4. Dangers of the Microscope in Tuberculosis.—In consonance with a number of other writers, Clapp decries implicit reliance on the microscopic findings for a diagnosis of incipient pulmonary tuberculosis. He says a skilled auscultator (and all physicians should be skilled auscultators) can very often recognize an incipient case before tubercle bacilli appear in the sputum. Very often, not by physical examination alone, but by a thoughtful consideration of symptoms and physical signs, in connection with a close study of the personal and family history of the patient, aided, if necessary, by the tuberculin test, a satisfactory conclusion can be reached weeks and months before the bacilli appear in the sputum or even before the sputum itself appears, and thus gain time enough, perhaps, to save the patient.

7. So-Called "Piroplasma Hominis."—A most careful study of this subject has convinced Craig that Chowning, Wilson and Anderson, who investigated the etiology of a fever prevailing in the Bitter Root Valley for a number of years, and who concluded that it was due to a minute parasite which inhabited the red blood corpuscles, have mistaken areas devoid of hemoglobin in the red cell, which occur frequently in disease, for a protozoan parasite. He also refers to a report by Stiles, Chief of Division of Zoology, which details the results of his study of ten cases of spotted fever, in none of which Stiles succeeded in finding any structure in the blood which he could interpret as a protozoan organism.

8. Problems in Dietsetics.—Thompson attempts to solve some of the complex problems in the matter of dieting that frequently confront us and in which regulation of the food is of special importance. On the other hand, there are a number of nutritional disorders the etiology of which is still so obscure that the formulation of proper dietetic principles becomes unusually difficult. In typhoid, he deprecates the undue prolongation of the milk diet, as it is liable to produce scurvy, it protracts convalescence and, by impoverishing nutrition, makes the patient more liable to serious complications. He makes it a rule to commence the feeding of semi-solid food, in ordinary cases, on the day when the body temperature first reaches normal. Soft cooked eggs, baked custard, junket, milk toast, mutton or chicken broth, thickened with rice or crackers, plain, delicate foods like blanc mange and wine jelly, and light farinaceous foods may then be given. On the third day, if convalescence be uninterrupted, a scraped beef sandwich is given. Thompson recommends early increase in the dietary in very mild cases in general, but not if there be much tympanites, diarrhea or recent severe hemorrhage. In asthenic cases the maintenance of better nutrition is imperative. When much tympanites exists during a milk diet, beef juice and egg albumin or broths should be substituted for

the milk for two or three days. Cases of arthritis deformans are treated very much as if they had chronic phthisis, or chronic sepsis—by forced feeding—using largely fat foods, such as butter, cream, eggs, oils, bone marrow, bacon, etc. With a little care this dietary is well tolerated. The ordinary meals should be supplemented by two or three luncheons during the day. The use of simple bitter before meals or of dilute hydrochloric acid with *nux vomica* after meals, and the promotion of elimination of waste are of value in most cases. In nephritis the problem is a very complex one, and although in acute cases the conventional diet is demanded, in chronic cases there is occasion for greater latitude. In these cases the danger of meat eating is overrated considerably, and there are some cases in which its moderate use is positively demanded. Such cases are (1) those of very long standing, in which the chief symptom is a moderate albuminuria; (2) those in which anemia and loss of strength and weight are the prominent features, and (3) those in which some associated disease makes the use of animal food desirable. In diabetes, the author is convinced that a routine dietary may beget more harm than good. Each case should be given separate dietetic study. Mild cases do well on a diet chiefly proteid. Serious cases should be given more fats, such as butter (one-quarter pound or more a day), cream diluted with water and drunk as a beverage (one pint or more a day), the fats of cod-liver oil, olive oil on salads, sardines, etc.; olives, oily nuts, eggs, bacon and ham fat, bone marrow, suet and lard; rich cheese, soups, enriched with "dripping" and fat fish, mackerel and salmon, fat meats, goose and duck and the tender fat of corned beef. Potato is given best in the form of "Saratoga chips." Lithemia requires more or less abstinence from proteid food, the copious use of water (60 or 70 ounces a day), plenty of fresh air and rest, especially before the principal meal of the day. The dietetic treatment of arteriosclerosis is somewhat similar to that of lithemia, though the quantity of water to be allowed must be judged carefully, so as not to overburden a weak heart or to encourage inadequacy in damaged kidneys. In gout, the following general principles are of prime importance: 1. To reduce the consumption of food as a whole; 2, to increase the consumption of water; 3, to eliminate entirely sugars and sweets of every kind, as well as alcohol; and 4, to reduce the consumption of red meats to a minimum. The dietetic treatment of rheumatism should, in general, resemble that of gout, a milk diet during the acute attack and restriction of meat and sweets in the interval. In closing, Thompson enters a word of protest against the common practice of basing dietetic and other treatment of stomachic disease on the results of a single gastric analysis. At least half a dozen tests should be made before any definite conclusions are justifiable, dietetic or otherwise.

10. Treatment of Pneumonia.—Manges defines pneumonia as a general disease, the tendency of which is to recovery after the lapse of sufficient time for the body to produce its own antitoxin. When treatment is required it must be directed against the toxemia: 1, to maintain life; 2, to support the heart; 3, to control undue fever; 4, to relieve suffering; 5, to control complications. Intelligent nursing and careful dieting will meet the first indication. The drugs which best support the heart are strychnin, caffeine, alcohol, camphor and ergot. There should be no hesitancy to use them freely, and hypodermic medication should be substituted promptly for medication by mouth, if the latter fails to produce the desired result. Adrenalin, the precordial icebag, cupping, and venesection are also useful measures. Fever may be reduced by the use of large, flat icebags to the affected area, but this is not to be looked on as a specific and it is to be remembered that carelessness in their use may give rise to an intercostal neuritis. Cold baths are absolutely contraindicated. Cold sponging and cold packs are often useful, but are to be used with caution. Properly applied moist compresses enveloping the entire chest often comfort the patient, although they are not of much therapeutic use. The rational use of small doses of any of the coal tar products may add not a

little to the patient's comfort. The suffering incident to the pleuritic pain and the distressing cough is best relieved by the hypodermic injection of small doses of morphin, grain 1/10 to 1/8, or heroin hydrochlorid, grain 1/8 to 1/6. The Paque-lin cautery often acts magically in quieting pleuritic irritation. All administration of drugs, etc., should be done at stated times; during the intervals between them, rest or sleep should be procured. The complications require the treatment pursued ordinarily. Manges warns against routine or "scheduled" plans of treatment.

12. Foreign Bodies in Appendix.—Mitchell gives a list of foreign bodies found in the appendix during his service as corner's physician. One or more grape seeds were present in 5 cases; one or more shot in 3 cases, and fragments of bone in 2 cases. Other objects found were a fragment of shingle nail, a globule of solder, a piece of nut-shell, the centrum of the vertebra of a small fish with part of the vertebral arch attached, and fragments, apparently, of ash or stone. None of the appendices containing these bodies showed any signs of inflammation, either past or present.

17. Circum-Rectal Infections.—Jelks' operation consists of free incision and thorough curettage after irrigating the abscess with a formalin solution. The cavity is then packed with iodoform gauze. After the second day, gauze saturated in balsam of Peru, castor oil and ichthyol is used, the preliminary formalin irrigations being continued. Should large cavities remain unfilled after repeated curetting, they may be closed with 20-day catgut. Under this procedure the abscess cavity is converted into a clean surgical wound, thus favoring healing without attendant suppuration; nor is the integrity of the rectal sphincter diminished. Jelks throws out the surmise that the external sphincter has a distinct ganglion, and that division of the nerves about the rectum may be accountable for temporary atony and impaired function.

23. Dentition and Epilepsy.—Spratling maintains that we are never justified in looking on the convulsions of infancy and early life as harmless manifestations, because they often end in established epilepsy. The lesson physicians often fail to learn is the necessity for constantly recognizing in such children the presence of the convulsive tendency. To keep the child free from convulsions in the future this tendency must be borne in mind and always respected. For some years Spratling has been studying the age at the onset of epilepsy in several thousand cases to determine what proportion of these children acquired epilepsy coincident with the first or second dentition periods. In 1,215 cases the disease occurred between the first and twentieth years, inclusive, represent-

ing 80 per cent. of all the patients admitted to the Craig Colony up to that time. After the first year there was a very decided and continuous decline in the number of cases up to the sixth year, when there was a decided rise, lasting for three years, during the period of second dentition. During the first year of life the greatest number of cases occurred during the seventh month, which marks the beginning of the influence of the first dentition period. It is evident, then, that difficult dentition may, in suitable subjects, constitute a sufficient irritant to cause convulsions, and these may ultimately lead to epilepsy. By suitable subjects, Sprattling means infants who inherited a neuropathic tendency to disease; whose parents had epilepsy or insanity, or who were alcoholic or suffered from some other general vice that could be transmitted to the offspring in some form capable of vitiating its powers of resistance to disease. He does not believe, however, that difficult dentition alone, in a child who inherited no ancestral taints, and who at its birth is free from a tendency to nervous disease, can cause epilepsy. He advises the exercise of caution in laying the true cause in cases of this kind where it belongs, for the reason that gastrointestinal disorders, the sequelae of the eruptive fevers and other factors common at this age may produce similar results.

25. **New Method for Staining Capsules of Bacteria.**—The method described by Buerger depends on the rapid fixation of the bacteria while still alive and when spread in a medium which prevents dissolution of their capsules. The necessary solutions are: Mueller's fluid, saturated with bichlorid of mercury (ordinarily about 5 per cent.). 2. Beef, human or other blood serum, diluted with an equal amount of normal salt solution; or acetic or pleural fluid. 3. Eighty to 95 per cent. alcohol. 4. Tincture of iodine, U. S. P. 5. Freshly prepared stain, anilin water gentian violet made up as follows: Anilin oil, 10; water, 100; shake, filter and add 5 c.c. saturated alcoholic solution of gentian violet; or, 10 per cent. watery fuchsin. 6. Two per cent. watery salt solution. The culture is thinly and carefully spread over a perfectly clean slip by means of a drop of diluted serum. Just as the edges begin to dry, the fixing fluid, solution No. 1, is poured on, the cover gently warmed over the flame for about three seconds, rapidly washed in water, flushed once with alcohol, and then treated with iodine for from one to two minutes. The iodine is in turn thoroughly washed off with alcohol and the specimen dried in the air. Staining for two to five seconds, and washing with salt solution completes the procedure. The specimen is mounted in the salt solution and ringed with vaselin. Sputum and pus can be stained in a similar manner, the addition of serum being unnecessary, except in very mucoid, stringy, purulent exudates.

27. **Intracerebral Injections of Antitetanic Serum.**—Hopkins reports two cases of traumatic tetanus treated successfully by intracerebral injections of antitetanic serum, which he considers the correct method of treatment for the disease. The first patient stepped on a rusty nail, and symptoms of tetanus supervened on the fourth day following. Through a small trephine opening in the right frontal bone, 20 c.c. of antitetanic serum were injected into the right frontal lobe of the cerebrum. The trismus and spasms, which were constant before the serum was injected, ceased 72 hours after the operation, and the patient made a complete recovery. The second patient had a blank cartridge explode in his hand, and 19 days later marked trismus was present. Roux's point was selected for injecting the serum into the brain substance. The needle of the syringe was introduced to a depth of two inches, with the point directed downward and inward toward the median line, and 10 c.c. of antitetanic serum were slowly injected during the withdrawal of the needle. Ten more c.c. were injected in the same manner, with the point of the needle directed forward and downward and not toward the median line. All the symptoms subsided after 43 hours, the patient made an uneventful recovery. In a third case, an exploding blank cartridge entered the right knee. Fourteen days after the accident the symptoms were so alarming that medical aid was sought. The spasms occurred so frequently that it

became necessary to use chloroform. The pulse was 150, temperature 101, respiration 50. Twenty c.c. of antitetanic serum were injected into the right frontal convolution, but the patient died two hours after operation. Hopkins believes that the success of this method of treatment depends on the use of large quantities of the serum.

28. **Serum Diagnosis of Tuberculosis.**—The use of homogeneous and glycerinated bouillon cultures of the bacillus of human tuberculosis has enabled Arloing and Courmont to investigate the agglutinating power of fluids and especially the serum of tuberculous patients, and thus establish serum diagnosis of tuberculosis. The advantages of the method, as enumerated by them, are those of serum diagnosis in general: 1. absolute harmlessness, since all that is necessary is to withdraw a little serous fluid, and it can be applied in all cases, whether febrile or not, whether seriously or slightly ill. 2. Ease and rapidity, since it is not necessary to have the patient under observation, and it requires only a few hours for its accomplishment. 3. The delicacy of the reaction in cases where the lesions are discrete or latent and difficult to recognize by the usual methods. The authors emphasize that the technic for maintaining suitable fluid cultures and the performance of serum diagnosis require that fairly exact and indispensable conditions should be followed, on account of the slight degree of agglutinative power of the serum in cases of human tuberculosis. In cases of slightly advanced pulmonary tuberculosis the agglutinating power of the serum is nearly always constant, but in varying degrees. It varies from 1 to 5, to 1 to 20, and more. In advanced cases, with very extensive or virulent lesions, the serum reaction is often absent, or very slight. It may also diminish in intensity and disappear as the disease becomes progressively worse. The authors have found that the agglutinative reaction in tuberculous subjects appears most often and within certain limits in inverse ratio to the gravity of the infection and the extent of the lesions. In case of suffering from other diseases and in which the clinical data do not reveal positive signs of tuberculosis, the serum reaction is an aid in disclosing a large number of cases of latent tuberculosis. Arloing and Courmont sum up the practical value of the procedure as follows: 1. A positive serum reaction in the case of a suspected subject is a diagnostic point of great value in establishing the existence of visceral tuberculosis still active or having become inactive recently. 2. A negative serum reaction is of less value as a negative sign, since agglutination is absent in a certain number of tuberculous cases. 3. The absence of the reaction in cases of advanced tuberculosis, where serum diagnosis is no longer necessary, may, in certain cases, confirm an unfavorable prognosis. On the other hand, in the case of suspected tuberculosis, in the absence of clinical signs and symptoms of importance, the absence of the reaction may aid in eliminating the disease.

30. **Diagnosis of Incipient Pulmonary Tuberculosis.**—Perkins comments on the tendency on the part of many to rely too much on laboratory findings and too little on thorough clinical work. He urges that the diagnosis of pulmonary tuberculosis in its early stages be made by judiciously connecting the physical signs and clinical history with the pathologic lesions and systemic effects of a slight tuberculous infection.

37. **Physiologic Action of Azoimid.**—Azoimid is a protoplasmic poison resembling in its action hydrocyanic acid. It can be made by the action of sodium nitrate on hydrazin hydrochlorid, but, on account of the difficulty of preparing it in this way, it is better prepared from hippuryl hydrazin, dissolving in dilute soda and boiling with sulphuric acid. Smith and Wolf have experimented with this substance with a view to ascertaining its exact physiologic action. They noted its effect when respired, and when given by intravenous injection, on muscle and nerve. They found that these structures are paralyzed, with a preliminary stage of increased excitability. They appear to be affected simultaneously. The vapor of azoimid inhaled causes excitation of the respiratory centers, with subsequent paralysis. The blood pressure is lowered, primarily because of the vasomotor disturbance. The intestine and kidney take part in vasodilation in exceptional instances only. Other of the viscera are the main factors in the process. The acid is the most powerful of the compounds containing the trinitrogen group. The introduction of a phenyl radical diminishes the effect of the complex. Azoimid forms a compound with methemoglobin similar to that formed by hydrocyanic acid. The authors could not make out the existence of an azoimid hemoglobin or an azoimid hematin.

41. **Histology of Vaccinia and Variola.**—Ewing presents the results of a study of vaccinia and variola begun by him in 1901 and still remaining incomplete. His work was mainly guided by the endeavor to distinguish between specific vaccine bodies and other cell changes, and to ascertain what differences in morphology exist between vaccine bodies, as occurring in rabbits and man and those produced in any other animals which may be made to react to vaccine. The work began with the examination of the material secured from autopsies on 30 cases of variola and was continued by a study of vaccine lesions. The latter studies lead Ewing to the conclusion that there is a specific vaccine body, many of which follow a definite cycle of development; but their minute morphology, especially the connection of many of them with the reticulum of the cell, strongly indicate that these bodies are degenerating portions of the cyto-reticulum. The specific vaccine body shows, in many instances, definite connections with the cytoplasm of the epithelial cell which are applicable only on the supposition that this body is a part of the cytoplasm. The form, size and structure of the vaccine body is so irregular as to suggest the cycle of a degenerative process rather than that of a living micro-organism. The general histology of vaccinia shows that an active diffusible toxin similar to that of diphtheria is at work in the process from its beginning, but the production of such toxins is not the rule with protozoa. The comparative study of the action of vaccine on different animals shows that the same general process and, in many respects, the same peculiar intracellular changes are produced in widely different classes of animals, and suggests that the vaccine body is a particular form taken in some warm-blooded animals of a universal property of degenerating epithelial cells. Regarding the intranuclear bodies, Ewing believes that the present data are insufficient to warrant positive conclusions either for or against the protozoan theory. The behavior of these bodies under different fixatives and stains is unsatisfactory for the protozoan hypothesis. The staining reactions are identical with those of certain nuclear elements, namely, nu-

cleoli and linin droplets. The intranuclear rings seem to occur only at a particular stage of the necrosis of squamous epithelial cells. The intranuclear cycle is imperfectly represented in specific lesions of mucous membranes, and may be entirely missing in the cutaneous necrosis of rapidly fatal secondary hemorrhagic cases. On the other hand, said Ewing, the full series of these bodies seems to occur only in variola and only individual forms seem to be duplicated, and these imperfectly, in other lesions.

- 46 Remarks on the History of the Mastoid and Radical Operation on the Middle Ear, with Demonstration of Anatomic Specimens. Emil Amberg.

42. **Value of the Tuberculin Test.**—Neff states that a reaction to tuberculin is positive proof of tuberculosis. Failure to react may be of negative value if the tuberculin test is used when the disease is far advanced. When the errors of the diagnosticians using tuberculin are eliminated, the percentage of failures is exceedingly small. Cases apparently recovered often react to tuberculin, thus proving that there is tuberculosis and that the disease is present in a latent form. Owing to the variability of the general and local symptoms of a reaction, Neff urges that reliance must be based entirely on the induced fever. The average time for the reaction is twelve hours, but in some cases it may be delayed as long as twenty hours. He advises the use of large initial doses on the ground that small doses tend to establish a tolerance, thus preventing a reaction. Extreme care is essential when a reaction to tuberculin is suspected. The preliminary temperature should be carefully considered and all errors eliminated. Advanced cases of tuberculosis do not, as a rule, react. If a reaction is secured, it is generally obscured by preliminary temperature oscillations. Neff recommends the use of the tuberculin test in general practice, providing physicians will remember the extreme delicacy of the test, its limitations, and the necessity of the employment of a thorough and unvarying technic.

44. **Plaster-of-Paris and Elastic Traction in Foot Deformities.**—Nancrede presents a feasible and convenient combination of the most essential factors of older methods for the treatment of deformities of the feet. After the forcible correction under anesthesia, preceded or not by tenotomy or the Phelps open operation, extreme care in padding is required, perhaps protecting the parts exposed to extra pressure by soap plaster spread on leather. In the Phelps operation Nancrede omits the division of the posterior part of the capsule and the internal lateral ligament of the ankle joint. The foot is then put in the best attainable position with plaster, incorporating in the dressing, a light wooden sole with crosspiece, and a few links of chain in the upper part of the leg portion. He says it is advisable to incorporate a strip of wire gauze in the healed portion of the splint to serve as a hinge and prevent breaking of this part of the dressing. After a proper interval, in from five to ten days, according to the nature of the operation on the foot, a segment should be sawed out of the superior aspect of the dressings over the medio-tarsal joint, and rubber bands be adjusted so as to make slight traction, which is to be increased from time to time. After the hiatus produced by the removal of the plaster has been brought into contact, Nancrede advises the application of an entirely new dressing, which in twenty-four hours should have a segment removed and traction is then recommended and maintained until the correction desired is secured, or it is plain that fresh operative measures are requisite, such as an open operation where none such has been done, or some form of osseous excision, where a Phelps incision has been made. Nancrede has never had to resort to osteotomy after the combined Phelps and elastic traction dressing. Careless padding or too rapid and severe traction will, as in all methods where fixed dressings are em-

ing 80 per cent. of all the patients admitted to the Craig Colony up to that time. After the first year there was a very decided and continuous decline in the number of cases up to the sixth year, when there was a decided rise, lasting for three years, during the period of second dentition. During the first year of life the greatest number of cases occurred during the seventh month, which marks the beginning of the influence of the first dentition period. It is evident, then, that difficult dentition may, in suitable subjects, constitute a sufficient irritant to cause convulsions, and these may ultimately lead to epilepsy. By suitable subjects, Spratling means infants who inherited a neuropathic tendency to disease; whose parents had epilepsy or insanity, or who were alcoholic or suffered from some other general vice that could be transmitted to the offspring in some form capable of vitiating its powers of resistance to disease. He does not believe, however, that difficult dentition alone, in a child who inherited no ancestral taints, and who at its birth is free from a tendency to nervous disease, can cause epilepsy. He advises the exercise of caution in laying the true cause in cases of this kind where it belongs, for the reason that gastrointestinal disorders, the sequelæ of the eruptive fevers and other factors common at this age may produce similar results.

25. **New Method for Staining Capsules of Bacteria.**—The method described by Buerger depends on the rapid fixation of the bacteria while still alive and when spread in a medium which prevents dissolution of their capsules. The necessary solutions are: Mueller's fluid, saturated with bichlorid of mercury (ordinarily about 5 per cent.). 2. Beef, human or other blood serum, diluted with an equal amount of normal salt solution; or acetic or pleural fluid. 3. Eighty to 95 per cent. alcohol. 4. Tincture of iodine, U. S. P. 5. Freshly prepared stain, anilin water gentian violet made up as follows: Anilin oil, 10; water, 100; shake, filter and add 5 c.c. saturated alcoholic solution of gentian violet; or, 10 per cent. watery fuchsin. 6. Two per cent. watery salt solution. The culture is thinly and carefully spread over a perfectly clean slip by means of a drop of diluted serum. Just as the edges begin to dry, the fixing fluid, solution No. 1, is poured on, the cover gently warmed over the flame for about three seconds, rapidly washed in water, flushed once with alcohol, and then treated with iodine for from one to two minutes. The iodine is in turn thoroughly washed off with alcohol and the specimen dried in the air. Staining for two to five seconds, and washing with salt solution completes the procedure. The specimen is mounted in the salt solution and ringed with vaselin. Sputum and pus can be stained in a similar manner, the addition of serum being unnecessary, except in very mucoid, stringy, purulent exudates.

27. **Intracerebral Injections of Antitetanic Serum.**—Hopkins reports two cases of traumatic tetanus treated successfully by intracerebral injections of antitetanic serum, which he considers the correct method of treatment for the disease. The first patient stepped on a rusty nail, and symptoms of tetanus supervened on the fourth day following. Through a small trephine opening in the right frontal bone, 20 c.c. of antitetanic serum were injected into the right frontal lobe of the cerebrum. 28. **Serum Diagnosis of Tuberculosis.**—The use of homogeneous and glycerinated bouillon cultures of the bacillus of human tuberculosis has enabled Arloing and Courmont to investigate the agglutinating power of fluids and especially the serum of tuberculous patients, and thus establish serum diagnosis of tuberculosis. The advantages of the method, as enumerated by them, are those of serum diagnosis in general: 1. absolute harmlessness, since all that is necessary is to withdraw a little serous fluid, and it can be applied in all cases, whether febrile or not, whether seriously or slightly ill. 2. Ease and rapidity, since it is not necessary to have the patient under observation, and it requires only a few hours for its accomplishment. 3. The delicacy of the reaction in cases where the lesions are discrete or latent and difficult to recognize by the usual methods. The authors emphasize that the technic for maintaining suitable fluid cultures and the performance of serum diagnosis require that fairly exact and indispensable conditions should be followed, on account of the slight degree of agglutinative power of the serum in cases of human tuberculosis. In cases of slightly advanced pulmonary tuberculosis the agglutinative power of the serum is nearly always constant, but in varying degrees. It varies from 1 to 5, to 1 to 20, and more. In advanced cases, with very extensive or virulent lesions, the serum reaction is often absent, or very slight. It may also diminish in intensity and disappear as the disease becomes progressively worse. The authors have found that the agglutinative reaction in tuberculous subjects appears most often and within certain limits in inverse ratio to the gravity of the infection and the extent of the lesions. In case of suffering from other diseases and in which the clinical data do not reveal positive signs of tuberculosis, the serum reaction is an aid in disclosing a large number of cases of latent tuberculosis. Arloing and Courmont sum up the practical value of the procedure as follows: 1. A positive serum reaction in the case of a suspected subject is a diagnostic point of great value in establishing the existence of visceral tuberculosis still active or having become inactive recently. 2. A negative serum reaction is of less value as a negative sign, since agglutination is absent in a certain number of tuberculous cases. 3. The absence of the reaction in cases of advanced tuberculosis, where serum diagnosis is no longer necessary, may, in certain cases, confirm an unfavorable prognosis. On the other hand, in the case of suspected tuberculosis, in the absence of clinical signs and symptoms of importance, the absence of the reaction may aid in eliminating the disease.

30. **Diagnosis of Incipient Pulmonary Tuberculosis.**—Perkins comments on the tendency on the part of many to rely too much on laboratory findings and too little on thorough clinical work. He urges that the diagnosis of pulmonary tuberculosis in its early stages be made by judiciously connecting the physical signs and clinical history with the pathologic lesions and systemic effects of a slight tuberculous infection.

37. Physiologic Action of Azoimid.—Azoimid is a protoplasmic poison resembling in its action hydrocyanic acid. It can be made by the action of sodium nitrate on hydrazin hydrochlorid, but, on account of the difficulty of preparing it in this way, it is better prepared from hippury hydrazin, dissolving in dilute soda and boiling with sulphuric acid. Smith and Wolf have experimented with this substance with a view to ascertaining its exact physiologic action. They noted its effect when respired, and when given by intravenous injection, on muscle and nerve. They found that these structures are paralyzed, with a preliminary stage of increased excitability. They appear to be affected simultaneously. The vapor of azoimid inhaled causes excitation of the respiratory centers, with subsequent paralysis. The blood pressure is lowered, primarily because of the vasomotor disturbance. The intestine and kidney take part in vasodilation in exceptional instances only. Other of the viscera are the main factors in the process. The acid is the most powerful of the compounds containing the trinitrogen group. The introduction of a phenyl radical diminishes the effect of the complex. Azoimid forms a compound with methemoglobin similar to that formed by hydrocyanic acid. The authors could not make out the existence of an azoimid hemoglobin or an azoimid hematin.

41. Histology of Vaccinia and Variola.—Ewing presents the results of a study of vaccinia and variola begun by him in 1901 and still remaining incomplete. His work was mainly guided by the endeavor to distinguish between specific vaccine bodies and other cell changes, and to ascertain what differences in morphology exist between vaccine bodies, as occurring in rabbits and man and those produced in any other animals which may be made to react to vaccine. The work began with the examination of the material secured from autopsies on 30 cases of variola and was continued by a study of vaccine lesions. The latter studies lead Ewing to the conclusion that there is a specific vaccine body, many of which follow a definite cycle of development; but their minute morphology, especially the connection of many of them with the reticulum of the cell, strongly indicate that these bodies are degenerating portions of the cyto-reticulum. The specific vaccine body shows, in many instances, definite connections with the cytoplasm of the epithelial cell which are applicable only on the supposition that this body is a part of the cytoplasm. The form, size and structure of the vaccine body is so irregular as to suggest the cycle of a degenerative process rather than that of a living micro-organism. The general histology of vaccinia shows that an active diffusible toxin similar to that of diphtheria is at work in the process from its beginning, but the production of such toxins is not the rule with protozoa. The comparative study of the action of vaccine on different animals shows that the same general process and, in many respects, the same peculiar intracellular changes are produced in widely different classes of animals, and suggests that the vaccine body is a particular form taken in some warm-blooded animals of a universal property of degenerating epithelial cells. Regarding the intranuclear bodies, Ewing believes that the present data are insufficient to warrant positive conclusions either for or against the protozoan theory. The behavior of these bodies under different fixatives and stains is unsatisfactory for the protozoan hypothesis. The staining reactions are identical with those of certain nuclear elements, namely, nu-

cleoli and linin droplets. The intranuclear rings seem to occur only at a particular stage of the necrosis of squamous epithelial cells. The intranuclear cycle is imperfectly represented in specific lesions of mucous membranes, and may be entirely missing in the cutaneous necrosis of rapidly fatal secondary hemorrhagic cases. On the other hand, said Ewing, the full series of these bodies seems to occur only in variola and only individual forms seem to be duplicated, and these imperfectly, in other lesions.

- 46 Remarks on the History of the Mastoid and Radical Operation of the Middle Ear, with Demonstration of Anatomic Specimens. Emil Amberz.

42. Value of the Tuberculin Test.—Neff states that a reaction to tuberculin is positive proof of tuberculosis. Failure to react may be of negative value if the tuberculin test is used when the disease is far advanced. When the errors of the diagnosticians using tuberculin are eliminated, the percentage of failures is exceedingly small. Cases apparently recovered often react to tuberculin, thus proving that there is tuberculosis and that the disease is present in a latent form. Owing to the variability of the general and local symptoms of a reaction, Neff urges that reliance must be based entirely on the induced fever. The average time for the reaction is twelve hours, but in some cases it may be delayed as long as twenty hours. He advises the use of large initial doses on the ground that small doses tend to establish a tolerance, thus preventing a reaction. Extreme care is essential when a reaction to tuberculin is suspected. The preliminary temperature should be carefully considered and all errors eliminated. Advanced cases of tuberculosis do not, as a rule, react. If a reaction is secured, it is generally obscured by preliminary temperature oscillations. Neff recommends the use of the tuberculin test in general practice, providing physicians will remember the extreme delicacy of the test, its limitations, and the necessity of the employment of a thorough and unvarying technic.

44. Plaster-of-Paris and Elastic Traction in Foot Deformities.—Nancrede presents a feasible and convenient combination of the most essential factors of older methods for the treatment of deformities of the feet. After the forcible correction under anesthesia, preceded or not by tenotomy or the Phelps open operation, extreme care in padding is required, perhaps protecting the parts exposed to extra pressure by soap plaster spread on leather. In the Phelps operation Nancrede omits the division of the posterior part of the capsule and the internal lateral ligament of the ankle joint. The foot is then put up in the best attainable position with plaster, incorporating in the dressing, a light wooden sole with crosspiece, and a few links of chain in the upper part of the leg portion. He says it is advisable to incorporate a strip of wire gauze in the healed portion of the splint to serve as a hinge and prevent breaking of this part of the dressing. After a proper interval, in from five to ten days, according to the nature of the operation on the foot, a segment should be sawed out of the superior aspect of the dressings over the medio-tarsal joint, and rubber bands be adjusted so as to make slight traction, which is to be increased from time to time. After the hiatus produced by the removal of the plaster has been brought into contact, Nancrede advises the application of an entirely new dressing, which in twenty-four hours should have a segment removed and traction is then recommended and maintained until the correction desired is secured, or it is plain that fresh operative measures are requisite, such as an open operation where none such has been done, or some form of osseous excision, where a Phelps incision has been made. Nancrede has never had to resort to osteotomy after the combined Phelps and elastic traction dressing. Careless padding or too rapid and severe traction will, as in all methods where fixed dressings are em-

ployed, be productive of blisters, sloughs, etc., but constant supervision, timely relaxation of tension and removal of portions of the plaster over points of pressure, will usually prevent any serious trouble. When the operator is in doubt it is advisable to remove the whole dressing, protect the projecting points with soap plaster, carefully pad, employ improvised rings of barness felt, or corn or bunion plasters, and remove portions of the wooden sole—in other words, adopt the usual methods employed to prevent undue pressure.

49 Milk Infection. E. W. Humphrey.

47. **Surgical Diseases of the Sigmoid.**—Niles operated on two cases of complete obstruction of the bowel due to volvulus of the sigmoid, the diagnosis being confirmed by operation, and attended two other patients suffering from incomplete stricture of the bowel, resulting, he believes, either from a twist or from some inflammatory lesion of the sigmoid. These two cases were not operated on and consequently the diagnosis was not positively confirmed. As a result of this work Niles carried on some investigations on the surgical anatomy of the sigmoid. The various pathologic changes to which the physiologic functions and anatomic structure and relations of the sigmoid render it especially susceptible, Niles regards as successive steps or stages of one morbid process, rather than as so many different diseases. An impartial study of the various successive pathologic changes that precede, accompany and follow inflammatory obstructions and malignant diseases of the sigmoid, furnishes convincing evidence of how little can reasonably be expected of medical treatment, and how much reliance must be placed on timely operative interference to correct disease in this region. Advanced malignant disease of the sigmoid is always preceded by pathologic processes which should be recognized early and corrected by timely operative procedures. Acute obstruction due to volvulus, unless relieved promptly by inflation of the rectum with water or gas, is always an indication for operative interference. So, too, are all torsions of the bowel with partial or complete stricture. All inflammatory or necrotic processes that include the peritoneal coat of the gut, with or without angulation, or stricture of the bowel, should be regarded as surgical conditions. Finally, says Niles, the known frequency of cancer and all forms of intestinal ulcers in this region, the occasional occurrence of volvulus, a practical consideration of the anatomic structure and relations of the sigmoid, all tend to confirm the belief that inflammatory lesions and obstructive distortions of the sigmoid are by no means rare, and that their rational treatment should be based on the surgical conception of the condition.

53 Urinary Antisepsis in Gonorrhoeal Urethritis. E. Reinhardt.

52. **Extraordinary Anemia.**—The history of Trebilcock's case, in brief, is as follows: The patient, a young woman, unmarried, showed the most intense air hunger. Her hair was exceedingly sparse and coarse, her face uniformly broadened, and, with the exception of the under eyelids which were noticeably bagged and soft, was very firm under pressure. All expression was lost. The countenance was a pale yellow white without the faintest trace of pink, even on the severest pinching and friction; the ears were translucent so that heavy newspaper print was distinguishable through the lobes. The bulbar conjunctiva was slightly muddy. The neck was uniformly enlarged, with no special swelling at any one point. The thyroid was not palpable; no marked pulsation was visible anywhere. The trunk was also uniformly enlarged and the abdomen more prominent. Careful examination showed no displacement of any organ. The cardiac impulse was forcible. The arms and legs were also swollen and hard. The skin was exceedingly

inelastic and dry; no perspiration for months; no rash, only a diffuse scurfiness and occasionally tense itching. The muscular system was normal. Pulse, 160; respiration, 70; temperature, 101. Digestive system normal, except for a marvelously large appetite. Under strict hygiene, simple food, abundance of fresh air, and daily alcohol baths, compound syrup of hypophosphites, with gradually increasing doses of arsenic and thyroid extract, the patient improved slowly but steadily. An interesting feature in this case is the fact that for six months the patient dressed every day a sloughing epithelioma, the odor from which was so obnoxious that she made a bag to cover her own nose and mouth—a sort of respirator—in which she kept pieces of gummed camphor. The camphor fumes would often cause her mouth and nose to be quite sore, and it was during this time that the anemia began to manifest itself.

 3 *Afebrile Enteric Fever. George Jubb.
 4 Case of Congenital Absence of Continuity Between the Large and Small Intestines. C. H. Souter.
 5 *Infant Mortality: Its Causes and Prevention. George C. H. Fulton.

2. *Micrococcus Rheumaticus*.—Beattie confirms the results obtained by Beaton and Walker with reference to the etiologic relationship of this organism to rheumatism. One of the organisms with which he worked was obtained from the synovial membrane of a girl with acute rheumatism and from the vegetations of an endocarditis in a rabbit. Intravenous injections in animals produced endocarditis, polyarthritides and chorea. Subcutaneous injections, even in large doses, were not followed by a suppuration. He believes that there is ground for but one conclusion, that this *Micrococcus rheumaticus* is a special organism and is causal in acute rheumatism.

3. *Afebrile Typhoid*.—Jubb based his diagnosis of this case entirely on the serum reaction. Without it, he says, there would have been some hesitation in confining the patient to bed and a milk diet for a prolonged period. There was no disturbance of the temperature until a complication took place—thrombosis of the left femoral vein.

5. *Infant Mortality*.—Fulton directs attention to the influence on infant mortality of premature birth, hereditary tendencies, inexperience and neglect of the mother, industrial conditions, social position, improper food and method of feeding, density of population and illegitimacy. He urges the district and municipal authorities to carry out fully the power they possess relating to cows, cowsheds and milk shops, so that the milk may be good; that printed instructions be handed to parents when the birth of a child is registered, containing advice on simple methods of rearing infants, great stress being placed on breast feeding, and by appointing lady inspectors or visitors in every town. He urges the need of teaching hygiene in public schools and of educating future mothers to a keener sense of their duty to their own children and to the state.

 10 Notes on a Few Cases of Trypanosomiasis in Man. G. C. Chatterjee.

6. *Treatment of Cancer*.—In this paper Robson reviews the entire subject of cancer, the infectivity of cancer and the preventive treatment of scrotal epithelioma, precancerous conditions of the skin, mammary glands, stomach, pelvic organs of women, intestines, and the radical treatment of all forms of cancer. Speaking of cancer of the breast, Robson gives the following brief account of all the operations for this form of cancer which he has done in private. They number 62; three alive and well twelve, ten and nine years respectively after operation; 2 eight years after operation; one each seven and a half and seven years after operation; 3 after six and a half years; one after six; 2 after four; one after three; 3 after two and a half; one after two, and 2 after one and a half years. One lived twenty years and died from chronic bronchitis. Four were without recurrence and died from various causes (meningitis, phthisis, enteric fever, apoplexy), from six months to two years after operation. Eight cases can not be traced. Twenty-nine cases had a recurrence of the disease in from four months to six years after operation; the greatest number, 13, in the second six months; in 8 it was over three years after operation. Of 161 patients admitted to the clinic with operable primary tumors of the breast on which complete operations were performed, between 1889 and 1899, in 1002 60 patients were living and cured; 7 had lived over three years and died from other causes, and 2 had died from other causes within the three years' limit, the necropsy showing no recurrence. This gives 69 cases positively cured. Of the whole number, 161, 83 survived the three years' limit. During thirteen years 305 patients with primary and 38 with secondary tumors were admitted to the clinic, and of these 83 were inoperable. Of 3 cases of the stomach, one, a man aged 42 years, from whom Robson removed the whole stomach except a small portion of the dome and the cardiac orifice, is robust and well four years after operation. A second case, a

ployed, be productive of blisters, sloughs, etc., but constant supervision, timely relaxation of tension and removal of portions of the plaster over points of pressure, will usually prevent any serious trouble. When the operator is in doubt it is advisable to remove the whole dressing, protect the projecting points with soap plaster, carefully pad, employ improvised rings of harness felt, or corn or bunion plasters, and remove portions of the wooden sole—in other words, adopt the usual methods employed to prevent undue pressure.

December 3.

- 1 Life History of Saprophytic and Parasitic Bacteria and Their Mutual Relation. E. Klei.
 2 *Micrococci Rheumatici: Its Cultural and Other Characteristics. James M. Beattie.
 3 *Afebrile Enteric Fever. George Jubb.
 4 Case of Congenital Absence of Continuity Between the Large and Small Intestines. C. H. Senter.
 5 *Infant Mortality: Its Causes and Prevention. George C. H. Fulton.

2. *Micrococcus Rheumaticus.* Beattie confirms the results obtained by Beaton and Walker with reference to the etiological relationship of this organism to rheumatism. One of the organisms with which he worked was obtained from the synovial membrane of a girl with acute rheumatism and from the vegetations of an endocarditis in a rabbit. Intravenous injections in animals produced endocarditis, polyarthritides and chorea. Subcutaneous injections, even in large doses, were not followed by a suppuration. He believes that there is ground for but one conclusion, that this *Micrococcus rheumaticus* is a special organism and is causal in acute rheumatism.

3. *Afebrile Typhoid.*—Jubb based his diagnosis of this case entirely on the serum reaction. Without it, he says, there would have been some hesitation in confining the patient to bed and a milk diet for a prolonged period. There was no disturbance of the temperature until a complication took place—thrombosis of the left femoral vein.

5. *Infant Mortality.*—Fulton directs attention to the influence on infant mortality of premature birth, hereditary tendencies, inexperience and neglect of the mother, industrial conditions, social position, improper food and method of feeding, density of population and illegitimacy. He urges the district and municipal authorities to carry out fully the power they possess relating to cows, cowsheds and milk shops, so that the milk may be good; that printed instructions be handed to parents when the birth of a child is registered, containing advice on simple methods of rearing infants, great stress being placed on breast feeding, and by appointing lady inspectors or visitors in every town. He urges the need of teaching hygiene in public schools and of educating future mothers to a keener sense of their duty to their own children and to the state.

 10 Notes on a Few Cases of Trypanosomiasis in Man. G. C. Chatterjee.

6. *Treatment of Cancer.*—In this paper Robson reviews the entire subject of cancer, the infectivity of cancer and the preventive treatment of scrotal epithelioma, precancerous conditions of the skin, mammary glands, stomach, pelvic organs of women, intestines, and the radical treatment of all forms of cancer. Speaking of cancer of the breast, Robson gives the following brief account of all the operations for this form of cancer which he has done in private. They number 62; three alive and well twelve, ten and nine years respectively after operation; 2 eight years after operation; one each seven and a half and seven years after operation; 3 after six and a half years; one after six; 2 after four; one after three; 3 after two and a half; one after two, and 2 after one and a half years. One lived twenty years and died from chronic bronchitis. Four were without recurrence and died from various causes (meningitis, phthisis, enteric fever, apoplexy), from six months to two years after operation. Eight cases can not be traced. Twenty-nine cases had a recurrence of the disease in from four months to six years after operation; the greatest number, 13, in the second six months; in 8 it was over three years after operation. Of 161 patients admitted to the clinic with operable primary tumors of the breast on which complete operations were performed, between 1889 and 1899, in 1902 60 patients were living and cured; 7 had lived over three years and died from other causes, and 2 had died from other causes within the three years' limit, the necropsy showing no recurrence. This gives 69 cases positively cured. Of the whole number, 161, 83 survived the three years' limit. During thirteen years 305 patients with primary and 38 with secondary tumors were admitted to the clinic, and of these 83 were inoperable. Of 3 cases of the stomach, one, a man aged 42 years, from whom Robson removed the whole stomach except a small portion of the dome and the cardiac orifice, is robust and well four years after operation. A second case, a

woman, aged 54 years, on whom a partial gastrectomy was performed, at the same time as removal of the gall bladder, both organs being cancerous, is well in the fifth year after operation. A woman, aged 50 years, is well nearly four years after the removal of the center of a cancerous hour-glass stomach, the proximal and distal healthy portions having been joined over a decalcified bone bobbin. One case of cancer of the tongue is well seven years after operation, another five years and others over three years, and in all these cases very good power of speech is retained. Of 21 operations for cancer of the bowel done in private there were 17 recoveries. Of these one is alive and well ten years after resection of the sigmoid flexure; one after four and a half years; 3 after three and a half years; 2 after three years, and one after one year. Others lived, one for three years; 3 for two years, and 5 for lesser periods and died from recurrence. One patient is living and well, with good control of the bowel, from whom Robson removed a cancer of the rectum by proctectomy twelve years ago; another after eight years, and others are well and enjoying life several years after operation. Of 12 cases of cancer of the gall bladder and liver, 10 recovered from the operation, 5 being alive at five and a half, 5 four and a half, four, and one and a quarter years after operation. Of 26 cases of cancer of the uterus operated on in private, 12 were total hysterectomies without a death, 5 of the patients being alive and well from five to eight and a half years after operation. Fourteen cases were very free supravaginal amputations of the cervix without a death, 5 cases being alive and well six, nine, ten, ten and a half and eleven and a half years after operation. One lived for five years and died from heart disease, without recurrence of the cancer. One lived four years and recurred, and five lived one year or less and recurred. Robson emphasizes the value of early diagnosis and early radical operative interference, and gives a place to palliative operations.

13. Quinin Injections in Malaria.—Because a number of men failed to react to quinin when administered by the mouth, Fleury resorted to hypodermic injection of acid quinin hydrochlorid of the B. P., as this preparation of quinin is readily soluble in distilled water when warm, and one minim of distilled water takes up one grain of the drug. It does not cause any irritation. Arguing on the assumption that the nearer to the spleen the injection is made the better the result, he determined to inject deep into the structures below the rib, just behind the midaxillary line on the left side, so placing the injection as near to the spleen as is consistent with safety. The parts were carefully washed and rendered as aseptic as possible. A 10-minim syringe with a fairly long and fine needle was used. The solution to be injected was prepared at the time, or not more than three days beforehand, the strength of the solution being such that the syringe when filled with 10

minims contained eight grains of quinin. The solution was always injected warm. The puncture wound was at once sealed with collodion and gauze on the needle being withdrawn. In some of the more severe cases Fleury found it necessary to repeat the injection in twenty-four hours, and in one or two cases he gave 16 grains at one injection. The results were, in practically all cases, most striking. Where no reaction followed the injection it was found subsequently that the patient was suffering from some disease other than malaria. Eighteen cases are cited illustrating the value of this method of treatment.

22. Nasal Treatment of Asthma.—An experience obtained from treating over 400 cases of various kinds of asthma is responsible for the opinion expressed by Francis that it is those asthmatics who present no gross nasal lesions and no subjective nasal symptoms, that give the best hope of affording relief by intranasal treatment. Of 402 recorded cases only 14 obtained no relief, and of these 3 suffered from polypi and 2 from such pronounced deflections of the septum that it was impossible to apply the galvanocautery without doing operations which were declined. Only eight cases that presented no gross nasal lesions, out of 346 cases treated, obtained no relief, and of these 3 were seen by Francis only three times and one four times. Of the remaining 4 cases, one was a pronounced morphinomania. In addition to these 14 known failures there are 17 cases where he was unable to obtain any record of the result, and a number of others that were completely relieved or greatly improved when lost sight of. From the experiences obtained in treating these cases Francis draws the following conclusions: 1. That asthma is due to reflex spasm of the bronchial tubes. 2. That the irritation may originate in the nose, as may be inferred from (a) the intimate association between hay fever and asthma; (b) the very common record of excessive sneezing at some period in the previous history of an asthmatic patient; (c) the not infrequent alteration between asthma and sneezing. 3. That asthma is not directly due to any mechanical obstruction of the nasal passages, and is not commonly caused by any gross nasal lesions. 4. That some part of the nasal apparatus has a controlling influence on the respiratory center; or there is in the nose, as it were, an apparatus through which the afferent impulses must pass.

[The author fails to describe his method of treatment, but it may be inferred from a report of several cases treated, that it consists of cauterization of the nasal mucous membrane with the galvanocautery.—Ed.]

Semaine Médicale, Paris.

- 31 (XXIV, No. 47.) *Le rôle pathologique des poisons de l'intestin. Charrin and Le Play.
- 32 Les fausses couches tubaires (tubal abortions). F. Lejars.

31. Pathologic Role of Intestinal Poisons.—The researches outlined here enlarge the conceptions of the pathogenic importance of intestinal poisons. Many of the experiences described were merely the production in animals of what is observed in the clinic. An entire series of deformities were engendered in very young animals. One phenomenon noted was that of autofunction, that is, that a substance derived from a given organ stimulates that organ to extra activity. Urine, for instance, has a diuretic action; thyroid extract stimulates the thyroid gland, and injection of substances derived from the wall of the ileum caused manifest hyperemia of the intestinal wall, exaggerated secretion and nuclear karyolysis. The experiments reported demonstrate that the alimentary canal normally contains innumerable poisons, including toxic substances, such as the diastases, which are required for the nutritive processes. They have further established that frequently a disease is due to the disorganization of its defenses rather than to the intrusion of any special pathologic agent. In therapeutics, while it is necessary to attack the enemy, yet in many cases it is important that more attention should be paid to strengthening the ramparts. The normal organic products may become morbid under certain circumstances, and some of these morbid elements are merely physiologic digestive secretions.

 40 Reduction of Obesity and Albumin in Forced Feeding.—Entfettung und Eiweissmast. K. Bornstein. (Commenced in No. 46.) Reply. A. Albu.

32. Treatment of Diabetes.—De Renzi has been treating diabetes for thirty-four years with a green vegetable diet. He thinks that this is not merely a symptomatic but a radical cure. The carbohydrates in green vegetables are well tolerated by diabetics. The power of assimilation is exaggerated in them, contrary to what is observed in tuberculosis. An amount of calories inadequate for a healthy subject amply suffices for a diabetic. His ration is five portions of green vegetables; five portions, that is, about 300 gm. of meat, five eggs and a pint of wine, forming a total of 2,104 calories. The only drug of any use in diabetes is sodium bicarbonate. He gives it in large doses and remarks on the strange tolerance for it. It neutralizes the beta-oxybutyric acid, while it improves the general condition and the glycosuria decreases. One diabetic woman took 40 gm. a day, fractionated, deriving astonishing benefit from it during the two years she was under observation. When the dose was reduced the improvement declined with it. He considers electricity harmful in diabetes.

35. Atropin Intoxication.—A woman mistook the bottles and gave her child a teaspoonful of an atropin mixture, ordered for instillation in the eye, and instilled in the eye a few drops of an iron syrup. In two hours the symptoms of severe atropin intoxication were pronounced. Holz injected 5 mg. of morphin, evacuated the intestinal gases through a stomach tube, and stimulated intestinal peristalsis with vinegar enemata. The soothing action of the morphin was apparent at once, and after a second injection in four hours, all danger was past. The antagonism between atropin and morphin and morphin and atropin is now established. They are not chemical antidotes in the chemical sense, but the morphin stimulates the nerves paralyzed by the atropin.

37. Treatment of Lupus by the Non-Specialist.—Drew announces that he has worked out a simple, inexpensive technic which is proving an effectual cure for lupus and can be applied by any practitioner. It consists in first freezing the lupus patch with ethyl chlorid and then rubbing into it crude hydrochloric acid saturated with free chlorine. He has thus treated 25 patients and the results, he thinks, justify the statement that any practitioner can now successfully treat lupus. He rubs the acid into the patch with a cotton-wound toothpick. In contact with tuberculous or lupous tissue, it induces immediately such an immigration of leucocytes that it is almost impossible to detect the tuberculous or lupous character of the tissue afterward. This immigration is much more extensive than has been observed hitherto under any circumstances. Even long-established cases of lupus yield to this treatment, and in three patients treated more than a year ago there has been no tendency to recurrence. The treatment is equally effectual for tuberculous abscesses and fistulas, applied under narcosis. Phototherapy was not used in any of his cases, but he thinks that a combination of the two methods might be advisable.

39. Rare Localizations of Rheumatic Processes.—Schreier has observed rheumatic processes in the periosteum of the ribs, costal arch, manubrium and long bones, which had been erroneously diagnosed by others. Also in the muscles of mastication, in the diaphragm and in the ligaments and muscles at the outlet of the pelvis. He gives the list of the 13 points for which rheumatism has a special predilection, and emphasizes

that movement is the best treatment for rheumatism. If a muscle is rheumatic and painful, use it and the rheumatic process will be aborted. Chilling after being overheated is the principal cause of rheumatism, not cold, even intense cold. Treatment of chronic rheumatism should be by exercise and movements, active and passive.

41. Pocket Mercury Manometer.—Sahli's manometer consists in a U-shaped glass tube to hold the mercury, with a bulb at each end. Above the bulb the right end of the tube bends at a right angle to connect with the rubber tube, a stopcock being interposed to prevent spilling of the mercury when the tube is disconnected. In the other end of the U tube another glass tube is inserted and stands upright, forming a vertical continuation of the left end of the U. This second tube is graduated in mm. and can measure a pressure of 260 mm. The U is fastened to a small board with standard which lies flat in the case when not in use and, when wanted, fits into a socket in the case and thus stands upright and firm. The manometer thus ready for use can be connected with the Riva-Rocci, Gaertner or Basch-Potain sphygmograph or tonometer. These instruments thus become pocket appliances for bedside use.

43. Treatment of Hyperacidity.—Ebstein reiterates his former announcements in regard to the remarkable efficacy of large oil enemata for the cure of chronic constipation, and also of hyperacidity accompanied by chronic constipation. He meets this combination very frequently, especially in young women. The total acidity in the healthy stomach averages about 50. In the cases he reports the acidity ranged from 60 to 150, and the constipation was extreme. A large oil enema every day for one to three weeks restored conditions to normal in every instance, and the patients gained rapidly in weight. Ordinary treatment of the constipation does not reach and expel old accumulations of feces lurking in out-of-the-way nooks. These lumps constantly grow in size, like a snowball, as new fecal matter arrives. In case of moderate constipation purgatives may expel them, but if this fails the subject is ready for the oil. The aim is to train the intestines to do their full functional duty, and consequently treatment should be kept up, after the constipation is relieved, until the bowels are functioning normally. If this is not accomplished the hyperacidity is liable to return sooner or later. Food rich in cellulose stimulates the intestines at first, but they soon become accustomed to this stimulus and fail to react to it. When this occurs the cellulose accumulates and clogs the intestines. They expel it occasionally in an attack of diarrhea, but the chronic constipation persists.

44. Action of Iodids in Arteriosclerosis.—It is announced from Romberg's clinic at Tübingen that the blood becomes less viscous under the influence of the administration of iodids. This fact supplies the explanation for the benefits derived from them in arteriosclerosis. The obstacles encountered by the blood are overcome by the blood's becoming less viscous. Moderate doses are enough, from .3 to .5 gm. potassium or sodium iodid three times a day, avoiding acid foods and drinks and taking alkalies with the iodids. In case the stomach re-

woman, aged 54 years, on whom a partial gastrectomy was performed, at the same time as removal of the gall bladder, both organs being cancerous, is well in the fifth year after operation. A woman, aged 50 years, is well nearly four years after the removal of the center of a cancerous hour-glass stomach, the proximal and distal healthy portions having been joined over a decalcified bone bobbin. One case of cancer of the tongue is well seven years after operation, another five years and others over three years, and in all these cases very good power of speech is retained. Of 21 operations for cancer of the bowel done in private there were 17 recoveries. Of these one is alive and well ten years after excision of the sigmoid flexure; one after four and a half years; 3 after three and a half years; 2 after three years, and one after one year. Others lived, one for three years; 3 for two years, and 5 for lesser periods and died from recurrence. One patient is living and well, with good control of the bowel, from whom Robson removed a cancer of the rectum by proctectomy twelve years ago; another after eight years, and others are well and enjoying life several years after operation. Of 12 cases of cancer of the gall bladder and liver, 10 recovered from the operation, 5 being alive at five and a half, 5 four and a half, four, and one and a quarter years after operation. 13. Quinin Injections in Malaria.—Because a number of men failed to react to quinin when administered by the mouth, Fleury resorted to hypodermic injection of acid quinin hydrochlorid of the B. P., as this preparation of quinin is readily soluble in distilled water when warm, and one minim of distilled water takes up one grain of the drug. It does not cause any irritation. Arguing on the assumption that the nearer to the spleen the injection is made the better the result, he determined to inject deep into the structures below the rib, just behind the midaxillary line on the left side, so placing the injection as near to the spleen as is consistent with safety. The parts were carefully washed and rendered as aseptic as possible. A 10-minim syringe with a fairly long and fine needle was used. The solution to be injected was prepared at the time, or not more than three days beforehand, the strength of the solution being such that the syringe when filled with 10

minims contained eight grains of quinin. The solution was always injected warm. The puncture wound was at once sealed with collodion and gauze on the needle being withdrawn. In some of the more severe cases Fleury found it necessary to repeat the injection in twenty-four hours, and in one or two cases he gave 16 grains at one injection. The results were, in practically all cases, most striking. Where no reaction followed the injection it was found subsequently that the patient was suffering from some disease other than malaria. Eighteen cases are cited illustrating the value of this method of treatment.

22. Nasal Treatment of Asthma.—An experience obtained from treating over 400 cases of various kinds of asthma is responsible for the opinion expressed by Francis that it is those asthmatics who present no gross nasal lesions and no subjective nasal symptoms, that give the best hope of affording relief by intranasal treatment. Of 402 recorded cases only 14 obtained no relief, and of these 3 suffered from polypi and 2 from such pronounced deflections of the septum that it was impossible to apply the galvanocautery without doing operations which were declined. Only eight cases that presented no gross nasal lesions, out of 346 cases treated, obtained no relief, and of these 3 were seen by Francis only three times and one four times. Of the remaining 4 cases, one was a pronounced morphinomaniac. In addition to these 14 known failures there are 17 cases where he was unable to obtain any record of the result, and a number of others that were completely relieved or greatly improved when lost sight of. From the experiences obtained in treating these cases Francis draws the following conclusions: 1. That asthma is due to reflex spasm of the bronchial tubes. 2. That the irritation may originate in the nose, as may be inferred from (a) the intimate association between hay fever and asthma; (b) the very common record of excessive sneezing at some period in the previous history of an asthmatic patient; (c) the not infrequent alteration between asthma and sneezing. 3. That asthma is not directly due to any mechanical obstruction of the nasal passages, and is not commonly caused by any gross nasal lesions. 4. That some part of the nasal apparatus has a controlling influence on the respiratory center; or there is in the nose, as it were, an agency through which the afferent impulses must pass.

[The author fails to describe his method of treatment, but it may be inferred from a report of several cases treated, that it consists of cauterization of the nasal mucous membrane with the galvanocautery.—Ed.]

- 32 Les fausses conches tubaires (tubal abortions). F. Lejars.

31. Pathologic Role of Intestinal Poisons.—The researches outlined here enlarge the conceptions of the pathogenic importance of intestinal poisons. Many of the experiences described were merely the production in animals of what is observed in the clinic. An entire series of deformities were engendered in very young animals. One phenomenon noted was that of autofunction, that is, that a substance derived from a given organ stimulates that organ to extra activity. Urine, for instance, has a diuretic action; thyroid extract stimulates the thyroid gland, and injection of substances derived from the wall of the ileum caused manifest hyperemia of the intestinal wall, exaggerated secretion and nuclear karyolysis. The experiments reported demonstrate that the alimentary canal normally contains innumerable poisons, including toxic substances, such as the diastases, which are required for the nutritive processes. They have further established that frequently a disease is due to the disorganization of its defenses rather than to the intrusion of any special pathologic agent. In therapeutics, while it is necessary to attack the enemy, yet in many cases it is important that more attention should be paid to strengthening the ramparts. The normal organic products may become morbid under certain circumstances, and some of these morbid elements are merely physiologic digestive secretions.

 40 Reduction of Obesity and Albumin in Forced Feeding.—Entfettung und Eiweißstamm. K. Bornstein. (Commenced in No. 46.) Reply. A. Albu.

33. Treatment of Diabetics.—De Renzi has been treating diabetics for thirty-four years with a green vegetable diet. He thinks that this is not merely a symptomatic but a radical cure. The carbohydrates in green vegetables are well tolerated by diabetics. The power of assimilation is exaggerated in them, contrary to what is observed in tuberculosis. An amount of calories inadequate for a healthy subject amply suffices for a diabetic. His ration is five portions of green vegetables; five portions, that is, about 300 gm. of meat, five eggs and a pint of wine, forming a total of 2,104 calories. The only drug of any use in diabetes is sodium bicarbonate. He gives it in large doses and remarks on the strange tolerance for it. It neutralizes the beta-oxibutyric acid, while it improves the general condition and the glycosuria decreases. One diabetic woman took 40 gm. a day, fractioned, deriving astonishing benefit from it during the two years she was under observation. When the dose was reduced the improvement declined with it. He considers electricity harmful in diabetes.

35. Atropin Intoxication.—A woman mistook the bottles and gave her child a teaspoonful of an atropin mixture, ordered for instillation in the eye, and instilled in the eye a few drops of an iron syrup. In two hours the symptoms of severe atropin intoxication were pronounced. Holz injected 5 mg. of morphin, evacuated the intestinal gases through a stomach tube, and stimulated intestinal peristalsis with vinegar enemata. The soothing action of the morphin was apparent at once, and after a second injection in four hours, all danger was past. The antagonism between atropin and morphin and morphin and atropin is now established. They are not chemical antidotes in the chemical sense, but the morphin stimulates the nerves paralyzed by the atropin.

37. Treatment of Lupus by the Non-Specialist.—Dreyw announces that he has worked out a simple, inexpensive technic which is proving an effectual cure for lupus and can be applied by any practitioner. It consists in first freezing the lupus patch with ethyl chlorid and then rubbing into it crude hydrochloric acid saturated with free chlorine. He has thus treated 25 patients and the results, he thinks, justify the statement that any practitioner can now successfully treat lupus. He rubs the acid into the patch with a cotton-wound toothpick. In contact with tuberculous or lupous tissue, it induces immediately such an immigration of leucocytes that it is almost impossible to detect the tuberculous or lupous character of the tissue afterward. This immigration is much more extensive than has been observed hitherto under any circumstances. Even long-established cases of lupus yield to this treatment, and in three patients treated more than a year ago there has been no tendency to recurrence. The treatment is equally effectual for tuberculous abscesses and fistulas, applied under narcosis. Phototherapy was not used in any of his cases, but he thinks that a combination of the two methods might be advisable.

39. Rare Localizations of Rheumatic Processes.—Schreiber has observed rheumatic processes in the periosteum of the ribs, costal arch, manubrium and long bones, which had been erroneously diagnosed by others. Also in the muscles of mastication, in the diaphragm and in the ligaments and muscles at the outlet of the pelvis. He gives the list of the 13 points for which rheumatism has a special predilection, and emphasizes

that movement is the best treatment for rheumatism. If a muscle is rheumatic and painful, use it and the rheumatic process will be aborted. Chilling after being overheated is the principal cause of rheumatism, not cold, even intense cold. Treatment of chronic rheumatism should be by exercise and movements, active and passive.

41. Pocket Mercury Manometer.—Sahli's manometer consists in a U-shaped glass tube to hold the mercury, with a bulb at each end. Above the bulb the right end of the tube bends at a right angle to connect with the rubber tube, a stopcock being interposed to prevent spilling of the mercury when the tube is disconnected. In the other end of the U tube another glass tube is inserted and stands upright, forming a vertical continuation of the left end of the U. This second tube is graduated in mm. and can measure a pressure of 260 mm. The U is fastened to a small board with standard which lies flat in the case when not in use and, when wanted, fits into a socket in the case and thus stands upright and firm. The manometer thus ready for use can be connected with the Riva-Rocci, Gaertner or Basch-Potain sphygmograph or tonometer. These instruments thus become pocket appliances for bedside use.

43. Treatment of Hyperacidity.—Ebstein reiterates his former announcements in regard to the remarkable efficacy of large oil enemata for the cure of chronic constipation, and also of hyperacidity accompanied by chronic constipation. He meets this combination very frequently, especially in young women. The total acidity in the healthy stomach averages about 50. In the cases he reports the acidity ranged from 60 to 150, and the constipation was extreme. A large oil enema every day for one to three weeks restored conditions to normal in every instance, and the patients gained rapidly in weight. Ordinary treatment of the constipation does not reach and expel old accumulations of feces lurking in out-of-the-way nooks. These lumps constantly grow in size, like a snowball, as new fecal matter arrives. In case of moderate constipation purgatives may expel them, but if this fails the subject is ready for the oil. The aim is to train the intestines to do their full functional duty, and consequently treatment should be kept up, after the constipation is relieved, until the bowels are functioning normally. If this is not accomplished the hyperacidity is liable to return sooner or later. Food rich in cellulose stimulates the intestines at first, but they soon become accustomed to this stimulus and fail to react to it. When this occurs the cellulose accumulates and clogs the intestines. They expel it occasionally in an attack of diarrhea, but the chronic constipation persists.

44. Action of Iodids in Arteriosclerosis.—It is announced from Romberg's clinic at Tübingen that the blood becomes less viscous under the influence of the administration of iodids. This fact supplies the explanation for the benefits derived from them in arteriosclerosis. The obstacles encountered by the blood are overcome by the blood's becoming less viscous. Moderate doses are enough, from .3 to .5 gm. potassium or sodium iodid three times a day, avoiding acid foods and drinks and taking alkalis with the iodids. In case the stomach re-

bels, iodopin can be injected subcutaneously. Two cases of cerebral arteriosclerosis are reported in which remarkable improvement was noted under potassium iodid, .9 gm. a day for thirteen days; the blood findings in regard to the viscosity kept pace with the improvement noted. Romberg thinks that iodin is liable to be directly harmful in cases of arteriosclerotic contracted kidney with cardiac asthma and in gitter accompanied by cardiac disturbances. The action of the iodine salts is strikingly favorable in incipient cerebral arteriosclerosis, in moderately severe angina pectoris, in case of moderate heart weakness with dyspnea after exertion, and occasionally in cardiac asthma and intermittent limping.

45. Diagnosis of Chronic Inflammations and Suppurations in Bones.—In this postgraduate lecture Graser reviews the data on which the diagnosis can be based, especially the differentiation of a tuberculous process and of the tardy processes resulting from otitis, tuberculosis, syphilis or actinomycosis.

46. Treatment of Sterility in Women.—Bumm believes that about two-thirds of the cases of sterility in women are due to defective development of the genitalia, the other third is acquired, generally the result of gonorrhoeal infection. The fact that nearly a fifth of the women delivered in the maternity again and again are suffering from chronic gonorrhoea shows that gonorrhoea can not be the sole cause of sterility. The internal genitalia may be infantile when the external are fully developed and the subjects robust. One or more parts of the internal genital organs may be defective while the rest are well developed. When the uterus is atrophied, the menses scanty, the prospects of a cure are very small. The only means of correcting the condition are by local application of the constant current, with gentle massage of the uterus. In 12 cases thus treated dysmenorrhoea was cured in all, menstruation was regulated, and in 5 the uterus increased in size and conception followed in 3. In 7 the uterus showed no increase in size, and the favorable effect on the menstruation was the only result obtained. He describes the various measures indicated when the uterus appears to be normal and menstruation is regular and abundant, showing that the source of the sterility must be sought elsewhere. Four out of 7 women with callous alterations in the mucosa of the cervix were cured by systematic dilatation of the latter. The prospects in case of gonorrhoea depend on the stage. If still incipient the aim should be to prevent its gaining access to the tubes. Hence all intra-uterine intervention is contraindicated. Gonorrhoeal catarrh of the cervix is tenacious and prevents conception. There is only one means of curing it, namely, to slit the os and the portio, to expose the mucosa and drain. Gonorrhoeal infection of the uterus usually heals spontaneously. Even in case the tubes are involved, six or eight weeks in bed with ice and afterward hot applications, are liable to lead to almost complete restitution, without permanent occlusion of the tubes. In case the latter has occurred, massage may prove useful, and, as a last resort, removal of the diseased adnexa on one side and freeing of the others from adhesions.

47. Artificial Abortion.—Fritsch remarks that the law in Germany condemns any one who artificially interrupts a pregnancy. No exception is made in any instance. And yet if a physician were to neglect to induce abortion when it was urgently indicated he would be liable to condemnation on account of professional neglect. The results in the latter case would be even more disastrous, as both mother and child are lost. He does not approve of inducing abortion in phthisis, although the physician's hand may be forced by threatening complications. In case of incoercible vomiting a decision is often difficult. In one case a woman vomited constantly night and day and her weight dropped from 135 to 98 pounds. After failure of every known measure abortion was induced and the patient then triumphantly informed the physician that she had starved herself and induced the vomiting artificially in order to be relieved of an unwelcome pregnancy. In another case a woman falsified a letter received from a physician, altering it into an approval of artificial abortion in her case, and the family physician acted on the supposed advice. Carcinoma of uterus or

vagina is not an indication for abortion. In case the latter is undertaken for any cause, at least three days should be devoted to it. He describes his technic and states that it is not dangerous and the loss of blood is not excessive. The completely empty uterus does not bleed, especially when large doses of ergot are given in the after-treatment.

48. Treatment of Catarrhal Gynecologic Affections.—Dührssen insists on the importance of determining the exact source of the catarrhal secretion. It may be the first sign of cancer. He adds that catarrhal affections of the uterus are not always due to gonorrhoeal, tuberculous or septic affections, but may be the result of mere hyperplasia of the uterine mucosa. This hyperplasia may be due to disturbances in the circulation, displacements, nervous influences, or be a reflex from chronic oöphoritis. By improving the circulation, restoring tone to the nervous system, etc., this hyperplasia may be restored to normal without direct intervention.

50. Deafmutism.—Bezold thinks that in rather more than half of all cases of deafmutism the condition is acquired, and generally during the first and second years of life. He has encountered a family recently in which two children were deaf mutes, as also both parents and a common great grandfather. He warns against consanguineous marriages between deaf mutes, although deaf mutes may intermarry under other circumstances. In his personal experience, 74 out of 233 cases of acquired deafmutism were consecutive to cerebrospinal meningitis. In 47 other cases there was precedent cerebral typhoid. Some brain process was noted in the antecedents of 51.9 per cent.; scarlet fever in 18 per cent. In 4 cases the deafmutism was referred to mumps; in 13 to inherited syphilis; in 6.4 per cent. to otitis media, and in 3 per cent. to a fall on the head. He found traces of hearing in all but 79 out of 276 deaf mutes examined. In cultivating this remnant of hearing a hand mirror is a great assistance. The subject watches in the mirror the lips of the person speaking directly into his ear. It is necessary that this training should be individual, not in class, especially not in a class with the totally deaf. By this individual instruction the deaf mute learns to speak with natural intonation.

52. Behavior of Red Corpuscles in Infections, Etc.—Arneht's experimental research has confirmed the existence in animals of the same phenomena as occur in man in infections, intoxications, etc., namely, a series of changes in the blood corpuscles, showing that they become used up in the course of the morbid process. The eosinophiles in the rabbit behave the same as the neutrophiles in man.

54. Intravenous Salicylic Medication and Rheumatic Affections.—Behr is delighted with the results obtained with intravenous injection of the salicylates, according to Mendel's technic. It is most effectual in acute cases of rheumatic affections, and does not induce sweating as when administered by other routes. Different individuals respond differently to the injections. He cites a few cases from his experience. In one an acute articular rheumatism was aborted with a single injection, as also a case of acute lumbago. His subjects were all tuberculous, with the exception of the gardener's lumbago. He also advocates the external application of the salicylates with massage of the part.

56. **Acute Dilatation of the Stomach.**—Hofmann reports a case which demonstrates that it is possible for acute, fatal dilatation of the stomach to occur without any previous appreciable stomach trouble. Also that in the lack of any preceding history of the case, acute dilatation of the stomach may lead to errors in diagnosis which may entail the most serious consequences. When uncontrollable vomiting develops, associated with circumscribed dullness predominating in the left half of the abdomen, the possibility of acute dilatation should be borne in mind and the stomach should be emptied with the stomach tube and rinsed. Acute dilatation of the stomach seems to occur preferably in young subjects. In the case described the patient was a young man suffering from extreme thirst, vomiting constantly dark brown matter, almost moribund. The presumptive diagnosis was partial peritonitis with encapsulated exudate, but at the immediate laparotomy the stomach was found distended until it measured 18x25x34 cm. Six quarts of fluid were evacuated, containing large undigested pieces of cucumbers. The other organs appeared to be normal. Death soon followed and postmortem examination showed that the head of the pancreas was enlarged and abnormally hard, with multiple islands of necrosis. Unsuspected atony of the stomach had probably existed for some time, and immoderate ingestion of cucumbers had induced the acute dilatation.

57. **Adhesive Plaster Dressings for Leg Ulcers.**—Philip writes from Unna's clinic to recommend the use of adhesive plaster which has a part free from the adhesive substance. This free part is placed over the ulcer. It allows the secretions to percolate through it while the adhesive substance on the rest of the plaster holds it firm. Such a dressing can be applied in a few minutes and is not changed for three to six days. It is being used extensively even for ulcers as large as 5 to 12 cm., substituting the "zinc glue dressing" formerly used.

64. **Hygiene of Tuberculosis.**—This article was presented by Hueppe at the English Hygienic Congress last July. He emphasizes the impetus given to a tuberculous process by inhalation of dust, citing the experiences at Vienna, which seems to be the "Windy City" of Europe. During the last decade the deaths from tuberculosis per 10,000 inhabitants were 46.4, in contrast to the 23.1 at Berlin and 17.7 at London. He states that as long ago as 1887 he called attention to the way in which when one disease seems to be diminishing in frequency another may vicariously increase. As the mortality from pulmonary tuberculosis has declined in Prussia, for example, the deaths from other lung affections have increased, raising the total proportion to 49 and to 50.4 for the German empire. By strengthening the resisting powers we not only combat tuberculosis, but all other lung affections. The importance of this, however, does not seem to be realized by the very short-sighted bacteriologic orthodoxy. Social hygiene should combat the three factors of tuberculosis—the predisposition, the germ and the environment—all variable quantities. The semicentennial of the pioneer Breher sanatorium assembled numbers of old patients, permanently cured for years, long before the tubercle bacillus had been discovered. He adds that he has succeeded in inducing a hypersensitive reaction in animals, so intense that fatal tuberculosis with infiltration and tubercularization of the tissues occurs in twenty hours, instead of the protracted process hitherto observed. He is confident that this will aid in the study of the various factors of immunization. He has further established that bacteria can remain latent and viable in the interior of the organism for a much longer period than hitherto admitted. Pathogenic bacteria can persist latent a long time even after specific immunization of the organism. The greatest danger for infection and acquirement of the predisposition to tuberculosis lies in the blossoming time of life.

66. **Tuberculous Spondylitis.**—Jehle reports several cases to illustrate the various clinical pictures that may be presented in this disease. It may occur in children in an unrecognized, latent form. In one case a slight deviation of the head to one side was long the only symptom.

68. **Modern Pediatrics.**—This address was read at the St. Louis Congress of Sciences last September. Escherich expatiated on the pathology of the child as it varies at different periods of growth. The first period is distinguished by the intensity of cell proliferation. The skin, mucose, organs, etc., are still undeveloped and are easily traversed by germs, so that the newborn infant is peculiarly susceptible to pyogenic and other infections. The high infant mortality is mainly due to the functional weakness of the still imperfectly developed vital organs. The rapid growth of the brain during the first year is frequently accompanied by abnormal sensitiveness of the nervous system. The skin and mucose are likewise still extremely sensitive, and the tendency to pyogenic infections still persists. From two to five the pathology is largely the result of defective ossification and of the habit of creeping on the floor and putting things in the mouth. Local and miliary tuberculosis and acute poliomyelitis are peculiarly frequent during this period of growth, and defective development of the

bels, iodine can be injected subcutaneously. Two cases of cerebral arteriosclerosis are reported in which remarkable improvement was noted under potassium iodid, .9 gm. a day for thirteen days; the blood findings in regard to the viscosity kept pace with the improvement noted. Romberg thinks that iodine is liable to be directly harmful in cases of arteriosclerotic contracted kidney with cardiac asthma and in goiter accompanied by cardiac disturbances. The action of the iodine salts is strikingly favorable in incipient cerebral arteriosclerosis, in moderately severe angina pectoris, in case of moderate heart weakness with dyspnea after exertion, and occasionally in cardiac asthma and intermittent limping.

45. Diagnosis of Chronic Inflammations and Suppurations in Bones.—In this postgraduate lecture Graser reviews the data on which the diagnosis can be based, especially the differentiation of a tuberculous process and of the tardy processes resulting from otitis, tuberculosis, syphilis or actinomycosis.

46. Treatment of Sterility in Women.—Bunn believes that about two-thirds of the cases of sterility in women are due to defective development of the genitalia, the other third is acquired, generally the result of gonorrhoeal infection. The fact that nearly a fifth of the women delivered in the maternity again and again are suffering from chronic gonorrhoea shows that gonorrhoea can not be the sole cause of sterility. The internal genitalia may be infantile when the external are fully developed and the subjects robust. One or more parts of the internal genital organs may be defective while the rest are well developed. When the uterus is atrophied, the menses scanty, the prospects of a cure are very small. The only means of correcting the condition are by local application of the constant current, with gentle massage of the uterus. In 12 cases thus treated dysmenorrhoea was cured in all, menstruation was regulated, and in 5 the uterus increased in size and conception followed in 3. In 7 the uterus showed no increase in size, and the favorable effect on the menstruation was the only result obtained. He describes the various measures indicated when the uterus appears to be normal and menstruation is regular and abundant, showing that the source of the sterility must be sought elsewhere. Four out of 7 women with callous alterations in the mucosa of the cervix were cured by systematic dilatation of the latter. The prospects in case of gonorrhoea depend on the stage. If still incipient the aim should be to prevent its gaining access to the tubes. Hence all intra-uterine intervention is contraindicated. Gonorrhoeal catarrh of the cervix is tenacious and prevents conception. There is only one means of curing it, namely, to slit the os and the portio, to expose the mucosa and drain. Gonorrhoeal infection of the uterus usually heals spontaneously. Even in case the tubes are involved, six or eight weeks in bed with ice and afterward hot applications, are liable to lead to almost complete restitution, without permanent occlusion of the tubes. In case the latter has occurred, massage may prove useful, and, as a last resort, removal of the diseased adnexa on one side and freeing of the others from adhesions.

47. Artificial Abortion.—Fritsch remarks that the law in Germany condemns any one who artificially interrupts a pregnancy. No exception is made in any instance. And yet if a physician were to neglect to induce abortion when it was urgently indicated he would be liable to condemnation on account of professional neglect. The results in the latter case would be even more disastrous, as both mother and child are lost. He does not approve of inducing abortion in pthisis, although the physician's hand may be forced by threatening complications. In case of incoercible vomiting a decision is often difficult. In one case a woman vomited constantly night and day and her weight dropped from 135 to 98 pounds. After failure of every known measure abortion was induced and the patient then triumphantly informed the physician that she had starved herself and induced the vomiting artificially in order to be relieved of an unwelcome pregnancy. In another case a woman falsified a letter received from a physician, altering it into an approval of artificial abortion in her case, and the family physician acted on the supposed advice. Carcinoma of uterus or

vagina is not an indication for abortion. In case the latter is undertaken for any cause, at least three days should be devoted to it. He describes his technic and states that it is not dangerous and the loss of blood is not excessive. The completely empty uterus does not bleed, especially when large doses of ergot are given in the after-treatment.

48. Treatment of Catarrhal Gynecologic Affections.—Dührssen insists on the importance of determining the exact source of the catarrhal secretion. It may be the first sign of cancer. He adds that catarrhal affections of the uterus are not always due to gonorrhoeal, tuberculous or septic affections, but may be the result of mere hyperplasia of the uterine mucosa. This hyperplasia may be due to disturbances in the circulation, displacements, nervous influences, or be a reflex from chronic oöphoritis. By improving the circulation, restoring tone to the nervous system, etc., this hyperplasia may be restored to normal without direct intervention.

50. Deafmutism.—Bezold thinks that in rather more than half of all cases of deafmutism the condition is acquired, and generally during the first and second years of life. He has encountered a family recently in which two children were deaf mutes, as also both parents and a common great grandfather. He warns against consanguineous marriages between deaf mutes, although deaf mutes may intermarry under other circumstances. In his personal experience, 74 out of 233 cases of acquired deafmutism were consecutive to cerebrospinal meningitis. In 47 other cases there was precedent cerebral typhoid. Some brain process was noted in the antecedents of 51.9 per cent.; scarlet fever in 18 per cent. In 4 cases the deafmutism was referred to mumps; in 13 to inherited syphilis; in 6.4 per cent. to otitis media, and in 3 per cent. to a fall on the head. He found traces of hearing in all but 79 out of 276 deaf mutes examined. In cultivating this remnant of hearing a hand mirror is a great assistance. The subject watches in the mirror the lips of the person speaking directly into his ear. It is necessary that this training should be individual, not in class, especially not in a class with the totally deaf. By this individual instruction the deaf mute learns to speak with natural intonation.

- 52. Behavior of Red Corpuscles in Infections, Etc.**—Arneht's experimental research has confirmed the existence in animals of the same phenomena as occur in man in infections, intoxications, etc., namely, a series of changes in the blood corpuscles, showing that they become used up in the course of the morbid process. The eosinophiles in the rabbit behave the same as the neutrophiles in man.

54. Intravenous Salicylic Medication and Rheumatic Affections.—Behr is delighted with the results obtained with intravenous injection of the salicylates, according to Mendel's technic. It is most effectual in acute cases of rheumatic affections, and does not induce sweating as when administered by other routes. Different individuals respond differently to the injections. He cites a few cases from his experience. In one an acute articular rheumatism was aborted with a single injection, as also a case of acute lumbago. His subjects were all tuberculous, with the exception of the gardener's lumbago. He also advocates external application of the salicylates with massage of the part.

56. **Acute Dilatation of the Stomach.**—Hofmann reports a case which demonstrates that it is possible for acute, fatal dilatation of the stomach to occur without any previous appreciable stomach trouble. Also that in the lack of any preceding history of the case, acute dilatation of the stomach may lead to errors in diagnosis which may entail the most serious consequences. When uncontrollable vomiting develops, associated with circumscribed dullness predominating in the left half of the abdomen, the possibility of acute dilatation should be borne in mind and the stomach should be emptied with the stomach tube and rinsed. Acute dilatation of the stomach seems to occur preferably in young subjects. In the case described the patient was a young man suffering from extreme thirst, vomiting constantly dark brown matter, almost moribund. The presumptive diagnosis was partial peritonitis with encapsulated exudate, but at the immediate laparotomy the stomach was found distended until it measured 18x25x34 cm. Six quarts of fluid were evacuated, containing large undigested pieces of cucumbers. The other organs appeared to be normal. Death soon followed and postmortem examination showed that the head of the pancreas was enlarged and abnormally hard, with multiple islands of necrosis. Unsuspected atony of the stomach had probably existed for some time, and immoderate ingestion of cucumbers had induced the acute dilatation.

57. **Adhesive Plaster Dressings for Leg Ulcers.**—Philip writes from Unna's clinic to recommend the use of adhesive plaster which has a part left free from the adhesive substance. This free part is placed over the ulcer. It allows the secretions to percolate through it while the adhesive substance on the rest of the plaster holds it firm. Such a dressing can be applied in a few minutes and is not changed for three to six days. It is being used extensively even for ulcers as large as 5 to 12 cm., substituting the "zinc glue dressing" formerly used.

64. **Hygiene of Tuberculosis.**—This article was presented by Hueppe at the English Hygienic Congress last July. He emphasizes the impetus given to a tuberculous process by inhalation of dust, citing the experiences at Vienna, which seems to be the "Windy City" of Europe. During the last decade the deaths from tuberculosis per 10,000 inhabitants were 46.4, in contrast to the 23.1 at Berlin and 17.7 at London. He states that as long ago as 1887 he called attention to the way in which when one disease seems to be diminishing in frequency another may vicariously increase. As the mortality from pulmonary tuberculosis has declined in Prussia, for example, the deaths from other lung affections have increased, raising the total proportion to 49 and to 50.4 for the German empire. By strengthening the resisting powers we not only combat tuberculosis, but all other lung affections. The importance of this, however, does not seem to be realized by the very short-sighted bacteriologic orthodoxy. Social hygiene should combat the three factors of tuberculosis—the predisposition, the germ and the environment—all variable quantities. The semicentennial of the pioneer Brehmer sanatorium assembled numbers of old patients, permanently cured for years, long before the tubercle bacillus had been discovered. He adds that he has succeeded in inducing a hypersensitive reaction in animals, so intense that fatal tuberculosis with infiltration and tubercularization of the tissues occurs in twenty hours, instead of the protracted process hitherto observed. He is confident that this will aid in the study of the various factors of immunization. He has further established that bacteria can remain latent and viable in the interior of the organism for a much longer period than hitherto admitted. Pathogenic bacteria can persist latent a long time even after specific immunization of the organism. The greatest danger for infection and acquirement of the predisposition to tuberculosis lies in the blossoming time of life.

66. **Tuberculous Spondylitis.**—Jehle reports several cases to illustrate the various clinical pictures that may be presented in this disease. It may occur in children in an unrecognized, latent form. In one case a slight deviation of the head to one side was long the only symptom.

68. **Modern Pediatrics.**—This address was read at the St. Louis Congress of Sciences last September. Escherich expatiated on the pathology of the child as it varies at different periods of growth. The first period is distinguished by the intensity of cell proliferation. The skin, mucosæ, organs, etc., are still undeveloped and are easily traversed by germs, so that the newborn infant is peculiarly susceptible to pyrogenic and other infections. The high infant mortality is mainly due to the functional weakness of the still imperfectly developed vital organs. The rapid growth of the brain during the first year is frequently accompanied by abnormal sensitiveness of the nervous system. The skin and mucosæ are likewise still extremely sensitive, and the tendency to pyrogenic infections still persists. From two to five the pathology is largely the result of defective ossification and of the habit of creeping on the floor and putting things in the mouth. Local and miliary tuberculosis and acute poliomyelitis are peculiarly frequent during this period of growth, and defective development of the

brain becomes apparent. From 6 to puberty the pathology is that of school life, contact infections and traumatic affections; it is possible that the vigorous play of the muscles at this age may set up inflammation of the appendix. Tuberculosis becomes less frequent, but a new, dangerous infectious disease appears, acute articular rheumatism with its sequelae. The pathology of puberty is generally restricted to females, chlorosis, hysteria, psychoses, heart affections. In other respects the morbidity is that of adults. Study of the pathology of each of these five periods of growth permits intelligent prophylaxis.

69. **Luys' Urine Segregator.**—This little instrument described in *THE JOURNAL*, xxxix, page 173, 1902, is highly commended by Lichtenstern, who is using it extensively. The operation or necropsy or the progress of the case has always corroborated its findings. It is a simple, reliable, aseptic and harmless procedure, and affords valuable information. When exact bacteriologic examination is necessary, catheterization of the ureters is sometimes preferable, as the urine in using the separator has to traverse the bladder, and the findings may be thus vitiated.

70. **Tuberculosis of Central Nervous System.**—Raubitschek states that he has been able to discover axis cylinders even in the midst of tuberculous caseous patches. This discovery has been rendered possible by the new Bielschowsky technic. It explains the almost symptomless course of the solitary tubercles in many cases of tuberculous meningitis. It also explains why even large tubercles in the brain never induce focal symptoms to the same extent as tumors of other kinds at the same points.

72. **Action of Radium on Nervous System.**—Obersteiner has been exposing 36 white mice to the action of radium bromid for from one to four days. All exhibited symptoms indicating severe disturbances in the central nervous system, convulsions, paralyses, turning around in a circle, trophic disturbances, such as panophthalmitis or necrosis of nose, ears or extremities. Histologic examination of the nerve tissue showed notable changes and also great disturbances in the circulation, with frequent hemorrhagic foci.

73. **Salzer's Radical Operation for Femoral Hernia.**—Riedl reports the results in 183 cases of femoral hernia treated by Salzer's technic since 1894. All but 46 were women. The proportion of permanent cures is 92.5 per cent. The proportion of permanent cures, after simple herniotomy, was merely 59.4 per cent. of the total 90 cases. The chief feature of the Salzer technic is that the femoral ring is closed with a flap taken from the pectineal fascia. When the detailed description was published in the *Centralbl. f. Chirurgie*, 1899, Brenner reported 91.8 per cent. permanently cured out of 63 patients thus operated on.

76. **Edema in Nephritis.**—Kövesi describes the chain of phenomena resulting in edema in nephritic subjects, and proclaims anew the importance of the dilution test as a means of determining the functional incapacity of the kidneys even before edema develops. This test was described in these columns, xxxviii, page 1338.

80. **Treatment of Hypertrophied Prostate with Incomplete Retention of Urine and with Dilatation of the Bladder.**—Nicolich's unfavorable experiences with the usual methods of treating this condition compelled him to seek a better one for the treatment of a particularly severe case in a man of 67. The bladder reached nearly to the umbilicus and there was nocturnal incontinence. He performed suprapubic cystotomy and excised the middle, obstructing lobe of the prostate through the bladder. He then packed the bladder with gauze. This stretched the walls, arrested hemorrhage from the wound in the prostate, and drained the bladder by absorbing the urine as fast as it entered. He changed the gauze daily, using less and less each time, and removed it entirely on the eighth day. The permanent catheter was not required. Within a month the patient was urinating normally, and the wound was finally closed about the fiftieth day.

82. **Blood Count in Gynecology.**—In the material at Chro-

bak's clinic leucocytosis of 15,000 almost invariably proved to be a sign of suppuraction, although the latter sometimes occurred without it. Even 11,000 to 13,000 were suggestive figures. Extruterine abortion was generally accompanied by moderate leucocytosis, and acute torsion of a cyst by considerable hyperleucocytosis.

83. **Inhalation in Therapeutics.**—Seiller's experiences were very favorable with various pulmonary affections treated by inhalation of medicated sprays. He found it possible to dispense with all other medication in many cases of bronchitis, bronchial asthma and acute laryngitis. The effect was almost magical in very severe cases of croupous pneumonia with weak heart and distressing dyspnea. The inhalations relieved the symptoms, but did not seem to affect the course of the disease. He gives the particulars of his tests with various drugs.

87. **Nervous and Mental Affections at Puberty.**—Anton has classified 3,720 cases according to age and also according to the first manifestations of the nervous or mental trouble. He further describes the special symptoms of the puberty psychoses, especially what he calls "perseveration" and "never finishing." He comments on the symptoms due to the lack of normal relations between the nervous system, the brain and the rest of the body. He defines hysteria as due to a lack of the normal relations between the dynamics of the cerebrum and the physical body. These relations differ in the child and in the adult. The disturbances of puberty are sometimes the result of injuries to the head, of intoxications from within or without, or of disturbances in the thymus gland. Treatment should aim to prevent degeneration and to promote hygiene. This hygiene should commence before birth and be particularly enforced during school life. Sexual morality is an important hygienic institution for the prevention of nervous and mental pathology. The physician should watch for the appearance of nervous irritability, for the crises in the sexual life and for the periodical fluctuations in the mental and moral spheres. Disturbances during puberty being frequently due to acquired or inherited intoxication and morbid metabolism, Anton sometimes applies energetic diaphoresis. An experience of ten years has more and more confirmed its efficacy. In the stuporous and catatonic forms, systematic saline infusion has frequently proved extremely beneficial. Some patients are cured by a change of climate, especially to the mountains. The life of the neuron axis being a great chain of simple and complex reflexes, it is possible to therapeutically influence the organism by systematically eliciting suitable reflexes. Morbid distress can often be dispelled by application of heat to the back of the neck. Massage of painful nerves in the neck will sometimes banish severe headache. Painful stomach cramps may be cured by a mild steam douche in the umbilical region. The sensation of excessive fatigue may sometimes be dispelled by merely tapping the muscle, or nervous vertigo be relieved by energetic compression of the head. The peculiar reflex connections between the nose and the genitalia are well known. All these reflex phenomena are subject to individual variations, and the physician, by these simple reflexes, is able to influence the nervous system, and should study to utilize this "reflex therapy." He should bear in mind that a family is liable to contain some person who has a nerve-racking influence. Home-sickness is another frequently overlooked factor. The task of the physician is to bring the subject into normal relations between mind and body, between psyche and environment. He should not be allowed to yield to the impulse for self-isolation, nor to the influence of stronger morbid wills, nor to companionship with degenerates. A periodical fluctuation of the entire nerve condition is frequently noticeable. Well-chosen work is an important feature of the medical training, but the final occupation should not be selected until after the crisis of puberty is past, as not until then is a final decision possible as to the definite personal equation.

88. **Radium Treatment.**—The conclusions of the research and experience at Kreibich's clinic, Graz, in respect to the therapeutic efficacy of radium, are that its destructive action on the tissues is analogous to that of electric light or sunlight, not

elective for neoplastic tissues and not affecting deep-lying tissues without superficial action. Preliminary injections of eosin do not enhance the effect. The destruction of tissue persists, long after suspension of treatment, and the defects are remarkably slow in healing. Hemangiomas are cured by the radium rays, as the coagulation induced in the blood over the exposed area spreads to the adjoining region and the thrombi become organized. Radium is inconstant in its action, and does not permit of exact dosage. On the other hand, it was found that intracutaneous injection of 1 per 1,000 eosin increased the power of absorption of the skin in respect to direct sunlight. Superficial ulcerations healed under this treatment very rapidly, but lupus did not seem to be affected.

92. Experimental Study of Obstipation.—Glæssner resected a long piece of the intestine in dogs, reversed it and sutured it again in place. The feces were not passed along in this stretch of the gut, and severe obstipation was the result. The nitrogenous elements in the urine increased progressively. The ammonia also increased after a defecation, sometimes to double the previous proportion, but sank again to normal after the next, commencing to rise again at once thereafter.

95. Spinal Analgesia.—This article describes the experiences with spinal analgesia in 232 cases at Moseitig's clinic, Vienna. It was found efficient for all operations in the groin, on the genital and urinary organs and on the legs, and can be used without hesitation for all subjects over 16. It is no more dangerous than inhalation anesthesia, while it does not change the parts like the infiltration technic. It will be found a most valuable substitute for general narcosis for debilitated and elderly subjects. The only proviso is that no drug so toxic as cocaine should be used. From 1 to 2 c.c. of a 3 per cent. solution of beta eucain in distilled water were injected into the dural sac after from 3 to 5 c.c. of the cerebrospinal fluid had been allowed to escape. The analgesia lasted from twenty-five minutes to an hour and forty minutes. It was so complete in 170 cases that there was no sensation except that of pressure during the incisions and traction on the soft parts and nerves. No by-effects were observed in 79.5 per cent. of the subjects. When the operation was undertaken in silence without asking the subject if he felt nauseated, etc., it proceeded without disturbances, or if any occurred they were slight and transient. The toxic symptoms indicated bulbar irritation, and in 5 cases there was dyspnea, dilatation of the pupils, cold sweat and small pulse, with tremor of the muscles in 2. A few drops of chloroform soon dispelled these phenomena. They occurred exclusively in persons under 16 or in hard drinkers. The recovery was so rapid that the operation did not have to be interrupted. The article concludes with the statement that the greater the experience with spinal analgesia the more unconditional the appreciation.

98. Vaccination Under Red Light.—Rösler refers to Goldmann's recent communication in regard to the favorable result of vaccination under red light. He then reports still more favorable experiences with the red light. A group of 250 soldiers were vaccinated as usual by daylight. The spot was then dressed with four layers of gauze dyed red with cochineal, covered with a protecting shield of red gelatin, and the whole fastened with a single thickness of cotton also dyed red. Another group of 42 men were vaccinated and the spot was protected with the same shields and outer dressing without the gauze inside. Another group of about 250 men were vaccinated at the same time and no dressings applied. The results demonstrate in his opinion that the pustule runs a typical course under the red light, but that it is much milder than usual and all complications are avoided. He was encouraged by the results observed to treat two severe horse bites on the arm by exposure to red light. A red gelatin shield was placed over the wound and left exposed when the arm was dressed. The patients lay in beds near a window, the red window in their dressings turned to the light and exposed to direct sunlight for an hour daily. The wounds healed remarkably quickly. It seemed as if the red light checked the growth and activity of pyogenic cocci.

99. Utero-Ovarian Sympathectomy.—Ruggi attributes to the pelvic plexus many of the disturbances in the gynecologic sphere, trophic, motor and sensory. This plexus transmits the peripheral stimuli to the brain, and if this transmission can be interrupted, then the severe pains in many instances can be abolished. Partial resection of the pelvic plexus is indicated, in his opinion, when severe pains persist after surgical intervention has proved ineffectual to cure, or the organs are apparently entirely or nearly sound. Up to 1900 he had performed this operation, on one or both sides, on 9 women who had previously submitted to various mutilating gynecologic operations without relief from their severe pains in the pelvic viscera. Cavazzani has also performed the operation five times, and Foschini here reports 3 additional cases. The results in every instance have been the permanent relief of patients from their sufferings, as, he remarks, was to be expected from the anatomy, physiology and pathology of the parts. In his 3 patients a constant symptom was the exacerbation of the pain when the abdomen was palpated along the psoas muscle. In one other case on record the pain here was spontaneous and severe. He is convinced that this operation of sympathectomy should supplant ovariectomy in many cases in which the latter is supposed to be indicated. Experimental research has rendered it probable that the genital function is gradually lost after bilateral resection of the pelvic plexus, but the pain—which frequently persists after ovariectomy—is cured, and the patient is spared useless mutilation of organs. His patients were 18, 25 and 44 years old. The first patient presented pelvic neuralgia, the viscera normal. The second—a hysteric epileptic—had been treated by ovariectomy and later by hysterectomy, but the pains persisted until relief was obtained by bilateral resection of the plexus. Examination was negative in the third patient, but the attacks of pain in the pelvis recurred with progressive intensity, and were completely conquered by bilateral resection of the plexus.

110. Treatment of Epilepsy with Brain Substance.—Soleri has been using in 7 cases of epilepsy and in a larger number of neurasthenics an oily extract of brain substance (cephalopin), as a therapeutic measure. He found that it had an unmistakable and effectual action in reducing the nervous excitability, even after failure of other extracts of brain substance. There were never any symptoms of intolerance; all the patients felt better and increased in weight. He injected from 1 to 2 or even 5 c.c. every second day, for nearly two months. The extract is prepared with oil; it is stable and free from albumin to coagulate while it contains a large proportion of lecithin. It is prepared at Maragliano's Institute for Infectious Diseases at Genoa, and is standardized with 1,000 anticonvulsion units per c.c.

brain becomes apparent. From 6 to puberty the pathology is that of school life, contact infections and traumatic affections; it is possible that the vigorous play of the muscles at this age may set up inflammation of the appendix. Tuberculosis becomes less frequent, but a new, dangerous infectious disease appears, acute articular rheumatism with its sequelae. The pathology of puberty is generally restricted to females, chlorosis, hysteria, psychoses, heart affections. In other respects the morbidity is that of adults. Study of the pathology of each of these five periods of growth permits intelligent prophylaxis.

69. **Luy's Urine Segregator.**—This little instrument described in *THE JOURNAL*, xxxix, page 173, 1902, is highly commended by Lichtenstern, who is using it extensively. The operation or necropsy or the progress of the case has always corroborated its findings. It is a simple, reliable, aseptic and harmless procedure, and affords valuable information. When exact bacteriologic examination is necessary, catheterization of the ureters is sometimes preferable, as the urine in using the separator has to traverse the bladder, and the findings may be thus vitiated.

70. **Tuberculosis of Central Nervous System.**—Raubitschek states that he has been able to discover axis cylinders even in the midst of tuberculous caseous patches. This discovery has been rendered possible by the new Bielschowsky technic. It explains the almost symptomless course of the solitary tubercles in many cases of tuberculous meningitis. It also explains why even large tubercles in the brain never induce focal symptoms to the same extent as tumors of other kinds at the same points.

72. **Action of Radium on Nervous System.**—Obersteiner has been exposing 36 white mice to the action of radium bromid for from one to four days. All exhibited symptoms indicating severe disturbances in the central nervous system, convulsions, paralyses, turning around in a circle, trophic disturbances, such as panophthalmitis or necrosis of nose, ears or extremities. Histologic examination of the nerve tissue showed notable changes and also great disturbances in the circulation, with frequent hemorrhagic foci.

73. **Salzer's Radical Operation for Femoral Hernia.**—Riedl reports the results in 188 cases of femoral hernia treated by Salzer's technic since 1894. All but 46 were women. The proportion of permanent cures is 92.5 per cent. The proportion of permanent cures, after simple herniotomy, was merely 59.4 per cent. of the total 90 cases. The chief feature of the Salzer technic is that the femoral ring is closed with a flap taken from the pectineal fascia. When the detailed description was published in the *Centralbl. f. Chirurgie*, 1899, Brenner reported 91.8 per cent. permanently cured out of 63 patients thus operated on.

76. **Edema in Nephritis.**—Kövesi describes the chain of phenomena resulting in edema in nephritic subjects, and proclaims anew the importance of the dilution test as a means of determining the functional incapacity of the kidneys even before edema develops. This test was described in these columns, xxxviii, page 1338.

80. **Treatment of Hypertrophied Prostate with Incomplete Retention of Urine and with Dilatation of the Bladder.**—Nicolich's unfavorable experiences with the usual methods of treating this condition compelled him to seek a better one for the treatment of a particularly severe case in a man of 67. The bladder reached nearly to the umbilicus and there was nocturnal incontinence. He performed suprapubic cystotomy and excised the middle, obstructing lobe of the prostate through the bladder. He then packed the bladder with gauze. This stretched the walls, arrested hemorrhage from the wound in the prostate, and drained the bladder by absorbing the urine as fast as it entered. He changed the gauze daily, using less and less each time, and removed it entirely on the eighth day. The permanent catheter was not required. Within a month the patient was urinating normally, and the wound was finally closed about the fiftieth day.

82. **Blood Count in Gynecology.**—In the material at Chro-

bak's clinic leucocytosis of 15,000 almost invariably proved to be a sign of suppuration, although the latter sometimes occurred without it. Even 11,000 to 15,000 were suggestive figures. Extruterine abortion was generally accompanied by moderate leucocytosis, and acute torsion of a cyst by considerable hyperleucocytosis.

83. **Inhalation in Therapeutics.**—Seiller's experiences were very favorable with various pulmonary affections treated by inhalation of medicated sprays. He found it possible to dispense with all other medication in many cases of bronchitis, bronchial asthma and acute laryngitis. The effect was almost magical in very severe cases of croupous pneumonia with weak heart and distressing dyspnea. The inhalations relieved the symptoms, but did not seem to affect the course of the disease. He gives the particulars of his tests with various drugs.

87. **Nervous and Mental Affections at Puberty.**—Anton has classified 3,720 cases according to age and also according to the first manifestations of the nervous or mental trouble. He further describes the special symptoms of the puberty psychoses, especially what he calls "perseveration" and "never finishing." He comments on the symptoms due to the lack of normal relations between the nervous system, the brain and the rest of the body. He defines hysteria as due to a lack of the normal relations between the dynamics of the cerebrum and the physical body. These relations differ in the child and in the adult. The disturbances of puberty are sometimes the result of injuries to the head, of intoxications from within or without, or of disturbances in the thymus gland. Treatment should aim to prevent degeneration and to promote hygiene. This hygiene should commence before birth and be particularly enforced during school life. Sexual morality is an important hygienic institution for the prevention of nervous and mental pathology. The physician should watch for the appearance of nervous irritability, for the crises in the sexual life and for the periodical fluctuations in the mental and moral spheres. Disturbances during puberty being frequently due to acquired or inherited intoxication and morbid metabolism, Anton sometimes applies energetic diaphoresis. An experience of ten years has more and more confirmed its efficacy. In the stuporous and catatonic forms, systematic saline infusion has frequently proved extremely beneficial. Some patients are cured by a change of climate, especially to the mountains. The life of the neuron axis being a great chain of simple and complex reflexes, it is possible to therapeutically influence the organism by systematically eliciting suitable reflexes. Morbid distress can often be dispelled by application of heat to the back of the neck. Massage of painful nerves in the neck will sometimes banish severe headache. Painful stomach cramps may be cured by a mild steam douche in the umbilical region. The sensation of excessive fatigue may sometimes be dispelled by merely tapping the muscle, or nervous vertigo be relieved by energetic compression of the head. The peculiar reflex connections between the nose and the genitalia are well known. All these reflex phenomena are subject to individual variations, and the physician, by these simple reflexes, is able to influence the nervous system, and should study to utilize this "reflex therapy." He should bear in mind that a family is liable to contain some person who has a nerve-racking influence. Home-sickness is another frequently overlooked factor. The task of the physician is to bring the subject into normal relations between mind and body, between psyche and environment. He should not be allowed to yield to the impulse for self-isolation, nor to the influence of stronger morbid wills, nor to companionship with degenerates. A periodical fluctuation of the entire nerve condition is frequently noticeable. Well-chosen work is an important feature of the medical training, but the final occupation should not be selected until after the crisis of puberty is past, as not until then is a final decision possible as to the definite personal equation.

88. **Radium Treatment.**—The conclusions of the research and experience at Kreibich's clinic, Graz, in respect to the therapeutic efficacy of radium, are that its destructive action on the tissues is analogous to that of electric light or sunlight, not

elective for neoplastic tissues and not affecting deep-lying tissues without superficial action. Preliminary injections of eosin do not enhance the effect. The destruction of tissue persists, long after suspension of treatment, and the defects are remarkably slow in healing. Hemangiomas are cured by the radium rays, as the coagulation induced in the blood over the exposed area spreads to the adjoining region and the thrombi become organized. Radium is inconstant in its action, and does not permit of exact dosage. On the other hand, it was found that intracutaneous injection of 1 per 1,000 eosin increased the power of absorption of the skin in respect to direct sunlight. Superficial ulcerations healed under this treatment very rapidly, but lupus did not seem to be affected.

92. **Experimental Study of Obstipation.**—Glaessner resented a long piece of the intestine in dogs, reversed it and sutured it again in place. The feces were not passed along in this stretch of the gut, and severe obstipation was the result. The nitrogenous elements in the urine increased progressively. The ammonia also increased after a defecation, sometimes to double the previous proportion, but sank again to normal after the next, commencing to rise again at once thereafter.

95. **Spinal Analgesia.**—This article describes the experiences with spinal analgesia in 232 cases at Mostetj's clinic, Vienna. It was found efficient for all operations in the groin, on the genital and urinary organs and on the legs, and can be used without hesitation for all subjects over 16. It is no more dangerous than inhalation anesthesia, while it does not change the parts like the infiltration technic. It will be found a most valuable substitute for general narcosis for debilitated and elderly subjects. The only proviso is that no drug so toxic as cocaine should be used. From 1 to 2 c.c. of a 3 per cent. solution of beta eucain in distilled water were injected into the dural sac after from 3 to 5 c.c. of the cerebrospinal fluid had been allowed to escape. The analgesia lasted from twenty-five minutes to an hour and forty minutes. It was so complete in 170 cases that there was no sensation except that of pressure during the incisions and traction on the soft parts and nerves. No by-effects were observed in 79.5 per cent. of the subjects. When the operation was undertaken in silence without asking the subject if he felt nauseated, etc., it proceeded without disturbances, or if any occurred they were slight and transient. The toxic symptoms indicated bulbar irritation, and in 5 cases there was dyspnea, dilatation of the pupils, cold sweat and small pulse, with tremor of the muscles in 2. A few drops of chloroform soon dispelled these phenomena. They occurred exclusively in persons under 16 or in hard drinkers. The recovery was so rapid that the operation did not have to be interrupted. The article concludes with the statement that the greater the experience with spinal analgesia the more unconditional the appreciation.

98. **Vaccination Under Red Light.**—Rösler refers to Goldmann's recent communication in regard to the favorable result of vaccination under red light. He then reports still more favorable experiences with the red light. A group of 250 soldiers were vaccinated as usual by daylight. The spot was then dressed with four layers of gauze dyed red with cochineal, covered with a protecting shield of red gelatin, and the whole fastened with a single thickness of cotton also dyed red. Another group of 42 men were vaccinated and the spot was protected with the same shields and outer dressing without the gauze inside. Another group of about 250 men were vaccinated at the same time and no dressings applied. The results demonstrate in his opinion that the pustule runs a typical course under the red light, but that it is much milder than usual and all complications are avoided. He was encouraged by the results observed to treat two severe horse bites on the arm by exposure to red light. A red gelatin shield was placed over the wound and left exposed when the arm was dressed. The patients lay in beds near a window, the red window in their dressings turned to the light and exposed to direct sunlight for an hour daily. The wounds healed remarkably quickly. It seemed as if the red light checked the growth and activity of pyogenic cocci.

99. **Utero-Ovarian Sympathectomy.**—Ruggi attributes to the pelvic plexus many of the disturbances in the gynecologic sphere, trophic, motor and sensory. This plexus transmits the peripheral stimuli to the brain, and if this transmission can be interrupted, then the severe pains in many instances can be abolished. Partial resection of the pelvic plexus is indicated, in his opinion, when severe pains persist after surgical intervention has proved ineffectual to cure, or the organs are apparently entirely or nearly sound. Up to 1900 he had performed this operation, on one or both sides, on 9 women who had previously submitted to various mutilating gynecologic operations without relief from their severe pains in the pelvic viscera. Cavazzani has also performed the operation five times, and Foschini here reports 3 additional cases. The results in every instance have been the permanent relief of patients from their sufferings, as, he remarks, was to be expected from the anatomy, physiology and pathology of the parts. In his 3 patients a constant symptom was the exacerbation of the pain when the abdomen was palpated along the psoas muscle. In one other case on record the pain here was spontaneous and severe. He is convinced that this operation of sympathectomy should supplant ovariectomy in many cases in which the latter is supposed to be indicated. Experimental research has rendered it probable that the genital function is gradually lost after bilateral resection of the pelvic plexus, but the pain—which frequently persists after ovariectomy—is cured, and the patient is spared useless mutilation of organs. His patients were 18, 25 and 44 years old. The first patient presented pelvic neuralgia, the viscera normal. The second—a hysteric epileptic—had been treated by ovariectomy and later by hysterectomy, but the pains persisted until relief was obtained by bilateral resection of the plexus. Examination was negative in the third patient, but the attacks of pain in the pelvis recurred with progressive intensity, and were completely conquered by bilateral resection of the plexus.

110. **Treatment of Epilepsy with Brain Substance.**—Soleri has been using in 7 cases of epilepsy and in a larger number of neurasthenics an oily extract of brain substance (cephalopin), as a therapeutic measure. He found that it had an unmistakable and effectual action in reducing the nervous excitability, even after failure of other extracts of brain substance. There were never any symptoms of intolerance; all the patients felt better and increased in weight. He injected from 1 to 2 or even 5 c.c. every second day, for nearly two months. The extract is prepared with oil; it is stable and free from albumin to coagulate while it contains a large proportion of lecithin. It is prepared at Maragliano's Institute for Infectious Diseases at Genoa, and is standardized with 1,000 anticonvulsion units per c.c.

Address.

ANTOINE FRANCOIS SAUGRAIN (DE VIGNI).

"THE FIRST SCIENTIST OF THE MISSISSIPPI VALLEY."*

N. P. DANDRIDGE, M.D.

CINCINNATI, OHIO.

In presenting my address, which custom has made one of the duties of the presiding officer, I shall depart somewhat from the practice of my predecessors, and instead of bringing before you some medical question based on my own work, or attempting a discussion of some topic now of active interest, I shall take you to the backwoods and try and interest you in the life and exploits of a pioneer physician, a life whose fine moral and intellectual fiber, I venture to assert, has much that is worthy of our consideration and respect.

I shall not be able to point out any such monumental work as was left behind by Daniel Drake in his "Diseases of the Mississippi Valley." Indeed, I have little to tell that is strictly medical or surgical history, but I hope to depict one of high scientific attainments and true culture with all the elements of character which become the physician and the man. Our wandering course will be a long one, and you will find yourself far afield as we cross over mountains and through the wilderness, and float down rivers whose banks conceal the danger of ever-hostile Indians, until at last our winding way will lead to the small French village of St. Louis, under its last French Governor, Zenon Trudeau. The courage of our hero in danger, his resourcefulness in difficulties, and his unflinching amiability and sweetness of character made him beloved by all who came in contact with him—and makes him a worthy predecessor of the great profession of this great city—a worthy son of France, the great country which gave him birth, and certainly entitles him to a place as *bon camarade* among the fellows of the American Surgical Association.

My information on the subject of my sketch has been largely obtained from a paper by Eugene Bliss of Cincinnati, presented to the American Antiquarian Society, and from the collection of papers relating to the settlement of Gallipolis, collected and arranged by John M. Newton, and now in the Cincinnati Historical Society, and a pamphlet on the "First Scientist of the Mississippi Valley," by W. V. Byars. From all of these I have freely drawn.

Antoine François Saugrain (de Vigni) was born in Paris Feb. 17, 1763. He came from a long line of "librarians, booksellers and printers," who, as far back as Charles IX and Henry of Navarre had served the royal family of France. The de Vigni, which was but occasionally used, seems to be explained from the cus-

tom at that time in vogue in Paris of sending children to nurse into the country, and on their return they were known by the name of the village in which they had lived. Little is known of his early life, but it is evident he was given a thorough general scientific education, and that he studied "chemistry, mineralogy and physic." His general scientific knowledge stood him in good stead in the wilderness and he was ever ready to put it to the most practical use in his daily wants. His knowledge of mineralogy made his advice often called for in the development of the mines in the Ohio Valley. He supplied himself with ink from a natural chalybeate water and an infusion of white oak bark, and when in need of a fire lighted it from a lens made by two watch crystals with clear water between. Wherever he found himself he established furnaces and chemical laboratories and had his electric batteries, and in time of leisure he made thermometers and barometers, which he readily sold. He was most observant of the resources of the country and its inhabitants, and has left acute comments on both.

He probably never practiced in Paris, for about the time his studies were completed his family, who were royalists, were compelled to flee across the Rhine, and for a time he did not know their whereabouts. Learning of a party of French coming to America, he joined them, and seems to have entered the service of the King of Spain, for we soon find him engaged in mineralogic investigations in Mexico, the friend of the viceroy, Don Galvez. This viceroy Humboldt calls "the enlightened Galvez." After his death Saugrain returned to France, but was never afterward able to shake himself free from the attraction which the life in the wilds possessed for him. In 1787 we learn from Brissot de Warville that Saugrain again came to America with a M. Piquet, a French philosopher, fully imbued with the ideas of Rousseau then in vogue on the "Rights of Man," and who believed in the "primitive innocence and goodness of the children of the forest." The two dined the night before they left Paris with Dr. Guillotin, who had married Saugrain's sister, and who, at that time, was undisturbed by his future celebrity. Piquet was a botanist, and Kentucky and the valley of the Ohio were their objective points for the purpose of studying the flora and probably also to ascertain the feasibility for a French colony. They reached Fort Pitt, too late to go down the river, and "established themselves in an abandoned cabin a few miles away." They suffered greatly from the cold and lived principally on "venison and potatoes." In spite of their hardships they busied themselves with their scientific work. Saugrain examined mines in the neighborhood and found iron, lead, copper and silver. With his hydrostatic scales he determined the weight and density of the various kinds of wood and tested their capacity for the production of potash: cornstalk he

* President's address delivered at the meeting of the American Surgical Association, at St. Louis.

found the richest. March 19, 1788, the two set out down the Ohio. Piquet did not find that his humanitarian views of the Indian worked out in actual practice, for they soon killed and scalped him. Dr. Saugrain has left a record of the trip.¹

My Friends:—The ice having caught us at Pittsburg, you know that we were obliged to remain there the space of four months, and that in the end, the Ohio having opened, we saw with regret our first boat depart, carried away by the ice. We had another one made, in which we embarked to the number of four, to wit: M. Pique and Raguet, French; Pierce, American, and myself. We set out from Pittsburg March 19, 1788. We stopped at Wheeling (Woulige) and at Muskingum, and at Limestone (now Maysville), a place where a fine town should be built; in short, we continued our voyage without accident until March 24, always admiring both banks of the Ohio, which in places are magnificent. But on March 24, at half-past 4 in the afternoon nearly, being opposite the Big Miami, as the wind had thrown us a little on the shore of the Ohio, on the Pennsylvania side, and while we were preparing to put ourselves rather more out in the current to go faster, M. Pique called my attention to a flatboat which was on the same bank. Alas! He was far from thinking this same boat would cause his death. As we were getting away from the shore mentioned

DR. ANTOINE FRANCOIS SAUGRAIN.
(From an oil portrait, painted from life.)

to gain the stream, we heard ourselves called by the Indians, who at the same time fired on us. At the first shot they killed my mare, and in struggling the poor creature pushed against M. Pique's which gave me a kick in the belly, throwing me flat, and with another she would certainly have killed me had she struck me, but she only grazed the skin on my forehead. As the mare had thrown me flat the Indians thought surely they had killed me. I conjecture that from the shore they fired nearly twenty times, but none of their shots hit us, except that M. Pique was just grazed in the head, as I thought, but as he did not complain I believed it a matter of no consequence.

To get beyond the range of the balls we all four took to the oars, but we saw that the Indians all went aboard the flatboat we had seen near the shore and in front of which they had put some planking to prevent their being seen, and in this same planking they made holes to put their guns through so that they might fire on us without danger of being killed themselves. I left my oar to see if our guns were in order. Of the three we had I found two loaded; one of these was mine, the other M. Raguet's carbine. I hastened to load the third, as well as to prime two pistols belonging to the same M. Raguet.

During this time the Indians advanced on us and as they did not fire, one of us, I know not which one, proposed to raise a white handkerchief in sign of peace, judging it would be better to be a prisoner among the Indians than to be killed. They got nearer and nearer to us, even with some sign of friendship, and as they were near us, one of them was on the point of entering our boat, and as this unhappy man held a knife in his hand, I judged, with some reason, I believe, that he had no praiseworthy intention. I seized a pistol and sent two balls into his stomach. The pistol was no sooner fired than all the Indians, who were then standing, threw themselves flat in the boat and in this position fired on us. Then M. Raguet took his carbine and fired in turn on them and I did as much. Raguet fired three or four shots, but unluckily in his haste he put the ball before the powder, which a little retarded the quickness of the firing, and when, having reloaded his carbine, he wished to fire, not well seeing how to aim, he put his arm outside the boat, and it was at once broken by a gunshot fired by the Indians. (In a note at this point Dr. Saugrain adds: Some one at the Falls of the Ohio said that I did wrong to fire; I think so too, for in the boats which have been taken before and since no one has been killed, inasmuch as no one made resistance.) I put my hand outside to hold my gun better and to aim better and had a finger of my left hand broken. At the first shots that the Indians fired from their boat into ours the American who was with us jumped out and swam to land. This did us much harm, for then the Indians, who perhaps had left us, fired much more. M. Raguet had his arm broken and I my finger. I think I fired but once afterward. As for M. Pique, he did not wish to fire, thinking, I believe, that the Indians would do him no harm if they took him prisoner, and instead of aiding us in our defense, he followed the example of Mr. Pierce. As there were left only M. Raguet and myself, we both threw ourselves into the water. As he had his arm broken and did not know how to swim, I believe he was drowned, preferring, as he told me, to be drowned to being scalped by the Indians. I had not yet reached the shore when I saw M. Pique and two Indians waiting for me, and I had no sooner reached the shore than they took me and bound my hands behind my back with some girths which serve them to hold up their blankets. They had no sooner finished tying me than I saw one of the two who held me go to M. Pique, throw him on the ground, and after having opened his coat and pulled open his shirt, give him four stabs with a knife on one side, and one on the other, and he scalped him. He put his scalp into a pocket-book which M. Pique had in his pocket. I leave you to think, my friends, what a spectacle for me! I expected for myself, as you well imagine, a like fate. But instead of killing me they made me run to overtake the boat, which, although it was headed toward the shore, had drifted nearly a quarter of a mile from the place where we swam ashore before they could come up with it. When we got opposite our boat one of the two went into the water and wished to take me by the hair to lead me, for the boat could not come near the shore on account of the trees which prevented it. As for me, such cruel fear seized me, seeing that he had not killed me and that he wished to cross the Ohio, I believed that he wished to burn me on the other side, and I made an effort violent enough to break the straps that held me bound and threw myself into the water. I swam with such force that he did not wish to run the risk of following me, and he did well, for my plan was, if they came after me, to seize one of them and drown with him.

Those who had jumped from their boat—swimming—to take us on shore, got into the one they had just taken from us and began to cross the Ohio. As for me, I held onto a tree, with my arms about it. Those Indians who were in the boat fired at me and wounded me in the neck. When I saw the boat mid-way of the Ohio, I regained the shore and when I went to see if M. Pique were dead, I perceived Mr. Pierce, who had concealed himself in the ravine. He came to me and we went to see M. Pique, who was dead, and in turning him over I saw that the Indians had not taken his watch. I took it and likewise a knife and two dollars he had in his pocket. Mr. Pierce

¹ Translation by Eugene Bliss of the Relation of a Trip Down the Ohio.

cut a piece of his coat to cover his feet. I had not the same forethought, of which I repented. We left M. Pique there and began to walk. It was very cold and I had nothing on me but a shirt and a pair of large breeches. I lost my shoes while swimming. At first we went a little away from the bank of the Ohio through fear of being seen by the Indians who were on the other side. After having made about four or five miles night began to come on. I was very tired. I lost much blood by the wound I had in my neck, and as we found ourselves in a good place to sleep, there being much dead grass there, we lay down, and Mr. Pierce had the kindness to pull up a quantity of the dead grass and we covered ourselves with it. I slept nearly three hours and my companion awoke me. We went back to the bank of the Ohio and he began to wish to make a raft. But he never could have succeeded, seeing that he was alone, for my neck was so swollen that I could not move my right arm, and my left hand was much swollen. Seeing that it was useless to work, for the vines of which he made use to fasten the pieces of timber all broke, we abandoned the attempt at a raft. We began to walk and walked a great part of the night. At last about 4 o'clock we lay down again. A fallen tree was the place Mr. Pierce chose. He lay down under it and I got as near him as possible. It came on to snow, and as my feet did not come under the tree and as it rained a little, I found my feet frozen when I awoke. I rubbed them a long time with snow, but uselessly. They caused me no pain, so we made a good day's march, always following the bank of the Ohio in the hope we might see some boat, which, going down to the Falls, would take us in. We were obliged to cross three or four creeks. The number of deer, pheasants and turkeys we saw is quite inconceivable. We also saw four or five troops of buffaloes, which came so near us that with a pistol I could have killed some. Night came on and we lay down. It still rained, little it is true, but that not the less caused much pain to my feet. The next day I could hardly walk, and my companion, who was impatient, left me often very far behind him. But I found a way of making him come. It was to sit down, and he, after having waited for me some time, thinking that something had happened to me, retraced his steps, and seeing my feet as black as coal and that I could not walk, he gave me his arm and cut a piece of his shirt to wrap up my hand. My neck was extraordinarily swelled, but it did not bleed any more. I chewed up a sort of agaric, which I put on it. We kept on walking, but very slowly. I saw a stinking beast, skunk (*bete puante*), and Mr. Pierce had no sooner seen it than he ran after it and with a blow with a stick he killed it. After skinning it he wished to eat some of it, but he could not. As for me, I cut off some little bits and I swallowed them like pills. This did me little good. I assure you. We could have cooked it had it not been for fear that the Indians would come to us, seeing the smoke. I could have made a fire without much trouble. The sun shone and I had two watches, the crystals of which would have made a lens by filling them with water and fitting them together. At last, after making so excellent a repast and a considerable halt, I took the rest of the stinking beast and put it in my shirt to carry it. About 5 o'clock in the evening we came to a house which had been abandoned. I was told (afterward) it was fifteen miles from the Big Miami, the place where we were attacked.

When we had rested half an hour a fresh desire seized us to make a raft, and we put into the water everything we could, and while my companion did the heavy business, as carrying the doors of the house, some fence or poteaux de barriere, etc. I cut into pieces my companion's jacket, which was made of buckskin, for that is very much used in America to make cords, and I cut the seat from my big breeches to make some socks to cover my feet. The whole affair went on very well. The raft was made and we were going aboard when from the other side of the river Indians fired at us. This did not alarm us much, considering the distance, but what did make us afraid, and especially me, was the Indians who replied from the side where we were to the cries of those on the other side. Then I took to my heels, and never in my life, I think, did I make so good

use of them. My feet no longer made me suffer; in short, I felt nothing. My companion, however, was still more alert than I, and in two minutes I lost sight of him. At last I was obliged to stop because in running a piece of stick ran into my foot. My companion in misfortune retraced his steps, and as night protected us from the Indians, we lay down, and it was one of the worst nights I have passed in my life. I could not sleep, and at each moment I thought I saw Indians, and the march the next day was still worse, for although wide awake I saw Indians behind all the trees; each bit of wood was a gun, and I believe to alarm us more, all the deer had conspired. I had a great need of food—much exercise, involuntary baths, the quantity of blood lost—I ate some stinking beast, "polecat." Before sunrise we were on the march; for the time I walked more on my hands than my feet. I drew myself along, I know not how. We came to a creek, which I believe is a few miles from Big Bone Creek, and there, for the first time, Mr. Pierce and I had a little dispute. The question was about crossing a large creek. Mr. Pierce wished to go up to cross it; I was strongly for swimming across it. Seeing that he wished absolutely to make the grand detour and leave the bank of the Ohio, I did as I always did. A violent part seemed to me the best. (How much he has since thanked me for it.) To put an end to the dispute I went into the water. He had his back turned and could not oppose my plan. I was already in the water before he was aware of it. Thus I crossed fortunately and he did not delay to follow me. It was about 11 o'clock in the morning. We stripped ourselves stark naked and dried our clothes. The bath did us good. When we were dressed we continued our route.

Nothing unusual happened to us until we got to another creek, which was nearly four miles from the last one we just crossed. As we were going to swim across it as we did the other, Mr. Pierce saw two boats coming down the Ohio. He called to them, but the boats kept off, believing we were Indians, but seeing our white shirts and our breeches, they determined to come to us. For this purpose they put all the men into one of the boats and left the other with the women and just one man to steer it. This took quite a long time, during which the current kept carrying them on. This time I did not have to beg Mr. Pierce to cross this creek, as well as two or three others which followed it. As for me, I followed him, but much more slowly. At last we swam out to join them, for they could not approach the shore on account of the trees which prevented them. It was surprising to me, arrived on board, to see all the people of the boat that received us with carabines in hand. But the fear of being surprised by the Indians obliged them to be on their guard. Arrived on board, they undressed me, warmed some whisky and rubbed all my body, which did me much good. I drank a little of it and ate a little bread, which seemed to me good. They dressed my neck, which was much swelled. As for my hand, they did nothing for it. They waited until we should be at the Falls to cut off the finger—which was not done, thanks to myself. My feet were in a very bad condition and gave me much pain.

Two days' sailing were enough to bring us to the Falls, where I passed the night of March 29. The next day, which was Sunday, I crossed the Ohio to go to a fort situate opposite Louisville, where I was most cordially received. I was introduced by Colonel Blaine,² and Major Willis gave me a reception for which I can not be too grateful. In short, I stayed in the fort with all possible comfort from March 30 to May 11. For three weeks I could not move, and every day they had to take out some portion of my foot which began to putrefy, but with the care of the fort's surgeon and with patience, all has been well and my foot is quite cured except the place where the piece of stick went in when I was running away in the woods. Thus far I have been unable to cure it.

Louisville is quite small. Nothing wonderful is found in it. The ruins of an old fort (Fort Nelson) are to be seen. They are on the bank of the Ohio, as is the town. I believe they do not at all exaggerate its unhealthiness. The city and its environs

2. Whose acquaintance I made at Fort Pitt. He had come down some time before us and arrived at the Falls without accident.

are very sickly. There are found, even in the lowa, low grounds filled with water, from which exhales the most dreadful stench, especially in the heat of summer. It would not, however, cost much labor to drain these marshes which give the inhabitants fevers, which, if not mortal, are long in curing. The other side of the Ohio, where I stayed for some time, where an American fort (Fort Steuben) is built and where there are 200 men in garrison, is not more healthy than Louisville, and there are few persons free from fever. This fort is in a very pretty situation. The land there is excellent and there are trees on every side.

In his record he states that he had left Pittsburg March 18 and had been attacked by the Indians March 23, was three days in the woods, and two days in the boat which picked them up. He made himself at once useful at the fort, examined some mines on Silver Creek, and analyzed a specimen which was brought to him which was supposed to contain gold, but which proved to be iron pyrites and copper. There was a lead mine fifteen miles from the post which yielded abundantly, but mixed with bismuth.

While at the fort Saugrain made a furnace and furnished the doctors fixed alkalies and amused them with electrical experiments. Salt, he states, was made in abundance in the neighborhood and sold at \$2 a bushel. From some stones which he picked up, and which were encrusted with shells, he came to the conclusion that this part of the country had once been covered by the sea, or a great lake. In this he anticipated the later demonstration of the glacial markings. Flint stones good for arrow-heads and gunflints were everywhere found. Quintucké (Kentucky), he remarks, was everywhere covered with a cane which makes a good food for cattle. Turtles, geese, turkeys, ducks, plover and quail were found immediately about the fort, but the deer had been frightened by drum and fife to a distance of several miles. It was here that he brought home some chalybeate water, and by adding it to an infusion of oak bark, made ink with which he was then writing, and which he thought would not fade. He also found a resin which he called copal, from a tree called the sweet gum. This discovery had not been made before, so in his honor they planted a specimen in the fort and called it Saugrain's tree.

From April 21 to May 3 he counted 34 boats passing down the river. May 7 a boat with fourteen rowers and eight or nine passengers arrived from Vincennes. They had been attacked 150 miles below and two of the party killed. This boat was going on to Pittsburg, and the doctor expected to go with them, but decided finally to accompany Colonel Blaine on horseback through Kentucky so as to see the country and then meet the boat at Limestone.

May 11 he set out, after expressing great regret at leaving the fort where he had received so much kindness, alone with Colonel Blaine. He comments on the fertility of the soil, the small size of the trees, the bad roads, and the fact that the plantations were mostly in barley. Their first stop was Bardstown, which had several stone houses and a handsome court house, which led him to believe that the people indulged in lawsuits.

Danville he found a charming settlement, with land the best in the world. Here they were joined by two Philadelphia ladies, both pretty, and Colonel Blaine's son. A party of fifty armed men passed through Danville, and two fugitives arrived of a party of seven from Richmond who had been attacked by Indians, one killed and the rest scattered. From here they went to Lexington, crossing the Kentucky River where the banks were high and rocky. Lexington he found pleasant, with good water and less idleness than elsewhere. A pest of cater-

pillars had stripped the maple trees which supplied the people with sugar, which would prove a severe loss. After two days they set out for Limestone, stopping at Bourbon; even at that early day visitors to Kentucky felt something was wanting unless they became familiar with Bourbon—a practice which prevails to the present day.

They dined at Saline Bleu (Blue Lick). Here you see the extraordinary spectacle of two springs, one salt and the other fresh, within ten feet of one another. Here salt is made by evaporation, requiring 1,000 gallons to make a bushel. Reaching Limestone they found the boats already there.

May 21 they set out for Muskingum with a party of sixty-eight armed men and forty-nine unarmed, in boats laden with goods from the Indians. They passed the Big Kanawha, which is beautifully situated but very dangerous from the Indians—two white men and four Indians had been recently killed. On May 30 they reached Muskingum, which he considered occupied the finest situation for a city he had ever seen, and ventured the prediction that it might become the largest city in America. The plan of the engineers he considered admirable. June 9 they left for Fort Pitt, where they arrived June 17, and soon left for Philadelphia with Mr. Pierce and Mr. Brason, the postmaster of Philadelphia, who had come out to establish a branch postoffice. The latter had been directed by Dr. Franklin to supply Saugrain with money if he met him. They traveled on horseback and stopped over night with one James Miers, then on to Greensburg, where he was invited, he says, out of curiosity, to many houses, for the people are not hospitable. The next day, though his foot was painful and required lancing, he traveled forty miles, and the next day the same distance over the Allegheny Mountains, and passed the night in a tavern in a deep valley between two high and barren mountains. "He would die of grief living in such a place where the sun shines for two hours only."

June 10 they stopped at Chambersburg, which had many stone and brick houses. A nearby creek turned fifteen or twenty revolving mills. The industries were remarkable. Gunpowder was made in quantities and sold for 50 cents a pound. They traveled over good roads and reached Carlisle, where the United States had magazines for the manufacture of arms. This town was famous for the dissension over the new Constitution. On the way they met large wagons which carried people to Fort Pitt, from whence they took boat for Muskingum. On the way to Lancaster they crossed the Susquehanna where it is half a mile wide and four fathoms deep. Here there was a fine courthouse and several churches, and it was noted for the fine rifles made there. The population was mostly German.

On June 20 they reached Philadelphia and found Dr. Franklin sick, but well enough to extend an invitation to dinner, which was gladly accepted, though Dr. Saugrain was quite ill and not very presentable in the clothes he had been traveling in. The journey from Fort Pitt to Philadelphia on horseback was made in seven days, while the trip out in a cabriolet had required fourteen days. It is not known when Dr. Saugrain left Philadelphia, but we next hear of him again in 1800, when he became engaged in the service of the Scioto Company to join a party of French settlers from Lyons and Paris, who were bound for the Ohio, and who founded Gallipolis.

This settlement furnishes one of the most picturesque and pathetic stories of the early west. The party, some 500 in number, was composed largely of high-classed

French artisans who were illy fitted to cope with the hardships of the wilderness. They were "carvers and gilders to his majesty, coach and peruke makers, friseurs and other artists, and only four or five farmers." The brothers, Caudevert, were sculptors and carvers who had already attained reputation enough "to have decorated two of the most beautiful churches in Paris."

The French imagination, still under the spell of Rousseau and the *Figaro*, was fairly fired by the accounts put forth by the promoters of the Scioto Company of "the free and happy life to be led on the banks of the beautiful Scioto" untrammelled by the artificial bonds of European society. The prospectus of the company, with a map, described the attractions in glowing terms.

"A climate wholesome and delightful; frost, even in winter, almost entirely unknown; a river called by way of eminence the beautiful, and abounding in fish of vast size. Noble forests, consisting of trees that spontaneously produced sugar (sugar maple), and a plant that yields ready-made candles (*Myrica cerifera*), venison in plenty, the pursuit of which is uninterrupted by wolves, foxes, lions or tigers. No taxes to pay, no military service to be rendered." Sangrain was sought because of his knowledge of the country. He was to serve three years, to have 200 acres and a house, and support for himself and three servants. For this he was to give his medical service.

The party reached Alexandria May 1, 1790, and arrived at Gallipolis October 20. Eighty cabins and a "council and ballroom" had been erected by Rufus Putnam for them. At first everything "was new, the colonist had means of support, and time passed agreeably between labor and pleasure. Woods were cleared, gardens planted, and everyone strove to make himself agreeable and useful. After a day of severe labor, dancing and singing or a social and cheerful meal succeeded." (Mrs. Mentle, Cincinnati *Evening Chronicle*, July 14, 1827.) July 14 they celebrated the fall of the Bastille. "They had brought with them costly dresses and expensive clothing, and rare and valuable laces, articles only suitable for a gay Parisian life." One of the descendants when quite an old woman, remembered seeing, when a girl, a barrel of silk stockings which was opened in St. Louis, where they had gone after the failure of Gallipolis, much damaged by being badly packed. The days of prosperity were not of long continuance—the company supplies stopped, there was great want, and their title to the land was found defective. Congress finally gave them 24,000 acres. "Now the ruffled shirt and the lace of the colonist were seen adorning the American hunter and mixing with the greasy hunting shirt and leggins, over which hung in laughable discordance the embroidered coat of the Frenchman, while beautiful rings shed luster on the blackened hands." "Nutmegs and spices were exchanged for eggs." Dr. Brackenridge, in his "Recollections of the West," gives a vivid picture of Dr. Saugrain in these surroundings. He seems to have kept an inn, and in a little back room, surrounded by his blowpipes, crucibles, chemical apparatus and electric batteries, he made aeromotors and thermometers and phosphorus matches, for all of which he found a ready sale. This work was regarded by many as uncanny and closely allied to the black art. On one of the other cabins tradition tells us of the sign "Bakery and Midwifery." Saugrain had established a reputation of inoculating for smallpox and crowds from the Kanawha Valley sought his service. On one occasion some Indians came to see him at work. The doctor placed a gold piece on a metallic plate and told the chief that he

might have it if he could pick it up. He received a severe electric shock and ran howling away. The doctor, to their great astonishment, then picked it up and put it in his pocket. The great fertility of the soil, he tells us, "brought emigrants without stop, full of energy to build their first cabin. They then played in the bosom of idleness. An inhabitant of the country which is in the middle of the forest scarcely works two hours a day for his living and that of his family. He spends nearly his whole time in reposing, in hunting and in drinking. The women weave linen and make clothes for their husbands, and he has seen good linen and woolen cloth made in the cabins. There is no silver. Whisky is bought with wheat and pork with mutton."

The Doctor married in Gallipolis, but soon left for Lexington, invited by a company that needed his knowledge in the manufacture of good bar iron, in which they had not been successful. He soon became popular. There is a tradition that while in Lexington he made for Henry Clay his first kite. He remained for six years, when, in response to an invitation of Trudeau, French governor of St. Louis, he moved there in 1800. The trip was made in a flatboat down the Ohio, and it took many days to work his way up the Mississippi. In 1805 he was appointed by Jefferson surgeon in the army and was stationed at Fort Bellefontaine, on the Missouri. In the *Missouri Gazette*, May 26, 1809, we find the following notice: "Dr. Saugrain gives notice of the first vaccine matter brought to St. Louis. Indigent persons vaccinated gratuitously." He continued to practice in St. Louis till his death, in 1820, and must have been eminently successful, for he left a large landed estate for the support of his wife and six children. Although thus busily occupied, he found time for his electrical and chemical work, and in the latter he is said to have anticipated the European inventors in the use of phosphorus for friction matches. His scientific work lives in tradition and has gained for him the title of the "First Scientist of the Mississippi Valley."³

His earnestness and modesty are well illustrated by a remark which has come down to us, made one day to his daughter, who was his assistant, in the laboratory: "We are working in the dark, my child; I only know enough to know that I know nothing." Can we to-day say more or less?

And now, in taking leave of our little French doctor, I may say that I felt we might turn from the great special surgical questions which now press on us for solution, to the early times when the scientific knowledge of the doctor enabled him to minister to the larger and more varied needs of those about him; from the "hurly-burly" of the great city to the noises and odors of the forest, from the blaze of electric lights to the beginning of friction matches, and find some interest and profit in the career of a pioneer physician who brought with him into the wilderness the highest culture of the day, and applied in his daily round the best that science could then afford for the benefit of those he was called on to care for.

Tradition still keeps warm his memory in the great city in which we meet, and I trust that the American Surgical Association may be the means of introducing him to his proper and larger place in the profession which we represent as one of the great pioneer physicians who has stimulated development, and place him in the position which fairly belongs to him by reason of his great attainments.

A PLEA FOR MORE THOROUGH EXAMINATION OF DOUBTFUL SPECIMENS OF ECTOPIC PREGNANCY.*

J. WESLEY BOVÉE, M.D.

Professor of Gynecology, Columbian University; Ex-President Southern Surgical and Gynecological Association; President Washington Obstetrical and Gynecological Society.

WASHINGTON, D. C.

Every abdominal surgeon meets with cases in which, before or during operation, the diagnosis of ectopic pregnancy is made, but in which no fetus or placenta is found. In such, absence of the fetus is attributed to the rapid absorptive action of the peritoneum on the nearly boneless ovum, and the absence of the placenta to interruption of the pregnancy before the development of that structure is commonly understood to begin. It is now known, however, that the trophoblast enters into the formation of that structure early in the developmental stage of segregation or cell division. In observing the work of others, I am sure this diagnosis is adhered to even without microscopic examination, if blood, either loose or encysted, is found in the peritoneal cavity, and a tube or ovary, or both, distended by blood coagulum. In my own experience, several times I have found that microscopic examination of such specimens has caused the diagnosis to be changed. I have had these specimens in my work carefully examined during the last ten years. In 1897, I read a paper entitled "Tubal and Ovarian Hemorrhage Resembling Ruptured Ectopic Pregnancy," at the St. Louis meeting of the Southern Surgical and Gynecological Association, in which I endeavored to prove the diagnosis of ectopic pregnancy was often wrong, even when made during an operation, and should not be made except by aid of the microscope. In that paper I cited many cases of error of diagnosis of this kind made by abdominal surgeons of world-wide reputation. I need not go into detail in explanation of the great harm of such error in the cases of virgins, widows and even married women, not to prove that such are not uncommonly made.

In these cases of tubal and ovarian hemorrhage from other causes, we have frequently a history of interrupted menstruation and sudden and severe pelvic pain, accompanied by profuse uterine hemorrhage and all the subjective and objective symptoms of disturbed ectopic pregnancy. In one of my cases the hemorrhage had continued for the six months preceding operation, and a mass practically filled the pelvis, forcing the uterus and opposite appendage far to one side and upward. At the operation the mass was found to be a large accumulation of partially walled-in blood, both fluid and coagulated, an ovary nearly normal and a large tube distended nearly to the isthmus by blood-clot. The fimbriated end was widely dilated and considerable free blood was in the peritoneal cavity. The indications were strongly suggestive of tubal pregnancy, but microscopic examination failed to find villi or any other evidence of pregnancy.

Between Jan. 1, 1899, and June 1, 1904, I operated on ten cases in Columbia Hospital for Women in which the macroscopic examination of the removed spec-

imens, taken with the case histories, gave very strong presumption of tubal abortion or ruptured tubal pregnancy, but in which the microscopic examination proved such diagnosis untenable.

In these ten cases the microscopic diagnoses were hematosalpinx in six, chronic salpingitis and ovarian hematoma in one, sclerotic ovary with profuse hemorrhage in one, ovarian papilliferous adenocystoma with salpingitis in one, and in another chronic salpingitis, with a sclerotic hemorrhagic ovary and a carcinomatous one.

In my services in two other hospitals I found a few cases, but at the time of this writing the reports of the microscopic examinations of the specimens removed were not accessible.

A study of these ten cases convinces me that many specimens removed and diagnosed as ectopic pregnancies are not such, and that in this class of cases the differential diagnosis is usually not made, as the aid of the microscope is not invoked as a routine procedure. I am equally as thoroughly convinced that the microscopic examination of every specimen presumptively diagnosed as ectopic pregnancy should be put to the microscopic test. It is only by this process that a most thorough knowledge may be secured of the causes of the conditions suggestive of disturbed ectopic gestation. It was only by a systematic microscopic study of his pathologic specimens removed that Webster of Chicago discovered the beautiful specimen of ovarian pregnancy presented to the American Gynecologic Society at Boston, and which caused him to recede from his former position that ovarian pregnancy was an impossible condition. In two of my ten cases malignant ovarian tumors were found.

The effect of such routine examination will be a more thorough knowledge of the pathologic conditions of the ovaries and tubes, more reliable statistics, and the prevention of stigma being placed on chaste women.

EXTRAUTERINE PREGNANCY WITH ATYPICAL SYMPTOMS.*

WALTER B. DORSETT, M.D.
ST. LOUIS.

A diligent search of the literature fails to reveal the record of many cases of extrauterine pregnancy in which anything aside from what may be termed typical symptoms were presented. The object of this paper, therefore, is to call attention to the fact that our knowledge of its symptomatology is by no means complete, also that it is a malady of more frequent occurrence than we are in the habit of assuming.

According to Hirst, the proportion of cases of extrauterine to normal pregnancy is about 1 to 500, and he gives that of Winkel to be 16 to 22,000 births, and of Bandl 3 to 50,000. While not giving his own experience, he states that he has operated 59 times with three deaths; 13 of these cases were operated on by him in nine months.

The subject of diagnosis as dealt with by most writers would lead one to believe that it is easy to decide by the subjective and objective symptoms that are presented, and while I agree that in the main this is true, still from my experience I am constrained to make this broad statement: There is no intraabdominal condition that is more frequently shrouded in mystery and

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women, and approved for publication by the Executive Committee: Drs. J. H. Carstens, A. Palmer Dudley and L. H. Dunning.

so devoid of pathognomonic symptoms as extrauterine pregnancy. The above statement may be due to my own experience, which I believe to be unusual, and which will be seen from the histories of the cases I present.

What should constitute the essential factors in making a diagnosis in this condition is well understood. The only exception that is worthy of note is the statement of Bland Sutton. He says: "A careful series of investigations on an abundant supply of material teaches us that a healthy fallopian tube is more likely to become gravid than one that has been inflamed." This statement was made in 1897. In his more recent work¹ he says: "The fact that pregnancy occurs in a tube after a long period of sterility in women who have borne children has given color to the suggestion that the patients have suffered from desquamative salpingitis, and the destruction of the proper epithelium will account for occurrence of tubal gestation, inasmuch as it puts the mucous lining of the tubes into a condition exactly similar to that of the uterus after menstruation." It will here be seen that he differs from most authorities in that he ignores the sequences of inflammatory disease as a factor in the causation of tubal gestations, and rather clings to the idea that the denudation of the tube alone fits it for an abiding place for an impregnated ovum. This is in marked contrast with the opinion of most writers on this subject, who hold to the theory that a tube robbed of

made by two good surgeons. An operation for the relief of the trouble revealed an extrauterine pregnancy of about five weeks' gestation and pathologic lesion of the appendix. A continuous and persistent hemorrhage from the uterus prompted me in another case to curette the uterus for a supposed retained placenta following a supposed early abortion. Failure to check the bloody discharge and the appearance of tumefaction in the right tube, accompanied by a sudden and violent pain on the side, suggested extrauterine pregnancy, and an operation revealed a distended broad ligament and ruptured tube with fetus enveloped.

I have operated on four other cases in which there was a diagnosis of hemorrhage following supposed abor-

Figure 1.

its ciliated epithelium, or strictured, or possessed of a congenital malformation, as a diverticulum, or twisted and contorted by bands of adhesion or displaced by new growths, is one of the essential etiologic factors in the production of tubal gestation.

I have operated on forty-one cases of extrauterine pregnancy, with a mortality of six. The indications for the operation have been varied. The results, considering the condition of the patients, have been good. Several cases had not been diagnosed as ectopic gestation, and while this was true, they were cases that presented symptoms demanding surgical intervention.

The first case that I personally attended was in a woman about 35 years old who fell dead after running violently upstairs at the St. Louis Female Hospital. The diagnosis in this case was heart failure, inasmuch as an examination on her admission to the hospital revealed serious cardiac lesions. The postmortem examination of the abdominal cavity revealed blood in large quantities in the cavity, a ruptured fallopian tube, and a fetus of about six weeks' gestation (Fig. 1).

The second case was one in which, on account of tumefaction and symptoms usually attending a suppurative appendix vermiformis, a diagnosis of appendicitis was

Figure 2.

tions, and in whom curettement had been done by attending physicians.

So far as literature is concerned, little is found to guide even the most careful student in an unerring manner toward a diagnosis, so that positive symptoms of ectopic pregnancy are frequently wanting. This is particularly true in tubal pregnancies prior to the rupture of the enveloping structure of the gestation sac.

Incorrect diagnoses as to the cause of hemoceles and pelvic abscesses have in many instances been made. The cause of error in these cases is often due to the want of clear histories to enable us to form a conclusion in a given case. Positive findings, as, for instance, the pres-

1. Surgical Diseases of the Fallopian Tubes and Ovaries, 1901, p. 208.

ence of a fetus or chorionic villi in or adjacent to a blood clot, will settle the question on operation, but we must remember that negative findings, as the absence of both fetus and chorionic villi, do not militate against a diagnosis of extrauterine gestation, for the reason that the peritoneal fluid often acts as a digestive agent and effectually destroys all such evidence.

The clinical history of the patient may or may not justify the surgeon in arriving at a diagnosis of extrauterine pregnancy, and he is often led to an operation solely by the indications for a celiotomy. In other words, does or does not a particular case present symptoms demanding an abdominal section? There may or may not be a history of shock, internal hemorrhage or concealed hemorrhage, the presence or absence of a discharge of decidual membrane from the uterus, the presence or absence of a tumor in the pelvis external to the corpus uteri, a clear history of a previous pathologic condition of the tubal mucosa (and, as a consequence, a history of sterility of from five to ten or fifteen years' standing, or no history of such condition), and still the patient may have an extrauterine pregnancy. The question, then, as to the propriety of an operation in most cases should be the urgent symptoms that are presented. This is true in most cases that come under the observation of the surgeon, but by no means does it include a few other cases of ectopic gestation in which urgent symptoms are not present, and in which the even clear histories of hemorrhage per via naturalis, the previous pathologic condition of the tubes, the presence or absence of a tumor or tumefaction. All of these, taken individually and collectively, should be the guides. We should always bear in mind that every case should be "a law unto itself." To illustrate the latter, these cases can be used:

CASE 1.—Mrs. H. S., aged 23, married six months, entered the hospital Dec. 19, 1900. Physical condition good; no history of previous inflammatory disease of tubes or ovaries prior to marriage. Menstruation always regular since its beginning; menstruated in normal manner one week after marriage. About one and one-half weeks later began to have pain in the right iliac region. On bimanual examination a painful tumor could be outlined midway between the uterus and the abdominal end of the tube. Temperature slightly elevated and pulse a little faster than normal. On opening, an encysted blood tumor was found, which, when disturbed, showed a tubal connection, and later a ruptured tube and small fetus with chorionic villi. Patient recovered without a bad symptom. In this case the only symptom worthy of note was the painful tumor.

CASE 2.—Miss E. S., aged 23, entered hospital Sept. 9, 1903. Gave no history of shock or sudden pain; no history of discharge of deciduous membranes from the uterus. About one week before entering the hospital she complained of heaviness in the pelvis. Bimanual examination revealed a fluctuating mass in the cul-de-sac of Douglas. Patient was anesthetized and Douglas' pouch incised. Quite a large amount of pus was discharged, and toward the last a macerated fetus. In this case the only guide was the fluctuating abscess in the pelvis.

CASE 3.—Miss A. A. No direct symptoms pointing toward extrauterine pregnancy. Chief symptom, vomiting and pain in the pelvis. No history of shock at any time. Examination revealed only a soft, retroverted uterus. Palliative measures to relieve the vomiting, and rest in bed, were ordered. Only after two weeks, when a bloody discharge from the vagina annoyed the patient, was another examination made and a tumor found. Operation showed a large hematocoele and fetus of about five weeks' gestation. This patient came very near dying, and was saved only after two intravenous injections of normal saline solution. The absence of food consequent on long continued vomiting, together with the loss of blood, had so debilitated her that death from exhaustion was threatened.

CASE 4.—Mrs. G., colored, was examined bimanually and a clearly outlined fibroid tumor made out between the layers of the broad ligament on the right side. Just above the growth a fluctuating mass was detected, which was taken for a fluctuating pus sac. None of the symptoms usually accompanying intra or extrauterine pregnancy was mentioned or suspected. Operation revealed tubal gestation near the uterine horn and fetus still *in situ*. Owing to ventrifixation and removal of the left tube and ovary some years previously, adhesions were so extensive that it was impossible, in doing a hysterectomy, to remove more than three-fourths of the body of the uterus. This patient made a good recovery and left the hospital in three weeks.

The presence of fibroid growths situated near the tubes is mentioned by Roberts as an etiologic factor in tubo-cornual pregnancy. He claims that distortion of the tube by the fibroid tumor is the cause.

These cases are cited simply to illustrate the difficulties which surround the diagnosis of some cases of extrauterine pregnancy, and also to indicate the necessity for surgical intervention.

From my experience I feel sure that extrauterine pregnancy is a much more frequent occurrence than is usually supposed, and that in a certain proportion of cases, typical symptoms and clear histories are not found.

DISCUSSION

ON PAPERS OF DRs. BOVÉE AND DORSETT.

DR. J. H. CARSTENS, Detroit, agreed with Dr. Dorsett that in some cases the diagnosis is very difficult. He had a patient who was operated on for pus tube on the left side. She was taken with a pain on the right side, fever of 100.5 F.; pulse, 80. He made a diagnosis of appendicitis, operated and found an extrauterine pregnancy on the right side. In this condition there ought to be no fever and a progressively increasing pulse. This woman had a normal pulse due to the small quantity of blood lost, about a pound. In another case he found a growth about the size of a walnut in the tube, with a rupture and a large hemorrhage, and the woman had not missed a single menstrual period. He operated and removed the growth, as he supposed. The tumor was examined microscopically and chorionic villi were found. He hardly ever finds a case that is not extrauterine pregnancy, but that does not make any difference. No matter what they are, operate first and study the pathology afterward.

DR. F. F. LAWRENCE, Columbus, Ohio, said that Dr. Carstens' statement that in extrauterine pregnancy there is always an increasing pulse rate and a normal temperature is not only misleading but, except in ruptured cases, contrary to the facts.

In the first place there are very few cases in which there is not some oozing from the end of the tube before occlusion takes place. In cases where the pregnancy occurs near the fimbriated end of the tube it becomes occluded later than where it occurs nearer the uterus, and there is consequently more or less continuous oozing with a resulting slight elevation of temperature; until there is considerable localized inflammation of the peritoneum or until considerable blood is lost there is practically no increase in the pulse rate. This is not only the logical teaching but the true clinical picture of an unruptured tubal pregnancy. After rupture there is rapidly increasing pulse, faintness, for a short time subnormal or normal temperature, followed by an increasing temperature with all the other signs of internal hemorrhage. That the diagnosis is not made before rupture is because of faulty teaching.

Dr. Lawrence reported a case a few months ago in which two extrauterine pregnancies occurred in the same patient within fourteen months.

Since that time he has had another experience with one which occurred about three and one-half years after the primary pregnancy on the opposite side. In both cases the

fetuses were well developed and both tubes unruptured. It does not matter whether we are positive of our diagnosis of extrauterine pregnancy, tubal mole or papilloma, either one should be removed, and Dr. Bovée's contention that all should be examined microscopically is well founded.

That is the only method by which we can obtain the exact pathology of these cases.

DR. G. B. MASSEY, Philadelphia, said that from his point of view there is here a rather remarkable condition of things. Two distinguished men tell us that as a result of these operations they are unable to make a diagnosis. Another tells us that there is no need of making a diagnosis, one must operate anyway. Dr. Carstens says that trouble comes in those cases that have gone beyond the time where absorption can take place. But there are also other cases, carelessly included in this list, in which it is difficult to examine the specimen and ascertain what it is.

Dr. Massey asked, is it not the teaching of both these papers that these affections are in process of cure at the time of operation? If by a surgical operation it is possible to save those bleeding into the abdomen by all means do so. Cases with arrested bleeding in the broad ligament are already in process of cure, and should be treated by the constant current to hasten absorption if not to kill the fetus. Moreover, if there is any excuse for operation it is for immediate operation when life seems to be in danger, and not days later when in all probability the fetus is dead and in process of absorption. A patient at present under Dr. Massey's care was operated on on the fifth day after rupture, when the pain had ceased and she was comfortable. According to all experience her danger was greatest five days before. Both tubes and ovaries were removed, and she has been a sick woman since.

DR. A. GOLDSPOHN, Chicago, said that he could not recollect a case of the ruptured class that he did not diagnose, or strongly suspect that as the diagnosis; in the absence of neoplasms, of course. There may be pelvic disease or abscess, and many other different causes, but after rupture, and extravasation of blood, these cases are not difficult to diagnose. The test of diagnostic skill is in diagnosing a tubal pregnancy before rupture. Dr. Goldspohn has not seen many of these; about half a dozen. He has taken one out through the inguinal canal in conjunction with a retroversion operation. He did not diagnose it previously, however, and therefore it does not count. In order to classify a case as one of tubal pregnancy, the chorionic villi should be present, and they can be found with the aid of the microscope when the fetus is frequently no longer recognizable. Dr. Goldspohn has found a number of times somewhere in the extravasated blood clot, usually near the center, a little cavern as if a large pumpkin seed had been lodged there, or a small almond kernel, with little films of membrane in it, but no fetal remnants, and with the microscope the necessary evidence in most of such cavities could be found. The fact that this little cavern is situated near the center and not near the surface shows that it is well out of reach of the peritoneal fluids. The idea of the peritoneal fluids digesting things is far fetched, and certainly can not be accepted as explaining the absence of chorionic villi. Dr. Goldspohn thinks that it is generally accepted now that operation is the most correct treatment.

DR. W. H. HUMSTON, Cleveland, Ohio, has never yet operated on a case where he had announced tubal and ovarian disease and found an extrauterine pregnancy, but he has made a diagnosis of extrauterine pregnancy and found tubal and ovarian disease. He had one case with severe hemorrhage from ruptured tubal pregnancy. The woman was nursing a baby of nine months; he operated, and in twelve months she was delivered of a perfectly healthy baby, and has continued in good health ever since. She certainly had good appendages to have become pregnant twice in this short time. He has been fortunate in his operations for extrauterine pregnancy, and believes in early, thorough operations. He does not wait until shock has subsided, as advised by some, but overcomes shock by injecting saline solution under the breasts the moment the anesthetic is commenced. He injects two or

three quarts, and takes the patients off the table in better condition than they went on.

DR. I. S. STONE, Washington, D. C., said that he for one did not always find the pathologic diagnosis and the clinical history and macroscopic appearance of the specimen agree. He has frequently found indications of pregnancy at the time of operation which were not considered such by the pathologist. A very interesting question often arises in this connection, namely, how often is the hematoma due to impregnation, and is the hematoma of pregnancy always within the folds of the broad ligament as taught by many surgeons? He has long believed and has frequently observed that the tube may rupture elsewhere and, in fact, does often rupture on its intraperitoneal side. In such cases the hematoma will often have an external adventitious membrane very similar to the peritoneum itself.

DR. SAMUEL M. BRICKNER, New York City, said he trusted that we will not get away from Werth's dictum that unruptured extrauterine pregnancy is to be regarded in the same light as a malignant neoplasm. He said that sometimes the pregnancy will be interrupted and there will be a deposit of blood in the tube, representing a hematosalpinx; but the end of the tube is closed, which differentiates it easily from hematosalpinx caused by atresia from the fact that the blood is always clotted, while in the latter condition it is always fluid. In these cases it is sometimes impossible to find chorionic villi or decidual cells, nothing but the clot of blood appearing on microscopic examination. In a recent case, at the margin or insertion of the clot, a few chorionic villi were found. Another point is the use of a modified Döderlein chart on which is registered the time and degree of menstruation. If we have several normal periods of menstruation, followed by a menopause and then continuous or interrupted bleeding, it is very suspicious of tubal pregnancy; the chart gives a graphic view of the type of bleeding and its severity.

DR. A. PALMER DUDLEY, New York City, said that the consensus of opinion in America is that ectopic gestation should be diagnosed and removed as soon as possible. Why remove the entire structure for a non-septic condition? In the vast majority of cases ectopic gestation is a septic, and how many thousands of cases of salpingitis are seen that are not treated surgically, but are relieved by local treatment, and these women bear children afterward. Last summer, while in Berlin, Dr. Dudley saw Ohlshausen operate for ectopic gestation. He made a small incision, turned out the fetus, washed out the abdomen, ligated the bleeding vessels, and dropped the tube back. If he, with his vast experience, has come to the conclusion that non-septic ectopic gestation does not justify the removal of the tube and ovary, why can not others pattern after him? If Dr. Dudley had to do such an operation in a case where nonsepsis could be made out, he certainly would not remove the tube and ovary, but would drop them back. Nature will take care of them.

DR. C. S. BACON, Chicago, said that Dr. Bovée will admit that after a certain length of time all evidence of gestation, the minute fetus, chorionic villi in the tube and the decidua in the uterus disappear, and asked him when do these disappear, in months, weeks or days.

DR. J. W. BOVÉE, in replying to a question, said that the microscopic appearances will prove whether there has been a pregnancy probably as long as three months after rupture. That has been his understanding, although he does not make the microscopic examinations.

He does not quite understand what the digestive function of the peritoneum would have to do with the contents of the tube when blood is flowing out of the tube and blocking the passage into the peritoneal cavity. The clot may become so firm and the internal pressure in the tube so great as to press out and absorb all the villi along the wall of the tube. He does not quite agree that the treatment should be left to nature. We can help nature materially. He would treat them the same if he knew beforehand that it was a tubal pregnancy or a hematosalpinx or a tubal hemorrhage. He would not leave the tube, as Dr. Dudley advised, because he does not like these

crippled tubes. He has seen ectopic gestation follow just such cases. He performed four laparotomies on one patient because he yielded to her wishes regarding a future pregnancy. If there is a crippled tube, and the abdomen is opened, we should not give it a chance to offend a second time. The diagnosis of these cases is not always clear. In most cases where there is a disturbed pregnancy it will be diagnosed as ectopic pregnancy; or if a simple hematosalpinx it will be diagnosed as ectopic gestation, either tubal abortion or threatened tubal abortion or rupture. Possibly we may learn to diagnose ovarian pregnancy later on. A large number of these cases will be ovarian and tubal hemorrhage. The cause of these hemorrhages, Dr. Bové thinks, is carelessness on the part of the woman at about the menstrual period or exposure to sudden changes in temperature, producing an engorgement in the broad ligament with subsequent hemorrhage. Another very productive cause is the use of oxytocics at about the menstrual period. He has found such a history in a few of his cases.

Dr. W. B. DORSETT said that he does not believe that there is a parallel in surgery where an organ that has been the cause of trouble, and can be removed safely, ought not to be removed. We know that the remote cause of hemorrhage in the tube is due to a previous pathologic condition, either a stricture, a diverticulum or a denudation of the epithelium. This is the almost universal belief. The only exception is made by Bland-Sutton, who claims that the tube must be healthy or else it can not exist. Dr. Lawrence spoke of a case in which all sorts of diagnoses had been made, and Dr. Dorsett said that that emphasizes the point he made in his paper, that we are often in the dark yet have to operate. A celiotomy is demanded and yet for no particular condition. Dr. Dorsett said he did not mean that the peritoneal fluid passed into the tube; he referred only to those cases in which the rupture is complete and the chorionic villi are removed and are outside of the tubal mucous membrane, but that does not militate against extrauterine pregnancy. In those cases where we find a hematoma and nothing else, we do not have extrauterine pregnancy, but when we do find chorionic villi in an unruptured or ruptured tube it is a positive evidence of ectopic gestation. In all the specimens he showed the diagnosis was made by the microscope. The chorionic villi are there.

THE TREATMENT OF LUPUS ERYTHEMATOSUS BY REPEATED REFRIGERATION WITH ETHYL CHLORID.*

M. B. HARTZELL, M.D.

Associate in Dermatology, University of Pennsylvania; Dermatologist to the Methodist Hospital of Philadelphia and to the Philadelphia Hospital.

PHILADELPHIA.

A distinguished teacher of dermatology was in the habit of saying to his class, when presenting a case of erythematous lupus: "Gentlemen, I show you an example of a disease which, although not incapable of recovery, is the most refractory to treatment of all cutaneous affections." And I am sure that all who have had any experience, even a limited one, in the treatment of this obstinate malady will agree with that teacher. The long list of remedies to be found in every text-book of diseases of the skin said to be more or less useful (usually less than more) in this disease is additional evidence, if any were needed, of its refractoriness to treatment, for the curability of any disease is usually in inverse proportion to the number of remedies proposed for its cure. So many forms of treatment, both internal and external.

have had their praises loudly sung in this affection, only to be cast aside as their uselessness became apparent, that it requires no little courage to propose a new one; and I hasten to say that the method of treatment which I am about to describe briefly is not brought forward as an infallible cure for erythematous lupus, but as one which I have found very useful in a number of cases, after the failure of other methods.

The method of treatment to which I wish to call your attention consists in the repeated freezing of the patches of lupus at short intervals by means of ethyl chlorid spray. The diseased areas should be thoroughly frozen and kept so for five to eight minutes, and the freezing should be repeated at intervals of two to three days. Occasionally considerable inflammatory reaction follows, in which event the intervals between the freezings may be made longer—four to five days, or even more. After ten days to two weeks of this treatment considerable desquamation occurs, and the diseased areas grow much paler; and at the end of six weeks to two months small and superficial patches of recent origin may completely disappear. As illustrating this method of treatment and its results, I shall very briefly relate a few cases which have been thus treated during the past three years.

CASE 1.—The first case to be treated by refrigeration was a woman, about 40 years old, who had a number of typical patches of erythematous lupus on the cheeks, nose, forehead, behind the ears and on the scalp, causing in the last situation extensive areas of baldness. The disease on the cheeks was of the florid, superficial type, being bright red rather than violaceous, but on the scalp was much deeper. The patient had had treatment of various kinds, without any material benefit, for two or three years. When she came under my care she was at once put on large doses of quinin internally and frequent applications of strong alcohol locally. Under this treatment improvement was for a time very marked, but after a while the patches on the cheeks, which had almost disappeared, again became active. It was then decided to try the effect of repeated freezing, the patches behind the ears being selected for the experiment. At first the freezing was done at intervals of four or five days, but owing to the difficulty in securing the patient's regular attendance it was frequently a week between the sances. A favorable effect was at once manifest; the patches gradually grew paler and finally disappeared. The lesions on the cheeks were then subjected to the same treatment, and improvement was also soon manifest here, but less marked than in the patches first treated. After three months of such treatment the patient left the city for her summer home, and the applications of the ethyl chlorid were unwisely trusted to members of the patient's family, with the usual unsatisfactory result. On the patient's return in the autumn but little further improvement was noticed, and the freezing was given up—unwisely, as I think—for the x-ray, which was entirely without favorable effect. The patient soon after passing from my care, the further course of the disease is unknown. Although carried out under somewhat unfavorable circumstances, the treatment was undoubtedly beneficial up to a certain point.

CASE 2.—D., a clerk, 35 years old, came to the skin dispensary of the University Hospital some two years ago for the treatment of a dime-sized patch of erythematous lupus situated on the bridge of the nose, of several months' duration. After some months of the usual treatment without any visible result, freezing with ethyl chlorid was begun. Owing to the fact that the patient lived some distance from the city and could not always obtain leave of absence from his place of business, the treatment was carried out in very irregular fashion, there being frequently periods of three or four weeks or more during which no applications of the spray were made. Notwithstanding this, a steady, although slow, improvement was manifest. When last seen, a few months ago, there was practically no

* Read at the Fifty-fifth Annual Session of the American Medical Association in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

trace of active disease, there being only a slight amount of the scar-like atrophy common after this affection.

CASE 3.—Miss M. S., 52 years old, had numerous patches of erythematous lupus on the scalp, nose, cheeks, sides of the neck, mucous membrane of the lower lip and backs of the hands. The disease had lasted eight years and had been treated by the family physician without benefit. The patch on the scalp was the largest, being about the size of a silver dollar; this was selected for the application of the ethyl chlorid spray. After the second application some slight improvement was visible, and after the fourth, to quote from my note-book, "remarkable improvement" was noted. Unfortunately, the patient found the freezing of the scalp extremely painful—so much so, that the treatment had to be given up. It may be said here that, while a certain amount of pain follows the freezing, it is rarely severe enough to cause much complaint from the patient. In this case, notwithstanding the small number of the applications of the spray, the improvement was immediate and marked.

CASE 4.—J. W., 29 years old, a stonemason by occupation, had a marked erythematous lupus of thirteen years' standing, affecting the ears and the cheeks. The disease was most severe on the ears, where it had produced a marked scar-like atrophy, the lobes having practically disappeared. This patient had been under the care of a distinguished dermatologist of Edinburgh for a considerable period, but had derived but little benefit from treatment. The use of the ethyl chlorid spray at intervals of five days to one week, which was as often as the patient could be induced to come for treatment, in six weeks' time produced decided change for the better; and this improvement continued until, at the end of three months, the small patches on the cheeks had disappeared. While there was some improvement in the condition of the ears, the favorable effects of the treatment in this situation were much less marked than on the cheeks. It may be noted that the use of the spray on the ears was attended by considerable, but not unbearable, pain.

CASE 5.—W. B., 25 years old, a clerk by occupation, has patches of erythematous lupus on both cheeks, on lower lids, and behind ears, the first of which made its appearance eighteen months ago. The patches on the cheeks and on the lower lids have been treated by freezing with ethyl chlorid during the past three months, at intervals of three to four days. After six weeks of this treatment the patch beneath the right eye, on which the freezing had been begun, was so much paler as to be scarcely noticeable, and the smaller of the two patches on the cheeks had likewise almost disappeared. That the improvement was due to the freezing is evident from the fact that there was no perceptible change under other local treatment employed prior to the use of ethyl chlorid. This case is still under treatment.

While it is difficult to draw any very positive conclusions from observations based on the treatment of so small a series of cases, yet I think we may conclude that repeating freezing of patches of erythematous lupus has a decidedly beneficial effect. In not a single one of the cases in which I have tried it has it failed to produce a more or less marked improvement, and in some it was followed by the complete disappearance of the disease in limited areas. In conclusion, I believe that, when employed in conjunction with large doses of quinin internally, repeated refrigeration is an extremely useful procedure in the treatment of this usually very intractable disease.

DISCUSSION.

DR. M. L. HEIDINGSFELD, Cincinnati—I wish to report my results from a preparation which I have been using for the treatment of this affection with a great deal of success and satisfaction for the past three or four years. It is the local application of 40 per cent. resorcin in gelanthum, applied once weekly or even fortnightly by means of a probe wrapped with a small pledget of cotton. Inasmuch as the gelanthum is somewhat troublesome to obtain, and is easily contaminated

by molds, I have substituted the following linamentum exsicicans as a solvent vehicle for the resorcin:

R. Gum tragacanth	grs. xxx	2
Glycerin	5iiss	6
Acidii salicylici	grs. xv	1
Aque destil, q. s. ad.....	3iiss	105

M. Coque. Ft. fluid. gelat.

This 40 per cent. resorcin preparation is easily applied, invisible, rapidly cleanses and detersgates the inflamed surface, and is soothing and unirritating in character. I have often applied it in close proximity to the mucous membrane of the eye without the slightest irritation or discomfort to the patient. I have effected an apparently complete and permanent cure in several cases and very favorable results in a number of others who are still under observation or treatment. Dr. Hartzell's remedy certainly merits our attention, and is worthy our careful consideration, in the light of his highly satisfactory results.

DR. C. W. ALLEN, New York City—There is no question that freezing is very beneficial in lupus erythematousus. You can freeze a patch with liquid air with great benefit, but since liquid air is not available to all, it is well we should know about ethyl chlorid, which can be obtained by any practitioner anywhere. There are very many methods of successfully treating lupus erythematousus and it is, on the whole, a rather interesting disease to treat. I approve of curettage, which usually is not mentioned and not much practiced. If the curetting is done in a particular way it is not very painful. If the border of the patch is undermined and the curetting done from within outward it can be done with comparatively little pain and with great success if followed up and carried out carefully. I have succeeded in that way in curing patients without other treatment. Dr. Hartzell mentioned the internal use of quinin in conjunction with the external use of ethyl chlorid. I think the internal use of quinin for the wandering cases, the scattering patches, the coming and going forms, is of advantage, and it can be used in connection with various external applications, one of them being iodin, which has been more or less exploited.

DR. DAVID LIEBERTHAL, Chicago—I had an opportunity to treat a case of lupus erythematousus with alcohol and ether, as employed by H. v. Hebra. I prescribed each separately, advising him to mix them before application. During the course of his treatment the bottle of alcohol was broken and the patient continued the use of the ether alone. The improvement was more apparent than before, which was no doubt due to the ether having a lower point of evaporation than the alcohol. Therefore, Dr. Hartzell's successful employment of ethyl chlorid seems very plausible.

DR. J. B. KESSLER, Iowa City, Iowa—it is difficult to treat this protean disease. I have tried scarification with good results and without result and have found from my limited experience that the form of treatment that is best for cases which involve the follicles sufficiently deep to produce pus, is the x-ray, but with the more superficial variety I have used the x-ray to a considerable extent without any benefit whatever. I remember one old man in our town, a constant rounder, who will receive treatment at any and all times if you do not charge him, who had a patch on his hand, nose and ear. He had some proprietary preparation for his nose, but we have healed the hand two or three times with the x-ray. I recall one man in particular who had a patch on his nose that was crusted with some pus beneath the crust. I used all the remedies I could think of in the way of carbohc acid, scarification, and other things. After eight or ten applications of the x-ray this remained healed and the skin was smooth. I saw the man a year after and the result was perfect.

DR. ISADORE DYER, New Orleans—In the past year I have cured two cases of deep-seated lupus erythematousus with the x-ray; in the irregularity of clinics in a large city I find that ichthylol in collodion gives me the best service. A 20 per cent. solution will remove the patch within ten or twelve days in the simple superficial types.

DR. MORTIMER A. MOSES, New York City—I have seen ethyl

-chlorid used in Lassar's clinic in Berlin in the treatment of superficial epitheliomas. The effects were good and I am surprised that no reports have been sent out from that clinic. The treatment mentioned by Dr. Allen, iodine locally and quinin internally, I have seen used in one case of severe, rather deep-seated lupus erythematosus, and there resulted an almost perfect cure within five or six months. The lupus was very extensive, almost every part of the face was involved and there was considerable thickening of the tissues.

Dr. A. RAVOGLI, Cincinnati—Dr. Hartzell's plan is a modification of the method of Hollander of Berlin, who spoke of this method at the International Congress last year in the Section of Dermatology. By the use of iodine and the internal administration of large doses of quinin I have treated a number of patients in my private and hospital practice, but I must say I did not get the improvement that Hollander claimed to have obtained. I think we should be careful in distinguishing the different varieties of lupus erythematosus. If we have one of the superficial forms of the disease, sometimes it disappears by itself, or with very little application, but after a while these cases come back and take the terrible proportions which we know as lupus erythematosus diffusus. I am treating a musician now whom I have treated three times on different occasions, the disease yielding under pyrogallic acid, resorcin and ichthylol; but when nearly well he would let go, and then be back again with the disease in a much more severe form. I have treated him recently with good results, by applying a paste of formo-resorcin, 3 per cent., but although greatly improved, I have not much faith that he will be entirely cured. The treatment of this disease is one of the most difficult questions with which dermatology has to contend.

Dr. H. C. BAUM, Syracuse, N. Y.—Cases of lupus erythematosus I find respond well to various sorts of treatment, but what is successful in one case often does not relieve another. I have had good results recently from the application of high-frequency currents, but how permanent these results will be I can not say, the oldest case since treatment being not more than four months. In two or three cases I was not able to complete the treatment from the fact that the patients were satisfied with the relative improvement. Those that continued seemed to have the patches cleared up entirely. In making this treatment I use the vacuum electrodes.

Dr. W. S. GOTHELL, New York City—There seems to be hardly any remedy that will not occasionally cure cases of lupus erythematosus; and, on the other hand, there are some cases that no remedy will cure. I have been more impressed with a series of bad cases that had been treated with the cautious applications of trichloroacetic acid, and which were shown by Dr. E. Pisko of New York, at the Manhattan Dermatologic Society last winter, than with any other therapeutic measures. A single light application of the deliquesced crystals was made, followed by wet applications or emollient salves. There was considerable though only temporary pain; and the resultant eschar left superficial scars behind. I should consider it applicable, however, only to advanced cases, in which cicatricial deformity is inevitable, or has already occurred. I have had cures from the use of the Finsen light, as I reported in the *International Journal of Surgery* last year. The treatment that Dr. Hartzell advocates, which is that which Dethlefsen proposes for lupus vulgaris, seems to be ideal.

Dr. F. J. WALLIS, Philadelphia—I think the suggestion is worth trying in other cases beside lupus, provided we could lessen the irritation. Oil silk covering the lupus might give the same results.

Dr. M. B. HARTZELL—In answer to Dr. Lieberthal's question regarding the applications made between the freezings, I would say that in some, perhaps most cases, no other applications at all were made. In a few absolute alcohol was mopped on. The only originality claimed for this treatment is its use in this particular disease; as has been said, this was introduced by Dethlefsen in lupus vulgaris. I am very glad that Dr. Dyer finds ichthylol so effective. If I understood him aright he said he had no occasion to use anything else.

Dr. DYER—In the superficial cases, the coming and going, evanescent cases.

Dr. HARTZELL—The disease is usually a very obstinate one, but in some instances the patches disappear spontaneously. One of the most extensive cases I ever saw treated with some indifferent application got well in two or three months' time, and in two months more was worse than ever. This method is not offered as an infallible remedy for lupus erythematosus. Ethyl chlorid was used because it was the most convenient and most effective method of producing freezing of the skin.

DISEASES OF CHILDREN OCCASIONED BY AFFECTIONS OF THE NOSE.

THE NECESSITY FOR RECOGNITION AND TREATMENT.*

LOUIS J. LAUTENBACH, A.M., M.D., Ph.D.

Surgeon-in-Charge Philadelphia Eye, Ear, Nose and Throat Institute; Nose and Throat Physician to the Odd Fellows' Home; Late Surgeon to Pennsylvania Eye and Ear Infirmary; Late Chief of Eye Clinic of the German Hospital, Etc.

PHILADELPHIA.

The members of this section, who are specialists in diseases of children, are far more conversant with the general conditions than I. I am more apt to see the special nasal disease, although I was in active, general practice for three years, and treated as many general cases as I could induce various public institutions and friends to entrust to me. For the past twenty years, since I relinquished general work, I have treated large numbers of children for special diseases, and have observed in most of them connections between the special work and the general conditions present. As the result of this experience I have arrived at certain conclusions which perhaps I may be able to present so as to be of practical value.

In the first place, the importance of the functions of the nose, its relation to other parts of the body, and its widespread influence when diseased, can scarcely be overestimated.

The two usual modes of ingress to the body are the mouth and nose. If any comparison be made as to their relative value the nose will be found to occupy a place fully as important as that of the mouth. The mouth admits food and drink, and in part prepares these for digestion; it is useful as a speech organ, and by the sense of taste stimulates digestion.

The nose admits air and moisture; it warms the air and moistens it; cleanses it of foreign particles which it expels, and in addition aids the mouth in determining the value of foods and drinks, as well as aids digestion by the sense of smell.

A man can live for weeks without food, for days without drink, and his lifetime without speech; but he can respire but a short time without moisture, and without air he can not live fifteen minutes. A man may be fed indefinitely through his nose, but he can not breathe with safety indefinitely through his mouth.

The noses of children are more susceptible to disease and more easily cured than the noses of adults. Whether or not all the inhabitants of our eastern seaboard have had catarrh may be a question, but it is undoubtedly the case that the children have almost invariably head colds or a tendency to one on the slightest provocation. While with some this may be an argument for neglecting such

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Diseases of Children, and approved for publication by the Executive Committee: Drs. S. W. Kelley, H. M. McClanahan and John C. Cook.

cases, it is really a very strong reason for an opposite course. The symptoms must be considered as danger signals which indicate that care and thoughtfulness must be exercised to avoid other conditions perhaps more grave. In addition, it is to be considered as a caution to avoid drafts of air, undue exposure, stomach derangement, or anything exhausting to the system. It is a signal to live a more normal life.

If the nose be not restored to normal, by treatment or by nature, this physical barometer, as the nose may be said to be, is not so sensitive when new exposures occur, and the result is that the physical condition of the child will be unduly lowered before the proper restorative steps are taken. With each neglected attack, the local condition becomes worse, the secondary results become more and more pronounced, the general vitality of the child is lowered, and if it continues indefinitely almost any form of wasting or dyscrasic disease may result, the form depending on the inherited or acquired susceptibilities.

A pitiful fact about the whole condition is the apparent carelessness with which such cases are regarded. "Oh, only a cold," is the common thought: well, "only a cold" in one part of the body or another is the cause of death of more than half the human race.

The functions of the nose are, 1, to admit air; 2, to warm it; 3, to moisten it; 4, to cleanse it, and, 5, through the sense of smell to stimulate digestion and to reject unhealthy substances. It is now a well known fact that the foods we desire or crave are more easily digested, and that the pleasant odors of many foods thus increase their digestibility.

In addition, the nose drains the eyes and ears, ventilating the latter through the eustachian tubes. Through the intimate association of its circulation with that of the meninges and the cerebrum it exercises an influence on our mentality, deciding often whether we shall be of a bright and cheerful, or of a crabbed and mournful disposition. In much the same way it exercises a potent influence on the memory, as many a one with nose disease can unfortunately testify.

It will be observed that the nose directly influences the brain, the eyes, the ears, the throat, larynx, lungs and digestion, as well as the general health.

Thus it is apparent, that the direct influence of the nose being so widespread, it must indirectly influence every tissue of the entire body. By affecting the digestion and respiration the nose influences the health of the most distant structures; by affecting the sense of sight, hearing and smell, it must have a similar influence through these protective organs, and as our judgment is the result of the experiences of our senses, plus the memory and mentality, it follows that even that is influenced considerably by the nasal condition. The conclusion follows that the entire body responds to the nasal condition, and that the memory, the mentality, and even the judgment, are influenced by the disease or health of this organ.

The dog's nose is supposed to be the indication of his health; we say when the nose is cold that he is well, and when warm that he is sick. A man's health, or lack of it, is not so easily determined in this way, but a careful study of the nasal fosse and the nasopharynx will, to the initiated, shed light as to his physical condition.

Any obstruction in the nose or the postnasal space, whether a foreign body, a nasal tumor, an adenoid growth, an enlarged turbinated, a deviated septum, a general hyperplasia, or hyperemia or an accumulation of

mucous or scabs will prevent proper, healthy breathing and induce mouth-breathing, all the nose function being interfered with directly in proportion to the severity of the abnormality present.

If the obstruction is at all considerable the child will become a confirmed mouth-breather. The air passing into the child in mouth-breathing is but slightly less warm than when inhaled through the nose, but the amount of air taken in is deficient, and to obtain even that minimum requires an unusual amount of effort of the chest muscles and the lung tissues, very exhausting to both; in addition the air is not cleansed, but enters the lungs directly, depositing all foreign particles there. Most important of all is the fact that the air enters the lungs deficient in humidity, the consequence being that the blood cleansing process is much interfered with, the reoxygenation of the blood occurring much more slowly, the carbonic acid gas being liberated with difficulty, as the blood must needs give up its serum in an unusual quantity to moisten the epithelial lung tissues.

DISTURBANCES OF THE DIGESTIVE TRACT.

Such a child will develop a dry throat, evidenced by a hacking cough and hawking, pharyngitis or laryngitis, or both may set in, the lungs begin to work less and less vigorously, adapting themselves gradually to the receipt of smaller volumes of air, the chest gradually flattens and becomes chicken-breasted, the apices fall, the collar bones begin to be more prominent, the heart's action in turn is interfered with and becomes less strong and regular. The digestion is often seriously deranged on account of the abnormal mouth-breathing with the deficient oxygenation and the diminished circulation, as well as the interference with the sense of smell, and also especially because of the constant injection of the nasal discharges and throat accumulations which, fermenting often before they reach the stomach, exercise a most harmful and serious influence on the functions as well as the structures of the stomach.

In this connection it is interesting to quote from Friedrieh:¹

"Dyspepsia is often associated with atrophic fetid rhinitis and pharyngitis and with abscess in the cavities adjoining the nose, obviously because the pus which enters the pharynx is often swallowed. It would be well worth while to examine these relations more closely from a clinical standpoint, for, so far as my experience goes, this cause for chronic gastric catarrh has so far barely received a passing mention. When complaints of failing appetite and bad indigestion are constantly heard in cases of ozena, where the cavities of the nose are enormously enlarged and its walls covered with crusts, where the pharynx and posterior pharyngeal wall is filled with offensive discolored masses of secretion, it seems but natural to attempt to establish a causal relation between the two conditions. A secondary chronic gastritis is readily explained either by the anomalies of smell and taste which result from the ozena and manifest themselves in paresthesia and anesthesias, destroying the appetite and causing a bad taste in the mouth, or directly by the irritation of the decomposing secretions in the stomach."

Malnutrition thus occasioned has the usual results. We find a faulty digestion causing stomach and intestinal pains, headaches, cold extremities, a lack of appe-

1. Friedrieh, E. P.: *Rhinology, Laryngology and Otology and Their Significance in General Medicine*; Philadelphia, 1900, pp. 28, 41, 72.

tite, disturbance of the bowels, a general lack of tone, enlargement of the liver, a tendency to disorders of the skin, leading to eczema and to the production of boils. The malnutrition in its effects still further exaggerates the catarrhal nasal trouble and this in turn the general disorders and the action and reaction goes on continuously and is endless. Indeed, very often after the head catarrh is cured by appropriate treatment the secondary stomach and intestinal catarrh, with its attending disorders, persists.

EYE AND EAR DISTURBANCES.

At the same time we may find developing as a result of the obstruction a catarrhal or phlyctenular conjunctivitis with epiphora, or closure of the *ductus ad nasum* or even a keratitis. There usually is an involvement of the eustachian tube, with a loss of hearing power either as the result of direct extension of the nasal inflammation, infection or closure of the tube, or as the result of pressure alone.

As deafness exists in about one-third of all adults, and as the proposition that catarrhal deafness (the usual cause of deafness) is practically always the result of disease of the nose is admitted, and as nose disease is not only most prevalent, but in addition is most easily corrected in childhood, the necessity for its careful treatment at this period is evident.

In these obstruction cases the memory, the mentality and judgment are more prone to suffer if the posterior nares is considerably involved.

How then, can the general health be perfect when the mischief is so widespread, when the digestion is impaired, the respiration diminished, and the heart's action interfered with and when the direct poisoning of the body is constant from the injection of inspissated, fermenting and diseased mucus?

If the condition continues, not only will all these structures gradually become more diseased, but the entire physical and mental growth of the child will be interfered with, the child growing to be a puny, stunted man. Many a child who under normal conditions was destined to attain a height of 5½ to 6 feet, has failed to reach it by half a foot or more, while his mentality, which was perhaps capable of reaching, say, 90 per cent. of an arbitrary standard, never afterward was able to soar above 60 per cent. Of course, this is presuming that the child did not develop the diseased conditions to such an extent as to cause death before the attainment of manhood.

The tissues of children, being in a growing or nascent state, are more easily subject to modifications than in adult life; they are, therefore, more subject to congestion and hyperemias, which are the first stages of the usual colds or catarrhs in the head. They are also more easily controlled by treatment, whether internal or local. A drop of tincture of aconite, with two drops of tincture of belladonna given to a child every hour for five hours, will have a much more favorable influence in such a case than a corresponding dose in the developed man.

On the subject of diseases of the ears being caused by nasal obstructions and congestions, I have many times given voice in my various pamphlets.² I might in addition quote from Friedrich:¹

Any and all diseases of the nose and postnasal space which are followed by obstruction of the nasal passages lead to passive hyperemia in the mucous membranes, which in turn produces occlusion of the eustachian canal. The recognition of this important fact is comparatively recent, and since the causal relation between these disturbances and the interference with nasal respiration by the presence of adenoid growths has been definitely established the attention of clinicians has been directed to the significance of nasal stenoses in occlusions of the eustachian tube. The interference may be due to a number of conditions within the nose, as hypertrophy of the mucous membrane, mucous polypi, tumors, syphilitic or tuberculous infiltrations, foreign bodies, etc. There may be a congenital narrowing of the nasal cavity from deformity, and hyperplasia of the septum or abnormal curvature of the turbinated bones. The obstruction may be situated in the post-nasal space, and may take the form of hypertrophied pharyngeal tonsils, tumors, syphilis, or tuberculosis occluding the posterior nares. Hence the recognition and removal of any obstacle to nasal respiration should constitute an integral part of every examination and treatment of the ears. There can be no hope of curing ear affection before the causes which are responsible for the congestion of the mucous membrane have been removed and the permeability of the tube has been restored.

The effects on the lungs of nasal disease may be caused by direct extension of the inflammatory process or by infection in addition to the nasal obstruction or modification of the nasal functions, as in atrophic catarrh, where the volume of air entering the lungs is not interfered with, but the air is not cleansed, nor is it properly heated, nor does it receive the necessary degree of humidity from its passage through the nose. The first of these conditions is apt to cause acute and chronic bronchitis, and at times asthmatic conditions, and tuberculosis. The last mentioned disease is more prone to originate the phthisical or pneumonic conditions. Unfortunately the cases of lung involvement are both frequent and serious in their import. I am confident that in children the larger proportion of lung diseases have their origin in this way. These conditions are not myths, but most serious realities.

In this connection it is necessary to again quote from Friedrich's¹ masterly work:

Diseases of the lungs may owe their origin to direct extension of disease of the upper air passages to the trachea and bronchi. The causes are the same as those we have referred to in discussing the relations existing between diseases of the upper air passages, chronic hypertrophic and chronic atrophic catarrh, and suppurative processes in the nose, in its tributary cavities, and in the postnasal space.

Rose colds and hay fever are not frequent in children, but when they appear are peculiarly severe and very prone to lead to serious involvement of the lungs. Any disease of the nose occasioning frequent paroxysms of sneezing seems to be peculiarly hard on the lung tissues of children. I have observed numerous cases of asthmatic conditions which have had their origin in this way, and the greatest measure of relief has been afforded by care directed to overcoming the primary cause.

Chronic bronchitis is the most frequent of the various sequelæ and proves very obstinate, especially in cases of chronic suppuration in the tributary cavities of the nose, where the pus trickles down from the naso-pharynx into

the deeper air passages and sets up a chronic irritation. The question of the relation between chronic catarrh of the upper and of the deeper air passages has not received the attention it deserves; it is barely mentioned in the most general terms in connection with bronchitis, and the possibility of emphysema; bronchiectasis or fetid bronchitis being due to such causes is usually ignored.

The peculiar connection, often definite, again but suggested, between nasal catarrh and rheumatism may perhaps in part be explained by what has been referred to in this paper, namely, the secondary involvement of the throat in nose affections and the later development of dyspepsia and liver derangement followed by symptoms of general malnutrition, and this gradually gliding into rheumatic disease. Later on in life, even though the catarrhal disease be cured or modified, the rheumatism or malnutrition, or both, may remain and be a constant threat to comfort and safety.

When early in life obstruction or inflammatory disease of the nose is present it often, and in adenoid disease practically always, exerts a marked influence on the nutrition, formation and position of the teeth and the development of the dental arches. Thus are caused inequality in the size and structure of the teeth and the formation of secondary, irregular and contracted arches. These effects are especially observable when the child has been affected in early infancy. Unfortunately this influence unless corrected will very soon leave its impress so deep as to follow the child into adult life, its permanent teeth needing much attention and being the cause of faulty mastication and digestion, as well as of difficult respiration.

In a pamphlet³ published some ten years ago I have referred at more or less length to a number of diseases to which nasal disease gives origin. In several other papers⁴ I have called special attention to the symptoms occasioned by such abnormal growths. In a later pamphlet⁵ I called attention to the influence of nasal disease on the curvature of the cornea through a probable action on the muscles of the eyeballs.

I hope I have been able to give you a few thoughts on the subject which may stimulate to further observations which will, I think, aid in proving the proposition that nasal disease, especially in children, is a not infrequent factor in the causation of disease, and that it modifies many diseases, interferes much with the cure of various affections, and that when carefully handled it is promptly controlled by proper local and general treatment.

TREATMENT.

The first indication for treatment is to avoid the causes of nasal diseases, such as colds, exposures, exhaustion, local mechanical irritation, and anything that tends to keep the general vitality below normal.

All obstructions to the proper inspiration of air must be removed, hyperemia and congestion must be modified and reduced by local treatment and internal medicine. Deviated septi must be straightened, enlarged turbinates must be reduced, hypertrophied tissue must be brought to normal size by operative measures, or other treatment or both. All nose diseases must be treated in

connection with the other diseases of which they may have been the cause. In all cases one should persist in the most perfect and antiseptic cleansing possible. Stimulation of the various tissues must be used when necessary, soothing preparations, however, are more often required. Albolin, cosmolen, glycerin and alkalin solutions are in constant demand. Acids, iodin, nitrate of silver, the electric needle, the snare, even the saw and knife have their uses at times. What to use and when to use it, is a matter of judgment.

Internal Treatment.—We must never neglect thorough antiseptic cleansing of the throat and nose, with a careful preparation and covering of the parts by oils or salves after our local nose work is completed. In addition to this, every case of nose disease demands internal treatment. It may be iron or phosphorus, or even iodin, or it may be a digestant or a nerve tonic or an alkali or a laxative. But the medicine which I believe is needed more than any other is cod liver oil.

Hygiene and Diet.—In addition to the avoidance of the cause, the child should be made to live, so far as possible, a perfect hygienic life. He should retire early, get plenty of sleep; take a sponge bath with friction in the morning on arising, if his vitality admits of it. He should wear proper and sufficient underwear for the season; the underwear should be of pure wool, usually very light weight. I believe linen underwear in our climate is unsuitable for the child. He should not be dressed in too heavy clothes. He should wear stout shoes with rubber overshoes whenever it is wet under foot or where there is snow on the ground. He should not use coffee nor tea; he should drink milk or water, with an occasional change to chocolate or cocoa or lemonade, as necessary. His food should not be predigested, but it should be digestible. He should not drink during the course of the meal. He should go out of doors every day, rain or shine, unless he is sick. He should have a proper variety of work, study and play. He should take his meals with regularity and not be fed too often. He should not be denied sweets and candies on all occasions. A child needs sweet foods, and as long as the stomach does not rebel they are agreeing with him. He should run and race and play with other children.

He should, as a rule, take his hot baths at night, on retiring. Beyond all else, perhaps, he should go to bed early. Children need a great deal of sleep; they can absorb all that is allowed them. By sleeping ten or twelve or more hours they are fitting their bodies not only for the present, but for the strain of adult life, as well. They are storing up energy and nerve force for future emergencies.

TREATMENT OF CHOREA BY PROLONGED WARM BATHS.*

W. C. HOLLOPETER, M.D.
PHILADELPHIA.

In this brief contribution I wish to emphasize the virtues of the prolonged warm bath in shortening the attack of chorea.

With the great increase in the number of adults suffering from nervous diseases, it would be natural to expect an alarming increase of chorea among school children. This, however, is fortunately not corroborated by statistics. We have less chorea to-day than we had

fifty years ago; Watson, writing at that time, analyzed 1,029 cases, against Holt's 146 of to-day. With the population of our cities rapidly increasing, and with this growth the crowding and struggling for higher educational and social preferment, we find the army of neurasthenics markedly augmented among the adult population; and while we have neurotic children, true chorea does not seem to be increasing in the same ratio.

Heredity and environment, the twin jailers of childhood, do not hold their victims securely now that domiciliary hygiene is better appreciated and more widely taught. While we know that few American children of city rearing escape the entanglements of neurotic heredity, we may also state that the very satisfactory advancement made in domiciliary and personal hygiene has neutralized in a great measure the benumbing influence of heredity. The great attention given to our children's comfort and their personal hygiene, in the better classes of society, has done much toward reducing the number of choreic children. The care of the child's teeth; food, and how it is taken; sleep, and its environments; study—all of these influence the development of the child, and all have been greatly improved during the last few years. Much more advanced study, considering the child's age has been demanded—more than is consistent with growing health. The child's intellectual advancement to-day is phenomenal, and this advancement has only been accomplished because of a wider knowledge of hygiene, both personal and domiciliary. Motley and Bancroft graduated from Harvard at 17, but the boys and girls of to-day are competent to cover more ground for their entrance into college than did either Motley or Bancroft at graduation.

Much has been said about pressure in school as a factor in producing nervous conditions. This is also a relative factor. I do not believe that we have so much pressure in our schools as we have poor personal hygiene and home irregularities. The boy who eats rapidly and irregularly of improper food, disregards his teeth and stomach, and the many other personal attentions which are so essential in attaining and maintaining a high standard of health in a growing child, soon lowers his vital resistance, and, in this way makes a bid for chorea, as well as the whole train of acute infectious diseases.

The cramming system in existence in most of our schools has been a favorite subject with many educators. Much can be said on the subject both for and against it, but I think that the cramming takes place more frequently in the stomach than in the brain. Irregular and improper feeding, with careless, exciting home life have more to do with making a nervous child than school life, although the studies be somewhat difficult.

THE RELATION OF RHEUMATISM TO CHOREA.

The relation of chorea to rheumatism is always interesting, because never satisfactorily answered; an equal force of authority being claimed both for and against it. Possibly chorea is a selective action of the rheumatic diplococcus on a nervous system with special predisposition to chorea. It is possible to find rheumatic histories for all our cases of chorea—what parents do not have rheumatism in some form after rearing a family?

REVIEW OF LITERATURE.

The professional drift is undoubtedly in the current leading us to believe that chorea has some youthful resemblance to mature rheumatism. An outline of the literature of the etiology and treatment of chorea will

show that my ideas of hydrotherapy in connection with chorea are not original, but have not been strongly held, therefore no favorable results were secured.

The very interesting discussion on the pathology and treatment of chorea which took place July, 1903, in the British Medical Association, is undoubtedly the most important recent contribution to our knowledge of this very important and interesting disease of childhood. The essence of this discussion was (and the majority of the members were of this opinion) that chorea was a disease of microbial origin—a diplococcus—some relationship existing between it and some previous microbial disease giving us a mixed infection. Drs. Poynton and Pain have isolated a diplococcus from rheumatic cases associated with chorea. A large number of observers have verified in part the results of these investigations.

Dr. E. P. Lees believes that chorea is a disease of the brain. He says concerning the symptomatology of chorea that its most obvious characteristics are disorderly muscular movements which are spasmodic, chronic, irregular, involuntary, and exhibit imperfect control and co-ordination. The muscles which are most affected in chorea are particularly those which are under the most delicate voluntary control, and in view of this fact and of the other attending symptoms, he believes that chorea is unmistakably a disorder of the brain, and particularly of the motor centers. If the cord is involved, it is but rarely, and only occasionally it is observed that the peripheral nerves are also affected.

The value of the routine treatment of rheumatism by the salicylates, in Dr. Lees' opinion, is strong corroborative evidence that the micro-organism is closely related to that of acute articular rheumatism—an English opinion, strictly speaking.

Two very interesting cases which prove but little of what is now taught and believed, and yet suggesting much that is new and interesting, will be sufficient to illustrate my theory. A brief history of each case will tell its own story.

CASE 1.—E., aged 12; the sixth child of German parentage.

Family History.—Father and mother both living and well. Father aged 48, mother 42. Father is a baker, health good; he is a hard worker. He has poor teeth, eats rapidly, has poor digestion, and occasional rheumatic and gouty pains. He has not lost a day from work by reason of sickness for 10 years. Mother is overburdened from childbearing and domestic toil with inefficient help, and may very properly be denominated a neurasthenic, yet performing her usual exacting domestic duties.

History.—The child was sent to school when 6 years old, and after being in school for several weeks commenced to manifest symptoms of chorea; the irregular movements increasing rapidly until every superficial muscle was twitching and jerking. The child could neither stand, walk nor rest. Every joint was sore and inflamed by reason of friction.

Treatment and Result.—She was encased in cotton and bandaged to protect the skin and limit friction. In 12 weeks the violence of the movements subsided and convalescence was established. The child has had six annual attacks, all commencing in the fall (September) and lasting from 3 to 4 months.

At no time did we find fever. This child has no heart lesion, and contrary to the most eminent authority has not been, nor is she at present, anemic.

Remarks.—The child's history is interesting because of the annual attacks and their violence; the duration, the absence of anemia and heart murmur. The last three attacks were materially shortened by prolonged warm baths.

The other case is that of a child whose family have for a long time been my patients.

CASE 2.—The oldest daughter died from heart and kidney sequelæ of scarlet fever. The father is inclined to have rheumatic manifestations, but the mother has unusually good health; even the grandparents possess to a slight degree the stigma of the rheumatic tendency.

History.—F., the second daughter, is the same age as the child mentioned previously. She has had five annual attacks of chorea, commencing each time at the end of her school year, thus showing nerve fatigue and loss of control. The attacks of the two earliest years lasted from three to four months; those of the last three years terminating within six weeks by means of my hydropathic treatment.

Treatment.—This treatment I have found to be eminently satisfactory. The usual detail as to personal wants, food and sleep having been fully observed, I found by accident, that the warm general bath was unusually soothing to the exhausted, twitching muscles. I noticed that after the bath, the child had a longer and more refreshing sleep; a sleep that strengthened and fortified her for the day; so rendering each day more comfortable than the preceding.

TECHNIC OF THE BATH.

The technic of the bath, which constitutes the entire and most satisfactory treatment in my hands, is to place the child in a bath at a temperature that will prove no shock nor surprise to it; a temperature of from 90 to 98 is sufficient, according to individual peculiarities, and cool down so as to be soothing to the whole cutaneous surface. Washing the face before the child is put into the bath is oftentimes advantageous.

The child, when once placed in the bath, is entertained by the nurse or mother by placing some plaything or floating toy in the water, and while the child's attention is so occupied the time will pass rapidly and the attendant's duty will consist in avoiding draughts and in maintaining the temperature of the water sufficiently high (from 90 to 96) so as not to produce any immediate or secondary shock to the child. In this way, the child may be entertained for a long time in the water; the whole body being immersed except the head and neck for at least one or two hours, twice a day. The last ten minutes of the time can be properly devoted to a gentle superficial massage of the arms, legs and trunk; after which the child will be sufficiently weary to take a nap.

I have treated probably 40 or 50 cases by means of the prolonged bath, following this method of procedure with the result of shortening the duration of the attacks from 3 months to 6 weeks.

DISCUSSION.

DR. C. F. WAHRER, Fort Madison, Iowa, said that he was certain that many cases of chorea, so called and so treated, are not chorea at all, in spite of the fact that many physicians think it is easy to diagnose chorea. He mentioned a boy about 8 years old who developed certain anomalous movements of the head; these would be frequently repeated, and terminated usually in a slow rotation of the head, also a slow shrugging of one shoulder. Within a few years these movements ceased, and instead of them he gave vent occasionally to a peculiar expression sounding like "ha-ha." This in turn ceased and gave way to an ear-splitting whistle, of which he was apparently entirely unconscious. Subsequently he developed other peculiar phenomena, such as licking the ends of his fingers, before answering when spoken to. He was treated in the usual manner with arsenic and antirheumatic remedies without any appreciable benefit. He was a very bright boy, distinguishing himself at his studies, and subsequently graduated in medicine and took a postgraduate course. He is now in active practice, and although an able

thinker and fine scholar, he still develops these little peculiarities. At present he frequently gives vent to a dry cough, which is particularly noticeable when his attention is relaxed. He has no heart lesion. Dr. Wahrer never regarded this as a case of chorea, but rather one of tic or habit spasm. Such cases are comparatively common, and the usual treatment for chorea has no effect on them. When the patient's attention is called to these movements he is able to stop them; this is not so in true chorea.

DR. W. C. HOLLOPETER said that by chorea he did not mean the cases of habit spasm to which Dr. Wahrer referred. Some children constantly bite their fingernails or have other forms of habit spasm, but those are not cases of true chorea. Dr. Hollopeter gave small doses of arsenic or iron to some of his patients who were anemic, but in the last series of fifteen cases he withdrew drugs entirely. Every child was examined carefully, and if there was any nasal obstruction, or stomach or intestinal disorder, the defect was corrected so far as possible. Dr. Hollopeter tried the hydropathic treatment as an auxiliary to the rest treatment and found it beneficial, but exceedingly irksome to the patients. Many would not remain in bed, but they had no objection to remaining in the bath, playing with boats and various water toys. He believes also that the water acts as a better support than the bed and is much more comfortable than the bandage sometimes applied to the extremities and exposed parts to prevent friction. In those cases in which a heart lesion existed it was not aggravated by the water treatment.

DOUBLE RADIAL RUPTURE OF THE IRIS.*

S. C. AYRES, M.D.

CINCINNATI.

This case of double radial rupture of the iris is very remarkable and, so far as I have consulted the literature on the subject, there is only one which corresponds to it. In that case, which occurred in the practice of Dr. Büniger,¹ in 1821, the left eye was struck by a chain, causing an artificial pupil which could be distinguished from one made by an operation, only by a band of iris remaining at the ciliary margin. At first, sight was very much impaired, probably from intraocular hemorrhage, but perfect vision was finally regained.

My case is as follows:

History.—G. U., age 10, was first examined Nov. 12, 1902, and gave the following account of the accident: He was struck by a BB shot from an airgun at a distance of about five feet. The shot struck the edge of the lower lid of the left eye at about its anterior third. It embedded itself in the bulbs of the cilie and almost passed through. It was removed at home by squeezing the lid, when it dropped out. I saw the boy five days later and found a well-defined coloboma of the iris as clean and sharply cut as if it had been done by an expert. It was about 4 mm. in width. There was no blood in the anterior chamber, and only a moderate injection of the conjunctiva. Lying in the coloboma was a mass of iris tissue. It was entirely separated from the iris on both sides as well as from its ciliary attachment (Fig. 1). The lens was opaque and vision was reduced to perception of light, probably on account of intraocular hemorrhage. Tension was normal and the eye not painful. In my judgment the posterior lens capsule was ruptured, as there was no evidence of soft lens substance in the anterior chamber at any time. Atropin was ordered.

In the course of time the edges of the coloboma gradually approached each other and the upper and inner portions of

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. I. Randolph.

¹ Graefe and Walther's: *Jour. d. Chir. und Augenheilk.*, vol. II, p. 669.

the iris drew up, leaving a long slit-like scar marked by a gray line of cicatricial tissue (Fig. 2). The iris mass shriveled up and disappeared under the approaching edges of the iris. In three months he was able to count fingers at one foot and at the end of a year could count fingers at three feet. The iris at the end of the scar responds to light and probably an iridectomy made at that point would restore useful vision.

I shall not attempt a review of the literature on this subject, but will only refer to the various papers which have been written.

Dr. E. Franke² reports 13 cases of rupture of the sphincter iridis, including an original one in his own practice. He discusses the mechanism of rupture of the choroid, and gives the opinion of some of the most eminent men on that subject.

Prof. L. Weiss and Dr. W. Klingelhoef³ collected 31 cases of rupture of the iris, including two original ones. They review the literature up to date. Their Case 1 is credited to Stellwag, but it really belongs to Büniger. Stellwag reviewed this case in an article published in 1855, as stated in the paper by Dr. E. Franke.⁴

The 31 cases are arranged chronologically, giving age of patient, name of author, cause of injury, condition of iris and pupil and complications. It is a valuable collection, and one can, at a glance, review this interesting group of accidents.

Fig. 1.—Five days after injury.

Dr. George Levinsohn⁵ of Berlin, in a paper on "Indirect Ruptures of the Iris," reports four new cases. In the first, there were three ruptures of the pigmented pupillary margin; in the second, there was a slight rupture of the pupillary margin and multiple perforations of the iris in the region of the dilator; in the third case, there were multiple slight ruptures of the pigment border; in the fourth case, the iris was atrophic from recurrent attacks of iritis. An iridectomy was attempted, but only small bits of iris could be removed. As a result of the operation, the pupil was drawn upward and the lower portion of the iris near its ciliary margin ruptured, thus giving him a small pupil. The case does not properly belong in the class of traumata as do the others.

Dr. George C. Harlan⁶ reports a case of "Rupture of the Iris at the Pupillary Margin and in Continuity from Contusion of the Eyeball." It is accompanied by an excellent illustration in colors. There was a notch in the temporal border of the iris, which extended to within 3 mm. of its periphery. There were also thirteen serrations in the margin of the pupil, which could be seen in favorable light. The lens was not injured. No iritis followed, and the eye recovered excellent vision. To this case he adds five more, stating that they formed six instances of pupillary rupture, and two of radiating

rupture in the continuity of the iris. These cases are tabulated by Weiss and Klingelhoef.

I find the following new cases which are not mentioned by Weiss and Klingelhoef:

Dr. W. F. Mittendorf⁷ gives in detail a description of a patient who was accidentally struck in the eye by a stone, and, as a result of the injury, had six distinct ruptures of the pupillary border.

Woodward⁷ relates a case of rupture of the pupillary border of the iris extending through one-half its width. There was an accompanying rupture of the choroid, which was in evidence when the intraocular hemorrhage had absorbed. The eye made an excellent recovery, with perfect vision with the aid of + cyl. 0.5.

If, to the cases tabulated by Weiss and Klingelhoef, we add the four reported by Levinsohn and one by Woodward and one by Mittendorf, and my own case, we will have a total of 38 cases.

This probably does not represent all the cases of slight ruptures of the pupillary pigmented border, or of ruptures in continuity, which very easily escape observation. The elasticity of the iris is such that the slight tears readily close and are thus overlooked.

The question as to whether the rupture occurs in the direction of the force or perpendicular to it has been ably discussed by the authors mentioned.

Fig. 2.—One year after injury.

It seems evident that no rule has ever been or probably ever will be formulated which will explain all of these cases. An eye is struck by a fist or by a flying fragment of wood or metal, and one can not tell definitely what part of the eye was most impinged on. The rupture of the iris may occur on the side of the injury or on the opposite side, and this result is governed by laws which are not yet well explained.

In my case there can be no question about the rupture occurring in the direction of the force and not perpendicular to it. The entrance of the pellet of lead into the margin of the lid and the location of the iridectomy coincide exactly. The detached piece of iris was lying in the coloboma plainly visible and could not be mistaken. The gray background of the opaque lens left no room for doubt.

DISCUSSION.

Dr. J. L. Borsch, Philadelphia, stated that several years ago he saw a case of this kind in which the injury was produced by a man throwing a loaf of bread at his wife. The blow caused a subconjunctival luxation of the lens and a complete hyphema and rupture of the iris. He extracted the lens, and the patient made a rapid recovery. When the blood disappeared from the anterior chamber the patient presented the appearance of having been iridectomized. Despite the great traumatism the eye sustained, the patient had normal vision, with a + 13 D. spherical lens.

Dr. G. C. HARLAN, Philadelphia, said that ruptures of the sphincter are found frequently if they are carefully looked for. More rare are ruptures in continuity, radial ruptures. These are very difficult to distinguish because the wound does not gap. They are best seen with the ophthalmoscope with a high power lens. Dr. Harlan has seen two or three such cases.

TWO ADDITIONAL CASES OF SYMPATHECTOMY FOR GLAUCOMA.*

WILBUR B. MARPLE, M.D.

Ophthalmic Surgeon New York Eye and Ear Infirmary.
NEW YORK CITY.

I wish to put on record the following two additional cases of sympathectomy for glaucoma, as it seems very desirable that all cases of this character should be reported so that we may arrive at a proper estimate as to the efficacy of the operation.

CASE 1.—Frank K., aged 65, Bohemian, was first seen June 20, 1903. There was nothing in his previous history, so far as his general health was concerned, which had any special bearing on the present ocular trouble.

History.—He says that four years ago he "caught cold" in the left eye, with severe pain all over that side of his head. Vision failed and in eighteen weeks he was totally blind. In a year or two the left eye began to shrink.

Status Præsens.—Phthisis bulbi. It is not unlikely that the trouble four years ago in the left eye was glaucoma degenerating into glaucoma absolutum. Right eye: Recently the sight began to fail. He saw as through a mist, and the eye became red. The tension is +3, field contracted, measuring above 15 degrees, temporal 45, below 40 degrees, nasal 30. pupil moderately dilated and irresponsive to bright light; shallow anterior chamber; cornea insensitive; marked injection of globe, and pain. Vision was reduced to perception of light. Eserin was instilled several times with the result of contracting the pupil and reducing the tension to normal. He was given a .25 per cent. solution of eserin to use at home every two hours; three days later the condition of the eye was almost normal, and vision was 20/70. When eserin was discontinued the tension returned, so it was evident that an iridectomy or a sympathectomy would have to be done. Had it not been that the patient's other eye was blind, I should not have thought of doing a sympathectomy, for the almost unanimous consensus of opinion of observers is that if sympathectomy is ever indicated it is in cases of chronic glaucoma, not in the acute form of the disease. As he had lost his other eye, however, I felt warranted in making trial of an operation which did not necessitate opening the globe (in which opinion several of my colleagues concurred), although, of course, the possibility of infection after an iridectomy for glaucoma is very remote.

Operation.—On June 30, 1903, the superior cervical sympathetic ganglion was removed by Dr. John F. Erdmann in his usual skillful manner. No pupillary changes were noted at the moment of evulsion, as the eye was under the influence of eserin. The healing was prompt, and *per primam*—but there was some hoarseness for a few days.

Results.—On July 2, forty-eight hours after the operation, the pupil was small and the tension normal without eserin. Ten days after the operation the patient had another attack of acute glaucoma. T. +2, great pain in the eye, all reduced by the regular instillation of eserin. A few days after the operation the field was somewhat increased above and to the nasal side, compared with what it had been before the operation. The patient continued the use of eserin and disappeared.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph.

On Sept. 15, 1903, he was readmitted to the hospital during the service of my colleague, Dr. Weeks, who did an iridectomy on the right eye. At that time he did not have the symptoms of an acute attack, but was entered as a case of chronic glaucoma. His vision has progressively failed and is to-day (May 15, 1904) reduced to the ability to count fingers at one foot. There is a deep glaucomatous excavation and the appearance of advanced atrophy of the optic nerve. The field is somewhat more contracted, especially above and to the nasal side than when taken some months ago. However, the atrophic element is most conspicuous, and his field shows concentric rather than the typical glaucomatous limitation to the nasal side. (Fig. 1.)

Fig. 1.—Right eye.

The contrast can be appreciated by comparing this field with that of the next patient. The importance of taking the fields carefully in these cases, and the significance of a concentric rather than a nasal limitation, has been emphasized, among others, by my colleague Dr. Gruening. That is in a case of chronic glaucoma, when the field is concentrically limited, especially if associated with impairment of color perception, there is, in all probability, a large element of atrophy present and we can consequently expect much less from an iridectomy.

Fig. 2.—Right eye.

CASE 2.—Chronic simple glaucoma. Mrs. D., age 61. United States.

History.—Was first seen Sept. 30, 1903. She had had a wide iridectomy skillfully performed a year and a half ago by Dr. Giles, to whose courtesy I am indebted for information as to the previous history of the patient.

Status Præsens.—Since the operation her vision has progressively diminished and is now in the right eye 20/100; left 10/200—unimproved in each. There is a deep excavation in each optic nerve, and the tension is +1 in each eye. The nasal half of the field (O. D.) is almost entirely gone, as the accompanying chart will show. (Fig. 2.)

Operation.—On Nov. 6, 1903, sympathectomy was done on the right side, again by my friend Dr. John F. Erdmann. The

healing was prompt and *per primum*. Following the operation there was narrowing of the palpebral fissure, with ptosis, also hoarseness, and a choking sensation in the throat as though there was a lump in the throat. The ptosis disappeared, but the hoarseness and choking sensation in the throat continued more or less.

Results.—November 13, one week after operation, with -1 Ds. = +1° Dc. 30, her vision was 20/50, although it seemed to come "in waves," as she expressed it. That is, one moment she would be able to read the letters on the card, and then they would all seem to disappear. The tension of the right eye was distinctly less than that of the left. I saw the patient once or twice more, the last time, Jan. 8, 1904. The hoarseness and feeling of constriction in the throat continued, the tension of the right eye remained apparently normal and less than that of the left. The slight visual improvement continued, she would slowly work her way down to the 20/50 line, stopping occasionally "to rest," as she said; and sometimes having read the letters one moment, she would seem not to be able to do so the next. With +3 Ds added to her distance glasses she could read Jaeger No. 7 at 30 c.m. slowly. The patient always insisted that the sight was worse after the operation than before; it wasn't "so steady."

The sudden death of the patient shortly after my last examination prevented my following the case further, as I should have liked to do. The impression of her family was that her vision was somewhat, though not much, better after the operation.

CONCLUSIONS.

As to the conclusions to be drawn from these cases I have seen where the operation was done (five), I would say:

First.—That it is not indicated in acute inflammatory glaucoma. In a paper on sympathetomy which I had the honor of reading before the New York State Medical Association in 1901, I referred to a case of Mohr's, which bears on this point. The operation of sympathetomy was done and two and a half months afterward the patient had an attack of acute glaucoma, for which an iridectomy was performed. Immediately after the section the iris protruded, followed by all the contents of the globe, with abundant hemorrhage and loss of the eye. In my first case reported to-day, the operation had apparently little effect on the process. In fact, the patient had an acute attack which was controlled by eserine while convalescing from the sympathetomy. Iridectomy likewise did not avail to prevent the progressive loss of sight.

Second.—If the operation is ever indicated, it is in cases of chronic simple glaucoma. In the second case reported by me to-day, and which was of this nature, there was apparently some slight improvement of vision. From a consideration of my own cases and those reported by others, I can not see a very brilliant future for the operation. The best that can be said for it is that it can not do any harm, and possibly may do some good. So long, however, as we have one such brilliant result as that which followed in Dr. C. W. Cutler's case, reported three years ago (this patient's vision is still 20/30 with a telescopic field) we certainly are warranted in suggesting the operation to these otherwise hopeless patients.

46 West Fifty-third Street.

DISCUSSION.

DR. W. H. WILDER, Chicago, referred briefly to some of the cases of this kind that he reported at the last meeting of this section, three of which showed a very favorable result. The most remarkable one, in which the fields were markedly reduced and central vision greatly impaired, was greatly improved after the operation. The fields returned to nearly nor-

mal and this improvement has continued to the present time. The other two cases were too recent at the time of that report to justify any conclusions, but now, although he has not had an opportunity to examine them, he has communicated with them in the last few weeks, and they report that the favorable condition that followed the operation continues. Dr. Wilder inclined to favor sympathetomy in certain cases. He has only had three cases in the past year where he thought that iridectomy offered no chance. The patient had 20/120 central vision, but very greatly contracted fields. After operation, his central vision doubled in a week and the peripheral vision has increased. After operation, this prompt benefit has been observed in certain cases. However, it may be transitory. To give it anything like a fair trial, it should be done early. In other words, it would seem justifiable in these cases of chronic simple glaucoma to first do a sympathetomy and then, if necessary, an iridectomy. Dr. Wilder believes the patient's chances are not jeopardized by this method, and it is only when done in the early stages of the disease that one can hope to get the best results.

DR. JOHN E. WEEKS, New York, stated that he has had some experience with the operation, and finds, in regard to the cases operated on more than one year ago, that in three of the six vision is about the same as when he reported them in New Orleans; that is, the vision has been retained, but in some of these cases there is an acute exacerbation of the glaucoma. He was obliged to perform iridectomy in two cases where it had not been done previously. He agreed with Dr. Wilder that in some cases of simple glaucoma sympathetomy would be permissible before iridectomy, but in the greater number of cases he should only perform it where iridectomy had failed and where sclerotomy had failed, and he might perform iridectomy twice on the same eye before doing a sympathetomy. In addition to the disturbance of the operative procedure, symptoms are apt to be produced which will greatly inconvenience the patient. In regard to performing iridectomy twice, he knew of a case, in the practice of Dr. Gruening, where iridectomy was done four or five times on one eye, and not until nearly all of the iris was removed was there arrest of the process.

DR. W. B. MARPLE said that he did not want to be understood as saying that he would not do a sympathetomy, but only that he did not see any very brilliant future for it; it can not do any harm. He agreed with Dr. Weeks that one should see what iridectomy will do first. He had a case where, after the iridectomy, the patient had a return of acute glaucoma. In one case he did a second iridectomy, immediately after the original one, and after that there was no recurrence of the former trouble. He removed about two-thirds of the iris in that case.

BLASTOMYCOSIS OF THE EYELID.*

WILLIAM H. WILDER, M.D.

Assistant Professor of Ophthalmology, Rush Medical College; Professor of Ophthalmology, Chicago Polyclinic; Surgeon, Illinois Charitable Eye and Ear Infirmary, etc.

CHICAGO.

The condition known as cutaneous blastomycosis which was first described in 1896 by Gilchrist¹ under the name blastomycotic dermatitis, is one that should be of interest to the ophthalmologist, inasmuch as among its favorite sites are the face and the eyelids.

The deformities produced by its action on the skin of these parts may prove to be very serious, and difficult to treat, as illustrated by the case that I shall record.

As stated by Drs. J. Nevins Hyde and Frank H.

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Randolph. Randolph, Randolph, 1. Johns Hopkins Hospital Reports, 1896, vol. 1.

Montgomery,² who have made most valuable contributions to the subject, "the disorder is probably more common than is generally supposed, and possibly has been confounded in the past with verrucous tuberculosis, unusual forms of carcinoma and with atypical manifestations of syphilis."

The following is a report of a case of this interesting disease which for the last six months has been under my care:

Patient.—S. Y., a Lithuanian coal miner of Bureau County, Illinois, 50 years old, came into my service at the Illinois Eye and Ear Infirmary, Nov. 10, 1903. He has lived in this country and state nine years.

Family History.—His father was 60 years old when he died, and the patient states that for the last seven years of his life he had a severe cough, expectorated blood and lost weight. His mother died at the age of 70 years, cause unknown. The patient has two brothers living, one of whom is perfectly healthy, the other has epilepsy. There have been four sisters in the family, one of whom died at the age of 12 years of some acute malady. The other three are well. Patient has no recollection of his grandparents. He is married and his wife is healthy. They have three healthy children. Three of their children died in infancy or early life.

Personal History.—The patient, a man of more than average height and fairly well developed, states that he has always been well, and gives no history of syphilis or tuberculosis. On the back of each hand and wrist, as well as on the sides and back of the neck, are well-marked areas of vitiligo. His present trouble began two years ago with a small red spot in the skin over the right eyebrow, which gradually became thickened, rather warty in appearance and covered by a crust. This patch increased in size and extended upward toward the scalp, and backward on the temple until it involved the skin as far back as the ear. As it advanced there was healing of the part originally affected, a smooth scar being left.

Several months before his entrance to the hospital the disease attacked the upper lid and the outer canthus, and caused extreme ectropion.

Appearance of Lesion.—The appearance on admission was that shown in the photograph (Fig. 1) and was as follows: The diseased area had extended upward for an inch into the hairy scalp, backward to a point nearly above the right ear, forward to the median line, and downward to the zygomatic ridge. The outer half of the right upper lid, the outer canthus and a portion of the lower lid were affected. A separate patch about 2 cm. in diameter was present on the forehead just to the right of the median line and immediately over the supra-orbital ridge. The inferior and posterior borders of the large area were well defined and elevated about one-eighth to one-quarter of an inch above the healthy skin, and sloped down to it. It was of a dark red color, rather warty in appearance and covered in places with a loosely attached crust. The adjacent diseased area presented a roughened papillomatous appearance, with here and there crusts, on the removal of which a seropurulent secretion escaped. Small miliary abscesses were seen in the advancing border of the diseased area, where the process seemed the most active. The central portion of the area described on the forehead and temple was occupied by smooth, glistening, tense but easily movable scar tissue, rather loosely adherent to the tissues beneath, not unlike that left after the healing of lupus erythematosus.

The little patch over the left eyebrow seemed to be a recent focus of infection. It was well defined, with an elevated border, was flat and covered in places with thin crusts. When these were removed there were seen irregular papilliform elevations covered with a glary mucopurulent secretion.

The advancing border of the disease had attacked the outer part of the right upper lid and the outer canthus. It had not quite reached the lid margin, and the conjunctiva, although greatly exposed, was not apparently involved. The contraction of the scar tissue above and to the outer side of the lid caused

an extreme ectropion as shown in the accompanying illustration, so that it was impossible for the patient to close the lids. For this reason the conjunctiva was edematous and suffering from a chronic inflammation. On account of the exposure of the eyeball, an infectious ulcer had started on the cornea that threatened to destroy it, and a hypopyon half filled the anterior chamber.

I suspected that I had to do with a case of cutaneous blastomycosis, and the patient was referred to the clinic of Drs. J. Nevins Hyde and Frank Hugh Montgomery at Rush Medical College, where the diagnosis was made positive by Dr. O. Ormsby finding the characteristic organism from the secretion taken from the miliary abscesses. Cultures of the organism were made on agar. To these gentlemen I am greatly indebted for valuable assistance in the study and treatment of the

Figure 1.

case. He was given a number of x-ray treatments and placed on large doses of iodid of potassium.

Treatment and Result.—The ulceration of the cornea became so threatening that about two weeks after his admission I decided to attempt a plastic operation to relieve the ectropion, although the field was so infected by the disease that I had faint hope of success. The lid was dissected free from the diseased area, the scar was well drawn down, and a large elliptical Wolff graft taken from the arm was planted in the gap. Singularly enough, although it looked for a time as if it would slough, it became attached in almost its whole extent, and greatly relieved the situation for the corneal ulcer rapidly healed and the hypopyon disappeared.

Soon after this the effect of the x-ray treatment and the large doses of potassium iodid, reaching 150 grains, three times a day, began to be felt, and the disease of the skin began to subside.

There was considerable shrinking of the graft, so that a sub

2. THE JOURNAL A. M. A., June 7, 1902.

sequent operation was necessary, and this was done on Dec. 31, 1903. This was only partially successful, for much of the Wolf graft sloughed, but the gap was filled with Thiersch grafts, which grew well.

Later there was contraction that drew the canthus outward and a pedicle flap was taken from the cheek, to restore the canthus, but the tip of this sloughed, and the defect was successfully filled in with Thiersch grafts and with a small Wolf graft.

His present condition is about as shown in the photograph (Fig. 2), but some additional patching will be necessary before the lid is quite satisfactory. The corneal ulcer healed with a scar below the pupil and he has very fair vision, viz., 20/200.

This case is fairly typical of cutaneous blastomycosis, more than 40 cases of which have been observed and recorded. The disease is caused by a peculiar fungus that gains entrance to the skin, and multiplying brings about the lesion and histologic changes that are characteristic of it. This organism seems to be allied to some of the fungi that infect the skin, such as the *oidia*, and Howard F. Ricketts,³ who saw many of the cases of Hyde and Montgomery, has made extended observations and has attempted a classification. In an elaborate article, he arrives at the conclusion that the so-called protozoic disease of Wernicke, Busse's and Curtis' saccharomycosis and Gilchrist's blastomyeetic dermatitis are various manifestations of the same disease. He also concludes that the organisms in these diseases are so closely related morphologically and biologically as to be included in a common genus *oidium*, and he proposes the name *oidiomycosis* as the proper term for the condition caused by such organisms.

SITE AND FREQUENCY.

The disease may affect any region of the body, such as the scalp, the back, breast, thigh, palm of the hand or sole of the foot. The mucous membranes seem to escape, although Montgomery² shows an illustration of a case in which the mucous membrane of the lower lip was affected. The face seems to be the most favorite site, as it was affected in 18 out of 32 cases mentioned by Montgomery, and the eyelids frequently suffer, with resulting ectropion. In a recent article by Dr. Casey Wood⁴ there is reference to nine cases, published and unpublished, in which the lesion involved the skin of the eyelids. In this number Dr. Wood includes one case of his own, and also the present case, notes of which were furnished him, and in none of them had the disease extended to the conjunctiva. More than 40 cases of this disease have been published up to date, and several more are under observation that have not yet been published.

This condition does not seem to be related in any way to tuberculosis or syphilis. In most of the case histories there is no evidence of either syphilitic or tubercular taint. Of the 32 cases studied by Montgomery, only 4 gave a history of tuberculosis, and one died of this two and a half years after the first appearance of tuberculosis. Four cases in which the disease either began as a systemic infection, or in which general infection followed the cutaneous lesion, have been reported—Montgomery,² Walker and Montgomery, "Systematic Infection with Blastomycosis, Autopsy,"⁵ Busse-Buschke,⁶ Ormsby and Miller,⁸ Cleary.⁹

In all of these the autopsy showed numerous lesions, small abscesses in certain of the viscera, lungs, pleura, liver, spleen, kidney and mesentery. The case reported by Ormsby and Miller was especially interesting, in that the cutaneous lesion seemed to follow the systemic infection.

LESION.

The disease usually begins with a small red papule, which soon becomes covered with a crust. It gradually spreads, involving a larger area, and presents the appearance of a flat wart-like growth, elevated to about one-eighth to one-quarter of an inch above the healthy skin. In some cases, as in the present one, there may be several separate foci of infection, and these may coalesce. An interesting case has been recently published by Gilchrist,¹⁰ in which there were multiple lesions on the face and limbs. There were sixteen separate foci of

Figure 2.

infection on the face and neck, none of them, however, involving the eyelids. The surface presents distinct papillary elevations, and depressions that give it a verrucous appearance, and it may be covered with dry crusts. When these are removed there may be some bleeding from the exposed papillae or the surface may be seen covered with a seropurulent secretion. A similar secretion may be pressed out of the depression between the papillary excrescences. The border of the growth is very characteristic. It is rather sharply defined, but slopes to the normal skin. It is dark red, elevated about one-quarter of an inch above the normal skin, and in it are seen numerous very small abscesses, varying in size from those invisible to the unaided eye to those as large as a pinhead. The contents of these military abscesses is a

viscid mucopurulent substance, and in it are usually found the organisms peculiar to the disease. Pure and uncontaminated cultures of the organism may be made by carefully opening one of these abscesses with proper precautions and inoculating a glycerin agar tube with a needle that has been introduced into the fluid from the abscess. As the diseased process extends, healing of the part originally affected may occur, so that one may observe all stages of the disease in same area. The scar that is left is a soft, smooth, rather flexible one, not firmly adherent to the underlying structures. When affecting the eyelid, marked ectropion may follow, as in the present case. After healing is apparently complete, new foci of infection and miliary abscesses may develop in the scar. Histologically, the papillary elevations are seen to be due to marked hyperplasia of the epithelial elements of the skin, and there are seen numerous irregular prolongations and processes of the epithelial layer extend-

Fig. 3.—Marked thickening of the epithelial layer of the skin which extends deeply into the corium. Numerous characteristic miliary abscesses are seen in this layer as well as in the corium. $\times 12$.

ing deeply into the corium, presenting a strong resemblance to epithelioma. Probably it has frequently been mistaken for this in the past. (Fig. 3.) There may be some tendency to the formation of epithelial whorls, but in blastomycosis the basal layer is never broken through and the epithelial elements never take on an independent growth in the subcutaneous structures. There is an infiltration of the corium with leucocytes, connective tissue and plasma cells. The cells of the rete are large, with well-defined prickles. The characteristic miliary abscesses occur in the epithelial prolongation and may also be seen in the corium. As has been said, they vary in size, and may be as large as a pinhead. The microscope shows these to contain leucocytes, epithelial and nuclear detritus, red blood cells and the peculiar organism of the disease. The organisms may also be scattered through

the corium, and the giant cells may contain several of them. They are more or less abundant in some sections, each field showing a number of them, while in other sections they may be difficult to find. In human tissues they appear as spherical, highly refracting bodies, about 10 microns in diameter, with a well-defined capsule, between which and the protoplasmic contents may be seen a prominent zone. The protoplasm is made up of a fine granular substance in which may frequently be seen larger, highly refracting granules, which may be sporules. In the older organism a well-defined vacuole may occasionally be seen. Reproduction takes place by budding, and this process may frequently be seen in the specimens. (Fig. 4.)

DIAGNOSIS.

For purposes of diagnosis, some of the secretion from an abscess may be placed on a slide and potassium hydrate added. This destroys the pus cells, mucus, etc.,

Fig. 4.—One of the miliary abscesses in epithelial layer, showing the structure of the abscess wall, the contents, and the characteristic organism. $\times 350$.

in about ten minutes and leaves the organisms clearly visible. The organism grows on glycerin agar or glucose agar at an ordinary room temperature, the growth showing in from two to eight days. The character of the growth varies in different media, and the individual organisms vary in different cases. In general, the growth presents a fluffy white appearance, or, in older colonies, a roughly granular surface, with elevations and depressions.

On different media the organism sends out mycelia with lateral buds or conidia. For a description of the appearances and the variations of the growth under cultivation, one should consult the various papers on this subject, of which that by Ricketts is one of the best.

PROGNOSIS.

Four fatal cases have been recorded, and of these, one

at least, that of Ormsby, started as a systemic affair. Under appropriate treatment, the diseased process promptly subsides. The deformity produced by the scar may be considerable, if such a part as the eyelid is affected, and the resulting ectropion may be disastrous to the eye unless the position of the lid is restored.

TREATMENT.

If the lesion is small, the diseased part may be thoroughly curetted or excised. Large doses of potassium iodid, as first pointed out by Bevan, produce a marked beneficial effect on the lesion, and cases are cured by this means. The dosage should be large, as much as 300 or 400 grains daily being given. The present case took regularly for some time 450 grains a day. This treatment should be supplemented by the use of the x-ray, especially if, after discontinuing the treatment by the iodids, there should be any signs of a return of the disease.

In the case of the lid being affected, the resulting ectropion must be corrected by a plastic operation. Naturally, one would not operate in the region affected by such a disease unless compelled to do so, but that it is not impossible to successfully perform a plastic operation for the restoration of the lids in such a field is demonstrated by the present case, where relief of the ectropion was imperative.

I wish to express to Dr. J. Nevins Hyde and Dr. Frank H. Montgomery my thanks for the privilege of exhibiting illustrations of many of their cases; and I am also indebted to Dr. E. V. L. Brown, pathologist of the Illinois Eye and Ear Infirmary, for the preparation of the histologic specimens of this case.

103 State Street.

DISCUSSION.

Dr. W. A. Pursey, Chicago, said that without knowing the actual statistics of the subject he should say that at least 50 per cent. of the cases show lesions on the lower lids, and that in most of these cases the lesion on the lower lid has been the primary lesion. In the nine cases of blastomycosis which have come under his care, six showed lesions on the lower lid, and in three of these only the lower lid was involved. As first seen, the lesion on the lid shows a papillary, warty growth, without distortiⁿ, but later there develops an ectropion which produces a very characteristic picture. Dr. Pursey emphasized the pathognomonic importance of the small miliary abscesses which are found in the borders of the lesions. These may be so minute as to be visible only under a hand lens, but they are characteristic and should be sought, and from them can be obtained frequently pure cultures of the organisms. This condition is usually due to a group of fungi similar to the yeast fungi, but whether it is due to a single organism or may be produced by several varieties, is yet undetermined. There has been an attempt recently to differentiate from these blastomycosis cases a group of cases which are supposed to be due to coccidia. He thinks that there can be little doubt that the differentiation has not been thus far demonstrated. As proof of the pathogenic relation of these organisms to the condition, granulomatous tumors have been produced in guinea-pigs and pure cultures obtained after death from these. It must be borne in mind that this condition is not entirely confined to the skin and that there is the danger of the development of general blastomycotic infection resulting in the death of the patients; a phenomenon which has been observed in several cases. A point of peculiar interest in connection with this disease is its relative frequency in certain localities. Since it was first described by Gilchrist a large percentage of the cases on record have been reported from Chicago; about 30 per cent. The condition has not yet been seen in New York or Boston, and only one case in Great Britain. In explanation of its peculiar frequency in Chicago and the contiguous territory, ef-

forts have been made to discover some relationship of the disease to certain occupations, as the handling of grain, farming, particularly the handling of manure, but thus far facts do not throw any light on this subject.

Dr. E. C. ELLETT, Memphis, showed a slide from what he supposed to be blastomycosis of the nose and asked Dr. Pursey's opinion of it.

Dr. PURSEY said that it certainly looked very much like it. Dr. ELLETT said that it seemed probable that that is what this case was. It was a recurrent nasal tumor. The first appearance was on the anterior extremity of the inferior turbinate body. The growth, then, was not examined. About a year and a half later the patient came under his observation again and he found a papillomatous looking growth on the anterior end of the inferior turbinate and a small growth further back on the inferior turbinate and a third projecting from the septum, looking like a spur. These three tumors were removed. He has not been able to see or hear from the patient again. No cultures were made, because it was thought to be a benign nasal tumor. The patient was a young white man, aged 17.

Dr. W. H. WILDER, Chicago, stated that the prognosis in these cases is good unless there is systemic infection. The disease seems to yield promptly to radiations of the x-ray combined with potassium iodid in very large doses. This case took 450 grs. a day for weeks. After several weeks the condition improved and now there are no active points of infection, for a test recently made was negative so far as the discovery of any of the organisms was concerned. The potassium iodid treatment was first suggested by Dr. Bevan of Chicago.

SUBJECTIVE REFRACTION.*

JOHN A. TENNEY, M.D.
BOSTON.

I call attention to the power of the pinhole disc found in trial cases in the examination of the eye. All are familiar with its use in detecting myopia and high degrees of hyperopia; and it is well known that if there is light enough and the opening of the screen is small enough, there would be no need of lenses in any condition of refraction, at any age. The pinhole disc does its work by lessening the diffusion circles on the retina; and too small an opening in a retinoscope or ophthalmoscope is a disadvantage because its masks errors of refraction.

In Foster's "Text-Book of Physiology" we find it stated that if the pinhole disc is held before the eye and moved laterally, the experimenter looking toward the bright sky, the retinal capillaries may be seen, looking like a cobweb. The vessels at right angles to the motion are best seen. If the disc is held at the right distance from the eye, one can see the image of the crystalline lens.

Dr. Gould, at the session of this Association in Denver in 1898, exhibited an instrument that he called the "Funduscope," which caused a small opening to revolve before the eye within the width of the pupil, and by means of which the retinal vessels could be seen in all directions alike.

Czermak pointed out the fact that if two screens are held before the eye toward the light, and the one in front is moved laterally, it will appear to move in the same direction that it actually does move; but if the one next to the eye is moved in the same way, the one in front will seem to move in the opposite direction. This is easily explained. The pinhole in the anterior screen is practically the source of light; its image

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Ophthalmology, and approved for publication by the Executive Committee: Drs. Frank Allport, John E. Weeks and R. L. Ranolph.

moves on the retina in the same direction that the posterior disc is moved; hence it is projected in the contrary direction. All ophthalmologists know that the nasal side of the retina sees toward the temporal side, and the temporal retina sees toward the nasal side.

If a convex lens is moved laterally before the eye, objects seen through it seem to move in a contrary direction to the motion of the lens; but if the lens is held still, and the head is moved, the same objects appear to move with the lens. In the first instance, the image moving on the retina with the motion of the lens, is projected in a contrary direction, as has already been explained; and in the second instance, where the lens is held still and the head is moved, the image seen through the lens moves in a contrary direction on the retina, hence it is projected in the same direction with the motion. Exactly the opposite phenomena are observed when a concave lens is used.

Very little literature has been produced within a

Figure 1.

century concerning the diffusion circles on the retina. Tscherning states, what is manifestly true, that in myopia and hyperopia every point of an object must appear on the retina as a circle or a part of a circle, and these circles overlap each other. In hyperopia the light is most intense at the outside of the circle, in myopia the intensity is greatest in the center. The resulting cones of light in myopia project forward toward the point of reversal in the vitreous.

If we take the pinhole disc, or what answers the same purpose, if we perforate a card with a pin and hold it close to the eye, the state of refraction in the eye is accurately and quickly told by moving the screen laterally. In hyperopia objects will appear to move against the motion of the card; in myopia, they will move with the card; and it is evident that there is a point between where there will be no motion, and that condition is emmetropia.

Figure 2.

In Czermak's experiment the eye is hyperopic for the anterior screen, if it is held nearer to the eye than its near point. The image seen moves with the posterior disc on the retina as far laterally as the width of the diffusion circle would be if light entered the eye the full size of the pupil. The projection is always in the direction contrary to the motion of the image on the retina. As might be expected, the motion of the image on the retina in myopia being contrary to that of the disc, it is projected in the same direction, and appears to move with it.

A schematic representation of what occurs in hyperopia is shown in Figure 1, the passage of light being shown by the arrows. Figure 2 shows how the light enters and leaves the eye in myopia. The small circles represent the motion of the disc from side to side.

As a matter of course, in simple hyperopic astigmatism, there will be no motion observed along the meridian of greater curvature, but at right angles to this the motion will be contrary. In simple myopic astigmatism there will be no motion in the meridian of lesser curvature; in the other meridian the motion will correspond to that of the disc. In mixed astigmatism in the myopic meridian the motion will be with the movement of the disc; in the other it will be contrary.

It will be seen that in all these anomalies of refraction, the motion of objects seen through the disc will be precisely the same as that seen when the lens that corrects the defect is moved before the eye in the same way and at the same rate; and as those familiar with lenses seldom find it necessary to neutralize them in order to tell their power, so the motion of the pinhole disc will reveal to the initiated his error of refraction.

I find in my own case that if the disc is moved before my right eye in the direction corresponding to the meridian marked 60 degrees on the trial frame, I see no motion. At right angles to this the motion is against the movement of the disc, and at the rate of that of a cylinder of half a diopter. In the left eye I find no motion in the meridian of 150 degrees, but at right angles to this the rate of motion is the same as that of a plus cylinder of half a diopter. The test is a delicate one, turning in a marked degree at a quarter of a diopter. It is understood that in all these experiments the accommodation must be at rest.

DISCUSSION.

DR. G. C. SAVAGE, Nashville, Tenn.—Dr. Tenney has given us the simplest and most accurate subjective test for refraction that we have. He wrote me some time ago to ask if I thought the idea any good and if it were new. I tried it and replied that so far as I knew it was new, and it certainly was good. In my own case it works out well. Nothing could be more accurate than the test. The judgment of direction and motion is a gift, therefore the ignorant can give as correct answers in this test as can the educated.

DR. M. BLACK, Denver—How far before the eye do you hold the disc, or does that make any difference?

DR. TENNEY—I hold the disc very close to the eye, just as close as I can. The patients certainly respond very readily to the test.

THE EFFECT OF PILOCARPIN HYDROCHLORATE IN STRYCHNIN POISONING.

S. J. MELTZER, M.D.,

AND

W. SALANT, M. D.,

Fellow of the Rockefeller Institute.

(From the Rockefeller Institute for Medical Research.)

NEW YORK CITY.

A case has recently been described under the title: "A New Remedy for Strychnin Poisoning;" hypodermic injections of pilocarpin were given and the patient recovered. The case was as follows:

A child of two and a half years was found with "a bottle of strychnin to his mouth and the contents being emptied into it." The mouth was cleaned out by the mother and the physician who arrived one hour later administered first morphin hypodermically which brought on vomiting, and later washed out the stomach. He gave further internally tannic acid and chloral, the latter until there was profound narcosis. Nevertheless, the convulsions became stronger and were coming every two minutes. As a "last resort" he gave pilocarpin hydrochlorate, 1/24 of a grain hypodermically and repeated the dose after eighteen minutes. The skin became moist and saliva

was flowing out of the mouth. The convulsions became lighter, occurred less frequently and after an hour subsided completely.

The reporter of this case is apparently not in doubt that the recovery was due to the administration of pilocarpin.

We became interested in this case, as we had ourselves planned to test the effect of pilocarpin on strychnin poisoning—for the following reason: In our studies on nephrectomized rabbits,² we found that in animals thus deprived of their chief eliminating organs, sub-minimum doses of the poison, if given at proper intervals, never accumulate in the blood to a dose sufficient to bring on a convulsion. We then thought that perhaps after the removal of the kidneys other organs might assume the task of eliminating the poison from the body. A study of the intestinal contents of such animals brought, however, no satisfactory results. We had therefore in mind to test also the saliva of such animals, especially as there is a statement on record that even in normal animals the salivary glands eliminate strychnin, and it was our plan to increase the salivation by the administration of pilocarpin.

However, the increased salivation in the above mentioned case was apparently not of a very unusual character, and if the recovery was indeed due to the administration of pilocarpin, it was probably not simply on account of the elimination of the strychnin through the increased salivation. The effect, if there was any, must have been brought about by a neutralization of the strychnin in the spinal cord—or some other yet unknown manner.

It became necessary first of all to establish the facts. We have therefore carried out a series of experiments on frogs and rabbits, in which the effects of the administration of pilocarpin on strychnin poisoning were studied. We shall illustrate the results we have obtained by a few abbreviated reports of some of our experiments.

Experiment 1.—Two small frogs. Frog 1 (control) received in the dorsal lymph sac 0.02 mg. strychnin; had hyperesthesia but no convulsions.

Frog 2 received in the dorsal lymph sac 0.02 mg. strychnin nitrate and in the ventral lymph sac 0.01 gm. pilocarpin hydrochlorate; had convulsions after 12 minutes.

A subminimum dose of strychnin became an effective toxic minimum through the addition of pilocarpin.

Experiment 2.—Two medium sized frogs. Frog 1 (control) received in the dorsal lymph sac 0.03 mg. strychnin nitrate; convulsions after 24 minutes.

Frog 2 received in the dorsal lymph sac 0.03 mg. strychnin nitrate and in the ventral lymph sac 0.01 gm. pilocarpin; convulsions after 14 minutes.

The pilocarpin animal had the convulsion 10 minutes earlier than the control.

Experiment 3.—Two large frogs. Frog 1 (control) received in the dorsal lymph sac 0.04 mg. strychnin nitrate; convulsions after one hour.

Frog 2 received in the dorsal lymph sac 0.04 mg. strychnin nitrate and in the ventral lymph sac 0.01 gm. pilocarpin; convulsions after 45 minutes.

The pilocarpin animal was a little larger than the control, but had the convulsions nevertheless, 15 minutes ahead of it.

In all these experiments the pilocarpin animals died, while the controls survived the convulsions.

The following illustrations are taken from experiments in which strychnin sulphate was employed, of which somewhat larger doses are required to bring on a convulsion than of the nitrate:

Experiment 4.—Two medium sized frogs. Frog 1 (control) received in the dorsal lymph sac 0.04 mg. strychnin sulphate; convulsions after two hours.

Frog 2 received in the dorsal lymph sac 0.04 mg. strychnin sulphate and in the ventral lymph sac 0.01 gm. pilocarpin; convulsions after 45 minutes. Both survived.

The pilocarpin animal had convulsions 75 minutes before the control.

Experiment 5.—Two medium sized frogs. Frog 1 (control), larger one of the two, received in the dorsal lymph sac 0.05 mg. strychnin sulphate; after a good deal of handling had a convulsion 47 minutes after injection.

Frog 2 received in the dorsal lymph sac 0.05 mg. strychnin sulphate and in the ventral lymph sac 0.01 gm. pilocarpin; first convulsion, 17 minutes after injection; did not recover.

Pilocarpin animal, though smaller, with the same dose of strychnin sulphate, had the convulsion 30 minutes before the control.

We should also mention the following experiments:

Experiment 6.—Several frogs of different sizes received injections of 0.01 gm. pilocarpin; no noticeable effect.

In all the experiments on frogs the additional injection of pilocarpin unmistakably increased the poisonous effect of strychnin. Either an ineffective dose of strychnin became effective, or the convulsion appeared earlier and the animals did not survive the attacks.

The following are abbreviated reports of a few experiments on rabbits:

Experiment 7.—Rabbit 1 (control), white, male, 1500 grams. Injected 0.45 mg. strychnin nitrate per kilo; remained under observation 75 minutes; no effect.

Rabbit 2, white, male, 1400 grams. Injected subcutaneously 0.45 mg. strychnin nitrate per kilo; also 4 mg. pilocarpin hydrochlorate. Had a violent convulsion 33 minutes after injection. Later had another fit of convulsions. Two hours and forty minutes after injection animal was found dead.

A dose of strychnin which was not even toxic for the control, was fatal for the pilocarpin animal.

Experiment 8.—Rabbit 1 (control), white, male, 1400 grams. Received an injection of 0.55 mg. strychnin sulphate per kilo; some hyperesthesia; no convulsions.

Rabbit 2, white, female, 1000 grams. Received 0.55 mg. strychnin sulphate per kilo, and 0.01 gm. pilocarpin. Fifteen minutes after the injection the animal had a violent convulsion and died.

Here again a dose of strychnin sulphate which caused only hyperesthesia in the control, brought convulsions and death to the animal which received in addition pilocarpin.

Experiment 9.—Rabbit 1 (control), gray, male, 1585 grams. Received 0.5 mg. strychnin sulphate per kilo; hyperesthesia but no convulsions.

Rabbit 2, black, female, 1175 grams. Injected subcutaneously 0.5 mg. strychnin sulphate per kilo, and two minutes later injected 0.01 gm. pilocarpin. Thirty-eight minutes later the animal had a violent convulsion and died.

In this experiment, with a trifle smaller dose of strychnin than in the foregoing one, and with animals (gray and black) which are a little less susceptible than those of the previous experiments (whites), the addition of pilocarpin again brought a fatal convulsion, while the control was hardly affected at all.

Experiment 10.—In a few animals the injection of 5 mg. and more of pilocarpin brought on copious salivation, diarrhea, etc., but there were no signs of convulsions or even hyperesthesia.

The hypothesis that a drug which, when given simultaneously with strychnin, aggravates distinctly its toxic effect might work, nevertheless, as an antidote to strychnin if administered later, is not sound enough to justify a prolonged series of experiments to disprove it. Two such experiments, however, were made:

Experiment 11.—Two frogs of the same size received 0.03 mg. strychnin nitrate such. Half an hour later both had con-

² S. J. Meltzer and W. Salant, Jour. of Exper. Med., vol. vi, p. 107, 1901.

convulsions. One frog was given 0.01 gm. pilocarpin and died after an hour; the other was alive and normal next day.

Experiment 2.—Two frogs of the same size, but larger than those in the previous experiment, received 0.03 mg. strychnin nitrate each. Forty minutes later neither had convulsions. One frog received 0.01 gm. pilocarpin. Five minutes later it had convulsions and was found dead next morning; the other had no convulsions and lived.

The foregoing experiments are sufficient to demonstrate the following two points: 1. Pilocarpin hydrochlorate does not act as an antidote to strychnin. 2. On the contrary, the addition of pilocarpin apparently supports the poisonous effect of strychnin, by its aid an ineffective subminimum dose may have a toxic or even fatal effect.

These are the conclusions we arrived at by our experimentation on two species of animals. What are we to think of the effect of injections of pilocarpin in strychnin poisoning in human beings? We are aware that conditions vary from species to species, and that what is harmful to rabbits and frogs might still be harmless or even useful to human beings. But until we have proofs of such deviations we have to be guided in our therapeutic efforts by the results we have obtained from animal experimentation. Surely we have to consider that as harmful to man which is found to be harmful to beasts until the contrary is proved. In other words, since the experiments on animals have demonstrated that pilocarpin increases the toxicity of strychnin, we are in duty bound to avoid the administration of pilocarpin in cases of strychnin poisoning in human beings, unless by many accidents a number of facts will be accumulated showing unmistakably that in this regard the human being behaves differently than the animals experimented on, i. e., that here the addition of pilocarpin does not increase but reduces the toxicity of strychnin.

Is the above quoted case such a fact, i. e., did the child really recover chiefly on account of the injection of pilocarpin which it received? We do not think so. We rather believe that the patient probably recovered not because it received pilocarpin but in spite of it. It was simply a case in which strychnin had a strong toxic but not a fatal effect. We do not know how much of the strychnin the child swallowed. Possibly it was altogether only a small dose; the immediate cleaning of the mouth by the mother and the washing of the stomach by the physician assisted in reducing the dose from a fatal to only a toxic one. It is possible that the profound narcosis produced by the liberal use of chloral contributed to the favorable outcome, not with the aid but in spite of the pilocarpin. In animals we have seen numerous cases of strychnin poisoning which without any treatment survived violent convulsions lasting many hours. The toxicologic literature contains reports of cases in which recovery took place after very large doses of strychnin—more than ten times the fatal dose. We have therefore no good reason to believe that the child recovered from the strychnin poisoning because it received pilocarpin. On the contrary, on the basis of our results, we have reason to say that it recovered in spite of the injections of pilocarpin.

Before we conclude, however, it seems to us to be a moral duty to call attention to one point. The recorder of that case says: "As a last resort I gave pilocarpin." etc. What authority did he have to consider pilocarpin a "last resort" in such a case? In looking over some toxicologic literature we failed to find it anywhere mentioned as a possible antidote for strychnin poisoning.

Pilocarpin is a poison and some authors state that in some cases it can even cause convulsions like brucin, nicotin, etc. If that child would have finally succumbed to the poisoning, in the face of our experimental results, we would have had no means to prove that the injection of pilocarpin did not have a share in the fatal outcome. Why do physicians forget the supreme law: first of all not to do harm? Physicians carry with them numerous alkaloids for use in cases of emergency. Their minds ought to be impressed by this obvious rule: On human beings each alkaloid should be employed only according to well established indications for its use and not according to theoretical notions. Well founded theoretical notions can and ought to be tested on animals.

IDIOPATHIC GANGRENE IN THE YOUNG.

M. L. STEVENS, M.D.
ASHEVILLE, N. C.

The following case, I believe, is of sufficient interest to merit a place in the literature of gangrene:

Patient.—Elizabeth W., age 13, farmer's daughter; parents in good health. Personal history good. In appearance is tall but undeveloped.

History.—March 6, patient walked to my office, one and one-half miles, to consult me in regard to her left foot, which for two days had been painful and slightly swollen. A diagnosis of rheumatism was made. Three days later the soreness and swelling had extended above the ankle and she was unable to walk. There was some malaise. Pulse, 100; temperature, 99.5. Her condition grew worse from day to day, the soreness and slight swelling gradually extending up the leg, the soreness being more marked posteriorly along the course of the large blood vessels and the pain usually deep-seated and of a burning character. The foot was never found hot to the touch; on the contrary, it was always cooler than the rest of the body. Evidence of endarteritis and thrombosis of the nutrient arteries became more conclusive each day. The heart was normal.

March 17. Pain and soreness began in great toe of right foot and gradually extended as they had done in the left. The condition of the patient grew steadily worse as the disease continued to advance up both legs toward the body. Temperature at this time seldom exceeded 101. Pulse 110 to 120.

March 24. A small blue-black spot of moist gangrene appeared on the inner side of the great toe and another the size of a half-dollar on the inner side of the instep of the foot first affected. The urine was free from sugar. At this time the soreness had extended along the popliteal and femoral artery to the groin and the swelling above the knee on the left side. On the right the foot and leg were involved to the knee and the soreness extended along the course of the popliteal above. The gangrenous spots gradually extended by continuity and by the appearance of new spots higher, which later coalesced, the extension being most rapid posteriorly in the parts which received pressure from the bed.

April 1. The gangrenous process began in the right foot and extended in a similar way. Notwithstanding efforts to prevent it, decomposition of some of the dead tissue took place. Lines of demarcation were established in a few places, but spots of gangrene were always present above them. During this stage of the disease the temperature ran from 101 to 103. Muttering delirium was present, and death occurred April 14, on the forty-first day of disease. At this time the gangrenous process involved the entire left foot and about half of the leg below the knee, and the right foot and part of the ankle. No autopsy.

Remarks.—It is at once apparent that this case can not be classed among the more common forms of gangrene. The age of the patient and the absence of evidence of sclerosis of the vessels in the other parts of the body exclude it from the angiosclerotic cases. The trau-

matic, the spreading traumatic and hospital forms of the disease must be excluded because of the absence of traumatism affecting the blood supply or serving as an infection atrium.

To the symmetrical gangrene of Raynaud and to Morvan's disease it bears no close resemblance; nor was it the effect of any destructive agent which might act directly on the cells of the tissues, as chemicals, heat, cold, electricity, etc. There was no previous history nor present evidence of any of those diseases which predispose to gangrene, as diabetes mellitus.

The gangrenous process in this case was clearly the result of thrombosis of the arteries supplying the parts, apparently accompanied and probably preceded by an endarteritis. The specific first cause of the trouble is not known. A careful search of such literature as has been accessible to me brings to light nine cases which have been reported as idiopathic or spontaneous gangrene.

Of these, one¹ was in a diabetic. Recovery.

One² was in a patient 79 years of age. Autopsy showed atheromatous degeneration, vessels of leg and thigh plugged with coagula and a dissecting aneurism of the left iliac artery.

One³ had agoneurotic symptoms (coldness and numbness of two fingers) for three years previous to the attack, and later paresthesia of the lower extremities, also previous to the attack. Amputation of part affected. Death. Pathology, thrombosis.

One⁴ was preceded by paralysis in the upper extremities and the gangrene confined to a small area around the patella. Age of patient, 52. Pathology, not clear.

One⁵ was in a patient 62 years of age. Death in eight days. Autopsy showed cardiac hypertrophy and an abscess of the heart opening in the left ventricle. To these five the name idiopathic gangrene can not be properly applied.

Of the remaining four cases, one⁶ was in a patient 33 years of age and three⁷ were in the insane. Of these last three, two were the result of thrombosis of the chief arteries and one the result of embolism.

In none of the cases herein cited did the disease occur in one so young as the patient whose case-history is herein contributed.

THE RESISTANCE OF THE PERITONEUM. ILLUSTRATIVE CASE.

CHESTER M. ECHOLS, M.D.
APPLETON, WIS.

A patient's liability to septic peritonitis following abdominal section or wounds involving the peritoneum depends manifestly on two factors: First, the virulence and number of the micro-organisms introduced, and, second, the vital resistance of the individual patient.

Concerning the first of these factors volumes have been written; as to the second, however, there is a singular paucity of references in the literature of surgery. To emphasize the rôle of the individual resistance of the patient in preventing or favoring peritonitis is the motive of this article. I consulted several systems of surgery

without finding any mention of the varying susceptibility of different patients to post-operative peritonitis. H. A. Kelly, however, gives recognition to the importance of the patient's condition in the following language:

"The more we learn of infectious processes the more we are convinced that the vital resistance of the patient plays an important, if not the greatest, part in the resistance to infection.

"If a patient is much depressed physically and is subjected to an abdominal operation in which there is extensive traumatism to the peritoneum attended by considerable oozing, the chances for a serious infection are much increased. To the individual factor of vital resistance are undoubtedly ascribable many of the discrepancies as to the apparently varying degrees of virulence of the same infection when under precisely the same conditions one patient will be infected and another escape. The gravity of the infectious process will, in a given instance, depend on the degree of absence of resistance to infection in the individual, the nature of the operation, the perfection of the technic employed, and the virulence of the entering micro-organism."

The following interesting case illustrates the remarkable resisting power of the peritoneum in certain healthy patients:

Patient.—J. D., a man aged 25, of fine physique and in rugged health, a professional burglar by occupation, was brought by the Chicago police to the Cook County Hospital with a bullet wound in his back.

History.—The following history was obtained from the police: About 6 p. m. on the preceding day, while burglarizing a house, the patient was shot from behind with a 38-caliber revolver. He made his escape, but was captured the following morning and brought to the hospital about seventeen hours after being shot.

Examination.—Examination showed the patient to be a strong, well-developed young man; he was pale, but otherwise showed no signs of severe shock. There was a bullet wound an inch above the crest of the right ileum and four inches from the spines of the lumbar vertebrae. Anteriorly the bullet could be felt in the abdominal wall of the epigastrium an inch to the left of the median line. The whole abdomen was tense and slightly tender to pressure.

Operation.—Immediate laparotomy was done by Dr. Owsley and myself: the peritoneal cavity was filled with intestinal and gastric contents and partially clotted blood. The bullet was found to have passed upward, forward and to the left, penetrating the small intestine twice, both walls of the stomach, and the margin of the left lobe of the liver. The small intestines were covered with flakes of fibrin. The intestinal and stomach perforations were all closed with Lembert sutures, and the peritoneal cavity irrigated with several gallons of warm salt solution. The incision was closed with figure-eight silkworm-gut sutures without drainage.

Result.—To our surprise the patient made an uneventful recovery—at any rate for the first nine days—his temperature never having gone above 100 degrees.

As the patient was a criminal with a police court record, an officer was detailed to sit on guard by his bedside day and night. On the night of the ninth day (the abdominal sutures were not yet removed), the patient, clad only in a short hospital shirt, jumped through the window, climbed the high fence and escaped, much to the chagrin of the policeman. Six weeks later I read in the *Chicago Tribune* that the fugitive had been recaptured, "still a little weakened from his operation."

This case is of unusual interest because laparotomy was not done till more than seventeen hours after the shooting and the gastrointestinal contents were spread diffusely through the abdomen. Yet the patient's extraordinary vitality enabled him to recover promptly

with no symptoms of peritonitis and a minimum amount of shock.

Since the adoption of the small caliber, high velocity steel bullet by the armies of the world, military surgeons have been astonished at the large proportion of soldiers who have recovered without operation from penetrating bullet wounds of the abdomen. This does not imply that the intestines escape injury, or that no infective material is carried into the peritoneal cavity. It is possible, and even probable, that many a fatal typhoid perforation is no larger than some of these bullet wounds from which so many soldiers promptly recover. Why, then, such a different prognosis? Chiefly because bacteria find so much more favorable a soil on the peritoneum of a weakened, moribund typhoid patient than in the belly of a hard-muscled, weather-seasoned soldier.

As a further illustration of the resistance of healthy, able-bodied soldiers may be mentioned an experience of an English army surgeon. After one of the battles of the Transvaal war he found a Boer soldier with a large lacerated wound of the abdominal wall, through which several feet of intestines had escaped and were covered with debris and dirt. He hastily performed an intestinal resection, washed off the exposed viscera with plain water and closed the wound. The patient made an uneventful recovery.

Since the beginning of what may be called the era of abdominal surgery the resistance to peritonitis of patients operated on has encouraged the propagation of many fallacious theories of asepsis and operative technic. The older and middle-aged surgeons remember well the time when it was a common practice to saturate all gauze and sponges with strong antiseptics (bichlorid or carbolic acid solution), before introducing them into the abdominal cavity in the course of a laparotomy. The survival of the patients in spite of the treatment has been adduced as an argument in favor of this or that procedure. Nor has the time passed when this vital resistance of the patient gives rise to erroneous ideas as to the perfection of the technic employed. Slovenly methods are certainly encouraged and perpetuated among certain operators because their results in a limited number of cases are apparently just as good as those of the most pedantic "rubber-gloved" surgeon. Many an amateur surgeon has complimented himself on his skill after the recovery of his patient from an appendectomy when in fact the technic employed should have revoked his license to practice. I know of a surgeon of considerable local reputation in a city of the middle west, who scouts at the "germ theory" of peritonitis, or at least professes to do so, and to demonstrate his convictions never uses any antiseptics whatever, either on his hands or in the preparation of the patient for operation. He enjoys a rather large surgical practice and his results are surprisingly good. Such extreme instances as this are always puzzling to the medical student and the newly graduated physician, whose ideas of the imperative necessity of asepsis and antiseptics are given a rude shock by this apparent immunity of certain patients to septic peritonitis.

With respect to these phenomena we should bear in mind: 1. That the peritoneum is by far the most extensive and complicated of the serous membranes; that it is capable of absorbing a large quantity of liquids in a short time; that it can in some patients resist the invasion of large numbers of pyogenic bacteria and withstand considerable handling and trauma with apparent impunity. 2. That a low mortality rate, in any limited series of laparotomies, is not to be construed as demon-

strating the operator's superior technic and careful asepsis. The patient's vital resistance may be, and perhaps is, after all, the chief factor in determining whether or not septic peritonitis will follow these operations.

Clinical Note.

AN INDIGENOUS CASE OF TUBERCULAR LEPROSY.*

OLIVER S. ORMSBY, M.D.
CHICAGO.

Introduction.—As it is uncommon for leprosy to originate in any part of the United States except Louisiana, any cases occurring elsewhere are of interest. There are only a few such on record. I am indebted to Dr. A. U. Williams, Hot Springs, Ark., for referring this case to me.

Patient.—The subject of this report was born in Iowa, of Norwegian parentage, is 27 years of age, and has always resided either in Iowa or in Nebraska.

Family History.—His father was born in Norway and came to this country while a boy, perhaps under 10 years of age. His mother was also born in Norway and was brought to America when three weeks old. The patient has one brother, aged 23, perfectly healthy. He has had four sisters, two of whom are dead. One died at the age of 18, twelve years ago.

Fig. 1.—Photograph showing the thickened tuberculated brow and the tubercles on nose, face and ear.

the cause of death being unknown. Another died last February of what he says physicians called erysipelas, aged 25. She had been ill for ten years. The patient says she complained of burning and pressure symptoms in the limbs, which were badly swollen and were covered with lumps. Her face, he says, looked as though she had smallpox, the eyebrows were gone, and she suffered at times with fever and chills, but had no cough. The patient has one living sister, aged 32, healthy except that she exhibits facial "pimples." She is married and has two healthy children. Another married sister, aged 34, also has two healthy children. The patient's father died between 35 and 40 years of age of consumption (?). The patient says his father had some trouble with the forehead, which was similar to that in his own person. One aunt has goiter. No other serious illness is reported in the family. The mother is living and is perfectly well.

History of Present Illness.—Until 21 years of age the patient was perfectly well, but at this time he developed what was termed "malaria," which lasted for three months. At some later date a lump appeared in the left eyebrow. New ones continued to appear on the forehead and extended over the face and nose and over the thighs and forearms, but no intelligible history can be obtained as to their chronological development.

*This patient and the microscopic specimens were shown to the members of the Chicago Medical Society, April 27, 1904.

During these six years the patient has been ill a great deal with chills and fever and epistaxis. He has had, however, but very little pain. He thinks he was ill at the date of the appearance of each new efflorescence on the skin. Five years ago he visited Omaha and remained a week in St. Joseph's Hospital. He has suffered but little with headache, his appetite is always good, and he sleeps well; he has been drowsy only when ill. He has always performed manual labor until one year ago, at which time he received an appointment rendering such work unnecessary.

Examination.—At present the patient exhibits the typical appearance of the tubercular leper. Tubercles and infiltrations varying in size are situated in the region of the eyebrows, on the forehead, nose and cheeks. The hair on the brows is completely lost, and the overhanging eyebrow gives the patient the characteristic expression (leontiasis) so often described (Fig. 1). There is also complete alopecia of the bearded region of the face, where some of the leprous nodules are large as a half-dollar. The forearms, dorsum of the hands, thighs

maculo-anesthetic variety. Several ulcers have existed on the feet, due to injury from lack of sensation, but these are always in the areas which are the seat of leprous infiltration in the skin. The section shown in Figure 3 was removed from the dorsum of the hand and presents the usual histologic picture with large numbers of lepra bacilli.

Remarks.—From the fact that the patient's father died as the result of a chronic disorder near the age of 35 and had some indefinite trouble with his forehead and various symptoms supposed to be those of consumption, it is quite possible that he died of leprosy. There is little doubt about this diagnosis in the case of the sister, as her symptoms above described are practically those of this patient, a fact the patient himself recognizes, so that we are justified in the opinion that the sister of the subject of this report probably died of lep-

Fig. 2.—Microphotograph ($\times 1600$). Smear from cut edge of tubercle from roof of mouth stained with carbolfuchsin showing numerous lepro bacilli.

Fig. 3.—Microphotograph ($\times 1600$). Section of tissue removed from dorsum of hand stained with carbolfuchsin and methylene blue showing lepra cells and large numbers of lepra bacilli.

legs and dorsum of the feet are also extensively involved. The individual tubercles and infiltrations present the usual picture, being bluish or darkish red in color and firm to the touch. They had occurred in groups, and many had disappeared, leaving pigmented areas. The mucous membrane of the roof and posterior part of the mouth is studded with small tubercles, from one of which enormous numbers of bacilli were demonstrated immediately in a smear from its cut edge (Fig. 2). The larynx and vocal chords are also involved, making it difficult for the patient to talk, especially when trying to use his normal conversational tone. The hoarseness is not so marked in his louder tones. I was able also to demonstrate numerous bacilli in the sputum, but these could readily have come from the back part of the mouth. The ulnar nerve is somewhat enlarged, but this fact is not demonstrable in other nerves commonly attacked. There is anesthesia over the areas of infiltration, but this symptom is not present in the areas supplied by special nerves, such as is the case in the

rosy and that the disease in this family originated in the father.

Other Recorded Indigenous Cases.—In 1879, Hyde,¹ in a clinical lecture demonstrating a case of leprosy in a man aged 43, a native of Sweden, stated that there was little doubt that the daughter of this patient was also suffering from the same disease, she having been born and reared in Nebraska.

In 1901 Burnside Foster² reported the case of a man aged 20, born and reared in Minnesota, who had suffered with leprosy for eight years.

Shamberg,³ in 1904, reported the case of a woman always a resident of Philadelphia and its suburbs, who died in 1892 at the Municipal Hospital of Philadelphia of leprosy.

1. Hyde: Chicago Med. Jour. and Examiner, December, 1879.

2. THE JOURNAL A. M. A., Aug. 21, 1901, p. 553.

3. V. Internationaler Dermatologen-Kongress, Berlin, vol. 1, 1904.

D. W. Montgomery,⁴ in 1892, reported the case of a native-born American who had contracted leprosy either in California or Nevada; in 1900 he reported the case of a white woman who contracted the disease in San Francisco.

Bloom,⁵ in 1904, reported a case of anesthetic leprosy in a man aged 39, born in Illinois and living in Kentucky.

New Instrument.

AN ADJUSTABLE TUBE FOR THE FINSEN LAMP.

GEORGE G. HOPKINS, M.D.
BROOKLYN, N. Y.

A treatment which consumes an hour or more and which necessitates having the patient perfectly immobile, should be administered with the patient in as comfortable a position as possible. The Finsen apparatus as constructed in Denmark is fixed and each case must be adjusted to the tube no matter how uncomfortable the position has to be.

My adjustable tube is designed to make an otherwise perfect apparatus adjustable to any position of the patient. The accompanying photograph illustrates both the mounting of the tube and the lamp. Instead of suspending the lamp in its frame with four wires I have arranged an easy and rapid method of adjustment, by using a yoke attached to a rod, passing into a tube and held at any height desired by a clamp screw (8). This admits the raising and lowering of the lamp, so as to secure the most rays, for the tube in its varying positions, as arranged for by the stand to be described.

The yoke is attached to the head of the lamp by two eye loops. A metal sextant with a circular slit to carry the bolt of a clamp screw is also attached to the head of the lamp. This bears against one arm of the yoke. The clamp screw passes through this arm, admitting a change in the angle of the lamp to correspond to any change in the angle of the tube. This adjustment I have found to answer every purpose. The next thing to be accomplished was to have a stand by means of which the tube could be raised and lowered without changing its angle.

The stand shown in the background (9) was the first one I had made, but I could not make the mechanic comprehend my ideas. This stand will accomplish all that I need, but every time I change the height I have to readjust the angle. The stand shown in the foreground is the second stand that I had made, by another mechanic. It meets every requirement, is as simple as possible and costs about one-third as much to construct.

At the joint (1) the rod (2) carrying the tube (5) is attached to the head of the stand. Another piece of iron, the segment of a circle, is hinged to the end of the tube rod (2) and passes through the upright portion of the stand above the point where it is invaginated in the tube of the stand: this arm is controlled by a clamp screw (3). By this adjustment the angle of the tube can be changed at will. The altitude of the tube can be changed without altering the angle, by the ratchet wheel (4), with a setscrew to fix it at any height. Two of the three legs of the stand have castors, while the other (6) is provided with a rubber bearing, so that the stand is not easily moved by accident.

Those who have used the Finsen apparatus will appreciate the difficulty in using it on many portions of the body when fixed in the immovable position, as we find it in Copenhagen and elsewhere. These adjustments were made particularly with a view to the use of the apparatus in the treatment of uterine carcinoma, where the cervical portion is involved and where there is a hemorrhagic tendency. In this class of cases the light is invaluable.

I have yet to see any apparatus that compares with the Finsen apparatus, as devised by him, in efficiency, for the treatment of lupus, rodent ulcer, uterine carcinoma, birthmarks, eczema, etc. I have tried to keep in touch with and have examined every new substitute for this apparatus and I have bought some, but have discarded them, and I have yet to find one which will accomplish as much good as, or which is in any way comparable to, the original Finsen tube. The tube is expensive, owing to the difficulty of securing as large,

clear pieces of quartz crystal as are necessary for these tubes. Further, the operating of the apparatus is expensive in the consumption of electricity. This has led to the effort to put on the market many sorts of apparatus that are cheaper in construction, as well as very much less costly to operate.

After five years' experience with this method of treatment I am fully convinced that it is the best yet devised for the treatment of lupus and kindred diseases.

THE INDEX.

This issue contains the index to the current volume of THE JOURNAL. As usual, it is in two parts. The "General Index" contains the index to the matter which has appeared in THE JOURNAL. While this index is probably fuller than that which appears in other journals, we make no distinctive claim for it, and there is no reason for reference to it in this place. We especially desire to call attention to that part which is the index to the current medical literature. It will be recalled that week by week we publish the titles of original articles appearing in the leading medical publications of the world, and the index referred to is an index to these titles. In one sense it is an index medicus of the medical literature of the world for the past six months. While it is not as full or complete as the *Index Medicus*, it is of great practical value to those who desire to refer to the original work of the past six months without much trouble on their part.

For the last three years we have been publishing a reprint of this index, including a list of the titles, so that easy reference can be made. We believe that this reprint is valuable, and we know it is appreciated by those who have had occasion to use it. Some months ago we sent out some 200 copies of this reprint, which is called the "Guide to Current Medical Literature," asking the recipients for their opinion as to its value. We did this for the reason that so few copies were called for that we concluded to give it up. The replies received were extremely gratifying. A considerable number stated that they were unaware that we published this in reprint form, and many had not appreciated the index in the slightest degree, because they did not know of it. This is one of our excuses for calling attention to the matter.

The reprint is sold at 50 cents for a single copy, or 75 cents for the year. We shall have to sell a good many more copies than we are selling at the present time to pay the expense of this reprint, much less make a profit. The latter is not our object.

We hope those of our readers who are interested in keeping up with any subject, and who consequently desire to know what papers are being published on such subject, will refer to the index to Current Medical Literature in this volume and study it carefully. Its simplicity will become evident to those who will try to look up a subject.

THE WATER-SUPPLY QUESTION IN FRANCE.

It is well known to sanitarians that for some time the condition of the Paris water supply has not been satisfactory in respect to either quantity or quality. The present supply is derived mainly from distant springs or ground-water sources, and certain occurrences on the drainage areas of these underground streams have given rise to some uneasiness among the general public as well as among the officials responsible for safeguarding the purity of the supply. The dubious quality of the supply is not the only difficulty. The quantity of water available from this source has proved at times inadequate for the city's needs, and it has had to be supplemented from other sources. In the year 1902 the municipal authorities began to add as part of the supply filtered water from the river Seine. In its raw condition the Seine water is far from being irrefragable, but it was thought that after being subjected to sand filtration it would be found, as has been the case with many other more or less polluted river waters, to be effectually purified.

The keen interest felt in Paris concerning the outcome of this measure has recently found expression in an animated controversy before the Société de Médecine Publique et de Génie Sanitaire. The respective partisans of the "eau de source" and the "eau de rivière filtrée" have held forth on the issue during several sessions of the society at great length, and, as it appears to an outsider, with some appearance of acrimony. Leaving one side the strong personal feeling evidently engendered by the discussion, there are several points of general interest. One is the signal failure of the attempt to show that the filtered river water has been positively detrimental to the health of the Parisians. The statistics advanced to support what, judging from the experience of many cities, is a rather surprising view, have not been able to withstand the searching criticism to which they were exposed. On the contrary, so far as the somewhat confusing and limited data warrant the expression of an opinion, the use of the filtered water has been accompanied by a diminution rather than by an increase of typhoid fever. As Chabal pointed out in the course of the discussion, those quarters of Paris that chanced to be supplied with filtered water at the time of the epidemic of typhoid fever in February and March, 1904, were among those where the disease did not assume an epidemic character. One of them, in fact, the 20th Arrondissement, did not furnish even a single death from typhoid fever during the course of that epidemic.

Another point of considerable interest is the evidence of the growth among French sanitarians of a favorable opinion concerning the system of sand filtration. The trend of the discussion plainly shows that the advocates of "spring" waters are losing ground. The stand taken by the advocates of filtered water was very de-

cided. One distinguished Parisian sanitary engineer went so far as to say that in the matter of water filtration his compatriots not only held a position of pupilage to Germany, but that they were poor pupils. It may be considered significant that "ground" waters are falling into disrepute in the country that has so long obtained its chief municipal supplies from this source, and that has committed itself so fully to the construction of costly aqueducts and storage basins.

It is, perhaps, a matter worth noting by Americans that a conspicuous feature of this discussion, and one that plainly carried a good deal of weight, was the report made by M. Le Couppey de la Forest on his recent extended official examination of American achievements in the domain of sand filtration.

The situation in France is certainly an interesting one. It seems likely that filtered waters are destined in the near future to displace to some extent the spring and ground waters of somewhat uncertain quality which have until recently been the dominant, indeed, almost the sole, source of public supply.

CHLOROMA AND ITS RELATION TO LEUKEMIA.

There is probably no group of diseases regarding which more confusion has existed than the diseases of the blood and of the blood-forming organs. The relation which exists between the different forms of leukemia, and the relations which this disease bears to chloroma and to lymphosarcoma, have given rise to endless discussion, much of which has been profitless and even rendered confusion more confounded on account of the lack of definiteness in the use of terms. In recent years, much light has been shed on the dark places by more careful study of the bone-marrow, and by more minute histologic examination, but much yet remains to be cleared up.

The question of the relation of the peculiar disease known as chloroma to the leukemias is an old one, and a close relationship has been suspected for some time. In a recent study of a case of chloroma, Dock and Warthin¹ give a very complete summary of the reported cases and formulate certain conclusions. From a clinical standpoint, the cases have often been confounded with leukemia on account of the fact that the green discoloration of the tumors, which gives the disease its name, can not, as a rule, be made out during life. In the most characteristic cases the clinical picture is that of a severe anemia running an acute course, and accompanied, as a rule, by tumors especially in connection with the periosteum of the cranium. As a result of the blood changes, we see pallor, subcutaneous and submucous hemorrhages and toxic symptoms, such as weakness, fever and emaciation, which are probably due to excessive leucocyte destruction. As a result of the neoplasms, we see exophthalmos, pain, deafness, and other less common symptoms, which are due to

mechanical pressure. The blood condition has, unfortunately, been carefully studied in but few cases. It seems probable that in almost all instances there is an actual increase in the white corpuscles, and that in the few exceptions to this there are qualitative changes suggesting lesions in the blood-forming organs. The blood lesions as a whole are those of leukemia, and as in leukemia, it is not always the same variety of cell which is increased. The most characteristic pathologic change is the presence of the peculiar green tumors which give the condition its name. These have been found most frequently in connection with the periosteum, but may also be found as definite metastases in the internal organs. The most recent studies seem to show that these periosteal tumors are secondary, and that the primary changes are to be found in the bone-marrow.

The conclusion which Dock and Warthin come to from the study of their case is that chloroma is a tumor-like hyperplasia of the parent cells of the leucocytes, primary in the red marrow, the periosteum being involved only secondarily. They concede the possibility that such a growth could arise in any of the blood-forming organs which produce white cells. The fact that this leukoblastic hyperplasia is accompanied by an increase in the blood of typical or atypical leucocytes leads them to class the disease with the leukemias. They consider it possible that as in other forms of leukemia there may be certain forms or stages of the disease in which there is no excess of the new-formed cells in the blood, i. e. an aleukemic chloroma. The essential difference between chloroma and ordinary leukemia lies in the greater malignancy of the former and in the green color of the tumors. That some cases of leukemia may have equal malignancy is shown by another case of Warthin,² reported elsewhere. The cause of the green color is still unknown; it is probably a parenchymatous color. The etiology of the process is just as obscure as that of leukemia, and for that matter, of neoplasms in general.

SEROTHERAPY IN TYPHOID FEVER.

Within the last seven or eight years several investigators have attempted to discover a prophylactic or therapeutic agent for typhoid fever based on antibacterial or antitoxic lines. In some cases a protective inoculation with a weakened virus has been employed, as in the protective inoculation of Wright, while in other instances an antitoxic serum has been used for curative purposes. Theoretical objections have been raised as to the possibility of making use of an antitoxin, on the ground that the typhoid bacillus does not excrete a soluble poison like the diphtheria bacillus, but forms instead an intracellular toxin. On this point, however, there is a good deal of disagreement, and some of the recent work on this subject seems to show that the typhoid bacillus produces a soluble toxin as well as an intracellular one.

One of the earliest observers who attempted to pro-

1. Medical News, vol. lxxxv, Nos. 22 and 23.

2. Trans. of the Assn. of Amer. Physicians, 1904.

duce an antitoxin to neutralize the typhoid poison was Chantemesse, who published his first clinical data in 1897. He has now used his antityphoid serum under uniform conditions for three and a half years, and has recently published¹ his statistics, as well as of those of two other physicians who have been using his serum independently in other hospitals. He has deferred publishing until the present, so that his statistics would cover cases observed in several different epidemics. He compares results obtained in his cases with those obtained in other Paris hospitals with a similar class of cases. The whole number of patients which have been subjected to his antityphoid serum numbers 765, of which number he himself treated 545. The remaining 220 were treated by Drs. Josias and Brunon, and were exclusively children. The mortality in both series of cases was the same—4 per cent. The average mortality of the other Paris hospitals during the same time was 13 per cent., and the lowest mortality in any of these institutions was 12.8 per cent. The causes of death under serum treatment were essentially those which cause death under other treatments, perforation, asthenia, and mixed or secondary infections. The average percentage of perforations in fatal cases is 2.6, while in Chantemesse's cases the average was 1.6.

Regarding the method of employing his serum Chantemesse is a little indefinite in this article. From his other articles one judges that the serum is given subcutaneously in rather small doses (not more than 10 to 15 c.c.), and that the dose needs to be repeated once or twice during the disease. Chantemesse states that it can not be compared with the diphtheria antitoxin, as in typhoid the severe cases often require the smallest doses, and vice versa. As in diphtheria, however, the best results are obtained if the serum is given early in the disease, and not much is to be expected if the patient shows profound nervous involvement. Chantemesse thinks that the serum produces a specific effect on the organs of defense, especially the spleen, lymphatic apparatus, and bone marrow, and that in order that this effect may be produced the patient must be in a condition to react.

The objections which have been brought against the idea that the action of this serum is specific, are, first, that Chantemesse's success is due to the personal care which he gives to his cases; and, second, that his success has been due to the use of the cold bath which he advocates as an adjunct to the serum treatment. He answers the first objection by citing the success which others have had with his serum, and the second by the statement that the cold bath is extensively used in the Paris hospitals, and that they, nevertheless, have a much higher mortality than he has in his institution.

The whole subject is one of ever-present interest, and one can not help feeling encouraged by Chantemesse's results. They are certainly better than the

results thus far obtained by any known method of treatment followed for a reasonable length of time. If any criticism can be made of Chantemesse's statistics it is that they cover a relatively small number of cases and a relatively short period of time. Making all allowances for this, however, the subject is one which it seems well to follow up further.

EFFECTS OF ENFORCED IDLENESS ON CONVICTS.

One special phase of the labor problem that comes to the front every little while is the question of the effects of the anticonvict labor laws on the health and mortality of prisoners. Owing to the demands of the labor unions, several states have passed laws which prohibit contract labor in the prisons, and which seriously embarrass the prison authorities in the management and discipline of the institutions. It is a well-known fact that idleness of prisoners tends to physical and mental deterioration; an increase of insanity, as well as a general impairment of the health and well-being of the prisoners, has generally followed the enacting of the laws aforesaid. Even under the best of conditions, with plenty of work, some mental deterioration is inevitable in prisoners. Add to this the restlessness and worry of enforced idleness, and the chances of mental breakdown are vastly increased. If our criminal laws were strictly punitive in their intent it would still be a serious question for criminologists whether it is just to add the deprivation of reason to the other punishments contemplated in the law. Yet this is practically what is being done in a large number of cases when convict labor is prohibited or seriously restricted. It would be, perhaps, more merciful and certainly more economical to the state to re-enact the old laws making capital punishment the penalty for nearly every serious crime. Under the enforced idleness plan, many a short sentence is made practically one for life; for prison-bred insanity is not, as a rule, of a curable type. The economic side of the question need not be discussed; its aspects are self-evident. The legislators who pass such laws, and those behind them who advocate them, have a serious responsibility to meet—a responsibility in which the medical profession shares if it fails to raise its voice in protest.

THE TOO STRENUOUS LIFE.

The announcement has recently been made that an all-night bank, which is to be literally open every hour of the day and night, has been organized in New York City. At recent trials of promoters and speculators and in the legal investigations of various large commercial concerns, it has been made very clear that not a few of the deals in modern business are not made during regular business hours, but in the evenings when men are supposed to be enjoying a much-needed rest after the labors of the day. The new bank is intended to cater only to travelers and others who may in emergencies need a certain sum of money after regular banking hours. It seems likely, however, that it will not discourage the making of various business transactions,

¹ Presse Medicale No. 86, 1904. The Journal, pages 1876 and 1905.

which will enable the over-strenuous to continue their money-making avocations during all their waking hours. The same newspaper that brings the news of the all-night bank also makes the announcement that the son of one of the richest men in the country, himself a very wealthy financier, has been compelled to break off his business engagements for a time, at least, though he is only about thirty years of age, in order that he may recuperate his strength before his health becomes seriously impaired. One of the best safeguards against over-devotion to business has been the fact that banking hours, up to the present time, have proved an inviolable limitation. It seems too bad that this safeguard is to be broken through under the specious pretext that travelers may need money, which they will not be able to procure except over the counter of a bank. The new institution promises to present many opportunities for the abuse of the already overburdened nervous systems of business men. At the present time, business life is run at such high tension that it is no wonder that nervous breakdowns are frequent. The old physician who used to tell his overworked patients that they had not brains enough to run their business and their liver, was expressing a great truth in a homely, telling way. "Nature may be pushed aside with a fork," old Horace said, "but she will always come back." The recoil and its consequences are not likely to be pleasant for those who allow the over-strenuous life to tempt them into the violation of the plainest rules of health.

Medical News.

ILLINOIS.

Town Physician for Rockford.—Dr. E. C. Lofgren, commissioner of health for Rockford, has been appointed town physician. Many contagious cases have come under the notice of the city health department, which have not been properly quarantined, thereby putting the entire community in danger. The new office is created as a protection for the city against contagious diseases which may be flourishing in the immediate vicinity of the city.

Committee to Select Staff for Cook County Hospital.—The nominating committee, which is to select the attending staff of the County Hospital, is announced as follows: Drs. Charles S. Bacon, Frank Billings, Daniel R. Brower, H. O. Brown, F. C. Hotz, Stewart Johnson, John B. Murphy, Hugh T. Patrick, Charles E. Paddock, Thomas J. Conley, A. C. Cowperthwaite, Casey A. Wood, Nathan S. Davis, Joseph B. De Lee, Fernand Henrotin, William E. Quine, E. M. Reading, Nicholas Senn, George F. Shears, H. M. Starkey, D. A. K. Steele, James H. Stowell, Henry S. Tucker, Charles S. Williamson.

Chicago.

Aids Passavant Memorial Hospital.—The benefit entertainment given at the Illinois theater December 22, to aid the Passavant Memorial Hospital netted that institution \$2,500.

Chicago's Health.—The Department of Health announces that after three weeks of unusually low December mortality the seasonal winter increase has set in sharply. The 548 deaths from all causes reported during the week represent a 7.6 per cent. increase over the previous week and nearly 4 per cent. more than the corresponding first winter week of 1903.

Good Record for Obstetric Dispensary.—Dr. Joseph B. De Lee, medical director of the Chicago Lying-in Hospital, reports the work done at the Maxwell street dispensary. In seven years 3,990 cases were treated at their homes without a maternal death. The next case was a complicated one in which death occurred. Since the hospital and the dispensary were established in 1895, 5,800 cases have been cared for, with only three deaths. This last death is the first since the spring of 1897.

MARYLAND.

Baltimore.

Office Building to Replace Dr. Osler's House.—Dr. William Osler has sold his residence for \$55,000. It is a two-story and attic house of colonial design and occupies a lot 59x100 feet in the very heart of the city. It was purchased by him about fifteen years ago for \$40,000. Possession will be given next May, when Dr. Osler will leave for England. The purchaser will build an apartment house on the property and the first and second floors will be arranged for physicians' and dentists' offices.

Public Hospital for Tuberculous Patients.—The first public hospital for the treatment of tuberculosis in the state was opened December 20. It was built by the city and is situated on a beautiful hill, with a fine outlook about a quarter of a mile from the city almshouse. The building is of brick and is three stories in height. It is so constructed as to give a maximum of light and sunshine. The kitchen and dining-rooms are in the basement. The other two floors are for the patients, of whom there are now about 50. The capacity of the building is 100. There are no separate rooms. Each floor, which is about 125x30 feet, is divided in the center by a wooden partition, so as to make separate male and female wards. Each ward is subdivided into compartments with canvas partitions so as to promote free access of air. In the front of the building are sun parlors and at the south side a long open porch with a fine view of the harbor. There are five female nurses, who occupy an old farmhouse nearby. There will be one resident physician, who will be assisted by the seven physicians at the almshouse in alternation. Dr. Benjamin J. Bond has been appointed resident. The treatment will be mainly fresh air, sunlight and special and abundant diet. There were no formal exercises attending the opening.

NEW JERSEY.

Personal.—Dr. B. C. Pennington, who was seriously ill in the German Hospital, Philadelphia, returned to his home in Atlantic City, December 20. His health is much improved.

Smallpox in Camden.—The first case of smallpox recorded in Camden since last May was reported to the authorities December 22. The victim was a young woman and she was admitted to the Municipal Hospital.

NEW YORK.

New York City.

Personal.—Dr. Virgil P. Gibney, who has been sued for damages growing out of an unsuccessful operation, had his case dismissed.—Dr. Emily Dunning, New York's only woman ambulance surgeon, on the occasion of her retiring from the service, was presented with framed resolutions by the attaches of Gouverneur Hospital.

New Bellevue Pavilions.—The construction of four new portable wards has been begun to relieve the overflow of patients during the winter. Although the busy season has not begun, the hospital is crowded. The same condition prevails in the Metropolitan Hospital and in the City Hospital, each of which has had nearly 100 patients lying on springs on the floors during the past week.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending December 17, 329 cases of diphtheria and croup, with 40 deaths; 310 cases of tuberculosis, with 134 deaths; 184 cases of scarlet fever, with 13 deaths; 103 cases of measles, with 12 deaths; 72 cases of typhoid fever, with 16 deaths; 2 cases of smallpox, 126 cases of chicken-pox and 26 deaths from cerebrospinal meningitis.

New York Polyclinic Medical School and Hospital.—This institution has just celebrated its twenty-second anniversary by a reception given to its board of trustees and medical staff. The Polyclinic was the pioneer medical school of its kind in America. In twenty-two years nearly 8,000 physicians have matriculated as students. A gratifying feature of the reports submitted by the president was that the medical staff not only gave their services as teachers without compensation, but from their own pockets had paid a mortgage of \$37,020 on the Polyclinic property during the past year. The institution, however, has outgrown its present facilities and the trustees and staff have undertaken to raise sufficient funds for a new building.

Continued Work for Pure Milk.—During the past week ten milk dealers have been fined for selling adulterated milk. The Metropolitan Company, whose charter was revoked by the Board

of health and a new charter refused, has been forced out of business and is selling its property. The dairy trade journals are giving their support to the Department of Health. Alderman Bennett of Brooklyn has introduced an ordinance requiring that all milk coming into the city in cans or receptacles of any kind shall bear a metal seal and those refusing to comply with this ordinance shall be fined. The milk commission of the county medical society, which has been working for the past five years, favors bottled milk, and has inaugurated a plan by which milk can be sent from the producer to the consumer without danger of adulteration by middlemen. The medical society, after inspecting dairies, furnishes them with lead foil bottle caps stamped by it and bearing the name of the dairyman. In order to secure these seals the producer must conform with certain strict regulations, but he realizes that as his milk brings better prices it is profitable to conform to the society's demand. Some of the requirements are that the barnyard shall be well drained and kept clean; the stables must be whitewashed twice a year and have tight floors, preferably of cement. The whole premises must have a supply of absolutely pure water. The cows must be examined twice a year by a skilled veterinarian, and no cow can be added to the herd without being examined for tuberculosis. The entire herd must be groomed daily and the milkers must wear light clothes and keep themselves clean. The milk must be cooled to a temperature of 45 degrees within an hour after milking. Specimens taken at random must be sent to the research laboratory of the health department for examination weekly. The milk commission reserves the right to inspect the certified farms at any time.

OHIO.

Board of Directors of Cincinnati Hospital.—This board recently organized for the new year by electing the following officers: President, Dr. A. B. Isham; vice-president, Dr. Louis Schwab; secretary, Dr. Byron Stanton.

Laboratory Examinations by the State Board of Health.—The State Board of Health will soon open its laboratory to all certified physicians of the state. Chemical, pathologic and bacteriologic examinations will be made on request and results promptly sent to attending physician.

Cleveland Medical Library Association.—The Cleveland Medical Library Association held its annual meeting December 10. After transacting routine business Dr. George Ben Johnston, Richmond, Va., read a paper on "The Medical Men Contributed to the United States by the State of Virginia."

Personal.—Dr. C. R. Roessly has been appointed district physician by the Board of Health in place of Dr. H. J. Strack, deceased.—Dr. Frank H. Lamb, Glendale, formerly clinician in medicine, Miami Medical College, has been appointed assistant to the chair of physiology in Harvard Medical School.

Fire in the Cincinnati Hospital.—Dr. Oscar Behrman, interne to the Cincinnati Hospital, prevented, on December 21, what might have been a very serious conflagration in that institution. An alcohol lamp in one of the wards became overturned and in a moment a mass of drapery was in flames. Dr. Behrman put out the blaze with no little risk to himself.

Closure of Cincinnati Presbyterian Hospital.—At a meeting of the board of trustees of the Presbyterian Hospital it was determined that the institution should close its doors as soon as the patients under treatment could be removed and the affairs of the hospital settled. This will take about thirty days. For a long time the hospital has been supported to a very large extent by Mr. Alexander McDonald of Cincinnati, who has contributed in all about \$250,000, and in addition allowing \$7,500 a year for maintenance. In spite of this, however, the hospital has been constantly falling behind and a few years ago Mr. McDonald met a deficit of \$25,000. Recently Mr. McDonald notified the board of trustees that inasmuch as the Presbyterian church had failed to support the hospital as liberally as he felt it might, he would not make any contribution in the future. This announcement was followed a few days later by the resignation of the "board of lady managers." Some years ago the hospital was run as a teaching branch of the Laura Memorial Medical College, an institution exclusively for women, and established and maintained by Mr. McDonald in memory of his daughter. Two years ago this college was closed because the attendance was steadily diminishing so that the outlay of time and money was not justified. The Miami Medical College took over the students, many of whom have since graduated with honors.

First Councilor District Medical Society.—The first councilor district of the Ohio State Medical Association held its first annual meeting December 8-9, in Cincinnati, at the rooms of the Cincinnati Academy of Medicine. Dr. Brooks F. Beebe, councilor for the district, called the meeting together and on his suggestion the nomination of officers for the ensuing year was in order. The nomination and election of Dr. Blair, Lebanon, for president, and Dr. Magnus A. Tate, Cincinnati, secretary, followed. The following papers were then read: "Chronic Catarrhal Cholecystitis," by Dr. E. S. Stevens, Lebanon; "Theories of Immunity," by Dr. Mark Millikin. At the afternoon session these papers were read: "Appendicitis," by Dr. Joseph Eichberg of Cincinnati; "The Pathology of Appendicitis," by Dr. S. P. Kramer (lantern-slide demonstrations); "The Time for Operation in Appendicitis," by Dr. C. A. L. Reed of Cincinnati. These papers were discussed by Drs. G. A. Fackler, H. J. Whitacre, Joseph Ranshoff, C. L. Bonifield, R. B. Hall, B. M. Ricketts, J. M. Withrow, B. F. Beebe, of Cincinnati, and R. Trimble of New Vienna, Ohio. Dr. P. S. Connor read a paper on "Modern Surgery." Friday was devoted to clinics. Dr. B. F. Lyle presented two patients suffering from tuberculosis, and one of aneurism of the arch of the aorta. Dr. Edwin reported a case of resection of the ovaries. Dr. M. L. Heidingsfeld presented cases of lupus, herpes tonsurans, nevus, linear nevus and syphilis. Dr. Robert Sattler presented a case of glaucoma of both eyes in a child of 12. Dr. Samuel Iglauer presented cases of adenoids and of tuberculosis of the larynx. Dr. Walter E. Murphy presented a case of fibrosarcoma of the ethmoid. Dr. Albert Freiberg presented cases and x-ray pictures of congenital dislocation of the hip. In addition, special clinics were held at the Cincinnati, Presbyterian, Jewish, Good Samaritan, Christ's and Ophthalmic hospitals, at the Miami Medical College and at the Medical College of Ohio. The First Councilor district of Ohio contains the following county medical societies, all represented at this meeting: Adams, Brown, Butler, Clinton, Clermont, Hamilton, Highland, Warren.

PENNSYLVANIA.

Personal.—Dr. Samuel M. Crawford, Columbia, has been appointed chief medical examiner of the Pennsylvania Railroad Relief Department, with headquarters at Harrisburg, vice Dr. James M. Brown, deceased.

Accidents.—Dr. Thomas J. B. Rhoads, Boyertown, in alighting from a moving train, November 27, fell, sustaining cuts and bruises.—Dr. J. Hervey Reynolds, Bellevue, while driving, November 29, was run into by an electric car and thrown out of his buggy, breaking one rib and causing severe shock.

School Principals Held on Vaccination Case.—Five of Altoona's public school principals have had information brought against them for permitting children who had not been properly vaccinated to attend school. The action was brought against them by the Board of Health and will be taken to court for decision.

Move for Pure Milk.—Prompted by the recent epidemic of typhoid fever at West Chester, a member of the legislature from that county will introduce a bill to provide for the more careful inspection of farm buildings from which milk is distributed to the public. The bill will also provide that no milk shall be bottled or prepared for consumption in any of the cow barns.

Staff Appointment.—The following chiefs of staff and assistants have been announced by the board of managers of the Reading Hospital: Dr. John L. Bower, assistant, Dr. George W. Overholzer; Dr. Clarence M. Kurtz, assistant, Dr. Abram K. Wanner; Dr. John M. Bertolet, assistant, Dr. Thomas C. Buchanan; Dr. John F. Feick, assistant, Dr. Floyd H. Feick; Dr. Albert F. East, assistant, Dr. Harry F. Rentschler; Dr. Israel Cleaver, assistant, Dr. Heister Bucher, and Dr. Samuel L. Kurtz, assistant, Dr. Samuel B. Taylor.

New Buildings Ready.—The new buildings of the East End Hospital, Pittsburg, which name will shortly be changed to the Pittsburg Hospital, were open for public inspection December 8. The main building is fireproof, five stories in height, and will accommodate 110 patients. The two-story pathologic building which is detached from the main building, but has a communicating tunnel 100 feet long, contains the autopsy room, morgue and pathologic and bacteriologic laboratories. The buildings thus far have cost \$200,000.

To Guard Health of State.—At the coming session of the legislature a bill will be introduced providing for complete reorganization of the scheme for conserving the public health.

The bill has the indorsement of the medical societies throughout the state, and the State Board of Health has also indorsed the measure. The bill is entitled, "An act to provide for the better protection of life and health in the several counties and townships of this commonwealth, by establishment of county boards of health, and county and township health officers, and to provide compensation for the same, and to provide for the notification of the existence of contagious diseases by practicing physicians throughout the commonwealth, and providing penalties for the neglect or violation of any of the provisions of the same." This auxiliary organization to the State Board of Health will include 1,500 physicians. The bill also provides that the State Board of Health shall appoint in each county a practicing physician of at least five years' experience to be the medical officer of said county. It is required that all physicians so appointed shall have special knowledge of sanitary law and administration. County courts will name the health officer, who is to serve in each township subject to the State Board of Health.

Philadelphia.

Alleged Malpractitioner Held.—Albert M. Hollis, known as "Doctor" Hollis, who conducts the Hollis Remedy Company in Philadelphia, was arrested on the charge of administering drugs with unlawful intent to a young woman. He was held in \$1,000 bail.

Year's Suicides Decreased.—Statistics from the coroner's office show that during the year 162 persons committed suicide. Nearly one-half of this number either committed suicide by taking poison or by shooting. In 1903 there were over 200 suicides reported from the coroner's office.

Christmas in the Hospitals.—Every effort was made by the officials of the different hospitals throughout the city to make Christmas day for the inmates as pleasant as possible. In many of the institutions special services were conducted, and for those who were able to partake a Christmas dinner was served. In some of the hospitals each patient was presented with a gift. This practice was universal with the children in all the institutions.

Missionary Returns.—Dr. Anna M. Fullerton, at one time chief resident physician in the Woman's Hospital, has returned to this city after five years' medical missionary service in the Punjab, North India, where she was in charge of the missionary hospital and a member of the staff of the training school at Ludhiana. On December 15 Dr. Fullerton addressed the staff and students of the Woman's Medical College, of which she is a graduate.

Used University's Name to Defraud.—Several persons have been victimizing unsuspecting people of this city and vicinity by representing themselves as authorized agents of the University of Pennsylvania for a medical book entitled "Medicology." The authorities of the university officially deny any responsibility for the publication and desire to warn the public against the misrepresentation of unauthorized persons in any matter pertaining to the university.

Tribute to Dr. Welch.—A medical society was formed in honor of Dr. William M. Welch. The first meeting was held at Dr. Welch's residence on December 19, and twenty-five names were enrolled. The society is composed of ex-resident physicians and some of the present resident physicians of the Municipal Hospital. Dr. Welch was for many years physician in charge of this institution, being appointed in 1870 and serving continuously until 1903. At the meeting Dr. Welch was presented with a loving cup. An informal banquet followed.

Personal.—Dr. John Marshall, professor of chemistry and toxicology in the university, was the guest of honor at the annual meeting of the alumni of the University of Pennsylvania of the northwest, held in St. Paul, Minn., December 5.—Dr. Herbert Huston Bethel has returned to Philadelphia after an absence of four years in Weisbaden, Germany.—Dr. and Mrs. Charles W. Fox have sailed for Europe.—Dr. Henry Tucker has been appointed physician in the genitourinary department of the Philadelphia Hospital. Dr. Tucker graduated from Jefferson Medical College in 1894.

Donation to the University.—At the dedicatory exercises of the new gymnasium of the University of Pennsylvania, December 14, Dr. J. William White announced that \$50,000 was donated from the estate of the late William Weightman as an endowment fund. In memory of Mr. Weightman's munificence the gymnasium will be called Weightman Hall and will contain a tablet bearing the inscription, "In Memory of John

Weightman, Class of 1866, Medical, and William Weightman, Jr., Class of 1867, Medical." The fund is to be used for the furtherance of physical education.

Work of Medical Inspectors.—During November 38,578 inspections of public school children were made. There were found 1,083 children suffering from disease of sufficient gravity to warrant exclusion from school. The most important of the conditions demanding exclusion were 11 cases of diphtheria, 14 cases of scarlet fever, 50 cases of chicken-pox, 3 cases of whooping cough, 395 cases of parasitic disease of the scalp and body, 136 cases of defective vision, and 31 cases of unsatisfactory vaccination. Communications to parents recommending medical treatment for children not requiring to be excluded numbered 2,078.

Health Report.—The total number of deaths for the week was 508. This is a decrease of 11 from those of last week and a decrease of 46 from the corresponding period of last year. Of the whole number reported 161 were attributed to diseases of the respiratory tract, 76 being due to pneumonia and 56 to pulmonary tuberculosis. The principal causes of death were as follows: Typhoid fever, 8; diphtheria, 12; cancer, 2; apoplexy, 23; heart disease, 42, and Bright's disease, 35. There were 218 cases of contagious disease reported with 20 deaths, as compared with 213 cases and 26 deaths for the preceding week. No new cases of smallpox were recorded.

House Disinfection.—Particular attention has been given by the Health Bureau to the work of disinfection. At the beginning of this work the test shows that only about 85 per cent. of test objects were destroyed by the methods previously employed. From laboratory experiments the officials have learned that better results are obtained from the employment of strong solutions of formaldehyd in a fine spray. This plan consists in spraying all surfaces of the room with a mixture of equal parts of water and a saturated solution of formaldehyd gas in water, three pints of the mixture being used for each 1,000 cubic feet of air space. The result of this method shows that instead of 85 per cent. of destruction 100 per cent. has been obtained, or complete disinfection. This method is also applicable to bedding and bedclothing, and has much more penetrating power than when applied as gas. Of 900 pieces of bedding material thus exposed all were completely disinfected.

TEXAS.

Personal.—Dr. T. J. Scott, Alvin, has been appointed local surgeon for the Santa Fe System.

Smallpox.—A physician of Venus reports eight cases of smallpox in Ellis County, five miles east of Venus. Efficient quarantine has been established.

Suit and Counter-Suit.—Dr. E. J. Mellish, El Paso, formerly of Chicago, has sued a patient for \$246 for surgical treatment during an attack of appendicitis. The patient filed a cross-action, claiming \$900 damages for the loss of his appendix, which, he avers, was unnecessarily removed.

County Society Election.—Smith County Medical Society held its annual meeting December 13, at which the following officers were elected: President, Dr. J. Charles Smith, Starrville; vice-president, Dr. Richard H. Urquhart, Tyler; secretary and treasurer, Dr. Edwin A. Woldert, Tyler (re-elected); censors, Drs. Thomas J. Bell, Tyler; Jasper D. Phillips, Tyler, and William Johnson, Winona; delegate to State Medical Association of Texas, Dr. E. Albert Woldert, and alternate, Dr. Thomas J. Bell, both of Tyler.

VIRGINIA.

Smallpox.—Abingdon has seven cases.—There are several cases in Lynchburg, Eavington and Oakville.—Washington, Campbell and Charlotte counties have been infected by negro miners returning from the coal fields.—There are still several cases in the upper part of Spotsylvania County.

State Medical Board.—On December 1 the governor appointed the following State Medical Board: Drs. Rawley W. Martin, Lynchburg; Lewis E. Harvie, Danville; John H. Neff, Harrisonburg; Vernon G. Culpeper, Portsmouth; W. Wamanch Chaffin, Pulaski City; Paulus B. Irving, Richmond, and Landon B. Edwards, Richmond.

Personal.—Dr. P. Casey has been made president of the Lynchburg Board of Health, and Dr. John J. Lloyd, a member of the board.—Dr. Paul Redd, Barton Heights, has been appointed a member of the Board of Health of Henrico County, vice Dr. Cathon Archer, deceased.—Dr. Harry B. Taylor, Norfolk, will go to Hankow, China, as a medical missionary.

GENERAL.

Sanitation Fund for Cuban Cities.—It is reported that the Cuban senate has passed a bill appropriating \$326,000 to be used in improving sanitation in the principal cities in Cuba, outside of Havana.

Tuberculosis in Prisons.—In a long report on "What are the best means of combating and treating tuberculosis and of avoiding its propagation in penal institutions of every kind," which Dr. J. B. Ransom, physician at the Clinton prison, Danmora, N. Y., submitted to congress, he said that the use of whitewash as a disinfectant and a cleansing agent is a delusion. He condemns confining prisoners in a dark, a light or a solitary cell. Pardon for the convicts suffering from consumption he believes is a most pernicious way of dealing with the disease. Notwithstanding the indifferent treatment which these patients receive he says that the mortality is only 10 in a thousand, while among the general population it is about 13. His statistics of observations cover 77 prisons containing a population of 44,285. As preventatives he recommends strict isolation, outdoor life on tuberculosis farms and a thorough destruction of the sputa. Tent treatment he considers impracticable because of the great number of guards that would be required.

Marine-Hospital Service Reports on Mosquitoes.—The annual report of the surgeon general of the Public Health and Marine-Hospital Service for 1904 contains a complete and interesting account of the work done in the national quarantine service, especially that on the Mexican border. An abstract is also given of the report of the French yellow fever commission concerning the work in Brazil. The commission found that yellow fever is transmitted either by the bite of an infected mosquito, the *Stegomyia fasciata*, or by direct inoculation of serum from a yellow fever patient. They found that the blood of a convalescent yellow fever patient possesses therapeutic properties of considerable curative value. In the opinion of the commission no other mosquito found at Rio Janeiro, or in the vicinity, has any relation to the transmission of yellow fever. The following deductions are drawn in regard to the transmission of yellow fever as a result of their observations: "First, yellow fever is not transmitted in nature either by direct contact with the patient or by contact with personal effects, or by his excretions; second, the transmission is effected by the biting of mosquitoes, and the only dangerous species, at least in the region in which our researches have been conducted, is the *Stegomyia fasciata*; third, this transmission never takes place during the day while the sun is above the horizon." In regard to protection against the infection of yellow fever the commission declares that "the introduction of merchandise is unattended with danger at any time." In regard to arrivals from a territory infested with yellow fever at a port or place where the disease does not prevail, the commission declares that "it is perfectly useless" to inflict a quarantine if *stegomyias* do not exist in the country at the time of arrival, since transmission can only be effected by this intermediary." The conclusions arrived at by the commission are practically the same as have been arrived at as the result of experiment and observations in the United States.

CANADA.

Twentieth Annual Report of the Hospital for Sick Children, Toronto.—In the year ended Sept. 30, 1904, 761 patients were admitted; of these 389 or 51 per cent. were discharged as cured; 231, or 30 per cent., were improved; 69, or 8 per cent., were unimproved; 81, or 11 per cent., died. The out-patients numbered 5,623.

Veteran Medical Teacher Resigns.—Dr. Michael Sullivan has resigned from the professorship of surgery in the medical faculty of Queen's University, Kingston, Ontario. Fifty years ago Dr. Sullivan entered the medical school at the time of its foundation, and he has been connected with it ever since as tutor, lecturer and professor. He will be appointed honorary professor of surgery and will be given the degree of LL.D.

Prevention of Tuberculosis in Montreal.—The annual meeting of the Montreal League for the Prevention of Tuberculosis was held December 10. During the past year the league's inspector paid 1,667 visits and 9,000 cuspidors were supplied. The league receives an annual grant of \$700 from the city of Montreal. Since November 7 the league has had a dispensary, where physicians call every day and attend to the patients. Sir George A. Drummond was re-elected president. Dr. A. J. Richer resigned the secretaryship.

Aid for Toronto General Hospital.—Mr. George Gooderham, for many years connected with the board of trustees of the Toronto General Hospital, has resigned from the chairmanship thereof, and in doing so announced that he would make a handsome donation toward the building fund for a new hospital. This, with donations recently announced, will make a working capital on which to begin the million-dollar institution which they plan to make one of the finest on this continent.

New Notre Dame Hospital, Montreal.—Mr. Rodolphe Forget has given a site for a new Notre Dame Hospital for Montreal. It cost \$31,000. At the annual meeting last week it was announced that the number of patients receiving treatment in the hospital during the year ending June 30, 1904, was 2,226. One hundred and fifty-six patients died in the institution during the year. In the outdoor services there were 20,458 consultations; the ambulances made 1,437 calls. The cost of a patient for a day was \$1.09. The new contagious diseases hospital for this institution will be ready by May 1.

FOREIGN.

Scarcity of Physicians in Russia.—As so many hospitals, etc., are left without due medical attendance by the absence of their medical force at the seat of war, the Russian government has ordered that the commencement exercises of the medical schools be held much earlier than usual so that the graduates will be free this spring to serve where needed.

Inoculation of Horse with Syphilis.—At the meeting of the Berlin Medical Society, December 7, Piorowski exhibited a horse which he had inoculated with blood from syphilitics. It presented a papular efflorescence on the thorax and abdomen which is not known to occur spontaneously, and which bore a resemblance to human syphilitic lesions. Aronson, however, stated that he had observed similar lesions on horses after inoculation of foreign serums.

Plan to Lessen the Strain of School Life.—A German physician, Dr. H. Molenar of Munich, proposes a radical reform in high-school life which is spoken of with commendation in some medical exchanges as worthy of the serious attention of pedagogists and medical men. He thinks that the same amount of study can be accomplished in less time if work is done in the morning hours. He therefore proposes to have the school session commence earlier, and the time devoted to each class be restricted to forty instead of sixty minutes. Commencing at ten minutes past 7, the time until noon would be divided into six hours of forty minutes each, with three ten-minute and one twenty-minute recess, and the pupils then be dismissed for the day, so that the entire afternoon could be devoted to sports or work in the open air.

Senator's Seventieth Birthday.—Prof. Hermann Senator's seventieth birthday was celebrated by his friends December 6. A number of our exchanges dedicated numbers in his honor, No. 49 of the *Berliner klin. Wochenschrift* containing articles from his clinic only. He has been living in Berlin since 1858, and besides his extensive practice and being at the head of the III medical clinic, has won special fame as an instructor and in scientific research. His works on metabolism have become classic, and many of his other contributions to scientific literature have carried his name far and wide, especially those on medicolegal questions, on diabetes, liver affections, infections and neurology. He was one of the first to call attention to the possibility of intestinal auto-intoxication, and has published 30 important monographs or special articles on kidney affections. He has also been co-editor since 1872 of the *Centralblatt f. d. med. Wissenschaften*. His pupils presented him with a *Festschrift* and a portrait bust for his clinic.

Correspondence.

The Propriety, Indications and Methods for the Termination of Pregnancy.

PHILADELPHIA, Nov. 25, 1904.

To the Editor:—It is with regret that I notice in THE JOURNAL, November 19, an article with the above title. During my service of nearly three years as senior coroner's physician at Philadelphia, I made thirty-three autopsies on those whose death resulted from abortion produced (1) accidentally, (2) by

their own hands, or (3) by others for money. Since May of the present year there have been eighteen different persons brought to the bar of justice by the proper authorities for performing criminal abortion, and there are a number of others suspected of carrying on this nefarious business who are now under police surveillance or whose records are being looked up by a committee recently appointed by the Philadelphia County Medical Society to aid the proper officials in collecting evidence against, and in securing the conviction of, criminal abortionists.

With this short preface, and now that the subject is under discussion, it would be interesting to have Dr. Frank A. Higgins of Boston, the author of the above paper, answer the following questions: How many induced abortions have you performed and at what period of gestation? What was the reason for so doing in each case? Have you induced abortion on the same woman more than once? How many of the patients were married women and how many were single? How many patients applying for this form of treatment were rejected by you? Of those rejected, did any one else perform the operation? Have the rich or the poor been the more prone to seek relief? Have you ever had to revise your diagnosis after performing the operation; like those who have stated that a cesarean section had to be undertaken to save the life of the mother and before the hour set for the operation have had her give birth to a living child without instrumental aid? Do you usually perform the operation in a hospital, at the home of the patient, or in your own office? Do you perform the operation only after consultation with a confrère? Would you consider pregnancy from rape a proper indication for the prompt termination of pregnancy? If you had a death following the operation, would you state on the certificate that you had induced abortion?

In some portions of America, I am well aware, abortions are frequently performed by regular practitioners of medicine and for no other purpose than to save the reputation of an unmarried woman or to prevent too great an increase in offspring. In discussing this question recently with a physician, the chief reason assigned for the permitting of the performance of abortion was that the girl would otherwise commit suicide, or she would do the operation herself, or have it improperly done. Thus possible infection and years of suffering would be prevented by having it performed by a skilled operator. There is a tendency to give by legal enactment to the boards of health more and more power, and the opinion expressed by Dr. Higgins and others who think as he does, if generally adopted, will pave the way for the compulsory application of the physician to the health office for a permit to perform an induced abortion! What the consequences of such a requirement might be, especially if politics prevail as they do in so many of our cities, few can tell.

HENRY W. CATTELL.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ABSORPTION AND ELIMINATION OF POTASSIUM IODID.

CINCINNATI, Dec. 13, 1904.

To the Editor:—Please state in THE JOURNAL the latest theories regarding the absorption and the elimination of potassium iodid.

X. Y. Z.

ANSWER.—Potassium iodid in aqueous solution is strongly dissociated into its constituent ions, the cation (positive ion), potassium and the anion (negative ion), iodidion. Each of these ions acts for itself and has its own properties independently of the other. Thus, in solutions of sodium iodid, potassium iodid and ammonium iodid, the properties of the iodidion are identical through the properties of the several negative ions—potassium, sodium and ammonium—are quite different from one another. The differences in physiologic effects of these various iodids are therefore attributable to the differences in the effects of their constituent cations. Iodidion is, further, quite different in its nature and effects from the element iodin in the ordinary state; iodidion is colorless, while iodin is violet or purplish black; iodidion does not color a solution of starch, while free iodin yields a fine blue color with starch. In a sense, iodidion and free iodin may be regarded as being two allotropic conditions of the same element. It will be readily understood, therefore, why the iodids differ

greatly from free iodin in their physiologic action. Thus, the application of a solution of potassium iodid to the skin has scarcely any appreciable effect, while the application of free iodin has an irritant effect and may even blister. The mucous membranes are capable of absorbing solutions of potassium iodid with rapidity. Administered by the mouth the iodids are absorbed quickly by the stomach and intestine, and iodidion can be demonstrated in the secretions within a few minutes. Most of the iodidion goes through the body unchanged and is excreted as such in the urine, always, of course, along with Companion Katicus. Entering the body with potassium as its companion it may exchange its fellow in the blood or body tissues for sodium or other cations and thus be given off in the urine, partly as dissociated potassium iodid, partly as dissociated sodium iodid or other iodids. A little iodidion is excreted in the saliva, stomach juice, tears, perspiration, milk, sebum and nasal secretion. The excretion of iodids is far more rapid than that of bromids, for about 75 per cent. of an iodid is said to be recoverable in the urine within twenty-four hours after administration, and after a week nearly all has been excreted. There is evidence that a part of the iodidion is decomposed in the body with formation of free iodin, the latter uniting at once with proteid substances to form organic compounds. Sometimes a little free iodin is excreted by the stomach after the administration of potassium iodid. Some authors, in order to explain the irritant phenomena of iodism, have assumed the formation of free iodin from the iodidion along the mucous membranes of the nose and other respiratory passages and in the skin; they thus seek to explain the coryza of iodism in the one instance and the troublesome eruption in the other. The proof of this view has not yet been brought, for while iodidion has been demonstrated in the sweat, saliva and nasal secretion, free iodin, so far as we know, has not. The various theories as to the mode of decomposition of iodids in the body with formation of free iodin are well epitomized by Cushny in his "Text-book of Pharmacology and Therapeutics," third edition, Philadelphia and New York, 1903, p. 513; on p. 517 of the same volume are to be found the more important references to the bibliography of the subject.

ALBUMINURIA.

BATH, MAINE, Dec. 14, 1904.

To the Editor:—Anent the tests for albumin given in your editorial columns Dec. 3, 1904, you state, "albumin being present it is desirable to determine if it be serum albumin or globulin, or both." If it is a fact that serum globulin always occurs in the urine when serum albumin does, why test for the serum globulin, unless, of course, lardaceous disease of the kidney be suspected? When does serum globulin occur alone in the urine, and what would be its clinical significance? As regards the Spiegler-Jolles reaction, it frequently happens that filtering the urine does not clarify it. I then use strong alkalies or a magnesium fluid, warm and filter, when I get a perfectly clear urine. Now, in using the Spiegler-Jolles reagent, I take it the urine should be perfectly clear. Would the use of strong alkalies, etc., in any way interfere with the reaction, and if so, how may the urine be clarified so as not to interfere with the Spiegler-Jolles reaction? HORACE FOX.

ANSWER.—For ordinary clinical purposes it is unnecessary to differentiate serum albumin from globulin in albuminuria. Globulin is present along with serum albumin in the majority of cases. There are exceptional cases, however, where serum albumin is unaccompanied by globulin, and still more rarely instances where globulin is present without serum albumin. The test we gave for globulin is only a rough clinical test; if one wishes to be absolutely sure of the presence of globulin he should proceed as follows: Ammonia is added to the urine until the acid reaction disappears, any precipitate of phosphates removed by filtration and the filtrate mixed with an equal volume of cold saturated solution of ammonium sulphate. Let stand one hour, until the white flocculent precipitate has settled. Filter and wash residue with a half saturated solution of ammonium sulphate until the wash fluid passing through the filter ceases to yield a precipitate with acetic acid and solution of ferrocyanid of potassium. The residue on the filter may consist of globulin and albumoses. Dissolve it in water, remove most of salt by dialysis and cautiously precipitate the globulin with acetic acid; the albumoses remain in solution. The clinical significance of pure globulinuria is not well understood. In forty cases of albuminuria exactly studied by Hammersten globulin without serum albumin was met with only once. It is stated that pure globulinuria is occasionally met with in leukemia. It is necessary to have a clear urine in order to satisfactorily apply the Spiegler-Jolles test. The objection to clearing with alkali and filtering is that the albumins may be quickly denaturalized by weak alkaline solutions even at the room temperature. Nor is it safe to clear by means of warm solutions of magnesium salts, for even in relatively low concentration some of the albumin bodies may be thrown out of solution. The best way to get a perfectly clear specimen, when filtration through paper is not satisfactory, is to filter through asbestos. It is not to be forgotten that Spiegler's reagent as modified and applied by Jolles is extremely

delicate, and that the presence of non-pathologic amounts of albumin may be demonstrated by it. If the reaction is positive a second test should always be made with heat and nitric acid or with acetic acid and ferrocyanid of potassium, for with these reagents non-pathologic amounts of albumin are not precipitated. Another point to be borne in mind is that if iodids be present in the urine Spiegler's reagent may give a ring of mercuric iodid.

THE INDEX.

PUEBLO, COLO., Dec. 20, 1904.

To the Editor:—I am interested in the subject of gastric ulcer. Will you kindly refer me to a few of the recent articles on this subject.

W. H. CAMPBELL.

ANSWER.—Our correspondent may find the information he desires by referring to the index. Over 40 references on this subject are indexed, the majority of which have appeared in THE JOURNAL either as original articles or as abstracts. Reference to the index of Current Medical Literature will show the name of journal and date of issue of copy containing articles which appeared in other journals. The articles are indexed under the heads of "Gastric Ulcer," "Ulcer," "Treatment of So-called Dyspepsia," etc.

FELLOWSHIP IN ROYAL MICROSCOPICAL SOCIETY.

PHILADELPHIA, PA., Dec. 5, 1904.

To the Editor:—Please give me some information concerning the right to use the letters F.R.M.S. (England). Is it honorary only, or may it be obtained by passing an examination, competitive or otherwise?

ANSWER.—Fellowship in the Royal Microscopical Society is honorary and is conferred by the society. Applications for fellowship must be signed by three fellows of the society, who must certify that the applicant is of established standing and is a microscopist or is engaged in microscopic work.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Dec. 24, 1904:

Hoff, John Van K., deputy surgeon general, assigned to duty at Fort Leavenworth, Kan., with the Infantry and Cavalry School and Staff College.

Mathews, George W., and Turnbull, Wilfrid, asst.-surgeons, ordered to report to Major Wm. C. Borden, surgeon, U. S. Army, president examining board, Washington, D. C., Jan. 4, 1905, for examination to determine their fitness for promotion.

Peshon, George D., surgeon, promoted major and surgeon, to rank from Dec. 5, 1904.

Smart, Charles, asst.-surgeon general, relieved from further treatment at the Army and Navy General Hospital, Hot Springs, Ark., and will repair to Washington, D. C., with a view to appearing before a retiring board.

Morrow, Charles E., asst.-surgeon, granted three months' leave of absence.

Hartnett, E. H., asst.-surgeon, granted three months' leave of absence, with permission to go beyond the sea.

Siler, Joseph F., asst.-surgeon, left Fort Logan, Colo., en route to Fort Douglas, Utah, for temporary duty.

Ewing, Charles E., surgeon, leave of absence extended seven days.

Jones, Percy L., asst.-surgeon, reports from duty as transport surgeon on the *Sumner* to detached service with recruits to Angel Island, Cal.

Kendall, Wm. B., surgeon, relieved from duty at Presidio of Monterey, Cal., and ordered to sail March 1, 1905, for duty in Philippine Islands.

Winter, Francis A., surgeon, relieved from duty at Fort Huachuca, Ariz., and ordered to sail March 1, 1905, for duty in Philippine Islands.

Fisher, Henry C., surgeon, relieved from duty at Camp Geo. H. Thomas, Ga., and ordered to sail April 1, 1905, for duty in the Philippine Islands.

Gray, Wm. W., surgeon, relieved from duty at Fort McPherson, Ga., and ordered to sail April 1, 1905, for duty in the Philippine Islands.

Shillock, Paul, surgeon, relieved from duty at Fort Meade, S. D., and ordered to sail on May 1, 1905, for duty in the Philippine Islands.

Ives, Frank J., surgeon, relieved from duty at Fort Sheridan, Ill., and on expiration of present leave will proceed to Manila for duty in Philippine Islands.

Stark, Alexander N., asst.-surgeon, relieved from duty with Isthmian Canal Commission and on expiration of leave of absence will proceed to Manila for duty in Philippine Islands.

Kellogg, Preston S., contract surgeon, left Omaha, Neb., December 8, on leave of absence.

Shellenberger, James E., contract surgeon, ordered from Fort Sam Houston, Texas, to Fort Clark, Texas, for temporary duty.

Brown, Henry D., contract surgeon, granted an extension of his leave of absence to include Jan. 1, 1905.

De Kraft, S. Chase, contract surgeon, ordered from Washington, D. C., to St. Louis, Mo., for duty with the battalion of Philippine scouts.

Enders, William J., contract surgeon, granted an extension of eleven days to his leave of absence.

Greenwell, Samuel A., contract surgeon, ordered from Cleburne, Texas, to Fort Barrancas, Fla., for duty.

Freeman, Charles E., Wilson, Ezerton T., and Dickinson, Clarence P., contract surgeons, arrived at San Francisco December 15 on the transport *Sheridan*.

Navy Changes.

Changes in the Medical Corps of the U. S. Navy for the two weeks ending Dec. 24, 1904:

Babin, H. J., medical director, retired from active service, Dec. 15, 1904, on which date he reached the age of 62 years, under the provisions of Section 1444, Revised Statutes, with the rank and pay of the senior pay grade of asst.-surgeon in the Navy.

Foster, T. G., A. A. surgeon, detached from the *Michigan* and granted leave until January 3, then to report at Washington, D. C., for examination for appointment as asst.-surgeon in the Navy.

De Vallin, H., A. A. surgeon, ordered to the *Michigan*.

Harnon, G. E. H., medical inspector, detached from duty in charge of the Naval Laboratory, Brooklyn, N. Y., and ordered to duty in command of the Naval Hospital, N. Y.

Bertholet, D. N., medical inspector, detached from the Marine Barracks, Washington, D. C., and ordered to duty in charge of the Naval Laboratory, Brooklyn, N. Y.

Nelson, H. T., asst.-surgeon, ordered to additional duty at the Marine Barracks, Washington, D. C.

Kennedy, J. T., P. A. surgeon, detached from duty at the Louisiana Purchase Exposition, St. Louis, and ordered to Annapolis, Md.

McCarthy, G., surgeon, detached from the *San Francisco*, ordered home and granted leave for one month.

Evans, S. G., surgeon, detached from the *Cleveland* and ordered to the *Illinois*.

Holcomb, R. C., P. A. surgeon, ordered to the *Illinois* temporarily and thence to the *Cleveland*.

Norton, O. D., surgeon, detached from the *Illinois* and granted sick leave for three weeks.

Carter, A. J., asst.-surgeon, ordered to the *Prairie*.

Pease, T. N., asst.-surgeon, detached from the *Hartford* and ordered to the *Columbia*.

Tolfree, H. M., asst.-surgeon, ordered to the *Hancock*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service, for the seven days ending Dec. 21, 1904:

Pettus, W. J., asst.-surgeon general, granted leave of absence for five days from December 27.

Stoner, C. W., surgeon, seven days' leave of absence, under paragraph 189 of the Regulations, from Dec. 16, 1904.

Carter, H. K., surgeon, detailed to represent the Service at meeting of the Pan-American Congress, to be held at Panama, R. P., Jan. 3-6, 1905.

Carrington, P. M., surgeon, reassigned to duty as medical officer in command at Fort Stanton, N. M., to date from December 15.

Holander, G. M., surgeon, granted leave of absence for one month, on account of sickness, from December 23.

Perry, J. C., surgeon, detailed to represent the Service at the meeting of Pan-American Medical Congress, to be held at Panama, R. P., Jan. 3-6, 1905.

Von Ezdorf, R. H., P. A. surgeon, granted leave of absence for four days from December 21.

Pierce, C. C., asst.-surgeon, detailed to represent the Service at meeting of Pan-American Medical Congress, to be held at Panama, R. P., Jan. 3-6, 1905.

Hall, L. P., pharmacist, relieved from duty at Cape Charles quarantine, and directed to proceed to Louisville, Ky., and report to medical officer in command for duty and assignment to quarters.

Van Ness, G. L., Jr., pharmacist, relieved from duty at Louisville, Ky., and directed to proceed to Evansville, Ind., and report to medical officer in command for duty and assignment to quarters.

Peck, H., pharmacist, services discontinued, to take effect December 16.

CASUALTY.

Echেমedia, D. M. A. A. surgeon, died at Havana, Cuba, Dec. 19, 1904.

PROMOTIONS.

Smith, Alexander C., P. A. surgeon, commissioned (permanent) as surgeon, to rank as such from Dec. 17, 1904.

Schereschewsky, J. W., asst.-surgeon, commissioned (permanent) as P. A. surgeon, to rank as such from Nov. 11, 1904.

Wille, C. W., asst.-surgeon, commissioned (permanent) as P. A. surgeon, to rank as such from Nov. 11, 1904.

Amesse, J. V., asst.-surgeon, commissioned (permanent) as P. A. surgeon, to rank as such from Nov. 4, 1904.

Wilson, R. L., asst.-surgeon, commissioned (permanent) as P. A. surgeon, to rank as such from Dec. 1, 1904.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ending Dec. 23, 1904:

SMALLPOX—UNITED STATES.

California: Stockton, Nov. 1-30, 2 cases.

Illinois: East St. Louis, Dec. 1-17, 18 cases, 2 deaths.

Indiana: Evansville, Dec. 17, 53 cases.

Louisiana: New Orleans, Dec. 10-17, 4 cases, 2 imported.

Michigan: At 20 cases, Dec. 5-10, present.

Minnesota: Dec. 5-12, Aitkin Co., 3 cases; Otter Tail Co., 2 cases; Rice Co., 1 case; Todd Co., 5 cases; Wilkin Co., 3 cases.

Missouri: St. Louis, Dec. 10-17, 12 cases, 1 death.

New York: New York City, Dec. 10-17, 2 cases.

Ohio: Canton, Dec. 3-10, 1 case.

Pennsylvania: Altoona, Dec. 10-17, 1 case.

South Carolina: Charleston, Dec. 14, 1 case imported.

Tennessee: Dec. 10-17, Memphis, 1 case imported; Nashville, 2 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Nov. 19-26, 12 cases.

China: Shanghai, Nov. 5-12, 2 cases.

France: Paris, Nov. 26-Dec. 3, 15 cases.

Great Britain: Bradford, Nov. 19-Dec. 3, 6 cases; Leeds, Nov. 26-Dec. 3, 2 cases; London, Nov. 19-26, 2 cases; Newcastle-on-Tyne, Nov. 26-Dec. 3, 11 cases, 1 death; Nottingham, Nov. 26-Dec. 3, 1 case.
 India: Bombay, Nov. 24-Dec. 22, 2 deaths; Madras, Nov. 12-18, 3 deaths.
 Italy: Catania, Nov. 24-Dec. 1, 3 deaths.
 Russia: Moscow, Nov. 19-26, 2 cases, 1 death; Warsaw, Oct. 15-Nov. 5, 15 deaths.
 Switzerland: Zurich, Nov. 19-26, 1 death.

YELLOW FEVER.

Mexico: Guayaquil, Nov. 16-23, 1 death.
 Ecuador: Cotacacanos, Nov. 26-Dec. 10, 4 cases, 5 deaths; Dec. 4-10, Juchitan, 2 cases; Tehmantepec, 1 case, 1 death; Texistepec, 1 case, 1 death.
 Panama: Panama, Dec. 5-12, 3 cases.

CHOLERA.

India: Calcutta, Nov. 5-19, 65 deaths.
 Russian Empire: Oct. 24-Nov. 19, Baku District, 20 deaths; Erivan, 254 cases, 134 deaths; Samara District, 64 cases; Serachis, 3 cases; Zaraguy, 21 cases, 17 deaths.
 Turkey in Asia: Nov. 21, 84 cases, 63 deaths.

PLAGUE.

Arabia: Aden, Nov. 3, present.
 Australia: Brisbane, vicinity of, Nov. 5, 1 case.
 Ceylon: Colombo, Nov. 3-11, 6 cases, 4 imported on steamship *Torrington* from Burmese ports.
 Egypt: Takh District, Nov. 12-19, 1 case, 1 death.
 India: Bombay, Nov. 15-22, 57 deaths; Calcutta, Nov. 5-19, 14 deaths; Karachi, Nov. 13-20, 13 cases, 8 deaths.
 Mauritius: Sept. 9-Oct. 13, 101 cases, 82 deaths.
 Peru: Oct. 24-31, Callao, 3 cases; Eten, 21 cases, 9 deaths; Pacasmayo, Oct. 31, present.

Deaths.

William Gilfillan, M.D. University of Edinburgh, Scotland, 1855, formerly house surgeon at the Royal Infirmary, Edinburgh; physician to the marquis of Bute, and surgeon on the Cunard Line; a member of the faculty of Long Island College Hospital; a member of the Kings County Medical Society, died at his home in Brooklyn, N. Y., from bronchitis, after an illness of two days, aged 71.

Clarence L. Elebash, M.D. College of Physicians and Surgeons in the City of New York, 1891, a member of the American Medical Association, a well-known ophthalmologist of New York City, for several years chief surgeon of the Brooklyn Heights Railroad Company, died at the Westminster Hotel, New York City, December 20, after an illness of three months, from typhoid fever, aged 45.

D. M. Echemendia, M.D., acting assistant surgeon, U. S. P. H. and M.-H. Service, a noted expert in yellow fever, who did good work in driving the fever from Havana, and also served during the epidemics in Florida in 1889 and 1888, died in Havana, Cuba, December 19, from a malignant fever.

Thomas S. Troxell, M.D. Jefferson Medical College, Philadelphia, 1881, of Gallitzin, Pa., a member of the American Medical Association, local surgeon for the Pennsylvania System, died at Cresson, Pa., while preparing for an operation, December 15, from apoplexy, aged 47.

Madison H. Rose, M.D. University of Buffalo Medical Department, 1861, surgeon of the Fifty-third Indiana Volunteer Infantry in the Civil War, died suddenly at his home in Thorn-town, Ind., December 16, from heart disease, aged 72.

John F. Baggot, M.D. Medical College of Georgia, Augusta, 1859, a surgeon in the Confederate service during the Civil War, physician of Bamberg County, S. C., died suddenly at his home in Bamberg, December 14, from heart disease, aged 78.

Edward J. Doud, M.D. the College of Physicians and Surgeons, Baltimore, 1880, formerly city physician of Trenton, N. J., despondent and in ill health, committed suicide at Denver, Colo., December 12, by taking morphin, aged 51.

Samuel Hemingway, M.D. Bellevue Hospital Medical College, New York City, 1875, one of the earliest ambulance surgeons in New York City, died suddenly at his home in that city, December 18, from heart disease, aged 50.

James D. Tantum, M.D. University of Pennsylvania Department of Medicine and Surgery, Philadelphia, 1878, of Trenton, N. J., died at the German Hospital, Philadelphia, December 18, shortly after a surgical operation, aged 48.

Henry B. Bessac, M.D. University of Michigan, Ann Arbor, 1873, physician of Butte County, Cal., died at his home in Oroville, December 3, from septicemia, after an illness of more than a year, aged 59.

William John L. Miller, M.D. Medical Department University of Buffalo, N. Y., 1884, who fell from a street car in St. Louis

in April last, died from his injuries at his home in St. Louis, December 19, aged 65.

Daniel E. Hartnett, M.D. Starling Medical College, Cleveland, 1897, of Toledo, died at St. Vincent's Hospital in that city, December 14, from acute gastritis, after an illness of about two weeks, aged 29.

Charles W. Manker, M.D. State University of Iowa College of Medicine, Iowa City, 1876, died at his home in Elliott, Iowa, December 7, after an illness of several months, aged 54.

Joseph A. Townsend, M.D. Baltimore University School of Medicine, 1892, member of the Board of Medical Examiners for the third district of Florida, died recently at Lake City.

John S. Brown, M.D. Kentucky School of Medicine, Louisville, 1883, died at his home in Taylor, Texas, December 17, after an illness of three months, from paralysis.

Conrad Wesselhoeft, M.D. Harvard University Medical School, Boston, 1856, of Boston, died at his home in Newton Center, Mass., December 17, aged 70.

Henry Pigeon, M.D. College of Physicians and Surgeons of Ontario, Toronto, 1884, died suddenly at his home in Peterborough, Ont., December 7, aged 65.

John T. Merrill, M.D. Rush Medical College, Chicago, 1856, died at his home in Mount Ayr, Iowa, December 18, after an illness of several months, aged 69.

James W. P. Seller, M.D. Cincinnati, 1844, died at his home in Greencastle, Ind., from catarrhal pneumonia, November 24, after a short illness, aged 83.

Archibald H. J. Galbraith, M.D. Edinburgh, 1868, died at his home in Conway, S. C., December 13, from apoplexy, after an illness of four hours, aged 64.

Clarence Willard Butler, M.D. New York, 1872, died at his home in Montclair, N. J., December 20, from cancer, after an illness of a year, aged 56.

Thomas A. Smith, M.D. Rush Medical College, Chicago, 1876, died at his home in Kansas City, Mo., after a long illness, December 19, aged 57.

Jerome A. Boarman, M.D., a pioneer physician of Kansas City, Mo., died at his home in that city after an illness of several weeks, aged 84.

Samuel W. Shell, M.D. Baltimore Medical College, 1899, died at his home in Lenoir, N. C., December 15, from heart disease, aged 28.

D. L. S. Bland, M.D. St. Louis Medical College, 1866, died suddenly at his home in Vandalia, Mo., December 18, from heart disease.

Bruno G. Jurgensohn, M.D. Illinois, 1892, died suddenly from heart disease at his home in Manawa, Wis., December 19.

John W. Fox, M.D., one of the oldest physicians of Nevada, died at his home in Carson, December 14, aged 82.

Thomas Tanner, M.D. Ohio, 1890, was suffocated in a fire at his rooms in Saginaw, Mich., December 10.

Death Abroad.

George Vivian Poore, F.R.C.P. London, 1877, M.D. London, 1871, M.R.C.S. England, 1866, emeritus professor of medicine, University College, London, one of the best known of the London physicians, died at Andover, Hampshire, November 23, aged 61. He was born in 1843 and educated at University College. In 1872 he was appointed lecturer on medical jurisprudence at Charing Cross Hospital. At that time the electrical treatment of disease was in its infancy. Dr. Poore perceived its importance and delivered courses of lectures on medical electricity at the hospital. In 1876 he was appointed assistant physician to University College Hospital and in the same year published his "Text-Book of Electricity in Medicine and Surgery."

In 1881 he published a useful book on "Physical Diagnosis of Diseases of the Throat, Mouth and Nose," and delivered the Bradshaw lecture of the Royal College of Physicians on "Nervous Affections of the Hand." He devoted considerable attention to hygiene and various sanitary problems such as the hygiene of the street, the water supply of country districts and the prevalent ignorance of sanitary matters among the middle class in England. He advocated the earth disposal of excreta as the best method both from the sanitary and economic standpoint. In his garden at Andover he raised luxuriant crops of fruit and vegetables by manuring with a mixture of fresh feces and earth. At the same time he proved that the subsoil water remained perfectly wholesome and fit for domestic use. He was a writer of considerable ability, lucid, witty and scholarly.

State Boards of Registration.

COMING EXAMINATIONS.

Utah State Board of Medical Examiners, Salt Lake City, January 2. Secretary, R. W. Fisher, M.D., Salt Lake City.
 Board of Medical Examiners of Arizona, Phoenix, January 2-3. Secretary, Alfred M. Smith, M.D., Phoenix.
 Board of Medical Examiners of the State of Oregon, Portland, January 3. Secretary, Byron E. Miller, M.D., The Dekum, Portland.
 Minnesota State Board of Examiners, State Capitol Building, St. Paul, January 3. Secretary, C. J. Ringnell, M.D., Minneapolis.
 North Dakota State Examining Board, Grand Forks, January 3. Secretary, H. M. Wheeler, M.D., Grand Forks.
 Washington State Board of Medical Examiners, Spokane, January 3. Secretary, C. W. Sharples, M.D., Seattle.
 Rhode Island State Board of Health, Providence, January 5-6. Secretary, Gardner P. Swartz, M.D., State House, Providence.
 Wisconsin Board of Medical Examiners, Hotel Pfister, Milwaukee, January 9-11. Secretary, Philip A. Forsbeck, M.D., Milwaukee.
 State Medical Board of the Arkansas Medical Society, Little Rock, January 10. Secretary, J. R. Tanyan, M.D., Little Rock.
 Indiana State Board of Medical Registration and Examination, State House, Indianapolis, January 10-12. Secretary, W. T. Gott, M.D., Crawfordsville.
 Vermont State Board of Medical Censors, Y. M. C. A. Building, Burlington, January 11-12. Secretary, S. W. Hammond, M.D., Rutland.
 Board of Medical Supervisors of the District of Columbia, Washington, January 12. Secretary, Wm. C. Woodward, M.D., Washington, D. C.
 Illinois State Board of Health, The Great Northern Hotel, Chicago, January 19-21. Secretary, J. A. Egan, M.D., Springfield.
 New York—Three Medical Boards, New York, Albany, Syracuse and Buffalo, January 24-27. H. J. Hamilton, Education Department, Albany.
 Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

Oklahoma June Report.—Dr. E. E. Cowdrick, secretary of the Territorial Medical Examining Board of Oklahoma, reports the written, examination, held at Guthrie, June 29, 1904. The number of subjects examined in was 9, total questions asked, 85. No percentages are assigned by this board, but each candidate is required to attain a grade of 66.6 or over, in each branch. The total number examined was 29, of whom 9 passed and 20 failed. The following colleges were represented:

PASSED.

Barnes Medical College (1904) had 1 representative. Rush (1896) 1, (1904) 1; Kansas Medical College (1904) 1, (1896) 1; Kansas City Medical College (1904) 1; Ensworth Medical College (1904) 1; Univ. Med. Coll., Kansas City (1895) 1; Northwestern University (1900) 1.

FAILED.

Kansas Medical College (1877) 1; Barnes Medical College (1904) 1, (1892) 1; Kansas City Medical College (1904) 2; University of Tennessee (1903) 1; Medico-Chirurgical College, Kansas City, (1904) 1; Central Med. Coll., St. Joseph, (1904) 1, (1898) 1, (1899) 1; Rush, (1903) 4, (1876) 1; Jefferson Medical College (1871) 1; University of Louisville, (1891) 1; Louisville Medical College, (1897) 1; University of the South Med. Dept., (1903) 1; ten year practice act in law 3.

Illinois October Report.—Dr. J. A. Egan, secretary of the State Board of Health of Illinois, reports written examination held at Chicago, Oct. 12-14, 1904. The number of subjects examined in was 11; total questions asked, 110; percentage required to pass, 75. The total number examined was 60, of whom 53 passed and 7 failed. The following colleges were represented:

PASSED.

College	PASSED.	Year Grad.	Per Cent.
Amer. Med. Missionary Coll., Chicago	(1904)	79
Baltimore Med. Coll.	(1904)	84
Chicago Homeo. Med. Coll.	(1904)	86, 82
College of P. and S., Chicago	(1903) 80, (1904)	78
Coll. of Med. and Surg., Chicago	(1904)	77
Dearborn Med. Coll., Chicago	(1904)	84
Georgetown Univ., Washington, D. C.	(1904)	87
Harvard Univ. Med. School, Boston	(1903)	86
Illinois Med. Coll., Chicago, (1904)	the grade of 86 was reached by one, 85 by two, 84 by two, 83 by one, 82 by two, 81, 80, 79, 78 and 77 by one each.		
Jenner Medical College, Chicago	(1904)	81, 78
Johns Hopkins Univ., Baltimore	(1901)	91
Kentucky University, Louisville	(1904)	84

College of Med. and Surg., Chicago	(1904)	55
Harvey Med. Coll., Chicago	(1904)	67
Hospital Coll. of Med., Louisville	(1904) 46, (1902)	72
Miami Med. Coll., Cincinnati	(1882)	73
Rush Medical College	(1875)	74

The general average attained by all graduates of the Illinois Medical College was 82. The general average attained by all graduates of Rush who passed was 84.8.

Nevada Report.—Dr. S. L. Lee, secretary of the Nevada State Board of Medical Examiners, reports the number of physicians licensed by the board in 1903 and 1904. The present practice act of the state does not require examination of physicians who hold diplomas from reputable colleges in the United States, but requires it of graduates of foreign schools.

In 1903 there were 120 applicants, of whom 108 were licensed and 12 were rejected. One person, a graduate of the Royal University, Pisa, Italy, 1899, was examined and attained a grade of 90.

In 1904 there were 140 applicants, of whom 105 were granted licenses and 35 were rejected. One person, a graduate of Laval University, Montreal, 1904, was examined and passed with a grade of 75. As he only reached this average by the most generous treatment of the board he was granted only a temporary certificate till the secretary could ascertain if he passed his collegiate examinations creditably.

Idaho October Report.—Dr. Robert L. Nourse, secretary of the Idaho State Board of Medical Examiners, reports the written examination, held at Lewiston, Oct. 4-5, 1904. The number of subjects examined in was 12; total questions asked, 120; percentage required to pass, 75. The total number examined was 21, of whom 14 passed and 7 failed. The following colleges were represented:

PASSED.

*Re-examined.

Medical Organization.

Arkansas.

THIRD DISTRICT MEDICAL SOCIETY.—On November 9 this society was organized at Brinkley. The following officers were elected: President, Dr. Philip E. Thomas, Clarendon; vice-presidents, the presidents of the component county societies; secretary, Dr. William H. Deaderick, Marianna, and treasurer, Dr. D. O. Bridgeforth, Forrest City.

Idaho.

NORTH IDAHO DISTRICT MEDICAL SOCIETY.—This district society, comprising the counties of Shoshone, Idaho, Nez Percés, Latah and Kootenai, was organized in Lewiston, December 5, on the standard plan and in co-operation with the Idaho State Medical Society. The following officers were elected: Dr. John N. Allen, Lapwai, president; Dr. John B. Morris, Lewiston, vice-president, and Dr. James M. Lyle, Peck, secretary and treasurer.

North Dakota.

TRI-COUNTY MEDICAL SOCIETY.—Physicians of Eddy, Foster and Wells counties met in New Rockford, December 13, and formed this society, with the object of bringing into organization the physicians of the three counties; to be a part of the North Dakota State Medical Association, and to be auxiliary to and subject to the rules of the American Medical Association. The standard constitution and by-laws were adopted and the following officers elected: President, Dr. Charles McLachlan, New Rockford; vice-president, Dr. John G. Johns, Bowdon; secretary-treasurer, Dr. Murdock MacGregor, Fessenenden; delegates to state association, Drs. John R. MacKenzie,

Carrington, and Guy D. Murphy, New Rockford, and censors, Drs. Charles McLachlan, New Rockford; Murdock MacGregor, Fessenden, and Edwin L. Goss, Carrington.

Society Proceedings.

NORTH BRANCH PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, Oct. 4, 1904.

Dr. Samuel Wolfe in the Chair.

Symposium on Chronic Bright's Disease.

ETIOLOGY AND DIAGNOSIS.

DR. SAMUEL WOLFE stated that there is usually as an underlying cause either inflammation or degeneration, probably both, and that it is a mooted question whether there is ever degeneration without inflammation. He referred to the fact that in many cases back of the inflammation and degeneration there is a toxin or specific infection, and cited among the causative factors malaria, tuberculosis, amyloid degeneration, syphilis, exposure and excessive use of alcohol, particularly beer. The disease is more frequent in males than in females and generally occurs before the fortieth year. He confined his remarks to the chronic parenchymatous variety and stated that the condition occasionally is associated with a slight form of pyemia, especially after pregnancy or with anemia. The urine is scanty, with a specific gravity normal or slightly higher than normal; a low specific gravity being indicative of the interstitial variety. The histologic elements are more scanty in the chronic interstitial variety and the edema is more marked. He referred to the diagnostic value of accentuation of the aortic sound, which, while not indicative of any specific form of Bright's disease, is very suggestive of renal trouble. Careful chemical and microscopic study of the urine, the condition of the heart, and the slowly progressive blood deterioration must remain the cardinal points in diagnosis.

PROGNOSIS AND TREATMENT OF CHRONIC NEPHRITIS.

DR. A. C. MORGAN stated that, as it is impossible to repair the damage done to the kidney, the treatment must necessarily be of an inhibitory character. The prognosis, he stated, is difficult to determine owing to the uncertain time the disease has existed, and the complications which may arise; the younger the patient the more serious is the prognosis, the variety in such cases being usually the parenchymatous. He referred to the fact that death is not always caused by the disease alone, and cited as chief among the terminal complications pneumonia, particularly bronchopneumonia, la grippe, cerebral hemorrhage, cardiac dilatation, and inflammation of the serous membranes, pericarditis being the gravest of the latter conditions. In uremia accompanied by convulsions, he stated that the prognosis is grave. In the treatment special attention should be directed to the removal of the cause, and much can be accomplished by the treatment of the patient as well as of the disease. Careful attention should be given to the general condition and hygiene, flannel should be worn the year round in order to stimulate the activity of the skin, and, if possible, the winter should be passed in a warm, equable climate. Mental labor must be cut down and exposure avoided. Cold bathing should be avoided, and benefit is derived from massage, rest in bed for 10 hours out of 24, or the entire time when the paroxysms are severe; malt liquors and spirits should be avoided and carbonated waters used freely. Nitrogenous foods should be reduced and milk may form an important part of the dietary. The treatment should be directed to arresting the sclerotic or degenerative changes and to overcoming the anemia. For the former condition potassium iodid, hydriodic acid and mercuric chlorid may be used, and for the

latter arsenic and iron. He then discussed in detail the treatment of high tension, low tension, effusions, drowsiness, dropsy, asthma, edema of glottis, epistaxis, obstinate vomiting and diarrhea, pruritus, palpitation and uremia; for the latter condition he recommended venesection, chloroform, chloral and the bromids. In the parenchymatous variety morphin in good doses may be used, but in the interstitial form they should be used but sparingly, although the author cited a case in which for five years he had employed morphin hypodermically for the asthma which had resisted all other measures, followed by pilocarpin the morning following without any untoward results.

DISCUSSION.

DR. JAMES TYSON said that while it has been stated that the pathology of chronic nephritis is so indefinite that no treatment can be based on it, he feels that this is going too far. He stated that there is no known agent by which the restoration of the structure of the kidney could be accomplished, and that the treatment naturally divided itself into two parts: 1. The placing of the patient in the condition most favorable for Nature to assert herself and to favor change in the structure, if possible; 2, the treatment of the symptoms. He referred to the former enormous use of drugs to diminish the albuminuria, and stated that there is no remedy which will prevent the transudation of albumin when conditions favor it. He recommended rest in bed for a few hours in the middle of the day in the mild cases, and longer if the case is severe. He said that he believes that the distinctions between white and red meats are unfounded, and recommended, instead of prohibiting red meats, the moderate use of all meats, and said that except in the acute exacerbations a moderate quantity may be allowed.

Climatic treatment is of value and the winters, if possible, should be passed in a warm climate. The treatment of the symptoms should be directed to the diminution of arterial tension. In the severer forms rest in bed is absolutely necessary; massage is also of value. The general practitioners frequently make a mistake in advising the too free use of water. Puncture under aseptic precautions is recommended in dropsical cases, and the danger from sepsis is practically nil. He recommended venesection and intravenous injections of normal salt solution in cases of uremia. If iodid of potassium can be used without producing unpleasant symptoms, it may be of value, but the chlorid of mercury he does not look on as of any use.

DR. WENDELL REBER stated that the ophthalmologic changes are of two kinds, degenerative and hemorrhagic; the inflammatory changes being most likely to occur in the acute forms, while in the chronic conditions there are more likely to be degenerative changes. He referred to the work of Dodd, who some years ago collected 700 or 800 cases and submitted statistics showing the value of these observations in computing the probable duration of life. He referred to the observation of a number of cases made by himself at Blockley, and stated that while about 45 per cent. showed albuminuria, very few revealed eyeground changes, and this had been further confirmed by the observations he had made at the Polyclinic Hospital. He reported the case of a male, 32 years of age, who has had albuminuria for at least 12 years, although he has been giving careful attention to hygiene and his habits are almost ideal. At one time he was able to find a few fine yellow spots, but they disappeared and have not recurred. He also referred to another case which had been watched closely for a long time, and in which there were no changes observed until shortly before death, when violent degenerative changes occurred.

DR. WILLIAM H. GOOD referred to the fact that, according to physiologic chemistry, the osmotic pressure of fluids depends not so much on the kind of molecule present as on their number, and said that perhaps the same line of reasoning will explain the effect of large quantities of proteins, by increasing the osmotic pressure of the blood, and also discussed the question as to whether this action is due to a chemical substance or to the lack of some chemical secretion.

DR. W. HERSHEY THOMAS mentioned the various surgical procedures which have been resorted to for the relief of this condition and stated that here, as elsewhere, much more valuable information could be learned regarding the pathology of the condition during operation than after death.

DR. MORGAN cited a case of chronic interstitial nephritis in which potassium iodid three times a day had been used with much benefit.

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulæ and outlines of treatment are answered in these columns without allusion to inquirer.]

Chronic Prostatitis.

In the treatment of chronic prostatitis, E. G. Ballenger, in *Amer. Medicine*, states that careful attention should be given to:

1. Hygiene, including the regulation of sexual intercourse, alcoholics, food, bathing, exercise, etc.
2. The treatment of complications such as posterior urethritis, stricture, inflammation of the seminal vesicles, anemia, constipation and to general health.
3. Treatment directed to the prostate itself.

HYGIENE.

Moderate sexual intercourse is rather beneficial than otherwise, unless attended by too great excitement or too much prolonged. In cases of single individuals this, of course, should not be encouraged because of the danger of another infection, if for no other. Alcohol in excess should never be permitted, for occasional spree hindrs the progress of the case, although light wines or beer taken at meal-times may be of benefit in increasing the appetite and digestion. The food should be plain and simple and not highly seasoned nor taken in too great quantities. Small amounts of tea and coffee will not harm the patient. Smoking should always be in moderation, but not necessarily entirely forbidden. Cold baths in the morning should be recommended, especially applied to the genital organs. Walking is better than riding and driving as an exercise on account of the jarring of the latter forms. Constant sitting is injurious, especially during long journeys in railway cars.

COMPLICATIONS.

Constipation, anemia and indigestion demand correction. Strictures should be dealt with in accordance with their nature, location and caliber. A meatus below 18 F. or 20 F. must be enlarged to more than 26 F. or 28 F. Cystitis, if present, should be treated by the administration of urotropin, grains 5 to 10 (.30-.65) three times a day, along with irrigations of mild warm solutions of mercuric chlorid, potassium permanganate or silver nitrate. If inflammation of the seminal vesicles and ampullations is present their lower extremities may be gently massaged and their contents expressed during treatment of the prostate by deep pressure. This treatment of the chronic posterior urethritis is most important and should consist of instillations, irrigations, sounds, cold, etc.

Massage is indicated when the prostate is large, soft and boggy or nodular, uneven or contains abscess cavities. It is contraindicated when the prostate is tender or hyperæsthetic; in tubercular prostatitis or when the treatment increases the irritability.

The author recommends instillations of silver nitrate of from 5 to 10 per cent. solutions in water in doses of from 10 to 20 minims (.65-1.30), deposited in the prostatic urethra with a

deep urethral syringe. These injections may set up an acute inflammation which passes away in a few days and absorbs part of the chronic exudate. The injection must be carried beyond the compressor urethræ muscle, otherwise the solution will run back along the syringe into the anterior urethra. These injections should be made from three to ten days apart. A small amount of urine should be in the bladder when they are made. Irrigations of the hot antiseptic solutions are indicated when abscesses or suppurating follicles are present.

Sounds chilled in ice water and left in the urethra from three to five minutes are often very beneficial on account of the pressure and the cold tones up the blood vessels and anesthetizes, so to speak, the nerve endings. The following method is also recommended by the writer:

Sterilize a sound one or two sizes smaller than the cold one passed (which should be as large as can be used) and dip it into the following ointment, brought to a melting point:

R. Argenti nitratiss	gr. v-x	30-.65
Olei theobrom.	ʒi	30
M. Sig.: As directed. Or:		
R. Argenti nitratiss	gr. v-x	30-.65
Cereæ albæ	gr. x	65
Balsami Peruv.	m. xxx	2
Olei theobrom.	ʒi	30

M. Sig.: Apply on a sound as directed.

The following ointment introduced into the deep urethra is also recommended:

R. Argenti nitratiss	gr. v-x	30-.65
Olei olivæ	m. xv	1
Liq. petrolati	ʒi	30
M. Sig.: Apply to the deep urethra on a sound.		

MASSAGE.

In giving massage the patient should be directed to stoop over with hands resting on a chair or placed in the knee-chest position on a table, or in the position to make a vaginal examination. The latter position is preferred by the author, as in this position the muscles are more relaxed and counter-pressure can be made over the symphysis pubis in massaging the seminal vesicles. The finger is protected with a finger cot or condom and anointed with glycerin and introduced. It is then carried from side to side toward the center and from above downward for about five minutes, paying special attention to nodules. By this means the secretion is milked out. Massage increases the tone of the vessels, stimulates the lymphatics and empties the distended follicles and cavities.

SUPPOSITORIES.

Suppositories should be used to meet the indications in the individual case. They may contain the following:

R. Potassii iodidi	gr. v-xx	30-1.30
Ext. belladonnæ	gr. ¼	015
Cereæ albæ	gr. v	30
Olei theobrom. q. s.		

M. Fiat suppos. No. i. Sig.: To be introduced into the rectum on retiring at night or every second night.

Hot and cold water applied to the prostate through a rectal irrigator is of service, as this treatment stimulates absorption and increases vascular tone. This may be repeated once every second day.

TONICS.

As tonics, iron, quinin and strychnia are of benefit. When a sedative is indicated, hyoseyamin is recommended in doses of from 1/100 to 1/60 gr. (.0006 to .001).

As to the employment of irrigation in chronic prostatitis, Lydston regards potassium permanganate as first in importance, used in strength of from 1 to 10,000, as 1 to 5,000, not stronger. The water should be warm and not hot, and used in quantity of not more than two quarts at a time. In cases where the use of the permanganate solution does not prove effectual the author recommends as the second remedy in importance, a silver nitrate solution in .5 to 1 per cent. solution, as the urethra will not, as a rule, bear a stronger solution. Weak solutions of mercuric chlorid is the third remedy recommended by this writer. He also advises antiseptic and astringent remedies

locally applied through the rectum. Iodoform, europhen and ichthylol in combination with anodynes are regarded as very efficacious applied in this way.

Counter-irritation applied to the perineum in the form of blisters is a very valuable form of treatment. Hepatic torpor must be corrected and the pelvic circulation kept active. In very serious cases of diffuse chronic inflammation the prostate and neck of the bladder should be put to complete rest by a combined suprapubic and perineal section with through drainage. The author cautions against the use of the sound before the acute inflammation has subsided, otherwise a recurrence of the subsiding acute inflammation may take place.

Pain in the Ear.

To relieve pain in the ear where the patient's condition demands immediate attention before a diagnosis can be positively made, the *Sour. des Pract.* recommends warm boric acid solution dropped into the ear and allowed to remain a few minutes and repeated every hour. During the intervals warm carbolized oil (1 to 20), placed on absorbent cotton, should be introduced into the ear and the organ covered with hot compresses. At bed time the following solution may be placed on absorbent cotton and introduced into the passage:

R. Morphine hydrochlor.gr. viiiss	50
Cocaine hydrochlor.gr. xv	1
Aque dest.3vi	24

M. Sig.: Six drops placed on a little absorbent cotton and introduced into the ear. Or:

R. Atropine sulph.gr. iss	09
Morphine hydrochlor.gr. v	30
Aque dest.3ss	15

M. Sig.: Six drops at night, on warmed absorbent cotton, and introduced into the ear.

If abscess formation should take place the abscess should be properly incised.

A combination of belladonna and opium frequently gives relief in neuralgic conditions of the ear as follows:

R. Tinct. belladonnæ	
Tinct. opii, aa.3ii	8

M. Sig.: Instill five drops warm into the auditory canal and repeat three or four times daily.

Ichthylol is frequently of service combined as follows:

R. Ichthylol	5i	4
Ung. aquæ rosæ	3ss	2
Liq. petrolati	3iiss	6

M. Sig.: The auditory canal should be thoroughly washed with a warm sodium bicarbonate solution, dried and the passage anointed with the preparation two or three times daily.

Medicolegal.

Sufficient Evidence That Varicocele Resulted from Injuries.

—The Appellate Term of the Supreme Court of New York says that, in the personal injury case of Bial vs. the Interurban Street Railway Co., the plaintiff testified that prior to the accident in question he did not suffer from varicocele, and, according to his physician's testimony, this condition did not become apparent until a day or two after the accident. The physician further testified that, while varicocele is not ordinarily of traumatic origin, it is so in about 10 per centum of the cases, and in this he was corroborated by another physician, a witness for the defendant, who testified that varicocele might result from injuries, but fixed the proportion of such instances at about 5 per centum of all the cases. The court says that argument appeared to be unnecessary to demonstrate that this testimony warranted a conclusion that the plaintiff's condition was attributable to injuries sustained in the accident complained of.

Damages Allowed in Personal Injury Cases.—The Third Appellate Division of the Supreme Court of New York says, in *Jones vs. New York Central and Hudson River Railroad Co.*, that in cases of personal injury there is no rule by which compensatory damages may be computed with accuracy. The plaintiff is entitled to recover his reasonable expenditures for

medical services, medicines and attendance, and also a reasonable amount in compensation for the pain and suffering occasioned by his injuries, and for the scars and deformities resulting therefrom, to which amount must be added a sum sufficient to compensate him for his loss of power to earn money. The verdict of juries and determination of courts in other cases can not be safely relied on as a rule or guide in determining whether a verdict is excessive, as each case necessarily depends on facts and circumstances applicable to or surrounding it. It is the province of the jury to fix the amount of the damages in each case, and it has been repeatedly stated by the courts that a verdict should not be set aside unless the jury has been misled by passion or prejudice, or coerced by some improper influence in fixing the amount of their verdict. Where it is plain that the amount of the verdict is out of all proportion to the injuries received, the court will assume that the jury misunderstood the rights of the parties or the effect of the evidence before them in determining the amount of their verdict, or that the verdict was affected by overpowering sympathy or improper influences.

Power of Society to Furnish Care of a Physician.—The Supreme Judicial Court of Maine holds, in the case of *Flaherty vs. the Portland Longshoremen's Benevolent Society*, that if a corporation or mutual association has for one of its lawful purposes the mutual aid and protection of its members, and has the power to raise and expend money for the payment of sick benefits to members, the power to afford relief to its members by furnishing them the care of a physician in time of sickness may be fairly implied from the general scope of the corporate purposes. But when one of the by-laws of a benevolent and protective society provides that "the funds of this society shall be appropriated for no other purpose than that necessarily incurred for the maintenance of wages, burying the dead and other incidental expenses," the payment of a salary to a physician is not thereby authorized, but is forbidden, although another by-law provides for the payment of sick benefits. When such a society by another by-law provides that "resolutions adopted at any general or special meeting of this society for any special purpose shall be as binding on its members as if they were embodied in its by-laws," it is held that by fair construction such resolutions are intended to have, and do have, the effect of by-laws only when they are inconsistent with the by-laws, and do not have the effect of amending or repealing them. A society having such by-laws as those stated can not lawfully vote to pay a salary to a physician for the benefit of its members. To hold otherwise would be to give to such a vote the effect of amending the by-laws.

Current Medical Literature.

AMERICAN.

Titles marked with an asterisk (*) are abstracted below.

American Medicine, Philadelphia.

December 17.

- 1 *Hypernephroma. W. W. Keen, G. E. Pfahler and A. G. Ellis.
- 2 The Value of the Physiologic Principle in the Study of Neurology. James J. Putnam.
- 3 *The Eye and the Digestive System. Mark D. Stevenson.
- 4 Early Recognition of the Therapeutic Virtues of Iron. John Knott.
- 5 *Some Results of Röntgen Ray Treatment. A. R. Ralnear.
- 6 *Röntgen Rays in the Treatment of Tuberculosis. J. Rudis-Jicinsky.

1. **Hypernephroma.**—This paper is based on two cases, both being absolutely well one year after operation, a nephrectomy having been done at that time. The cases recorded in the literature are also studied and analyzed. The pathology of the condition is considered by Dr. Ellis.

3. **Eye and Digestive System.**—Stevenson attempts to show that improperly fitted glasses may be responsible for digestive disturbances and vertigo. He is also of the opinion that the nausea and vomiting of seasickness are chiefly due to reflexes of the eyes and semicircular canals rather than from anything in the stomach itself. He describes the anatomic nerve relationship between the digestive system and the eyes.

5. Roentgen Ray Therapy.—Rainear discusses this subject in general and narrates the results obtained in several cases, such as lupus, nevus, epithelioma, mammary cancer and leg ulcers. He considers the ray an important therapeutic agent, one that must appeal to the surgeon as one of his best adjuncts as a surgical synergist, apart from its diagnostic function.

6.—See abstract in THE JOURNAL of September 24, page 907.

Medical News, New York.

December 17.

- 10 *Association of Cancer and Tuberculosis. W. A. Bastedo.
- 11 *The Minin Ray. Wm. G. Schaulfer.
- 12 *Tropical Malaria. John V. Shoemaker.

9.—See abstract in THE JOURNAL of October 29, page 1330.

10. Association of Cancer and Tuberculosis.—Bastedo shows that these two affections not infrequently occur together in an active state and may be intimately associated in the same tissue. A few reported cases tend to show that one of the affections seems to have exerted a modifying influence on the course of the other. Cancer is more common among those with latent tuberculosis than among others at the cancer period of life. But there is probably neither specific favoritism nor specific antagonism between the two types of disease. However, a family history of tuberculosis is more frequent in the cancerous than in the general community, and there may be some hereditary relation between the two. Bastedo found that a latent tuberculous process in a lymph gland may become active when a cancer develops in the neighborhood, although lymph gland enlargement in the vicinity of the cancer is not always cancerous and may be solely tuberculous.

11. The Minin Ray.—Schaulfer has been using these rays in the treatment of a number of cutaneous affections and asserts that it may be regarded as a safe and reliable means of treating many inflammatory conditions, including joint affections.

12. Tropical Malaria.—The principal points in the series of cases recorded by Shoemaker are their gravity, the very marked and prolonged debility produced by the disease, the resemblance of some cases to yellow fever and of others to typhoid, the diagnostic value of the scientific tests, and the efficacy of quinin administered in the form of suppositories, from 5 or 10 grains, every two or three hours.

- 19 *Case of Diffuse Encephalitis Showing the Pneumococcus. W. N. Bullard and F. R. Symes.
 - 20 *Flies and Tuberculosis. F. T. Lord.
 - 21 Innocent Cases Reported as Diphtheria. H. W. Hill.
 - 22 Remarks on the Jurisprudence of Civil Malpractice, Based Principally on the Decisions Rendered by French Courts. (Concluded.) C. G. Cumston.
19. Diffuse Pneumococcus Encephalitis.—After a month of

severe bronchitis in a man of 50 there developed a group of cerebral symptoms, weakness and mild delirium, followed by flaccid paralysis of the left side, with rigidity on the right and incontinence. Death ensued on the seventh day, after gradual failure and coma, with elevated temperature. The autopsy disclosed an extensive diffuse encephalitis and bronchitis with bronchopneumonia. The pneumococcus was found free in the tissues and within the phagocytes of the cerebral lesion. The lesions were related to branches of the cortical arterial system of both hemispheres and consisted of accumulations of phagocytic cells and small numbers of lymphoid and plasma cells. There was no evidence of acute leptomenigitis or of ependymal changes.

20. Flies and Tuberculosis.—Lord says that flies may ingest tubercular sputum and excrete tubercle bacilli, the virulence of which may last for at least fifteen days. The danger of human infection from tubercular fly specks is by the ingestion of the specks on food. Experiments lead Lord to believe that the spontaneous liberation of tubercle bacilli from fly specks is unlikely. If mechanically disturbed, infection of the surrounding air may occur. The author suggests that tubercular material (sputum, pus from discharging sinuses, fecal matter from patients with intestinal tuberculosis, etc.), should be carefully protected from flies lest they act as disseminators of the tubercle bacilli. During the fly season greater attention should be paid to the screening of rooms and hospital wards containing patients with tuberculosis and laboratories where tubercular material is examined.

- 23 Alcohol in the Tropics. Charles F. Woodruff.
- 24 *Twenty Years' Experience with Manual Dilatation of the Os and Cervix Uteri to Effect Immediate Delivery in the Latter Months of Pregnancy. A New Obstetrical Uterine Dilator. Philander A. Harris.
- 25 *An Interesting Case of Tuberculosis of the Larynx. E. Harrison Griffin.
- 26 *The Transmission of Syphilis by Barbers. Wm. T. Belfield.
- 27 Report of a Case of Tetanus Following Labor. A. Strachstein.

24. Dilatation of Os.—Harris details his experience, extending over a period of twenty years, with his method of manual dilatation of the os and cervix uteri. He cautions that the strain on the cervical ring should be equable and constant and not too strong. The greatest strain is needful in acquiring the first four or five inches of dilatation, after which the strain is gradually diminished, for it is at this time that the danger of producing lacerations is greatest. Fifty minutes is the average time required to dilate safely from the size of one's finger to a circumference of twelve inches. Twenty-five minutes should be the average time for rupture of the membranes and delivery of the child and placenta. Harris describes a simple multi-lever dilator which possesses some advantages over the manual procedure. The hand becomes fatigued; its action is more or less irregular; it can not be sterilized by boiling; the hands must frequently be alternated to rest them, thus entailing loss of time and some risk of infection. Although the instrument may not be used very often by the general practitioner yet its use is of advantage because it is ample in force, continuous in action, it may be boiled, usually requires but a single introduction, every vagina will admit it without injury, and the danger of laceration of the cervix is somewhat less with the instrument than with the hand.

25. Tuberculosis of the Larynx.—Griffin's case was remarkable because of the fact that three attacks of the local lesion, each time going on to the stage of ulceration, were promptly relieved by sending the patient to Colorado or to the Adirondacks. The internal treatment consisted in the use of a creosote preparation and small doses of morphia, 1/20 of a grain, in tablet form, the tablet being allowed to dissolve in the mouth. Open windows day and night, proper clothing, cold bath every morning, and sponging with alcohol or cold water when the patient is thirsty, eggs, beef juice, blood, anything that will support the impoverished system and help nature is important in combating this affection. [The author does not mention the preparation of creosote used nor how used.—Ed.]

26. **Transmission of Syphilis.**—The returns obtained from inquiries addressed to twenty-five prominent syphilographers by Belfield seemed to indicate that the transmission of syphilis by barbers must be a rare incident. However, says Belfield, the prevalence of syphilis among barbers and their patrons, and the general neglect to sterilize their tools, warrant a doubt of the extreme rarity of such transmission. The razor seems, for obvious reasons, least likely to convey the infection, while the alum stick, forceps and clipper are the most frequently culpable. Belfield also calls attention to the fact that sore throat and fever are not infrequently, especially in women, the first discovered symptoms of syphilis. Syphilis could be minimized, if not virtually eradicated, far more quickly, surely and easily than can tuberculosis; not by licensing prostitutes, nor by educating youth to chastity, but by making the acquisition of syphilis practically impossible through the general practice of circumcision. The later evils of syphilis can be restricted by impressing on the subjects of the disease two injunctions: to take antisyphilitic remedies for two months in every year after the termination of active treatment, and (especially) to inform any physician consulted for relief from an obscure, chronic ailment of the earlier syphilitic infection.

1. **Arterial Pressure in Lead Poisoning.**—Vaquez points out that from the diagnostic and prognostic points of view the variations in the blood pressure are of more importance than its absolute figure. Gaertner's tonometer is a simple and reliable instrument for determining these variations. In lead poisoning the arterial pressure is unusually high during the attacks of colic. It rises still higher during the paroxysms, and does not subside to normal during the intervals, but persists as long as the colic lasts. It parallels the course of the abdominal contractile vascular spasm which he has found constant in lead colic. Among the signs of it are the retraction of the liver and the flatness or depression of the abdomen. This long persistence of hypertension is remarkable, as hypertension due to vasoconstriction was always supposed to be more briefly transient. The hypertension does not commence to subside until after the bowels move, and then it gradually drops to the previous figure. In 4 subjects under observation the arterial pressure rose to 19 to 22 cm. (Potain apparatus). During the paroxysms the rise was 5 to 10 cm. The rapidity and the intensity of these variations in the pressure is a feature of lead poisoning. The vascular spasm is the forerunner and maintainer of the hypertension. The vasocontractile action of the poison is at first limited to the splanchnic region, and it here induces the intestinal spasm and the colic. When the vascular spasm and consequent hypertension become generalized, the circulation in the brain suffers and the encephalopathy follows. The existence of the vascular spasm can be read in the eye fundus, in the blanching of the papilla and the contraction of the vessels. These signs do not require the assumption of chronic nephritis to explain them. They may exist before the development of the nephritis, and the latter throws no light on the predilection of lead poisoning for the brain.

2. **Local Cold to Reduce Fever in Nurslings.**—Thévenet has been much pleased with the benefit derived from the applica-

tion of a coil of tubing, containing cold water, in several cases of febrile enteritis in infants of four to fourteen months. The abdomen is comparatively much better developed in infants than in adults, and it contains a larger proportion of the total blood. By prolonged local refrigeration it is possible to lower the temperature in fever. In his experience, all the symptoms, both local and general, were much improved in non-moribund cases. The water was kept at a temperature of 18 to 20 C.

6. **Arteriosclerotic Abdominal Colic.**—Buch describes 11 cases, including 5 personally observed, in which attacks of severe colic above the umbilicus developed in persons of over 40 and 50 years old. The attacks were always brought on by some emotion or extra exertion or by lying down. The abdominal aorta was usually sensitive to pressure, as were also the parts over the spine and on either side of the aorta. The arteriosclerotic origin of the pain is best corroborated by the remarkable efficiency of theobromin, 1.5 to 2 gm. a day; diuretin, 3 to 4 gm. a day, or tinct. strophanthi, 5 to 8 drops, three times a day. These will alleviate or entirely relieve the attacks, especially if supplemented by rest in bed. No other form of abdominal colic is thus amenable to these drugs, and this success is pathognomonic of arteriosclerotic colic. The attacks lasted usually only a few minutes, but, exceptionally, fifteen to thirty, and still longer in a case of hyperchlorhydria. He has further observed 2 cases and found one on record in which this colic accompanied contracted kidney. The signs of general arteriosclerosis were more pronounced than in the first group. A remarkable feature of this group was that the pain was relieved by moderate pressure on the aorta and over the sympathetic, the points most sensitive in the first group. In a third group of 7 cases, including 4 personally observed, epigastric colic was an accompaniment of angina pectoris, although it sometimes occurred alone. Intermittent limping was suggested in one case, and arteriosclerosis of the brain was probable in some of the others. The heart was usually enlarged and the accentuation of the second aortic sound was a constant phenomenon. Ingestion of food had little influence on the attacks. The subjects were usually well nourished and sometimes corpulent, which aids in the differentiation of this splanchnic colic from cancer. Nervous gastralgia and pseudo-angina pectoris generally affect persons under 40, except possibly during the menopause. They are not brought on so constantly by physical exertion, and they usually occur on going to bed, while the splanchnic colic generally wakes the subject from sleep. In case it occurs in a neurasthenic, diuretin and strophanthus will aid in the diagnosis.

7. **Suprarenal Preparations in Affections of the Esophagus.**—Janowski found that patients with esophagitis from swallowing some caustic substance were much benefited by frequent, small doses of some suprarenal preparation. Some who were unable to swallow found that they could easily do so five to ten minutes after taking the preparation, and dysphagia was always much relieved. Three or four days caused permanent improvement, evidently shortening the course of the inflammation and also alleviating the concomitant gastric inflammation. The effect on the latter was less decided than on the process in the esophagus. In 3 cases of cancer of the esophagus the patients could swallow much more easily after taking the suprarenal extract, the improvement being in great contrast to the failure of all preceding measures. This improvement

was not constant in all the cases of esophageal cancer, but it occurred often enough to warrant its tentative use in all cases. In another instance, a supposed cancerous stricture of the esophagus was very much improved by the suprarenal extract, as also in a similar case reported by Peters. But in both these cases the progress of the affection revealed that it must have been a nervous stricture. Janowski knows of no cases recorded in the literature of undeniable cancer of the esophagus treated by suprarenal extract.

10. Rupture of Gravid Uterus After Cesarean Section.—Ekstein reports a case, the first on record, of spontaneous rupture during a pregnancy following a cesarean section done according to Fritsch's technic. The ovum had settled exactly at the point of the cicatrix, and the growth of the placental tissue through the latter had produced conditions which invited rupture. The possibility of this location of the placenta must be borne in mind as one of the disadvantages of conservative cesarean section. It might possibly be guarded against by using for the second of the four tiers of sutures a ribbon-like strip of lead from .5 to 1 cm. wide and .3 to .5 mm. thick. Experience has demonstrated that a suture of this kind lies in the tissues without reaction, owing to its softness and flexibility. The interposition of this inassorbable suture would provide a solid foundation for natural resistance. The number of stitches should be restricted to the minimum, in order not to interfere with the involution of the uterus.

11. Paralysis of Non-Gravid Uterus.—Kossmann has observed several instances in which the uterus allowed the insertion of a broad curette to a distance of 14 cm. Afterwards the organ contracted so that it was impossible to insert any instrument farther than the normal few inches. Laparotomy showed the uterus intact, without a trace of perforation. He thinks that we must accept the possibility of paralysis of the non-pregnant uterus in explanation.

12 and 13. Lumbar Puncture in Eclampsia.—Henkel relates 16 cases of eclampsia treated by lumbar puncture in 1901. The results were apparently negative and discourage further attempts in this line. The cerebrospinal fluid showed the usual pressure, or below, in all but 4 cases; one of the latter terminated fatally. Kleinwächter criticises Krönig's recent publication on the treatment of eclampsia by lumbar puncture as non-conclusive in several respects, and as also showing disregard of what had previously been published on the subject. He remarks that it would be desirable if young confrères would take the trouble to look up the literature before publishing a supposedly new idea or discovery. They might find that others had suggested, and perhaps tried, the same thing before them.

15. Nephrotomy in Anuria of Eclampsia.—Sippel advises that the new conceptions in regard to surgical treatment of kidney affections should be extended to the anuria of eclampsia, but not until better foundations can be provided by careful and extended observation from this standpoint. The question to be decided is whether the nephritis of pregnancy is capable of inducing such acute intracapsular pressure as to compromise the circulation and function of the kidney. In certain cases the increased pressure may be the primary, and the changes in the kidney the secondary phenomena. The presence or accumulation of specific metabolic products in the blood of pregnant

women may raise the pressure in the kidney capsule, and entail altogether different consequences than occur in the case of non-pregnant women. [Pestalozza remarks editorially in *Ginecologia* (Florence, Italy), that Sippel's communication is a curious commentary on Kleinwächter's criticism of Krönig, mentioned above. Sippel confesses that he was unaware of Edebohls' previous announcements on the subject of nephrotomy in the anuria of eclampsia, and even at the date of this writing seems to know of Edebohls' first case alone. The second, a comparatively more important case, was duly chronicled in Pestalozza's journal, *Ginecologia*, soon after it was published in America. He adds that it is hard to keep up with the dizzy onward rush of the scientific publications of the day, but at least those who propose new and hazardous procedures should not restrict their outlook to the literature of their fatherland alone. They should remember that science is the patrimony of the world at large.—Ed.]

18. Saline Infusion in Puerperal Infection.—Jaworski presents data which unmistakably establish the favorable action of saline infusion in puerperal infection, showing that the course is modified for the better and the patient displays slow but constant improvement. In order to be effectual the emunctories must be still functioning. When the kidneys and the glands are no longer working properly, then saline infusion can do comparatively little good. A large amount of fluid should be removed from the intestines or the blood pressure should be reduced by venesection. In this way we free the body from a certain amount of toxins, reduce the blood pressure and favor the diffusion of the artificial serum through the vascular system when it is injected later. In the chronic forms of puerperal infection, saline infusion is especially valuable, on account of its stimulating, cleansing and eliminating action.

19. Yeast in Treatment of Vaginal and Uterine Catarrh.—Cronbach remarks that yeast has a promising future in the treatment of vaginal and uterine catarrhal affections, especially for gonorrhœa in pregnant women and in children. He does not know that it has ever been used in the treatment of gonorrhœa in males. It is an entirely harmless and active antiseptic, but there is still room for improvement in the mode of its preparation.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

PROGRESSIVE MEDICINE, Vol. IV, December, 1904. A Quarterly Digest of Advances, Discoveries and Improvements in the Medical and Surgical Sciences. Edited by Robert Amory Howe, M.D., Professor of Therapeutics and Materia Medica in the Jefferson Medical College of Philadelphia. With 79 Illustrations. Paper. Price, \$6.00. Philadelphia and New York: Lea Brothers & Co.

FIRST REPORT OF THE WELLCOME RESEARCH LABORATORIES AT THE GORDON MEMORIAL COLLEGE, KHARTOUM. By the Director, Andrew Balfour, M.D., B.Sc., M.R.C.P. Edin., D. P. H. Camb., Fellow of the Royal Institute of Public Health. Cloth. Pp. 85. Department of Education, Sudan Government, Khartoum, 1904.

PHYSIOLOGICAL ECONOMY IN NUTRITION, with Special Reference to the Minimal Protein Requirement of the Healthy Man. An Experimental Study. By Russell H. Chittenden, Ph.D., LL.D., Sc.D., Director of the Sheffield Scientific School of Yale University. Cloth. Pp. 478. New York: Frederick A. Stokes Co. 1904.

HOW TO STUDY LITERATURE. A Guide to the Intensive Study of Literary Masterpieces. By Benjamin A. Heydrick, A.B. (Harv.), Professor of English Literature, State Normal School, Millersville, Pa. Third Edition, Revised and Enlarged. Cloth. Pp. 150. Price, 75 cents. New York: Hinds, Noble & Eldredge.

A LABORATORY GUIDE IN ELEMENTARY BACTERIOLOGY. By William Dodge Frost, Ph.D., Assistant Professor of Bacteriology, University of Wisconsin. Third Revised Edition. Cloth. Pp. 395. Price, \$1.60. New York: The Macmillan Co. 1903.

TWENTY-THIRD ANNUAL REPORT OF THE STATE DEPARTMENT OF HEALTH OF NEW YORK FOR THE YEAR ENDING DEC. 31, 1902. Transmitted to the Legislature, Feb. 2, 1903. Part I. Albany: The Argus Co. 1903. PARTS. State Department of Health for the Year 1902. Parts I and II.

LECTURES ON DISEASES OF CHILDREN. By Robert Hutchison, M.D., F.R.C.P., Assistant Physician to the London Hospital. Cloth. Pp. 338. London: Edward Arnold. New York: Longmans, Green & Co. 1904.

POVERTY. By Robert Hunter. Cloth. Pp. 382. New York: The Macmillan Co. 1904.

GENERAL INDEX

The general index includes references to all the reading matter that has appeared in the pages of THE JOURNAL for the past six months. Use of the index will be facilitated by bearing in mind that subjects are frequently given under two or more headings; for example, brain, cerebral, tumor, etc.; heart and cardiac; cirrhosis, liver, hepatic, etc. Often, too, writers treat of the eye, ear, nose and throat under one title. There is no longer a department index such as used to follow the general index, but all the "Deaths" are together at the end of the letter "D." Similarly, all societies are under the heading of "Societies" at the end of the letter "S." All matter pertaining to the American Medical Association is placed together under "Association News." All books are listed under "Book Notices." The following letters are used to indicate the nature of the matter referred to: "E" indicates editorial, "O" original article, "T" therapeutic item, "M" an item in the medicolegal department, and "ab" an abstract of an article that has appeared in full elsewhere. The titles and the authors of the articles which are listed each week as having been published in other journals are given under the Current Medical Literature Index on pages 2076 to 2118.

CURRENT MEDICAL LITERATURE

INDEX OF TITLES

Explanation: This index includes the titles and the subjects of original articles published in the leading medical journals of the world during the past six months. The titles and the names of the journals in which they appeared were published weekly in the Current Medical Literature Department, to which references are made. The figures in parentheses refer to the paragraph; the number following, to the page in THE JOURNAL. For instance, "Abdomen, firearm wounds of the, (84) 437—ab," refers to page 437 of THE JOURNAL, on which is found opposite paragraph 84 the title of the paper and the name of the author, viz.: "Firearm Wounds of the Abdomen, B. K. Finkelstein." This title is listed under the journal in which the article appeared, "Rousskii Vrach, St. Petersburg, ii, No. 39." The "ab" indicates that an abstract of the article appeared in THE JOURNAL, which will be found below the title. Titles of articles which appeared in THE JOURNAL are indicated in the index below by an asterisk (*) before the page number. Index to authors of all the articles below is on pages 2105 to 2118 of this index. The reading matter which appeared in THE JOURNAL is indexed in the General Index on pages 2057 to 2070.

- A**
- Abdomen, firearm wounds of, (84) 437—ab
 Improved technic of palpation of, (42) 701—ab
 plea for exploratory incision in masked conditions of upper, (82) 80
- Abdominal aneurism, corrected report of, (39) 634
 cases, four, (6) 81
 crisis caused by Meckel's diverticulum, (62) 1662
 infection with micrococci tetragenus, (58) 848
 Inflammation, management of acute stages of, *1841

 extensive mobilization of, (70)
 1247—ab
 forward displacement of, (115)
 1827—ab
 polyvi in female, (43) 1825
 posterior, treatment of rup-
 ture of, (27) 695—ab
 repaired by transplantation of
 urethra of animals, (49)
 1008—ab
 ruptured, treated by combined
 drainage, (4) 1012
 technic and indications for
 electrolysis of strictures of,
 (31) 156
 Urethritis, chronic, etiology and
 modern methods of treat-
 ment of, (14) 425—ab
 chronic new instrument for
 treating, (82) 923—ab
 Urethritis, chronic posterior,
 treatment of, (134) 918
 chronic, treatment of, (49)
 1825
 gonorrhœal, antimetorrhagic
 ureas in, (17) 839
 gonorrhœal, urinary antiseptics
 in, (35) 1999
 Urethrolithotomy, (40) 756—ab
 urethrotomy, external, median
 lateral, (27) 1505
 Urethrotomy, internal, in treat-
 ment of stricture of mem-
 branous urethra, (32) 840
 Urethrovaginal lavage, technic of,
 (46) 762
 Uric-acid delusion and prevention
 of acute, (145) 1485
 metabolism, (3) 534
 pathologic increase of, (3) 148
 urinary bladder, acute necrosis
 of lining membrane of, (24)
 1507
 incontinence, epidural injec-
 tions in treatment of, (41)
 1506—ab
 incontinence, faradic treatment
 of, (32) 156—ab
 obstruction, clinical and patho-
 logic phases of, (121) 573
 passages, antiseptic catheteriza-
 tion of, (31) 756—ab
 Uricæ, acute retention of, early
 symptom of, (41) 1667
 analytic examination of, (14)
 1504
 and their significance, patho-
 logic products of, (109) 430
 as index to metabolism, (114)
 1728
 chemical examination of, (99)
 80, (35) 762—ab
 diætic acid reaction in, (3)
 430
 Eberth's bacillus in, (94) 1097
 in health, in rheumatic affec-
 tions and after salicylic med-
 ication, (45) 1094—ab
 incompetence of, (50) 1825
 inspections, suggestions from,
 (32) 756
 intravascular separation of, from
 each kidney, (5) 286, (13)
 1264
 nocturnal incontinence of, treat-
 ment of, (13) 352
 pathologic, antihyalic properties
 of, (4) 154
 segregation of, (51, 64) 1825,
 (60) 2004—ab
 test glasses and holder, im-
 proved, *1395
 vesical retention of, (1) 76—ab
 Urohematin reaction, (40) 287
 Urotropin in prophylaxis of
 nephritis in scarlet fever,
 (53) 1094—ab
 mode of action of, (58) 577
 Uterine appendages, conservative
 surgery of, (25) 293—ab
 catheterization, suggestions for,
 of, (77) 1553
 contractions, nerve elements
 of, (77) 1553
 Clitor, modification of Bossi,
 (64) 638
 dilator, Farrier's and its ap-
 plication, (47) 576
 displacement, effect of opera-
 tions for, on subsequent preg-
 nancy, (104) 634
 malpositions, (45) 629—ab
 retroversion of, (85) 356
 segment, lower, and cervix,
 (53) 638
 Utero-ovarian sympathetomy,
 (9) 206—ab
 Uterus, acute inversion, (19)
 1664—ab
 anatomy of mesometrium in
 carcinoma of, (5) 576
 atmospheric pressure as sup-
 port to, (63) 842
 autoplactic suspension of, (50)
 1089—ab
 bipartite, (26) 1371
 carcinoma of, statistics of in-
 operable, (136) 1828
 correction of deviations of,
 by shortening the round and
 sacro-uterine ligaments by
 abdominal laparotomy, (47)
 1015
 complete descent of, surgical
 treatment of, (74) 1343—ab
 didelphus, in puerperium, (29)
 228
 dilatation and curettement, (4)
 1416
 etiology of prolapse, (42) 1586
 gravid paralysis of non-gravid,
 (11) 2054
 hour-glass contraction of, (13)
 154—ab
 Inversion of, (4) 1818—ab
 Uterus, lower segment of, during
 childbirth, physiologic behav-
 ior of, (52) 638
 operative treatment of retro-
 version and retroflexion of,
 (20) 1821—ab
 pathologic anteflexion of, (67)
 1175
 puerperal, acute inversion of,
 (24) 82
 resection of ureters and blad-
 der in extensive carcinoma
 of, (46) 1586
 retroversion of, new modifica-
 tion of operative procedure
 for, (43) 224—ab
 ruptured, after cesarean sec-
 tion, (10) 2054
 rupture of, (58) 79—ab
 rupture of, during labor, (7)
 1012, (132) 1430—ab
 rupture of, in pregnancy, (57)
 1507
 study on physiology of, (63)
 763
 surgical treatment of complete
 descent of, (85) 1583
 tardy rupture of, after curet-
 ting, (77) 86
 treatment of complete rupture
 of, (78) 1427—ab
 anterior, diagnosis and
 treatment of, (125) 844
 from congenital syphilis, ex-
 ternal appearances of, (43)
 283
 V
 Vaccination, (62) 284—ab, (90)
 356, (100) 699
 and the law, (28) 568
 present status of, (28) 223
 under Fed. H. H., (133) 1269
 —ab, (98) 2004—ab
 Vaccine and vaccination, (31)
 77—ab, *318
 notes on, *318
 Vaccinia and variola, comparative
 histology of, (41) 1998—ab
 Vagina and perineum, laceration
 of, (133) 1828
 artificial orifice, by intestinal
 transplantation, (50) 1005
 congenital absence of, (33) 1728
 restitution of, by transplanta-
 tion of anus and rectum,
 (64) 763—ab
 sarcoma of, in children, (39)
 156
 Vaginal route in pelvic surgery,
 (68) 1421
 wall, anterior, injuries to in
 labor, *1431
 Vaginitis, chronic, (31) 228—ab
 Vaginifixation for retrodeviation,
 (51) 1381—ab
 Vague muscular pains and aches,
 (124) 573
 Vagus function, experiments on,
 (65) 131
 reflex in 380 individuals, study
 of, (2) 839
 Val-Sinestra waters, study of,
 (45) 301
 Valuable adjunct, a, (112) 844
 valve syringe, (83) 289
 Valvular defects, liver noise and
 compensation of, (61) 84—ab
 defects, pressure in right auricle
 in, (88) 925—ab
 lesions of heart, mechanical
 version of diagnosis of, (68)
 1175
 Varian's infections, (25) 1340
 Varices, paraffin prothesis in
 treatment of, (129) 1429—ab
 treatment of, by walking, (41)
 287—ab
 Varicocele, (80) 1504
 Improved method of operat-
 ing for, (27) 1724—ab
 Varicose veins and ulcers of leg,
 treatment of, (35) 1083
 veins, cure of, by intercurrent
 phlebitis, (36) 762—ab
 veins of lower extremities, re-
 mote results of operations for,
 (8) 1582—ab
 veins, surgical treatment of,
 (79) 916—ab
 veins, treatment of, by walk-
 cure, (20) 767—ab
 Variola and Flinsen light cure,
 (94) 1504
 hybrida (Happell) and vaccina-
 tion, (109) 1263, (32) 1821
 —ab
 ocular complications of, (125)
 1420
 study of etiology of, (47) 1342
 Various presentations, causes of,
 (48) 576
 Vascular myxoma in liver region,
 (91) 851
 system, pathology of, (50) 1507
 Vasometric factor in clinical
 measurement of blood pres-
 sure, (66) 1502
 Vein valves and their relation to
 varices, (38) 1667
 Venereal diseases, individual
 prophylaxis of, (107) 852
 disease as social menace, (98)
 1583
 disease in Germany, warfare
 against, (155) 81
 diseases, plan for prevention
 of, (99) 1553
 diseases, prophylaxis of, (141)
 2054
 prophylaxis, humanity and com-
 mon sense vs. idealism, (74)
 1175—ab, (120) 1583
 statistics in Michigan, (56)
 632
 warts, (54) 1502
 Venesection, (15) 2052—ab
 and hypodermoclysis in rheu-
 matism, *1630
 indications for, (118) 1589
 Venom of Bungarus Corulius,
 action of, (17) 431
 Venoms, different species of
 antivenomous snakes, action of,
 on nervous system, (11)
 760, (14) 1505
 Ventilation, discussion on stand-
 ards of, (16) 1507
 Ventral decubitus in after-treat-
 ment of peritonitis, (62)
 1346
 Ventricular bigeminy without
 compensatory cause, (128)
 1589
 Ventrofixation, avoidance of, (45)
 638—ab
 cause of severe post-puerperal
 disturbances, (79) 763
 Vermiform appendix, chronic
 cystic dilation of, (10) 1819
 appendix, origin of, (19) 425
 appendix, surgical relation of,
 to typhoid perforation, (65)
 80—ab
 Veronal, (65) 85
 Influence of, on animal organ-
 ism, (98) 852
 Version in delayed or obstructed
 labor, (6) 351
 in primipara with contracted
 flat pelvis, (75) 436—ab
 Vertigo, (41) 1173—ab
 removal of semi-circular canals
 in unilateral aural, (10) 82,
 (15) 358—ab
 Vesalius' and Leonardo Da
 Vinci's anatomic plates, (79)
 1588
 Vesalius Da Vinci plagiarism,
 (96) 1910
 Vesical trigone, the, (110) 572
 Vesico-prostatic calculus, rare
 cases of, (55) 1843
 Vesiculectomy, seminal, (98) 1344
 Vesiculitis, chronic seminal, ob-
 servations on, (121) 81
 Vibration massage as an aid in
 inunctions, (88) 1588
 Vibrations and nerve vibrations
 without the medium of ma-
 chines in acute and chronic
 diseases, (57) 1843
 Vibratory massage, technic of,
 (75) 1668
 sensibility, researches in, (39)
 1175
 Vienna, new physiologic institute
 in, (40) 848
 Vincent's angina, (13) 431
 Vincent's angina and noma,
 cases of, (4) 424—ab
 angina and stomatitis, case of,
 *246
 Visceral disease, mental phenom-
 ena of, (109) 760
 Vision, deterioration of, during
 school life (5) 154
 disturbances of and develop-
 ment of blindness of nasal
 origin, (2) 1664
 monocular and binocular, histo-
 ric note regarding, (119)
 918
 Visual centers, education of, (13)
 621
 cortex, progressive evolution
 of in mammalia, (7) 2000
 Vital statistics, fallacies in, (11)
 —ab
 ocular complications of, (125)
 1420
 study of etiology of, (47) 1342
 Various presentations, causes of,
 (48) 576

CURRENT MEDICAL LITERATURE

INDEX OF AUTHORS

This Index includes the names of authors of articles which have appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, as well as of those listed under Current Medical Literature. It practically includes the names of all who have published articles in the leading journals of the world. The * preceding the page reference indicates that the article appeared in full in THE JOURNAL.
