donations and bequests, among them one of \$480,000 by the late Sir Thomas Elder. The Elder Conservatory of Music, opened in 1898, commemorates this munificent gift. Its present attendance does not exceed 400, of whom about 120 are medical students. The primary branches of the medical school are taught in separate buildings. The anatomy building, the real home of Professor Watson, is a large one-story brick building. Here he dwells along with his students from morning until dusk, often unconscious of the lunch hour, his mind bent on unraveling the mysteries of human anatomy and in supervising, directing and encouraging the students in their work. If any new discovery is made in anatomy anywhere in the world he is sure to learn of it, test it, and make use of it in his teachings. He takes special delight in demonstrating to his students Byron Robinson's utero-ovarian circle. He fully appreciates the importance of applied anatomy and never loses an opportunity to show the intimate relationship between it and operative surgery. A visit to Adelaide without seeing and knowing this interesting man would be about as unprofitable as a journey to Rome without seeing the pope or at least making a visit to the Cathedral of St. Peter. Another most interesting member of the medical faculty of Adelaide University is Professor Stirling, professor of physiology and director of the natural history museum. A combination of these two important offices makes him one of the busiest men in Adelaide. He is equally at home in his physiologic institute as in the great hall of the museum crammed from floor to ceiling with the choicest specimens of the animal and vegetable kingdoms of his own country as well as from all parts of the world, and the products of man's ingenuity from the stone age up to the most recent inventions. This part of his work is to him a labor of love. He has made this museum what it is, the best in Australia and the peer of many in countries that count their age by centuries. From what has been stated it must become clear to anyone that the Australian universities offer to medical students advantages and opportunities equal to if not superior to any of the medical schools of America and the United Kingdom. It would be folly for any Australian medical student to cross the ocean in either direction in search of something better, because if he did he would certainly meet with keen disappointment.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Olive Oil Injections for Constipation.

Hershell, in the *Lancet*, Oct. 1, 1904, describes his method of treating selected cases of constipation by the injection of olive oil. The two points which he emphasizes as necessary to be observed in successful results obtained with this method are: 1. Select suitable cases; 2, that the injections be given in the proper manner. Cases like the following we can not hope to benefit: Constipation depending on improper food or hard drinking water, or as a result of pyloric stenosis or gastric myasthenia. The following classes give the most gratifying results by the use of olive oil injections: 1. Cases depending on chronic colitis. 2. Constipation associated with spasm of

the bowel such as we so frequently find in neurasthenia. 3. We may use this method with advantage to secure a daily action of the bowels in atony of the intestines whilst the affection is being treated by electrical methods. In these last cases the first week or two are most trying to both physician and patient, as all purgatives have been abandoned and the treatment has not yet had time to restore sufficient tone to secure a daily relief. In these circumstances oil injections render us invaluable aid, and if properly given are usually sufficient to keep the patient comfortable.

THE METHOD OF INJECTION.

The method consists in the injection of from 3 to 10 ounces of warm olive oil in the rectum at bedtime. This is retained during the night and usually results in an evacuation after breakfast on the following day. If the oil is introduced slowly, at a low pressure by the force of gravity, the patient should have no difficulty in retaining it for some hours. The following is described by the author as the best apparatus to be used in giving the oil injections: "A glass funnel of a large relative capacity to its height and provided with a metal loop by which it can be suspended at a convenient height above the bed on which the patient lies, is fitted with about 27 inches of rubber tube of large caliber, and terminates in a nozzle of special construction. This latter has a large bore to allow the ready passage of the oil which invariably clogs the nozzle supplied with ordinary enema apparatus, and has the end bore well rounded, so that even when roughly and unskillfully used it is impossible to damage the mucous membrane of the rectum, and from its shape it is self-retaining. For durability and cleanliness it has been constructed of aluminum. The outflow of the oil is controlled by a spring clip which is so contrived that when opened it will remain so until a catch has been released. The injections can easily be made by the patient without assistance. The oil is first heated by standing the beaker containing it in a basin of hot water. The funnel is hung on a nail or hook driven into the wall above the bed. The patient lies on his back directly under it with the hips on a pillow, introduces the nozzle and waits until the funnel is empty. For the first few times it may be necessary to apply a pad of wool to the perineum to absorb any oil which may be expelled. It is best to commence with five or six ounces and to reduce the dose daily until the smallest amount which will produce an action of the bowels is found. If five ounces is not sufficient it may be raised to ten, but beyond this it is not advisable to go, and in cases where this is insufficient the oil may for a few days be supplemented with a small water injection before breakfast. In any case after a few days it will probably be found that a few ounces of oil alone at bedtime will produce a daily evacuation. When this stage has been arrived at this dose can be given nightly for two or three weeks. The effect may then be tried of using the oil on alternate nights. It will probably be found that the bowels will be opened on the days following the intermission, and as the case progresses the action of the oil will extend over a longer time until it will be followed by several daily stools. When this period arrives the injection should be ordered to be taken only on the evening of the day on which an action has not taken place."

Eczema.

The following methods of treating this condition are given by Lassar, in the *Dermat. Ztschr.*, 1904, No. 2:

1. It is necessary to inquire very carefully to discover the cause of the cutaneous inflammation. Very frequently the cause is found to be some external irritant rather than some perversion in the constitution or the blood. If the dermatitis is recent, induced by some external irritant, it is necessary to purify the surface, which may be done as follows: A warm bath with the addition of bran and a bland, never a medicated, soap, or by fomenting with an infusion of camomile flowers. Then the affected parts are to be enveloped for half an hour, three times a day, in compresses moistened with a 1 to 1,000 watery solution of zinc sulphate. The compresses are to be replaced by fresh ones as soon as they become warm. This

alternation of evaporating fomentation and cooling contraction imitates the natural activity of the absorbing capillaries, and is grateful to the patient. Directly on the moist follows the dry treatment, which consists of the free application of a simple dusting powder, the cheapest and most serviceable being a fine pure talc. If itching is prominent a 1 to 2 per cent. solution of carbolic acid may be added. If burning is present it is well to add from 1/2 to 1 per cent. of menthol. By the establishment of a protective layer, frequently renewed and kept in position by bandages, the damaged epidermis is replaced by a regenerated epidermis. This method of procedure in time renders the skin dry and its smoothness can be restored if a paste composed of zinc oxid 60 parts, olive oil 40 parts, be thickly smeared on, dusted over with talc, covered with cotton-wool and a light bandage applied. In the morning the part is best cleansed by olive oil to avoid fresh irritation. If pustules form each one should be opened with an aseptic knife, compresses moistened with aluminum acetate are to be applied and later a vaselin starch paste:

R. Zinci oxidi	
Amyli, āā5ii 8
Vasellini3ss 15

M. Sig.: Apply as directed.

Acidi salicylicy gr. x-xx (.6-1.2) may be added if itching is intense. In the parasitic forms, if superficial, this same paste with the addition of from 10 to 20 per cent. of sulphur is efficient. When deeper infiltrations are present a success is hardly possible without tar. The crusted eczema of the face in children can be rapidly cured if managed as follows: It must be carefully cleansed, oiled over, then washed without so much friction as to occasion bleeding; then thickly smeared with a salve of

R. Olei rusci	
Sulphuris sublimati, āā3ss 15
Vasellini	
Saponis domesticy, āā3i 30
Crete albe5iiss 10

M. Sig.: Apply locally, cover with powder and bandage.

Chronic Furunculosis.

Gaucher, in *Rev. de Therap.*, July 15, 1904, recommends boric acid internally against relapsing furunculosis. He says that this is a harmless substance if it is chemically pure and not taken in too large doses. He prescribes it as follows:

R. Acidi boricy (C. P. recrystallized)3i 30
Aque destl.5xxxiii 1000

Of this solution the patient is to take a tablespoonful at each meal, well diluted. If undiluted it is apt to give rise to cramps. The boric acid is alternated with tar (a teaspoonful of tar water in half a glass of Vichy water), and with arsenical preparations in the following manner: During the one week the tar and alkaline water, during the second week the boric acid solution, during the third week a solution of sodium arsenate. Repeat the same cycle.

Medicolegal.

Insanity and Criminal Responsibility.—According to the recently reported decision of the Court of General Sessions of Delaware, in the case of State vs. Jack, a prosecution for assault with intent to commit murder, it was claimed that some four years previously the accused had been injured in his head in a game of football, which occasioned concussion of the brain and occasional fainting spells; that for some time prior to the alleged assault he had also been addicted to the excessive use of cocaine, and that from these causes his mind was so affected that at the time of the alleged assault he was insane—that is, so demented as not to be criminally responsible for his actions. This, if true, it was held, was a complete defense, it being said that the law regards a person in such mental condition as incapable of committing crime. Insanity may be either total or partial in its character. It may be either permanent or temporary in duration. Where insanity of a permanent charac-

ter is once established by the evidence, it is presumed to continue until the contrary is proven satisfactorily; but, if the insanity be of a temporary character, no such presumption arises. To exempt a person from responsibility for crime, the insanity must be of such a character as either to deprive him of the capacity to distinguish between right and wrong in respect to the particular act committed, or to deprive him of sufficient will power to choose whether he would do the act or refrain from it. So long as a person has capacity to distinguish between right and wrong in the particular act, and has will power to do it or not to do it, he will be held criminally responsible, even though the mind is subject to hallucinations, melancholy, exhilaration, or is otherwise affected from the use of cocaine, intoxicants, or any other cause. In considering the defense of insanity, the jury must direct their attention to the time of the alleged assault particularly, for, while much testimony had been admitted as to the mental condition of the accused before and after that time, it was admitted only with the view to throw light on that precise time and event. If he was sane at the time of the alleged assault, he was responsible, it mattered not what may have been his condition at any other time or place. Every person is presumed to be sane until the contrary is proved to the satisfaction of the jury. Insanity being a matter of defense, the burden of showing it is on the defendant. It must be proved as a fact to the satisfaction of the jury. If the proof does not arise out of the evidence offered by the state, the defendant must so establish it by distinct evidence. Evidence tending to show the absence of motive may be considered in determining the question of insanity of the accused, if any such evidence there be.

Why Insanity Must Be Proved, Rather Than Sanity.—The Supreme Court of Rhode Island says, in the homicide case of State vs. Quigley, that the question as to the rule of evidence where insanity is a defense to crime has arisen in almost every state of the Union and in the courts of the United States, and between the decisions of these courts there is a hopeless conflict. It would be a fruitless task to review in detail the cases where the question has been considered, for they are divided into two classes, which follow substantially the same two divergent lines of reasoning. The English rule implies that the question of guilt and the question of insanity raise two distinct issues, and that, while both may be involved in the final verdict, the burden of proof upon each issue lies upon different parties. The American rule, so called, holds that in a criminal case there is but one issue, and that the burden throughout is on the prosecution to prove not only the criminal act, but the capacity of the accused to commit it beyond a reasonable doubt. This court thinks the first of these positions is the more logical. Sanity is not an ingredient of crime. It is a condition precedent of all intelligent action, as well benevolent as nefarious. It is a quality of the actor, not an element of the act. It is incumbent on the prosecution to show the commission of the act, and from this showing and its circumstances to sustain the inferences of malice and such emotions as the particular crime may include. But sanity is not one of these inferences. It is a pre-existing fact which may be taken for granted as implied by law and general experience. We do not infer sanity from the criminal act as we do malice and premeditation. Sanity is a premise, not a conclusion. It is argued that criminal intent, malice and premeditation are facts to be proven by the prosecutor; that these can not exist in an insane mind; hence sanity must be proved by the prosecutor. But these are facts of mental condition and action, and they can only be proved by inference from material facts, circumstances and acts. It is incumbent, therefore, on the prosecution to prove such material facts, circumstances, and acts as would compel the inference of guilt in a sane person, and this is the limit of his burden. In murder the prosecution must establish the act, and, either by inference or additional evidence, malice and premeditation. If these ingredients of the crime can not exist without sanity, sanity is presumed. The defense of insanity admits the act, but not the crime. Sanity of a human being is an assumed fact, never depending on evidence until it is disputed. The presumption of sanity continues after the

presumption of innocence has been overcome. Evidence is required to overcome it, and the accused must furnish this evidence. If the evidence on this point simply balances, and so produces no probative effect on the mind, the presumption of sanity survives, and the judgment that the man is guilty remains unshaken. Sanity is a condition which does not require proof until its existence is denied. When the well-established, but absolutely arbitrary, rule is announced that all facts constituting the crime must be proved beyond a reasonable doubt, it can not logically be held to include a fact which is not required to be proved at all. Insanity is not a normal condition, but a positive disease; and positive proof may reasonably be required to establish it as a fact to be regarded in making up a judgment on any question where it is relevant.

A Novel Crime and Its Punishability.—The Court of Appeals of Kentucky says that, taken as a whole, the case of Commonwealth vs. Hicks presented an anomaly seldom found in the annals of actual crime. The crime with which the accused stood charged was the somewhat novel one of being accessory before the fact to the self-murder, or suicide, of one Chris Haggard. Section 1123, of the Kentucky Statutes of 1903, provides: "In all felonies, the accessories before the fact shall be liable to the same punishment as the principal, and may be prosecuted jointly with the principal, or severally, though the principal be not taken or tried, unless otherwise provided in this chapter." The court holds that it can not be said that an accessory before the fact in self-murder is not liable to punishment under the terms of the statute, because, his principal being of necessity dead, he can not be punished by any earthly sentence for his crime. Suicide at the common law is murder, and the Kentucky statute fixes the punishment of willful murder at death or confinement in the penitentiary for life, in the discretion of the jury. The case stands, in principle, as if one was accessory before the fact for the murder by his principal of a third person, and, after the commission of the crime, the principal should immediately kill himself. In this case, it would be impossible to punish the principal, but it is not believed that under any sound reasoning the accessory would thereby go scot free. On the contrary, the very object of the statute is to make the punishment of the accessory entirely independent of the conviction or punishment of the principal. Wherefore, the court concludes that under the law as it now stands in Kentucky, an accessory before the fact in a case of suicide is subject to the punishment for the crime of willful murder. In this case, the accused smilingly said to one Sears: "I am on my way to purchase morphin for Chris Haggard. I reckon he is going to kill himself." In the presence of his sister, Lucy Hicks, Haggard, while playing on a guitar, and seemingly in the best of spirits, appointed the day of his death and refused to extend the time to accommodate the engagements of a friend beyond one day—from Friday until Saturday. At the appointed time he was found by a physician dying from opium poison. No one seemed to have regarded the matter otherwise than in the light of a joke, and the motive, if there was one, was not disclosed. An analysis of the evidence, and the enforcement of the provisions of the code on the subject of confessions, the court holds, warranted the trial judge in giving a peremptory instruction to find the accused not guilty.

1. **History of Pathogenic Micro-Organisms.**—Smith points out certain biologic problems which seem to lie on the surface, as it were, and which illustrate the close relationship existing between bacteriology and general biology. He also advances the hypothesis that the tendency of all invading micro-organisms in their evolution toward a more highly parasitic state is to act solely on the defensive while securing opportunity for multiplication and escape to another host. It is largely through the phenomenon of parasitism that nature attempts to restore the equilibrium, and in this micro-organisms play the most important part. As soon as the individual falls below a certain level, he may become the prey of a microscopic, or even ultra-microscopic worm. Hence, the importance of bacteriology in medical science.

3. **Early Diagnosis of Pulmonary Tuberculosis.**—Cheney is a firm believer in the value of old and well-tried methods—the clinical history and the physical examination—in the early diagnosis of pulmonary tuberculosis. Of the newer methods, sputum examination does not give information early enough; tuberculin may give a reaction when no active tuberculosis is present, and may fail to give a reaction when active tuberculosis is present. The Roentgen ray confirms what physical examination has already discovered, but does not tell us anything that can not be found out in other ways. Furthermore, Cheney doubts the value of the Roentgen ray in the diagnosis of early pulmonary tuberculosis; he has not found it reliable. The sources of error in the diagnosis of early pulmonary tuberculosis mentioned by Cheney are: 1. Preconceived ideas: Physicians are apt to approach the examination of a case with their minds made up before hand that the patient has or has not tuberculosis, and then proceed to find facts which will support their view. 2. Inattention to details: In early diagnosis the changes from the normal are very slight, and it is by many little things that by themselves mean nothing, but put together mean everything, that a diagnosis must be reached. 3. Lack of persistence in examinations: It is impossible to reach a definite decision after one examination. The evidence obtained must be gone over again and again before a conclusion is arrived at.

4. **Dilatation and Curettement of the Uterus.**—Fisher reviews the indications and contraindications for the performance of this procedure and describes in detail the various steps of the operation, and instruments to be used, and the after-treatment, but offers nothing new.

9. **Light Therapy.**—Rosenberg is convinced, more than ever, "that in light we possess a remedy of no mean order, and one which in the near future will occupy a most exalted position as a therapeutic agent." He reports 27 cases confirming his statement, and showing that blue, violet and ultra-violet rays are almost a specific against pain, such as lumbago, torticollis, pleurodynia, acute and chronic neuritis. The ultra-violet light rays are obtained from an iron-carbon arc of high amperage. The bactericidal powers of the chemical light rays are easily demonstrated in inflammatory conditions of the skin of parasitic origin. In acne and ferunculosis, the curative effect is both prompt and certain. His results in gonorrhoeal peritonitis and catarrhal inflammation of the deep urethra and adjacent structures have been encouraging and justified by the trials, he thinks. In rheumatic arthritis the rays failed to be of much benefit; Rosenberg's results, in this respect, being at variance with those reported by German authors. He believes that the

ultra-violet rays may be of some assistance in the treatment of pulmonary tuberculosis, gonorrhoeal and tuberculous infections of joints and in lessening the pains accompanying locomotor ataxia.

10. **Ainhum.**—Blum gives a brief résumé of what is known concerning this disease and cites one case, a negro woman, aged 65. The disease occurs almost exclusively among the dark-skinned races of certain tropical and sub-tropical regions, and is characterized by a progressive constricting sclerotic ring around the bases of the digits of the hand or foot, especially selected the little toe of either or both feet, and ending in a gradual amputation of that portion of the affected member distal to the constriction. Formerly the disease was characteristic of the negro race, but it has gradually become a disorder to which other races may be subject. Blum suggests that this is probably due to the emigration of the negro from his former home. Ainhum is very insidious, the condition progressing slowly for years, in some cases lasting as long as twenty years. The disease is painless at first, but as the constricting ring grows tighter and fissures appear, pain becomes very troublesome. It is purely a local condition and it never recurs at the site of amputation. Its duration is sufficient to differentiate it from Raynaud's disease. In leprosy, which may be confused with ainhum, changes are to be seen in other parts of the body and pain is absent. Blum agrees with Mats that the disease is a tropho-neurosis, and not an infectious disorder. In the case he reports, the toe was disarticulated at the metatarso-phalangeal joint under cocaine anaesthesia. The wound healed rapidly without any further manifestation.

11. **Two Fatal Cases.**—The first case reported by Haynes is one of hypertrophic cirrhosis of the liver on which a Talma's operation was done. The patient died on the morning of the sixth day after the operation with symptoms suggesting sepsis; temperature, 102.6; pulse 136, and respiration, 30. In the second case, one of carcinoma of the head of the pancreas, a cholecystenterostomy was done between the gall bladder and the transverse colon, a Murphy button being used to effect the anastomosis. The union between the two viscera was apparently so even and firm that no supporting sutures were added, which, in the author's opinion, was an error of judgment. The region of the anastomosis was drained by a small gauze wick on either side, with a medium-sized rubber drain placed within the gauze and the wound closed by layer sutures. All went well until the tenth day, when the patient complained of a diffuse pain in the abdomen. Temperature, pulse and respiration became high, to be followed by a subnormal temperature, as low as 96, which lasted for three days, when the patient succumbed gradually. Haynes believes that the failure of the approximation to produce firm union allowed leakage of bile after the slough had freed the button. The abdominal cavity was filled with bile-stained fluid and the cause of death was failure of the gall bladder and colon to unite, only one-half of the area constricted by the Murphy button having joined.

14. **Roentgen Rays in the Treatment of Fractures.**—Gilchrist details the advantages of using the x-rays in the treatment as well as for the diagnosis of fractures. The apparatus necessary for this method of managing fractures is a complete x-ray outfit, of either coil or static machine, and the usual accessories. An ordinary wooden-top table can be utilized for the patient, or one can be improvised by laying two

pieces of pine lumber, 6 feet long by 12 inches wide and 1 inch thick on a firm support about 18 inches high. The tube is placed on a stand underneath the table, from 4 to 8 inches from the under surface of the board. As an extra precaution to prevent burning, the table can be covered with a rubber blanket. By placing the fluoroscope over the injured part the conditions of the fracture can be seen constantly, as can also every movement of the fracture extremities during their adjustment, thus avoiding the necessity of giving an anesthetic for diagnostic purposes, saving the patient many painful manipulations, and the tissues from bruising and laceration by unnecessary handling. The method, in short, consists of setting the fracture under the fluoroscope.

17. **Intramuscular Injections of Mercury Salicylate in Syphilis.**—Sinclair says that intramuscular injections of salicylate of mercury possess many advantages over inunctions, fumigations and the internal administration of mercury. They are more scientific and accurate; the gastrointestinal tract and the skin are relieved of irritation; they are quick and sure of action, the symptoms disappearing with wonderful rapidity; they are applicable in all three stages of the disease, non-compromising, easy of administration; do not produce abscesses, and permit of perfect control of the patient. Because of their insoluble properties and slow absorption, they can be given in larger amounts than could be used of the soluble salts of mercury. The salicylate of mercury needs to be injected but once in 7 days. Relapses are extremely rare and are due to the smallness of the dose. The local phenomena following the injection are nil in nearly every case, although there may be slight pain, due to the introduction of the needle. In a small number of cases there is apt to follow, in from 6 to 24 hours, slight lameness, with dull pain more or less severe, at the site of the injection. This may be accompanied by an itching or burning subcutaneous nodule. The drug should be suspended in a heavy liquid. The dose of an injection in ordinary cases is 1½ grains of the drug. The most favorable site for the injection is the gluteal region. The calf of the leg or the muscles of the back or chest may be chosen.

- 26 The District Nurse in Her Relation to Cases of Pulmonary Disease. Arthur W. Falbanks.

21. **Surgical Physiology of the Lymphatic System.**—Mayo calls attention to the fact that the relation of the lymphatic system to surgery seems to have been appreciated but little. He reviews the microscopic and gross anatomy of this system and devotes considerable space to a discussion of its physiology with reference to the production of surgical lesions, and its rôle in preventing sepsis. The lymphatic system is a drain and where there are few lymphatics, artificial drainage for some time after operative interference is absolutely necessary.

22. **Infections of the Prostate.**—Bierhoff suggests that the fact that the gonococci which enter the prostatic ducts are brought into and enter in constant contact with a secretion of a distinctly alkaline reaction, may be the explanation of the generally mild character of gonorrhœal prostatic infections. He discusses the clinical history of prostatic infection and the methods of treatment followed by him.

- 28 *Heart Complications in Diphtheria. A Clinical Study of 946 Cases. Franklin W. White and Howard H. Smith.
- 29 *The Assouan Cure. F. Gordon Morrill.

28. **Heart Complications in Diphtheria.**—White and Smith present the results of a clinical study of nearly one thousand cases of diphtheria, made to determine the condition of the heart, the character and frequency of heart lesions, and their

practical importance in prognosis and treatment. About 5 per cent. of the cases were less than one year old, nearly 40 per cent. less than 5 years, and about 70 per cent. less than ten years. In about one-fourth of the cases the course was mild, about one-half were moderately ill, and in one-quarter the illness was severe. Over one-half of the severe cases proved fatal, namely, 132. About one-half of these patients died of bronchopneumonia, usually following operative interference, such as intubation or tracheotomy. About one-fourth died of heart complications. Of the remaining one-quarter, the majority died of early severe toxemia and a few of asphyxia or late paralysis. The physical signs of a greater or less degree of cardiac disturbance, such as murmurs, rapid and irregular pulse, were very common. Ordinary symptoms of heart disease, such as dyspnea, dropsy, cyanosis and hemorrhage, were not common. About 65 per cent. of the cases had a maximum pulse rate of less than 140, and the mortality among these was about 5 per cent. In general, the higher the pulse rate, the greater the mortality. Irregularity of the pulse was noted in nearly 60 per cent. of the cases. In the majority of cases its time of onset was one or two weeks after entrance. It was observed at entrance to the hospital in 12 per cent. of the cases. Irregular rhythm was most frequently observed in the severe and fatal cases. Heart murmurs were found in 94 per cent. of the cases. All the murmurs were systolic in time, with the exception of those in a few cases of chronic heart disease. These observations were confirmed in each case by two or three competent observers. In the 6 per cent. recorded as having no murmurs, the heart examination for obvious reasons, was unsatisfactory. The murmurs were heard at both apex and base in 77 per cent., at the apex alone in 30 per cent., at the base alone in about 3 per cent. The majority were associated with accentuation of the pulmonic second sound and with irregular heart action, and they outlasted the fever. The mere presence of these murmurs does not affect the prognosis. Gallop rhythm, late vomiting, and epigastric pain and tenderness are important, as danger signals of severe heart complication. The association of late vomiting with gallop rhythm renders the outlook almost hopeless. Frequent examination of the heart and pulse in the second and third week of the illness are necessary, that being the time when severe heart complications most frequently occur. Heart murmurs and irregularity are of long duration in many cases, and make it necessary to watch the condition of the heart long after convalescence in all severe cases.

29. **The Assouan Cure.**—Morrill writes of the benefits to be derived from a sojourn in the Nubian desert. The benefit is obtained from the air only, which differs from that found in conjunction with the comforts of civilized life. Dryness is its main characteristic (an average relative humidity of 41 degrees during the "season") together with a comfortable degree of warmth. This dryness, taken in connection with an average mean temperature of 67, and absence of rain, constitutes an almost ideal winter climate. The diseases which derive the greatest benefit from a prolonged stay at Assouan are nervous exhaustion, from any cause; delayed convalescence, chronic bronchitis, with emphysema and cardiac dilatation; rheumatic affections and neuralgias; cases of prolonged albuminuria, and Morrill has observed two or three cases of incipient pulmonary tuberculosis which have done remarkably well.

35. Papillary Cysts and Tumors of the Ovary.—Pozzi lays down the following proposition: 1. Papillary tumors of the ovary (cystic or solid) must not always be considered as malignant. Not infrequently some of these tumors never undergo malignant degeneration, and do not relapse after removal, or only after a long time, and then but locally, without metastases. 2. It is necessary to make a careful distinction between carcinomatous generalization (which takes place through lymphatics and blood vessels) and simple grafts which result from contact or from growth on the peritoneum of detached papillary vegetations of the ovary. This latter process is benign and can be compared with what happens with papillomas and warts of the skin. 3. Some of these tumors undergo a malignant process which, at the beginning very limited, may afterwards extend all over the mass and at last brings on a real generalization with cancer metastases. Before this last period and at the outset of the malignant transformation it is quite impossible to discern it with the naked eye and microscopic investigations are necessary. Even then, the examination can lead to misinterpretation if it has not been carried all over the tumor, for the malignant process may be very limited in extent. 5. In the absence of positive symptoms of malignancy, operators must always behave towards these tumors as if they were benign, and proceed to remove the largest extent possible of the neoplasm. The disseminated growths or even small parts of the papillary tumor detached and lost in the peritoneal cavity may disappear. In other cases they will be the origin of local recurrence; but these relapses can be treated successfully by major operations. 5. Frequency of successive invasion of both ovaries by papillary tumors constitutes indication for removal of the adnexa of both sides, even if those of one side are still healthy, at least in women who are approaching the menopause. In young women it would be preferable to venture a new laparotomy. Conservative operations must be performed in young women, unless the tumor removed seems indubitably cancerous, in which event it is best to make a complete removal, even taking away the uterus. 6. With bilateral papillary tumors, operative technic will be greatly simplified by performing sub-total or total hysterectomy, according to the case. Hysterectomy should be total if malignant degeneration is feared. If the bilateral papilloma is benign, sub-total hysterectomy is preferable since it is more rapid and less serious. Hysterectomy, in bilateral tumors, simplifies, to a considerable extent, the technic and makes the control of bleeding much easier. 7. Drainage is not necessary when cysts do not present outside vegetations, and when there is no ascites. When ascites is present, it is right to drain the peritoneal cavity for some time, for three or four days, with gauze, and the following days with a tube. In some special cases, a Mikulicz dressing may be necessary, but Pozzi never leaves it in longer than four days. Incomplete removal or even an exploratory incision in inoperable cases is often accompanied by a real diminution of ascites with local and general improvement. This does not justify the systematic performance of incomplete operations either through mistake or as a last resource. Exploratory celiotomy, especially if followed with temporary drainage, has a good effect even in malignant cases and inoperable neoplasm. A little incision followed by drainage for 48 hours is preferable to a simple tapping, in every kind of ascites.

36. Intrapelvic Hematoma.—Williams advises that in the vast majority of cases the treatment should be purely expect-

ant, and the attempt made to tide the patient over the emergency by the subcutaneous use of intravenous salt solution and the administration of the ordinary stimulants. If, however, the tumor increases rapidly in size and the collapse becomes more pronounced, the best means of coping with the hemorrhage is by laparotomy. It is vastly superior to attacking the hemorrhage from below, as under such circumstances all that can be done is to pack the wound in the dark and then be haunted with the fear of not having successfully checked the bleeding and the possibility of a secondary rupture into the peritoneal cavity. On the other hand, if the patient is not seen until some time after the occurrence of the accident, when the acute symptoms have subsided, or the clinical picture points toward the recurrence of suppurative changes, attack by the vaginal route would appear preferable; as under such circumstances the danger of fresh hemorrhage is nominal, while the possibility of contaminating the peritoneal cavity is done away with.

37. The Hematom-Mole.—Taussig adds one case to eight previously reported. He considers hematom-mole a form of "missed abortion" in which the uterine retention lasts usually from six to eleven months; in which not merely the ovum as a whole, but also the amniotic cavity and the fetal membranes that at points lie in folds, is proportionately very large in contrast to the minute embryo, and in which there are found subchorionic hematomata varying in size and number, usually of a tuberosous or polypoid shape. Examination of the fetuses has thus far revealed no reason for their premature death. They are somewhat smaller than their stage of development would indicate, due probably to shrinkage, but even allowing for this shrinkage the disproportion between ovum and embryo remains very great. Taussig's conception of the formation of the mole is that after the death of the fetus in the first or second month of gestation the fetal membranes and the amniotic fluid increase in volume. Thus arises a secondary hydramnios-ovum. This growth continues up to a certain point. The ovum is retained. The amniotic fluid is then gradually absorbed and the ovum, as a whole, shrinks somewhat in size. By the negative pressure thus produced, folds or invaginations of the membranes arise which become filled with the blood circulating in the intervillous spaces. By continued absorption of the fluid, together with a certain degree of stretching of the membranes by the blood clots, a hematoma is formed. In this process the insertions of the villous stems act as fixed points. If the stems are close together, a hemispherical or broad base hematoma results; if far apart, a tuberosous or polypoid hematoma.

40. Vaginal Cesarean Section.—In the opinion of Bacon the most important element in making a prognosis in eclampsia is the presence of, the amount of, and the persistency of, albuminuria. Next to albuminuria in prognostic importance is general edema. The prognostic value of albuminuric retinitis, so far as convulsions are concerned, is no greater than that of albuminuria without retinitis. Hydramnion and multiple pregnancy are factors in the causation of eclampsia, and so are of importance in prognosis. Therefore, Bacon urges that more attention should be given edema and albuminuria when found in connection with twin pregnancy or hydramnion than when occurring in more normal conditions. He says that in cases of chronic Bright's disease the indications for operative delivery are not only those of threatened eclampsia, but likewise concern the pathologic condition due to special anatomic changes wrought by this complication. With no apparent symptom of eclampsia, life may be in danger from kidney disease aggravated by pregnancy. The emptying of the uterus having been decided on, it is necessary to choose between induction of labor and cesarean section. The objections to the induction of labor, says Bacon, are that it may excite convulsions, and it is a tedious procedure. On the other hand, after the occurrence of convulsions, when the cervix is not yet in a condition to be rapidly dilated, vaginal cesarean section is the safest method of treatment of eclampsia, if proper facilities for the operation are at hand. Possibly, in any case where cesarean section is required for any other indication than that of con-

tracted pelvis or disproportion between the size of the passage and the passenger, the vaginal section will replace the abdominal operation. Unless it is followed by hysterectomy in cases of cancer of the uterus, the peritoneal cavity is not opened. All the dangers of peritoneal contamination are avoided as well as the disadvantages of peritoneal adhesions. The incision does not reach the placental site, and thus much hemorrhage is avoided. In many cases there is no need for the hasty removal of the placenta, and hence there is much less hemorrhage than from abdominal cesarean section from this cause. The scar in the uterus is probably in a less dangerous location than in case of abdominal cesarean section. The avoidance of a scar and the frequent resulting weakness in the abdominal wall is certainly a great advantage. Finally, it will often be an advantage to employ the vaginal route, because it will be easier to secure the consent of the patient to the operation. Two cases are cited illustrating the advantages of vaginal cesarean section and describing the details of the operation.

Journal of Advanced Therapeutics, New York.

- 44 Electricity in Medicine. A. D. Rockwell.
 45 *Cataphoric Treatment of Cancer. Amédée Granger.
 46 *A Case of Fibromyxosarcoma of the Sacrum of Large Size. Successfully Treated by Cataphoric Operations, with Preservation of the Sphincter. G. Betton Massey.
 47 *Radiography. Herman Grad.
45. Cataphoric Treatment of Cancer.—Granger, who is a firm believer in mercuric cataphoresis, discusses the physics of the method, and reports twelve unselected cases treated by him. He divides the cases into three classes: First, those cases which were operable; second, those which were inoperable, and third, those which were hopelessly inoperable. The head or neck was affected in 75 per cent. of the cases. The disease was recurrent after some cutting operations in 3 inoperable cases. Radiotherapy had been employed in 3 cases, and all 3 were made worse by its use. As the treatment had to be applied within the mouth in the majority of the cases, he constructed four electrodes for the purpose of overcoming some of the disadvantages of the ordinary style zinc points. The advantages of these points are: That after being inserted into the diseased part, they can be kept in position more easily; that two, and even three, can be employed at the same time; that, except when inspecting the mouth or changing the electrodes the mouth can be kept almost closed. Thus the patient can be kept more thoroughly under the influence of the anesthetic and with a smaller quantity of the latter. His results are summarized as follows: Operable cases.—Number treated, 3; cured, 3. Inoperable cases.—Number treated, 6; cured, 2; improved, 2 (one of these cases is still under treatment and progressing so satisfactorily that Granger hopes to include it among the cases cured); palliated, 1; failed, 1 (in this case the major application which was indicated could not be employed). Hopelessly inoperable cases.—Number treated, 3; palliated, 1; failed, 1; died, 1.

46. Cataphoric Treatment of Fibromyxosarcoma of Sacrum.—The tumor in the case reported by Massey was about the size of two fists and nearly filled the pelvis, the lower border curving back to the sacrum at a point about two inches from the anus. The skin over the upper portion of the coccyx was incised to admit a sharp pointed zinc-mercury electrode somewhat larger than a lead pencil, the unusual thickness of the electrode being arranged to prevent breakage when softened with mercury. Through the slit thus made in the skin, the electrode was forcibly thrust into the still healthy tissues surrounding the coccyx and directed upward into the middle of the growth by a finger in the rectum. This route was selected to avoid interference with the anal sphincter and also because it was anticipated, as subsequently occurred, that the slough would be too large to come away through an intact anus. The powerful current was slowly turned on; this quickly developed the ionized chemicals by electrolytic destruction of the anode, and disbursed them radially from the electrode, necrosing and sterilizing an increasing area of skin, subcutaneous tissue and malignant tissue surrounding the electrode. The current was gradually raised to 1,600 milliamperes, after two other elec-

trodes of smaller size had been inserted alongside the first, and was allowed to flow steadily for three hours, when it was turned off and the patient placed in bed. The conditions present after the application were as follows: A round, grayish colored area of devitalized and sterilized skin, subcutaneous tissue and sarcoma tissue had been produced with a diameter of about three inches, extending deeply into the growth. The growth itself had become shrunken and softened. On the twenty-first day after the operation three of the bones of the coccyx and about half of the tumor came away bloodlessly. A second and final application was made one month after the first, 1,200 milliamperes being turned on and maintained for two hours. Sixteen days later the remainder of the mass came away, somewhat larger than a man's fist, and three days later the detached, devitalized, first segment of the coccyx was lifted out of the wound. Twelve months after the second application the patient was in unusually good health, with no evidence of recurrence. A microscopic examination made of a small portion of the tumor showed it to be a fibromyxosarcoma.

47. Radiography.—In this, the second paper of his series, Grad considers the nature of the x-ray, fluoroscopy, skiagraphy, the technic, and time of exposure, and the location of foreign bodies by means of the x-ray.

48. Treatment of Face and Brow Presentations.—DeLee says that not all face presentations are pathologic. The large majority of cases, if left alone, terminate spontaneously and happily for mother and child. After a careful study of many reported cases and a close review and consideration of 21 cases of face presentation coming under his care, DeLee presents the following as a guide to the treatment of such cases: 1. Normal pelvis, normal child (size and condition), chin anterior—watchful expectancy. 2. Normal pelvis, normal child, chin posterior—at first expectancy: when it is apparent that the chin shows no tendency to rotate to the front—manual correction of the presentation, that is, changing the face to occipital presentation; failing in this—podalic version. 3. Normal pelvis and child, face deep in pelvis, with chin in anterior or nearly anterior position, give a strict indication for delivery—forceps. 4. Normal pelvis and child, face deep in pelvis, with chin in posterior position, version being contraindicated—a careful trial of manual correction. If it fails—craniotomy or symphysiotomy are the alternatives. Forceps are nearly always contraindicated, because fatal to child and injurious to mother, therefore the cranioclast is more humane. 5. Flat contracted pelvis, of mild degree, normal child—version as the operation of election. 6. Generally contracted pelvis of mild degree, normal child—manual correction, followed by expectancy. 7. Face presentation complicated by placenta previa, prolapse of cord, or extremities, rigidity of cervix, threatened rupture of the uterus, a dead or dying child, monstrosities and highly contracted pelvis—offers no good field for the manual correction, although rarely it may be done. Version and other operations are preferable. One must individualize strongly and carefully weigh the indications and conditions of each case before determining the course of procedure. DeLee's method is to correct the attitude of the fetus by internal manipulation mainly, and aided by the outside hand. Certain conditions must be fulfilled before deciding on manual correction of the mal presentation. First, the cervix must be dilated. Second, the bag of waters is ruptured. Third, the child not too large nor the pelvis too small. Fourth, the uterus must not be on the point of rupture. Fifth, the child must be living and viable. Anesthesia is needed and it should be profound. The operation is divided into four parts: 1. Raising and freeing the head and shoulders. 2. Flexing the chin and pressing down

the occiput. 3. Pushing the shoulder and chest to one side. 4. Forcing the flexed head down into the pelvis. The steps of the operation are described in detail. During the operation the back of the hand should give warning of any thinning or tear of the uterus, which is a signal for the immediate cessation of all manipulations. A gentle trial of the high forceps is then in order, failing which, craniotomy is the alternative. Brow presentations always require interference and DeLee believes that they should be corrected early in labor, the head not being allowed to enter the pelvis in this abnormal attitude. The conditions and contraindications surrounding the manual correction here are the same as in face presentation. After molding is well advanced the forceps may occasionally bring a living child, but the operation should not be forced, as the object striven for, a living child, is likely to be lost in the attempt, and an injured mother will have to be accepted with the bad bargain.

54 *Embolism of the Axillary Artery Following Chronic Endocarditis. George E. Sherwood.
55 Expert Evidence in Court. R. S. Joyce.
56 *Singultus. W. B. Gulick.

53. **Treatment in Diabetes.**—That the treatment of diabetes requires not only the closest attention to details on the part of the physician, but also absolute obedience on the part of the patient is the burden of Crummer's paper. He says that in the severe cases a single dietary indiscretion on the part of the patient is just as dangerous as a single slip on an unsplinted leg with an ununited fracture. Care must be taken not to advise any treatment that will favor the production of acids and the ensuing danger of coma. As a third consideration, one must reduce, or cause to disappear, the dextrose in the urine. All this is done by calculating the proper diet for the individual case—one that does not contain too little carbohydrate, for there is the danger of acid production; nor too much, for then there is the danger of further impairing the already diseased sugar-retaining power.

54. **Embolism of Axillary Artery.**—Sherwood reports a case of embolism of the axillary artery consecutive to a chronic endocarditis in which gangrene of the forearm ensued, necessitating disarticulation at the shoulder, which was done after the oval flap method of Larrey. The patient rallied from the operation, and after a somewhat slow and eventful convalescence, made a complete recovery. The points emphasized by Sherwood are: First, the rarity of this complication following chronic endocarditis; second, would it not be possible in the case of an embolus lodging in as large an artery as the axillary or femoral, to attack the condition surgically as soon as the diagnosis could be made, open up the artery, remove the embolic plug, sew up the vessel and thus save the patient's limb and possibly his life.

56. **Singultus.**—This subject is discussed by Gulick, and a case is narrated in which the usual methods of treatment failed to give any relief. Finally ether was administered, after which the patient hiccupped less often. After six hours of sleep, produced by the administration of $\frac{1}{4}$ grain of morphin, the hiccup became less frequent and within two days had stopped altogether.

57. **Examination of Apparently Healthy.**—If a man in apparent health shows a proclivity to weakness in one or more parts of the body, that tendency, says Campbell, should be overcome by careful observation and necessary treatment.

Diseases of the lungs, circulatory system, blood and ductless glands, nervous and digestive system, may be recognized before they have any apparent effect on the health. The individual should be examined periodically, at least yearly, in every detail. Whenever there is the slightest indication a bacteriologic and chemic diagnosis should be made. People in apparent health should be educated to the necessity of subjecting themselves to a periodical physical examination.

58. **Intratracheal Injections.**—Anderson has made a large number of experiments on dogs to prove the absorbability of drugs in the bronchial mucous membrane, and to prove that a considerable quantity of a non-irritating liquid can be introduced into the bronchi without injury. He has tried various liquids with a view to testing the relative irritability of the different vehicles, and olive oil was found to be non-irritating, and in every way suitable as a vehicle for the medicaments. Intratracheal injections offer a direct method of introducing medicaments and allow germicides to come directly into contact with the affected part. He is convinced that they are absorbed into the circulation and act systemically as well as locally, without taxing the stomach. Among the substances experimented with were the oils of eucalyptus, thyme, cinnamon and wintergreen, which may be employed singly or in combination in from 2 to 5 per cent. solution in olive oil. Menthol he found to have a local sedative action. It may be combined with camphor. Campbell's favorite formula is a sterilized mixture of camphor, menthol 5 per cent., oil of eucalyptus 5 per cent., guaiacol 2 per cent., in olive oil. The solution and syringe should be warmed to body temperature before they are used. A syringe with a suitable curved cannula is used. From 1 to 2 drams is the proper dose, which may be repeated in a few minutes. Daily treatments usually give the best results. The injection should be given with the aid of a laryngoscopic mirror or direct. The tongue in each case is held out and the patient inhales as the injection is given. He advocates the use of these injections in the congestive stage of acute bronchitis, the so-called "winter coughs," asthma, and phthisis, except in advanced stages.

7. Pathology of General Paralysis.—Orr and Rows publish a preliminary note of a study of the lesions in the posterior columns of cords taken from cases of general paralysis with acute and constant excitement, with bedsores, with right-sided

pyopneumothorax, with staphylococcus infection, with convulsions, and acute general paralysis. The spinal cords from these cases were treated by the Marchi method, each segment from the lowest sacral to the upper cervical being cut in serial sections. As the lesions had in no instance reached the stage of secondary sclerosis, their starting point was determined without difficulty. In every case the following features were constant: 1. The portion of root between cord and posterior root ganglia showed no degeneration. 2. Degeneration of the internal division of the sensory root in its intramedullary path, commencing at the point of entrance into the cord. 3. The external division, or Lissauer's area, was almost intact. 4. The collaterals and terminals passing into the gray matter shared in the degenerative process. 5. The long fibers derived from segments situated low down in the cord were also affected, as shown by the presence and position of the degenerative fibers in Goll's column in the upper parts of the cord. Without doubt the degeneration was a primary one, due to the direct action of toxins on the myelin sheath and axis cylinder. From here they spread up the perineural sheath without attacking the nerves, and degeneration took place immediately beyond the point at which the neurilemma is lost.

9. Treatment of Pruritus Ani.—Constitutional treatment, says Morris, is of as much importance as local treatment, and every effort should be made to determine the underlying constitutional cause of the affection, and proper treatment instituted. The first principle of local treatment is to remove any cause of irritation. The most scrupulous cleanliness must be enjoined. As an anodyne application, Morris advocates the use of a suppository containing half a grain of cocaine, or a 4 per cent. ointment with lano-vaselin or boric-acid ointment as a base. Cocain may also be used in lotions with glycerin. Because of the danger of producing a cocaine habit, the patient should not be allowed to use this agent either too freely or for too long a time. Menthol, a strong solution of bicarbonate or bisulphate of soda, or carbolic acid may be combined with cocaine or with mercury. Compresses soaked in oil of cade, Peruvian balsam in vaselin, and the tarry preparations are also useful. Among other sedative remedies which may be tried are extract of belladonna, $\frac{1}{2}$ grain in suppository, lead in spirit and water, nitrate of silver in sweet spirits of niter (3 grains to 1 ounce), ichthyol, chloral hydrate, borax, benzoïn, tincture of iodine, ointment of galls, chloroform ointment and oxid of zinc. Among antiseptics the most useful is mercury in the form of the oleate, combined with the oleate of morphin. Black wash, calomel ointment, and ammoniated mercury in benzoated lard (20 grains to 1 ounce) are valuable. Of caustics, nitrate of silver is the best, applied in solution, $\frac{1}{2}$ dram to 1 ounce of sweet spirits of niter. The actual cautery may be applied, the patient having been anesthetized. In the purely neurotic forms of pruritus the less local treatment is used the better it will be for the patient. The right remedy can be found only by trying all things and holding fast to the good. The practitioner will be most successful who gives the greatest attention to detail, studying each case as a distinct problem and leaving untried no resource that can help in its solution.

20. Gigantic Renal Calculus.—Shield reports the case of a man, aged 39, who, after several very severe attacks of renal colic with hematuria, noticed a swelling which filled the left flank and loin, was rounded, firm, very tender, not moving with respiration. The diagnosis inclined toward a large ma-

lignant tumor with intrarenal hemorrhage. Operation was determined on and on opening the abdomen in the left semilunar line, an abscess containing a quantity of pus and two small stones was immediately opened. The kidney was greatly enlarged and firmly adherent to the surrounding parts. An enormous stone, which was subsequently found to weigh more than a pound, was removed with some difficulty. A nephrectomy was done, and when the kidney was sectioned two small stones were found in its substance. The difficulties of the operation were great. Pus and urinous fluid were pouring from the diseased mass over the intestines and wound. The operation, though performed with all possible speed, lasted one hour, and the patient at its termination was collapsed. The after-treatment consisted of saline and nutrient enemata, a small quantity of laudanum being used with the rectal injection. The patient eventually recovered. The stone, soaked in blood and fluid, weighed 19 ounces. When weighed dry on chemical scales, it weighed exactly 1 pound and half an ounce. It was 5½ inches long; circumference at the largest part, about 10 inches. Portions of the stone were broken away accidentally so that its original weight probably exceeded 19 ounces.

21. Fracture Dislocation of the Cervical Vertebrae.—A case of fracture dislocation of the neck is reported by Ringrose which is remarkable because of the disproportion between the accident and the mischief produced thereby, being the converse of what is usually found in these cases. The patient, aged 14, while diving into the river, collided with a man who was swimming by at the time. He was partially stunned, and said he felt "queer" in his head. On admission the patient complained of headache and pain at the lower part of his neck, which was rigid and slightly tender. There was no bruising, and no deformity was to be seen. There was neither loss of power nor of sensation anywhere. He was, however, unable to move his head except to a very limited extent, the side-to-side movement and extension being much more restricted than flexion. After a three days' stay in the hospital the boy returned home and no further symptoms developed. For six months he was in the habit of holding his head with his right hand under the right side of the lower jaw when walking about. Subsequently he joined the militia, having been passed as sound by the military surgeon. He appeared to be perfectly well, but carried his head rather stiffly. A skiagraph made at the time disclosed a forward displacement in the lower cervical region, the center of the body of the fifth cervical vertebra resting on the anterior superior edge of the body of the sixth. The bodies of the fifth and sixth vertebrae were small and wedge-shaped, the apex of the wedge being anterior. The body of the fourth vertebra is almost directly anterior to the fifth. The sixth and seventh cervical and first dorsal vertebrae are pushed backwards, while the cervical curve is greatly increased from the fifth vertebra upwards, the intravertebral spaces being considerably opened; a line drawn through the center of the body of the fourth and one drawn through the center of the body of the seventh forming an angle of about 100 degrees.

22. Pulsating Gangrene of the Lung.—The postmortem examination made in the case recorded by Steven showed that the pulsation was caused by the intimate relationship of the gangrenous lower lobe of the left lung to the left surface of the pericardial sac. There was a distinct tumor-like projection inwards of the pericardial wall which would receive the systolic shock of the heart, and this was transmitted to the chest wall through the semifluid contents of the gangrenous cavity. There was no localized bulging of the chest wall, as in most of the cases of pulsating empyema—the bulging in this case being internal into the pericardium. The pulsation was distinctly felt in the intracostal spaces of the left axilla, and at the base behind, and was of the same character as that felt over the apex beat of the heart. It was a distinct systolic pulse. The heart was neither hypertrophied nor fixed. The anatomic findings seemed to indicate that in order for an empyema to pulsate, the pus-filled cavity must directly abut

on the pericardium, and the adjoining lung must be firmly bound to the chest wall by adhesions.

23. Blood Poisoning from Tonsillitis.—Owen's patient was suffering from a very severe sore throat. Both tonsils were swollen and a patch of membrane was observed on the left tonsil, but a bacteriologic examination failed to reveal either diphtheria bacilli or streptococci. The left tonsil later showed fluctuation, and on opening it, pus was discharged. The condition of the throat thenceforward improved, but the temperature continued to rise, notwithstanding repeated sponging, reaching 104.7. The chest was filled with rhonchi, the abdomen became distended and tympanitic, and the tongue became dry. The patient grew weak, tremulous, and began to wander in his mind. Two days later the left knee had swollen and there was evidence of effusion on the inner side of the joint. The next day both the delirium and sweating had increased. A blood examination was made and streptococci were found. The Widal test was negative. Owen then commenced treatment by injecting antistreptococcus serum. The injections were made subcutaneously in the flank, four injections of 20 c.c. within three days, but without any apparent result. Five days later the shoulder became painful and there was obvious swelling of the joint. Tubular breathing was heard over the left lung about the angle of the scapula. The apex beat of the heart had extended outside the nipple line and a "slapping" second sound was heard in the pulmonary area. Microscopic examination of the blood now revealed nothing abnormal. In the course of the next five days eight subcutaneous injections of 20 c.c. each of Roux's serum (Lister's having been used before) were given. The temperature sank steadily, the delirium disappeared, the shoulder became less painful and the general condition of the patient improved markedly. Treatment by Roux's serum was then recommenced, one injection of 20 c.c. being given on each of five days and 3 on the sixth. After an interval of two days, the serum was again resorted to and injections were given once a day for eight days, after which the patient was treated with a mixture consisting of 30 minims of tincture of perchlorid of iron, with 25 minims of dilute hydrochloric acid and 3 grains of sulphate of quinin, to be taken every six hours. Under this treatment the patient made an uneventful but protracted recovery. Owen attributes to the perchlorid of iron the destruction of the residual toxic elements which were not destroyed or neutralized by the anti-serum.

28. Role of Digitalis and Theobromin in Edemas and Retentions.—Ambard remarks that the knowledge recently acquired in regard to the part played by the chlorids in the production of edema has cast new light on the pathogenesis of both edema and retention. He has been studying the action of digitalis and theobromin from this new point of view. It is currently assumed that digitalis induces diuresis by its action on the heart, and theobromin by its action on the kidneys. He affirms, however, that digitalis has very little action on the heart. When it seems to be acting on that organ it is only indirectly, by means of the diuresis which it induces. Theobromin does not act directly on the kidneys, but only indirectly, by the same mechanism of induced diuresis. We have learned that certain metabolic albumino-toxic substances, non-crystalloids, have a powerful action on the blood, concentrating it and expelling the serum from it, driving it into the tis-

sues. He believes that digitalis and theobromin belong to a group of substances which have an opposite action, attracting the serum out of the tissues and drawing it into the blood—a process entirely distinct from osmotic action. The blood thus diluted gets rid of the excess of fluid by pouring it into the kidneys. The drugs in this group have an antagonistic action to the substances of the category first mentioned. They either neutralize these albumino-toxic substances directly, like an antibody, which theobromin accomplishes, or they induce the elaboration in the organism of certain other neutralizing substances; this is accomplished by digitalis. The retention or elimination of the salts, which in turn induce osmotic currents, is not a mere physico-chemical phenomenon, but is subsidiary to secretory phenomena which dominate the entire mechanism. Osmosis and diffusion are sufficient to explain conditions during a state of repose, but the secretory phenomena are the key to the conditions when things are stirring.

30. Sauerbruch's Air Chamber.—Lejars describes in detail the Sauerbruch air chamber and gives his impressions of it. (See THE JOURNAL, page 1181.) In the chamber are installed a large electric lamp, telephone and all the paraphernalia of an operating room with the advantages that the glass walls can be effectually washed and disinfected and spectators outside can watch the proceedings. The door is double, with an air space between. A dog was operated on under chloroform, the thorax opened and the lung seen to be on a level with the long incision made in the sixth left interspace. Respiration remained even and tranquil. The upper third of the stomach was drawn up into the wound and the esophagus severed, the cardiac stump closed with purse-string suture and the upper stump implanted in the stomach wall to the right of the cardia. During the entire operation the lung retained its normal aspect, size and relations. It was pushed out of the way under a compress like the intestine during a laparotomy. Toward the close of the operation one of the aids left the room and neglected to see that the inner door was closed air-tight before he opened the outer door. The air rushed in, the lung collapsed and the respiration became rapid and jerky. It lasted but an instant, as the door was shut at once and the pneumatic pump worked a little faster to restore pre-existing conditions. Gradually the lung filled out and expanded again. As the pressure was increased to a trifle over the standard 10 mm. the lung ballooned out, protruding from the incision. The pump was regulated, the lung resumed its normal place and the operation was concluded. It had lasted an hour. There were six persons besides Lejars inside the air chamber during the entire intervention. It was rather warm, but they were able to breathe without discomfort. They felt the pressure only when the door was opened and then only in the ears. The pressure of 10 mm. is merely equivalent to an altitude of 900 feet. The pressure in the room was very slowly increased to this point, and as slowly restored to the ordinary pressure. The point that most impressed him in the whole experience was not the absence of pneumothorax so much as the permanence of the calm, regular, normal respiration of the animal, notwithstanding the extensive breach in his thorax. Sauerbruch has established that it is possible under these conditions to open both pleurae and resect the sternum and ribs almost to the spine; in short, remove almost the whole of the "thoracic cage," without interfering with the calm regularity of the respiration. The clinical experience to date with the pneumatic chamber has been 10 operations on human subjects, with 4 recoveries. The subjects were all in desperate condition, enfeebled by the pathologic processes, which included gangrene of the lungs, stab wound of the heart and cancer of the esophagus. The phenomena observed in animals were reproduced in the human subjects. Deep narcosis is indispensable for the success in both. Sauerbruch is now studying the effects of hypertension, for application in operations on the skull, etc. He demonstrated the effects of a pressure of 60 to 70 mm. on the protrusion of the brain after trephining.

31. Abuse of the Tourniquet.—Ahlberg relates a number of cases to show the danger of gangrene from prolonged use of

the tourniquet. He urges that it should be removed at the earliest possible moment, and never be left for twenty-six to thirty-six hours. It is also dangerous to apply the tourniquet any higher than is actually necessary. He thinks that the physician is frequently to blame, as he finds the tourniquet an easy mode of arresting hemorrhage when it would be much better in most cases to ligate the bleeding vessel.

32. Phototherapy of Nevus.—Bordier reports the complete cure of an extensive multiple vascular nevus on the face of a young girl. He applied a compressor to cover the region, with pressure sufficient to blanch the skin, the sound skin between the patches being protected by tin foil. The current of 16 to 18 amperes was turned into the arc light for an hour, the sittings repeated daily. The exposed parts in time looked as if they had been burned, and the applications were suspended until the burned tissues had been eliminated, which required about ten days. The daily applications were then resumed, four of these series being required. Under their influence the entire nevus was finally cast off as an eschar leaving sound skin in its place.

33. Guaiacol in Treatment of Suppurating Wounds.—Two Russian physicians simultaneously report excellent results from tamponing purulent wounds with gauze moistened with 20 to 30 drops of pure guaiacol. It even arrested the morbid process in one case of fulminating gangrene requiring amputation of the arm. After the operation the extension of the process in the muscles of the shoulder was completely checked by the guaiacol dressing.

34. Muscular Connection Between Auricle and Ventricle.—Braeunig has found a well differentiated muscular apparatus which appears first in the higher animals and serves to transmit the muscular contractions from the auricle to the ventricle. The heart in reality is merely a muscular tube with peristaltic movements, and the supposed gap between the auricle and ventricle is bridged by this muscular connection which he has discovered in the septum cordis of rats, mice, a lion, in two monkeys and in man.

35. True or Inoculated Hydrophobia?—Heydenreich describes minutely a case of apparent hydrophobia which developed into complete idioy. Five days after having been bitten by a dog suspected of rabies, the patient, a robust, intelligent house-keeper, 45 years old, submitted to Pasteur treatment. After 24 injections during twelve days an illness developed, accompanied by gastrointestinal and multiple paralytic symptoms, indications of the disturbances in swallowing and breathing of true hydrophobia, and a general decay of the mental faculties, with fatal termination in the tenth month. He queries whether the case can be regarded as one of true hydrophobia or whether it was a modified hydrophobia induced by the Pasteur

injections. Comparing the case with others in which the symptoms developed between the ninth to the fifteenth day after the bite, he thinks that they can be explained better by inoculation of the vaccin than by the bite. Another person, who had been bitten but had not been treated, remained healthy. The dog was a young one, and the probabilities are against its having been rabid.

36. Caneroy on Lupus in a Diabetic Treated with Roentgen Rays.—Levy-Dorn's patient had been diabetic for six years, and had had a patch of lupus on the buttocks for nearly twenty-eight years. The caneroid had developed on this patch. The ulceration, 5 by 6 cm. in size, healed under Roentgen treatment to a most satisfactory extent. The results observed show that diabetes (7 per cent. sugar on ordinary diet), is no contraindication to Roentgen treatment. The success in this case was especially gratifying on account of the duration and extent of the lesion and the lack of any special reaction to the exposures.

37. Infectious and Toxic Hematogenic Dermatoses.—Jadassohn's article was partially summarized on page 1180. In this concluding portion he discusses the question whether some of the toxic hematogenic erythematous dermatoses are not in reality inflammations. Many of the drug and serum exanthems are of an unmistakable inflammatory nature. He pleads that the term erythem may be restricted to the unmistakable vasomotor disturbances, and all other erythems be called what they truly are, that is, inflammations. His article is a comprehensive study of the subject from every point of view, based on his own experience and careful sifting of the literature. He expatiates on the importance of the co-operation of dermatology and internal medicine, adding that in many points the dermatologists may be givers as well as receivers.

39. Molecular Concentration of Blood in Kidney Affections.—The question which Loeb and Adrian propound in the title of their article is whether increased molecular concentration of the blood in case of a kidney affection necessarily means that both kidneys are affected. They describe a case which shows that this is not invariably true. The patient had a malignant tumor in the left kidney and the other kidney was supposed to be diseased on account of the fact that the freezing point of the blood was minus .635 C. The patient refused operation and, on account of the blood findings, the surgeons did not insist, but the necropsy revealed that the other kidney was free from any trace of chronic inflammation. We are not justified, therefore, in concluding, merely from the increased molecular concentration of the blood, that the second kidney is diseased in case of a demonstrated surgical affection of one kidney.

41. Recurring Pyloric Spasm as Indication for Operation.—Schirokauer describes 3 cases characterized by attacks of pains with copious vomiting, with intervals of complete health. The patients were extremely nervous subjects and he explains the symptoms observed as a chronically recurring pyloro-spasm and equally constant hypersecretion on a nervous basis, forming a complex neurosis. The pyloric spasm is the result of disturbance in the motor nerve tracts of the stomach, and the hypersecretion, of disturbance in the secretory nerve tracts. With the underlying neurosthenia, they form a vicious circle and relief is possible only by breaking up the circle. This can be accomplished by appropriate surgical measures, and he advocates gastroenterostomy as the most rational method of treatment of pyloro-spasm with chronic succorria. It may be a lifesaving measure in some cases, even when there are absolutely no organic changes at the outlet of the stomach. Two of his patients were restored to complete health; the other refused operation until it was too late to prove effectual and died in coma.

45. Digitalis as Cause of Cardiac Dissociation.—The graphic tracings and postmortem findings of a case are given to show the danger of routine treatment of heart affections with digitalis. The clinical diagnosis was rheumatic endocarditis and endarteritis on an alcoholic basis. After each dose of digitalis the action of the right heart became much stronger, while that of the

left heart became weaker. Such a disturbance in the co-ordination could be explained only by changes in the right coronary artery which prevented it from contracting. The right ventricle was stimulated to excessive action. The left ventricle was unable to take charge of all the blood delivered by the right, and dyspnea and edema indicated the disturbed compensation. These phenomena could be explained only by assuming that digitalis had an exaggerated action on the right heart, which would be the consequence of dilatation of the right coronary. The clinical assumption that the right coronary was dilated was confirmed by the postmortem findings of sclerosis and a lumen 14 mm. in diameter, while that of the left coronary was only 8 mm. Pharmacologic dissociation, resulting from degeneration of the right coronary artery, has been observed by the writer in 2 previous cases. The curves show the weak pulsation of the left ventricle and the excessive action of the right. The duplicated pulse in the jugular vein was probably attributable to an accessory contraction of the right auricle. Dissociation of the heart action can be studied at the bedside more instructively than on animals' hearts.

46. Treatment of Inward Squint.—Cohn tabulates the statistics gleaned from his personal experience in respect to the heredity of squint. The more he inquired the larger the proportion of squint in the family history. Out of 27,000 patients he found 805 with squint and there was a history of squint among the relatives in 16 per cent. of the first series, 25 per cent. in the second, and 33 per cent. in the last. The various relatives were parents in 25 per cent., grandparents in 7 per cent., brothers or sisters in 26 per cent., and uncles or aunts in 12 per cent., a total of 172 relatives with convergent squint to 805 patients with the same. Worth's statistics show 52 per cent. heredity and Jensen's 70 per cent. In all Cohn's hereditary cases the squinting eye exhibited hyperopia, which he cites as a significant fact. He thinks that there is probably some unknown factor at work here, possibly a congenital alteration in the internus, which ophthalmologists will do well to seek. We are not positive even as to whether amblyopia is cause or effect of the squint. In regard to treatment he follows the following principles: 1, up to the fourth year he has the sound eye bandaged for a few hours every day while the child is at play; 2, during the fifth year he commences special exercises with convex glasses and the stereoscope; 3, corrects total hyperopia; 4, refrains from operating until the child is 10 years old, and does tenotomy in the sixth year only in case of great disfigurement; he promises improvement but not total cure, and advances the externus in extreme degrees of squint.

49. Expectant or Forced Delivery in Eclampsia.—Kermtuner sifts the records at the Heidelberg gynecologic clinic in regard

to delivery in eclampsia. The principles followed are those of conservative treatment, and he thinks that the cases of aggravation of the attacks after delivery, and of the first onset during the puerperium, favor the assumption that the evacuation of the uterus alone is not sufficient. It is only a part of the general treatment.

50. **Vaginal Cesarean Section in Eclampsia.**—Hammerschlag reports 4 cases of vaginal cesarean section, and tabulates the others on record, a total of 21, including Stamm's case. In 8 instances no convulsions occurred after delivery; in 2 others this point was not mentioned, and in 3, one to eleven convulsions are mentioned after the operation (iodoform gauze tamponing). The mortality was 9 in 21; 2 deaths were due to infection and 1 to pneumonia. In 34 cases of abdominal cesarean section on record the mortality amounted to 55 per cent., and 4 of the deaths were due to sepsis. Even the most favorable statistics give 6 to 8 per cent. mortality.

51. **Extramedian Symphysectomy.**—Ferroni adds another to the 26 cases on record in which symphysectomy was performed to one side of the median line, according to Gigli's technic. In every instance the incision healed by primary intention with the exception of one "chloroform death." It is eminently superior to median symphysectomy in the opinion of all who have performed the operation, both in the simplicity of its technic, the immediate results and the definite enlargement of the pelvis which it produces without interfering with the gait. The pelvic organs are left intact and the severed bone heals with most remarkable *restitutio ad integrum*. The present case is the only one known in which there was considerable hemorrhage from the bone and a puerperal hematoma of the labia. Notwithstanding these complications the operation was brilliantly successful in every particular. Gigli's technic was followed in every detail. (See page 764, abstract 81.)

52. **Sounding of the Tubes.**—Thorn presents arguments to prove that it is absolutely impossible to pass a sound through the fallopian tube in normal conditions. The cases in which it has been supposed to have been done must have been in reality perforations of the uterine wall. He found it impossible to pass a sound through the tube even in an inverted uterus and on the cadaver. In case of a myomatous uterus or deformity, with unusually wide opening into the tube, it may be possible to introduce a sound, as has been reported in 4 such cases in the literature and as occurred in a case personally observed. The orifice has to be unusually large, the walls of the tube exceptionally hard, straight and resistant, with other conditions which are seldom encountered.

53. **Eclampsia in the Fifth Month of Pregnancy Without a Fetus.**—Hitschmann reports a case from Schauta's clinic which he believes is without a parallel in the literature. Eclampsia is very unusual at so early a stage as the fifth month. Schauta, in his study of 342 cases of eclampsia in 134,345 childbirths, never observed any from the fourth or fifth month. The placenta had become completely transformed into a hydatid mole and not a trace of a fetus could be discovered. The patient—a *hipara*—was seen at the second week of the fourth month. The size of the uterus corresponded to the seventh month and on account of 7 per 1,000 albumin in the urine the patient was kept in bed on a strict milk diet. Labor commenced soon after, and the next day two very severe eclamptic attacks were observed, with complete loss of consciousness. Under Scheich narcosis the patient was delivered. Not a trace of normal placenta could be discovered in the hydatid mole which filled the uterus, and the fetus—if there had been any formation of a fetus—must have perished at a very early stage. This case is an argument against the theory that eclampsia is due to toxins from the fetus. The peripheral parts of the fetal ovum are probably the source of the toxin generation. The case in question unmistakably indicates this, as the villi were of unusual size and development, the epithelium itself proliferating. Veit's theory of deportation of the villi is superfluous in presence of such a case. Only 2 cases of eclampsia in connection with a hydatid mole are known, besides

the present case. Veit succeeded in inducing albuminuria in animals by injecting placenta tissue. The patient recovered rapidly after delivery, with no recurrence of the eclamptic seizures.

56. **Transverse Abdominal Section.**—Vertes lauds the Pfannenstiel incision as destined to rank most prominently in gynecologic abdominal operations. He reviews the literature on the subject, and states that at Döderlein's clinic 133 patients have been operated on by this technic, which is being adopted more and more as a routine measure. The skin, subcutaneous tissue and fascia are incised transversely at the edge of the hair, above the symphysis. The fascia is detached from the muscles below and mobilized, and then the rectus muscles and peritoneum are incised on the linea alba.

57. **Permeability of Tubes for Fluids Injected into the Uterus.**—Thorn describes 6 cases of gynecologic affections in which he injected a solution of iodine or methylene blue into the uterus without the usual precautions to prevent its passage into the tubes. The solution of iodine was never found in the tubes, but the methylene blue did get into them to a slight extent. He is convinced that the permeability of the tubes for the blue is due to some physical capillary attraction of this fluid, absent in case of iodine, and that this explains the supposed permeability of the tubes. He is convinced that with ordinary precautions there is no danger of an injected fluid finding its way into the tubes.

60. **Lumbar Puncture in Eclampsia.**—Krönig's 3 eclamptic patients were treated by lumbar puncture. No immediate benefit was apparent, but the general condition was notably improved by the seventh to eighth hour, and all the patients recovered. He was impressed with the extremely high tension of the cerebrospinal fluid. The normal standard is said to be 120 mm. water column. In one of the patients the pressure was 500 mm. and during the attack it rose to 600 mm. and more. The fluid was withdrawn to an amount of 37.5 to 47 c.c. before the pressure fell to normal.

61. **Early Diagnosis of Pregnancy.**—Sarwey has never missed finding the fetal heart sounds in the thirteenth week of pregnancy since he has begun listening for them. They were distinctly audible even during the twelfth week in one instance. Good hearing and a practiced ear are necessary to detect them, with absolute silence in the room and anteroom, not even a clock ticking. A still more indispensable condition is persevering patience on the part of the investigator. Sometimes he has auscultated for twenty to thirty minutes before the faint heart sounds were perceptible. The difficulty in hearing them is probably due to the fact that they are audible only at a certain part of the uterine wall, and as the fetus changes its position it may be necessary to go over the entire area before they are located. They were generally found when the stethoscope was placed over the lower segment of the uterus, in the anterior wall, where it is thinnest. He therefore commences to auscultate at this point just above or back of the symphysis, continuing the auscultation over the entire accessible uterine wall, if necessary, stroking the intestines out of the way, the bladder empty, and paying due regard to the location of the uterus and to the possible location of the fetus within. A displaced uterus must be corrected beforehand. In multipare with relaxed and thin abdominal walls it may be possible to draw the uterus into pronounced antelexion and thus be able to auscultate its rear wall. When the fetal heart sounds are detected their frequency must be determined with the watch and compared with the maternal pulse. When they correspond the diagnosis of a pregnancy is certain, even in the twelfth to the thirteenth week, seven or eight weeks earlier than the text-books admit as possible.

66. Principles for Treatment of Syphilis.—Hallopeau's principles are intensive treatment for four years, and not only intensive but continuous. General treatment must be accompanied by local measures as often as practicable. Metallic mercury is the one specific, the dose the largest amount that can be given without symptoms of intolerance, preferably through the skin or into the muscles. Later potassium iodid should be given a larger place and local treatment assume a more prominent rôle. In the after-affections vigorous specific treatment during the premonitory or incipient stages of tabes offers the only prospect for complete success. Vigorous treatment should also be resumed whenever a new symptom indicates the development of a new syphilitic focus in the spinal cord. Patients in the incipient stages of tabes can thus be kept in satisfactory condition for years. The same applies to progressive paralysis except that mercury alone is indicated in this case. Edema may be benefited by compression, cicatricial keloid by radiotherapy; ectropion and sequesters may require operation, dystrophies may be cured by electrotherapy. In inherited syphilis, after-affections resulting from disturbance in the embryonal elements, are scarcely amenable to treatment. The physician should treat the syphilitic with mercury, internally and externally, without cessation, and with potassium iodid as long as he is justified in assuming that the causal agent still lingers in the body.

67. Treatment of Syphilis.—Rosenthal advocates a chronic intermittent mercurial treatment of syphilis, adapting it to individual cases. He prefers subcutaneous injection of the less soluble salts of mercury. When inunctions are employed he thinks the effect is enhanced by keeping the patient in bed, as the inhalation aids in its absorption. This is particularly important in tabes, as the repose is also favorable in this nervous affection.

68. Remarks on Cancer.—Hutchinson's views in regard to the importance of certain drugs, especially arsenic in predisposing the tissues to malignant growths, were mentioned in these columns, page 1180. He thinks that this fact excludes the possibility of a parasitic origin for cancer. He knows of 12 examples of cancer developing in subjects who had been long under the influence of arsenic. He ascribes the tendency of chimney-sweeps to cancerous affections to the large proportion of arsenic in certain coals. He suggests that the gradual transformation of many eczematous or psoriasis affections into mycosis fungoides may be partially due to the protracted arsenic or iodine treatment applied. Some physicians maintain that syphilites are predisposed to carcinoma. It is possible that, not the syphilis, but the drugs employed to combat it, may be responsible for this tendency if it exists. In conclusion, Hutchinson describes some rare malignant affections, including ulcus crateriforme, lentigo maligna senilis and "potato" tumor of the neck. He advises extirpation of a neoplasm without waiting always for certainty in regard to malignancy.

69. Paraleprosy.—Hansen has examined a number of the descendants of lepers and never found any indications of the disease in them nor signs of resulting degeneracy. He also

remarks that the thickening of the ulnar nerve, recently described as a "paraleprosy" symptom, is merely due to the greater accessibility of the nerve in certain individuals.

70. Treatment of Leprosy.—The tuberculous form of leprosy is essentially a skin affection, while the maculo-anesthetic variety is almost exclusively a nerve affection. The nervous system reacts to the latter with swelling of the nerves involved, accompanied by pain and fever. This reaction may be so strong that the infection is conquered, and the subject recovers. In the tuberculous form, in which the process is restricted to the skin, this reaction seldom occurs in the early stages. When it does occur, it is much more intense and is not restricted to the nervous system, but involves also the skin and internal organs. A fatal termination is the rule, on account of the consequent degeneration of important organs, especially of the liver. Treatment should be based on these facts. The maculo-anesthetic form may be favorably influenced by general treatment, especially by potassium iodid and tuberculin, if the latter is given according to the principles in which it is being applied now in tuberculosis. Both these substances act by promoting the reaction on the part of the organism, and both promise good results. The action of chaulmoogra oil is similar, but less constant. Carassquilla's serum probably acts in the same way, but is very uncertain and not always harmless. In cases in which no reaction follows the treatment, some other substance should be given a trial. It may be possible, Lie adds, that leprosy may be found transmissible to anthropoid apes, and that an effectual serum may thus be produced in time. "Science will have to climb up another round of the ladder, however, before we can see what prospects bacteriology has to offer in leprosy."

71. Phototherapy After Sensitizing the Tissues.—This communication proceeds from the Pinsen Light Institute at Copenhagen, and reports extensive clinical research with phototherapy after the tissues had been injected with a 1 per 1,000 solution of erythrosin according to Dreyer's technic, to render the tissues more sensitive to the action of the light. About 350 exposures were made, the subjects—23 lupus patients. The results were negative in respect to any favorable action from the "sensibilization."

72. Influence of Photodynamic Substances on the Action of X-Rays.—Kothe is enthusiastic over the enhanced action of the x-rays after the tissues have been previously injected with a 1 per cent. or per thousand solution of eosin, an hour before exposure. He describes experiments on animals and with lupus and warts in the clinic. The injection of eosin enables the course of x-ray treatment to be much shortened, the exposure need not be so long, and the reaction occurs sooner and is more intense than without the eosin. The eosin injections also permit the energetic reaction to be restricted to a circumscribed area, while the uninjected, sound tissue around or above scarcely feels the action of the rays.

77. Lung Stones.—Stern describes 3 cases of the expulsion of concretions from the lungs after the sputa had been blood-stained for a longer or shorter period. They all consisted of calcium carbonate and phosphate with a trace of magnesia, and all seemed to have an organic foundation, containing tubercle bacilli in one instance. The stones or gravel were multiple, and expelled during coughing. One of the patients had coughed up 20 stones, some of them $\frac{3}{4}$ of an inch long, after years of a catarrhal condition of the lungs, with symptoms finally suggesting a gangrenous focus. Tubercle bacilli were never found in his sputa, but streptococci were numerous. The patient was operated on by Mikulicz in the Sauerbruch air chamber. The right middle lobe was found covered with a pleuritic deposit, and felt unduly tough. It was sutured to the parietal pleura and the wound tamponed. The patient passed through the operation well. Lung stones may simulate tuberculosis or they may obstruct the air passages or induce actual crises or asthma or bronchial colics. The latter were marked in a fourth case.

78. Treatment of Complete Rupture of the Uterus.—Küstner recommends extensive laparotomy, careful wiping out of all

accumulations of blood or fluids in the peritoneal cavity, re-fraining from rinsing. Hemorrhage from the rupture should be controlled by ligatures. The bladder should be sutured in case of injury, and the tear in the uterus should be sutured or not, according to the circumstances. Extirpation of the uterus is required only in exceptional cases. The intervention should conclude with extensive Mikulicz tamponing of the uterus wound up to the laparotomy wound. Seven cases thus treated are described in full, with 40 per cent. recoveries, with 2 recoveries out of the 5 non-moribund patients. Two of the deaths were due to pneumonia or pre-existing infection. In future he intends to inject nucleic acid to promote local leucocytosis as a preliminary to operation. He draws a sharp distinction between complete and incomplete rupture, the latter not requiring the energetic intervention which he advocates for the former.

80. **Metastatic Carcinoma in Ciliary Body.**—Uthoff reports a case of this kind which was at first assumed to be a syphilitic gummatous affection with secondary iridocyclitis, but which proved to be a carcinoma. He rejects the possibility of a primary carcinoma in this region. Metastatic carcinoma of the choroid has a more rapid growth than other intraocular tumors.

83. **Inoculation of Monkeys with Syphilis.**—Neisser reports the results of inoculation of various kinds of monkeys with syphilitic virus. All were dubious or negative, except the inoculation of anthropoid apes. Passive immunity seemed to have been acquired by the chimpanzee, as subsequent injections were negative. His attempts to obtain an effectual serum from the animals have been failures so far, but he still hopes for better results in the future. Among the questions pressing for solution are those in regard to the various development of the primary and constitutional phenomena when the virus is inoculated into or under the skin or by direct injection into the blood; which organs serve as nests for the parasites; are these nests in the glands, and especially in those exhibiting lesions; is it possible in this way to learn points which will be useful in diagnosis to distinguish between the subjects really cured and those in whom the infection is merely in a deceptive, symptomless state? Special attention should be paid in such research to the organs of generation, to solve, if possible, some of the problems of hereditary syphilis. The question of reinfection is also one for experimental study. In regard to the virulence, is there a quantitative difference between the early and late forms, or is merely the age of the syphilis or the kind and intensity of the previous mercurial treatment, responsible for the variations in the virulence of the syphilitic processes, irrespective of whether they belong to the secondary or tertiary phase. [Neisser leaves for the tropics next March to carry on this research on monkeys under more favorable conditions. He expects to go to the Sunday islands for several months.—Ed.]

87. **Cancer Research Committee.**—Benda referred to the case of pavement epithelium cancer in the bronchi published by his assistant, Watsuji, in the last *Zeitschrift f. Krebsforschung*. The patient was a young physician who presented the syndrome of pulmonary phthisis for years, but at the necropsy a small bronchial carcinoma was found. It had induced chronic bronchitis and recurring pneumonia. In another case, adhesions with the aorta simulated the syndrome of aneurism of the latter. In still another instance an attack of apoplexy was the only symptom of a carcinoma in a bronchus. Cerebral embolism had occurred from a thrombotic vein in the vicinity of the cancer, as also in 2 other cases in which the supposed brain tumor proved to be a metastasis from a small cancer in the lung. When careful search is made for cancer of the lung it is found to be more frequent than generally credited. His own statistics show that it forms 4 per 1,000 of all the deaths, and 4 per cent. of all cancer deaths. During one year, 1900, the proportion rose to 12 per 1,000 of the entire mortality. It almost invariably develops near the hilus. It is at first always concealed beneath a large layer of normal lung tissue, and later by indurated or suppurating pneumonic processes.

The first or second branch of the bronchus is the usual site. (The discussion that followed is reported in detail, Orth, Behla and others taking part.)

100. **Leucocytosis in Appendicitis.**—Sprengel concludes from a study of 83 cases that the leucocytosis averages lower early in acute appendicitis than during the later stages. It increases parallel with processes in the peritoneum as well as in the appendix, and reaches its maximum in the later stages of destructive appendicitis. The count is less regular in the early than in the later stages. No characteristic difference could be discovered between the blood count in the serofibrinous and the purulent varieties of appendicitis.

102. **Gastric Juice Under the Ultra-Microscope.**—Bickel announces that the ultra-microscope has revealed that pure gastric juice is not a simple solution, but contains innumerable minute corpuscular elements in suspension. It is thus an emulsion. He proposes to call these minute bodies the "ultra-microscopic granula of the gastric juice." Pure water, saline solution and diluted hydrochloric acid show no such elements. Further study of the gastric juice showed that it varies in its molecular concentration at different periods of the digestion of meat, and sometimes is more concentrated than the blood. These researches were conducted on dogs with Pawlow fistulas.

104. **Radiotherapy of Uterine Tumors.**—Deutsch describes a number of cases of uterine tumors which retrogressed under Röntgen treatment. They were diagnosed as myomata, and one patient, whose case is reported in detail, measured 120 cm. around the waist, but under treatment was reduced to 95 cm. After 5 exposures the previous bladder troubles were relieved and vanished entirely after 7 more. The course of treatment lasted two years, with 90 exposures. A large coexistent struma has entirely vanished. In one of the cases the myoma rapidly

retrogressed during the course of 30 exposures, but another tumor, probably an ovarian cyst, showed comparatively little change. Two of the patients had blood-stained serous discharges from the vagina every time after the exposures. The myoma had caused hemorrhages in one instance, but these were much reduced under treatment. Two of the patients exhibited symptoms similar to those noticed during thyroid treatment of goiter, but they ceased when treatment was suspended. Patience and perseverance are needed to accomplish any results with radiotherapy of deep-lying tumors.

106. Steam Substitute for Cataplasms.—A steam generator over a spirit lamp connects by a tube with a very light metal pad which fits over the part to be treated. When the thermometer fastened in the generator indicates the boiling point, the faucet is turned and the steam sent through the metal pad, whence it passes by a return tube into a condenser. It thus works continuously for twenty hours without attention, a safety valve keeping the temperature always below a certain point. Cloths can be interposed to regulate the temperature felt by the skin. Pads of various shapes are provided to fit different parts of the body, including the eye.

108. Avoidance of Perforation of Living Child.—Veit has not allowed perforation of a living child to be done in his clinic at Leyden since he assumed charge in 1896. There have been 8,000 births since. In 26 cases in which it might have been indicated, he performed cesarean section or symphysectomy, and all the children were born alive, except two, who probably succumbed to the gases of putrefaction from a physometra. Two of the mothers died; one was previously infected, but possibly might have been saved if the uterus had been removed with the child; the other succumbed to the results of the tearing out of the suture of the uterus. To avoid the necessity for perforation, the women should be taken to a maternity at once when trouble is anticipated.

112. Danger to Cecum from Distension in Ileus.—Kreuter relates the history of a case in which distension of the cecum from incomplete occlusion of the intestines caused gangrene. The ilocecal valve is liable to close backward, and the cecum has the thinnest walls of the entire large intestine, while it is liable to be kinked, and, even in normal conditions, always contains more gas and fecal matters than other parts of the bowels. He advises to make an opening at once into the cecum in case of suspicion of occlusion and evidences of localized distension. Irrespective of the point of the occlusion, whenever it assumes a threatening aspect, the chief danger always lies in the distension of the cecum which, in certain circumstances, inevitably occurs and may lead to the most serious consequences.

115. Results of Sanatorium Treatment.—See editorial.

116. Milk Supply in Cities.—Trumpp advocates that the Red Cross should assume charge of the milk supplies in cities, backed by the authority of the state and aided pecuniarily by the municipality. The dairies should not be more than an hour's ride from the city, and should deliver the milk in cans to central stations, where it should be put up in bottles containing a day's ration for an infant. The bottles should be distributed to numerous branches, conveniently located, perhaps in drug stores, and sold at cost price or given free to the poor. He states that 200,000 infants die every year in the German empire, and that three-fourths of this mortality is due to the feeding. The Red Cross is well organized throughout the country, the "Vaterländische Frauenverein" alone numbering 250,000 women members.

121. Sanitary Service in Russian Army.—Dworetzky draws a graphic picture of the Russian sanitary and medical service and its workings in the far east. Five "flying columns" were organized for general prophylactic measures against infectious diseases, and 10 for the disinfection service. Each contains 4 skilled bacteriologists. One was organized by the Moscow Internal Medicine Society. It has its own train, one car fitted up for the laboratory, one for the disinfecting apparatus and electric light plant, one for the living rooms of the

detachment, with other cars for the ice plant. The St. Petersburg Institute for Experimental Medicine fitted out another detachment, which comprises 19 disinfectors and 2 physicians. All the personnel of the sanitary service were vaccinated against typhoid and dysentery free of charge. The army has suffered much less from infectious diseases than in any campaign before. At Moscow special courses were given to train persons in caring for the sick and wounded, and the lectures were attended by 600, while 150 more attended the hospital nurses' course, and 200 the Sisters of Mercies' course. He pays an exalted tribute to the devotion of the physicians in the field and their heroic deeds. Never has such unqualified appreciation and praise fallen to the lot of the profession as now. Major General Schupinsky telegraphed to the mayor of Moscow that he bowed his grey head low in homage to the medical detachment from that city, and such expressions are to be heard on every hand. For the first time in history the military order of St. George (for bravery) has been awarded to two physicians, Chabrostin and Banschtschikoff. The Red Cross at date of writing already had had to replace a number of physicians completely worn out by their services.

123. Text of the Sanitary Agreement between the South American States.—The representatives of the presidents of the republics of Brazil, Argentina, Paraguay and Uruguay signed the sanitary convention last summer, the text of which is here given in full. It is to be binding for four years, with the privilege of extending it for another four years, if all agree. The measures coincide with those generally adopted at the present time for sanitation against plague, yellow fever and cholera, with special measures against transmission of plague by rats. The contracting powers agree not to close their ports against each other, but reserve the right to limit the number of ports open to vessels from infected countries. In order to benefit by the provisions of the present convention, the ships intended to carry passengers must have a physician permanently on board with apparatus for disinfection and extermination of rats and mosquitoes, with an ample supply of disinfectants, and suitable quarters for the isolation of the sick. One section of the convention is devoted to mosquito prophylaxis. Ships must guard against invasion by shore mosquitoes at the docks in ports infected with yellow fever. Ships arriving from an infected port must take measures to exterminate the mosquitoes on board under direction of the sanitary inspector. A corps of trained, international sanitary ship inspectors is to be appointed, the recommendations of these inspectors to be taken under consideration by the various states, irrespective of the nationality of the inspector.

129. Paraffin Prothesis in Treatment of Varices.—Bassewitz has been much pleased with the results of injection of paraffin to control incipient hernia. The success of this measure suggested to him the possibility of applying it to cure varices. He injects paraffin around the internal saphenous vein at one or more points, in amounts sufficient to compress the lumen of the vein, its obliteration following in time from the inflammatory reaction of the tissues. This supplements the incompetent valves of the vein. He prefers hard paraffin, and makes the principal injection near the junction of the saphenous with the femoral vein, with another injection below, if necessary. He has thus treated 2 patients. The severe neuritis varicosa observed in one case ceased as if by magic after the injections.

The patient can leave the bed the next day. Even if the paraffin should be absorbed in time, as it is always substituted by connective tissue, the compression of the vein that has been realized will be necessarily permanent in any event.

130. Salt in Yellow Fever. Ferrari relates experiences to show the great retention of salt in yellow fever, and its discharge in large amounts as convalescence is established. Administration of salt is not tolerated by yellow fever patients.

134. Giant Growth.—Josefson does not believe that there can be normal giant growth. He considers excessive growth as necessarily pathologic in every instance. It is probably the result of acromegaly occurring before the termination of physiologic growth. In a case which he illustrates, a young man of 21, over 7 feet tall, exhibited unmistakable evidences of acromegaly. The lower jaw was unusually large, and there was pronounced cervico-dorsal kyphosis. Radioscopy also revealed enlargement of the sinus frontalis and of the sella turcica. The young man has a sister, not quite 17, who is already taller than he is.

137. Prophylaxis of Tuberculosis.—Runborg advocates compulsory notification as a most important measure in prophylaxis.

138. Graphic Annotation of the Respiratory Sounds.—Holmgren uses in his practice and at the hospital a couple of rubber stamps which print an outline of the front of the chest as shown in the illustration, and another similar stamp showing

the back of the thorax. Each clinical chart in which the characteristics of the respiration are to be noted is stamped with these two figures, and the peculiarities of the respiration are briefly noted down by arbitrary signs previously adopted as a kind of cipher. The upper part of the line on the left of the diagram represents bronchial inspiration and expiration; the fine waves below represent broncho-vesicular inspiration and

bronchial expiration. The larger waves, vesico-bronchial inspiration and broncho-vesicular expiration. The lower part of the line on the left represents coarse vesicular breathing with prolonged expiration, and the lower part of the line on the right, coarse vesicular breathing. A line, slanting down to the right represents inspiration, and to the left, expiration. The line of loops represents normal sounds, and so on. The areas of pronounced dullness and moderate dullness are also marked off by horizontal lines. By this means it is possible to note down a complete record of the characteristics of the respiration in each case in much less time than it takes to describe it. Every physician can select a set of signs or an arbitrary cipher to suit himself. The words and lines in the illustration refer to the dullness.

INJURIES TO THE ANTERIOR VAGINAL WALL IN LABOR.

THEIR PRIMARY, INTERMEDIATE AND SECONDARY
REPAIR.*

B. C. HIRST, M.D.
PHILADELPHIA.

There is no dispute as to the desirability of repairing the pelvic floor, posterior vaginal wall and perineum in the puerperium, although there is ample room for improvement in the manner of doing it in general practice. The old custom of immediate repair, even before the placenta is expressed, as one authority recommends, must be unlearned. The necessity for as careful a preliminary vaginal examination as any expert gynecic surgeon would make before attempting a secondary repair must be appreciated and the operation itself must be conducted like any other vaginal operation with a good table, proper implements and sufficient assistance if women are to be spared the secondary operations to which thousands of them are now subjected.

It has been demonstrated by ample clinical experience that the cervix may be repaired with perfect success and with entire safety to the patient during puerperal convalescence, not only in well-appointed hospitals, but in the homes of both the rich and the poor. It must soon be generally acknowledged that no woman should suffer the disadvantages and risks of cervical injuries in her after-life from which she can be saved by proper attention during the lying-in period.

The nature of the common injuries to the anterior vaginal wall in labor resulting later in urethrocele, cystocele, partial incontinence of urine, decomposition of residual urine, cystitis, and contributing to the causes of prolapsus uteri; the recognition of these injuries; the methods of repairing them during puerperal convalescence are not yet understood even by many of the masters of our principal maternities and of the leading specialists in obstetrics and diseases of women, not to mention the general practitioner. And yet, as I hope to demonstrate, these injuries, as common and often more serious than those of the pelvic floor and cervix, are easily recognized soon after their occurrence, and may be securely repaired by a simple operative technic during puerperal convalescence.

It is necessary, first, to understand the anatomy of the region; second, to comprehend the nature of the injuries of the anterior vaginal wall in labor; third, to be

able to recognize these injuries when they occur, and fourth, to devise an operation that will repair them by restoring the original anatomic condition.

We are indebted mainly to Waldeyer for our knowledge of the support and attachments of the anterior vaginal wall.

The pelvic outlet is closed anteriorly, in the triangle under the symphysis pubis by the diaphragm of the urogenital trigonum, consisting of the aponeurosis, the muscle and the fascia of the urogenital trigonum. The muscle constitutes the greater part of the diaphragm. It arises from the periosteum over the ischio-pubic junctions, and from the tendinous extensions of the sheaths of the obturator internus. It is inserted in the preurethral ligament, encircles the urethra and is actually inserted in the anterior and lateral vaginal walls. As half the length of the vaginal canal lies below the level of the pelvic outlet, the greater part of the anterior vaginal wall finds its only support in its attachment to the structures of the diaphragm of the urogenital trigonum. The older view that the anterior vaginal wall is supported by the muscles, particularly the levator ani, encircling the posterior vaginal wall, is not correct. These muscles may be destroyed as a pelvic support without the development of a cystocele; they may be intact or perfectly repaired and yet a cystocele appears.

The injuries experienced by the anterior vaginal wall in labor are two-fold. Transverse rugæ are nipped between the child's head and the symphysis; the fold of the vaginal wall is pushed down in front of the head and is separated from its subjacent attachments to the loose connective and elastic tissue between its upper third and the bladder. This injury, however, is of subordinate importance. The more serious damage is a laceration of the musculotendinous diaphragm of the urogenital trigonum running across the anterior vaginal sulci. As the head at the pelvic outlet is oblique, and as it almost always lies with its longest diameter in the right oblique diameter of the pelvis, the structures in the left anterior sulcus are most extensively torn. Frequently the injury is confined to this side alone.

Of the two injuries the first may be ignored in diagnosis and treatment. No one ever saw such a complete detachment of the anterior vaginal wall that a cystocele appeared at the end of puerperal convalescence. It takes years to develop. What one does see very frequently is a bulging downward and outward of the lower half of the anterior vaginal wall. As years elapse the constant pull of this prolapse drags the upper half of the vagina and the bladder after it, pulls the cervix forward, tilts the uterus backward, and is one of the most important contributory causes of prolapsus uteri. The cause of this dropping of the anterior vaginal wall

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

can easily be recognized by inserting the forefinger in the vagina, palmar surface upward, and making pressure upward and outward in the anterior vaginal sulcus toward the pubic bone. On the sound side the elastic and resistant cushion of the urogenital trigonum diaphragm is plainly felt; on the injured side the finger comes immediately in contact with the sharp edge of the bone, nothing intervening but the vaginal mucosa. Usually this injury is submucous, but frequently the vaginal wall itself is also torn through, as I have demonstrated in scores of cases to my students. In such instances one gets a most convincing demonstration of the true nature of this injury, and sees a raw surface strikingly like the denudation to be discussed later.

If the anatomy of this region is understood as Waldeyer enables us to understand it in his admirable work "Das Becken"; if the nature of the injury to the anterior wall is comprehended, as it can be by a close observation of a sufficiently large clinical material, the remedy is easy enough to devise. It is obviously to reunite the torn fibers of the anterior pelvic diaphragm, restoring the normal anatomic support of the lower half of the anterior vaginal wall and, in the case of an old, neglected, well-developed cystocele, to remove the redundant thinned-out vaginal wall in the middle line, rejoining the stronger connective tissue fibers which have been crowded to either side by a tier suture.

It is almost unnecessary to dilate on the technic of accomplishing these purposes. Any one well trained in plastic vaginal surgery will devise a method to suit himself. Some practical points, however, suggested by a large experience,¹ may be of interest.

In the primary repair of this injury, if it is submucous, the sutures should be inserted so as not to crowd the vaginal mucosa between the ends of the lacerated muscle and connective tissue fibers. This is done by making one deep insertion of the needle, a returning shallow insertion under the mucosa, and the junction of the suture to one side of the injured area.

If the repair is postponed for five to seven days, as it should be if the cervix must also be repaired, a denudation of the anterior sulcus must often be made, and as in all plastic operations on the vagina, the whole thickness of the vaginal wall should be removed so as to expose the muscles and fascia beneath. The most convenient way to expose the anterior vaginal sulcus is to fasten an Allis forceps alongside the urethra and another opposite it, to the lateral vaginal wall at the introitus. By making traction upward and laterally the triangular cleft, if the anterior sulcus is injured, comes plainly into view. The quickest way to make the denudation is to mark out its boundaries with a sharp knife and to excise the triangular piece of vaginal wall with scissors. In inserting the sutures the needle is deeply inserted with the same turn of the wrist that is used to catch the muscle and fascia in the Emmet operation on the posterior vaginal wall.

If there is a very well-marked cystocele of long standing with thinned-out and redundant tissue in the middle line of the vaginal wall, the cystocele is pushed back; the anterior sulci are denuded, the stitches are inserted but not united; the cervix is pulled out of the vulva, a Martin anterior colporrhaphy is performed; then the stitches on the anterior sulci are shotted or tied, as the operator prefers

In cases of injury to the muscles and fascia of the sulci with incipient cystocele, or with that partial incontinence of urine so common in middle-aged women who have borne children, the operation need only include the denudation of the sulci and suturing. If, in addition, there is also a repair of the posterior sulci, one can not fail to be impressed with the normal and nulliparous appearance of the lower vaginal canal.

Attempts have been made before by Simon, Velpeau, Emmet, Fehling and Skene² to perform lateroanterior colporrhaphies for urethrocele, cystocele and prolapse, but a study of the methods described by these authors shows, I think, that they are not based on accurate anatomic knowledge, and that they could not accomplish their purpose so well as the method I advocate and have attempted to describe.

THE ETIOLOGY AND PATHOLOGY OF CYSTOCELE AND A NEW OPERATION FOR ITS RELIEF.*

J. RIDDLE GOFFE, M.D.
NEW YORK.

The early procedures for the relief of cystocele consisted simply in building up a strong perineal body that should retain the prolapsed tissue within the vulva. Simon practiced this for many years, but his experience developed the fact that this method was only a temporary expedient; the weight of the sustained mass and intra-abdominal pressure gradually absorbed the artificially constructed dam and allowed the former condition to be reproduced. Marion Sims brought his batteries to bear directly on the offending tissues, and devised the procedure known as anterior colporrhaphy. Emmet followed the suggestion of Sims, and improved on it, modifying in various ways the denuded surfaces, with the idea of building up a resisting line of tissue that should act as a lever in holding the cervix high in the hollow of the sacrum. E. C. Dudley shifted the seat of operation to the lateral sulci of the vagina in the operation that he denominates "lateral elytrorrhaphy." Stolz' operation, the purse-string suture about an elliptically denuded surface in the center of the protruding mass, has had considerable popularity. This is due more to its simplicity than its efficiency. In addition to its temporary character, it introduces the most objectionable element of shortening the anterior vaginal wall, the baneful consequences of which are universally recognized.

All of these procedures utterly fail in grasping the true cause of the difficulty and attacking it on rational principles. Granting that a cystocele is a hernia, it would seem quite as rational a procedure and give promise of quite as satisfactory results to denude the skin over an inguinal hernia and bring its edges together with stitches as to expect to cure a cystocele by simply denuding the vaginal mucous membrane, tucking in the prolapsed bladder and stitching together the freshened edges of mucous membrane. The fascia is the sustaining tissue, and if there has been a pocket or hernia produced in it by overdistension until it has lost its power of recovery, the only permanent relief consists in cutting out the overdistended and atrophied area of

2. See Fehling, *Centralbl. f. Gyn.*, No. 43, 1889, p. 746, and Skene's *Diseases of Women*, 2d ed., p. 866, 1892.

1. Of a total of more than 2,000 gynecologic cases yearly in the hospital services under my direct control, exclusive of private and consulting practice, more than 700 are women recently delivered. More than 200 of these anterior wall operations have been performed in the last two and a half years.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

the fascia and bringing into apposition the strong, well-nourished areas beyond, that have not been subjected to or have resisted the destructive pressure.

Stone¹ of Washington has emphasized the importance of wide dissection at the base of the bladder and resection of the entire area of overstretched fascia and mucous membrane, giving credit for the suggestion to Saenger of Prague. In addition to this, he strengthens the upper support of the vagina by attaching the vagina to the anterior face of the uterus—a vaginal fixation of the uterus.

Reynolds of Boston, in a paper read before this Section last year, also laid stress on the importance of cutting out the weakened overstretched fascia. His idea is to obtain support also from the anterior vaginal wall by fastening its upper end to the bases of the broad ligaments at either side of the cervix uteri. This is accomplished by swinging around in front of the cervix, the bases of the broad ligaments attaching them together in the middle line and connecting this common point with the vaginal fascia in line with the urethra. To use the author's own language: This approximation of the firm lower and upper attachments of the anterior

Fig. 1.—Cystocele produced by supravaginal elongation of the anterior lip of the cervix uteri, found in virgins and nulliparous women. When both lips are elongated the posterior vaginal wall comes down and rectocele is also produced.

wall has been arrived at in Emmet's and Watkin's operations, and I believe underlies their success.

I have not attempted this operation. Theoretically, it is open to the objection that there is danger of wounding the ureter in passing a suture through the base of the broad ligament at the side of the cervix. It is also open to the objection, common to all the other operations that have been considered, namely, that by tucking up or invaginating the excess of bladder wall and then diminishing the size of its inclosing fascia, the base of the bladder is thrown into multitudinous folds in various directions. In the pockets of these folds the urine accumulates, is retained, undergoes decomposition and is apt to inaugurate an unfortunate train of sequelæ, such as cystitis, calculus, ureteritis, pyelitis, etc.

METHOD OF OPERATION.

It has been my endeavor in the procedure which I offer to-day not only to provide a good strong support

for the bladder, but also to do away with the redundant folds of bladder wall at its base. In diminishing the size of the inclosing fascia, as stated above, not only is there a redundancy of tissue from side to side, but also anteroposteriorly. This can be obviated by dissecting the bladder entirely free from its attachments to the uterus, the broad ligaments and the vagina, the entire organ rotated on its transverse diameter, and the excess of bladder wall in the cystocele spread out on the face of the uterus and the broad ligaments.

The anterior vaginal incision, as employed in vaginal section for the relief of diseased ovaries and tubes, and retrodisplacement of the uterus, affords every opportunity for accomplishing this procedure. This became strikingly apparent to me in a case in which I was operating for the relief of these conditions. The case was one of those multiple injuries resulting from childbirth, in which there was present laceration of the cervix and perineum, rectocele, cystocele, retroversion of the uterus with prolapsed and adherent appendages. After the uterus had been curetted, trachelorrhaphy performed, the anterior vaginal incision made, the ovaries and tubes treated and the fundus uteri restored to its normal position by shortening the round ligaments, the bladder, which pouted through

Fig. 2.—Cystocele and rectocele with retroversion and prolapse of the uterus.

the vaginal incision, was rotated on its transverse diameter, and its base carried up onto the anterior face of the uterus and stitched there with chromicized catgut. This took in all the slack in the anteroposterior line of the base, and by stretching out first one side of the bladder and then the other and stitching it on to the respective face of the broad ligament, the lateral folds were also obliterated. The pouting sac had entirely disappeared. It only remained, then, to make the vaginal wall fit this new position of the bladder. This was accomplished by cutting away all the overstretched vaginal sheath and membrane at either side of the longitudinal vaginal incision and bringing together the bare strong facial edges with interrupted catgut sutures. This made the vaginal wall fit snugly against the base of the bladder, and it was at once apparent that the anterior vaginal wall, instead of sagging into the lumen of the vagina, maintained a straight line from the pubis to the cervix uteri. Perineorrhaphy was then performed, and the result was all that could be desired.

1. Trans. Am. Gynec. Soc., vol. xxvii, 1902.

In order to understand the thoroughness of this work, it is necessary to keep in mind the method of making the anterior vaginal incision. A cross incision, slightly curved or straight, is made in front of the cervix, as in vaginal hysterectomy. From the middle point of this a second incision is made at right angles to it down the entire length of the anterior vaginal wall. These incisions go through the fascia down to the bladder wall. The bladder is then dissected widely and freely from the interior of the fascia on either side of the median line till the entire organ is set quite free throughout its entire base and sides. The vesico-uterine pouch is then entered and the peritoneum torn across the face of the uterus and well out on to the face of the broad ligaments. The bladder is stitched by an interrupted suture of chromic gut at three points only, the middle of anterior face of the uterus and two points on the broad ligaments sufficiently wide apart to spread out the bladder wall. The method of passing the sutures is important: The sutures are all passed and left sufficiently long to protrude from the vulva before any one is tied. When all three are in place the middle one is tied first, then the others.

Fig. 3.—Transverse incision in vaginal section reduced from M to N. The bladder is then dissected from the uterus from N to O. A longitudinal incision is then made through the mucous membrane and fascia from N to P, and the bladder is dissected from the vagina as shown in Figure 4.

The principle involved here is that which Nature has employed in sustaining all the organs of the human body, viz., suspension from above. The bladder in this operation is carried up and suspended from the uterus and broad ligaments. In addition to this the true method of treating a hernia is also brought into requisition.

To apply this principle in detail to all cases of cystocele, it is necessary to classify them in accordance with the etiology. In virgins and nulliparous women, as a rule, the uterus, i. e., the fundus, remains in place. Exceptions to this appear rarely in instances of prolapsus. The etiology consists in an elongation of the supravaginal portion of the cervix, due to hypertrophy of the uterine tissue. This permits the descent of the points of support, at the upper end of the vagina, producing a sagging of the vaginal wall and the base of the bladder. This initial elongation pushes down the vaginal supports, but later the rôles are reversed and the vaginal prolapse drags on and increases the elongation

of the cervix. In these cases there may or may not be a hernia of the bladder through the vaginal sheath. There is prolapse of all the vaginal wall accompanied by the bladder. In many of these cases the primary hypertrophy of the supravaginal cervix is confined to the anterior lip. In these instances there exists a protrusion of the anterior vaginal wall with the bladder behind it, but unaccompanied by a rectocele. In the first variety of this class of cases the entire attachment of the upper end of the vagina must be cut away, the elongated cervix amputated, and the attachments of the vagina shifted to a higher level. If it is of long standing and a hernia of the bladder exists, the uterovesical attachments must also be lifted to a higher level and the details of the operation, as previously described, applied. If only the anterior lip is hypertrophied, of course only the anterior attachments of the vagina to the uterus need to be dealt with. In both classes of cases, however, great facility is afforded by the transverse and longitudinal incisions and free dissection of the bladder from the vagina and uterus.

The most common cases of cystocele are found in

Fig. 4.—The vagina has been dissected from the bladder at either side of the longitudinal incision and the vesico-uterine peritoneum torn through. Point B is selected, which when carried to C, will lift the curve A B to a straight line A C, when it is secured by suture.

multipara, and associated quite uniformly with descent and retroversion of the uterus. In these cases it is necessary, before attacking the cystocele, to restore the uterus to its normal position and secure for it sufficient support, not only to maintain that position for itself, but also to support the bladder. It must be borne in mind, however, that the higher attachment of the bladder operates equally in lifting the bladder to a higher level and maintaining the uterus in its normal anteverted position.

This procedure is applicable to all cases of this class in which the condition is not so extreme or of so long standing as to have robbed the connective tissue of all recuperative power. Extreme cases, however, are surprisingly restored by this operation, when even a more radical procedure seems indicated; for by the restoration of normal circulation and nutrition the sustaining power of the connective tissue is restored and a normal healthy condition established. The extreme cases in which hysterectomy, extreme vaginal fixation of the

uterus or complete removal of the uterus and appendages, together with the entire vagina, panhysterocolpomy, as described by Edebohls, do not come within the scope of our consideration in this procedure.

I have performed this operation eight times, all with most satisfactory results. The first case was operated on in September, 1902. Two of these cases about one year after operation were presented before the New York Obstetrical Society in a preliminary report I made to that association. A committee of three was appointed to examine the cases, and reported individually and collectively that the results in all were eminently successful. All of these cases were in laboring women, well advanced in years, and sufferers to an extreme degree from multiple lesions of the generative organs. All of these lesions in each instance were relieved at one sitting. The reports of the cases follow. I give the first one in full to set forth the various steps of the procedure in all its details:

CASE 1.—Mrs. M. M., age 49.

History.—Married 23 years, five children, the last fifteen years ago; one miscarriage eleven years ago. All labors were

Fig. 5.—Point C in Figure 4 is carried to C Figure 5 and B to B. The vaginal membrane and fascia have been trimmed to fit and suture applied.

prolonged and difficult. Complaints of pain in both ovarian regions and back, accompanied by a "dropping-down feeling" in the pelvis. Menstruation is irregular and painful. Suffers from frequent difficult and painful micturition; is disturbed by it during the night.

Diagnosis.—Retroversion of the uterus, laceration of cervix and perineum, rectocele and cystocele.

Operation.—Sept. 24, 1902. Uterus was curetted and packed with gauze; the lacerations of the cervix were repaired, and the round ligaments shortened through the anterior vaginal incision. In making this incision the bladder was dissected entirely free from the vaginal sheath and fascia well out at either side. The vesicouterine peritoneal fold was pierced and the peritoneum torn across well out on to the surface of the broad ligaments. To relieve the cystocele the bladder was then rotated on its transverse diameter and stitched in the following manner: A point was selected in the middle line of the base of the bladder wall which could be carried up to the torn edge of peritoneum on the anterior surface of the uterus, middle point, and by so doing take up all the slack in the base of the bladder, making a comparatively straight line from the urethra to the uterus. Through this point a suture was passed and carried also through the selected point on the anterior face of the uterus. The suture was of chromicized

catgut No. 2. It was left long and was not tied. Two points were then selected, one at either side, on a transverse line with the first and about equally distant. Through these similar sutures were passed and carried through a point on the torn off edges of peritoneum on the surface of either broad ligament, sufficiently wide at the middle line to take in all the

Fig. 6.—Showing the method of dissecting the vagina from the bladder after longitudinal incision in anterior vaginal section.

Fig. 7.—Showing the method of making the longitudinal incision in anterior vaginal section. The edge of the transverse incision is grasped by artery clamps and the vaginal wall put on the stretch and an incision made from the neck of the bladder to the middle of the transverse incision.

slack in the base of the bladder from side to side. These sutures were also left long. The three sutures were then tied successively, beginning with the middle one. The effect of this was to stretch the base of the bladder taut and smooth in every direction. The fascia along the middle line of the vaginal incision and the mucous membrane as well were then trimmed

off sufficiently to make them fit the base of the bladder snugly, and were stitched with interrupted sutures of chromicized gut. The perineum was also repaired. The vagina was gently packed with gauze and the patient put to bed. Convalescence was afebrile, smooth and comfortable. When last seen in January the support of the bladder was perfect and all the bladder symptoms had been relieved. The other surgical procedures were equally satisfactory and successful.

CASE 2.—Mrs. L. S., aged 41; married; five children.

Diagnosis.—Rectocele, cystocele, extensive lacerations of cervix and perineum, hemorrhoids.

Operation.—Nov. 15, 1902. Curettage, repair of cervix, shortening of the round ligaments, cystocele treated by method described, perineorrhaphy and Whitehead's operation for piles. The perineal operation was not entirely satisfactory; the results in other respects were exceptionally good.

CASE 3.—Mrs. M. H., age 50; four children; youngest 6 years.

Diagnosis.—Endometritis, cystocele, rectocele with prolapse of the uterus.

Operation.—Feb. 11, 1903. Curettage, anterior vaginal section, shortening of the round ligaments, treatment of cystocele by method described, repair of perineum.

Results.—Entirely satisfactory.

CASE 4.—Mrs. M. M., age 39; mother of five children, last two years ago.

Diagnosis.—Endometritis, retroversion and extreme prolapse of the uterus, cystocele, rectocele, lacerations of cervix and perineum.

Operation.—March 7, 1903. Curettage, repair of cervix, posterior and anterior vaginal section, shortening of the uterosacral and round ligaments, treatment of cystocele by method described, perineorrhaphy.

Results.—Entirely satisfactory.

These are typical cases; the narration of the last three would be only a repetition.

REPORT OF COMMITTEE.

The report of the men composing the committee of the obstetrical society was as follows:

DR. CLEMENT CLEVELAND—I examined the two cases of Dr. Goffe's and one especially impressed me very much. She was a large, stout woman in whom he restored a retrodisplaced uterus. There had been also an excessive cystocele and large rectocele. I examined this patient very carefully and found the uterus in normal position. The anterior wall was as nearly normal as any one could expect after any operation. In the second case the results were not quite as good, but were very satisfactory.

DR. G. G. WARD, JR.— . . . In both cases I particularly noticed that the anterior wall was not shortened in any way. The bladder was suspended and seemed to be supported without the aid of the perineorrhaphy which had been done in both cases.

DR. G. H. MALLETT—One of these patients was a large, stout woman, and she appeared to be in a normal condition. In one there seemed to be left a rectocele.

DR. HENRY C. COE in discussion said: "I have always been convinced that ordinary cystocele operations were of little value. Dr. Goffe's operation is certainly a most ingenious one, but to successfully perform it requires the special skill in vaginal work which he possesses."

The closing remark of Dr. Coe's I uncompromisingly disclaim. A very limited experience in anterior vaginal section promptly convinces any reasonably experienced pelvic surgeon of the practical feasibility of the procedure.

DISCUSSION

ON PAPERS BY DRs. HIRST AND GOFFE.

DR. RUDOLPH W. HOLMES, Chicago, said that we must know the condition of the pelvic structures in pregnancy and the puerperium to appreciate Dr. Hirst's report of 200 operations for cystocele, two weeks after labor in 257 patients confined in

his clinic. During the progress of pregnancy there is a marked relaxation of all the pelvic muscles and connective tissue; this is evidenced by the relaxed vagina, the more patulous vulva which may even be gaping in some primiparæ, and is usual in those already the mothers of children. As the vulva is opened with the fingers the anterior wall of the vagina is seen more dependent, even to such an extent as to be a mild cystocele; this is due to the fact that intra-abdominal pressure readily may force down the anterior vaginal wall when a pelvic floor relaxation exists—as it almost invariably does exist in advanced pregnancy—a fact pointed out by Schroeder years ago; this is specially characteristic in multiparæ, but is not limited to them. Further evidence of this relaxation is demonstrated in the increased pelvic floor projection which has been so well studied by Drs. Hart and Barbour. Cystocele, to a slight degree, is characteristic of pregnancy; if it is a physiologic condition in pregnancy, it must also be a physiologic condition of the puerperium until involution is completed, and then only may it be characterized as pathologic and present the question of an operative procedure. Ten or fifteen years ago Dr. Hart showed that the anterior wall from its relations to the anterior boundaries of the pelvis is not liable to injury during labor. Dr. Holmes has not seen injuries of the anterior wall of the vagina during labor except in operative cases. If these rare injuries occur they should be repaired immediately. Therefore, it is inadvisable to perform a cystocele operation at a time when cystocele is physiologic, with, perhaps, a certain amount of pathologic entity. Cystocele, as a pathologic condition is rare, and in nearly all instances is due to the action of abdominal pressure unopposed by an intact pelvic floor; if the posterior vaginal wall and perineum are repaired the cystocele will take care of itself and the anterior wall will return spontaneously to its normal condition. The second week of the puerperium is a very bad time to operate for vaginal conditions because of the increased liability to infection; the lochia is teeming with septic bacteria which would jeopardize a favorable result.

DR. MORDECAI PRICE, Philadelphia, agreed with Dr. Hirst that repairs should be made immediately after delivery of the placenta. Dr. Price, however, disapproved of closing a wound in the birth canal a week after labor, as such work done in the midst of filth is not good surgery, and no one can say that the birth canal, torn and mutilated, is clean and aseptic at that time, no matter what antiseptics are used; one can not get below the area of sepsis. Dr. Price said that he had recently seen a woman with a temperature of 105 F. on the eleventh day, who had had no sign of trouble prior to that time. Can one say that vaginal repair a week after labor is not the cause? Can an operator say conscientiously that his sutures have not enclosed septic material?

Dr. Price believes that Dr. Hirst is wrong, and that there is not one in ten who can say what is the cause of the fever that follows childbirth. He has stood by patients for weeks and at last there was a little swelling of the leg and a little fever, indicating a condition having its origin, probably, in some disturbance in the large veins of the birth canal. One could not say, having done an operation a week after parturition, that it was not the result of that operation. He would not operate at that time and considered it radically wrong.

DR. SWITHIN CHANDLER, Philadelphia, said that many a general practitioner has been condemned because a cystocele, due to injury to the vaginal wall, has followed labor. The physician was often unable to diagnose such an injury as the mucous membrane was intact, the tissues beneath it being ruptured. Dr. Chandler thought that Dr. Goffe's paper clearly demonstrated that we have displacement as the result of tears in the vaginal wall, and stated that he had removed stitches placed in the vaginal wall from three to ten days after labor, and had found green pus abscesses from the enclosed tissue in the vaginal wall which were the cause of the fever in the patient. He asked if Dr. Goffe examined the bladder after his operation to note its condition, and if so, what that condition was. He said that a question which might bother us is whether the fixation would cause

trouble because the bladder, properly speaking, is not a fixed organ. It is loosely adherent, so that it can expand when required in any direction, and that even though the folds which Dr. Goffe has made by his operation are in the top of the bladder, it is well to remember that they are covered by epithelium, and that any interference might cause cystic or other trouble, which might spread to the kidneys and surrounding parts. Dr. Chandler did not consider that Dr. Goffe had proven his point in regard to cause and effect due to elongation of the cervix, because other factors enter into this question besides the elongated cervix, and the operation for the relief of this elongation will not cure the whole trouble.

Dr. I. S. STONE, Washington, D. C., stated that his work up to 1900 culminated in an operation which was very much like Dr. Goffe's in making section at the cervix, pushing away the bladder, pressing it out from the broad ligaments and attaching the vaginal wall as high on the uterus as possible; at least as high as the insertion of the round ligaments. There was no trouble in closing the two sides of the vaginal rent and getting a very good result. The idea of placing the bladder high up was entirely original with him. He reported the operation in 1900, when he had gone far enough to excise an elliptical piece from the vagina, after separation from the bladder, according to Dr. Goffe's method so that we get an entirely new implantation, and he also attached the bladder out on the sides of the broad ligament. There is not only a cystocele, but also a prolapse, and a hernia; the chief thing to overcome is the hernia. In the average operation all that is done is to shorten a line which may be compared to a cord stretched across the room and tied up in the center, as in the old Stoltz operation or the anterior colporrhaphy of Sims. It tightens the rope in the center, leaving the same strength at either end with the same weight to bear. Therefore, the idea was to attach the bladder in a new position on the sides of the pelvis and utilize all the surplus of fascia instead of leaving it suspended by its former thin attenuated portions. Dr. Stone spoke of a woman, 60 years old, quite senile, with thin vaginal walls and small uterus, who had a complete hernia of the rectum and bladder, effacing the whole cul-de-sac. The hernia was about the size of a child's head; a typical case for a plastic operation. The operation was done precisely as described by Dr. Goffe. The result was that about six months ago the woman returned after having enjoyed several years of good health. She had a slight hernia of the cul-de-sac itself; the bladder was held in position, firmly anchored; no prolapse of the bladder, and the rectal operation was a success, but there is a slight hernia of the cul-de-sac. The rectal operation is the same in principle as the anterior operation, and both of these special operations are best suited to those difficult cases occurring in women who are not likely to become impregnated.

Dr. J. WESLEY BOVÉE, Washington, D. C., thinks that these operations, as a rule, are overdoing the work required. It is not the attachment of the uterus or the bladder to the peritoneum which is giving trouble; it is an injury of the connective tissue between the vagina and the bladder, and he failed to see the necessity for so complete separation of the bladder and opening the peritoneal cavity, and then lifting it up and attaching the bladder higher. It is a matter of properly repairing the supporting structures, leaving its normal load, the bladder, and improving the support, the anterior vaginal wall. Sometimes this connective tissue is thinned out very materially; the tear not being in one line, but the fibers torn in various positions, and in such a case it is best to support the fascia and splice or overlap it. Do not cut away any connective tissue. If the position of the uterus promotes the sinking of the anterior vaginal wall, perhaps from an elongated cervix, or some other condition, repair this at the time, but, if possible, without entering the peritoneal cavity,

Dr. J. H. BURTONSHAW, New York City, thinks that this new operation marks a distinct advance in anterior-wall surgery. In the ordinary operation for the correction of cystocele an area is denuded and the muscle backed up against itself, which naturally results in a puckering of the posterior bladder

wall into rugæ. This factor has always been objectionable for obvious reasons. He said that more than a year ago, Dr. Reynolds of Boston devised an operation which provided for the excision of an elliptical section of the entire thickness of the vaginal wall, the bladder being separated from its attachment above the edges of the wound, and the ellipse closed by deep sutures. In such a case the absence of rugæ will depend entirely on the amount of tissue removed and on the extent of bladder-wall separation. An objection to the technic lies in the possibility of the giving way of the cicatrix, in which event a hernia of the bladder would result, and a secondary operation be necessary. The operation described by Dr. Goffe does away entirely with the formation of rugæ and with the complications which might arise from their presence. Dr. Burtonshaw said that if the bladder wall is attached to the broad ligaments above the level of the internal os uteri, at a considerable distance from the median line, there is danger of including the ovarian arteries in the ligature, and that when the viscus is attached to such a friable structure as the broad ligament, when it becomes overdisted there is a probability of the permanent sutures and adhesions giving way. Then, too, the anterior vaginal wall is split from a point corresponding to the entrance of the urethra to the cervix; is there not a probability that the resulting cicatrix may contract longitudinally, and so diminish the length of the canal?

Dr. B. C. HIRST said that no one should think of repairing the posterior vaginal wall unless he knew the nature of its injury in labor, nor should he repair the cervix unless he knows how it was lacerated in childbirth. It is exactly the same with the anterior vaginal wall. He said that some of the gentlemen who had discussed the subject had ignored the effect of labor on the anterior wall and had proposed operations which had no more relation to the injury the structure experienced in labor, than if the woman had never been delivered. Dr. Hirst considers that the first essential in devising a permanently successful operation for cystocele is to understand exactly what caused the cystocele, and claimed that his method is based on correct anatomic knowledge and a sufficiently large experience in the examination of women recently confined. Much that has been said illustrates a weakness of American gynecology. During the last generation too many specialists in diseases of women have lacked experience in the greater half of gynecology—the child-bearing period. Our school of gynecology is not so good as it would have been had we followed the custom of other civilized countries by preparing ourselves in the whole science of the diseases of women; familiarizing ourselves with child-bearing, and all stages of the diseases and injuries which follow. He also stated that these operations can be done five or six days after labor with perfect safety. He has been doing this work for some time in a large clinic, and many masters of the best maternities in the world have performed and preferred the intermediate operation. He also said that Dr. Price need have no concern for the safety of the patient, because, if his aseptic technic is what it ought to be, he also could perform the intermediate operation without morbidity or mortality. Dr. Hirst said that though a few surgeons have done successful operations for cystocele, as demonstrated by an experience of two or three years, it is not sufficient to demonstrate the advantage of any surgical procedure for this condition. We have all seen recurrences after nine or ten years following cystocele operations well performed. It requires at least that length of time to demonstrate the permanent value of any operation for this purpose, and his conviction is that ten years hence only such operations as are based on a knowledge of the anatomy and of the original injury of this region will be acknowledged and accepted by the profession as permanently successful.

In reply to a question Dr. Hirst said he thinks the majority of injuries in the anterior vaginal wall are in the lateral sulci.

Dr. GOFFE said that Dr. Chandler thinks that the folds in top of the bladder are dangerous to the ureters and kidneys, but that if he considers this a little longer he will see that they are in the top of the bladder where drainage is perfect and there is no danger of an inflammatory process going

on. Dr. Goffe said that it is in the base of the bladder that his operation smooths out the tissue; that is where inflammations are dangerous to the kidney and ureters. He said that we had elongation of the cervix only in primipara and nullipara, and that the only thing to do is to dissect off the bladder and amputate the cervix. If the cervix is amputated at this point, there is a certain amount of superfluous tissue at the base of the bladder that must be disposed of. He does that by raising up the bladder, but, of course, that is only in a limited number of cases. In the majority of cases, such as Dr. Hirst describes, in multipara, the injuries are multiple. Dr. Goffe said that Dr. Bovée enters the peritoneal cavity about as often as any surgeon he knows and with equal impunity. Entering through the vagina, dealing with the pelvic peritoneum, is freer from danger than entering through the abdomen; the bladder is not carried up high enough on the broad ligament to interfere with the ovarian artery. Of course, there is a line of union and a scar no matter where the incision is made. He finds that Dr. Stone's attachment of the uterus to the vagina so as to carry the bladder up over it and make the uterus act as a cushion is an admirable procedure in advanced cases of senile women, where the uterus has finished all its functions. He recently had operated on such a case. He turned the uterus beneath the bladder and stitched the fundus fast to the vagina, far down near the neck of the bladder, making a cushion of it on which the bladder could rest. It seemed a very useful purpose to which to put the uterus. Some men in Germany are doing the same thing.

CLINICAL EXPERIENCES WITH THE APPENDICULO-OVARIAN LIGAMENT.*

DANIEL H. CRAIG, M.D.

Surgeon to Out-Patients' Free Hospital for Women; Instructor in Clinical Gynecology, Tufts College Medical School; Instructor Boston Polyclinic, Etc.
BOSTON.

Notwithstanding the fact that a rather extensive study of the literature of the subject has convinced me that no such structure as the appendiculo-ovarian ligament, as an independent entity, exists, and that there is neither reason nor professional justice in the association of the name of Clado¹ with the structure thus named by him, I have retained that nomenclature in the title of this paper because, largely through the writings of Durand,² the name has become fairly well known to the gynecologists and abdominal surgeons of America.

I can not better justify the above statement of opinion than by quoting directly from the exhaustive monograph of Nagel,³ in which he says: "The plica genito-enterica, as described by Treitz in 1857, was known long before the work of Clado and Durand, and it is not becoming that this fold should be associated with the name of Clado, as the appendiculo-ovarian ligament, as many authors have associated it, inasmuch as Clado merely mentions it incidentally. The fold under consideration has, like peritoneal folds in general, been described by Treitz, Rouget,⁴ and Waldeyer,⁵ and later

also by Toldt,⁶ Jonnesco,⁷ Broeseki,⁸ Poltauf and the author."³

If the appendiculo-ovarian ligament is not an entity existing apart from other portions of the peritoneum, what is it? A careful study of the region comprised within the true pelvis and extending up over the pelvic brim convinces me that it is merely the continuation upward in varying degrees of prominence of the outer end of the infundibulopelvic ligament. A careful observation in each pelvis opened in which the normal arrangement of the peritoneal folds has not been grossly distorted by growths shows that it is utterly impossible, in about one-third of the cases, to demonstrate any connection whatever between the peritoneal folds about the head of the cecum and the true pelvic portion of the infundibulopelvic ligament. In the remaining two-thirds, drawing the cecum upward and putting the infundibulopelvic ligament on the stretch will clearly demonstrate a direct connection through a peritoneal fold between the infundibulopelvic ligament and the fold of peritoneum extending downward from the cecal region to meet it at the pelvic brim. The upper termination of this fold varies; in about one-third of the cases observed it is directly continuous with the lower angle of the meso-appendix, but in many cases runs behind various portions of the cecum, or in some cases the mesentery of the ileum, and has no manifest relation with the appendix whatever.

An important element in the production of confusion in the study of this structure is the variety of names under which various authors have described it. Beginning with Treitz, it was called the genito-enteric fold. Since this time the Germans have generally spoken of it by this name, or perhaps even more commonly as the *Ligamentum suspensorium ovarii*. The French have either followed Rouget, and called it the superior round ligament, or more recently, following Clado¹ and Durand,² have called it the appendiculo-ovarian ligament. In this country it has been most commonly called the appendiculo-ovarian or lumbo-ovarian ligament. Careful study proves conclusively that the structures mentioned under these various names are identical.

Much error has arisen from the ambiguity of Clado's¹ original description, in which he says: "On raising the appendix it is seen that a peritoneal fold is formed which is continuous with the superior border of the broad ligament at its superior concavity. It is falciiform, with its narrowest part corresponding to the iliac vessels, and measures at this point only one or two centimeters in height." How this has caused confusion is seen later.

Clado's writing was given greater prominence three years later by the more specific work of Durand,² who says: "The ovary is attached to the posterior part of the lateral wall of the pelvis by a ligament which suspends, in a measure, its outer extremity. This agent of fixation has been described under different names. Henle calls it the infundibulopelvic ligament; Rouget⁴ gives it the name of superior round ligament; Clado calls it the appendiculo-ovarian ligament, while others call it simply the lumbo-ovarian ligament."

Durand further states that the appendiculo-ovarian ligament may take its origin:

1. From the meso-appendix; this is most frequently the case.

2. From the peritoneum which envelopes the terminal portion of the ileum.

3. Exceptionally, behind the head of the cecum.

From a careful study of the embryologic origin of this structure, as described so lucidly by Treitz, Hammerschlag,⁹ Nagel¹ and others, it is quite evident that it is an error to speak of this fold as taking its origin from anywhere in the lower part of the abdominal cavity. It is certain that this fold marks the path followed by the ovary and its vessels in their descent from their place of first appearance in the Wolffian body, high up near the liver and kidney, and that Nagel is correct when he says: "The *Ligamentum suspensorium ovarii* springs, developmentally, from the phrenic ligament of the kidney, being, therefore, naturally situated on the posterior abdominal wall." He further remarks that the spermatic vessels, lymphatics and nerves constitute the essential causal element and foundation of this fold, later to become the suspensory ligament of the ovary.

From the above description, which confirmation by many competent observers leads me to accept as correct, it seems grossly inaccurate to speak of the origin of this ligament in connection with the appendix. The cecum and appendix are also formed high up in the region of the right kidney and liver, where they remain until a relatively late period of fetal life, arriving in the iliac fossa only at about the sixth month. In their descent they follow the same path as that taken by the ovary. It, therefore, seems apparent that the point of disappearance of the suspensory ligament will depend entirely on the position which the cecum finally assumes as permanent with relation to the path of descent of the ovary. Both structures traveling downward retroperitoneally, it inevitably follows that the more bulky cecum will at a given but variable point, cause such a lateral tension of the peritoneum as to obliterate the lesser fold produced by the ovary and its vessels. We should, therefore, speak of the point about the cecum or pelvic brim as that at which the suspensory ligament becomes indistinguishable rather than that at which it arises.

Many authors could be quoted to sustain this view, but two of those better known to all will suffice. Abel¹⁰ says: "The ovary is suspended between the suspensory ligament of the ovary (running to the cecum and the vermiform appendix on the right side and to the sigmoid flexure on the left), and the ovarian ligament (running to the uterus)." He thus distinctly marks the disappearance rather than the origin of the ligament in the iliac region.

Lockwood,¹¹ too, perhaps unconsciously, confirms this view when he says: "This (the appendiculo-ovarian ligament of Clado), is a fold of peritoneum which is prolonged upward and outward from the infundibulopelvic ligament to the meso-appendix, and I would add, in some cases, to the cecum and mesentery."

If this view of the situation be correct, it would seem that any such lymphatic connection between the uterus and its appendages and the appendix as Clado described would be incidental and dependent entirely on anastomoses between the two sets of vessels after their migration was complete, and might or might not exist

in any given case. Therefore, even though the extra-pelvic portion of the suspensory ligament—as I prefer to designate this fold—be well marked, there would not necessarily be any clinical connection between the right uterine appendages and the appendix vermiformis.

Clinically, this view receives ample support because, since beginning the study of this subject, several cases have been personally observed in which, notwithstanding the existence of a well-marked extra-pelvic ligament and suppurating going on at one or the other end of it, the ligament was in no way involved and was apparently of not the slightest clinical significance in the case.

The literature of the anatomy, embryology and pathology of this structure, when divorced from the specific name of appendiculo-ovarian ligament, is enormous, but on turning to the clinical side of the question it is equally meager. To Clado its clinical significance depended entirely on the ability of its lymphatics to convey infection from the uterine appendages to the appendix, and *vice versa*.

Fraenkel¹² quotes Treub, Olshausen and Stratz as reporting cases in which the "plica genito-ovarian" played such a clinical part.

Charpy¹³ speaks of the significance of this upward extension of the broad ligament in determining the reason for the so frequent association of broad ligament and iliac suppurations.

Kustner¹⁴ speaks of the contraction of the suspensory ligament of the ovary as causing a certain degree of uterine torsion.

Deaver¹⁵ speaks of the appendiculo-ovarian ligament as constituting a close bond, clinically, between the appendix and the right appendages.

Graves¹⁶ considers this structure, under the name of the lumbo-ovarian ligament, capable of producing retro-displacements of the uterus in cases in which the descent of the ovary has been incomplete.

While many cases have been personally observed in which extra-pelvic portions of the suspensory ligament could be plainly demonstrated, I have observed only five, with a problematical sixth, cases in which this structure was of actual clinical importance. The sixth is spoken of as problematical because not yet confirmed by operation.

The histories of these six cases are as follows:

CASE 1.—Mrs. E. H. McL., private patient, Feb. 2, 1902; aged 35, married three years; never pregnant; would be glad to have children. Husband healthy. Father living. Mother died of consumption. No other tuberculosis in the family.

History.—When 17 she fell down stairs during menstruation; this stopped the flow and caused much neuralgic pain. Catamenia began at 13. Always regular but painful during girlhood; no pain now. Flow lasts five days, using from twelve to fifteen napkins and having some clots. Last menstruation on Jan. 6, 1902, exactly on time. Developed la grippe on first day of flow and flow ceased for three days, after which it was resumed and its course was normal. She has much distress in base of brain and has stiff neck. Not much backache, but

back is not strong. She has much pain in both iliac regions, which is relieved by drawing up the thighs. She has a small inguinal hernia on the left side. There is considerable pain of a dragging character high up in the right hypochondrium. Nearly constant leucorrhœa, "bearing down" pains and marked dyspareunia, which was not present in the earlier part of matrimonial life, but which is steadily increasing. Micturition is frequent and considerable in quantity, requiring her to rise once or twice each night. Urine looks clear; there is occasionally painful smarting after urination. She has flatulent dyspepsia; bowels usually regular. She drinks three cups of tea a day. Appetite is variable and she is very nervous. She sleeps well, but is not rested in the morning, and dreams constantly.

Physical Examination.—Slight cardiac hypertrophy. Right kidney low but not freely movable. Considerable tenderness over appendix. Uterus normal size; cervix anteflexed. Thickening in left side, which might be thickened broad ligament or a small prolapsed ovary. Right ovary large, low, close to postero-lateral aspect of the uterus. Utero-sacral ligaments short and sensitive. Under date of April 6, 1902, following entry appears: Has been ill with severe pain in the right hypochondriac region, extending up into the right shoulder. Now has tenderness over the site of the gall bladder. Pelvic condition as when last seen.

Operation.—April 12, 1902. Median incision. Many loops of small intestine bound down to right tube and ovary by soft adhesion, easily separated. Right broad ligament presents a broad triangular surface superiorly. This surface was divided into three distinct ridges with two fossæ between them. The anterior ridge was produced by the round ligament, the middle one by the tube and the posterior by the ovarian vessels. This posterior fold was the analogue of the suspensory ligament of the ovary and was unique in that the ovarian vessels ran in its free border instead of, as usual, in the deeper portion, and they persisted in its free border, quite away from the posterior abdominal wall, to the point of their disappearance behind the cecum and base of the mesoappendix. The ovarian vessels were of normal size and could be traced high up behind the ascending colon. A second artery ran in the anterior ridge below the round ligament nearly as large as the ovarian and seemed to be an anomalous origin of the deep epigastric. The ovary, large and of unhealthy appearance, was on the posterior aspect of the broad ligament, low down close to the uterus. Marked tension and thickening of the entire broad ligament, and especially of the extra-pelvic portion of the suspensory ligament was plainly manifest. The left tube and round ligament were entirely absent, the left border of the uterus being perfectly smooth and round. The broad ligament extended only slightly above the level of the internal os and was firm and strong, and contained in its depths what felt as though it might have been a small rudimentary ovary, although nothing in the left side of the pelvis gave the slightest evidence of an ovary having descended through it.

A relatively large V-shaped piece was excised from the suspensory ligament just below the pelvic brim and all but a small, comparatively healthy portion of the right ovary was removed. Exploration of the gall bladder and kidney showed them to be apparently entirely normal. Appendix normal.

The subsequent history of the patient has been excellent and I have heard from her frequently. The right hypochondriac pain has never appeared since the operation and appears to have been the direct result of the downward traction on the vessels.

CASE 2.—Miss A. T., referred to me at my clinic at the outpatient department of the Free Hospital for Women by Dr. Johnston; aged 28; single; worked in carpet works; heavy work. Family and past history irrelevant.

Present History.—For the past two months she has had nearly constant pain in the right loin, which is worse when fatigued. She was obliged to give up work over a month ago. First catamenia at 13. Always regular and always painful. Pain one day before and relieved by flow. Duration, three days, requiring four napkins. Last catamenia May 6, 1903,

exactly on time. Rectum feels sore as though something were pressing on it. Bowels inactive. Micturition normal. Appetite and digestion good. Very nervous. Has a constant burning sensation in the gluteal region, which is aggravated by sitting. Poorly nourished.

Physical Examination.—Chest and abdomen negative except that abdominal muscles seem lacking in tone. Marked tenderness at McBurney's point, and a band can be plainly felt extending from cecal region down into right true pelvis. Uterus drawn a little backward and far to the right. Cervix anteflexed and undeveloped. Right ovary high up.

The preoperative diagnosis made to Dr. Johnston was that of chronic appendicitis with a strong probability of the existence of an appendiculo-ovarian ligament of Clado in a state of pathologic contraction. With the consent of Dr. Johnston I referred this patient for operation to a surgeon whom I knew to be engaged in the investigation of the appendiculo-ovarian ligament, thinking he would be glad of the case. Much to my astonishment, a little later Dr. Johnston reappeared with Miss T., saying that the surgeon mentioned said that there was nothing the matter beyond a general run-down condition and that a rest and vacation would make her all right in a short time. Inasmuch as the patient had been under his care constantly for four months and had done no work for one month and was steadily growing worse, Dr. Johnston was indignant.

Operation.—May 22, 1903. Present, beside my regular assistants and nurse, Drs. Johnston and Badger. Appendix was found bound down to posterior aspect of the head of the cecum, which was relatively long below the ileocecal junction. From the base of the mesocolon the extrapelvic portion of the suspensory ligament was clearly defined, exactly confirming the physical diagnosis. The appendix and a V-shaped piece of the ligament were removed. The pelvic organs were otherwise normal and not involved in the operation.

Result.—Just one year from the date of operation I called up Dr. Johnston and he assured me that Miss T. had been entirely relieved by the operation; that two months from the day of operation she resumed light work with her old employers, and has now for six months been at her old heavy employment in the enjoyment of perfect health.

This is, so far as I am able to learn, the first case recorded in which the existence of the appendiculo-ovarian ligament, so called, was made before operation.

CASE 3.—Mrs. C. E. S., private patient referred to me by Dr. E. S. Winslow of Orange, Mass; aged 23; married six years and has had two children and three miscarriages. Older child 4 years and younger 3 years old.

History.—First miscarriage at three and one-half months, second at four months and third at only a few weeks. First procured. In bed ten days after first child, seven days after second, and only two or three days after the miscarriages, which were accompanied by considerable hemorrhage. First catamenia at 12. Irregular during first two or three years. Pain variable in amount for one or two days before and first day of flow. Duration of flow from four to five days. Last catamenia just ended. Has had typhoid fever and several attacks of pneumonia, and had diphtheria three years ago. Present trouble began after first child and has been worse since the second. The miscarriages have all occurred since the second child and have added to her ill-health. Much pain in sacral and right iliac region, and also some pain in the right hypogastrium and in the left iliac region. She has attacks of severe pain in the epigastrium, and has pelvic "bearing down" pain. Leucorrhœa not constant but produced by exertion. Micturition normal. Bowels inactive. Appetite variable. Digestion poor; pain after eating. Sleeps poorly. Lying in bed makes back and side ache worse. Dyspareunia, causing more pain on right than on left.

Physical Examination.—Heart normal. Slight bronchitis. Right kidney very much enlarged. Perineum torn. Wall between vagina and rectum very thin in median line of perineum. Cervix lacerated and everted, but not much eroded. Uterus in normal axis, but drawn to right and slightly enlarged. Left

ovary enlarged and very tender, but not prolapsed beyond the utero-sacral ligament. Right ovary enlarged and apparently cystic and not freely movable. Very tender. Moderate tenderness starting at McBurney's point and increasing as pelvis is approached. No tenderness at Boas' point.

Operation.—Jan. 9, 1904. Dilated and curetted uterus. Trachelorrhaphy and perineorrhaphy. Median abdominal incision and both ovaries suspended to uterine cornua after removing cystic portion of the right one and removing a V-shaped piece from the thick, tense extra-pelvic portion of the suspensory ligament. Exploration showed appendix normal, but angulated by downward traction by suspensory ligament, which was entirely freed by the above mentioned excision. The appendix was not removed. The mass supposed, on physical examination, to have been an enlarged, movable kidney, was found to be a rolled-up mass of omentum. Adherent to several loops of small intestine and to the ascending colon. Without the removal of any organs this patient is reported as recovered and back at her work after five months.

CASE 4.—Mrs. W. R. C., private patient, aged 35; married six years. One child six and one-half years ago. No miscarriages. Family history irrelevant. Present trouble began in 1896.

History.—Got her feet wet during menstrual period and flow ceased suddenly with severe pain in hypogastrium and both iliac regions. First catamenia at 14 and always regular. Pain was slight at first, but was worse after undertaking a sedentary occupation. Later standing also produced pain in lower abdomen and back. Flow lasts two or three days, requiring five or six napkins. Lately it is more profuse and lasts longer. Last catamenia started Feb. 12, 1904, and on going out in a storm on February 15 she became wet and chilled and the flow ceased and pain has been severe ever since (four days). Pain in lower abdomen and back is constant, of a dull, aching character. There is also a "bearing down" pelvic pain, and a sensation of dragging in the right side. Little inconstant leucorrhœa. Bowels inactive, probably partly due to large quantities of opiates required for pain. Micturition frequent. Frequent frontal headaches. Appetite and digestion variable.

Physical Examination.—Heart normal except for accentuation of aortic second sound. Abdomen shows abnormal tenderness at McBurney's point extending continuously down to ovarian region. Colon much loaded. Uterus slightly ante-flexed and a very little drawn to the right. Perineum intact. Cervix shows fair result of trachelorrhaphy done in September 1903, at Homeopathic Hospital.

Operation.—April 9, 1904. Uterus, both tubes and both ovaries and rectum matted together in posterior part of pelvis. Right ovary completely degenerated with an outgrowth from one side. Left ovary hard and cirrhotic. Both tubes nodular and occluded. Extra-pelvic portion of suspensory ligament very prominent, thick and tense. Appendix normal and not removed. Both tubes and both ovaries removed; suspensory ligament completely relaxed after removal of right ovary. Patient has required no opiates since operation and, although too early to speak of ultimate results, she is already in much better health than for years. There is neither pain nor tenderness in the appendicular region.

CASE 5.—Mrs. N., operated on at the Free Hospital for Women, Nov. 27, 1903. The long hospital history is abbreviated because irrelevant, as regards the structure under consideration, except for the existence of right iliac pain and the manifestation of tenderness about the appendicular region extending down to the ovarian region. The traction of the tense extra-pelvic portion of the suspensory ligament, transmitted through the mesoappendix, produced a sharp angulation of the appendix, which angulation disappeared on severing the ligament. The subsequent history of this case is not known.

CASE 6.—Mrs. A. D., patient of Dr. Farnum of Randolph, Mass. Has the history of right iliac pain with tenderness extending continuously into the right ovarian region and a band can be felt similar to that which determined the diagnosis in Case 2. This case is, however, as yet of no value, in the present connection, as the diagnosis lacks operative confirmation.

These cases possess several points in common which should serve as diagnostic guides in the future. There is, first, the tenderness starting high up in the right iliac region and extending continuously down to the true pelvis; second, there is the sense of dragging in the iliac region; third, there is the more or less pronounced displacement of the uterus to the side of the pelvis in which the contracted ligament exists. In every case, instead of the tenderness being localized about the appendix or instead of having, as is so often the case, an area of tenderness at the appendix and another lower down in the ovarian region, the tenderness has been found continuous.

The studies of Rouget,¹ Testut¹¹ and Sappy, among others, show conclusively that there is a very considerable amount of smooth muscle fiber in the suspensory ligaments, and any irritation at either end of this ligament may produce contraction of these fibers, which may bring it into no slight clinical importance. One fact in the clinical significance of this structure seems to me to have been misinterpreted by some authors, namely, the ability of this structure to cause retro-displacement of the uterus.

We ordinarily think of the broad ligaments as extending out, nearly transversely, to the pelvic walls and of the appendiculo-ovarian ligament as a band coming down from above to join the superior border of the broad ligament. This, of course, would convey the impression that shortening of the appendiculo-ovarian ligament would pull the top of the broad ligament toward the posterior wall of the pelvis, which would, equally, of course, produce retroversion. When, however, the anatomy is carefully studied, and it is realized that the so-called appendiculo-ovarian ligament is in reality but the extra-pelvic continuation of the infundibulopelvic portion of the broad ligament, it is easily seen that the only uterine displacement which tension on this band alone can cause is exactly identical with tension on the remainder of the broad ligament, namely, lateral deviation with possibly slight torsion, as noted by Kustner, and as exemplified in each of the above cases.

It is also manifestly a fact that this structure is as liable, anatomically, to become of clinical importance on the left side as on the right, although, so far as I have been able to learn, no instance of this has as yet been reported.

The fact that in all but one of my cases the appendix appeared normal, and on being left in the abdomen has given rise to no symptoms, seems to negative the tentative opinion that the existence of the appendix on the right side makes that ligament more liable to irritation.

In all these cases the extra-pelvic portion of the suspensory ligament of the ovary, or as more commonly known in American and English medical literature, the infundibulopelvic ligament, certainly was an important clinical factor, and in three of the cases was apparently the only disease-producing factor.

386 Commonwealth Avenue.

17. Testut: *Organes Genitaux de la Femme. Traite d'Anatomie, Humaine*, Paris, 1901, pp. 783-896.

The Surgery of the Ancients.—At a recent meeting in Athens M. Smyrniotis exhibited some surgical instruments from a tomb near the long wall of the Piræus, dating from about the first century A. D. Many of these are similar to those now in use and he thought they gave evidence of an eminent surgeon, now unknown, who resided there nearly 2,000 years ago.

PELVIC DEFORMITY.*

GEORGE M. BOYD, M.D.
PHILADELPHIA.

Pregnancy or labor complicated by pelvic deformity will always be of great interest to the obstetrician. As the subject is one that has attracted attention from the earliest times, it would now seem that the ground had been pretty well covered, but there still exists some difference of opinion in regard to the treatment of these cases.

My conclusions are the result of following the work of the Philadelphia Lying-in Charity Hospital for the past fifteen years, during which time over 10,000 cases have been cared for in its various departments. The hospital, owing to its central location, does a large amount of emergency work, many of the cases entering at the end of gestation, and some already in labor.

When the American Medical Association last met at Atlantic City, in 1900, I presented to this Section a paper entitled "The Classical Cesarean versus the Porro Cesarean." In that paper¹ I reported six successful cases for pelvic deformity. Since that date I have had six additional cases, all successful to mother and child. Five of the latter cases have also been reported, and I will in this paper place the twelfth on record.

Sufficient material is now at our command to enable us to better approximate the frequency of pelvic deformity in this country. Reynolds² reported that he had observed 1.34 per cent. of contracted pelves in 2,327 women delivered in Boston. This percentage is estimated from the cases requiring operative interference, and does not include those delivered spontaneously. Edgar states that the frequency of contracted pelves in native-born American women has been estimated at 2 per cent., and among foreign-born women at 6 per cent.

In a study of the records of the Philadelphia Lying-in Charity Hospital for the past ten years (1894 to 1904), we find 3,224 deliveries, with but 76 cases, or 2.5 per cent., of deformity of the pelvis demanding surgical interference. As in Reynolds's report, this study does not include cases of pelvic deformities delivered spontaneously.

Williams³ reports that he has met with 131 contracted pelves in the first 1,000 women delivered in the lying-in department of the Johns Hopkins Hospital. In June, 1901, he gives the results obtained in 1,123 additional cases, which showed exactly the same percentage as in the previous report. A total of 2,133 cases with a percentage of 13.1. He states that one reason for the marked frequency of contracted pelves in Baltimore is probably due to the fact that more than half of the patients are colored, 941 in the entire series being white and 1,182 black women. In the former he found 6.9 per cent., and in the latter 18.82 per cent. of contracted pelves.

From the study of these reports we find pelvic contraction occurs in 7 or 8 per cent. of white women in America, and only in 2 per cent. of cases studied from the standpoint of demanding surgical interference.

It is evident that no one can practice obstetrics without meeting some such cases. Although pelvic deformity is primarily readily diagnosed, the more so the

greater the deformity, the habit of forming quick judgment is not justifiable, as the extent and nature of the malformations are not easily ascertained, and a more general use of the pelvimeter will lead to an earlier recognition of pelvic deformity. While the pelvimeter is invaluable in securing accurate measurements of the external pelvis, the difficulties of determining the capacity of the pelvis by present methods are easily recognized. Fatalities have resulted where most careful measurements made on the living patient showed errors oftentimes of over half an inch at the postmortem. Recognizing the inaccuracy of pelvic measurements, either by means of the pelvimeter or manually, we acknowledge the truth in Barbour's comprehensive opinion, "the fetal head is the best pelvimeter."

Müller's method of estimating the relative disproportion between the pelvis and fetal head, and Kerr's modification of this method, are not always reliable. The cephalometer of Perret and Budin, by which an attempt is made to measure externally the biparietal diameter, must necessarily also be unreliable.

What we are interested in is not so much the variety and degree of pelvic deformity, but whether the passenger is or is not too great for the passageway.

In the cases of great deformity, which are rare, the diagnosis is easy and the course to pursue clear, but in the larger group of cases of moderate deformity, it is not possible to accurately estimate the disproportion between the pelvis and the fetal head.

TREATMENT.

In pelves of great degree of deformity, the treatment is not so difficult; the forceps, symphysiotomy and cesarean section with the living child, and craniotomy if the child is dead, must be resorted to. In the larger group of cases, however, there exists only a moderate degree of contraction, and in this class great judgment must be exercised. The proper solution of the problem will depend on the study of many factors: 1, Whether one first sees the case during pregnancy or after labor has commenced; 2, the general condition of the mother; 3, the nature of the presentation; 4, condition of the fetal heart; 5, multiple pregnancy.

It is not my desire to take up each method of treatment. There is one, however, concerning which there exists a difference of opinion, namely, the induction of premature labor. The advocates of this method of treatment recommend it in minor degrees of pelvic contraction.

The induction of premature labor would be ideal were it possible to accurately measure the length of the period of gestation. I have never been able to satisfy myself that this is possible, and prefer to permit the patient to go to term.

Hirst,⁴ favoring the induction of labor, says: "If the conjugate diameter measures as low as 9.5 cm., it is a safe plan to induce labor four weeks before the expected term of pregnancy."

Norris⁵ states that he is inclined to feel that cesarean section is too frequently resorted to; he reports 29 cases of induced labor with no maternal mortality; and only 10 per cent. fetal mortality. He would resort to induction of labor only in pelves of minor degree of contraction.

Reynolds, Williams and Edgar, on the other hand, pre-

fer to permit the patient to go to term, giving her the trial of labor, and then instituting the method of delivery most expedient.

The high fetal mortality, and the difficulty of estimating the length of gestation, has led many to follow the expectant plan. Kleinwochter, after an exhaustive study of the subject, concludes that 78.3 per cent. of the children are born alive, but that many of them die soon after birth, and only 60.4 per cent. leave the hospital in good condition.

Is the induction of premature labor justifiable admitting the difficulty of estimating the length of gestation?

My experience has not been as satisfactory as that of those who advocate this operation. Even with a clear menstrual history, we must admit the fact that the patient may have conceived at any time before the next menstrual epoch, a period covering three weeks. Then, again, in some cases it is impossible to get the menstrual history. These cases must, of course, be excluded from this method of treatment. Again, the methods of inducing labor are not always satisfactory. The Simpson method, the introduction of one or two bougies into the uterus, does not always bring on labor promptly; the bougies sometimes rupture the membranes, and in some cases necessitates hydrostatic methods by dilatation. I therefore feel that I can best serve my patient by permitting her to go to term.

How frequently we have all prepared for a difficult forceps operation, version, symphysiotomy, and even cesarean section, only to have the patient spontaneously deliver herself. Admitting this fact, how, then, can one, four weeks before the end of gestation, feel sure that the induction of premature labor is indicated? Each case must be a study in itself. In the primipara the course to pursue will be more intricate than in the multipara, where we have the history of the previous labor to guide us. In the majority of cases the forceps will suffice; failing in this method, version is indicated, or cesarean section in the exceptional cases.

In reviewing my eleven cesarean sections, I find that in seven of the cases they were given the test of labor. The twelfth case, with the following history, was an elective operation:

Mrs. —, a negro and primipara, aged 18 years, an American, was admitted to the Medico-Chirurgical Hospital, Oct. 3, 1903.

Her last menstrual period was Feb. 22, 1903, and from her own calculation she expected her confinement November 29. The patient showed marked evidences of congenital rickets and gave a clear history of same. She had the characteristic general bony and pelvic deformities.

The following measurements of the pelvis were made: Interspina measurement, 22 cm.; intercrestal measurement, 22 cm.; external conjugate measurement, 16 cm.; diagonal conjugate measurement, 7.5 cm.; true conjugate measurement, 6 cm.

The elective cesarean section was performed for the absolute indication. The patient made an uneventful recovery and left the hospital Dec. 15, 1903, in good condition.

CONCLUSIONS.

In conclusion I would say:

1. The fetal head is the only trustworthy pelvimeter.
2. It is essential to give the patient the test of labor in the majority of cases of moderate pelvic deformity.

3. It is the duty of the practitioner in attendance on a multipara with the history of one or more dead children to be prepared to perform cesarean section. If he does not possess the necessary surgical training, he should call to his assistance the obstetric surgeon.

1909 Spruce Street.

DISCUSSION.

DR. C. S. BACON, Chicago.—The most important point in Dr. Boyd's paper is the objection to the induction of labor for contracted pelvis. The objections that he makes to the operation of inducing labor are the difficulty of determining the length of gestation, the difficulty of the operation and the unsatisfactory results. In regard to the length of gestation, I believe that is not so difficult as Dr. Boyd intimates. In the majority of cases we know the date of the last menstruation, and, if we take a careful history, we can often find the date of conception. If we will note the time of the beginning of the morning sickness, and the time of the first fetal movements, we have two very important data. It is not usual for the morning sickness to begin before the third or fourth week after conception, and it is uncommon for it to begin very much after the seventh or eighth week. That gives us a period of uncertainty of only two or four weeks. Then, as a rule, the fetal movements begin about the eighteenth or nineteenth week of pregnancy. And if we have this date we are not more than two or three weeks away from the date of the termination of the labor, provided it terminates at the usual time. With regard to inducing labor, the use of the bougie frequently is slow, but the bougie, combined with the metreuxyter, after the first twelve or twenty-four hours, is a reasonably rapid method, and it is no real objection to the operation. With regard to the results, the mortality of the children often is high, but principally because they are not taken care of properly. No one should induce labor in contracted pelvis without taking all precautions to save the child. With a good incubator and a trained nurse there is little difficulty in raising the child, if it is thirty-four weeks old, and often when it is only thirty-three or thirty-two weeks old. With such results to be obtained, it would seem that this method should not be abandoned. Of course, there is the test of labor which Dr. Boyd mentioned. That is always necessary. One should not induce labor for the first child. But with a moderate degree of contraction, with the history of the first labor, where, perhaps, a dead child was delivered with forceps, the induction of labor at any time between the thirty-second and thirty-sixth week is a method worth considering. Those who will follow this out carefully will have results that will not justify the conclusions at which Dr. Boyd has arrived.

DR. ROSA WISS, Meridian, Miss.—I am glad to hear Dr. Boyd say that it is only fair to the patient to give nature a chance. Some time ago I was called to a case when the labor was in progress. The patient was 40 years old and had never had a child. She had been married three times, and this was her first pregnancy. She lived in a squalid home, and I had nothing at hand for the performance of a radical operation. I made an examination and found a masculine contracted pelvis. I told her husband that I had little hope, but would do all I could. I sent for the nearest physician to help me. The labor progressed rapidly but with severe pains until the head reached the floor of the pelvis, when we had trouble. While the physician was preparing his instruments in the next room I introduced my hand and pressed on the child's head. While I was doing this the woman had a very hard pain and the head came down a little. I continued the pressure, and, much to my surprise, the woman delivered herself of an eight and a half pound child, which began to cry before the whole body was delivered. The perineum was not torn, and the patient made a rapid and uneventful recovery. Two years later I was called again, but before I could reach the house the child had been born.

DR. FRANK CARY, Chicago.—I was very much pleased to hear Dr. Boyd advocate the expectant plan; there are, however, a few points that he did not mention and which are important. We know that cases with quite contracted pelvis frequently deliver themselves normally, sufficient time being allowed. I have in mind a case I saw in Schauta's clinic on which a cesarean section was performed successfully. Within two years she presented herself again, but refused absolutely to have another section. After a long and tedious labor she was delivered of a living child, showing that these cases can

terminate normally. I want to put in a plea for this, i. e., consider the relative size of the child's head and degree of ossification of cranial bones before resorting to cesarean section on pelvic measurements alone.

DR. GEORGE BOYD—I do not wish to condemn the induction of labor, but I maintain that I am unable to judge when it is right to perform the operation, because I can not measure the length of gestation, and, I believe, we never will be able to do so. A miscalculation of two or three weeks means much. In one way the induction of labor is of no value, and in the other the baby has not reached the stage of viability and will not live, even with the best of care. Only recently I saw a photograph of a patient in whom there existed a degree of pelvic deformity so great that the attendant felt that it was beyond the induction of labor, and that there might be a necessity for performing a cesarean section. That same patient was delivered in easy labor. If premature labor had been instituted that operation would have received the credit for the delivery. I can not decide what to do before the patient comes to term, and particularly in cases of moderate degree of contraction. Dr. Cary speaks of the necessity of studying the size of the head. I mentioned Mueller's method, which consists of pressing the head into the pelvis, in that way hoping to approximate the amount of disproportion between the fetal head and the pelvis. I have always tried to study the size of the child's head, but even with that precaution, in a case in which the head is high and apparently movable at the brim, or high and not movable, give that patient five or six, or even eight hours labor, and you will be surprised to find the head in some cases well down in the pelvis.

IS CESAREAN SECTION A RATIONAL METHOD OF TREATMENT IN PLACENTA PREVIA?*

JOHN F. MORAN, M.D.

Professor of Obstetrics, Medical Department Georgetown University;
Obstetrician to Columbia, Georgetown University Hospital, Etc.
WASHINGTON, D. C.

The importance of this subject is not from its frequency, but from the emergency of the situation, which demands early recognition and prompt decision by the physician, in that it involves the lives of both mother and unborn child, and, as regards himself, points of professional honor and conscience. In the complications that confront the obstetrician there is none that is fraught with more danger or attended with greater anxiety than placenta previa, save, perhaps, eclampsia. Its sudden onset, often alarming hemorrhage and consequent anemia, shock, and possible sepsis present a formidable array of difficulties that even in the hands of the most skillful has been attended with a high maternal and fetal mortality. It is true that in recent years, with more definite method of treatment and advances in asepsis and antiseptics, the maternal death rate has been greatly lessened, but the extraordinarily high proportion of infants lost remains unchanged.

If we analyze the statistics, we can not fail to recognize that it is the lateral and marginal varieties that have contributed largely to this improved showing by directly sacrificing the life of the child by using it as a plug to control the hemorrhage. In central implantation, modern methods have not materially affected the death rate. It was quite natural, then, that other measures would be evolved with the hope of reducing the frightful infant mortality, while still not decreasing, if not improving, the chances of the mother. Hence for more than a decade from time to time the justifiability

of cesarean section in certain cases of placenta previa, in the interest of the child as well as of the mother, has claimed the attention of the medical profession. Ford,¹ Dudley,² Zinke,³ Boyd⁴ and others have recommended it on theoretical grounds, with the conclusion that it is not only justifiable, but indicated in central implantation of the placenta. On the other hand, there are those who are equally positive in their belief that cesarean section has no legitimate field in placenta previa, contending that the mother's life is of paramount importance; and further, that many of the infants will of necessity be born prematurely and likely to succumb shortly after birth. The physician has no moral right to decide between the value of two lives, nor is he in conscience capable of determining whether the child will survive or not. Both are his patients, entitled to his best skill, and he is in honor bound not to deliberately sacrifice the life of one to save the other.

It has been contended also that there is danger of postpartum hemorrhage after section, as the placenta occupies the lower or passive segment of the uterus, which will interfere with its retractility, which, together with the muscular contractility of the uterus, controls hemorrhage under normal conditions. I have carefully studied all of the cases, and find but one instance where it was necessary after doing a Sanger operation to follow it by a Porro on account of hemorrhage. Donohue says that the hemorrhage may be prevented by allowing the uterus to contract and retract, and permitting the centrally or marginally implanted placenta to separate spontaneously. It is also suggested that the same end might be accomplished by packing the uterus with gauze. In a case in which I recently performed cesarean section for contracted pelvis complicated with inertia uteri, in which the uterus remained relaxed, I adopted the latter procedure in conjunction with normal salt solution with excellent results.

My only personal experience with this method of intervention in placenta previa is a case I saw in consultation:

The patient was 31 years of age, had been married nine years and was pregnant for the first time. At four and a half months she bled, again at five and a half months, and again at six months, when she had labor pains. Examination under chloroform disclosed a small vagina, cervix not effaced, and placenta covering the internal os. The vagina was tamponed and patient carried to the hospital. Labor pains increased. The tampon was removed, cervix found to be shorter but os about the same, and the vagina was repacked on account of hemorrhage. Owing to age of patient, small vagina and undilated cervix, I had no hesitation in assenting to section, as in my judgment she would suffer less shock, hemorrhage and traumatism than if attempt was made to deliver per vaginam. The child and placenta were removed through the incision and uterus contracted satisfactorily. The mother made an uneventful recovery.

If any lesson is to be learned from this, it is that the weighing of the factors in each case and decision as to operation should be prompt, and the method of relief performed as speedily as circumstances may permit.

SUMMARY OF CASES REPORTED.

In looking over the literature for placenta previa, I have been able to collect twenty-four cases of cesarean section, performed by twenty-one operators. Seventeen of these were of the complete implantation, two lateral,

4. Boyd: Proceedings Philadelphia Med. Soc., Philadelphia, 1901, xxli.

and in five the variety is not mentioned. Fourteen were operated on according to the Sanger method, seven by the Porro, and three not stated. The majority of these were emergency cases, and were in unfavorable condition from repeated hemorrhage and were operated on after other methods had failed. Of the mothers who died, three died within twenty-four hours of shock; one on fourth day after secondary operation for obstruction of the bowel, and the other of septic peritonitis fifty-six hours after operation.

Nineteen mothers and eleven infants recovered, a mortality of 20.8 per cent. and 54.3 per cent., respectively. Eight of the infants were operated on before viability, or were dead before extraction, and five died from various causes in from several hours to four days after delivery. It is reasonable to suppose that the five that died after birth would have shared the same fate after delivery *per vias naturales*, or might have perished during delivery, though certainly their chances of life were increased by section. This 54 per cent. should not properly be taken as the statistical basis of the operation of the future. In selective cases, when pregnancy is far enough advanced for a viable child, and where the operation is done at once and before protracted bleeding has taken place, the figures will be far better than this.

These cases and the references to the records thereof may be briefly given as follows:

Those who advocate cesarean section for placenta previa seek to justify their contention by the brilliant

results obtained by the classical methods in elective cases of contracted pelvis by Reynolds, Zweifel, Leopold, Evert and others, who have reduced the mortality below 2 per cent. This is unfair, however, because the pathologic condition is essentially different, the choice of operation and even diagnosis of lesion radically different, and the results must vary materially. We should only compare section in placenta previa with the results obtained by other methods of intervention, and further, class the latter according as the case was of the partial or complete implantation. This is a difficult matter, however, since statistics are usually gathered from all varieties, and in partial and marginal cases the mortality should not be high. Gillette, in 216 cases collected from various sources, found 88 of the central variety, and in 20 of these the mothers died, or 22.8 per cent.; infants, 66, or 70.5 per cent. Shauta, in 234 cases occurring in his clinic reports, 50 complete implantations with a maternal mortality of 9, or 18 per cent.; infants, 35, or 70 per cent. In 16 cases occurring at Columbia Hospital, 3 were of the complete variety, one patient died, or 33 1/3 per cent. I have had 7 cases, 2 occurring in the same patient; 3 of these were of the central variety. One of the mothers died, and all of the infants of the latter were dead before the cases came under my observation.

From the foregoing figures it will be seen, then, that there is very little difference in the maternal mortality of cesarean section as compared with the various other methods of intervention, while the mortality of the infant has been reduced from 70 per cent. to 53 per cent., and can be still further reduced.

These statistics are yet too small to formulate any fixed rule for guidance regarding the absolute and relative indications of cesarean section for placenta previa; future experience alone can determine. Whether they will be improved on will depend on a more thorough study of the cases during pregnancy, early recognition and prompt action while the patient is still in good condition.

2426 Pennsylvania Avenue N. W.

DISCUSSION.

DR. GEORGE T. HARRISON, New York City—Modern gynecology has gained many triumphs, especially in the direction of surgery, and so successful have modern gynecologic surgeons become that they have brought within the domain of surgery a class of cases to which surgery is really not applicable, so I classify the treatment of placenta previa by cesarean section. I have had a large practice in obstetrics for many years, in lying-in hospitals and in private practice, and I have yet to see the case of placenta previa where any such surgical interference was indicated. I want to plant myself fairly and squarely on the side of the opponents to this operation. There are two dangers that assail a woman when she has placenta previa; death may occur from hemorrhage and from sepsis. With the methods at our command for dilating the uterus, it is an easy matter to bring down a foot, and the hemorrhage is completely under control. The great objection to this method is that you must deliver very slowly. Of course, the child runs some risk, but that risk has been diminished by the use of the balloon, either the Champetier de Ribes, or its modification. I have found that it is better for both mother and child if we ignore the latter. With these methods at our command, I can not see any indication for cesarean section. In a recent number of *THE JOURNAL*, Dr. Deaver tells us that he was called in consultation in a case of placenta previa, and performed the operation of cesarean section. He said that he thought that operation was indicated, but the second reason that induced him to operate was sublime. He said he operated because he was more familiar with the technic of abdominal

surgery than with the methods of podalic version. It is only necessary for a man to give such a reason to confute himself.

DR. A. PALMER DUDLEY, New York City—Dr. Harrison said that he has never seen a case of placenta previa in which cesarean section was justifiable. Let me tell you a story. A poor woman, a few months ago, was expecting her confinement. She felt that there was something wrong about it, and she consulted a physician. He brought in his assistant and they discovered that she had placenta previa. They told her that she was in some danger, but they would watch her and one of them would be ready any moment. In the early morning she was cooking her husband's breakfast when she had a hemorrhage, and before a physician could be called, the woman was dead. There was a case where cesarean section was justifiable, and those two physicians were guilty of criminal neglect. They knew that the woman had placenta previa, and yet they failed to do what they should have done. Every obstetrician should have his obstetric "kit" ready, and in it should be the instruments necessary to make a cesarean section—a knife, a pair of forceps, a ligature, a needle and some silk. Every obstetrician of to-day should be equal to a cesarean section, else he is remiss in his duty. I contend that Dr. Moran has touched a note that will sound over the country. It can not be stopped. The one incident I cited will be sufficient to emphasize my position.

DR. F. F. LAWRENCE, Columbus, Ohio—No reformation ever was effected without there being radical men on both sides. The radical fellow rubbing against other radical fellows wears off the rough edges. However, one thing we must remember, and that is, that the statistics of the best methods of treating placenta previa, as compared with the statistics of cesarean section for placenta previa, makes a very unjust comparison. Why? Because comparatively few of the cases of placenta previa that bled themselves into the grave have been reported. Comparatively few of those who have died out in country towns, or even in the city, from attempts at manual or instrumental dilatation, have been reported. Why? Because the stigma of death in ordinary obstetric practice is felt most keenly by every physician; it is one of the things that will damn the physician quicker than anything else, and it will, therefore, not be reported. But let the case be taken to the hospital for cesarean section or operated on at home, and everybody in the neighborhood knows of it, and the doctor is compelled to place the case on record as an argument in his defense. I wish each and every one of you would take this position: If this were my wife, my daughter, my sister or my mother, what would I want done? We know that the operation of cesarean section can be performed in a very few minutes, and that hemorrhage is under the control of the operator, as is also the matter of sepsis to a great extent. I would not want my wife or daughter—if the victim of this condition—to be denied the life-saving properties of a cesarean section done by a skillful man. One speaker says bring the foot down and the hemorrhage is absolutely controlled. I have been unfortunate enough to see three or four cases in which bringing the foot down did not control the hemorrhage. And why? Because the patient had bled so much before the presenting part was brought into position to act as a plug, that there was inertia of the uterus. These are things that we must consider. It requires only a few minutes for a woman to bleed to such an extent that the uterine muscle will not contract. In placenta previa centralis, cesarean section should in my opinion be the procedure.

DR. RUDOLPH W. HOLMES, Chicago—Dr. Ehrenfest of St. Louis published a paper on this subject a few years ago, in which he stated that the mortality of placenta previa was not so high as was generally believed, and that the mortality of the cesarean operation was greater than we are led to believe by reported statistics. In fact, nearly all the quoted statistics of cesarean section are those with the "corrected" mortality, which, while it eliminates the operations on the unfavorable cases followed by death, does not eliminate like cases which had the good fortune of recovering. For example: Zweifel had 76 conservative sections, with 1 death—by

exclusion he makes it 75, with no death; Schanta, 58 cases, with 6 deaths—by exclusion he has 56, with 4 deaths; Leopold, 71 cases, with 7 deaths—by exclusion he makes it 68, with 4 deaths. As placenta previa is rarely diagnosed until the hemorrhage manifests itself, which should not necessarily be the case, the woman is very unfavorably placed for a cesarean section on this indication; therefore, the mortality of placenta previa from infection, when treated by section, will necessarily always be high in comparison to the mortality in sections performed in women with contracted pelvis in which a timely diagnosis is made. I believe there is a place for cesarean section in placenta previa, but I am glad to say it is a very small place indeed. If there be a rigid cervix one may want to consider a cesarean section, but a rigid cervix in the practice of obstetricians is very rare in previa, even though our surgeons and general practitioners would have us believe differently. If the attendant on a placenta previa case will treat the case intelligently and properly with a slow extraction, or perhaps spontaneous expulsion, a rigid os will be rarely found by them, as it is seldom encountered by obstetricians. Braun, Schroeder and Strassmann do not consider such a complication in this connection. There can be no question that in contracted pelvis one should do a cesarean section when placenta previa exists—but it is the pelvic distortion which indicates the operation, not the placenta previa. The indications for the cesarean section in placenta previa offer very pertinent hints as to the stand of obstetricians: of twenty-five cases operated on and reported, the professional rank is obtainable of nineteen operators of twenty-two cases; the indications were:

Five general practitioners, one rigid os.

Three gynecologists, one rigid os.

Five surgeons (6 cases), one rigid os; one where the operator knew how to do the section, but did not know the technic of a version.

Six obstetricians (8 cases), all complicated: one rupture of the uterus; one rigid cervix tympani uteri, fibroids; one rigid os with infection; four contracted pelvis; one in which the cesarean was done for contracted pelvis—incidentally in delivering the placenta it was found to be a low lateral previa.

In other words, this operation is done by men not versed in obstetrics; to-day not one obstetrician of repute and of large obstetric experience has countenanced the operation, *per se*: if the operation, to repeat, is done on the indication of a contracted pelvis with the presence of hemorrhage, the hemorrhage did not call forth the indication. When men like Lawson Tait and Deaver, men who stand at the top of their respective specialties, recommend cesarean section for placenta previa, when they candidly admit they know nothing about obstetrics, they stultify themselves and belittle the ideals of medical practice. Tait's says: "I have all my life avoided in every possible way contact with obstetric practice, and for thirty years have had no personal association with it save in occasional consultations." No wonder his placenta previa mortality was 50 per cent., yet he, with statistics such as these, recommended treating by surgical means what should be treated obstetrically.

Surely there were enough obstetricians obtainable in Philadelphia who could have treated the above-mentioned surgeon's case obstetrically and relieved him of the necessity of doing a surgical operation when a version, whose technic he did not know, was indicated. The case cited by Dr. Dudley was an indication for the attending physicians to be up and doing: that only does it suggest. Imagine the outlook for a poor woman after such neglect treated by cesarean section. The time for the section is due before the procrastinating general practitioner wastes valuable time, not after. To analyze the mortality as was done for the indications of the section in previa gives these results:

Five general practitioners: maternal deaths, 40 per cent.; fetal, 60 per cent.

Three gynecologists: maternal deaths, 33 per cent.; fetal, 0 per cent.

Five surgeons (6 cases): maternal deaths, 16 per cent.; fetal, 50 per cent.

Six obstetricians (8 cases): maternal deaths, 12.5 per cent.; fetal, 87.5 per cent.

Two of the obstetricians' cases had non-viable children, the same being true of one of the surgeon's cases. The gross mortality was 5 deaths of 24—20.8 per cent.—fetal, 70.8 per cent.

There are three dangers that confront women with placenta previa—antepartum and intrapartum hemorrhage, postpartum hemorrhage and sepsis, rupture of the uterus and emboli not being considered in this connection. These are of great importance if the woman be treated by section as by operations through the vagina, and more, too; in addition there are two others, hemorrhage from the uterine incision and shock from peritoneal manipulations in the section cases. If cesarean section is forced on the operator he should not stop short of removing the uterus; a Porro, or its modifications, will safeguard the woman against puerperal complications in a great measure. Of the cases reported six recovered, 100 per cent.

DR. F. B. DORSEY, Keokuk, Iowa—Unfortunately, we can not always elect as to the performance of a cesarean section. If it is our privilege to examine patients early in their pregnancy, and we then discover the placenta previa, we have an opportunity to elect what course we will pursue. My personal experience leads me to believe that it is jeopardizing the life of the patient to allow her pregnancy to proceed many days after the discovery of the presence of an abnormal implantation of the placenta. We know that often it is very difficult to effect dilatation of the os, and it is also extremely difficult at times to control the hemorrhage, particularly if we find inertia, and we are very apt to lose our patient. My practice and teaching has been that when we discover placenta previa in the early months of gestation, we are justified in producing an abortion or a premature labor. Of course, if the progress of the pregnancy is advanced to the period when the child is viable, we are justified in electing cesarean section inasmuch as the vast majority of children are lost in the delivery through the vagina. In most cases we must elect to do that which is indicated according to the condition of the patient at the time she presents herself. Often we are called to see a woman in labor who is losing blood, and on examination we find some form of faulty implantation of the placenta. What is there to be done? If we elect to perform a cesarean section the woman may die while we are preparing for the operation. That is not a time for preparation but for immediate action, and the only justifiable procedure to be carried out at that time is podalic version and immediate delivery.

DR. CHARLES J. HASTINGS, Toronto, Canada—I think that the cases of placenta previa that justify cesarean section are very few indeed and are practically limited to primipara with alarming hemorrhage, or evidence that an alarming hemorrhage has occurred, and a rigid os that will barely admit one finger. If there is one thing more than another that these discussions impress on us, it is the lack of ballast in the medical profession. A glance over the past decade will quickly show us the tendency of the pendulum to rapidly swing from one extreme to another. Another point that we must consider is that what would be a rational treatment in hospital practice would not be such in private practice, and the operation should only be undertaken by an experienced operator, and these cases usually demand rapid action. Dr. Dudley cited a very pathetic case, but I did not take the moral from it that he did, that is, that cesarean section should have been done. The moral is that any physician who will leave the house of a patient who is in labor and who has had a hemorrhage where he has diagnosed placenta previa, is guilty of criminal neglect. Had those physicians kept their patient in bed, remained with her and as soon as possible brought down a foot, they would, in all probability, have saved the woman's life. For the benefit of the young practitioner especially I endorse as heartily as I can the statement made by Schroder—that the physician who has the least regard for the life of the infant will have the lowest maternal mortality.

DR. HENRY D. FRY, Washington, D. C.—I performed one cesarean section for placenta previa. The woman did not know that she had been operated on until a week afterward, when I removed some stitches. Her convalescence was normal, as much so as if her labor had been natural. In 1901 I read a paper on placenta previa at the gynecologic meeting in Chicago. At that time I was opposed to cesarean section in any case, because I reported at that time 14 cases of placenta

previa without a single maternal death. Since that time I have had five others, making 19. In the discussion on that paper Dr. DeLee of Chicago reported 25 cases of placenta previa delivered in the natural way with only one death. In another paper which I read later on the same subject, I reported my cases, Dr. DeLee's and Dr. Harris', some seventy odd, with only one death, a mortality of less than 2 per cent. The position I took at that time was that if we could treat this complication with such a low death rate, we had no right to do a cesarean section. Afterward I looked into the matter more carefully, looked up the statistics, wrote another paper and said that I thought there was a limited field for cesarean section. I mentioned that the woman must be a primipara, that the vagina must be small, the cervix undilated and undilatable. With these conditions, and a placenta previa centralis, you have the indications for a cesarean section. Most of the statistics for placenta previa are worthless because they do not mention the variety of placenta previa, a matter of great importance. The death rate in the marginal variety is low, whereas in the central variety it is high; statistics say 20 per cent. What would be the death rate if we performed an elective operation? Not over 5 or 6 per cent., for one which ceases 20 per cent. Dr. Holmes says that a rigid os is a very rare finding in placenta previa. Books on obstetrics tell you that it occurs in 15 per cent. of all cases. I have seen several. I remember one very distinctly. The os was so rigid that I had to begin dilatation with steel instruments, following with rubber dilators of graduated size, and finally my finger. I brought down the foot, and it took five hours of labor pains to dilate the cervix. Much will be said for and against cesarean section in placenta previa, but after a while it will find its proper place. It is really one of the simplest operations and every practitioner ought to be able to do it. Dr. Deaver's case was not one for cesarean section, but for podalic version.

DR. P. E. TRUESDALE, Fall River, Mass.—At no time in the career of the obstetrician does his courage receive such a severe test as when he is brought face to face with a case of placenta previa, almost exsanguinated, with the fetus in the uterus. I had one such case in which I did a cesarean section. The baby died an hour after the operation, but the mother recovered. I reported this case before the Obstetrical Society of Boston in 1903, and was then criticised by some for having performed the operation. Among the statistics quoted favoring the vaginal method of delivery were those of Dr. Fry, and it affords me great pleasure to hear him say now, that there is a limited field for the operation of cesarean section for placenta previa. My case was a multipara eight months pregnant. The os was dilated about the size of a silver quarter. She had had frequent hemorrhages for two months, and after each examination there was a violent hemorrhage. She was an ideal patient for cesarean section: thin abdominal walls, good recuperative powers and good resistance. After transfusing saline solution I operated, and I believe that by saving her the loss of any more blood I saved her life. In all our operations the recovery of the patient depends largely on the amount of shock produced, and this shock is materially in proportion to the amount of blood lost.

DR. I. S. STONE, Washington, D. C.—I believe that Drs. Moran and Fry are doing nearly all the cesarean sections done in Washington. I think what has been done by all the rest of us has never been and, perhaps, never will be reported. Less than a year ago Dr. Fry was not willing to admit that the statistics of placenta previa warranted cesarean section. Not more than two months after that, however, he began to work the question out in his own mind, and then formulated the views which he has announced to-day. I want to take issue with Dr. Harrison. Dr. Moran is not the only man who has been criticised by Dr. Harrison. Some years ago I reported cases before the Virginia Medical Society and was severely criticised by Dr. Harrison, but he found in a little while that the world was moving on, and that he had to change his position. I think no medical question would be discussed properly unless Dr. Harrison waved the flag of con-

servatism. I admire conservatism, but when a gynecologist is sent for in a case requiring cesarean section he is better prepared to do that operation and save the life of both mother and child than by the old-fashioned way of bringing down a leg. With regard to the question of election in surgery: The time was when in a case of appendicitis three-fourths of the profession advocated conservatism. Now we operate in every case. The time was when we waited for a woman with placenta previa to bleed herself almost into the grave before we attempted to do anything. Now we are coming the other way. I realize that there is a place for this operation, and whenever the indications point that way we should not hesitate to undertake it.

DR. JOHN F. MORAN—The three great dangers in placenta previa are hemorrhage, sepsis and rupture of the uterus. To my mind, these three dangers can be met better in complete previa with cesarean section than by any other method of delivery. Although I have not gone into the details of these methods, yet I believe that they have a place; how much remains to be seen. At the present time, however, we can but say that with a rigid os, a small vagina and an aged primipara, cesarean section is indicated, rather than the exposure of the patient to the dangers of sepsis, increased hemorrhage and traumatism, which follow an attempt to deliver by podalic version or any other method. Dr. Harrison certainly did not mean to say that he would use bags in a central placenta previa. If he does, he must perforate the placenta and thereby diminish, if not entirely destroy, the chance of the child. We have two persons to consider, for the unborn child has some rights. As to who should operate, if you want your eye examined you would not go to a gynecologist. You want a competent man. When this paper was written it was not to advocate that it should be done by the general practitioner. A competent obstetrician should be called in to take care of a case of placenta previa, particularly when cesarean section is indicated. There is a field for this operation; whether it will be broadened will depend on future experience. With it we can obviate sepsis, hemorrhage and rupture of the uterus, and we also increase the chances of the child without decreasing the chances of the mother.

PROSTATECTOMY IN GENERAL. ESPECIALLY BY THE PERINEAL ROUTE.*

GEORGE GOODFELLOW, M.D.
SAN FRANCISCO.

Indubitably the sufferer from the effects of prostatic disease, especially hypertrophy, is just now in the "lime-light" of the surgical theater, while around him are grouped the performers, each avidly anxious to assure him that his ails may be bettered, his anguish assuaged by some particular method.

Not so many years ago the catheter was the implement in the surgical armamentarium most relied on to alleviate the almost unendurable pangs experienced day and night by those unfortunates afflicted with the results of prostatic hypertrophy; but in a large proportion of cases the catheter ultimately added to their torments, although temporarily of benefit. Taken usually from some unclean repository, once or oftener during the twenty-four hours, it was thrust into the ailing penis, the patient writhing in agony while the urine was withdrawn from its fleshy environment.

While the question as to the precise method of dealing with hypertrophied prostate is still an exigent one, the answer is rapidly formulating, so swiftly that we can feel confident even now to assure patients that no

longer need they lie "from weary chime to chime," longing for, yet dreading the death that is to release them. That that class of invalids can now be assured of permanent relief is certainly a testimonial to the brilliant work of modern surgeons.

The first systematic operation for the removal of hypertrophied prostate was the suprapubic in the mid 80's, recommended by Belfield and McGill. That passed gradually into desuetude, while divers blind cutting and puncturing methods, to a great extent, took its place. Finally, removal through the perineum came to elicit discussion, provoke opposition, stimulate investigation, and I believe eventually to become the operation of election for all except unusual cases.

The necessity for thorough preliminary examination before operation—as thorough as in all contemplated operations on the individual—is patent, and nothing suggesting itself to the experience of the operator should be neglected.

Palpation, wherever used, as we all know, even to the most skilled, holds an element of uncertainty that should be eliminated by instrumental aids so far as possible without risk to the patient; yet even with finger and instruments in all pelvic troubles, the information gained is many times far from accurate; nevertheless, that should not prevent us from availing ourselves of every aid to diagnosis. But here I must utter a word of caution; instrumentation of the urethra and bladder has been productive of great harm, and the greater experience I gain leads me to say that unless great urgency exists, for explorative purposes, an instrument should not be entered into a virgin bladder. In this I refer especially to the cystoscope and kindred instruments. What tactile dexterity in this condition fails to elucidate an instrument can rarely, if ever, be expected to find.

The indications for prostatectomy lie in the urinary difficulties that by processes of exclusion can be placed nowhere else than in the neck of the bladder; there are no contraindications if the patient's condition is such that any operation would be within the jurisdiction of prudence. Age is no bar—a man of 80 may be potentially younger than a man of 60. Not always, as is the generally accepted idea, is there residual urine with an enlarged prostate; contrariwise, there may be residual urine where the prostate is little if at all enlarged, where the condition that I have elsewhere called "doughnut hypertrophy" or hyperplasia exists; where, when the finger enters the bladder, merely an extremely tight ring of thickened tissue strongly elastic constricts the finger, and from which a very small nodule, if any, can be removed. Operative interference is as urgently demanded in such cases as in those wherein the volume of the prostate has attained palpable and obstructive dimensions.

There is another class of cases usually unappreciable to touch, and not always distinguishable by instruments, wherein may or may not be retained urine, but which cause irritative symptoms, i. e., moderate median lobe hypertrophy, wherein operation is required.

So far as known, the prostate has no physiologic function commensurate with its importance as a pathologic factor. The secretion is presumed to impart motility to and vivify the spermatozoa. I have tried to verify that hypothesis in several patients from whom the gland has been removed, but without success; the length of time intervening between the emission and examination making the latter futile.

The moot question as to whether the prostate has a

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee; Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

The joints of the lower extremities finally became painful and other signs observed that induced a course of K. I., 30 grains every two hours. In two weeks the wound closed, the patient was up, and in six weeks after the operation he left the hospital feeling and acting well.

CASE 2.—Referred by Dr. DeVecchi. Male, Italian, 66; married. Eight children; all healthy but neurotic. For many weeks preceding had been having hematuria constantly, with symptoms of obstruction at vesical neck; residual urine, catheter used every four hours or oftener. Both epididymes enlarged and fluctuating, skin over them discolored. No temperature. Although venereal infection was denied, some scars in each inguinal region and the condition of the testicles led to specific treatment, with the result of inducing rapid subsidence of all symptoms and apparent recovery. The testicular swellings were incised and a grumous fluid discharged from each. The first impression given was that of sarcoma of prostate and testicles.

CASE 3.—Male, 68. Usual symptoms of prostatic obstruction with hematuria. Prostate enlarged. Residual urine, 6 to 8 ounces. Denied venereal history, but cicatrices in groins, a tumor on scapula, with other minor evidences, caused him to be placed on specific treatment. The enlargement both of the scapula and of the prostate disappeared, control of the bladder was regained and when last heard from he was enjoying as good health as any man of his years.

Syphilis of the prostate is an unusual form of prostatic trouble, concerning which little has been written. Careful search through the literature on prostatic disease has failed to bring to light any mention of syphilitic affections of that organ, and I shall be pleased if any of my readers can direct me to publications wherein is mention of such complication. French, German and English periodicals and text-books covering the past ten years have been unavailingly investigated. Objection may be made that the diagnosis was not accurate or precise. The criticism is a good one, to which only one reply can be made; that the test of treatment is the only test of the nature of the malady. If pronounced symptoms of cerebral tumor are present and a course of specific medication is followed, by virtual recovery, it is assumed, however unjustly, that the cause of the trouble primarily was syphilis. Likewise with other obscure pathologic manifestations of that disease, the protean forms of which are as the sands of the sea; if in doubt, specific treatment is tried; if the result be favorable, the presumptive accuracy of our guess is assumed, as demonstrated.

One only of these cases being operated on, no specimens are available for examination. In that one the specimen was lost. The patient died some months later from some cerebral difficulty, presumably apoplexy. The other two remain in good health, with control of urinary functions. Perceptible enlargement of the prostate remains, but with no residual urine. They have continued the treatment intermittently to the present time.

The history of the foregoing cases compels the query: Are not a larger proportion of enlarged prostates than heretofore supposed sequelæ of syphilis? The term sequel is here used as suggested by Hutchinson, who looked on all tertiary manifestations of syphilis as sequelæ and not complications, a view with which I agree. Obviously immutable certainty of diagnosis is not assured, because enlargements disappear under iodids, but as said, such result makes strong testimony amounting almost to evidence.

PROSTATECTOMY.

IS IT WISE TO TRY TO MAKE ANY ONE OPERATIVE METHOD APPLY TO ALL CASES?*

EUGENE FULLER, M.D.
NEW YORK CITY.

The excellent results which follow the radical removal of obstructing prostatic hypertrophy have caused the profession as a body to change its position of skepticism, or I might say almost open hostility toward the radical operation, to one of lukewarm favor. Before the time of McGill's operative work a surgeon called in one of these cases had nothing to suggest aside from the catheter. After that time, however, it becoming more or less generally known that operative surgery at the hands of a few pioneers had effected cures in these cases, a surgeon in consultation no longer felt safe in confining his discussion entirely to the catheter. He had to bring up the subject of radical operation, if only to condemn it, so far as that particular case was concerned. Next in order came the various surgical makeshifts devised to get around the troublesome subject of radical operation. Beside being easy of surgical accomplishment, it was hoped by their originators that thereby relief, with a less degree of mortality, would be attained. Most of these makeshifts have already passed, or are now fast passing into oblivion, and this has been due to two causes: (1) The unsatisfactory results attending them; and (2) the increasingly better results following prostatectomy at skilled hands. All this has made it evident to thoughtful surgeons interested in this particular, that the time has come to study and to master the operative problem and no longer to try to get around it or to discredit it. The operative problem includes the following points: The removal of the prostatic obstruction, the avoidance of mishaps and subsequent surgical complications, the complete restoration of the vesical function, and the preservation or improvement of the sexual function. At the present time most writers on the subject concern themselves with little aside from the operative removal of the obstruction; and in this connection also there is a strong tendency shown for each writer to advocate some special and exact operative procedure which he advises adopted in all cases, other methods of operation to accomplish the same purpose being either condemned or ignored.

All prostatectomies can be grouped under three headings: (1) Where the hypertrophy is removed through the employment of a suprapubic cystotomy; (2) where it is removed through the employment of a perineal cystotomy; and (3) where it is extracted along the path of a perineal dissection, the aim of which is to avoid opening the urinary tract or the rectum.

So far as the mere accomplishment of the removal is concerned, I think I am safe in saying that I can do it in any case through the employment of any one of the three general methods. If I should, however, undertake to use one method for all cases, I should feel that I was violating an important principle of surgery, in that I had neglected in each particular instance to consider the choice of operative method; and I also feel certain should I do so that my record of mortality would be much greater than it is. In making the above statement I do not wish it to be inferred that I should

Opium Smokers in the United States.—Opium smoking is not so purely an oriental vice as is generally supposed. It is estimated that there are at least 1,000,000 opium smokers in the United States.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

not expect to invite surgical mishap in connection with my prostatectomies should I, for instance, try to remove obstruction in all instances by the third method. For, take a case as illustration wherein the prostatic hypertrophy is surrounded by old inflammatory adhesions which bind an attenuated bladder wall firmly to that structure. In such a case it would be impossible to radically remove the obstruction extravesically without at the same time opening the bladder at least by a rent, and in all probability by tearing away a piece. The third method of operation will, in my opinion, never become the one generally employed. In order to explain why I hold that opinion I will enumerate the class of cases in which I consider it contraindicated, together with my reasons for so thinking.

The operation requires for its accomplishment more time, on the average, than the other procedures. With many elderly and feeble individuals the time spent on the operating table is an important element. It should be for such as short as possible. The danger of meeting with the surgical mishap of tearing the urethra and bladder is great, as has already been mentioned, except, perhaps, in hypertrophies uncomplicated by an inflammatory element, which practically means hypertrophies which admit of easy enucleation. There is no way in which a surgeon can positively determine beforehand that in a given case a condition susceptible of easy enucleation will be encountered. In quite a number of the cases reported wherein this method has been employed the rectal wall has been torn during the operative procedure, an accident which threatens to establish rectovesical fistula. In order to combat these surgical objections, some advocates of this method have begun to advise that it be employed only as a partial operation, or in other words, that the attempt should be made through it to remove only a portion of the hypertrophy, the operator avoiding the part lying too near the urethra, bladder or rectum. The fatal objections to such an operation are that it would only partially relieve a patient of his vesical obstructive symptoms, and would, in all probability, only temporarily effect even that much relief. This operation does not provide vesical drainage, and so is contraindicated in all cases wherein complications of the urinary tract have resulted from prostatic obstruction, conditions which require for their cure vesical drainage and rest. Such complications are purulent cystitis, urethritis, generally associated with dilatation of the canal, pyelitis, bacillary nephritis and the lesions of the bladder wall induced by long-continued overdistension or resistance to obstruction, such as atony, diverticula and ulcerations. It will be seen that the above enumeration excludes practically all of the complicated and severe instances of prostatic obstruction.

The second method, which relates to prostatectomy through the medium of a perineal cystotomy, has, at the present time, the greatest number of advocates. It is a very feasible operation, and one that I am constantly employing. I must say, however, that I do not use it to-day on as large a percentage of cases as last year or the year before. In connection with the operation itself, I feel that much that has been written lately regarding it serves only to make the procedure seem complicated and to mislead the reader. In the first place, if the thighs of the patient are sufficiently flexed, there is no need of a complicated perineal dissection extending laterally to either side of the median raphe, such as so many writers have described, all that

is necessary being a small median incision which enters the perineum just above the rectal sphincter and which extends above the rectal wall to the prostatic urethra. The tissues in this region are very elastic, consequently this narrow incision can be dilated sufficiently for purposes of extraction. It dilates, in fact, much as does the vagina at childbirth. In the clinic I have frequently called attention not only to this fact, but also to the similarity in instrumental manipulation between the forceps extraction of the baby and of the prostatic hypertrophy. In this form of operation, if the prostatic mass is found to be too large to admit of easy extraction, it should be broken into two or more pieces.

It is urged against this method of operation that the incision I have described does not allow the operator to see the prostatic obstruction and to detach it under the guidance of his eye. It surely does not; neither do I use my eyes in the accomplishment of detachment or of enucleation. I use that which is much surer and much better in this particular, my sense of touch. With my trained finger I can map out the hypertrophy and separate it from its attachments to the bladder and seminal vesicles without in most instances inflicting injury on either of those organs. In some instances, where I have found great difficulty in separating the hypertrophy from the bladder, I have thought best to abandon the attempt by the perineal route, completing the operation by suprapubic cystotomy; but this subject I will mention later.

Perineal prostatectomy by this method, when thoroughly performed, as it should be, radically removes all obstruction, and leaves the patient able, easily and voluntarily, to completely empty his bladder. Convalescence from this operation—by that I mean the time in hospital—averages some days, though considerably less than a week shorter than after the suprapubic operation. If a prostatic has a good expulsive force to his bladder, I am inclined, in most instances, to advocate prostatectomy through perineal cystotomy. Bladders which have their expulsive force represent those whose walls are normal, and those whose walls are thickened and strong through muscular hypertrophy which has been developed to overcome a slowly progressive state of prostatic obstruction. The size of the hypertrophy does not, as a rule, influence me. If, however, the prostatic hypertrophy lies surrounded by a mass of dense tissue, the result of repeated attacks of inflammation, I might then, especially if I were in any doubt as to the strength of the bladder walls, decide against the perineal operation.

In cases complicated with very foul cystitis, associated with attacks of vesical hemorrhage and phosphatic calculus formation, I should decide against the perineal operation, as I should then consider a suprapubic vesical opening necessary, as well as the perineal one, in order to secure for the bladder the requisite degree of rest and drainage. The same reasoning would likewise decide me in cases where the renal pelvis and structure had become secondarily involved to any marked degree. The reason why I should decide against the perineal operation in cases where the bladder wall is lacking in expulsive force, lies in the danger which such a patient so operated on runs should much blood clot accumulate in the bladder after the operation; for if, under such conditions, blood clot accumulates, the bladder has no force to expel it, the perineal tube becomes blocked, the continuance of bleeding is then encouraged by the incessant though ineffectual tenesmus which the lack of drainage encourages, urine accumulates behind the blood clot, and overdistension of the

bladder results. In such a contingency artificial suction through the perineal tube or removal of the tube and of some of the clot by means of forceps may result in effectual relief; still, in my experience, the safest method of remedying such a complication is by immediately opening the bladder suprapubically, emptying it of clot and establishing counter-drainage in that part.

Not long since I lost a case from this accident which, owing to its interest, I will briefly detail. The case was an old prostatic, whose bladder was atonic and diverticulated. The cystoscope showed the ureteral orifices dilated sufficiently to admit the tip of the little finger. This state of affairs, to my mind, contraindicated perineal prostatectomy. The patient refused to take an anesthetic, but was willing to have an operation under spinal cocainein. He had chronic bronchitis, and that, of course, favored the cocaine. I did the perineal operation without difficulty. Six hours after operation his bladder filled with clot, causing much tenesmus. The hospital staff succeeded after a time in freeing the bladder by removing the tube and extracting clot so that perineal drainage was re-established. The patient gradually developed uremic symptoms, together with tenderness over the right kidney. At the end of two weeks, the patient gradually getting worse and the tenderness over the right kidney increasing, I performed nephrotomy, and on opening the renal pelvis found it packed with old decomposing and partially deliquescent blood clot. Aside from some dilatation, the mucous lining of the pelvis did not show lesions, and as the patient had never in his previous history had renal hemorrhage, I was forced to the conclusion that the blood clot I found there was made up of a bloody reflux from the bladder along the dilated ureter, which had occurred at the time of the vesical hemorrhage just subsequent to his operation. Had a suprapubic vesical vent been left in the case at the time of operation, I have no doubt recovery would have followed.

In the performance of my suprapubic prostatectomies, it is my practice to leave a perineal as well as a suprapubic vesical vent, in order to establish perfectly free drainage. On numerous occasions wherein I have been in some doubt as to choice of operation, I have first made my usual perineal opening, through which I have inserted my finger, in order, by means of the sense of touch, to more exactly study existing conditions. If, after such study, I have decided against extraction of the prostate through the perineal incision, I have then done my customary suprapubic operation, using the perineal incision for drainage purposes only. Should I find, owing, perhaps, to dense adhesions, that I could not complete the enucleation of a prostatic hypertrophy through the perineum without resorting to a degree of traction or force greater than might be safe for the patient, it is also a simple matter to abandon that operation, leaving its incision for vesical drainage only, and complete the extraction by the suprapubic route.

Suprapubic prostatectomy I consider the operation of choice in practically all cases which do not fulfill the requirements I have enumerated for the perineal operation. In the majority of instances in which I choose that operation, I really employ it chiefly for its suprapubic vesical vent, a feature of so much importance where the freest urine drainage and the greatest vesical rest is necessary. In other words, it is the method of choice in advanced cases of prostatic disease, complicated by the resulting lesions of the urinary tract.

There is also little danger of injuring the sexual apparatus in the performance of this operation. Yet the majority of surgeons at present are inclined to condemn it as operatively dangerous, for the good reason, apparently, that much mortality can be attached to it. Still, if certain rules are observed in the performance of this operation, if the incision is properly sutured and drained, and if the surgical supervision of the after-treatment is efficient, the suprapubic operation should in itself give no extra mortality.

I first published my operation relating to suprapubic enucleation of prostatic hypertrophy in June, 1895,¹ so it is not here necessary to reiterate it in detail. It is the same operation in everything essential that Freyer two years or so ago published as his own. The gentleman's attention was, however, called to that fact at the time by signed communications, which several English surgeons as well as myself published.

My experience to date with prostatectomy is somewhat over 300 cases. I feel that if cases complicated with very marked uremia are excluded, I can operate with an average risk to the patient of not more and probably under 5 per cent. Death from the operation itself is practically *nil*.

CONCLUSIONS.

I wish, in conclusion, to enter a protest against classing as true prostatectomy, or at least prostatectomy as the profession understands it, which relates to senile hypertrophy only, cases of middle-aged or even younger men seemingly from their histories, to represent simply inflammatory effusions in connection with the prostate or its periphery. Some time since a report came to my notice which seemed to merit this objection. In it the remark was made that the finding of any hypertrophy which could be enucleated was very unusual. Hypertrophies which can be enucleated do not exist in connection with simple inflammations.

252 Lexington Avenue.

DISCUSSION

ON PAPERS BY DRs. SYMS,* GOODFELLOW AND FULLER.

DR. ORVILLE HORWITZ, Philadelphia—An unusual opportunity to study a large number of cases of senile hypertrophy of the prostate gland during the past two years has convinced me of two facts. First: The danger to the patient commences as soon as it becomes necessary to resort to the daily use of the catheter. A radical operation performed as soon as the symptoms of obstruction begin to appear, with the low mortality which attends such cases, offers the individual a better chance for health, comfort and prolongation of life than the unfortunate patient who leads a catheter life. Second: A routine method is not applicable to the treatment of prostatic hypertrophy. Every case is a law unto itself, and the treatment will depend on the various conditions treated in each individual case. The earlier the operation is performed, the less is apt to be the mortality. It will be found that the mortality of 6 per cent. is usually obtained in those patients who are operated on at the outset of the prostatic obstruction; between 15 and 16 per cent. The Bottini operation is of real surgical merit. Accumulated evidence shows that in suitable cases it is capable of giving better results than cutting operations with much less danger to life, and therefore should always be resorted to in cases suitable for its employment. My experience with this method of treatment is based on 99 cases with 3 deaths, 86 per cent. of cures, 10 per cent. unimproved. In 1892 I tabulated 886 Bottini operations

1. Jour. of Cut. and Genito-Urinary Dis., N. Y., and later in my book, Diseases of the Genito-Urinary System, The Macmillan Co.

* The paper by Dr. Parker Syms appeared in THE JOURNAL November 5.

by 48 operators. Of this number of operations, 84.3 per cent. were cured or improved, the mortality being 5.7 per cent. The genitourinary surgeon who desires to maintain his position in the front rank of the profession can no longer afford to treat this operation in a contemptuous manner and refuse to acquire the skill which is necessary in order to perform it. This operation is indicated principally in those cases in which there is a contracture of the neck of the bladder, associated with a thickening of the prostatic isthmus joining the lateral lobes. Prostatectomy is as much the subject of controversy as is the Botini operation. My experience with this method of operating is 9 complete suprapubic prostatectomies with 2 deaths; 7 partial suprapubic prostatectomies, with 1 death; 39 perineal prostatectomies with 6 deaths. In the latter series of cases, two were unimproved, two had dribbling of urine, and in one a recto-urethral fistula formed.

Those who advocate some one of the various methods of operating by means of an extensive dissection of the perineum claim that so performed the operator can see to perform the various steps of the operation, and the bleeding vessels can be seen and ligated. Unfortunately, the advantages just enumerated are more theoretical than practical. Special instruments are required; the extensive dissection necessary in order that the various steps of the operation may be seen, occupies a much longer time than where the median perineal incision is employed; more blood is lost, the shock is greater and the anesthetic prolonged; the danger of wounding the rectum enhanced. When we take into consideration the fact that the individuals requiring prostatectomy are usually advanced in years, it becomes evident at once that the lowest mortality will be found on the side of the surgeon who adopts the median incision in preference to the extensive dissection. That the danger of the formation of a recto-urethral fistula in those cases in which an extensive dissection of the perineal tissues is made is a real one, at once becomes apparent on consulting the recent literature of the subject, where it will be found that this unfortunate accident has occurred in quite a large number of cases. Ninety-five per cent. of cases of hypertrophy of the prostate gland can be reached by median perineal incision. I have never found it necessary to employ either the inverted Y or the transverse perineal incision. The gland can be excoculated, as a rule, by means of the index finger, in from seven to fifteen minutes with little or no loss of blood and with slight shock. The only instruments required for the operation are a scalpel, grooved urethral staff, half a dozen hemostatic forceps, a small pair of laparotomy forceps, a pair of scissors and a uterine dilator. It has been found that after the membranous urethra has been opened, if a uterine dilator is inserted into the prostatic portion of the canal and the parts thoroughly dilated, this relaxes the anterior leaflet of the triangular ligament, thus permitting the gland to be brought well down into the wound so that it is easily accessible and can be readily enucleated. A perineal prostatectomy is best suited for those cases where the enlargement of the lateral lobes has a tendency to progress towards the rectum or obstruct the urethra. When the growth projects well back into the bladder, a suprapubic prostatectomy is the operation of choice. It is claimed that it is impossible to remove a small fibrous prostate without dissecting away almost the entire prostatic urethra, and I have found this necessary on five occasions; in every instance recovery was uninterrupted and a new urethra was formed without difficulty. It has recently been claimed by some surgeons, that when performing perineal prostatectomy, if the technic suggested by them be adopted, the gland can be enucleated without injury to the ejaculatory ducts. This is cited as one of the great advantages of selecting the perineal route. Curiously enough, Fryer makes the same claim for his suprapubic method of excoculation. It is stated that injury to the ejaculatory ducts gives rise not only to sterility, but impotence. This last condition is the most important one to avoid.

DR. ROBERT H. M. DAWBARN, New York City—Where we can spare the patient an additional week we should do so. If we can determine that there is a stone and remove it, then

I approve of Dr. Syms' instrument. I used it once and it burst in the bladder. I have not tried it with the canvas lining which he now uses. Where one does not think there is a stone or sacculation I advise the method I have used in 3 cases with recovery. It is simply a distention of the bladder used as Dr. Kean advises in suprapubic cystotomy. The bladder may be dilated by passing a catheter into the urethra. The urethra may be constricted and the bladder distended until the latter can be felt in the abdomen, the patient being in a sitting position. This position suffices to make the bladder firm, and without difficulty the prostate gland may be dissected out, the patient subsequently urinating without any need of an instrument in the perineum.

DR. JOHN C. MUNRO, Boston—Dr. Bottomley and I have done only 36 of these operations and have used mainly the method of operating in two stages, because most of the cases that have come to us seem too ill for us to complete the operation at one step. We open the bladder over the pubes and drain for a few days, until the urine clears up, then enucleate through a median incision in the perineum. Of the 36 cases, 3 were carcinoma, one patient died, but not of the operation. Of the benign cases one man died of suppression during convalescence. I believe in some of the cases of foul bladders that come to us it is the part of caution to do the operation in two stages rather than to undertake the entire operation at one sitting. Dr. Young's operation has proven an immense step in advance and I shall adopt it in suitable cases at once.

DR. MARTIN B. TINKER, Ithaca, N. Y.—To save these very feeble, old patients the danger of general anesthesia. I have adopted local anesthesia, using infiltration of the nerves supplying the parts in conjunction with the massive infiltration method of Matas. I employ eucaïn B, 1 to 500, and adrenalin, 1 to 120,000. From a large number of dissections I found that the entire perineum is supplied mainly by two nerves, the pudic and the long pudendal. In these very thin old men it is not usually difficult to strike the nerves approximately with a long hypodermic needle. The adrenalin reduces bleeding to almost nothing, prevents absorption and thus lessens the danger of poisoning from eucaïn. In a perineal prostatectomy recently performed by this method the patient's only complaint was of the cramped position on the operating table. The very small amount of blood lost and the use of local instead of general anesthesia often makes the difference between life and death for these very feeble old men.

DR. D. N. EISENDRATH, Chicago—I believe that it is of the utmost importance to know whether a cystitis is present at the time of operation, and I am greatly interested to know what proportion of the cases reported had an advanced cystitis at the time of operation, and also what percentage was followed by a permanent perineal fistula. One of my own deaths following prostatectomy was due to a septic condition of the perineal wound and a phlegmon in the prevesical space resulting in a severe intoxication and death from urosepsis. In this case the patient had a severe cystitis, with marked ammoniacal odor of the urine. Unfortunately, the case was not seen by me until two days before the time set for the operation, which latter it was impossible to postpone on account of other reasons. I believe that in such cases, especially in men above the age of 60, it would be far better to drain the bladder for some weeks prior to an operation through a suprapubic opening.

DR. HUGH H. YOUNG, Baltimore—Drs. Syms and Goodfellow pretended to have a holy fear of "the big dissecting operation" which they say I do. One glance at the description and the plates of my article in *THE JOURNAL*, Oct. 26, 1903, will show that no important structures are injured and that the entire exposure of the prostate is by incising the skin and dividing the central tendon and the insignificant recto-urethralis muscle beneath it in the median line—(both of which are necessarily severed in all perineal exposures of the prostate) the remainder of the procedure is done by blunt dissection with the forefingers. The levator ani muscles and other important structures are merely separated and held apart by retractors so that no more injury (and perhaps less) is done than in those blind opera-

tions done by touch alone. Why these gentlemen should prefer darkness to light and object to a technic carried out under full visual control is incomprehensible. There was a time when the subcutaneous ligature of varicocele and of hernia and of fractured patella were considered ideal procedures, and other forms of blind surgery were much in vogue, but who to-day would countenance such procedures? The same rule would seem to hold good with the prostate and, in my opinion, the near future will see the surgery of the prostate on the same rational basis of careful technic under visual inspection as that of other parts of the body. Who to-day would merely amputate the breast for carcinoma for fear of the time consumed in a modern, careful dissecting operation? The much vaunted difference of time consumed in our methods of prostatectomy does not count for much in view of the absence of mortality in my 50 cases and its presence in theirs. In fact, one can easily employ careful, intelligent technic, seeing what he is doing and still not consume more than 10 or 12 minutes in exposing and removing the prostatic lobes; and when the operation is finished he has the satisfaction of feeling that he has done no unnecessary mutilation. The presence of mortality (two deaths each in the list of Syms and Goodfellow) shows that there is no excuse for the desire to tear out the prostate as rapidly as possible, blindly and without regard to such innocent but important structures as the prostatic urethra and the ejaculatory ducts, both of which are in no way concerned in the obstruction to urination.

DR. PARKER SYMS—There were 78 cases reported by Goodfellow, 58 by Young and 33 by myself, being a total of 169 cases, with only 4 deaths. This certainly speaks well for perineal prostatectomy, showing as it does a mortality of only 2.33 per cent. Especially is this true when we consider that perineal prostatectomy is not a half way procedure, for it removes the whole trouble. The practical question as to operating in two stages is very important. Among my own cases I have resorted to this procedure in several instances. It has not always been on account of local conditions present, but usually on account of the patient's lack of strength and vitality. In some instances it has been resorted to when patients have been brought to the hospital with complete retention and with complete obstruction to the introduction of the catheter or with false passages, which had been made by attempts at catheterization before the patient came to the hospital. Under such circumstances I do not allow the patients to even await my arrival, but I have my assistant do an external perineal urethrotomy at once, and a few days later I remove the prostate through the original wound.

DR. GEORGE GOODFELLOW—The external incision, or the extent thereof, whether it be an inverted Y, cruciform, or sigmoid, is of little importance, it is the subsequent dissection that counts. Dr. Young thinks we have not studied the question of impotence sufficiently, and this may be true. However, there is no patient on whom I have operated that I have not carefully questioned concerning his sexual powers, and all say they have power, but it is probable that pride of occupation leads them to make statements inconsistent with actual phenomena. I have had two temporary, but no permanent, perineal fistulae, but no rectal fistulae. Spinal anesthesia has been used exclusively of late.

DR. EUGENE FULLER—I think there is a great deal in what Dr. Young has said about the sexual function. I do not think sufficient general attention has been paid to this matter. I have always operated to avoid injury to these parts, and if one is careful it is rarely necessary to injure the sexual apparatus. How many patients are able to procreate after prostatectomy I do not know. Most men are through raising families by that time. As to the cystoscope, I do not condemn it nor put much stress on it, but it may at times be a good preliminary to the operation. I was somewhat surprised at Dr. Syms' philippic against the suprapubic operation. It hardly seems to me that a person can condemn the operation as he does if he knows anything at all about it. If one has not mastered the operation, results are naturally bad. One must be able to do suprapubic work at the present time if he is doing serious

genitourinary surgery. As to the troublesome cystitis following prostatectomy, there should not be any, provided there is good drainage. No phosphatic decomposition must be allowed to occur.

ERYTHEMA NODOSUM.*

ISAAC A. ABT, M.D.
CHICAGO.

Erythema nodosum is a disease of childhood which is of interest to the dermatologist as well as to the practitioner who treats sick children. The disease was first termed erythema nodosum by the French physician, Robert Willan. In his text-book on "Diseases of the Skin and Their Treatment," which appeared in the year 1799, the foregoing name is applied to this disease. The older authors, however, paid little heed to the constitutional symptoms which were present; they were more particularly concerned about the lesion of the skin. They believed that this was a variety of the erythema group. Trousseau pointed out that erythema nodosum differed from the general erythema group in its form, location and in its clinical course. Modern dermatologists differ among themselves as to the relation of erythema multiforme and erythema nodosum; for example, Lesser believes that the two are to be distinctly separated. In the same manner Jarisch, writing in the Nothnagel system, separates the two diseases. On the other hand, Joseph of Berlin does not believe that the two varieties can be separated; he believes that both symptom groups may occur combined in a single individual.

THE ETIOLOGY OF THE DISEASE.

The disease should be classified as one of the exanthematous fevers, on account of the typical course, the prodromata and complications; among the latter may be mentioned conjunctivitis, pharyngitis, joint lesions and, more rarely, endocarditis or pericarditis. Lewin, who conceded the foregoing facts, was nevertheless inclined to believe that the disease occurred on an angioneurotic basis. When the severe constitutional symptoms, the persistently high temperature and the complications just mentioned are considered, one is inclined to the first-mentioned view. Finger, who made a special investigation of this disease, came to the conclusion that it was the expression of a septic process; he found from histologic studies that, aside from localized edema, round-cell infiltration occurred in the cutis, and streptococci were present in the inflammatory tissue. The disease is particularly liable to attack anemic, debilitated or scrofulous children, though perfectly normal and healthy children are not immune. The disease may occur after one of the infectious diseases, or after rheumatism or malaria, or it may occur in the midst of perfect health.

THE CLINICAL COURSE.

The patients are for the most part children from the second to the fourteenth year. The disease usually begins with vague pains, gastrointestinal disturbances and fever. The temperature is usually continuous; the disease rarely runs its course without some fever. The fever in some cases is remittent, usually falls by lysis, and lasts, as a rule, from two to seven days; in the relapsing cases it may last two to three weeks. After several days of vague pains about the joints, especially of the lower

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

extremity, and some pain and tenderness over the tibia, the eruption makes its appearance; it occurs in the form of node-like swellings. It is most frequently located on the shinbones, though in some cases it occurs on the dorsal surfaces of the feet, on the forearms and on the thighs; it rarely occurs on the tongue and on the face. The lesions are usually distributed symmetrically, and come out in crops of two or three at a time, or a large number may appear at once.

The swellings are usually round or somewhat oval—a long axis, corresponding to the axis of the limb. They vary in size from a walnut to a hen's egg. These nodules are not distinctly circumscribed; that is, they have no well-defined border. Two or more nodules never coalesce to form a larger one; they tend to merge gradually into the surrounding skin; the swellings are tense and firm, at first painful and tender to touch; they do not cause itching, nor do they tend to suppurate. They are of a bright red color; the skin over the surrounding area is swollen and tense; the red nodule itself is glossy, as though it had been polished. In the majority of cases the nodes disappear in from eight to fourteen days, though the duration of the disease varies according to the intensity of the eruption. Sometimes the disease is terminated by a single crop of nodes in a very few days; in other cases, the repeated occurrence of the eruption in succeeding crops, prolongs the disease, so that it may last three, four or even eight weeks.

It has been maintained that erythema nodosum is in a sense infectious. Moussons¹ observed that a child who was admitted with erythema nodosum seemed to infect another child in an adjoining bed in a hospital ward. Heim² reported that a child who fell sick with erythema nodosum seemed to communicate the disease to a little sister, in whom the usual symptoms developed.

THE ASSOCIATION OF ERYTHEMA NODOSUM WITH OTHER DISEASES.

In the seventeenth and eighteenth centuries many of the writers considered rheumatism the cause of erythema nodosum. Among others, Sydenham, Boerhave, Andraen and Sauvages spoke of an exanthematous arthritis. One of the writers, Piffard, believed that the retrograde products of metabolism, such as uric acid, oxalic acid, kreatin and kreatinin, were excreted through the skin and caused disturbance in this localization. Clinical observations do not confirm the rheumatic views of the older writers concerning this disease. It is true that these patients complained of arthritic pains, but that does not necessarily signify that they are rheumatic in character. Joint pains are common in other infectious diseases, as, for example, scarlet fever, measles, typhoid, also in scurvy.

Stephen Mackenzie,³ quoted by Cheadle, records 108 cases of erythema nodosum. In two of the cases endocarditis occurred with the eruption, without joint affection. Cheadle, however, continues to believe that erythema nodosum is of rheumatic origin in many cases. To prove this, he points out the tendency of the erythema nodosum to occur in young girls who are most liable to rheumatic arthritis, as well as to endocarditis and chorea; he believes that this is in agreement with a view of its rheumatic nature. Later on he says: "The fact that erythema occurs in cholera and septicemia, as the result of some form of toxic absorption, would lead me to believe that erythema depended on the ex-

istence of some irritant matter which is in circulation, acting either directly or by reflection on the skin."

The pains which occur during the prodromal stage, and during the height of the disease, are readily explained by the infiltration and inflammation in the skin.

HEART LESIONS.

A more frequent complication than rheumatism is endocarditis in association with erythema nodosum. The endocardium, pericardium and myocardium may be involved; that is, heart lesions need not necessarily be looked on as rheumatic inflammations; they may be considered infectious in nature, depending on the same cause which produces the erythema nodosum.

THE RELATION OF ERYTHEMA NODOSUM TO TUBERCULOSIS.

In one of my own cases, the history of which is given in this paper, a seven-year-old boy developed tubercular meningitis after an attack of erythema nodosum. In 1872 Uffelmann observed several children who, after having suffered from erythema nodosum, were attacked with general tuberculosis and died. It is true that clinicians of wide experience with this disease claim never to have seen a tubercular complication or sequela, notably among whom may be mentioned Baginsky, Bohn and Pfeiffer. Philip Kuhn,⁴ who had opportunity to study 22 cases of erythema nodosum, found that eight children—that is, 36 per cent.—came from families in whom a tubercular history could be obtained, though he remarks that these figures would not permit him to conclude that tuberculosis was causally connected with erythema nodosum, because tuberculosis is very prevalent in Berlin, and it occurs many times without erythema nodosum. One of Kuhn's patients died of tubercular meningitis six weeks after the erythema. Another little fellow developed tubercular pleurisy three months after an attack of this skin affection. Kuhn concluded, however, that, because tuberculosis followed erythema nodosum in two cases out of 22, it is not proof sufficient to justify the belief that erythema nodosum is concerned in the production of tuberculosis. He goes on to say that it has been conceded by clinicians that erythema nodosum is an infectious disease.

Other infectious diseases, like measles and whooping-cough, frequently prepare a soil for tubercular infections, particularly the miliary type. Perhaps the erythema nodosum acts in the same way. The indisputable fact remains that in some cases, after longer or shorter period, erythema nodosum has been followed by symptoms of tubercular infection.

Erythema nodosum has been noted during an attack of scarlet fever, in a child 3 years of age. It has also been noted as a complication of measles, the erythema occurring four weeks after the measles disappeared. Moncorvo has seen the disease follow malaria. It is to be particularly noted that in quite a number of the reported cases sore throat has preceded by several days the development of the disease. In one of my own cases this course was observed.

COMPLICATIONS.

The question of heart disease and tuberculosis has already been discussed. Curschmann observed hemorrhagic nephritis; Lewin reported neuralgias; Quinke has reported cases of bilateral paralysis of the perineal nerves in a case of erythema nodosum. Multiple neuritis, involving the cranial nerves and those of the ex-

4. Archiv für Kinderheilkunde, 1903.

termitics, has been reported by Baumber. Psychoses in the form of mania and melancholia have been described by Jolly. Most children suffer from anemia after the disappearance of the disease.

HISTORIES OF CASES.

CASE 1.—James H., aged 7 years, was brought into my service at the County Hospital from St. Joseph's Orphans' Home; admitted on Nov. 27, 1903.

History.—Mother dead, cause unknown; father and one brother are alive. The patient is said to have had typhoid fever and pneumonia during the past summer.

Present Illness.—The little fellow took sick five days previous. The disease started with fever, headache, nausea and anorexia, pains in the legs, followed later by swelling and redness. On entering the hospital he reported that the swelling was increasing steadily, and that the pains in his legs persisted. He complains at present of swelling and tenderness and some pain in both legs, also a slight cough. His appetite is good, bowels are regular, he sleeps well, sight and hearing normal. The little fellow is small for 7 years of age; looks poorly nourished; seems bright mentally.

Examination.—Examination of the head, face and thorax was negative; the examination of the abdomen showed the spleen somewhat enlarged; liver negative; on the anterior surface of both legs were from seven to ten raised, red, tender areas; they were firm in consistency, painful on pressure, irregular in shape, not well circumscribed, some the size of a half dollar and considerably raised. Other nodes were scarcely raised at all; one, over the tibia of the left leg, was the largest of all, though it did not differ in general appearance from those already described. On the external surface of the right arm were two round, red nodes, the size of a nickel; they were not elevated, though the surrounding skin was infiltrated, and the nodes themselves tender to the touch. For three days after his admission, however, the temperature increased, he complained of not feeling well, and in a very short time new eruptions were observed over the extensor surface on the upper and also on the lower extremities. A few eruptions also occurred on the flexor surface of the legs. The anterior tibial surfaces of both legs showed considerable swelling and glossiness of the skin, and the nodes themselves continued tender. The urinary examination showed a trace of albumin and a few hyaline casts. Widal examination was negative; there were 11,000 leucocytes per cm. The patient was discharged on Dec. 18, 1903, somewhat anemic, though fully recovered from his disease. The Orphans' Home reports at this writing, May 24, 1904, that the little fellow has been perfectly well since his discharge from the hospital; he has had no return of the disorder and has improved in general health.

CASE 2.—Frank C., aged 5½ years, was brought into my office by his mother, after having been sick for three or four days.

History.—The mother gave the following history: The patient is the second child. Her little girl, three years older, is not robust in health, though she does not suffer from any chronic disease; the father and mother are both healthy; the little patient suffered from measles one year ago and had a sharp attack of lobar pneumonia when he was two years old. For three or four days before he came to see me he complained greatly of pains in the legs, difficulty of walking, fever, chilliness and headache.

Examination.—Examination showed that the little fellow was intensely pale, his pulse rapid, temperature 101, and he seemed exhausted; examination of the heart, lungs and abdomen was negative. On his legs, over the tibia, were noted several well-defined, red, infiltrated nodes, with the usual shining and swollen appearance of the skin. There was pain and tenderness on pressure.

Course of the Disease.—After three days in bed the spots began gradually to disappear, the infiltration became less, the red gradually faded, the color became fainter and fainter till it appeared like a slight pigmentation over the area of the previous nodular swelling. It was noted, however, that the temper-

ature continued, in spite of the fact that the lesions over the tibia had disappeared. The morning temperature was from 99 to 101, while his evening temperature was frequently as high as 104. The little fellow was extremely irritable and was restless in bed. This febrile condition, with irregularity of the pulse and an occasional vomiting attack, continued for two weeks.

He refused food, lost in weight and in strength, the pallor increased, and at the end of the second week a convulsive seizure occurred. After this he passed into a comatose or stuporous state, which continued for ten days, until his death. No convulsions occurred after the initial attack. The eyes and ears were examined with negative result; the urinary analysis was without positive findings. Widal examination was negative; rigidity of the neck became marked, slight facial paralysis occurred, pulse and respiration were manifestly irregular, paresis of the extremities occurred, the abdomen became retracted, *Tache cérébrale* marked, Babinski sign present, bowels constipated, urine was passed involuntarily. As stated, he remained in this condition for ten days. For hours he would lie perfectly quiet; then, in turn, he would arouse for a very short time, become extremely restless and delirious, and sink back into this comatose state. Toward the end the respirations were extremely irregular, approaching the Cheyne-Stokes variety; the picture was typical of basilar or tubercular meningitis.

CASE 3.—Another little patient, Cecil W., aged 11, father and mother living and well.

History.—The patient lost a younger sister one year ago from a malignant scarlet fever; the patient himself has suffered several times within the past five years from attacks which have been diagnosed as meningitis. He is large for his age, but has a well-marked scoliosis; in other respects the physical examination was negative. About the last of December, 1903, I treated him for a well-marked membranous tonsillitis, which proved on bacteriologic examination to be a streptococcus infection (no antitoxin was administered). He was confined to the bed in the house for nearly a week.

Present Illness.—About ten days after his recovery from the tonsillitis I was again called to see him, because he was suffering from severe pains in the lower extremities. His temperature was 103, pulse rapid, he was drowsy, desired no food, and gave the impression of being severely ill. On the second or third day, the eruption began to appear on his leg; later, also, on the extensor surfaces of his arms; the temperature continued high, pulse rapid. After a week the rash tended to disappear and made its usual involution; the patient felt well and asked for his discharge.

I have seen him frequently since the illness; he has suffered no complication as a result of his erythema nodosum.

DISCUSSION.

DR. DAVID LIEBERTHAL, Chicago, declared that pediatricians have as much opportunity to see this rare affection as do the dermatologists. Unfortunately there is much confusion in medical nomenclature, especially of diseases of the skin, and although older writers claim that erythema nodosum and erythema exudativum are identical, there are many features of distinction. Pharyngitis, pleuritis, pericarditis and endocarditis can not be considered as sequelae of erythema nodosum, but must be looked on as concomitant symptoms. We have little certain knowledge of the etiology of the disease, as knowledge of its bacteriology has not led to any positive conclusions. The pathologic conditions present are serous infiltration of all the layers of the skin, engorgement of the lymphatic vessels and spaces, vascular stasis, moderate cellular infiltration and extravascular foci of red corpuscles—findings similar to those observed in simple urticaria.

Chloral.—From an experimental research published in *L'Echo Medical du Nord* Oct. 23, 1903, Dubois concludes that chloral possesses a cholagogue action which is due to its special action on the upper intestine and also to some extent by its absorption by the vessels.

PROPHYLAXIS OF TUBERCULOSIS IN CHILDREN.*

LOUIS FISCHER, M.D.

Visiting Physician to the Willard Parker and Riverside Hospitals.
NEW YORK CITY.

In order that we can intelligently apply the proper treatment for the prevention of the disease, an inquiry into the method of its propagation must be made. The postmortem examinations of hundreds of cases of tuberculosis show that it is a rarity to find primary intestinal tuberculosis.

Heubner's results in a series of studies were as follows:

844 nurslings, age 1 day to 3 months,	tuberculosis none.
218 nurslings, age 3 to 6 months,	3.6 per cent.
Age 6 to 9 months,	11.8 per cent.
Age 9 to 12 months,	26.6 per cent.
Age 2 to 3 years,	14.2 per cent.
Age 3 to 4 years,	13.4 per cent.
Age 4 to 5 years,	11.1 per cent.
Age 10 to 11 years,	5.0 per cent.

Heubner argues that, as not one single case appeared in a series of 800 nurslings during the first three months, the disease was acquired and not transmitted by inheritance.

Küss proved anatomically that primary tuberculous lesions are most frequently found in the bronchial glands. This corresponds with inhalation tuberculosis in animal experiments; hence it must be presumed that the inhalation of the *Bacillus tuberculosis* may cause this infection. Infants are constantly exposed to infection when in the same room with adults affected with tuberculosis. Heubner describes a case of a child with sound parentage that succumbed to tubercular meningitis after being exposed to a tuberculous adult.

It is impossible to trace by distinct means the source of infection in any case of tuberculosis. We know that tubercle bacilli abound in dust, in the form of dried sputum, and that these pathogenic bacteria can easily be disseminated by drafts of air. We know that mats and carpets are the hiding places of millions of these germs.

STATISTICS OF NECROPSIES.

Latent tuberculosis is frequently found in children at autopsy. Bollinger studied a series of 500 autopsies in children up to the fifteenth year. He found lesions of tuberculosis, either inactive or latent, in 218 cadavers. Küss, in studying tuberculous lesions in children, found that the maximum number of deaths appears between the second and fourth years.

Dr. Walter Carr reports statistics of necropsies on tuberculous children at the Victoria Hospital. He found 79 in which the disease most probably started in the chest, and 20 in which it seemed to have begun in the abdomen. Here the relation between the two forms of infection is as 1 to 4. In 26 children of early or limited tuberculosis, the thorax alone was affected in 12 cases, the abdomen in 7, being in the proportion of 1 to 1.7. Of 53 tuberculous children under 2 years of age, the disease most probably began in the chest in 43, and in only 5 certainly in the abdomen, the proportion in this case being as 1 to 8.4. Out of 27 children over 5 years of age, the disease began in the chest in 12, in the abdomen in 6, the relation being as 1 to 2.

These statistics, being all from English sources, are fairly comparable, and it appears to me they sustain Dr. Thorn's contention that the returns in England of tabes

mesenterica represent with fair accuracy the abdominal tuberculosis of children.

Bollinger, in his address at the International Tuberculosis Congress of Berlin, in 1899, quoted with approval the record of autopsies by Heller (Kiel) of 248 tuberculous children, which showed in 45.5 per cent. of the cases tuberculosis of the mesenteric glands. From these, it was concluded that milk played a leading rôle in the so-called transmitted tuberculosis of children.

BOVINE TUBERCULOSIS.

It is plain from what has been said that in some countries where bovine tuberculosis is very frequent there is also a frequency of tuberculosis in children. Bollinger concludes that "although the tuberculosis of cattle and swine do not stand in the first line as source and starting point of human tuberculosis, nevertheless, considering their enormous distribution and progressive additions, and the great danger from the ingestion of the milk of tuberculous cows, they are certainly for humanity the most important and the most dangerous of all animal plagues, and deserve the most earnest attention from the sanitarian and the state."

The question as to the transmissibility of tuberculosis by means of drinking milk from cows whose udders are tuberculous is admitted by a great many authors. Koch, however, is authority for the statement that "bovine tuberculosis is an entirely different disease from human tuberculosis, and can not be transmitted from a cow to a human being." He, therefore, insists that raw milk may be taken *ad libitum* without any risk of infection. There must be a certain disposition or predisposition to the development of this disease.

OTHER PREDISPOSING FACTORS.

Other factors which are prominent in this connection are poor hygienic apartments, rooms in which sunshine is absent, and in which foul air stagnates, will certainly lower the normal resisting power of any and all individuals.

When a child has passed through an acute infectious disease which has already lowered its vitality, then an infection of tuberculosis more easily takes place.

Among the diseases which predispose to the development of tuberculosis are whooping cough and measles. The same is also true in exhaustive diseases which drain the vitality of children for a long time, as, for example, a prolonged attack of summer complaint.

The disease frequently accompanies the nursing period, hence even the youngest child may become infected. Baginsky reports eight cases of tuberculosis among 871 nurslings which died at his hospital. These were all under 10 months of age. On the other hand, he found, among 266 children in the second year, 13 died of military tuberculosis.

Out of 611 children between the second and fourth years, 182 died of military tuberculosis.

Out of 152 children examined between the fourth and sixth year, 6 had military tuberculosis.

ENGLISH STATISTICS.

Still¹ considers these facts and offers some interesting statistics, based not on clinical observation, but on post-mortem findings, for the solution of this problem. In 769 autopsies of children, tubercle was found in 269, or 35.2 per cent. Tuberculosis was the actual cause of death in 252, or 32.8 per cent. From these statistics, therefore, it can be roughly estimated that about one-

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClenahan and John C. Cook.

third of the deaths in childhood are due to tuberculosis in one form or other. While children are thus shown to be specially subject to this disease, they are equally so at all ages, for Still shows that up to the age of 4 the percentage is as high as 71, and between 4 and 8 is still 22.5; after 8 it diminishes to 6.5. Moreover, the greater part of the tuberculosis under the age of 4, 43.4 of the 71 per cent. occurred in children under 2 years of age. This great frequency of tuberculosis in infancy has been used as an argument in favor of the idea of infection through milk, the primary lesion being in the digestive tract. It is true, Still says, that intestinal tuberculosis is exceedingly common in children; it existed in 52 per cent. of his cases examined, but also in that of the brain and meninges, 48 per cent., and that of the lungs is far more frequent, 78 per cent.

AUTOINFECTION BY THE SPUTUM.

Tuberculosis has so great a tendency to generalize itself in children that the question of the primary infection is not to be settled by the mere frequency of the lesions. The fact that children swallow their sputa is to be kept in mind. There is no question as to its infectiousness, while that of ingested milk in the human species has not been absolutely demonstrated. He finds that his statistics show that in 25 cases taken consecutively of children under 3 years, who did not expectorate, intestinal lesions were found in 19, while in a similar series, aged between 3 and 12, they were found in only 10. It would thus appear that autoinfection by the sputa in infants is a matter of serious importance.

DIFFERENCE OF OPINIONS OF VARIOUS AUTHORITIES.

It is interesting to note the difference of opinion held by various writers on this subject; for example, Osler believes that the point of entrance is the respiratory tract. The opposite view is expressed by Delépine. This observer states that tuberculosis gains entrance to the body through the intestine, hence milk is the source of danger. He cites postmortem evidences of mesenteric glands showing tuberculous lesions. Sims Woodhead published a series of statistics showing that tuberculosis was rare during the first year of life. He then points out that from year to year the number of cases increases. He believes that milk causes intestinal and mesenteric tuberculosis, the transmitting agent being milk. George F. Still of London does not believe that inhalation is the most frequent means of infection, hence the reason for the frequency of lung tuberculosis is apparent. Still argues that the reason for the prevalence of intestinal lesions is due to the swallowing of the sputum, so that primary tuberculosis of the lung can be followed by secondary tuberculosis of the intestine.

Friedman studied a series of palatine tonsils derived from 91 autopsy cases and 54 living subjects. The examinations were histologic and bacteriologic. His object sought was to study the entrance point in tuberculous cases. As the result of his work he found that tonsillar tuberculosis exists as, *a*, primary infection from food; *b*, secondary infection from sputum containing bacilli.

Lewin² describes a series of children having serofulous glands and lupus. These cases invariably suffered from adenoids. It was impossible to discover tubercles in the adenoids.

A series of interesting animal experiments are recorded by this writer. Lewin used adenoids from 20 cases and introduced them into the peritoneal cavity of guinea-pigs. Nineteen were failures and one guinea-

pig was infected. The child from whom the adenoid tissue was taken that infected the guinea-pig seemed to be in good health.

STATISTICS OF AUTHOR'S CASES.

The statistics of my cases of tuberculosis from the children's service of the German Poliklinik in New York City are very interesting. Five thousand children were examined at random for the presence of tubercular lesions. More than 4,900 cases out of this number showed no sign of pulmonary disease; 1,700 of these cases have suffered with adenoids, pharyngeal disease, catarrh of the nasopharyngeal tract, or infectious conditions due to poor ventilation and general insanitary surroundings. The cases were taken in children from the first to the tenth year, inclusive; 59 cases out of this whole number showed distinct evidence of pulmonary tuberculosis. Only 9 cases of this whole number showed the presence of tubercular bacilli in the sputum. The difficulty in procuring sputum was an obstacle in making more frequent examinations. Forty-three cases of this number had bone and joint tuberculosis in addition to distinct evidences in the lungs. In two cases tubercular empyema was found. Five of these 59 cases had Pott's disease.

Feeding.—Two cases were breast-fed. Their mothers were very anemic and dyspeptic and suffered with general evidences of malnutrition. Thirty-seven of these cases were bottle-fed. The food consisted of grocer's milk. Eighteen cases were fed on condensed milk exclusively. Two were fed on modified cow's milk.

CASE 1.—Abie W., 8 years old, was brought to my children's clinic five years ago with the history of cough, fever and emaciation. There were general evidences of malnutrition.

Diagnosis and Treatment.—The diagnosis of capillary bronchitis was made and the child given restorative treatment. The cough continued. The sputum was examined at least once a week for a period of two months, and no tubercle bacilli were found. The child was sent to the country, and showed some improvement. He had a recurring winter cough for three successive years. When 7 years old a pleurisy developed, followed by an effusion. The effusion did not disappear, and an exploratory puncture revealed pus.

Operation and Results.—The case was operated on by a surgeon, but in spite of careful attention to asepsis a fistula remained for months. Tubercle bacilli were present in the discharge. Restorative treatment was given and the child removed to the country, and finally cured. The pythorax remained about fifteen months.

The father of this child, I learned, was an inmate of the Montefiore Home for Incurables, suffering with pulmonary tuberculosis. Here a distinct family tuberculosis was found.

CASE 2.—Michael J., 5 years old, was referred to me by Dr. Mehrenlander with a history of cough, fever and emaciation.

Diagnosis and Treatment.—The diagnosis of empyema was made, and an exploratory puncture showed the presence of pus. With assistance of Dr. Mehrenlander, I performed a thoracotomy. As there were thick, croupous masses, two ribs were resected and a drainage tube inserted. In this case the wound discharged several months, and an examination of the pus showed the presence of tubercle bacilli. With the aid of fresh air and restorative treatment, such as cod liver oil, creosote, carbonate and special attention to the outdoor life, the child recovered.

Family History.—The child's father and mother are living. Their occupation as janitor in a tenement house gives them very insanitary surroundings. The bedrooms are dark and very insanitary. An older brother, 17 years of age, has acute apical tuberculosis. This older brother, when brought to me for a slight cough, showed no evidence of disease; in fact, he appeared well-nourished. His sputum contained tubercle bacilli.

2. Archiv f. Laryngologie und Rhinologie, 1899, vol. ix, part III.

We, therefore, have in the two cases just described empyema associated with family tuberculosis.

The co-existence of empyema and a family history of tuberculosis strengthened my opinion that, living under the same insanitary conditions and associating together, these cases were most probably transmitted or communicated.

ETIOLOGY.

Two agents must be held responsible for the transmission of the disease—human sputum and the milk of animals. It is a difficult matter to trace the causal relation between infected milk and infantile tuberculosis. Pathologists state that in from 90 to 95 per cent. the bronchial glands contain the oldest foci, and, therefore, they reason that the point of entry of the bacilli must have been by inhalation into the bronchi. Primary intestinal tuberculosis is rarely seen. Bovaird has reported this condition in this country. Dupont reported a large number of infected school children in whom a tuberculous teacher was believed to be the source of infection.

In a series of tuberculous children studied by me, the interesting point noted was that the large majority suffered with rickets. Tracing these rickets back to infancy, it was found that these children were one and all bottle-fed. As bottle-feeding means cow's milk feeding, *ergo*, there may be a possible association, i. e., cause and effect.

That environment is an important factor can be seen when we consider that all cases seen are in the densely crowded tenement districts. I have seen three distinct cases of tuberculosis in one family, all bottle-fed children.

It is rare to find tuberculosis in breast-fed children. There seems to be an immunity conveyed through the serum in breast milk. Another point, and one which has frequently been noted, is the co-existence of pharyngeal catarrh and tonsillar enlargement. This point is of more importance than one would consider off hand. In a discussion on tuberculosis before the Eastern Medical Society of New York City, I called attention to the fact that mechanical obstruction due to the presence of adenoids and enlarged tonsils interferes with respiration. This interference causes defective oxygenation of the lungs, and hence invites pulmonary disease. Pigeon-breast is one of the deformities frequently seen as a result of disease of the upper air passages.

PREVENTIVE MEASURES.

What preventive measures can be applied to check infantile tuberculosis?

1. Insist on each infant being breast-fed; in other words, start the baby right. Have a good foundation.

2. If the mother can not nurse her child, secure a wet-nurse. Let the wet-nurse nurse her own child in addition to her foster child, and give both infants alternate bottle-feeding. This mixed form of infant feeding is very successful.

3. In foundling asylums and day nurseries a wet-nurse can be procured who will nurse two infants. In this way we lessen the danger of tuberculosis.

The secret of health and the vitality and endurance of the enormous tenement house population is that they are or have been breast-fed.

Compare the bottle or cow's milk babies with the breast-fed babies, and you will find that the ratio of death is 9 in 10, whereas the breast-fed child dies in the ratio of 1 in 10.

CONCLUSIONS.

To sum up, we have two prophylactic measures for infantile tuberculosis. They are:

1. Breast milk.
2. Fresh air and sunshine.

Remember that the serum of breast milk contains an immunizing substance which accounts for the rarity of infectious diseases in the newborn.

65 East Ninetieth Street.

DISCUSSION.

DR. A. JACOBI, New York City, asked what we shall do with a tenement-house baby whose mother is tubercular. How shall such a child be fed, with breast milk, or artificially? If the mother is tubercular, he would forbid her to nurse the baby, not so much, perhaps, because he believes that her milk is dangerous, but because, by holding the child in her lap, etc., there is a distinct danger while the mother is coughing of its becoming infected through the sputum. If such a child can be taken away from its tubercular mother, and kept in a healthy environment, tuberculosis need not be feared, because there is almost no such thing as hereditary tuberculosis. On the other hand, a healthy infant is known to become tubercular when raised in the tubercular family. So far as tubercular milk or the milk of tubercular cows is concerned, Dr. Jacobi thinks that there is one safeguard that probably many have the advantage of, without knowing it. The milk of a single tubercular cow is undoubtedly dangerous; the milk of a tubercular cow that forms one of a herd of thirty or more is not dangerous. This has apparently been settled experimentally. Tubercular milk, when diluted to a sufficient extent, becomes innocuous.

Tuberculosis is transmitted by inhalation, but there is also intestinal tuberculosis. It is not necessary that tubercle bacilli in the intestinal tract should limit themselves to that locality; they will perforate not only diseased, but healthy mucous membrane. This is certainly so in the lung and it seems to be so in the intestines. Some writers insist that when the bacilli get into the mouth or nose, they are not inhaled directly into the lungs, but are absorbed in the posterior nares and tonsils. These observers claim that the first deposit of the tuberculosis is in the glands of the neck; from there it travels downward through the three tiers of lymphatic bodies into the mediastinum. If this explanation is the correct one, then it would appear that every conglomeration of lymphatic bodies is dangerous, for they may harbor tubercle bacilli.

DR. W. B. ULRICH, Chester, Pa., agrees that tuberculosis, *per se*, is not transmitted from parent to child, but he believes that the tendency, the weakness, the diathesis, is transmitted, and that on the least exciting cause or provocation tuberculosis may develop. Prophylactic treatment should be in the direction of reforming or controlling the marriages of the world. People rush into wedlock through their emotions rather than through their reason. As long as forty years ago the Kentucky farmers appreciated the wisdom of careful selection in the breeding of their horses. At least as much care should be taken in the breeding of children as in the breeding of horses, but unfortunately it is not.

A child should be removed from a tubercular mother. Tubercle bacilli may exist in the lungs for years without doing any harm. An autopsy on a man who had died accidentally while apparently in the enjoyment of perfect health, showed the lungs to be filled with miliary tubercles that had probably been there for years, and yet the man was strong and well-nourished and had shown no symptoms of tuberculosis. Dr. Ulrich has known more children to be injured by overfeeding than by underfeeding, and he thinks that children are given the breast too often. Every time a child cries, it is nursed, even as frequently as every half hour. Educate mothers how to feed children.

In the treatment of tuberculosis, however, forced feeding and out-of-door life, plenty of sunshine, and pure air, are important. Dr. Ulrich referred to a little girl, about five years

old who had tuberculosis of the ankle. The child's father was in Denver, suffering from pulmonary tuberculosis. There are many similar instances, and they show a transmission of the disease, perhaps not directly, but through its tendency or diathesis.

DR. CHARLES C. BROWNING, Highland, Cal., called attention to the fact that isolating a child from its tubercular mother is, among the poorer class, impracticable. Parents are not able to put their children out; in many instances, they are unwilling to do so; we can not compel them to and Dr. Browning said that he was not sure that it would be right if we could. Recently, in looking up this subject, which is a vital one in southern California, he found that in a series of autopsies held previous to the first month of life, less than 0.1 per cent. of the deaths were due to tuberculosis. The percentage of deaths from tuberculosis increased rapidly from the third month until about the eighteenth month, then rapidly declined. The manner of infection of those children, he believes, is largely due to the tubercle bacilli being inhaled and admitted through the mouth during the time children are creeping about the floors. The decrease in tuberculosis begins with the period of walking and the increase of independent existence of the child. We can teach parents to keep the floors clean.

DR. R. B. GILBERT, Louisville, asked Dr. Fischer if he agreed with Dr. Koch that tuberculosis is not transmissible through cow's milk. He said that when Dr. Jacobi made the statement that tuberculosis is not directly communicable by the mother's milk, it came to him as a sort of revelation. He thought that such a method of infection was possible, and has always strongly advised against tubercular mothers nursing their children.

DR. A. JACOBI, New York City, said that he meant to say that the transmission of tuberculosis from a tubercular mother was less due to her milk than to the inhalation of her sputum. He certainly did not exclude the possibility or even the probability of the milk being directly injurious. Children have been taken away from tuberculous parents, put into public institutions and have remained well, while on the other hand, healthy children have been placed in tuberculous families and became infected, simply from their surroundings.

DR. C. F. WAHNER, Fort Madison, Iowa, gave it as his opinion that if a child born of two healthy parents was exchanged for a child born of one or two diseased parents, so that the healthy parents were to take care of the child born of diseased parents, and the diseased parents were to care for the child born of healthy parents, the child that is reared by the healthy parents will have a far better chance of life, notwithstanding its inheritance, than the child that was born of healthy parents but reared in unhealthy environment. Every mother should be instructed how to feed her child intelligently, not by food prepared in the chemical workshops, according to the latest fads, but by using common sense methods as agreed on by the best pediatricists. Few mothers will consent to give up a child, and in many instances it is well-nigh impossible. No one knows whether mother's milk will transmit tuberculosis or not. It is not heredity that we must teach people to fear so much as the constant exposure of the child to the infection from its diseased parents.

DR. PAULUS A. IRVING, Richmond, Va., gave a striking illustration of the possibility of bovine infection. In his city there is an infant asylum accommodating about 30 infants. A public-spirited citizen gave it what he thought was a very fine cow, whose milk was sufficient for the entire need of the institution. Soon after the cow was received, it was noticed that the infants began to droop and pine away, and in less than a year only one infant survived. The cause of this high mortality was vainly sought for. Finally, the milk from the cow was suspected. A veterinarian examined the cow and found that she was tubercular. When the animal was killed unmistakable evidences of the disease were found. Such an example furnishes very strong evidence of the transmission of bovine tuberculosis to the human family.

DR. LOUIS FISCHER thinks that the tubercular mother should not only be isolated from her healthy child, but also from her husband and from everyone else who is receptive to tuberculosis. Among 5,000 cases taken at random he found that 1,709 suffered from adenoids, pharyngeal disease and catarrh of the nasopharyngeal tract, 59 showed evidence of pulmonary tuberculosis, and 5 had Pot's disease in addition to the pulmonary manifestations. Of these 59 tuberculous cases, only 2 were breast fed; the rest were bottle fed, the food consisting of grocer's milk, condensed milk and modified cow's milk. The great immunity of breast-fed children from tuberculosis is certainly worth noting. He thinks that condensed milk furnishes the poorest foundation for the child. It is deficient in proteids, contains a great deal of sugar and develops fat in place of muscle. It consists largely of cane sugar, which is put in to preserve it. Many of the children fed on condensed milk suffer from constipation, which is often an early manifestation of rickets. It is largely used by the poorer people, because it is cheap and sold in a convenient form for use. It is this poor form of infant feeding, added to insanitary living apartments without sunshine and fresh air that devalorizes and invites tuberculous infection. There are two usual modes of entrance of the tubercle bacillus: (a) By inhalation. (b) By food. In inhalation tuberculosis the tubercle bacillus is carried into the nose, throat, bronchi and lungs by means of dust or dried sputum from a tubercular patient.

The tubercle bacillus can also enter the system by means of the lymph channel if inhaled and so enter the circulation.

In food tuberculosis, when infected milk or meat or any article of food containing tubercle bacilli enters the body an infection takes place primarily in the intestine, and enters the circulation by means of the lymph channels.

Dr. Fischer does not believe that we can prove to-day that milk alone is a causative factor of tuberculosis. He believes that there are other conditions which predispose to infection and that there are thousands of people who have tubercle bacilli in their throats, together with all sorts of pathogenic bacteria, and still remain unaffected because their bodies are not in a receptive condition. When, for some reason or other, they get into a subnormal condition, then they are receptive to anything under the sun. He believes that we must await further evidence before we can say that milk alone is a factor that transmits tubercle bacilli to the baby, as it is difficult to trace the bacilli into the body. We have no other theory at the present day than to associate the bacilli in the cow's milk with their effect on the infantile respiratory and digestive tract.

THE PRESENT STATUS OF THE TREATMENT FOR DEAFNESS DUE TO CHRONIC CATARRHAL OTITIS MEDIA.*

PHILIP D. KERRISON, M.D.

Instructor in Otology, University-Bellevue Medical College; Aural Surgeon, Willard-Parker Hospital; Assistant Aural Surgeon, Manhattan Eye and Ear Hospital; Otolologist, University-Bellevue Dispensary.

NEW YORK CITY.

In responding to your committee's invitation to prepare a paper on this particular subject, my first impulse was to decline the task as presenting too many difficulties. The subject is manifestly too broad to be adequately outlined in a single paper. I hope, however, that my paper may serve the purpose of inducing a larger and more useful discussion by others.

Chronic catarrhal otitis media is an elastic term, rather indefinitely applied to a variety of tympanic conditions, which are, perhaps, best considered under the following headings:

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otolology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

1. Chronic tubal catarrh, without marked tympanic changes other than those due to retraction of the membrana tympani.

2. Chronic hypertrophic otitis media.

3. Chronic hyperplastic otitis media; dry middle ear catarrh; otosclerosis.

Obviously no classification is of practical value which divides these cases into groups which can not be recognized clinically. The differential diagnosis is not easily reduced to any system of rules. In the early stages the functional reactions do not greatly aid us, serving merely to locate the lesion in some part of the conducting apparatus. Nor do the physical appearances of the drum membrane, considered alone, afford as reliable data as might be expected. Thus marked retraction of the drum membrane may be found either in simple tubal catarrh, chronic hypertrophic otitis media, or in cases of sclerosis secondary to hypertrophic otitis media. Calcareous deposits may occur in either the hypertrophic or hyperplastic form of otitis.

DIFFERENTIAL DIAGNOSIS.

The differential diagnosis should take into account, therefore, not only the type and duration of the deafness, and the physical defects of the drum membrane and tubes, but also the history of the patient, and, perhaps, most important of all, the manner in which the deafness responds to treatment.

Previous History.—With deafness of one or more years' duration, the patient should be interrogated as to the following predisposing conditions:

(a) A history of a preceding obstructive lesion within the nose or nasopharynx is somewhat suggestive of the hypertrophic form of chronic otitis media.

(b) Frequently recurring attacks of acute otitis media, whether of mild or severe type, predispose markedly to the development of chronic hypertrophic otitis media.

(c) Rheumatism is said not infrequently to be accompanied by local manifestations within the ear. Obviously such lesions, especially in recurrent attacks, might act as a predisposing cause of chronic hypertrophic otitis.

(d) Gout, on the other hand, is said to frequently co-exist with sclerotic changes within the ear, and to this extent the gouty diathesis should be considered in arriving at a diagnosis.

Constitutional syphilis, either congenital or acquired, is regarded by German otologists as one of the causes of otosclerosis.

As the time at our disposal is limited, it may be well to bring together briefly the characteristic or distinguishing features—so far as we are able to recognize them—of the three classes of cases under discussion.

In chronic tubal catarrh, the deafness is of tympanic type,¹ and usually of several months' or a year's duration. The past history may be negative or may include an account of chronic nasal catarrh or recurrent attacks of acute rhinitis. The degree of deafness is variable, sometimes clearing up for days or weeks, only to return with a fresh attack or exacerbation of nasopharyngeal catarrh.

Physical Examination.—This usually shows the nose or pharynx to be more or less inflamed. The drum membrane is markedly retracted, but may be otherwise normal. The otoscope during inflation usually gives characteristic signs of tubal congestion or narrowing.

If, after inflation, the drum membrane is seen to have resumed in part its normal position, and the hearing is markedly improved, the diagnosis would seem to be complete.

In chronic hypertrophic otitis media, the impairment of hearing may have been noticeable to the patient during several months or as many years. The deafness is of the same character as in tubal catarrh, but is less subject to variations in degree. There may be a previous history of nasal obstruction of long standing; of rheumatic attacks of the usual articular type, or occurring as recurrent attacks of acute tonsillitis. The ear may have been the seat of prolonged suppuration in childhood, or of repeated attacks of acute catarrhal otitis.

Examination.—Inspection usually reveals considerable retraction of the drum membrane, which may exhibit uniform thickening, localized calcareous deposits or the cicatrices resulting from old perforations. It may, on the other hand, be nearly normal in appearance. Evidences of tubal narrowing or obstruction are invariably present.

In such cases inflation should result in moderate but appreciable improvement in hearing, which would confirm the diagnosis of chronic hypertrophic otitis media.

In chronic hyperplastic otitis media the progress of the deafness is often slow and insidious, it being in many cases difficult to obtain from the patient a reliable statement as to its duration. The previous history may include gout or constitutional syphilis, or may be absolutely negative. The eustachian tubes are patent and may be abnormally wide. The physical signs of the drum membrane may be absolutely normal, or may show calcareous deposits. But slight functional gain, if any, results from inflation. Excluding a primary labyrinthine lesion, the above picture would justify the diagnosis of chronic hyperplastic otitis media.

From the above notes, it will be seen that in all these cases the immediate effect of inflation on the deafness is regarded as an important test.

FUNCTIONAL REACTIONS AND THEIR BEARING ON PROGNOSIS.

I would like also to be allowed a word as to the value of certain functional reactions as affecting prognosis.

The deductions to be drawn from the tone limits—i. e., relative impairment of hearing for the upper or lower tones of the musical scale—do not appear to be as reliable as they were formerly thought to be. While loss of hearing for the upper tones undoubtedly points in a general way to labyrinthine disturbance, such impairment may be greatly increased by an obstructive lesion within the tympanum. In certain depressed conditions of the general nervous system, and also with advancing years, the auditory nerves become less responsive to sound waves of every description, and most notably in the two extremes of the range of normal hearing. When such a patient develops an obstructive tympanic lesion, it is not surprising that the range of audition may be curtailed in the upper as well as the lower limit. It is only on the above hypothesis that one is able to explain certain cases in which considerable loss of hearing for the higher tones is found side by side with normal or perhaps slightly increased bone conduction. With such reactions to functional tests, it has not been unusual in my experience to obtain a considerable improvement in the upper tone limit as a result of simple measures directed against a tympanic lesion. Obviously in such a case the change in the upper tone

1. Presenting functional reactions characteristic of disease of the conducting apparatus.

limit is not to be regarded as an evidence of grave labyrinthine disease, and should not of itself be made the basis of an unfavorable prognosis.

Of much greater prognostic value are marked changes in the perception of sound by bone conduction which, when considered in their relation to other functional tests, furnish our best guides as to what may be expected from treatment. Thus in any case of chronic deafness marked diminution in bone conduction must be regarded as an unfavorable prognostic sign. With this condition the upper tone limit is often considerably lowered, and in this connection the latter is an important sign as further pointing to serious labyrinthine involvement. Marked increase of bone conduction, i. e., increase to the point where a fork of 256 D. V. is heard longer by bone conduction than by air conduction, is also an unfavorable sign to the extent that it usually indicates an advanced tympanic lesion in which the hearing may be considerably improved, but will not be restored to the normal standard. On the other hand, moderate increase of bone conduction is often in cases of slight deafness a sign of good omen as indicating a stage of tympanic disease, for which local measures should be followed by good results.

Before taking up, briefly, the subject of treatment, I wish to state very frankly my belief that there are comparatively few therapeutic measures which have any value in these cases; and that our success in any case will depend on our skill and judgment in the use of these, rather than a resort to many remedies of less known value.

CHRONIC TUBAL CATARRH.

Obviously a catarrhal condition of the tubes may exist for a considerable period without producing ear symptoms. Only those cases, therefore, are of interest to the otologist in which the caliber of the tubes is so reduced as to interfere with the passage of air to the tympanum. The result of such occlusion is always mechanically the same, viz., absorption or rarefaction of the air within the tympanum, with consequent retraction of the drum membrane. The deafness, then, is a mechanical one, and due, not to pathologic changes within the middle ear, but to partial fixation of the membrane and ossicles by atmospheric pressure from without.

Under chronic tubal catarrh, it is, perhaps, admissible for therapeutic purposes to recognize three conditions causing retraction of the drum membrane, viz.: (a) Nasal obstruction; (b) tubal congestion; (c) tubal constriction or stenosis.

Nasal Obstruction.—There are certain cases in which, as a result of an obstructive nasal lesion, the air in the nasopharynx is more or less rarefied with each inspiration. In consequence of this the air pressure within the tympanum becomes constantly negative.

The history is usually that of deafness characterized by periods of amelioration. Interrogation elicits the fact that the patient is at times a mouth breather. On physical examination the drum membrane is found markedly retracted. The physical evidences of nasal obstruction are more or less pronounced. Inflation per catheter, however, results in a fairly good current of air to the tympanum, partial or complete replacement of the drum membrane and prompt relief of the subjective symptoms. The relief thus afforded may last a few hours or several days, when the deafness returns. Closer observation of the patient may now disclose a faulty method of breathing. While not a typical mouth

breather, the mouth is frequently opened to compensate the nasal difficulty. Obviously in such a case no amount of treatment by sprays, inflations, pneumatic massage or what not will be of any permanent value until the nasal lesion has received attention.

Chronic Tubal Congestion.—Belonging more properly to this group are those cases in which the tubal mucous membrane is the seat of a chronic venous congestion. These patients present symptoms and physical signs almost identical with those just described. Inflation, however, gives unmistakable signs of obstruction due to congestion, the sounds through the otoscope being at first muffled, rasping or accompanied by rales, then becoming clearer as air enters the tympanum in greater volume. Inflation results in marked temporary relief of the symptoms, and the rapid improvement in the auscultatory signs shows more or less clearly that the lesion is chiefly one of chronic venous congestion.

TREATMENT.

These cases usually respond readily to proper treatment. This should include correction of any condition within the nose or nasopharynx which may act as an exciting cause of tubal catarrh; application of astringents to the inflamed pharyngeal mouth of the tube; regular inflation of the middle ear, at first on alternate days and then at longer intervals.

For adult patients, inflation per catheter possesses the following advantages over the Politzer method: It enables one by means of the clearer otoscopic sounds and the force required in propelling air to the tympanum, to determine with greater accuracy the condition of the tube; to regulate the force of the current of air, and to inflate only the diseased ear. It eliminates the danger—where one ear only is diseased—of producing undue relaxation of the opposite drum membrane.

Many of these cases require no other treatment than regular inflations, with appropriate measures to relieve congestion within the nose or pharynx.

Tubal Constriction.—There is still another class of tubal cases in which the obstruction depends not only on chronic venous congestion, but also to some extent on the formation of new connective tissue. The hyperplasia may occur as a uniform thickening of the tubal mucosa, or as localized deposits having a tendency to contract. During inflation the sounds through the otoscope are insufficient, high-pitched or whistling, clearly indicating the reduced caliber of the tube. With such a lesion we are justified in classifying under tubal catarrh those cases of moderate deafness which show sufficient improvement after inflation to exclude serious lesions elsewhere.

The indications for treatment include those already described under tubal congestion, plus active measures for the restoration of the tube to its normal caliber. While considerable improvement often results from inflation, it usually becomes necessary to resort to some form of mechanical dilatation to overcome the constriction within the tube.

THE EUSTACHIAN BOUGIE.

The technic of introducing the eustachian bougie begins with the proper placing of the catheter within the pharyngeal mouth of the tube. Beyond this there are, in my opinion, two points of major importance in this method of dilatation, viz.: First, the selection of a small rather than a large bougie; and second, that it be al-

lowed to find its own way through the stricture or constriction, rather than be made the subject of force.

When the tube is not actually stenosed, it is probably the contact of the bougie with the diseased mucous membrane rather than its action as a forcible dilator which is of value in overcoming the obstruction. Only in this way can be explained the improvement which sometimes follows the introduction of a small bougie which has met with no appreciable resistance. The eustachian tube is not, like the urethra, a distensible canal. Surrounded in its narrowest part by firm unyielding walls, attempts at forcible dilatation can result only in compression of its mucosa between the dilating instrument and the osseous walls of the canal. When the bougie meets with obstinate resistance at the isthmus, it must be explained on one of three hypotheses, viz.: Either that (1) the bougie is not exactly following the direction of the tube; that (2) the caliber of the bony tube is too small for the bougie; or that (3) a firm fibrous stricture exists at this point. Even in the latter instance the application of force might result in serious injury.

The points which I wish to emphasize are: The danger of attempting to force a large bougie through a small and rigid channel lined with mucous membrane; and the importance of avoiding force in its manipulation.

In my opinion a bougie, the terminal bulb of which measures not more than one mm. in diameter, is as large as should be used in the great majority of cases. The particular style of bougie that should be used is largely a matter of personal choice. Those of whalebone or celluloid are most satisfactory.

DILATATION BY ELECTROLYSIS.

No discussion of this subject would be complete without mention of the electrolytic method of dilatation devised by Dr. Duel of New York. In hospital practice this method has been thoroughly tested by Drs. Brandegee and Kenefick, in the New York Eye and Ear Infirmary; and their reports would seem to leave little doubt as to its value in properly selected cases. In my experience there have been many cases of tubal narrowing or stenosis which have yielded more readily and favorably to treatment by this method than by any other.

When, in a case of simple tubal catarrh, the obstruction has been overcome and a satisfactory gain in hearing attained, the end of local treatment should be considered accomplished.

CHRONIC HYPERTROPHIC OTITIS MEDIA.

Pathologically, these cases are characterized by morbid changes within the eustachian tubes and also within the tympanum. They resemble those described under the last heading in that tubes are usually abnormally narrow and may be practically closed. The middle ear is the seat of a productive inflammation involving primarily the tympanic mucosa. The new connective tissue may be evenly distributed throughout the tympanum, may be massed chiefly in the region of the labyrinthine windows, or may occur as fibrous bands passing between the ossicles and adjacent structures.

Obviously the deafness is dependent on two distinct lesions, either of which alone might cause impairment of hearing, viz., chronic tubal catarrh, with consequent retraction of the drum membrane, and the hypertrophic changes within the tympanum.

TREATMENT.

The indications for treatment are: (1) To re-estab-

lish the normal patency of the tubes; and (2) to restore as nearly as may be a normal condition within the middle ear.

The treatment of tubal catarrh has already been described and need not be repeated. Since the tympanic disease is usually secondary to the tubal lesion, the importance of fully meeting the first indication hardly requires argument. The restoration of the balance in air pressure on both sides of the drum membrane is almost invariably followed by a very considerable increase in hearing power. From this point the improvement is usually slow, and will depend on the gradual restoration of the intratympanic structures to their normal condition. To this end nothing is more important than the automatic ventilation of the tympanum through the eustachian tube. Occasional gentle inflation may serve to relieve congestion, to free the ear of accumulations of mucus, and to maintain the drum membrane in its normal position. The employment of stimulating vapors, e. g., of iodine, chloroform, menthol, etc., thrown into the middle ear through the eustachian catheter, seems often to add to the patient's comfort, and may have a restorative influence on the diseased mucosa. Occasional pneumatic massage is of advantage in certain cases. It should be practiced only with the drum membrane under direct observation and with an apparatus producing the smallest excursions of the membrane that the eye can appreciate. These measures should at first be tried tentatively, and continued only so long as continuous improvement in function can be demonstrated.

So much for the plan of local treatment which, in a general way, may be applicable to any case of chronic catarrhal otitis media. There are certain conditions, however, which should be noted as calling for some modification of this routine. The drum membrane, for instance, may be held in an abnormal position by intratympanic adhesions. During pneumatic massage by means of the Siegel otoscope, the excursions of the membrane are seen to be exceedingly limited, and without influence on the hammer handle, the lower end of which may remain in apparent contact with the promontory. In such cases it is evident that inflation will not result in replacement of the drum membrane; and that unless practiced with gentleness and judgment, it may result in further alterations of tension, very seriously influencing the patient's hearing.

Atony of the drum membrane is another condition which should not pass unnoticed. The drum membrane may appear slightly thickened or fairly normal in texture. During pneumatic massage, however, the posterior segment is seen to make unusually wide excursions, clearly indicating a condition of undue relaxation. As a result of this loss of tension, sound waves expend themselves on the relaxed posterior segment, and are not adequately communicated to the ossicular chain.

The practice of making multiple incisions through the relaxed drum membrane has not generally given good results, its failure depending on the fact that the resulting cicatricial tissue eventually weakens the membrane, rather than adding to its tone. Application of paper discs to the relaxed posterior segment increases the hearing power in certain cases. More often no functional gain results. Occasional application of contractile collodion to the posterior segment will sometimes result in a considerable gain in hearing. Its efficacy may be enhanced by inflating the ear immediately before the collodion is applied. Even where no immediate functional gain results from this procedure,

it is sometimes of service in preventing further relaxation of the drum membrane during inflation or pneumatic massage.

ATROPHY OF THE DRUM MEMBRANE.

There are other cases in which the membrane has undergone extreme atrophy, having somewhat the appearance of thin tissue paper. In two cases coming under my observation during the past two years, the drum membrane was so attenuated as to be easily ruptured by inflation under ordinary pressure. It is difficult to suggest any rational treatment for the relief of such patients. They have seemed to me most favorable cases, if any there be, in which to perform the operation of ossiculectomy for the improvement of function.

Fortunately, a fair degree of hearing is not incompatible with marked changes within the tympanum. In the treatment of all these cases the point of first importance is the recognition—when it exists—of a tubal stricture or constriction, and the employment of adequate measures for its correction.

Other than tonics, drugs have no value in this disease, except as they influence some constitutional condition or diathesis.

CHRONIC HYPERPLASTIC OTITIS MEDIA.

Dry middle ear catarrh; otosclerosis.

Under this group the following lesions have been recognized:

1. In typical cases there is a productive inflammation which originates within the tympanum, and in which congestion at no time plays a prominent part. It is, therefore, subacute or chronic from the start. There is an abundant deposition of new connective tissue within the substance of the tympanic mucosa, which is converted into a thickened, dry, sclerotic membrane, closely adherent to underlying structures. This hyperplasia is often most marked in the region of the oval window. The same changes occurring within the eustachian tubes, these passages are often unusually wide. The drum membrane is, therefore, not retracted.

2. There are other cases in which, independently of or in addition to the above changes, a true osseous ankylosis exists. There is a proliferation of new bone in the vicinity of the oval window resulting in osseous union between its margins and the foot plate of the stapes. The hyperostosis may spring from the promontory, from the margin of the oval window, or may be confined to the labyrinthine surfaces of this region. In the latter case, proliferative changes are not uncommon in contiguous portions of the membranous labyrinth.

3. A third class of cases belonging to this group are those in which sclerotic changes occur as a final stage of chronic hypertrophic otitis media.

TREATMENT.

The results of treatment are not encouraging. The prediction of Politzer that the deafness occurring in advanced stages of the disease will remain forever beyond the ability of the otologist to cure, is one which few at the present time will care to contradict.

Inasmuch as it is impossible clinically to exclude osseous changes in the stapedia region local treatment is to be entered on tentatively. Were the diagnosis made early there is probably no class of cases in which constitutional treatment would give better results. The patient should be placed in the best possible hygienic surroundings. Tobacco and alcoholic drinks should be used in the greatest moderation, or not at all. Constitutional syphilis should receive thorough and

persistent treatment. Gout or rheumatism, or in fact any constitutional diathesis, should receive due attention. Occasional exhibition of potassium iodid is thought by many to be helpful in these cases, and is made a part of the general routine.

LOCAL TREATMENT.

In the early stages benefit may result from simple measures aiming to prevent ossicular fixation. To this end occasional pneumatic massage may be employed. Forceful inflation at long intervals may also be of service. Local medication in the form of stimulating vapors may be used to increase the local blood supply, a result favoring the restoration of the mucous membrane to its normal condition. Obviously these measures can have no beneficial influence in those cases complicated by osseous changes at the oval window.

There is a later stage of the disease in which the drum membrane, malleus and incus, instead of aiding in the conduction of sound, seem to act rather as a barrier to the passage of sound waves to the inner ear. Palliative measures are powerless to relieve this condition.

SURGICAL MEASURES FOR THE IMPROVEMENT OF HEARING.

Various operative procedures have from time to time been proposed for the relief of deafness due to intratympanic adhesions. Division of the posterior fold; of the tensor tympani tendon; of the stapedius; severance of adhesions between the umbo and promontory; any of these measures, plus division of adhesions between the crura of the stapes and the walls of the oval niche, are among the operations which have been performed for the improvement of function. The fact that they are now seldom discussed in otologic literature is perhaps a sufficient commentary on their value.

The operation of ossiculectomy, i. e., removal of the drum membrane, malleus and incus—is practically the only surgical measure which is now considered for the improvement of hearing. As the results of this operation have been subjected to the crucial test of time, the number of its advocates have diminished.

Among recent expressions of opinion as to its value, we find the following:

Politzer¹ says "the results of this operation were so unsatisfactory that it is hardly spoken of at the present time." He states that he has seen cases in which the operation was "followed by great loss of hearing, ending in deafness."

A. H. Cheate² of London, considers the operation justifiable, the patient being made to understand that it is more or less of an experimental nature.

Dench³ records favorable results and considers the operation a useful one for appropriate cases.

The operation is based on the hypothesis that the drum membrane, malleus and incus are no longer of value in the conduction of sound, and proposes their removal in order that the stapes acting alone may be permitted to take up sound waves from without and transmit them to the inner ear.

Unfortunately the subsequent effective mobilization of the stapes is often difficult or impossible. This difficulty and the tendency of adhesions to reform between stapes and adjacent structures, have led many to condemn the operation *in toto*.

The good results reported by Dr. Dench are presuma-

1. Politzer: Diseases of Ear, p. 323.

2. Wright: Diseases of Ear, pp. 1191-3.

3. Dench: Medical News, February, 1903.

bly explainable by a very happy and fortunate selection of cases.

In considering the uncertainties of the operation it must be remembered that in the class of cases for which it is proposed, the condition so far as the hearing is concerned is usually a desperate one.

58 West Fifty-sixth Street.

THE HOT-WATER DOUCHE IN TREATMENT OF CHRONIC CATARRHAL DEAFNESS.*

GUSTAVUS P. HEAD, M.D.

CHICAGO.

So many factors enter into the causation of the deafness accompanying chronic middle ear catarrh that any treatment looking to the relief of the condition must be directed along several different lines. For this reason when any new treatment is presented it is, as a rule, mentioned that it is to be used in connection with the usually practiced measures. Therefore, in presenting the method I shall suggest, it is to be understood that the treatment of nasal and nasopharyngeal disease and of tubal disease will be carried out as seems necessary in each case.

Recognizing the value of heat in causing the absorption of inflammatory exudates even when such exudates have become partially organized, there has been a persistent effort on the part of otologists to devise some practical method by which this active agent may be utilized in the treatment of diseases of the middle ear. With this object in view a number of instruments have been devised for the purpose of applying a stream of hot air either to the drum membrane through the external canal, or else to the middle ear through the eustachian tube.

There is no doubt of the possibility of applying a stream of hot air to the drum membrane through the external canal, but many who have tried the application through the eustachian catheter have expressed grave doubts as to the possibility of delivering a stream of air through the catheter so that it may reach the tympanic cavity hot enough to be of much value. With the various instruments used by me I have been unable to satisfy myself of any good results secured by the eustachian hot-air douche. Although practiced in a number of cases during a period of several years, it was invariably abandoned because of lack of results commensurate with the time and labor expended by the operator and the expense to the patient.

Considering that the tympanic cavity is the part which we usually desire to reach by the absorbent agents, and that this cavity is a shallow one, separated from the external canal by a thin membrane only, it would certainly seem that sufficient heat might be conducted to the cavity from the external canal without the necessity of resorting to the more difficult, doubtful and not always harmless expedient of forcing the heat through the eustachian tube. That the effect of the heat on the more or less occluded eustachian canal should be of benefit regardless of the effect in the tympanic cavity can not be denied, but that I have seen any individual case so benefited I am not able to assert.

In the use of the hot-air douche through the external canal, several difficulties present themselves: It is al-

most impossible to deliver a stream of air at an even temperature hot enough to be of value. The patient will either complain of the burning and draw away, or else the air soon ceases to be hot enough to be effective.

The treatment must remain wholly in the physician's hands. This means that it can not be used more than two or three times a week in the case of the average patient on account of the expense. It also means a great loss of time to the otologist. The douche should be in operation ten minutes for each ear, so that with other necessary treatment, preliminaries and delays, not less than thirty minutes will be required for each patient.

A trial of the hot-air treatment in which the heat is applied through a canvas tube attached to cover the ear, impressed me that this is a most clumsy way of reaching the part which we really desire to reach, and I was very uncertain as to how much heat reached the tympanic cavity. The same objections apply, though to a lesser degree, to this method as to the hot-air douche.

With the objections to the treatment in vogue and looking for a method whereby as good or better results might be attained in a more simple way, the use of hot water suggested itself.

In the course of a general practice, having so often seen the melting away of the exudates, inflammatory and non-inflammatory, from the pelvic cavity through the agency of the hot douche, it occurred to me that in the tympanic cavity we had a region far more easily reached by the douche and one in which the exudation lay much nearer the stream of hot water than in the pelvic cavity. Although the hot-water douche is in almost universal use in the acute inflammations of the tympanic cavity, I could find no literature on the use of this agent in chronic catarrhal conditions. When first experimenting with the use of hot water in the ear I invariably began the treatment in the worse ear, after having treated both ears sufficiently by the ordinary methods to ascertain about what rate of improvement might be expected.

In these cases the ear treated with the hot douche immediately showed a greater improvement than the other ear, and in no case was there any injury shown in the ear thus treated.

In the use of hot water the difficulties attending the hot-air treatment were not encountered. In the first place, this branch of the treatment is placed entirely in the patient's hands, thus allowing it to be used twice daily if so desired.

Secondly, the doctor is spared the necessity of devoting so great an amount of time to each treatment, the patient coming to the office only to have the usual treatment applied, and now with the stimulating effect of the heat on the contents of the tympanum and attic, the air or vapor douche through the eustachian tube or the external meatus becomes much more effective in loosening adhesions.

TECHNIC OF DOUCHE.

The patient readily adapts the heat of the water to his comfort. My instructions are to use the water as hot as can be borne without burning. A specially small tip is ordered, or a straight glass medicine dropper may be inserted into the tube of the fountain syringe, the patient being instructed just how to hold the tip and how deep to insert it. The fountain bag is hung from 18 to 24 inches above the ear, or just high enough that the water will be surely carried to the drum membrane.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Laryngology and Otology, and approved for publication by the Executive Committee: Drs. G. Hudson Makuen, George L. Richards and John F. Barnhill.

If the tip be small and the bag not too high, two quarts of water will run for about ten minutes and will remain hot enough through that time. Allowance must always be made for the cooling of the water in passing through the tube, so that the water in the bag itself must be too hot for comfort. If the matter is fully explained to the patient he will soon learn to make proper allowance.

It must be insisted that the patient feel the continual impact of the stream of water against the membrane, for it is easy for the outcoming and ingoing streams to neutralize each other so that only a small portion of the water reaches the membrane. I am informed that Dr. T. W. Chambers has devised an ear tip with a return tube which much simplifies the treatment in the hands of the patient. The treatment has usually been used once a day, ten minutes for each ear.

Some patients will complain of dizziness from the injections, in which case the force of the stream is too great, the water too hot or the treatment too long, and these various points may be investigated.

In some cases it has been found more satisfactory to have the patient use a demulcent solution in the ear after douching to prevent the unnatural dryness which results from the frequent washing. Glycerin and water, one or two drams of glycerin to the ounce, or one of the simple hydrocarbons, as albolene or benzoïnol, has been found to meet the indication.

LIMITATIONS OF THIS TREATMENT.

This treatment will necessarily have its limitations. Cases in which the source of deafness lies in the internal ear are not very likely to be benefited. It is particularly adapted to those cases in which there is evident congestion and inflammation of the drum membrane. A drum membrane displaying considerable patches of sclerosis is very likely to show improvement. Tinnitus when due to intratympanic causes has been readily relieved by the hot-water douche. When due to conditions in the internal ear, it is not to be expected that treatment directed to the middle ear will relieve it, though it is quite possible that the internal ear may be affected to some degree by application of heat in such close proximity to it. In nearly all cases there is tubal occlusion of greater or less degree; this, of course, will be affected only indirectly by treatment through the external canal. That improvement of the health of the tympanic lining and contents will necessarily cause some response in the eustachian tube is obvious, although the response may be but slight.

I will cite two cases of deafness and one of tinnitus as illustrative of the results attained. I will state that I have no miraculous improvement to report. Were I to make such a report, you would be justified in dismissing the matter as too evident a fabrication for further consideration. I could wish that the improvement had been greater, and I confidently expect further treatment in the same cases will give additional improvement:

CASE 1.—Miss F. E., age 20 years, Dec. 5, 1903.

History.—The patient had deafness of 10 years' standing. Had earache in infancy, but never any rupture of drum membrane. Moderate sclerosis of both tympanic membranes. Nasal passages somewhat obstructed up to three years ago, when they were cleared out by removal of bone and are now in a fairly normal condition. Received considerable treatment for the ears by an expert otologist at the time of nasal operations, but with practically no results.

Examination.—Hearing, left, watch, 3 inches; whisper, 24; right, watch, contact; whisper, 12. (I would say that unless

specially stated otherwise I use the loudest whisper possible.) Tuning fork, bone conduction excellent on both sides. After inflation, left, watch, 3 inches, and whisper, 30; right, watch, 1 inch; whisper, 24.

Treatment and Result.—After treatment with nebulized mentholated oil through catheter December 5, 8 and 11, no particular improvement noted except that right ear gave watch one-half inch before inflation. Also used moderate massage with Siegle's otoscope. December 11 ordered hot-water douche in right ear. Two weeks later ordered hot water in both ears. January 27, stopped hot water. Under two treatments a week with catheter and massage there was fairly steady improvement, which continued after stopping hot water, so that by February 2, after inflation, the hearing was: Left, watch, 5 inches; whisper, 9 feet; right, watch, 4 inches; whisper, 3 feet. Hot water was again used for three weeks and on March 12 the test showed: Left, watch, 10 inches; whisper, 9 feet; right, watch, 7 inches; whisper, 3 feet.

While the improvement in this case was not great, yet it was quite marked. The patient stated that under the treatment three years ago she received no benefit, while now she realized a very encouraging improvement, and that so far as she could judge, the treatment was exactly the same both times except for the hot douche.

CASE 2.—Miss L. I., age 26, May, 1903.

History.—Deafness in both ears increasing for past three years, but had existed some years before. Both tympanic membranes considerably sclerosed, nose and throat in fair condition except septal thickening on left side. Has had treatment for one or two years by Politizerization and mechanical massage, with no improvement.

Examination.—Test, left, watch, 1 inch; whisper, 8 feet; right, watch, 1 inch; whisper, 8 feet. Bone conduction better than air.

Treatment and Result.—Removed septal thickening and used nebulizer with catheter, with some improvement—watch increasing to 6 inches for left and 4 inches for right; whisper, 15 feet.

Patient was away during the summer. In the fall occasional inflation kept up hearing to about the same standard except that the right ear showed only 2 inches for the watch. January began the use of hot-water douche. January 21 hearing showed: Watch, left, 9 inches; right, 5 inches; whisper best that it has ever been. This condition has been maintained under occasional inflation after use of the hot water for about four weeks. In this case inflation by catheter has been continued once or twice a week up to the present and the last test, May 31, showed: Watch, left, 20 inches; right, 11 inches; soft whisper, 15 feet, both ears.

In judging of improvement, I always insist that the patient shall make home tests as a control for the office tests. The watch test is not at all a sure indication as to voice hearing, and the patient becomes accustomed to the physician's voice, thus often showing an improvement which may be apparent instead of real. Both these patients, as well as the others having this treatment, brought very satisfactory reports as to improvement in hearing in their ordinary environment.

CASE 3.—A. C. F., age 40, April 23, 1904.

History.—The patient has had ringing in his right ear for the past three or four years. When ringing is bad, confuses him. Has had attacks of vertigo at various times. Sometimes six months without attack. Family history bad; father, grandfather, uncle and aunt died from apoplexy, one uncle of tabes. Examination: Right tympanic membrane sclerosed and somewhat congested along manubrium. Tuning fork C 2048 heard in air, but not on bone. C 128 heard better on bone.

Treatment.—Under hot douche tinnitus improved at once. Patient left city after second examination to be gone some time and I can not report as to effect on hearing. I am satisfied

the vertigo, and to a great extent the tinnitus, are due to digestive disorders and may be controlled by the patient by proper diet.

REMARKS.

A number of patients have shown decided improvement in hearing, and relief of tinnitus on using the hot douche after improvement had ceased under the usual treatment without hot water.

After the use of this method of treatment in suitable cases for the past five months, I have no hesitancy in recommending it with considerable confidence as a valuable addition to the ordinary measures used in treatment of chronic catarrhal deafness. While the period in which it has been used is not long, and the number of patients treated has not been large, yet hydrotherapy is so old and well established in other regions of the body, and is so especially adapted to the region under consideration that it has seemed to me quite proper to bring the method before the Section for discussion and criticism.

DISCUSSION

ON PAPERS BY DRs. KERRISON AND HEAD.

DR. W. S. BAYANT, New York City.—The term chronic catarrhal otitis media covers nearly everything except suppuration that occurs in the middle ear. It is impracticable to treat all these pathologic changes as one condition which can be handled as suppuration can. The long list of remedies mentioned are all well known and have a certain standing with the profession. The pathology should be better worked out and generally understood. How this is to be done in this country it would be hard to say, on account of the difficulty met with in getting pathologic material. Dr. Head has made an important suggestion in treatment, in line with experiences I have had in gynecology, and one which offers a reasonable hope of success. The dangers, if there are any, aside from the distress of the patient due to too hot or too forcible injection, are those of starting up a low-grade inflammation in the tympanum, with an increase of deafness.

DR. S. F. SNOW, Syracuse, N. Y.—It has been my experience that all bad cases of catarrhal deafness are due to well-defined causes and that if we can determine these causes and remove them the problem of treatment is much easier than generally supposed. We must not forget that the olfactory regions of the head are often much occluded, deflecting the current of air into the lower part of the nostril, the current taking its course along the floor of the nose and escaping by the eustachian orifice. If we wish to get the eustachian tube in normal condition we must alter the course of that current of air, and this will require nasal surgery. We must get the nose as nearly physiologically perfect as possible, as a preliminary step in all cases. Then, if this is done, it is not well to forget the systemic disturbances which, in many cases, are the all-important factors. If our patient is one with a turbid liver, whose system is infected by auto-intoxication from the bowels, that factor must be taken care of. If this is done, the process of absorption from inflammatory products may be facilitated by hot water or stimulating vapor. Beautiful results are often obtained, not in the cases with osseous changes around the stapes, but in that multitude of cases in other stages. Here our results will depend largely on the amount of work we do. I have had a large experience with this class of cases, though I confess that I have been slow to put hydrotherapy into practice. I intend to try it.

DR. W. H. F. FITZGERALD, Hartford, Conn.—It seems to me that instead of looking for something in the mechanical line or for new therapeutic measures, we should allow Nature to help us a little in this direction. We all know that from 80 to 90 per cent. of aural difficulty is due to the fact that the individual does not use his nose as he ought to. The first thing to be corrected is the habit of mouth breathing. I venture that there are not half a dozen members of this Section present this morning who breathe as Nature intended they should. Those

who are not absolute mouth breathers talk, sing, whistle and take most of their air through the mouth. Every breath taken through the mouth is at the expense of the ear and the entire respiratory tract. I have followed this up carefully for two years and a half and have given up nasal douching, and teach my patients how to breathe physiologically. I should hesitate about telling you the splendid results I am getting in this way. I have followed this line of work for a number of years, having worked in Europe with Professor Politzer and others for nearly three years, and in the Boston City Hospital for two years and a half, so that I think I am in a position to criticize the usual methods of treatment. In the *Medical Record*, September 5, I made a note of this method, and I am told that it was the first time it ever appeared in print. I can not understand why this important point has been neglected. Normally we know the nose was intended to breathe through, and if the nose is not normal it should be made so and these patients should be taught to breathe properly.

DR. H. E. SMYTHE, Bridgeport, Conn.—I wish to call attention in this connection to the use of vibratory massage on the mastoid. While in charge of the dry middle ear cases in Dr. Wendell C. Phillips' clinic at the Manhattan Hospital, New York City, I employed vibratory massage extensively, and although the treatment was not confined to massage alone, the subjective noises were unquestionably benefited by it, the hearing in some cases seemed improved, and the progressive secondary dullness of the auditory nerve, so common in these cases from lack of use, was, I believe, retarded. An inexpensive apparatus which I have made use of in my office for the past year for this purpose is attained by attaching a pad to a Black nasal saw handle in place of the saw blade and using it with a flexible shaft and motor. The vibrations are not so rapid as with a more expensive apparatus, but the results have been very satisfactory.

DR. J. A. STUCKY, Lexington, Ky.—We come here to present our failures as well as our successes. I want to say that I have practically disregarded pneumatic massage except in very carefully selected cases. I think that there is danger of increasing the relaxation of the drum membrane. Our average case of chronic catarrhal middle ear trouble is overtreated locally. I think a great deal is to be expected from constitutional treatment. I want to speak in favor of the massage method mentioned by Dr. Smythe, for it will undoubtedly give good results. It takes a little time and we can teach an assistant how to give it. It should always be given in the recumbent position and with an apparatus capable of giving a stroke felt through the whole head. Patients with this trouble soon become listless, and it is a good plan to get them to test their hearing and acquire the habit of listening, paying attention with the ear as well as the eye. I will try the hot-water treatment.

DR. J. M. RAY, Louisville, Ky.—It seems to me that the whole question of the treatment of chronic catarrhal middle ear disease depends primarily on the diagnosis. Before any line of treatment is instituted a thorough functional test of the case should be made. As Roosa and others have pointed out, the ear possesses a surplus amount of hearing and a great deal of this can be lost before the patient begins to think about his ear: this is especially true in cases without tinnitus. Thus in most cases the disease has passed beyond the eustachian tube and pathologic changes have occurred before they come to us. I believe there are quite a number of cases of the kind known as oto-sclerosis, in which there is no change at all in the mucous membrane of the middle ear, the process being primarily a disease of the bony wall of the labyrinthine capsule. I fully agree that cases of tubal catarrh are, as a rule, well managed by nasal treatment, inflations and injections of solutions through the catheter. When we come to catarrhal middle ear disease proper we have a more difficult proposition to encounter. When we look around on the number of patients in our offices with nose and throat trouble, and see the number of cases of deviated septi, nasal polypi, etc., without any ear disease at all, there is a reason why we must consider what influence the nose has on these cases. I do not believe that we

ever see cases of well-defined middle ear disease influenced by nasal surgery. It is well to bring about the normal function of the nose, but if the characteristic changes are once fairly established in the middle ear I doubt very much if we gain anything at all by nasal surgery.

DR. R. W. SEISS, Philadelphia—We often lose sight of the fact that many forms of middle ear catarrh are an extension of one process, and our anatomy and physiology are often weak. These are all cases of fibrosis, beginning as a simple exudation of inflammatory cells; hence, we should avoid any thing that would cause fresh migration of leucocytes. The eustachian tube is not a dilatable canal; I have absolutely abandoned the use of the bougie, and I do not see how it can be introduced without rubbing off the ciliated epithelium, and if this is done it is replaced by the squamous variety, serious results following. As to the dependence of ear disease on the nose and throat, it starts there in all cases, but the immediate connection is often not apparent. We have no idea why certain catarrhal patients have ear disease and other persons do not. As to pneumatic massage, we are familiar with the good effects of massage on other parts of the body, and its value in causing absorption has been proved experimentally on the rabbit. The reason some men do not get good results from it may be because they do not use it properly. The advanced cases of sclerosis are as absolutely hopeless as is locomotor ataxia. All that can be done is to help the patient along. I use external vibration and that does some good, but it is simply another string to our bow and is not curative. As to excision, I was among the first to operate, some eighteen years ago, but I have never seen any good results from it in anyone's hands in aural catarrh. One case was recently shown me as being "successful," but the patient told me he was "nearly crazy" with tinnitus.

DR. E. PYNCHON, Chicago—This condition is far more prevalent than we recognize. We usually do not consider that we have catarrhal deafness to deal with until the patient complains of deafness. We ought to make a functional test of the hearing in each nose and throat case treated. I make a practice of so doing and find in about 75 per cent. of cases presenting themselves for nose and throat treatment some impairment of hearing, and often unrecognized by the patient. These chronic catarrhal cases are much more amenable to treatment in the early stages, and it is our duty to discover them in time to benefit them. I am in the habit of doing very little in the way of ear treatment until I have corrected those conditions of the nose and throat which have preceded the ear trouble and are causative factors. One speaker said that he thought patients with marked nasal trouble had no ear disturbances. I must disagree with him. The patient may not make any complaint of it, but an examination will generally show that the hearing is below par. Another speaker mentioned the importance of introducing methods to correct mouth-breathing, which, in other words, is simply an indication of nasal stenosis. There are two conditions which I find are most often instrumental in causing tubal trouble. The first is enlargement of the middle turbinal, and the second a buried or submerged condition of the tonsil, which is usually associated with chronic pharyngitis. Just how these submerged tonsils affect the eustachian tube is problematic, but it is probably first through continuity of tissue; second, through the swallowing of the secretions; third, through the increase of circulatory disturbances; and fourth, through the bulk of the tonsil. In such cases complete removal of the tonsil leaves a cavity large enough to hold the end joint of my index finger.

DR. JOHN O. McREYNOLDS, Dallas, Tex.—I wish to report an accident which materially relieved a case of chronic catarrhal deafness which had resisted all treatment. This patient was bathing in the Gulf of Mexico and arose to the surface after diving and discovered that his hearing was perfect. A number of days later the deafness returned.

DR. S. MACCUEEN SMITH, Philadelphia—We should aim to establish free nasal respiration. I believe we should first correct the nasopharyngeal trouble which is the cause. The deaf-

ness is entirely a different matter. For a few years I used both catheter and bougie very frequently. I found later that I was doing damage in using either one too frequently, and each succeeding year I have used them less, especially the bougie. I had a case recently in which the bougie broke off in the eustachian tube and the patient developed tubal inflammation, which extended to the ear and acute suppurative resulted. The physician in charge turned the case over to me and I made a free incision in the drum membrane, but it seemed impossible to keep this open. I eventually found it necessary to remove the malleus, incus and drumhead to keep the wound open. All symptoms finally subsided and what became of the portion of the bougie I do not know. It may have been discharged at some time, but I mention the case to show what may happen with the bougie. As regards removal of the ossicles and drumhead, eight or ten years ago I performed a series of 160 operations of that character on various cases involving the ear, sclerotic cases, the majority being patients who were willing that anything be done that would relieve them of the noise and vertigo. In practically all of these cases there was considerable improvement primarily. In very few, however, was this improvement maintained; in a few weeks the improvement became less marked and eventually they arrived at the point from which they started, and probably the hearing decreased more rapidly than it otherwise would have done. There were a few cases in which the improvement was maintained, and after eight years I still see some of them with very good hearing. I believe that will bear out the experience of Dr. Dench, who, in a scientific way, has got it down to a very fine point and can select his cases for this operation much better than I can ever do. We have been using hot air with some success. About three years ago I saw a patient in a town in Pennsylvania who had chronic catarrhal deafness. I told the attending physician that I saw little to be done except correct the catarrhal condition, which he was already doing. He went home, however, and started in with irrigations of hot water in the ear, allowing three quarts to run in every second day. Six months later I was perfectly astonished to see the improvement that had taken place. All the noises and vertigo had entirely disappeared.

DR. B. A. RANDALL, Philadelphia—I have used hot air, but expect little from it. In acute inflammation I have confidence in the douche in the external ear and shall use it in these catarrhal cases. These patients are numerous in class and character, as well as in absolute numbers. The statement made fifty years ago that one adult in three is deaf in one or both ears is well borne out to-day. I do not believe the typical sclerotic cases with change in the labyrinth capsule are very numerous. The other form, which is amenable to good treatment by establishing proper nasal respiration and practice of the individual in good breathing, is undoubtedly of great importance. Harrison Allen, the father of rhinology, insisted strongly on the point of teaching patients how to breathe. When this is done the catheter treatment, carefully employed, but not kept up too long, will cure or benefit a very large proportion of these cases. The measure which I have set in dealing with this class of cases is a very practical one. We must treat the patient again before the benefit of the previous treatment is lost. When treatment after some six weeks ceases to give growing duration of benefit it is suspended; pneumatic massage should be kept up and hot gargling, by which the astringent heat is applied where the gargle itself does not go. When we begin to note relapse it is time to begin treatment again, though the course of treatment should be shorter. This is old-fashioned treatment, and not brilliant, but it is rational and commends itself to experience.

DR. E. B. DENCH, New York City—I do not think anyone will doubt the advisability of opening up the nose and establishing good breathing in these cases. Yet it is true that we find some of our most difficult cases have perfectly free nasal breathing. Every case must be treated individually and not according to any set rule. If the eustachian tube is obstructed it must be opened up mechanically and the bougie is the only thing that will do this; it does not make much difference what

kind of a bougie is used. Use anything that will go through. External massage over the mastoid does not appeal to me, but I am glad to hear of the good results. I have found massage advantageous over the eustachian tube, and I think massage of the tissues of the neck valuable in certain cases. It can be applied by the vibratory apparatus or by the hands. It seems to me that massage over the mastoid would be productive of evil results, but others have found it beneficial. I am surprised no one has mentioned massage by means of sound, the massicon. I have seen it used by other people, and in every case the result was had. Marvelous reports have been given out by some men, but I can not recall a single case where the ultimate outcome was not unsatisfactory.

I have been quoted in regard to ossiculectomy and I agree with Dr. Smythe that it is of value in selected cases. The patient must understand that the surgeon is very human and that the result may not be good even in selected cases. We are often afraid to operate on cases in the very early stages, and it would be better if we would do this early. The cases I operate on are those in which the hearing is reduced, tone conduction increased, lower tone limit elevated and the upper tone limit is normal. I never touch a case where I have diminished bone conduction or reduction of the upper tone limit. I have had some poor results, but, as a rule, they are good in selected cases. I follow Dr. Randall's plan exactly and I suppose that is why I get good results. Repetition of treatment must be governed by its effect in each case. I have often found that after these patients have reached a certain point they complain that the hearing is temporarily impaired after treatment, and then it is time to stop for a while. They can fix the length of the interval much more accurately than the physician. I think hot water may be successfully used in certain cases, but it is more applicable to hypertrophic otitis than to the hyperplastic form. There we have a condition analogous to pelvic cellulitis and hot applications may be of benefit. But I should not look for benefit in chronic hyperplastic otitis media. Where there is a history of repeated attacks of subacute inflammation following cold in the head, etc., the hot water treatment might be of decided benefit. We must remember that we are dealing with a different tissue from that of the pelvis and that this tissue is not so readily acted on by hot water.

DR. J. J. KYLE, Indianapolis—The object aimed at in the treatment with hot water and with vibration is the same, i. e., stimulating the metabolism of the middle ear and absorption of the exudate. I think the vibration treatment is better than hot water. If you leave the hand in hot water for a time, you will find that the epithelium shrinks; inject water into the nasal chamber and you get the same effect. Throw it into the ear and you have the same result. In the treatment of catarrhal conditions, it would be better to use normal salt solution to stimulate absorption. My results with the vibratory treatment have been good, but there is no one case that can be treated just like another. I have removed obstructions in the nose and throat and found the case get worse. Some cases have gone to the coast with satisfactory results. We simply have to be governed by the circumstances in each case.

DR. PHILIP D. KERRISON—As to the value of the eustachian bougie, which one of the speakers condemns as injurious to the tubal mucosa, we must remember that in the cases in which the bougie is indicated we have to deal with a mucous membrane which is already diseased. If the tube is stenosed, or considerably narrowed, the first and most positive indication is the restoration of its normal caliber. When this can not be accomplished by inflation, the bougie becomes a necessity and must be employed. After the patency of the tube has been re-established, I believe that the subsequent treatment should be continued only so long as continuous functional improvement can be demonstrated. When the hearing tests show that no functional gain is being accomplished, the treatment—for the time at least—should be discontinued. This I think is important.

DR. G. P. HEAD—When we remember the results secured in

very large joints of the body, in ankylosis, by the combined use of heat and massage, it seems to me we have not very much right at present to limit the effect we may get in hyperplastic or hypertrophic otitis media by the combined use of some form of heat and massage.

THE ELIMINATION OF DISEASE.—Surgeon-General Wyman of the United States Public Health and Marine-Hospital Service delivered an address at the University of Missouri, Columbia, Mo., Sept. 26, 1904. He took as the subject of his remarks "The Elimination of Disease." He referred first to the great epidemic diseases, such as cholera, yellow fever, bubonic plague and smallpox, and showed how, under modern methods, these diseases have lost their terrors. He declared that there was not one of them that was not amenable to treatment by scientific repressive measures, and stated that the day is not far off when the dread born of these great epidemics will be a matter of history.

He then referred to what he termed the lesser epidemic diseases, and stated they were in reality of greater importance than the others; that they caused more sorrow, a greater number of deaths, and greater physical suffering than the others, but that these, too, can be eliminated. By these lesser epidemic diseases he meant such diseases as tuberculosis, typhoid fever, measles, scarlet fever, malarial fever and diphtheria.

He spoke especially to the students of the university as the men who in the future will have the molding of public opinion from which will be crystallized the necessary laws, organizations and other means for the elimination of these diseases. He declared that while many of his audience might deem this idea Utopian, it really is not Utopian. The end would be attained through an enlightened public sentiment, by a wider and more popular diffusion of sanitary knowledge, and by the perfection of municipal, county, state and national health organizations. Already the co-ordination of these various bodies has been in a measure secured—at least, a good beginning has been made—and it devolves on the people, the voters, to make impress on their city councils, their state legislatures, and the National Congress, so that the official health organizations shall be made perfect and adequate appropriations be made.

He declared that the time is near at hand when the people themselves will be unwilling to have remain insanitary conditions which permit the development of diseases that may be prevented by improving the environments of man; so that pure air and plenty of it, sunlight, pure water supplies, and effective disposal of wastes, will be as strongly demanded as is now the cleanliness of the household.

He showed the influence of international effort to this end, through international sanitary conventions—both official and unofficial in character—and how the influence of one nation on another is becoming daily more acutely felt.

He appealed for a support of these ideas by reason of their effect in the general advance of civilization and in placing humanity on a higher plane of living; that with removal of insanitary environments and the resultant health of body and mind, all other efforts being made for advancement along lines represented in the recent World's Congress of Arts and Science would be enhanced.

He closed with an appeal for the development of public sentiment which will demand existence under more perfect conditions.

THE ACTION OF THE X-RAYS IN LEUKEMIA.

Since the publication, in August, 1903, of Senn's report of a case of leukemia treated with the x-rays, the number of recorded cases has been increasing weekly. In March, 1904, at the time that Brown¹ published the second recorded case, we commented editorially on the subject, mentioning the fact that the way in which the rays acted was obscure, and suggesting conservatism in drawing conclusions as to the permanent effect of this form of treatment. The publication of the numerous cases above mentioned and the accumulation of certain scientific data make it worth while to draw attention to this subject once more.

The experimental work of Heineke² seems to throw some light on the *modus operandi* of the x-ray in leukemia cases. This author shows that the exposure of certain of the lower animals to the action of the x-rays leads to definite changes which affect particularly the blood-forming organs and the blood. The changes in the spleen affect the follicles, and in the lymphatic apparatus of the intestines, pharynx and other portions of the body the germinal centers are particularly affected. The changes which take place after the application of the rays are in the form of a necrosis of the cells of the affected part, the necrotic particles being removed by phagocytes. These changes begin to occur from eight to twelve hours after exposure to the x-rays, and reach their maximum at the end of about twenty-four hours. The changes in the bone-marrow are quite intense, and there may be destruction of the bone-marrow elements on a large scale with their replacement by fatty tissue. The destruction of leucocytes in the circulating blood, while it undoubtedly takes place, is slight in degree. The point of greatest importance brought out by these experiments is the specificity of this reaction, the changes being limited to the blood-forming organs, and not affecting the other tissues of the body. It seems reasonable to assume that these changes occurring in the animal body may, at any rate in part, be the same as those which occur in man. There are, however, certain difficulties in the way if we desire to assume that all the changes which occur as the result of x-ray treatment can be explained on the basis of this experimental work. The mere decrease in number of the leucocytes and the decrease in size of the

spleen can doubtless be explained by the specific destructive action of the rays, but this will not explain the qualitative changes in the white corpuscles. It is to be noted in looking over the reports on this subject that the decrease in the number of the leucocytes under x-ray treatment was sometimes accompanied by a normal differential count and sometimes not. In some cases, even after the spleen had greatly reduced in size and the number of leucocytes was normal, the differential count still showed the presence of myelocytes in the circulating blood. Evidently something else than a mere destructive agency is needed to explain such qualitative changes.

The clinical reports of the last six months, most of them of American origin, a few of French and German, show that the x-rays have a palliative effect on leukemia. In the great majority of the reported cases the patient has gained in strength and weight, the color has improved, and often the patient has regained the appearance of health. In some instances unpleasant effects have been observed, and the treatment has had to be temporarily discontinued. Aside from the unpleasant local effects of the x-rays, some patients have suffered from fever, headaches, weakness and other unpleasant symptoms, which may have been due to a too rapid destruction of leucocytes with absorption of broken-down cell products. While spontaneous improvement of this disease, similar in all respects to the improvement under x-rays, may occur, studies of series of cases which were treated before the x-ray treatment was established show without doubt that such spontaneous improvement is very much the exception under normal circumstances. If there was any doubt of the action of the rays, some of the published charts, showing decrease in leucocytes during x-ray treatment, and increase during absence of treatment, would dispel it.

Whether the apparent cure which has resulted in some cases is a permanent one is the important question, and time alone will answer it. The blood reports in the recorded cases are, unfortunately, not always scientifically impeccable; still there are many which leave nothing to be desired, and some of these hold out the hope that the cure may be permanent in some cases. In other cases, as we have stated above, the differential count of the leucocytes has shown the presence of myelocytes, even when the number of leucocytes was normal. It seems doubtful whether such patients will permanently recover; at any rate, they certainly can not be regarded as well so long as the myelocytes are present. It is well to note, too, that patients apparently recovering may die very suddenly, and in some of them the internal organs have been found to show the lesions of leukemia distinctly marked. Capps and Smith³ bring forward the fact that in no case has complete disappearance of the spleen tumor been noted as an argument against permanent cure. We would point out that in

chronic cases, and many of the recorded cases had lasted two years at least, there is a good deal of fibrous tissue formation in the spleen, and this could not be expected to disappear under the *x*-rays. We believe that the evidence up to the present indicates that a great deal is to be hoped for in the treatment of leukemia by the *x*-rays, so far as the palliation of the disease is concerned, and that there are reasonable grounds for the belief that such treatment may be actually curative in certain cases.

A PRELIMINARY FIFTH YEAR IN THE MEDICAL CURRICULUM.

In another column, Dr. John Rogers, the secretary of the Cornell University Medical School, suggests a plan for securing a better preparation of students for the practice of medicine, which is worthy of consideration. From the statement that there is necessity of providing more time for both pupil and teacher—of demanding a better preparation for medical work—there can be no dissent.

With the conditions existing in medicine at the present time, it is reasonable and necessary to demand a longer period of preparation than is afforded by an ordinary high-school course, plus four years in the medical college. Medicine has made more progress in the direction of scientific exactitude in the last quarter of a century than in all its previous history, and needs for its intelligent study and comprehension a broader and more thorough training in the principal facts and methods of the fundamental sciences than is afforded by the secondary schools.

We are in accord with Dr. Roger's suggestion that an added preparation should be made in the premedical branches, for it is in these that the deficiencies of our present-day students and of the profession are most obvious and of most serious import. As to the proposal, however, that the instruction in the subjects should be given in the medical school rather than in the college or university proper, there is room for difference of opinion. It would seem that in such a step the medical school would be usurping the function which belongs properly and logically to the institution for general learning. The premedical subjects enumerated by our correspondent come logically within the domain of the college proper, and, with the possible exception of bacteriology and physiology, there are few, even of the smaller colleges, which are not well prepared to teach them—better equipped, indeed, both in faculty and in teaching appliances than the majority of medical colleges.

Medicine is applied science, its study and practice consisting in the application to the investigation and treatment of disease of the principles, facts and methods of certain fundamental sciences—among them physics, chemistry and the several biologic branches. Preparation for medicine, as for any other profession,

naturally divides itself into a general education, whose chief purpose is the training of the faculties and the mastering of the fundamental subjects, and technical instruction in the application of these fundamental sciences to the specific problems of medicine.

General education is the province of the institution devoted to that purpose—the secondary schools and the college or university. The medical school should devote itself exclusively to the technical instruction, the applied science, and this it can only do to best advantage when its students have already mastered, in a broad and comprehensive manner, the principles and methods of the sciences to be applied. The curriculum of our better colleges includes those sciences fundamental to medicine. Is it a serious hardship to demand of every student intending to take up medicine that he spend one or two years in such a college? Surely a year in such an institution would be more economical and advantageous than the proposed extra year in the medical school. Such colleges are numerous in all portions of the United States, and, in the matter of tuition and cost of living, much less expensive than the majority of medical colleges.

If one year of such college work be demanded for admission to every medical school, a larger proportion of those who enter the college intending to take only this one year, will be inspired, and will find it possible to take one or two additional years—in many cases to secure the bachelor's degree and to pursue other studies which are nearly as essential to the adequate education of the successful physician as are the premedical branches above enumerated. Many medical students of the present time are unable to speak and write the English language as correctly as is befitting to the members of a learned profession; a majority have not had the training in mathematics which is essential to the thorough and intelligent comprehension of modern physics and chemistry; and a reading knowledge of German and of French is acknowledged to be of great advantage to the physician who is ambitious to be at the front. Our correspondent would hardly consider these subjects as coming within the province of the medical school, yet they are as important as some of the premedical sciences he mentions. It would be of far greater advantage, for example, for the student designing to enter the Cornell University Medical School to spend the suggested premedical year in the University at Ithaca, than in the medical department in New York City.

The time has arrived when every medical college should demand at least one year of college work, in specified, essential branches, as a prerequisite for admission. It will, however, defeat the very purpose which is sought to be accomplished, if, encroaching on the domain of the institution for general learning, the medical college attempts to give instruction in subjects entirely without its province and which it is wholly unfitted to undertake.

There is a fifth year, quite within the legitimate and logical sphere of the medical college, which, when the time is ripe, may with great advantage be required, and that is a practical clinical year, to be added to the further end of the present curriculum, and to consist of a hospital internship. When the annual enrollment of medical students has been reduced to only such proportions as are actually needed to supply the demand; when the ratio of internes to patients in the larger hospitals has been doubled, as it must be to render adequate attention to their patients, and when the hospitals which are springing up so numerously in the smaller cities and towns throughout the country have created a greatly increased demand for internes, it will be easily possible to provide every medical student who has completed his fourth year in the medical college with a hospital service. Any technical difficulties—legal, educational or administrative—which may arise will find a ready solution. No such step should be undertaken, however, until an adequate premedical education, prescribed in the requirements for admission, has been fully and universally secured.

THE CYTOLOGIC EXAMINATION OF EXUDATES AND TRANSUDATES.

Although the methods introduced by Ehrlich as a result of his classical research on the blood were well known to the profession as early as 1880, it was not till sixteen years later that any serious attempt was made to apply these methods to exudates and transudates. As a matter of fact, the attention of the entire profession was not drawn to the subject until after the work of Widal and his associates in 1900. It will be remembered that it was Widal who gave the name "cytodiagnosis" to this method, although he did not, as many suppose, originate it. In a recent editorial¹ we called attention to the value of this procedure in diseases of the central nervous system, but its value in exudates and transudates in other situations, more especially in pleural effusions, was not discussed.

Within the last few weeks two important papers bearing on this subject have appeared; that of Lewkowicz,² which deals with the subject in general, and that of Musgrave,³ which deals with cytodiagnosis in pleural effusions. As Lewkowicz points out, cytodiagnosis has gone through the same phases as did its ancestor the differential blood count. In the earlier days of blood work it was thought that each disease had its own specific blood picture, a conception which was soon shown to be false; the earlier observers in cytodiagnosis also seemed to think that they had at last found the specific diagnosticum, but time has shown that their views were based on insufficient experience, and we are now in a position to take a more rational view of the matter. As far as technic is concerned, we need add nothing

to the description given in a previous editorial, except to insist once more on uniformity in technic, without which it is useless to compare the work of the different observers.

In their discussion of the pictures observed in the smears, both Lewkowicz and Musgrave follow the classification first definitely proposed by Widal, i. e., they classify the cellular formulae according to the predominating type of cell. Thus if lymphocytes predominate in a given exudate, this comes under the head of exudates having a lymphocytic formula. In the same way we recognize the polynuclear formula, the mononuclear formula, the endothelial formula, and the erythrocytic formula. It is, of course, apparent that in many cases several varieties of cells are present, but it is the predominant cell which classifies the picture.

The class of effusions to which this form of diagnosis seems especially applicable are those occurring in the pleural cavity. In serous pleurisy particularly there would seem to be room for some method which will tell us within a short time, and with reasonable certainty, the etiology of the affection. While it is true that the probable tubercular nature of such effusions has been preached in certain quarters for some time, the proof that such is the case often depends on such slow processes as animal inoculation, or is lacking until after the death of the patient, when it is of no value. It has been shown, too, that animal inoculation frequently fails when subsequent events show without doubt the tubercular nature of the process. It is also true that a certain percentage of serous effusions are not tubercular, and it is in just such cases that cultures may be negative. The old observations of Widal and Ravaut led these observers to conclude that a lymphocytic formula meant tuberculosis, a polynuclear formula infection with some of the ordinary pus formers, and an endothelial formula either some mechanical injury or a transudate. They modified their statement regarding pleural tuberculosis somewhat by dividing the cases into primary tuberculous pleurisy, and pleurisy secondary to tuberculous lesions in the lung. In the latter class of cases they showed that the lymphocytic formula was replaced by a polynuclear one, in which the individual cells showed very marked necrotic changes. Naunyn, who confirmed these observations in the main, showed that a lymphocytic formula might occur in transudates of long standing, near the end of pyococcal pleurisies, or in pyococcal pleurisies where the infection had been mild from the beginning. It is obvious that in the case of long-standing transudates the specific gravity and percentage of albumin would serve as a differential point, while in the case of infectious pleurisies with an atypical cyto-count, the history should put one on the right track. Musgrave's work confirms conclusively the original observations of Widal and Ravaut. In twenty-three cases definitely proved to be primary tuberculous pleurisy, the lymphocytic formula was present in twenty-two, and in the twenty-third a polynuclear

3. Boston Med. and Surg. Jour., vol. cli, Nos. 12, 13 and 14.

formula with great cell necrosis suggested that the case was really one of secondary tuberculous pleurisy. Lewkowicz also concludes from the examination of a large number of pleural exudates that the lymphocytic formula, almost without exception, means tuberculosis. Musgrave was also able to confirm the observation that the polynuclear formula means pyococcal infection; he shows, too, that in pneumococcus infections there are generally present very large phagocytic cells; that their presence in large numbers indicates a favorable outcome, and that their absence, especially if large numbers of bacteria are present, means a subsequent empyema. The significance of the endothelial formula is somewhat changed by the work of Musgrave and Lewkowicz; while they support Widal's original statement that this formula is present in transudates and mechanical lesions, they both find that it is also present in malignant growths involving the pleura. Musgrave states that in these cases lymphocytes are also present as a rule, while Lewkowicz mentions the occasional presence of polynuclears, which he thinks indicate a secondary infection of the growth.

As far as pleural effusions are concerned, then, we think it can safely be said that this method seems to be well worthy of a more extended use. It may be of distinct value in confirming or refuting the diagnosis in some cases, while in others it may have prognostic value. In general terms it may be stated that the endothelial formula means mechanical irritation, transudation from heart or kidney disease or new growth, the polynuclear formula indicates pyococcal infection, and the lymphocytic formula infection with an organism leading to a chronic serous inflammation, such as the tubercle bacillus. Those who have had the most experience with the test are the last to claim absolute specificity for it. It must never be forgotten that medicine is, after all, as Oliver Wendell Holmes once remarked, mainly a question of probabilities. Nor must it be forgotten that all such laboratory procedures are merely aids to diagnosis, and must be used to support close clinical observation and not to supplant it.

HYPNOTISM AND INEBRIETY.

Hypnotism has had its enthusiastic advocates for the treatment of almost every ill to which mortal flesh is heir, including even the mental and moral deficiencies. Its recommendation, therefore, for the cure of alcoholism is a perfectly natural one. We can not, however, support the belief apparently held by certain physicians that it alone, applied as a purely therapeutic measure, will be found to meet the claims of its advocates. There may be cases of periodical drinking, due to organic physical defects, often hereditary, in which hypnotic suggestion properly applied at just the right time might, like any other therapeutic measure, ward off or mitigate the attack. In such cases we have a physical disease, not an acquired vice, and the will power

is ordinarily not necessarily defective during the interval.

Such cases are not hopeful ones, however, when well pronounced, under any merely medical treatment, hypnotic or otherwise. The most rational and effective method with them would be isolation and compulsory deprivation of alcohol from the first symptoms of the attack, together with such medical treatment as might be needed for supporting and toning up the system through the crisis. The great majority of inebriates have an acquired craving with weakened will power to resist it, and in most cases hypnotism or even suggestion in its wider sense, is insufficient to effect a cure, excepting under the most favorable circumstances. Only the very strongest moral stimulus, changing the whole moral nature and impulses, is effective. There are, however, many cases cured in this way. Every great temperance revival has been followed by such, but this is not hypnotism in any ordinary acceptation of the term. The alleged successes of the so-called alcohol cures are based on the honest desire of the individual to be cured of this habit, and not on the drugs, injections and other accessories of the treatment. Suggestion, of course, plays a large part in any treatment, but to be a success it must be permanent and constant, auto-suggestion reinforcing the patient's will and honest desire. The patient who puts faith in hypnotism alone and does not follow it up by earnest effort is not a hopeful case, and will sooner or later give way to the temptations that surround him.

While there are many cases that reform by auto-suggestion—started, it may be, by a hypnotic treatment, but far more frequently by some moral movement, temperance revival, etc.—in many cases, and probably in the majority, pronounced inebriates require other therapeutic measures to support the organism in throwing off the physical craving and relieving the disturbance caused by the removal of the customary stimulant. Hence the value of really scientific institutions for the treatment of these subjects where a certain amount of compulsion and removal from temptation can be provided for.

A CHINESE EDDYITE.

It is said the empress of China, once the *bête noire* of all foreigners in "The Long-Lived Empire," has succumbed to the combined influence of the wife of the American minister and of Eddyism. The former modestly refrains from any positive statement as to her conversion of the empress to the new cult, and at present the matter rests on the presumption that the liberalizing of the royal old lady's views has been accomplished by the personal efforts of the ambassador's wife. Should history record that the "yellow peril" had been diverted from "ways that are dark" to the relatively calm pursuits of occidental industrialism by the intervention of one of the morbid religious obsessions of our time, the psychologist will instantly be reminded of
