FEDERAL - STATE - PRIVATE
COOPERATIVE
**SNOW SURVEY and WATER SUPPLY FORECASTS
for
MONTANA & NORTHERN WYOMING**

UNITED STATES DEPARTMENT of AGRICULTURE...SOIL CONSERVATION SERVICE,
and
MONTANA AGRICULTURAL EXPERIMENT STATION

Data included in this report were obtained by the agencies named above in cooperation with the Bureau of Reclamation, U.S. Forest Service, U.S. Geological Survey, National Park Service, State Engineers of Montana and Wyoming and other Federal, State, and private organizations.

AS OF
FEB. 1, 1961

UNITED STATES DEPARTMENT OF AGRICULTURE - SOIL CONSERVATION SERVICE

To Recipients of Cooperative Snow Survey and Water Supply Forecast Reports:

The climate of the cultivated and populated areas of the West is characterized by relatively dry summer months. Such precipitation as occurs falls mostly in the winter and early spring months when it is of little immediate benefit to growing crops. Fortunately, most of this precipitation falls as mountain snow which stays on the ground for months, melting later to sustain streamflow during the period of greatest demand during late spring and summer. Thus, nature provides in mountain snow an imposing water storage facility.

The amount of water stored in mountain snow varies from place to place as well as from year to year and accordingly, so does the runoff of the streams. The best seasonal management of variable western water supplies results from fore-knowledge of the runoff.

A snow survey consists of a series of about ten samples taken with specially designed snow sampling equipment along a permanently marked line, about 1000 feet in length, called a snow course. The use of snow sampling equipment provides snow depth and water equivalent values for each sampling point. The average of these values is reported as the snow survey measurement for a snow course.

Snow surveys are made monthly or semi-monthly beginning in January or February and continue through the snow season until April, May or June. Currently more than 1400 western snow courses are measured each year. These measurements furnish the key data for water supply forecasts.

By relating snow survey measurements taken over a period of years to spring-summer runoff during the same period, relationships have been developed which make it possible to forecast seasonal runoff several months in advance of occurrence. In order to make a forecast, once a forecast relationship has been developed, the maximum snow water content at previously selected key snow courses is usually entered in the forecast relationship. More accurate forecasts are often obtained when other factors such as soil moisture, base flow and spring precipitation are considered and included in the forecast relationships.

Listed below are the Federal-State-Private Cooperative Snow Survey and Water Supply Forecast reports available for the West which contain detailed information on snow survey measurements, streamflow forecasts, reservoir storage, soil moisture and other guide data to water management and conservation decisions.

MONTANA WATER SUPPLY OUTLOOK
as of
February 1, 1961

The present water supply outlook for Montana is poor. The February first snow-pack is considerably below average and generally less than last year by 20 to 50 percent.

If moisture conditions do not improve through the remainder of the snow season, the water supply in many areas will be very critical during the irrigation season. Farmers who depend upon natural streamflow for irrigation should give serious consideration to planting early maturing crops, such as small grains, that require less water than later maturing crops. Good water management and proper application will be necessary in most areas to obtain the most beneficial use of a limited water supply.

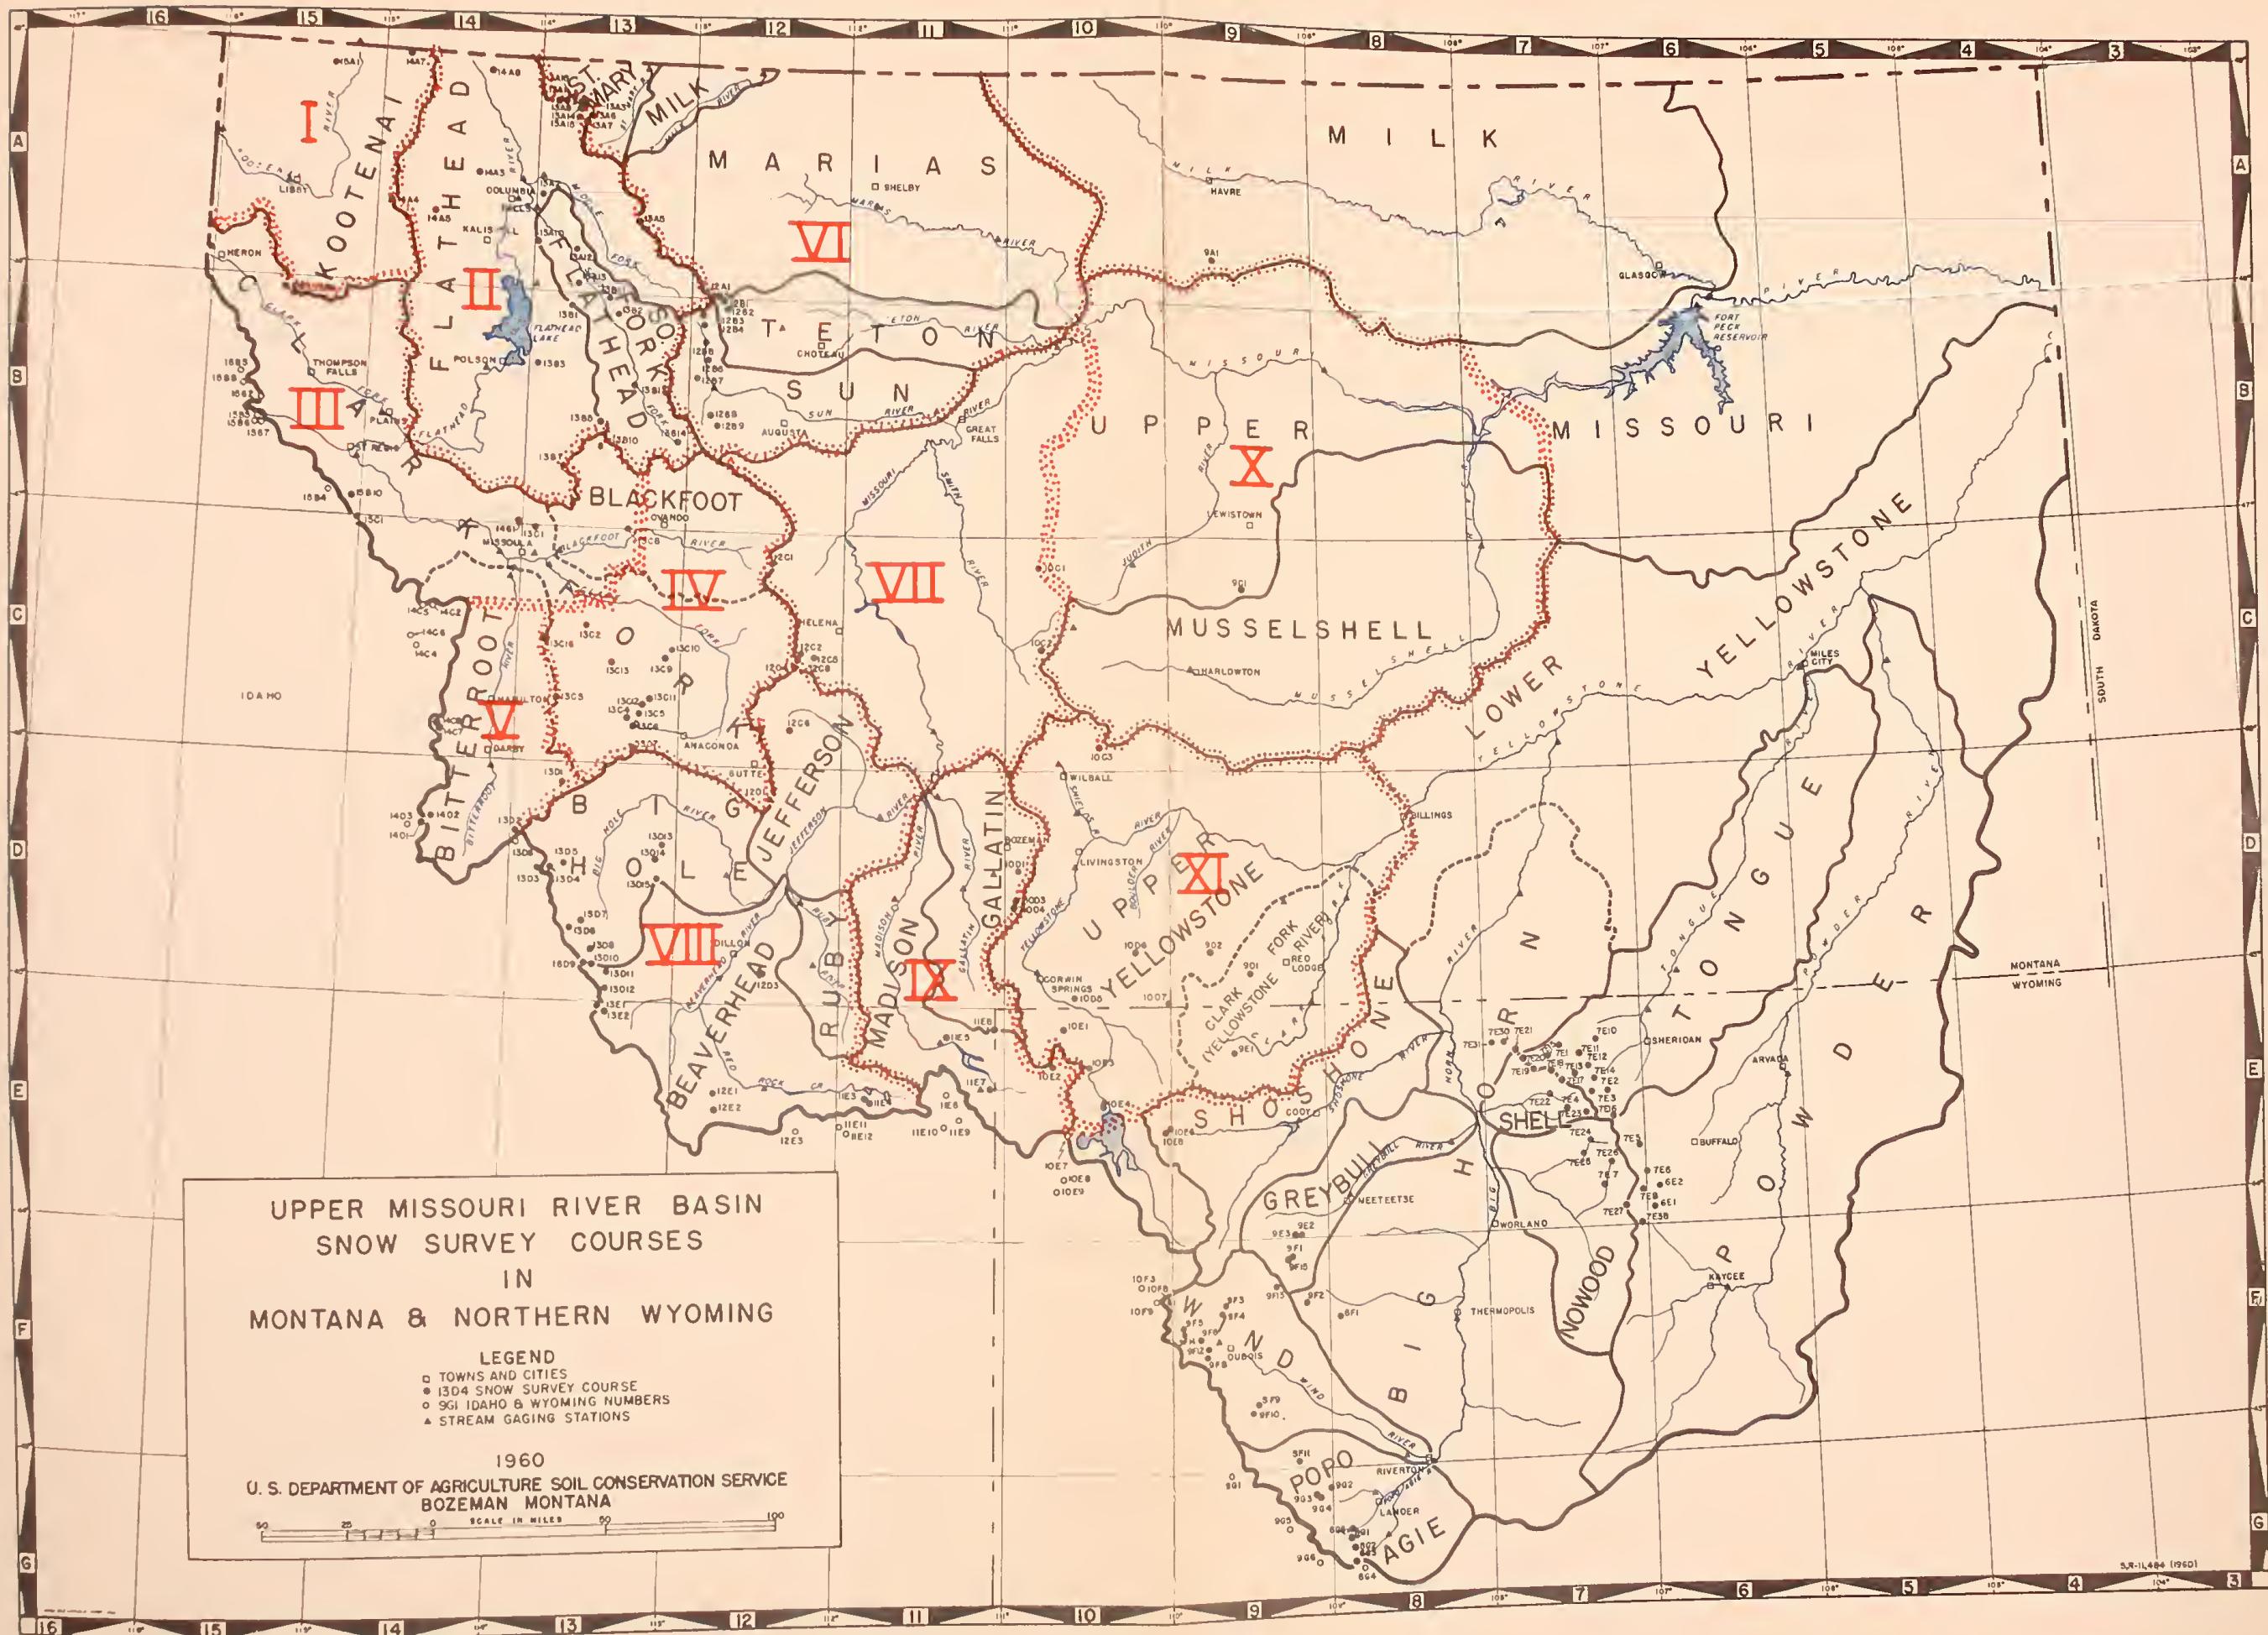

In the Missouri River Drainage, the Madison-Gallatin River basin snow-pack is 115 percent of last February, but only 66 percent average. In the Yellowstone River basin it is 110 percent of last February and 67 percent of the February average. The Beaverhead-Jefferson River basin is covered with a snow-pack which is 80 percent of last year and 49 percent average.

In the Columbia River Drainage in Montana, the outlook is not much better. Comparison with last year on the Kootenai River above Libby indicates a 9 percent better supply than last year, but 6 percent less than average. In the Flathead and Clark Fork River basins, the snow-pack is 20 percent less than last year and only 67 percent of average.

The deficient moisture condition in the soil underlying the snow-pack will have a great effect on this year's streamflow, producing less runoff than would normally be expected from an equivalent snow-pack.

Irrigation reservoir storage is generally below average throughout Montana.
