The Outlook for the Hume Pipe Co.

PROFIT. £37,714—ADDITIONAL PRODUCTIVE CAPACITY—POINTS FROM ANNUAL REPORT.

The annual meeting of the Hume Pipe Company, Ltd., will be held on September 14. The annual report, issued this week, shows that the profit for the year, after making provision for bad and doubtful debts and contingent liabilities in respect of maintenance periods under municipal and other contracts completed and in course of completion, amounted to £46,594 3s. 4d. From this has been deducted depreciation on property, buildings, machinery, plant, etc., provision for income tax, etc., leaving a net profit for the year of £37,714 4s. 5d. After deducting the debit balance brought forward from last year there remains to be carried forward a net balance of £23,525 15s. 5d. During the year, Mr. Robert Niven resigned his seat on the Board. Mr. M. C. Bird has been appointed a Director of the Company, and confirmation of this appointment will be asked for at the meeting. Messrs. E. G. Izod and T. W. Reynolds retire from the Board in accordance with the Company's Articles of Association, but are eligible and offer themselves for re-election. The Company's property holdings were increased during the year by the purchase of Stand No. 251 South Germiston Extension, and of three cottages close to the Germiston Factory. The greater portion of the extensions of the

Company's factory and plant at Germiston, referred to in the last directors' report, has been completed. The Hume Pipe Factory at Bellville, Cape Province, has been completed, and is in running order. The Company's buildings, machinery and plant at Germiston and Bellville, including the brick and tile works, have been maintained in excellent condition.

Wit. Deep: August Results.

The estimate of results for the month of August, 1921, is as under:—Tons milled, 31,060; gold recovered, 9423.274 czs.; average of stamps running, 180; stamps running time, 21,516 days; tube mills, 5. The working expenditure, including head office charges for the month, is £42,789 or 27s. 7d. per ton. The estimated working revenue based on an estimate of £5 11s. 6d. per fine oz. (less 1s. 6d. realisation charges) is £51,874 or 33s. 5d. per ton. The estimated working profit is £9,085 or 5s. 10d. per ton, from which is to be deducted the capital expenditure for the month of £1,689, leaving a surplus of £7,396.

Rand Mining Economics.

SUGGESTIONS TO IMPROVE EFFICIENCY AND LOWER WORKING COSTS IN AND ON THE MINES OF THE WITWATERSRAND.

By E. C. Ranson.

The making or marring of any mine depends to a great extent on what takes place underground, and this is where some improvement has got to come from to help keep the gold mining industry of the Witwatersrand going. The great trouble, if one might call it such, on these fields up to recent years has been too big a margin of profit, too much to play with, and too easily made. Now that wages are up, cost of materials up, deeper mining, and grade down, the old methods will not carry. The profits of any mine depend principally upon:—

- (1) The value of the ground mined; and
- (2) The cost of getting that ground to the mill.

I want to deal with points under each heading, and try to show where improvements can be made.

1. The amount of gold that a reef carries is determined by nature, but the value of the rock mined depends to a large extent upon the mining conditions in the stopes. The great aim ought to be to send out stuff as rich as possible from the stoping areas, and this, as everyone knows, can be regulated by varying the stoping widths. There is too much attention paid to "tally" underground on most mines. Everyone, from the trimmer up, seems to be obsessed with the idea that the holding of his job depends upon the number

In this article I confine myself to the cost of materials and the general working in stopes, where the bulk of the producing is done.

On the Central Rand it must be patent to everyone employed in the area that during recent years there has been a great change in the conditions underground, especially in the stoping areas. Before the present depths were reached, it used to be an easy matter to keep the hanging up. At the present time, wherever ground is being stoped, the overlying strata seems to be "weighing" very considerably, and under present conditions, in order to win ground, it is necessary to practically fill a stope with pigstys and packs, and even then the hanging comes down. The system of supporting and keeping up huge back areas of worked out ground is not the ideal system of mining, although possibly until recent years the conditions here have not lent themselves to any other system. Under present conditions of heavy hanging, with a certain amount of movement and tendency to break easily, I think the ideal system in stoping areas where developing is done under the reef, would be to draw out back pigstys or supports systematically up to a solid prepared breaking off line, and allow the hanging to fall.

Under present conditions, by supporting and trying to keep up huge stoped out areas, the hanging is always on the move, weight is thrown where it is not wanted, and the places never get a chance to settle. If the hanging was allowed to fall up to a certain distance from the face systematically, the back areas would become choked and solid, and the working places safer; the supported hanging next to the face would become "winded," and the stope faces as pleasant to work in as they are now difficult.

Under present conditions it is possible, if back supports were taken out, to make the hanging break at any particular line, provided a good solid breaking off set was put in. Wherever skeleton pigstys are put in a stope, and the weight settles on them, the hanging soon "nieks" itself up at the solid face. The same thing would happen, and much more easily, if the back pigstys were taken out clean up to a good solid breaking off line.

Even if it were only a case of making the working places safer and more pleasant to work in (and as we increase in depth, conditions will not improve), the proposition would be attractive. When one comes to consider the number of pigstys that have to be put in a stope to-day, and each one is filled with the average product of these working places, the proposition becomes doubly attractive; 10 per cent. of the ground broken goes into pigstys, and owing to the number of supports in a stage, making clean lashing difficult, probably another 2½ per cent. is left behind and lost. Considering a stope, say, 50 inches wide, the whole value being carried in a reef channel of 20 inches or probably less; it is not difficult to see that much of that reef may, and probably does, go into pigstys, or is left behind, and low grade stuff trammed from the stope. To think that present working conditions result in an absolute loss of 12½ per cent. of the ground broken is, to say the least, startling. If a system such as that advocated were adopted, the saving would be very considerable; not only would all this ground be recovered, but the timber as well. All drawn timber would be carried forward, and most of it used again on the face. Timber is a very heavy item on mines these days. On a mine, say, hoisting 50,000 tons a month, the number of, say, 8 foot lagging poles which go down for stope timbering alone is not far short of 15,000 a month. If such a reclamation system were adopted, and the quantity of new timber needed was cut down by only 50 per cent., taking the cost to a mine of an average 8 ft. stick at 4s., the saving would be appreciable. To summarise, by the successful exploitation of this system of working, we would save, on a low estimate, seven or eight thousand lagging poles a month at an average of, say, 4s. each, and

— FIG. 1 —

of cars that he gets out, and naturally it concerns him little what the grade of the stuff is they carry so long as the tally is obtained. Too much attention is given to this kind of thing, and too little to economic mining. Let us in the first place be assured that the ground we are breaking and transporting to the mill is carrying the maximum amount of gold possible, and time and money is not being spent in dealing with dead stuff. Stopping widths should be brought down to the minimum necessary to win the whole of the value in the reef and to give comfortable working conditions. On the deep level mines of the Central Rand, where the reef body is not usually very wide, and the ground usually heavy, this calls for a more general use of the Jack hammer. I may casually mention here that the carrying of a narrow stope is also advantageous in a system of working I wish to advocate under heading 2.

2. Although the cost of getting the rock to the mill depends upon the efficiency of many operations underground.

recover anything up to 6,000 tons of rock per month of the average grade of the mine for practically the cost of lashing and trammung.

The idea is to timber the stope faces in panels, the pigstys being put in systematically a certain distance apart on the strike and dip. Where necessary, they would be thoroughly filled and made solid. When one knows that all stuff in the pigstys will eventually be recovered, it matters little what quantity or how rich the stuff is stowed away. A panel would consist of a breaking off line of well-built solid

below, and maintain communication between the faces for travelling purposes and for ventilation. To make these pigstys as rigid as possible, they could be studded at the four corners and also studded on to the solid ground at the bottom of the stope as shown. As the panels in the lower stage were drawn, the few pigstys left immediately above in the old stope would be taken out systematically.

The drawing of the panels would be done on the night shift. One experienced timberman working each night would be able to do all the timber drawing in an average mine captain's section. A shift boss would report when he had a

— FIG. 2 —

pigstys, say, 12 ft. x 8 ft., and two intermediate lines of 8 ft. x 8 ft. pigstys. The distance apart of the packs would be, say, 8 feet on the dip and 4 feet on the strike. Fig. 1 shows a stope which has been opened up sufficiently to allow three complete panels to be put in. When a stope was in this condition it would be ready for the removal of the middle panel. There would always be a width of about 11 or 12 yards of supported hanging next the face. Being a new departure in mining practice, many will look upon it with suspicion and put it down as unworkable. To go into a stope, which has been worked for a few years, and 300 feet or more

panel ready for drawing, and the drawer would go from stope to stope as required. A pigsty would be readily unkeyed by stope as required. A pigsty would be readily unkeyed by knocking out the wedges and chopping out one of the sticks. A panel would be drawn from the top downwards and kept in a line as shown in Fig. 3, always preserving the chute ways for lashing. After unkeying and pulling down the pack, if necessary, all timber could be recovered from a place of safety between rigid pigstys by means of a "pout," a long-handled tool with a spike at one end. The lashing boys could also be provided with long rakes for pulling the

— FIG. 3 —

between the faces, and try to draw the packs, would be unwise. It must be commenced as soon as possible in a new stope before much weight has come on the place. Once the middle panel was drawn out in a new stope and the place had fallen, it would give little trouble afterwards. The hanging next the face would become "winded," and I question whether it would be necessary to fill more than half the pigstys outside the breaking off line.

When the panels were drawn it would be necessary to leave, say, a double line of filled pigstys along the solid ground at the bottom of the stope as shown in Fig. 2. This would allow the machines to get to work on the stope faces

reef into the chute ways, where it could be handled with a shovel.

By cutting down stoping widths to the minimum, thus producing stuff of maximum grade, and a system of reclamation as suggested, the outlook would be much brighter for some of our deep level, low grade propositions of the Central Rand.

There is just another point I would like to mention in which improvement might be made, although I believe more attention is paid to it now than used to be the case. That is the systematic recovery of all materials such as pipes, track, etc., when a place is worked out. There is still the desire to leave everything behind when a place is being started up and ask for new material when a place is being started up, as in the more prosperous days of the reef.

East Rand Mining Leases Inspector's Report.

POINTS FROM GOVERNMENT INSPECTOR'S REPORT ON SPRINGS, GOVERNMENT AREAS, NEW STATES, WEST SPRINGS AND BRAKPAN MINES.

The following extracts are taken from the latest official reports of the Government Inspector of Mining Leases on the Far East Mines, in which the Government has a direct interest. The reports deal with the quarter to June 30.

Spring Mines, Ltd.

The ore reserves as at the 30th June, 1921, are estimated by the company at 3,002,981 tons of an average value of 8.76 dwt. over a stoping width of 62.53 inches. This figure indicates an increase of 276,803 tons compared with the previous estimate as at the 31st December, 1920, when the value and width were 8.76 dwt. over 63.48 inches. Further particulars concerning these reserves will be given in my next report.

No. 3 Shaft.—During the quarter 711 feet of station headings have been accomplished, together with 841 feet of development, which latter footage is dealt with under the head "Development."

Work is proceeding in connection with additional surface plan consisting of hoisting engine, compressor, boilers, and permanent steel head-gear, etc.

No. 4 Shaft.—The erection of the permanent steel headgear has made good progress and is nearing completion. The winding engines and boilers are completed, and various buildings, including drill-shops and change-houses, are erected, and the surface equipment may be said to be practically completed, although it is not likely that a commencement of sinking operations will be immediately made.

Development.—A summary of the development work is as follows:—

Drives	1,010 ft.
Winzes and raises	1,384 "
Haulage ways	2,909 "
Crosscuts, etc.	12 "
Total	5,315 ft.

Footage on reef	3,850 ft.
Footage sampled	3,795 "
Footage payable	2,050 " = 54 per cent.
Average reef channel width payable footage	22 inches.
Average reef channel value payable footage	24.5 dwt.

Of the total footage developed, 841 feet were driven from the No. 3 Shaft, of which 265 feet were sampled, 96 per cent. being payable. The average value and width was 22 dwt. over 31 inches.

Compared with the previous quarter, there has been an increase of 351 feet in the footage developed, and 317 feet in the footage sampled. The payable percentage of the footage sampled fell from 56.8 to 54 and the average value from 630 inch dwt. to 546 inch dwt.

Mining.—The rock broken in the mine according to survey measurements amounted to 150,298 tons; in addition, 31,020 tons were dumped as waste.

The rock came from the following sources:—

	Tons.	Percentage.	Sampled value	Dwt.
Payable ore reserves	102,829	68.4	10.17	
Other than payable ore reserves	21,575	14.4	6.92	
Development	25,894	17.2	4.64	
Total	150,298	100.0	8.75	

Average stope width	60 inches.
Average reef channel width	26 inches.
Average stope width in payable reserves	60 inches.

Compared with the previous quarter, there has been an increase of 7,804 tons in the tonnage mined, and an increase of 0.27 dwt. in the value.

The average value and width of the ore mined from the payable reserves, according to data adopted in the estimation of reserves as at the 31st December, 1920, were 8.53 dwt. over 64.16 inches, whilst the payable reserves as a whole at that date average 8.76 dwt. over 63.48 inches.

The value of the ore mined from the payable reserves, after allowing for the difference in the stoping width, was 0.60 dwt. higher than the corresponding block estimate.

A very satisfactory decrease has taken place in the stoping width as, in comparison with the previous quarter, this width has been reduced by close on 5 inches.

Compared with the previous quarter, the mining costs, exclusive of development, show an increase of 7.14 pence per ton mined. The chief increases are 3.333 pence in "stopping" and 2.408 pence in "shovelling and tramming," the former principally due to the decrease in stoping width producing a smaller tonnage, and the latter to a considerable increase in the number of trucks underground.

Of the total revenue from gold, the sum of £57,088 11s. 2d. represents the estimated gold premium, being at the rate of slightly over 20 shillings per ounce, and equivalent to 8s. 11.545d. per ton milled. The estimated premium for the previous quarter was equivalent to 8s. 3.257d. per ton milled.

Exchange for the quarter, allowed for in the gold revenue, amounted to £1,933 12s. 9d., as compared with a credit of £353 1s. 6d. for the previous quarter.

The total working costs show a decrease of 1s. 7.508d. per ton milled, compared with the previous quarter, during which period the costs were adversely affected by the February strike.

The working profit, excluding the gold premium and exchange, shows an increase of 2s. 6.28d. per ton milled, but, including both the premium and exchange, the profit shows an increase of 2s. 10.05 per ton milled.

To the working profit of £107,065 4s. 10d. may be added the sum of £6,277 8s. 11d., representing the difference between the estimated premium and actual premium on gold for the three months ended 31st May.

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to devine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

P.O. Box 3807.

ROCKWOOD PRESSED STEEL UNIONS

H. ALERS HANKEY - - - Sole Agent.

Considering the satisfactory condition of the payable ore reserves, it has been decided to increase the nominal crushing capacity of the plant from 40,000 tons to 50,000 tons per month by the addition of four tube mills. There will be no addition to the stamp mill, as recent experiments have shown that the necessary increase can be obtained by increasing the tube milling and coarse crushing plant only.

Government Gold Mining Areas (Modderfontein).

Development.—A summary of the development work is as follows:—

Drives	2,141 ft.
Winzes and raises	2,888 ,,
Haulage ways	644 ,,
Crosscuts, etc.	3,387 ,,
Total	9,060 ft.

Footage on reef	3,714 ft.
Footage sampled	3,860 ,,
Footage payable	2,070 ,, = 53.6 per cent.
Average reef channel width payable footage ...	53 inches.
Average reef channel value payable footage ...	13.6 dwt.

Compared with the previous quarter, there has been an increase in the total footage developed of 1,040 feet, and in the footage sampled of 90 feet.

The development for the quarter shows a slight increase in the percentage of payability from 52.4 per cent. to 53.6 per cent., but the value has decreased from 834 inch pennyweights to 723 inch pennyweights.

Compared with the previous quarter, there has been an increase of 19,000 tons in the tonnage milled and an increase of 8,040 ounces in the gold obtained. The percentage of sorting increased from 14.03 per cent. to 15.44 per cent.

The rate of milling for the quarter has been very satisfactory and is the highest so far reached, the daily average having been 182 tons above the nominal capacity of the plant, making a total of 14,000 tons for the quarter.

Of the total revenue from gold, the sum of £160,670 represents the estimated premium, being at the rate of practically 20 shillings per ounce and equivalent to 8.054 shillings per ton milled. The estimated premium for the previous quarter was 7.73 shillings per ton milled.

Compared with the previous quarter, the working profit shows an increase of 0.486 shilling per ton milled, but, excluding the gold premium and exchange, the working profit shows an increase of 0.55 shilling per ton milled.

The total working profit for the six months ended 30th June amounts to £780,937 18s. 10d., to which may be added the sum of £30,136 0s. 7d., representing the difference between the estimated and actual premium on gold for the five months ended 31st May, and a further sum of £667 8s. 6d. realised by the sale of by-products, bringing the total working profit for the six months to £811,741 7s. 11d.

New State Areas.

Development.—A summary of the development work is as follows:—

Drives	1,111 ft.
Raises	623 ,,
Winzes	174 ,,
Crosscuts, etc.	1,735 ,,
Total	3,643 ft.

**MINES DEPT. EXAMS.

1920 (12 months) 66%	34%
1921 (6 months) 64%	36%

No failures for 6 months, 1921.

MANAGERS' CERTIFICATES.—Our record is 100% passes. 1912-20 we claimed 165 certificates; 40 in 1919-20; last 3 Exams., 29 certificates (total). 10 Coal Certificates in last 3 Exams.

TUITION (Metal or Coal) by class, correspondence or privately.

The above passes are based on official returns; any claims based on number of entries are obviously unreliable.

**Mining Institute (Prof. Yates),
St. James' Mansions, Eloff St.**

Of this total 1,605 feet and 2,038 feet were accomplished at the North and South Shafts respectively

Footage on reef	412 ft.
Footage sampled	400 ,,
Footage payable	330 ,, = 82.5 per cent.
Average reef channel width payable footage ...	62 inches.
Average reef channel value payable footage ...	17.2 dwt.

The development sampled at each of the shafts were:—

Shaft.	Total feet.	Per-centage.	Channel Channel		
			able width payable.	value payable.	
	feet.	centage.	feet.	Inches.	Dwts.
North	70	17.5	—	—	—
South	330	82.5	330	100	62 17.2

Totals and averages	400	100.0	330	82.5	62	12.2
----------------------------	-----	-------	-----	------	----	------

Of the total footage developed, 1,352 feet were in connection with the lay-out of the shaft stations.

Compared with the total footage developed, including the footage in connection with the shaft station approaches, etc., during the previous quarter, there has been an increase of 2,481 feet.

A ventilating fan has been installed on the main station of each shaft and connected up with the various working faces by galvanized iron piping, and the working conditions are good.

Capital Expenditure.—The capital expenditure amounted to £73,268, made up as follows:—

Shafts and equipment	£14,957
Development and mine	43,779
Compressor plant	4,264
Additions to compounds	3,157
Other plant and surface works	7,111
Total	£73,268

General.—The thirty-drill air compressor was put into commission during the quarter, and the erection of the fifty-drill air compressor is nearing completion.

The new change-house for whites is completed, with the exception of some of the fittings.

West Springs, Limited.

No. 1 Shaft.—The footage sunk amounted to 213 feet and the footage timbered to 233 feet, the total depth of the shaft now completed being 4,105 feet, the whole of which is timbered.

Considerable progress has been made in connection with the lay-out of the stations and roadways. The main station and loading station have been cut, and 360 feet of roadways and cross-cuts have been driven; a temporary loading bin has also been installed.

No. 2 Shaft.—The footage sunk amounted to 350 feet and the footage timbered to 353 feet, the total depth of the shaft being 2,940 feet, of which 2,917 feet are timbered. At 2,590 feet and 2,680 feet reefs of the Kimberley Series were intersected, the values and widths being respectively 0.6 dwt. over 49 inches and 0.3 dwt. over 29 inches. A further reef was passed through at 2,784 feet, giving a trace over 61 inches.

In June the company notified the Government in terms of the mineral lease that it was resolved temporarily to suspend sinking operations in the No. 2 Shaft. At the end of May the shaft had been sunk 2,890 feet without encountering the Kimberley shales, it being then more than 700 feet below the point at which the shales were expected. This indicates considerable faulting and a much greater depth of shaft involving larger expenditure than was originally calculated. Sinking operations were stopped early in June, and diamond drilling was started from the shaft bottom to locate the shales and the amygdaloidal diabase. At the end of the quarter under report the drill had reached a depth of 3,272 feet below the collar of the shaft. At a depth of 3,222 feet the drill located the Kimberley shales. This makes these

shales about 1,000 feet deeper than was anticipated. In the course of drilling, three bodies of reef were passed through, their depths, values, and widths being:—At 2,941 feet, trace over 8 inches; at 3,044 feet, trace over 38 inches; at 3,085, 0.3 dwt. over 381 inches.

Development.—The following is a summary of the development work carried out from the Springs Mines property:—

Haulage ways	597 ft.
Footage on reef	312 ,,
Footage sampled	290 ,,
Footage payable	60 ,, = 21 per cent.
Average reef channel width payable footage	11 inches.
Average reef channel value payable footage	50.5 dwts.

Compared with the previous quarter there has been an increase of 80 feet in the footage developed. The payable percentage of the footage sampled has fallen from 58 per cent. to 21 per cent., but the value has increased from 371 inch pennyweights to 576 inch pennyweights. The payable reef channel width has decreased from 40 inches to 11 inches.

A second heading from the Springs Mines' property has entered the West Springs area, and was 51 feet over the boundary at the end of the quarter. This is approximately 2,600 feet to the north of the main east haulage, and is known as 8 haulage east.

Capital Expenditure.—The capital expenditure amounted to £93,173, made up as follows:—

Shafts and equipment	£49,869
Development	19,170
Buildings, surface works, etc.	17,985
General expenditure	6,149

General.—The concrete foundations for the two additional compressors at the No. 1 Shaft are completed, and good progress is being made with their erection.

The erection of two Babcock boilers at the No. 1 Shaft is completed, and the boiler house is well in hand.

The construction of the railway siding from Springs Mines to the coal bunkers of the No. 1 boiler plant is practically finished.

Brakpan Mines, Limited.

The ore reserves as at the 30th June, 1921, are estimated by the company at 2,549,625 tons of an average value of 8.77 dwt. over a stopping width of 69.78 inches. These figures indicate an increase of 23,108 tons, compared with the previous estimate as at the 31st December, 1920, when the value and width were 8.88 dwt. over 70.08 inches. Further particulars concerning these reserves will be given in my next report.

KROONSTAD COAL ESTATE COMPANY, LIMITED.

TENDERS

are invited and will be received by the Undersigned up to and including Saturday, 1st October, 1921, for the purchase of the **MACHINERY, PLANT, EQUIPMENT, MINE STORES, TOOLS, ETC.**, lying for disposal at the above Company's property at Vierfontein, O.F.S.

Tenders must be for the whole of the above, and the successful tenderer will be required to remove same at his own expense and risk within one month of the acceptance of the tender.

The highest or any tender not necessarily accepted. Lists and further particulars may be obtained from

SALISBURY, BEATON & RAYNHAM,

Secretaries,
Kimberley.

17th August, 1921.

Shafts.

No. 3 Circular Shaft.—The footage sunk amounted to 334 feet and the footage ringed to 345 feet, the total depth of the shaft being 4,530 feet, of which 4,506 feet are lined or ringed.

The main reef was passed through at a depth of 4,437 feet. Seven sections taken around the shaft gave an average assay value of 1.9 dwt. over an average width of 18 inches. The reef was lying on an interbedded quartz-porphry dyke 11 feet in thickness, with shale underlying it.

A loading station and winch-chamber have been cut, representing a footage of 36 feet.

No. 4 Circular Shaft.—During the quarter 304 feet of station roadways were driven, the whole of which footage, with the exception of 42 feet, was off reef. The reef exposure was sampled over a distance of 40 feet, but the average value was below the pay limit, being 4 dwt. over 37 inches.

Development.—A summary of the development work is as follows:—

Drives	1,897 ft.
Winzes and raises	1,105 ,,
Haulage ways	1,692 ,,
Crosscuts, etc.	501 ,,
Total	5,195 ft.

Footage on reef	3,457 ft.
Footage sampled	3,470 ,,
Footage payable	1,310 ,, = 38 per cent.
Average reef channel width payable footage	40 inches.
Average reef channel value payable footage	16.3 dwt.

Compared with the previous quarter, there has been an increase of 149 feet in the total footage developed and a decrease of 30 feet in the footage sampled. The payable percentage of the footage sampled has decreased from 43 per cent. to 38 per cent., but the average value has increased from 531 inch pennyweights to 655 inch pennyweights.

Of the total revenue from gold, the sum of £65,906 15s. 1d. represents the estimated gold premium, being at the rate of 19s. 10.79d. per ounce, and equivalent to 8s. 0.92d. per ton milled. The estimated premium for the previous quarter was equivalent to 8s. 0.48d. per ton milled.

Exchange for the quarter included in the gold revenue shows a debit of £2,204 17s. 6d. compared with a credit of £766 10s. 3d. for the previous quarter.

Compared with the previous quarter, the total working costs show a decrease of 4,779 pence per ton milled.

WHY PAY SHOP PRICES?

The Discovery of the Kimberley Mine.

By W. P. Taylor.

As the train steams up from the Cape and passes the Modder River and the trenches where Boer and Briton met; as the line swerves away through low mimosa and kopjes, it nears huge mounds of debris and in the distance lies a scattered town. Along the roadsides are terrible tin huts, for pinned together are the sides of petrol tins and larger pieces on greater little houses; all quaint, and quaint still are the high cheek-boned yellow Griquas and Koranas that fill these squalors. In all these years there has been no evolution in the flotsam and jetsam of Kimberley. In the earliest days they were discovered with perhaps fewer rags, and now, with less of their old language of clicks, they hang on to ancient sites, clothing their abodes with collections from garbage heaps, and side by side with their white neighbours exist as a kind of their own, fringing the scene that leads you to where but yesterday greatness was more apparent.

The Kimberley Mine.

Kimberley was named after Lord Kimberley ere he became the Earl of Carnarvon. It was under his administration that all the mines that group together, in that arid limestone and basalt, became British. Yes, fifty years ago last July. There were the mysterious movements of diggers and secret meetings. As the strange hum in the hive

Company have enough left in their mines to-day to supply the world for a hundred years or more. The first real treasure house of African romance was Kimberley. In the crisp winter days of July, 1871, the first holes were made, and under the shade of the camelthorn tree men rested and showed each other the first diamonds from this wonderful mine. The mine itself was a mound, a low mound; in places hard white limestone in great flat slabs, which protruded through soft red sand. The wild aardvark, or anteater, the porcupine and other strange denizens of the veld, had mined there long, long before man thought of invading their sanctuary, and it was in this red softness that a few men were sinking their prospecting holes just fifty years ago. Cawood and Rawstone were names I distinctly remember as the first to claim its discovery.

"The New Rush."

They named it Colesberg Kopje, but for a considerable time it was known to us all as the "New Rush." Most of the men who rushed to peg went from De Beers; the distance was about a mile and a half. Our party lived at De Beers for a long time and worked our claims, walking to them in the early morning and returning at night. When one hears of a new diamond mine to-day and that it contains 10 or 20 carats to the 100 loads, it causes quite a little flutter; but

Kimberley Mine, 1874.

proclaims the sovereign's nuptials, so the sound of something great preceded the discovery of this wonderful mine. Dutoitspan, Bultfontein and De Beers were all working, and there was too much mining ground and not enough diamonds. Diggers went for weeks without a find, and a curious conglomeration of poor farmers and Kafirs worked at the two former mines; in fact, Dutoitspan and Bultfontein were very poor class, in a way, and the knowing ones, the *bon ton* were out for something better. It is opportunity that makes the man, and although South Africa has furnished some men of great ability, I question very much their wonderful evolution without the mines of gold and diamonds. There is a peculiar aspect of concentration in the diamond part. It is not different to-day; no one knows, but I venture to think that if mankind will continue to buy diamonds the De Beers

O! ye Gods, what a mine Kimberley was! They literally picked them up, and in all sizes. In a week or two after its discovery, with just a sieve and a table, they sorted them out in hundreds of every size from half to over 100 carats in a single stone; great stones worth £5,000 apiece. I remember passing a man's table which was over full of gravel, and as I passed it a great yellow diamond rolled towards me. The man sorting never saw it. I picked it up and threw it over the gravel on to his hand. Unfortunately he was a mean man. Some six months afterwards he fumbled out a halfcrown and said he had almost forgotten to give me a present. Fortunately, for myself, I was not poor or dependent enough to accept it. He sold the stone for £2,000. It is curious how men listen and follow wrong ideas, for although they actually found diamonds in the lime-

stone capping, they would not break it up and sort it. Many thousands of tons of rich limestone were wheeled out and cast away, and many years afterwards it was put through rotary machines and returned hundreds of thousands of pounds to strangers. The mine, as it opened up, contained great long ribs of floating reef—a mass of shale that had been twisted and contorted with the boiling of the volcano. In this mass there were no diamonds, but under it and along its sides and in each crevice, where there was a rich pocket of "yellow," there the gems were found concentrated in masses. The eastern part of the mine produced a good glassy stone, the centre and the north and south sides yellows and cleavage, and the western part was all glassy and the smoky stone, the latter until then unknown. The western part of the Kimberley Mine had great depths of extremely light matter. It appeared burnt out, with many round rotten basalt pebbles as big as a tennis ball. Soon we knew where every class of diamond in the mine came from, and the smoky stone was something to shudder at. A beautiful octahedron, white and clear, with just a tiny tinge of smoke in one corner, and as if its modesty could not brook the sunlight, within a few hours of its advent into the world, it was a shattered mass of flaws and practically valueless.

Herbert Rhodes.

Amongst the men who pegged out the first claims was Herbert Rhodes. There was a number of men with him and several more Natalians. Henry Nourse was there, a lad

as issued licences. When we were merged into Crown Colony, the office went to Market Square. Mr. William Smith for many years issued our licences. Mr. Ortlepp returned to Bloemfontein, which was, I believe, Lady Phillips' home.

Old Time Conditions.

There were no nice burnt brick residences in those days. Water was sixpence a bucket. Everyone lived in his tent. The lucky ones sheltered under a great old camelthorn, and around their tents were reeds tightly laced into hedges to keep the cold gales and sand off. The elite had green baize linings and a canvas fly which kept off heat and rain. The sanitary arrangements were as Adam's, and yet the camp was clean and only soiled by red dust, which a cloth dispelled. Wagons from Natal, Port Elizabeth and Queens-town brought great loads of provisions and goods, and as time went on the inevitable corrugated iron. Then the early white softness gave way to metallic corrugations, the surveyor made straight lines, streets eventuated out of tortuous labyrinths, and gradually we became extremely rigid. Each digger's claim was 31 feet square, and these were cut up into quarters, eighths and sixteenths. I have known men secure all they desired and return to their homes from the returns of a 1-32nd of a claim. The ground my father and I made about £200 a month out of in No. 6 South, when the mine was discovered, was 8 ft. wide and 10 ft. long. We worked it for quite a time with four Kafirs. I think the whole mine was 440 claims. To-day it is a terribly deep, trumpet-

Kimberley Camp, 1872.

then. The Grays, Ghisling, Roos, Lings, Edwards, Stanfords, Zheasbys, were all names I remember. The *Diamond Fields Advertiser*, through the efforts of Mr. George Beet and Mr. R. H. Giddy, gives a list of the first men whose finds are recorded, and there are such names as Thackeray, Maeder, Battenhausen, Fleet, Cuming, Kuillen, Battleden, and others. I dare say I could enlarge on it in time, but these are some of the names of men who fifty years ago found and gave to the world the wonderful mine that once and for all settled the destinies of a country that was near starvation. Midway between Kimberley and De Beers a little mud room was built. It was clothed with reeds and plastered with red mud. A board announced that it was the Claim Registry Office and gave the hours of business. On entering one saw a handsome tall man with a great blonde beard, our first Claim Inspector, Mr. Ortlepp—the father of Lady Lionel Phillips—who settled disputes as well

shaped hole, whose sides become hard and ever narrowing, until at 3,000 feet it is but a small thing no bigger than some of the little outside mines that struggle for a reputation. But for all it was Kimberley, a spot where many lived the happiest days of their lives. It saw a great emergence. It gave one of the world's greatest men his opportunity. Yet, it is good to have lived and seen things grow out of nothing. I saw the first blush of this new life in diamonds, and I saw it in gold, and would that the human mind could trace relativity and know its effects, but as it is to-day, it is a city of shadows, and some of them great shadows. A vivid mind can picture back its days of sunshine and happiness, its days of stress and famine, the sound of guns booming distantly when General Cronje held up the great British Army at Magersfontein, and in a siege that meant touch and go, a great heart that never wavered and whose thoughts went out to one and all and made man feel that he was not alone, that he was resting on one of the great corner stones of an Empire.

Mozambique Portland Cement Works' Progress.

SLOW BUT SOLID FOUNDATION OF IMPORTANT INDUSTRY BEING LAID—A NUCLEUS FOR OTHER UNDERTAKINGS—QUESTION OF RAW MATERIALS—INTERVIEW WITH THE CONSULTING ENGINEER.

Through the courtesy of the directors of the company, a representative of this paper had an interview a few days ago with Captain Pooley, of the firm of Brown and Pooley, Consulting Engineers to the Mozambique Portland Cement Co., Ltd. Captain Pooley, who belongs to the well-known London firm of consulting engineers, who have specialised in Portland cement manufacture, has been on a visit to the works of the Mozambique Company at Delagoa Bay and he has made an exhaustive report to the directors of the company in regard to its general prospects.

Excellent Prospects.

Captain Pooley expressed himself as most favourably impressed with the prospects of the new concern. He made a thorough examination while at Delagoa Bay of all the factors, and though naturally a little disappointed at the inevitable delays attending the starting up of an ambitious undertaking of this sort under such conditions, he predicts a highly successful future for the industry. The anticipations regarding the date of supply and delivery of the machinery have not been fulfilled, and it is not considered likely that the actual work of production can commence before some nine or ten months. But a great deal has already been done. The railway siding has been completed, the foundations for the works laid, and the erection of substantial quarters for the employees completed. This last won the special approval of Captain Pooley, who is fully alive to the importance of the best possible housing accommodation as a factor in efficiency in a climate such as that of Delagoa Bay. The power plant to be provided will be of the safest type, reciprocating steam engines, with ample reserve plant, so that all risks of stoppage from this source will be obviated. The actual cement-making plant itself comes from Germany, the tenders from that country having proved so much lower than others that the directors considered themselves in duty bound to their shareholders to accept that which was lowest by so large a margin.

Raw Materials.

Captain Pooley made a very thorough examination of the raw materials available for the work of cement making. He visited and analysed the extensive lime and clay deposits belonging to the company, and he is satisfied that in point of quality and extent these leave nothing to be desired. The lime deposits are conveniently situated and may be described as for practical purposes inexhaustible. Coal is, of course, cheap, and easily transported by rail. The water supply is on the spot, and generally the position of the factory is ideal in regard to proximity to supplies of the necessary raw materials. Moreover, a large and ready market is available in the neighbourhood for the product of the works, and the requirements of Delagoa Bay alone will more than suffice to absorb the whole output. It will be necessary, of course, to provide for

extension to the productive capacity of the plant, and this contingency is not being overlooked. Captain Pooley declared himself as very much impressed by the possibilities of the undertaking and regards it as the nucleus of a whole host of other industries bound in time to spring up around it. The sympathy and assistance of the Government was assured owing to the considerable proportion of Portuguese capital interested in the undertaking, and the Administration had shown itself most helpful and encouraging in its attitude hitherto. In regard to the all-important matter of management and expert direction, the company has been fortunate enough to secure some of the best available brains, and since successful cement making is mainly a matter of chemical engineering science, the company has not hesitated to follow the advice of its consulting engineers in this matter, regardless of the expense. It will thus be seen that though shareholders may have to wait longer for returns than they had been led to believe, the delay is likely, in the long run, to have its compensating advantages. When production does start, it will be under the best possible conditions and under the best expert advice. The foundations of the new industry for Delagoa Bay are being laid with the utmost care and attention to detail. The success which seems assured is bound to result in the expansion of the industry as originally contemplated to much larger proportions and also to lead to the founding of new subsidiary industries in the vicinity. The shareholders of the undertaking are therefore not only laying the foundations of their own prosperity, but are also, indirectly, rendering a useful public service to the Province of Mozambique.

“CLIMAX” COMBINED AUTOMATIC COUPLER and AIR TAP.

THIS is a “Climax” accessory that will save your drillman’s time and stop waste.

A combined Automatic Coupler and Air Tap that enables the drillman to connect or disconnect hose in a second—just as quickly as he can push it on to the connecting nipple.

All he has to do is to push it home—locking is automatic.

It can be used on any “Climax” tool and can also be adapted to any other make.

Ask for full particulars.

The Labour Trouble at the Van Ryn Deep.

HISTORY OF THE AFFAIR—PROF. LAWN'S LETTER—MATTER SETTLED.

Trouble arose at the Van Ryn Deep last Sunday night owing to a difference between the management and the reduction workers. The Chamber of Mines considered the matter during the week and a settlement was reached on Thursday afternoon. As several *ex parte* statements have been made regarding the origin of the trouble, which are denied by the management, we print the following official explanation of the matter published by Professor Lawn, the joint managing director of the "J.C.I." group. Professor Lawn writes:—

"As certain statements have been published with regard to the strike of reduction workers at the Van Ryn Deep Mine, I shall be glad if you will publish the following:—

"It has been stated that owing to the longer time that the men would work on the plates if the reorganisation were

The suggestion of the Reduction Workers' Association was that there should be two full-time men in the mill on each shift, and that there should be four men in the plate house on the morning shift and only three during the afternoon and night shifts. This would clearly mean that the men on the afternoon and night shifts would spend more time on the mercury-covered plates than they do now. Further, it might be mentioned that the question of mercurial poisoning was not introduced in the earlier stages of this dispute.

"It is stated that a new battery manager about two years ago cut the staff by nearly half. This is not the case. Consequent upon the reorganisation three years ago there was no reduction whatever in the number of men employed; only three who were previously called shiftsmen were raised to the status of shift leaders. Since that reorganisation

Surface View of Van Ryn Deep.

carried out, the dispute has some connection with the question of mercurial poisoning. There is no wish to deny the importance of mercurial poisoning, and at the present time a committee with Dr. Orenstein as chairman is carefully investigating this question, and the Van Ryn Deep is prepared to fall in with any suggestions that this committee may make for improving conditions; but the dispute at the Van Ryn Deep has no bearing on mercurial poisoning. This is clearly demonstrated by the fact that neither of the two alternatives offered to the company by the shop steward would improve the position of the workmen with regard to the time they would spend on the plates. The one alternative was to leave things as they were. The other alternative was to put on an extra man who would work on the morning shift. It should be pointed out that there are no plates in the mill. The old arrangement was that there was one shiftman on each shift regularly in the mill, and that the shift leader looked in from time to time to help as necessary. There were four men in the plate house on each shift.

more men have been employed, because the number of battery plates was increased.

"It has also been stated that at five minutes before midnight on Sunday the manager of the mine was at the mill with his watch in hand telling the men that he would give them five minutes in which to start, otherwise there would be no start until they accepted the conditions laid down in his instruction. As a matter of fact, the manager did not see any of the men until after 12 o'clock. The mill at the Van Ryn Deep has always started work promptly, and seeing that it did not start as usual he went into the plate house soon after midnight. About ten minutes after twelve o'clock the shop steward approached him and asked him whether he would not concede one of the two alternatives offered. He said that it was not in his power to do so. He further asked the shop steward to reconsider the question of striking, and told him that if the mill started up in five minutes' time, the delay in starting would be overlooked. No threat of any kind was used."

Oil Shale Treatment Problems.

Assertions have been made somewhat frequently that shales will not yield a satisfactory commercial oil product. Those who make these assertions, when confronted by the proved success of the Scottish shale industry, maintain that the Scotch instance is one of the few exceptional cases where the shale is adapted for yielding a commercial product. Broadly, however, all oil shales yield products of the same type when retorted, the difference in the character of the shales calling for treatment not differing in principle but only in manipulative detail.

Treatment of oil shale comes under two main heads—(1) retorting and (2) refining. Of the two the retorting is perhaps the more important, because the refining process is largely influenced by the products yielded by the retorting, which will vary within fairly wide limits, depending upon the care and skill exercised in distilling the shale. Oil shale contains no oil as such; it is simply the raw material from which oil and other valuable products can be manufactured. The retort is the oil factory, and the products obtained from it depend upon the conditions maintained within this factory. Experience has proved that the application of heat to the retort and other conditions must be carefully controlled to obtain maximum quantities of oil of commercial grade. Scottish practice favours the use of superheated steam in the retorts. This is not so much to influence the oil yield (although it has a favourable effect) as to increase the ammonia yield, which is one of the principal sources of revenue. It is claimed that the use of steam trebles the ammonia yield, shortens the time of treatment, and thus permits a larger output.

Scottish practice is the result of many years of experience, and it might have been assumed that those now starting in the industry would desire to profit thereby. According to Professor George, this is not the case in the United States. Of 41 different processes being tried in that country by as many different companies, only two are on lines following Scottish experience. Probably many of these pioneers will suffer disappointment and loss, but it would be surprising if, out of these many attempts, there did not emerge some valuable points in connection with oil shale treatment, and the industry as a whole probably stands to gain by this display of American enterprise.

Problem of Treatment.

The problem of retorting oil shales may be briefly stated thus: (1) To convert as much as possible of the oil making part of the shale into oil; (2) to produce crude oil which

will yield the largest possible percentage of the most valuable products, such as motor spirit, paraffin, and lubricating oils; (3) to secure as large a yield of ammonia and other valuable by-products as possible without sacrificing more desirable results.

The refining of crude oil obtained by retorting oil shale is by no means a simple process, but experience gained in the petroleum refining and gas by-product industries is available to point the way, and these industries can also furnish the skilled operators for oil shale refining. The success obtained in refining Scottish shale oils shows that no insuperable difficulties are encountered. But with regard to shales yielding products comparatively high in sulphur, it is often stated that they have very little commercial value. This statement appears to have its origin in expressions of opinion made some years ago by certain oil technologists. These experts rightly maintained that the presence of considerable sulphur in the oil products largely discounted their commercial value. The objectionable odour imparted by the sulphur both to the oil before burning and to the products of its combustion would at least create a strong prejudice against its use.

It is, therefore, gratifying to know that the exclusion of sulphur in objectionable quantities from the refined oil products of shale is no longer difficult or costly. It is now only a question of deciding which of several processes, all-effective and inexpensive, is the most satisfactory in practice. Now that this difficulty has been solved it can be asserted with confidence that any other difficulties that might be experienced at the refining stage will be only those inseparable from the working of a complex chemical industry, and will not differ in character from those constantly being met in every oil-refining and gas by-product manufacturing plant.

Stienies Diamonds.

The Secretary of the Stienies Diamond Syndicate reports that further 14 loads washed yielded $4\frac{3}{4}$ carats. The largest stone weights $3\frac{1}{2}$ carats, and is of excellent quality.

Monteleo Diamonds.

The Manager of the Monteleo Diamonds, Ltd., reports that 3,638 loads of blue were mined, hauled and floored during the month of August, and that an excellent quality, good-shaped, fine white cleavage weighing $23\frac{3}{4}$ carats was found in picking. Washing operations were resumed on Friday last.

The Johannesburg Municipality has accepted the tender of Messrs. Hubert Davies & Co. for the supply and erection of a Patent Lightning Refuse Crusher, together with motive power and necessary building, for the sum of £2,624, plus £122 17s. 6d. for spare parts.

The Real Value of Gold.

By S. J. Speak, A.R.S.M., M.Inst.M.M.

In the following important article Mr. Speak, a well-known authority, pleads that the appreciation of gold should be regularised, and that its price should be put at six guineas per ounce. In other words, Mr. Speak supports our proposal of last week.

Obviously where gold is the unit of currency its value in terms of money is constant, though its real value is its value in relationship to other commodities. The true value of any commodity is equal to the energy and sacrifice required to produce it, but its market value is subject to the varying effects of supply and demand. Gold differs from all other commodities except silver, in that the demand for it is almost entirely for money purposes, so that should it ever lose its place as the basis of currency the demand for it would be almost negligible, and its market value would be subject to the usual effects of supply and demand, which would result in the closing of nearly all gold mines.

Bankers are generally agreed that some basis unit for currency is essential, and that the most suitable one is gold. Its supposed suitability depends entirely on its past history, which has been that its production has not been subject to violent fluctuations. The discovery of a large and fabulously rich goldfield would destroy its value as a basis of currency.

Gold, therefore, is unlike most other commodities in that the demand for it is mainly of an artificial character. In this respect its position compares unfavourably with that, say, of diamonds, for possession of the latter is desired for their beauty, whereas few would hold gold on that account.

Even bankers desire to hold as little gold as possible, for without power to issue notes against the gold that they may have in their vaults, they can secure no interest upon it, and gold is, therefore, held by them only as an emergency precaution. Their aim is to hold as little of it as possible, in accordance with their own ideas of safety.

Thus gold is in the paradoxical position that the demand for it is of an artificial character, and no one in ordinary times wishes to hold it as a commodity.

The Paper and the Gold Pound.

The indifference displayed by our bankers to the dwindling gold output of the Empire shows that they regard gold mainly as an international token, and overlook the fact that gold takes much labour to produce, and that such labour has not since the War been as relatively well paid as labour in other industries. Of course, there is to be remembered the fact that a year's production of gold is only a small proportion of the world's stock of gold, and bankers may properly regard a temporary deficiency of new output as of small consequence; yet, on the other hand, currency has been considerably increased during the War, and deflation will have to be exceedingly drastic if the world's currency can ever have the same gold backing as before the War. The declared policy of our own nation, which is no doubt indicated by the bankers, is towards that end. The paper pound is, if possible, to be made equivalent to the old gold pound.

To achieve this end strong efforts are being made to reduce the price of other commodities. The attempt with coal has resulted in a strike which has cost a loss of national wealth of probably over £200,000,000. This was a real loss, which can never be regained, because it was labour being idle instead of productive. The only gain is in the direction of improving the value of our paper currency. Deflation is obviously going to be a very expensive process, and the patient may be killed by it instead of cured.

An alternative method is to recognize the existing inflation, and thereby avoid wage reductions, which we know our workmen will stupidly resist. In comparison with American currency, ours is inflated about 30 per cent., and it is recognized that American currency is also inflated, possibly 50 per cent.

America, as a creditor nation, having secured thereby large stocks of gold, will be able to deflate and probably at a much more rapid rate than we, and it may be expected that our exchange with America will go further against us.

Results of the Scheme.

Under these circumstances, if our country now recognized an inflation of 50 per cent. and adopted a free gold basis on such ratio, the immediate results would be somewhat as follows:—

- (1) Wages need be little disturbed for some time.
- (2) The Bank of England could purchase gold for internal requirements.
- (3) American exchange would fall to near 3-24.
- (4) Gold producers would receive nominally more English currency for their output.
- (5) Interest payments on internal national debt would be greatly relieved. This would not be equivalent to capital confiscation if, say, all loans, debentures, etc., raised before 1915 were allowed an increase of 50 per cent., because most of the money raised since that date was in inflated currency. Capitalists would suffer little damage, for they would benefit by the consequent reduced taxation.

(6) All present possessors of cash or bank deposits would suffer possibly to the extent of 15 per cent., which, anyway, is more equitable than that they should benefit to the extent of about 50 per cent. at the expense of the rest of the nation, which is what the present deflation policy aims to do.

Unfortunately such a scheme would probably hit the bankers more particularly than anybody else, and it is, therefore, to their supposed interest to avoid it. When, however, we witness the serious trade difficulties and unemployment, and compute what national loss that means, it would probably pay all capitalists in the end to take a possible loss now, a loss more apparent than real.

For the sake of brevity, no argument is offered to show the justice of a 50 per cent. premium on gold. Your readers, however, know the general conditions of mining throughout the world, and are aware how poorly the gold miners have been paid for their work as compared with the coal miners of England. Of course, this has arisen from the effects of supply and demand.

To Obviate Deflation.

What is now suggested amounts to legalising a 50 per cent. premium on gold with the object of avoiding the present painful and wasteful process of currency deflation. In such way we would more quickly attain a settled basis of currency, whereas the existing deflation process must take considerable time, and may never succeed, and, in the meantime, will be a constant embarrassment to trade.

The gold output of the world has fallen about 30 per cent. since the commencement of the War, and may fall further unless the principal nations return to a free gold basis at an early date. If Great Britain will require, as has been estimated, ten years to complete its present deflation policy, by that time gold will be relatively scarce, and it will be difficult to acquire sufficient gold backing for its currency. This aspect of the question appears to be overlooked by most financial experts, and the main object of this article is to draw attention to the fact that the matter of gold production has an important bearing on the currency question. The world is an expanding community, and unless gold output keeps pace, currency deflation will have to go beyond the pre-war basis. As the British Empire is now contributing 70 per cent. of the world's output, it is of particular interest to us to support that industry. During the War its product was commandeered at pre-war prices, a treatment served out to no other industry, and since then and is now suffering from lack of normal demand. Meanwhile, America is securing a stock of gold at a price below the fair cost of its production. The danger of the present system if continued is that when we do want gold we shall be required to pay dearly for it, whereas a bold stroke as above advocated would establish a stable currency which would enable the trade and commerce of the country to revive rapidly.—From the *Mining Magazine*.

The Great Wankie Coal Areas!

FOUR HUNDRED SQUARE MILES OF COAL—NEW COLLIERY BEING OPENED—POSSIBILITIES OF EXPORT.

Several prominent Randites have recently visited the Wankie coalfield and all have been much impressed with its wonderful potentialities.

The Wankie area lies between Bulawayo and the Victoria Falls on the Northern Railway line. Wankie, the headquarters of the Wankie Colliery Co., is a station on the main line, 212 miles north of Bulawayo and 78 miles south of the Falls.

The area of the coal concession is approximately 400 square miles. Three seams of workable thickness exist in this area, but only one of these, known as the main coal, has been worked. In the present workings this seam varies from 6 feet to 12 feet in thickness, but recent borings to the west of the colliery have proved a gradual thickening of the

from the surface to the main coal as proved over an area of roughly 25 square miles varies from the outcrop to a depth of about 300 feet. The gradient of the seam averages about 1 in 30. Approximately one square mile has been worked up to the present, about 33½ per cent. of the coal being left in pillars, which will be subsequently worked out. The coal is of exceptionally good quality, as shown by the following average of 83 analyses recently made on samples taken from all parts of the existing workings. Analyses of the coal proved in boreholes show a continuation of this quality.

Moisture	0.95
Volatile and organic matter	23.62
Fixed carbon	66.90
Ash	8.52
Calories	7,159
B.T.U.	12,887
E.P. in lbs. H ₂ O	13.33

Part of the Yard at Wankie.

main seam up to nearly 40 feet in a distance of about five miles, while the other two seams have thinned down, and at this point are not of much value. The indications are that this gradual increase in thickness continues in a westerly direction. The greater portion of the area is remarkably free from faults of any size. The depth

Output Capacity.

The coal output capacity at the present time is 60,000 tons per month, including coal for coke manufacture. The extensions now in hand will considerably increase this capacity. Large quantities of coke are sold to the Union

Minière, and Rhodesia Broken Hill. Estimated probable tonnage in area, 6,000,000,000 tons.

A deposit of fireclay—average thickness, 80 ft.—runs through the Concession, its position being immediately above the coal shales. From the fireclay in this deposit excellent refractory material is obtained and manufactured at the Colliery into such articles as bricks, special material for

Mine.

The width of coal mined in the mine now at work varies from 6 ft. to 12 ft. in thickness, and is worked on the pillar and stall system. The coal is reached by two incline shafts 600 ft. long with a grade of 1 in 7, one of these inclines being operated by a hauling engine, on which sets of twenty tubs each are manipulated, while on the other incline shaft

First 44 Ovens of 140 now in use at Wankie.

The Coke Plant at Wankie.—First 44 Ovens of 140 now in use.

coke oven construction, firebrick for furnace work, locomotive fire-box arches, material for muffle furnaces, crucibles, etc. In addition to fireclay, limestone and fair deposits of hematite iron exist.

The company owns twenty square miles of surface rights, on which cattle to supply the camp with milk are run. The camp is well built for a mining camp, in that excellent building stone and first-grade bricks are obtained locally.

an endless haulage is in operation; this second shaft is used as a standby only. At the point where these incline shafts intersect the coal three main roads radiate, one being a continuation of the shafts, while the other two are set off at an angle of 45 deg. to the right and left. Levels are set off every 300 ft. along the centre main road, while corresponding levels are set off from the east and west slants at 425 ft. apart to correspond with the levels on the main slant.

In the levels stentons are cut through every 66 ft., and in the extraction of the coal approximately 33 ft. of coal is taken out and 33 ft. left standing, while these pillars are again pierced by stentons at 66 ft., so that pillars 33 ft. x 66 ft. are left to support the roof. This practice is much varied, depending on conditions, and in some parts of the mine pillars larger than the size specified are left standing.

Coal-cutting machinery has been experimented with, but in no instance have the results equalled those obtained from hand labour. The coal is drilled with Elliott or Conqueror hand-drilling machines, two natives being able to

value exists and the unfavourable conditions mentioned as slips, etc., have not set up difficulties in mining, and are therefore an unimportant item in a coal deposit which has such immense possibilities.

New Mine.

As the present colliery site is congested, which makes further expansion difficult, it was some time ago decided to open a new colliery approximately four miles to the north-west of the present mine. The main coal at this point is 33 ft. 4 in. thick to 200 ft. below surface. The analysis of coal from the boreholes in this section shows even better

Wankie Collieries.—A General View.

Another View at Wankie.

drill sixteen holes to a depth of five feet comfortably for the shift's work. Roughly 5 ft. 6 in. of the seam is taken out in the first operation, and the top coal dropped down afterwards. The explosive used is 60 per cent. gelignite.

Some faults exist, especially in the eastern section of the mine, where the coal is thinner, one fault displacing the coal 16 ft. With the exception of this large fault, no faults over 8 ft. occur, some faults showing about a 2 ft. slip. The western section of the mine, where the coal is thicker, is free from this condition, the general condition underground being that a coal seam of excellent width and

results than are now being obtained at the present colliery. The incline shaft at the new colliery is now sunk to a depth of 600 ft., and excellent progress has been made with the stone walling in connection with banking arrangements on the surface.

The West Coast Scheme.

An important project at present merely under consideration, but which will probably be given effect to in the near future, is to construct a railway line from Wankie to Grootfontein, in South-West Africa, and to export coal from Swakopmund and Walvis Bay.

THE NEW UNION MINT.

The photographs reproduced on our front page this week provide a pictorial reminder that the new Union Mint at Pretoria is rapidly approaching completion. In the two years that have elapsed since the project to establish a Union Mint was adopted by the Union Parliament, several events have occurred to overshadow its importance, and in some quarters there is a disposition to question the necessity for its completion, in view of the altered circumstances. Since it was decided upon, the market for gold in London has been made free, and the Union has embarked on the bold policy of establishing its own Reserve Bank, coupled with an embargo on the export of gold, and its withdrawal from currency. Within two years, of course, gold may come back into currency in the Union, under the provisions of the new currency and banking legislation, and then, doubtless, all the advantages claimed for a South African Mint will be realised, and its establishment thoroughly justified. It will be remembered that the controversy over the question of a site, in 1919, led to a compromise, the Mint being located at Pretoria and the Refinery—now also nearing

completion—at Germiston. The history of the project is not without other features of interest. It may be remembered by pioneers that the banks in this country opposed the idea when first mooted by President Kruger, in the pre-Boer War days, and that Sir Lewis Mitchell especially distinguished himself by demonstrating the shortcomings of the original scheme under the conditions then prevailing in South Africa. A Mint afterwards established at Pretoria never quite became a success, largely it was said by reason of its distance from the gold fields. Profiting by that experience, the Government decided upon the compromise—already mentioned, and with the examples of Canada, Australia, and India to guide it, there seemed, when the scheme was passed, little possibility of failure. Credit for keeping the idea before the industry and the Government must be given to Mr. Samuel Evans, who prepared for the Chamber of Mines an elaborate report on the whole question, which brought together all the available figures gleaned from other parts of the British Empire. Amongst the arguments for establishing a Mint, which still hold good, was the amount which was lost by importing silver currency. It appears that we obtained in one year £400,000 worth of silver coins from India which we might have struck off ourselves. Another argument was that every self-governing Dominion of the Empire, except New Zealand—which gets its gold cheaply minted in the adjoining Commonwealth—has its Mint or Mints. If it is economically sound for Australasia, with the maximum gold production (1903) of 18 millions sterling, to have three Mints, it seemed economically unsound for South Africa, with a production more than double this amount, to be without one. When the subject was somewhat perfunctorily discussed in the Union Parliament in 1912, the Finance Minister (then General Smuts) was inclined to look askance on the proposal on the grounds that the payability of a Mint was somewhat doubtful, and that the Imperial Government had specifically refused to share the profits on the coinage of silver and copper. Against that it was urged that there would seem to be no doubt that the Australian Mints were very profitable to the producer and not unprofitable to the Government. To illustrate the latter point it was proved that at the Perth Mint in 1912 the average amount charged for assaying, refining and coining was 2.73d. per ounce of deposit. In that year the amount treated was 1,479,079 ozs., consisting of 4,779 separate deposits. A profit was made equal to 1.5d. per ounce of deposit. The question of profit to the Government, however, was regarded as of far less importance than that of the gain to the industry. When the War broke out the Bank of England, on behalf of the British Government, agreed to buy the bullion in South Africa, the producers to defray all expenses up to the time of the delivery of refined gold to the Bank of England in London. On the other hand, the gold produced in Canada and Australia was refined and minted on the spot. This is to say, the gold mines of South Africa had to incur extra charges under the following heads as compared with gold producers in Australia and Canada: Packing for export, railage to the coast, freight from Capetown to London (or, as it was during the War, to Ottawa or Bombay), insurance, bank charges for handling the bullion at Johannesburg, Capetown and London, exchange, extra expenses on assaying and refining, and 1½d. per standard ounce to the Bank of England. In reference to the last item, it was stated that the Australians got 77s. 10½d. for their gold from the local Mints, while the South African producer got only 77s. 9d. per standard ounce for it, while Canadian and Australia producers, without incurring any risk or expense, got 77s. 10½d. per ounce for their gold in their own countries. The loss to the Rand industry and to South Africa during the War owing to the lack of a Mint was estimated to exceed £300,000 to £400,000 a year. During the War realisation charges, we believe, came to as much as 2s. per ounce. The moral is that though apart from the profit on silver and copper coinage, the new Mint may not be of much service to the country under present conditions, with the return of gold into circulation, under any of the schemes now mooted, its establishment is bound amply and ultimately to justify itself.

THE CURRENCY STABILISATION QUESTION.

It is gratifying to know that the article in our last issue dealing with the stabilisation of the currency has evoked widespread discussion and expressions of agreement with its main proposal from many quarters. It would seem that contemplation of the chaotic condition of the currencies of European countries has set many men thinking along very similar lines towards a solution of the difficulty. One London paper puts it thus: "Whether gold is to go back to its original value, or whether we are to continue to send the metal to the United States and live on paper in this country, is the chief financial problem of the day. The only orthodox way of bringing gold back to its par value is to cut wages and public expenditure in this country." In this issue we publish extracts from an article by Mr. S. J. Speak, who demonstrates the inability of the British Government and the financial authorities in London to effect this desirable reinstatement of the basic principle. Mr. Speak's opinion is that the appreciation of gold should be regularised, and that its price should be put to six guineas per ounce. In this way the relation of prices to values would be more easily revised without the working-classes being provided with a reason for strikes. In this connection, Barclays Bank's *Monthly Review* has the following suggestive passage: "It is important to remember that, although at the present time it is not possible for this country, or indeed most countries, to establish a standard of currency consisting of gold, or of paper backed by 100 per cent. of gold, yet a gold standard can be established by the maintenance of an adequate percentage of gold in support of any existing volume of currency. This method does not, of course, provide the same convertibility; but, properly regulated, it provides an efficient gold standard system." Prior to the War the leading countries of Europe were able to maintain the gold standard not by holding 100 per cent. in gold against their paper currency, but by maintaining a certain ratio of gold against it, this ratio being determined by experience over a number of years. The restoration of the gold standard in Europe is not now regarded as so remote a prospect as the idea of a 100 per cent. gold cover would suggest. It is of interest to note that this is also the opinion of Mr. Goodenough, the chairman of a group of British banks—"the big five"—controlling funds amounting to 1,500 million pounds. Writing on the currency question nearly two years ago in these columns, Mr. C. F. Tainton declared: "What is wanted as the first step in reform is a world conference to deal with standards of value. It may be of service to suggest that the present price for gold is an obsolete convention which is not in any sort of work-a-day relation to the value standard of to-day. . . . Let new values be put upon gold and silver values more in accordance with the realities of to-day than those antiquated metal estimates of Calonne in 1779 and of Peel in 1844, and let these values be standardized by the consent and laws of all the leading civilised nations." In a paper read eighteen years ago before the Institution of Mining and Metallurgy in London, the late Mr. Hennen Jennings suggested much the same idea, and there is a growing unanimity of opinion among thoughtful observers that some united action must be taken by the nations to readjust official currencies to the new conditions. It has been suggested to us that the forthcoming International Conference at Washington would furnish just the stage setting and opportunity for the discussion of this great world problem; and possibly some of the leaders of the gold mining industry may, in the interests equally of the Rand and of a currency-sick world, bring the matter to the attention of the powers that be

Notes & News.

The Diamond Outlook.

According to a London cable, London diamond merchants' opinion is that as the stocks confiscated by the Soviet are now practically exhausted, the legitimate trade has little to fear on the score of further Russian dumping, and the market

will gradually assume its normal appearance. It is estimated that the Soviet flooded Europe with 10 millions sterling worth of gems during the past 18 months.

The Deepest Mine.

The deepest mine in the world is apparently the St. John del Rey, which is now being worked to a depth of 6,426 ft. What should be a normal temperature of 117 degrees Fah. at this level is reduced to a comfortable working temperature by pumping down refrigerated compressed air. On the City Deep it is proposed to sink to an ultimate depth of 7,000 ft. Next in the list appears to be Village Deep, with operations a little over 6,000 feet in vertical depth.

The Transvaal Coal Trade.

The falling off in the export and bunkering trade at Delagoa Bay and accumulation of stocks resulted in restriction of the Transvaal output during June, but recent shipments have relieved the congestion and some improvement is expected. The following are the output figures in the Middelburg district for the month of June:—Number of collieries producing, 20; tons of coal mined, 492,560; tons of coal sold, 415,138; total value realised, £137,235; value per ton at pit's mouth, 6s. 7.28d.

Oil Shale.

Success has attended the initial trials of the Ironside oil shale reduction process, mentioned briefly in our last issue. Waiihoek cannel coal, which averages 28 gallons to the ton, but which was reported on by Mr. McKillop, of the Scottish Oils, as being unsuitable for Scottish retorts owing to its tendency to clinker, was treated by the Ironside method. A yield of approximately 30 gallons to the ton was obtained and with no clinking. A small test of Grenfell coal gave a yield of 25 gallons. The oil is produced within a minute. A representative of this paper will report upon the process for our next issue.

The Diamond Trade.

Exports during July (excluding the Premier Mine and South-West Africa) totalled 20,763 carats valued at £108,319. A certain amount of selling is reported on the Continent, but so far there is not much indication of an improvement in the American demand. It is stated that during the first three months of the year diamonds to the value of £2,100,000 were imported into America, practically the whole of which came from Bolshevik sources. Prices on the river diggings are improving, and the finest quality stones have appreciated by 20 per cent. to 25 per cent. during the past few weeks, but no general improvement in the industry is anticipated until America re-enters the market.

T.G.M.E.

At a meeting of shareholders of the Transvaal Gold Mining Estates, Ltd., held recently in London, Mr. Matthew T. Brown, who presided, said that the tonnage crushed in the past year, 194,560 tons, was the largest on record, but unfortunately the yield per ton milled was the lowest, being about $\frac{3}{4}$ dwt. less than in the previous year. This deficiency, however, was almost made up by the better price obtained for the gold, so that the average realised value per ton of ore treated, £1 17s. 1d., was only 4d. less. The working costs at £1 9s. 1.2d. were one-fifth of a penny less. This left a working profit of just under 8s. a ton, or one-half the average profit per ton earned during the twenty-five years life of the company. Under the circumstances, the net profit, £89,752, or £2,292 increase over the previous year, seemed not unsatisfactory, but if the gold had been sold at the old standard price, all but £400 of this profit would have disappeared. Dealing with the passing of the May dividend, he explained that the Board deemed it necessary to maintain a strong cash position until they saw their way a little more clearly ahead, or until there was a reduction in the high level of working costs, which would enable their large low-grade ore reserves to be treated at a profit without help from the uncertain and fluctuating gold premium. After some discussion an informal resolution was passed urging the directors to reconsider the position, with the view to paying a dividend at as early a date as possible.

Lonely Reef Mine.

The July development report of the Lonely Reef Gold Mining Company announces an exceptionally good strike at the lowest, the 24th level—namely, 60 ft. of ore, assaying 3½ ozs. of gold per ton. The previous 32 ft. had only averaged 13 dwts. over 29 ins. The cable reads:—"No. 24 level, north drive, 100 to 160 ft. averages 3 ozs. 10 dwts. over 40 ins. No. 23 level, north drive, 221 to 261 ft. averages 15 dwts. 19 grs. over 45 ins. No. 19 level, south drive, 997 to 1,014 ft. averages 2 dwts. 10 grs. over 9½ ins." The company's output for July is as follows: "Mill ran 704 hours, crushing 5,400 tons, yielding 5,180 ozs. of fine gold. On the basis of a net realisation price of 110s. per fine ounce the estimated profit is £16,467." The June yield was 5,280 ozs. and the estimated profit, taking gold at 107s. 6d. per ounce, £14,384.

* * * *

The Cinderella.

At a meeting addressed by General Smuts in Capetown last week, a questioner asked why for the last 12 years the Cinderella mine had been closed down. "The Cinderella Deep," replied the Prime Minister, "cannot find capital, and it has for years been trying to find further capital. It is a deep mine, and it has cost an enormous sum of money to bring it where it is. In order to develop it further capital is required, and there is no chance of raising it." The questioner: "Is it not possible to let this mine out on tribute to other mines on the Rand?" The Prime Minister: "The Government is at present making very serious efforts to see what can be done for the Cinderella by working it with other mines, and I suppose the Cinderella is a good mine, but it has proved very costly, and the Cinderella, as such, cannot be worked. The Government has now under consideration how it is possible to work the Cinderella."

* * * *

Rhodesia Broken Hill.

Mr. Edmund Davis, presiding at the annual meeting of Rhodesia Broken Hill Development Co., Ltd., said that the Board were advised that they had two lodes running through the property about 1,000 yards apart, the one outcropping on kopjes Nos. 1, 3 and 4, containing lead and zinc ores, and the other outcropping on kopje No. 2, containing essentially zinc. Borehole tests had given satisfactory results, and showed about 200,000 tons of ore, averaging 24 per cent. zinc and 2½ per cent. lead, and about 300,000 tons averaging 27 per cent. zinc and 10 per cent. lead. The problem of treating these reserves is receiving the serious attention of the management. During the past year 14,602 tons of lead have been produced, showing a satisfactory increase, whilst since the close of the financial year production has further improved. The transport rates have been slightly reduced by the Rhodesian railways; but, in view of the importance of the industry to the country, the Board is of opinion that a further concession should be made.

* * * *

Profit Sharing on Rand Mines?

The adoption of the principle of profit sharing in large industrial undertakings in South Africa has been expounded in theory, but no one has as yet had the courage to put it into practice. It is noteworthy that the General Mining and Finance Corporation held a meeting with representatives of all sections of the workers at the Roodepoort United last week in order to discuss the principle of the matter. The profit sharing procedure proposed was that the employees should forego one-half of the existing union rates of pay. Then the interest on the large amount of money which the company owed would be paid, and afterwards, before any profits went to the shareholders, a first charge on the further proceeds of running the mine should be the making-up of the wages to existing union standards. If, after this had been done, there still remained any surplus profits, the men should share in these with the shareholders. It appears that this experiment is being suggested in order to see if its adoption will in any way improve the efficiency of the workers, lack of which, of course, is at the root of all the troubles of the low-grade mines of the Rand.

The Grootfontein Borehole.

The Rhodesia Consolidated Company announces that the average values of the reef in the Grootfontein-Vogelstruis-bult borehole is 1 dwt. over 75 ins. The Van Ryn reef was struck in the above borehole at a depth of 3,340 ft., and the information obtained as to the regularity of the strata gone through by the drill and the width of the ore body encountered is of far greater importance than the assay value at the point of intersection. The rich chutes in the Eastern Rand are always separated from one another by larger or smaller stretches of poor reef. In the Springs Company's No. 3 shaft not far north of the above borehole the reef when first struck went only a third of a pennyweight over 61 ins. On the other hand, the New State Areas' first shaft was lucky enough to strike the reef in a rich chute, assays going all but 1½ ozs. of gold per ton over 19 ins.

* * * *

The World's Gold Reserves.

In the latest issue of the official *Monthly Bulletin of Statistics*, now transferred to the League of Nations, figures are given showing the total of gold reserves held by various national banks, or banks otherwise under Government control, together with the presently current note issues. As the statistics apply not only to Europe (excluding Russia), but to the British Dominions and India, and to the United States and Japan, they are of interest as throwing light on exchange problems. The total of gold reserves held, and to all intents for the present withdrawn from circulation, comes to £1,448,000,000. Of this total £498,500,000 is credited to the United States Federal Reserve Banks, while the Bank of England holds £128,300,000, the Bank of France £220,700,000, and the Italian banks £85,500,000. Together in the three countries the holding is £434,500,000. There is, however, a lock-up of £99,400,000 in the Bank of Spain. Germany's holding is £53,700,000, and that of Japan £114,700,000. On the other hand, the note circulation (again excluding Russia) has, taking the countries in the list, expanded to £11,962,515,000. Roundly, that is to say, it is eight times the gold reserve presumed to cover it. Of the total, however, considerably more than half, or the equivalent of £6,741,419,000, is represented by German and Austrian paper currencies. The balance, £5,221,096,000, has to be considered in relation to gold reserves of £1,394,300,000, leaving out the German holding, which reduces the ratio to gold, 100; notes, 375.

Consolidated Mines Selection Group.

Mr. J. S. Wetzlar, the managing director in London of the Consolidated Mines Selection Co., Ltd., has just returned to London from a short visit to this country, in the course of which he naturally devoted most attention to the affairs of the prominent Eastern Rand Mines controlled by the group with which he is associated. In an interview with a representative of the *Financier*, Mr. Wetzlar said that outside mining circles, where there was, perhaps, some pessimism, the feeling of the commercial classes in South Africa was quietly optimistic, the common opinion being that although the country had had its troubles, yet it was recovering, and there was confidence that the enormous natural resources of South Africa would assist it to overcome any difficulties which the future might bring. As regards his own group, Mr. Wetzlar said that the Springs Mines had never looked better, while the Brakpan Mines might be said to have established its position. With regard to the Daggafontein Mines, there was no dissatisfaction with the developments. Financial reasons were the cause of the property being closed down, and it would be re-opened when the needful funds became available. The West Springs Mine was opening up quite satisfactorily, and he was satisfied with regard to its prospects. Reduction in working costs on the field was necessary, for the life of the Rand really depends upon the possibilities of successfully treating the enormous quantities of low-grade ore found in the rich as well as the poor mines. The new all-sliming process tried out at the Springs Mine was no longer an experiment but a proved success. A high percentage of extraction was possible and considerable savings would be effected in installation and running costs.

Latest London Market Report.

On the Stock Exchange last week the news from India and the perplexities of the Irish situation and Continental politics caused hesitation, while in the distance loom the probabilities of a general election. Industrial stocks revived under the influence of improving trade reports. Later the markets were more active and stronger, notably in investment stocks, due to a sudden ease in the money market in consequence of the disbursements of Government dividends amounting to twenty millions sterling, together with big German payments in connection with reparations. Kaffirs relapsed into comparative quietude, but afterwards rallied, helped by a revival of the bull tendency in Paris. Regarding the uneasiness felt in some quarters in connection with the possibilities of Germany selling Kaffirs on the official termination of the War, it is pointed out that inasmuch as large German holdings remained under the control of the public custodians, the question of stock coming on the market is obviated. The recent activity in Kaffirs, together with the revival of rumours hinting at the possibility of Rhodesia joining the Union, stimulated some buying in Rhodesians, mainly low-priced shares. Diamond shares advanced, chiefly on Paris buying.

Concerning Mines and Men.

Sir Lionel Phillips, Bart., has returned to the Rand.

Mr. Gibson, of the Anglo-Persian Oil Company, is on a professional visit to South Africa.

Mr. A. F. French, of the General Mining and Finance Corporation, will return to the Rand before the end of the month.

Mr. J. L. Siddall, London Secretary of the Central Mining and Investment Corporation, is paying a six months' visit to the Rand.

MAGNOLIA ANTIFRICTION METAL

"FLOWER" BRAND.

HAS THE LOWEST CO-EFFICIENT OF FRICTION.
KEEPS down the bill for lubricants, making BEARINGS smooth as glass and keeping them COOL under heaviest pressures and highest speeds.

S.A.R. & the Coal Trade.

According to the latest bulletin of the General Manager of the S.A.R., railway earnings for the week ended 20th August were £399,132, £35,770 below the estimate—an estimate framed in April, 1921, on what was then thought to be a conservative basis. The extent of the drop in railway earnings will be appreciated when it is mentioned that the figures for the week ended 20th August are less by £122,000 than those for the record week in December last.

The Administration's difficulty is that, while revenue is rapidly declining expenditure is not going down in proportion, notwithstanding the economies introduced. 187,485 tons of coal were shipped at Durban in July, compared with 210,037 tons in June, while 75,188 tons were shipped at Delagoa Bay in July, compared with 84,732 tons in June, but the number of vessels now in port and the estimated requirements for the near future indicate that South Africa will be able to retain a considerable proportion of the trade, notwithstanding the settlement of the British coal strike and the big drop in the price of bunker and export coal at British ports.

The detention of truckage at Durban still continues. Notwithstanding present difficulties large numbers of trucks are still detained at the port by the collieries for storage purposes. The supply of empties at the coal mines within the last few weeks has not been what the Administration would have wished, but though the requisitions have not been fully met a good supply of coal has been available at the ports for shipment.

Exception has been taken by a section of the public press to statements contained in Bulletin No. 21, to the effect that the Delagoa Bay coaling appliances had again broken down and were out of commission for 48 hours from 14th June, and that the coal trade at that port was by no means heavy at the time.

The statement made in the Bulletin was merely a statement of fact and had no other significance. The previous breakdown was mentioned in Bulletin No. 20.

The following figures, which speak for themselves, show the tonnages of coal bunkered at and exported through Delagoa Bay during the months of May and June last:—

	May. Tons.	June. Tons.	Decrease. Tons.
Bunkered	27,640	26,747	893
Exported overseas ...	78,377	57,985	20,392
Totals	106,017	84,732	21,285

The tonnage of coal railed from all Union collieries during June, 1921, shows a decrease of 4,969 tons compared with the corresponding month of the previous year. The tonnage from Transvaal collieries shows a decrease of 71,038 tons, but Natal and Orange Free State collieries show increases of 63,580 tons and 2,598 tons respectively.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

IV.

By Arthur Stenhouse.

On a moonlight night in 1886 I started from the camp of the Witwatersrand to ride across the trackless veld to Pretoria, in order to telegraph an urgent offer of some claims on the Main Reef to my principals in Kimberley. By midnight I had lost my way; off-saddling, I laid me down to rest beneath the starry sky, and in the stillness recalled

memories of a visit to the beautiful island of Barbadoes, with its white pebbly beach, and the coconut palms. Once more I wandered along the coral roads through "Fontabelle," the charming suburb of Bridgetown, with its neatly kept gardens of tropical trees and flowers. Again I watched the bright hued lizards lazily blinking in the blazing sunshine. . . .

At daybreak next morning I resumed my journey, and shortly afterwards approached Struben's mill and, to my discomfiture, discovered that I was entirely off the track to Pretoria! Re-directing my route, I resumed the journey, occasionally resting at a Boer farmer's homestead, where we conversed by symbols, and at eventide, dusty and weary, I arrived at my destination. At Pretoria, I "wired" to my principals about the claims and duly received a reply stating that they were not buying claims as they had no faith in the permanency of the Witwatersrand gold mines, and urging me to proceed to Barberton, where claims were booming.

In the silence of the night, beneath the outspanned wagons, at Ferreira's Camp, we watched the camp fires burning and listened to the crooning of the Kaffirs seated around the anthraps' purple flames. Life was not altogether a bed of roses, but optimism buoyed us up in our wanderings.

Looking back to those early days, though deprived of the charm of female society, we were entertained by men of every nationality who had arrived from the four corners of the globe. Intensely interesting were the yarns and experiences of these men from afar. Romance figured largely in many of their stories; some, however, had to be swallowed with a few grains of salt. Anticipation was our mainstay—the pleasures of hope are greater than the pleasures of memory, so we were universally happy in our primitive surroundings in those days of long ago. Sad, but sweet, are some of our remembrances.

THE TRANSVAAL COAL OWNERS ASSOCIATION

(1910), LIMITED

Head Office: GENERAL MINING BUILDINGS, JOHANNESBURG.

Totals and averages £588,625 23/701 £372,497

July totals £566,125 24/085 £331,703

Note.—The above results are arrived at by calculating the gold at £5 11s. 6d. per fine oz.

Monthly Gross Profits.—January, £269,638; February, £187,423; March, £253,627; April, £261,506; May, £250,900; June, £281,801; July, £331,703; August, £372,497.

GENERAL MINING & FINANCE GROUP.

The August operations of the producing mines of this group were as follow:—

Company.	Tons Crushed.	Total Cost.	Cost per Ton.	Total Revenue.	Profit.
Aurora West ..	11,050	£14,778	26/75	£16,184	£1,406
Meyer & Charl.	14,500	18,483	25/49	45,720	27,237
New Goeh	17,500	19,980	22/83	21,530	1,550
Roodepoort Un.	23,000	26,819	23/32	25,182	*1,637
Van Ryn Est...	33,400	42,219	25/28	53,315	11,096
West Rand Cn.	32,500	44,996	27/69	50,263	5,267
	131,950	£167,275	25/35	£212,194	£46,556
				Less loss	1,637
					£44,919

* Loss.

In calculating the revenue, gold has been taken at a value of £5 11s. 6d. per fine oz., less estimated realisation charges.

CONSOLIDATED MINES SELECTION GROUP.

The following are the results of operations for the month of August, 1921:—

	Stamps Working.	Tons Milled.	Working Costs per Ton Milled.
Brakpan Mines	110	58,600	25/ 6/601
Springs Mines	80	41,500	28/ 6/872

Totals and averages 190 100,100 26/ 0/636

	Value of Gold declared.	Yield per Ton.	Working Profit based on standard value of Gold.	Working Profit per Ton.
Brakpan Mines	£95,185	32/ 5/838	£20,324	6/11/237
Springs Mines	76,765	36/11/944	17,477	8/ 5/072

Totals & averages £171,950 34/ 4/268 £37,801 7/ 6/632

	Estimated Premium taking Gold at £5 11s. 6d. per fine oz.	Total Estimated Profit.
Brakpan Mines	£28,075	£48,399
Springs Mines	23,091	40,568

Totals and averages £51,166 £88,967

Brakpan.—Placed to gold reserve, 2,624 fine ozs.

CONSOLIDATED GOLD FIELDS.

The following are particulars in regard to the outputs for the month of August, 1921, of the undermentioned companies of the Consolidated Gold Fields Group:—

Company.	Stamps Running.	Tube Mills.	Tons Crushed.	Gold declared, Fine ozs.	Profit.
Simmer and Jack ..	320	7	53,700	13,772	£14,020
Robinson Deep	160	10	61,600	17,871	21,199
Sub Nigel	30	2	10,200	5,491	6,903

Totals 510 19 125,500 37,134 £42,122

Gold in Reserve.—Simmer and Jack, 1,200 ozs.; Robinson Deep, 900 ozs.; Sub Nigel, 2,013 ozs.; total, 4,113 ozs.

The revenue derived from gold for the month of August is calculated at the rate of £5 11s. 6d. per fine oz., less estimated gold realisation and exchange charges of 1s. 6d., or a net figure of £5 10s. per fine oz.

Geology of Heidelberg—IV.

MR. BLELOCH'S REPLY TO DR. ROGERS—UNCONFORMABILITY OF THE VENTERSDORP SYSTEM.

A Fundamental Question.

I will now proceed to deal as briefly as possible with the other fundamental question—that of the Langerman's Kop and Reitfontein beds, which I have already touched upon. I find that in his paper entitled "Some Structural Features of the Witwatersrand System, read before this Society on the 30th March, 1911, Dr. Mellor, who has just told you that his views about the reefs has not changed, states (page 37): "To return to the beds associated with the Reitfontein reefs, of which I hope later to give a detailed description, it may be noted that many points of similarity with the Langerman's Kop beds have been pointed out by several geologists, and this is a matter upon which even those holding the most diverse views as to the geological position of the beds are agreed. The similarity is certainly as great as one would expect to find in a formation of coarse conglomerates, and therefore likely to show considerable difference in the composition of individual beds in different areas, and it seems extremely probable that the Reitfontein series must be ultimately grouped with the Langerman's Kop beds and other similar rocks already referred to. The disposition of the Langerman's Kop beds and the Reitfontein series apparently in conformity with the lower Witwatersrand beds certainly suggests an intimate relationship between the two."

So far as these statements go, I am in complete agreement with Dr. Mellor. I cite them as evidence from Dr. Mellor himself of the identity of the Reitfontein beds with those of Langerman's Kop and of the position of both in the lower Witwatersrand beds for which I have for many years contended, and as Dr. Mellor states, geologists—even those holding the most diverse views—are also in agreement in this matter. The facts are that near the north base of Langerman's Kop there are outcrops of gold-bearing reefs identical in character and appearance with the gold-bearing and payable reefs of Reitfontein. These reefs are known as the Buckshot Reef, the Pay Reef and the Carbon Leader. I have brought specimens of the Buckshot Reef here to-night, both from Langerman's Kop and Reitfontein, to which I will refer later. Lying to the south of the Reitfontein mine at Reitfontein there are outcrops of certain large pebble blanket reefs which have been called by several observers, including Dr. Hatch and Dr. Corstorphine and also Dr. Mellor—the South Reitfontein series. I have brought here to-night specimens of these South Reitfontein beds so that you can compare them with specimens of the large pebble blanket reefs which occur in the upper portion of Langerman's Kop in the same relative position to the Buckshot leader and the other reefs of the Reitfontein series which outcrop near the north base of the kop, as that of the South Reitfontein beds relative to the Reitfontein reefs at Reitfontein. I ask for the earnest attention of the members present to these specimens, and I think you will agree that Dr. Mellor was correct when he stated in 1911 that "It seems extremely probable that the Reitfontein series must be ultimately grouped with the Langerman's Kop beds (page 38, Trans. Geo. Soc. S.A., Vol. XIV.). At that time, as shown in the paper from which I have quoted, Dr. Mellor had come to the conclusion that both the Langerman's Kop and Reitfontein series "belong to a formation unconformable to the Witwatersrand system" (page 39). Although he goes on to say that more evidence, however, than that at present available as to the relationship of the diabase (Ventersdorp beds) to the sedimentary beds appears desirable before any close connection between the two can be said to be established" (Proceedings Geo. Soc., Vol. XV., page xlix.). Dr. Mellor says: "The Reitfontein area . . . is the one in connection with which the whole question of the conformity of the Reitfontein series arises."

Mr. C. B. Horwood.

In 1912 in discussing Dr. Mellor's paper of 1911 before this Society (Proceedings Geo. Soc. S.A., Vol. XV.), Mr. C. B. Horwood said that "He was technically connected with the Reitfontein mine in 1907 and 1908, and although he had studied the subject carefully he was unable to find any sufficient evidence to show that the Reitfontein series was unconformable. On the contrary, it appeared to be regularly interbedded in the lower Witwatersrand system." Mr. Horwood also cited strong evidence by Mr. F. Graham Bell, who mapped certain beds of quartzites admitted by Dr. Mellor to belong to the lower Witwatersrand beds and found that the windings of the Reitfontein reef in the levels of the mine followed the windings of these quartzites.

Mr. Graham Bell in 1920 wrote to me the following: "As the result of 2½ years' experience in development work on Government Areas mine—during which 70,000 ft. of development was done—I came to the conclusion that the Van Ryn series was the Reitfontein series and not the Main Reef series."

Dr. H. L. Krause stated (Trans. Geo. Soc. of S.A., Vol. XV., 1912): "In regard to the grouping of the Reitfontein bankets and their mineral association, I am persuaded that the Main Reef series in no part of the Rand where I have laboured present a parallel to them."

Mr. J. S. Olver, the author of "Faults and Dykes," in the same discussion referred to Dr. Mellor's opinions as a creed and said: "It has not been accepted by anything like the whole body of geologists—in fact no single article has been universally accepted as yet. Perhaps the most powerful body of dissentient opinion is that voiced by Mr. Bleloch." This heresy had been treated somewhat scornfully by the exponents of orthodox opinion, but a large number of the heretics are still unconverted. They hold that there is no duplication in the Bezuidenhout Valley and that the orthodox idea of the succession of the lower Witwatersrand beds is therefore wrong; that the Reitfontein reefs are an integral part of the lower Witwatersrand system, that the Kleifontein (Van Ryn) reefs are identical with those at Reitfontein and do not represent the Main Reef series." And again Mr. Olver said: "As to the disciples of Mr. Bleloch, the very basis of their creed is the identity of the Reitfontein and the Kleifontein (Van Ryn) reefs. I have already stated that this resemblance is so striking that it cannot be overlooked by any observer who is familiar with the reefs in both areas. My theory amply explains the likeness—in fact it establishes the basis of the Bleloch theory."

I think I should remark here that it was Mr. Olver who first put forward the idea that the Reitfontein reefs were a faulted portion of the Main Reef series, and it seems remarkable that Dr. Mellor and Dr. Rogers who have since adopted Mr. Olver's idea have not more definitely recognised him in their recent papers as a first exponent, although it is true that Dr. Mellor did say in 1912 that he saw no great improbability in Mr. Olver's view, but he could see no striking similarity between the Reitfontein reefs and the Main Reef series. It must be understood that I do not agree with Mr. Olver in correlating the Reitfontein reef with Main Reef, but as Mr. Olver correctly says, I believe it to be the same as the Van Ryn Reef, which in my opinion is much lower in the Witwatersrand system than the Main Reef series.

Randfontein, Reitfontein and Van Ryn the same Reef.

In the paper read before this Society, to which I have already referred, Mr. C. B. Horwood gave details showing similarity in physical character between the Reitfontein reefs and those of the Randfontein leader. In that valuable paper he described the Buckshot Reef, the Pay Reef, and

Carbon Leader of Reitfontein. Since that paper was read further abundant evidence has become available of the similarity of the beds of the Van Ryn series of reefs of the Far East Rand with those of Reitfontein. In these beds of the Far East Rand, too, there are to be found bodies identical with the Buckshot Reef, the Pay Reef, and the Carbon Leader of the Reitfontein series, and they occur in the same order of deposition. I have seen specimens of the Carbon Leader from the New Modder mine and from the Government Areas mine indistinguishable from the Carbon Leader at Reitfontein, and as I have already stated I am presenting for your inspection to-night specimens of the Buckshot Reef from (1) the north base of Langerman's Kop, (2) from the Reitfontein mine, and (3) from the farm Klippoortje adjoining the town lands of Heidelberg. This farm belonging to Houtpoort, Ltd., is one of the farms mentioned in the Government cables, and the specimen of the Buckshot Reef is from the outcrop of one of the reefs referred to in the cables. I have chosen the Buckshot Reef for your inspection of specimens from these several places because it is the most distinctive reef of the series. Although that rising young geologist, Mr. Pirow, may not be able to see in them either resemblance, distinction or difference, every prospector can do so and every prospector for the past thirty years knows the Buckshot Reef. I earnestly ask the members of this Society to examine closely the specimens of this very remarkable reef which I have brought here to-night from these three widely-separated places.

Dr. Mellor Changes Round.

I must now call your attention to what has happened since the statements about Reitfontein and Langerman's Kop were made by Dr. Mellor in 1911; the dogmatic change is wonderful and complete. In 1916 in the Knox Arbitration Case, a case in which the principal question was the existence or otherwise of payable banket reefs occurring at a lower horizon than the Van Ryn Reef of the Van Ryn and New Modder mines, it was contended by the Government side, for which Dr. Mellor gave evidence, that no payable gold reefs existed below the Van Ryn Reef in that area. In the course of his evidence on oath, Dr. Mellor said: "Reitfontein classified geologically, I am inclined to connect it with Main Reef series. Conclusion is from the succession on which it lies. The footwall of the reef is similar and assists conclusion. I don't know any respect in which it is not similar. To the south whole succession of strata up to Kimberley Reef . . . I have seen them. I could not say I have seen Elsberg. I have seen what I think is Bird." Question: "Have these Kimberley and Bird Reefs the same characteristics of the same south of Main Reef?" Answer: "All the essential characteristics; I account for this by the fault."

That is to say, Dr. Mellor's opinion as thus expressed in 1916 was completely different from Dr. Mellor's opinion in 1911 as expressed in the quotations I have made from his paper read in that year. By 1917 Dr. Mellor had adopted Mr. Olver's idea completely. In that year Dr. Mellor's Geological Map of the Witwatersrand Goldfields was published by the Government, and accompanying it there was issued a pamphlet by Dr. Mellor explaining the map. In the pamphlet Dr. Mellor says: "The reefs exploited at Reitfontein most probably belong to the Main Reef group" (page 22), and on page 35 he states that "on the farm Reitfontein No. 9 we have a considerable area of upper Witwatersrand beds usually referred to as Reitfontein series lying to the north of the fault." "These beds include the well-known Reitfontein series which were for many years successfully mined." After casually remarking that other views placed the Reitfontein reefs among the lower Witwatersrand beds, he goes on to say: "Another view based chiefly on the similarity of some of the coarse conglomerates associated with the Reitfontein series to the conglomerates of the Langerman's Kop is that the beds occurring at Reitfontein are of Elsberg age," and he then proceeds to back up his new reading of 1915 in the following words (page 35): "These coarse conglomerates (known as the South Reitfontein series) are, however, much like the Kimberley reefs in type, and in the writer's opinion belong to that group of reefs." An arresting conclusion!

The marked resemblance of these beds to those of Langerman's Kop, of which Dr. Mellor made a strong point in 1911, had evidently been weathered off in the meantime! Dr. Mellor goes on to say: "The correlation is greatly strengthened by the fact, either not generally known or universally overlooked, that the reefs in question are underlain by a considerable thickness of shales of the Kimberley type below which comes a series of quartzites and conglomerates closely comparable to the 'Main Bird' series of the Rand proper." For Dr. Rogers's information, seeing he admits he does not know these beds, I will state that similar shales in the same relative position outcrop on Langerman's Kop. These same beds in 1917 "comparable to the 'Main Bird' series of the Rand proper" were in 1911 found by Dr. Mellor "to lie outside the outcrop of the Witwatersrand formation and to belong with the Langerman's Kop beds to a formation unconformable to the Witwatersrand system." "The lowest of these reefs," goes on Dr. Mellor, "formerly worked at Reitfontein (North Reef) lies upon a 'slate' footwall in the same way as does the principal reef of the East Rand (the Main Reef Leader) and is almost certainly to be correlated with it. The principal 'Pay Reef' lies at a somewhat higher horizon." Wonderful transubstantiation of these reefs in the short space of six years. One wonders what will these Reitfontein beds be, according to Dr. Mellor, in, say, 1927. And Dr. Rogers says "Yes" to this, although when asked by me at the last meeting of the Society about the South Reitfontein reefs, whether they were the Kimberley reefs, as Dr. Mellor now states, or Elsberg reefs faulted down like those at Langerman's Kop as Dr. Mellor stated in 1911, Dr. Rogers replied that he had not examined these reefs, and he could not answer. Dr. Rogers swallowed the "Main Bird" camel, but strained at the South Reitfontein gnat.

Sir Robert Kotzé was more cautious, for he refused to swallow either! On the 30th January, 1917, while giving evidence before the State Mining Commission, the Government Mining Engineer, Sir Robert Kotzé, was asked whether he agreed with Dr. Mellor (Question 9,826) in identifying the Reitfontein reefs with the Main Reef Leaders. He replied: "I do not care to express an opinion, not knowing sufficient about the geological facts." Now, in all seriousness, I ask you, is it not remarkable that on a fundamental and crucial question in Rand geology like this of Reitfontein-Langerman's Kop, until I asked him about it at the last meeting of this Society, Dr. Rogers had never referred to it at all? Dr. Rogers admitted that he had not yet had sufficient experience to justify him in making dogmatic pronouncements on Rand geology before this Society or in the form of cables to the High Commissioner in London. Can anyone here justify geological dogmatism in that form?

Doctors in Conflict.

Mr. President and Gentlemen, what are the facts? I have shown you Dr. Mellor to be in conflict with Dr. Mellor on these very questions. Dr. Hatch and Dr. Corstorphine in conflict with Dr. Rogers; Dr. Carriek, Dr. Krause and Mr. Horwood in conflict with Dr. Mellor and Dr. Rogers; and Dr. Molengraaff—perhaps the most authoritative of all—in conflict with the whole school of the one-reef "Main Reef Leader" theorists, for he says that in his opinion the Main Reef cannot be present on a shallow basin like the Far East Rand. In this welter of conflicting, though learned, opinion, who, I ask, among you will justify dogmatism and least of all dogmatism by cable liable to being misunderstood and liable to do great damage to thousands of unoffending people?

We find Dr. Mellor describing in 1911 the close similarity of the Reitfontein reefs with those of Langerman's Kop. We have their close similarity with those of Randfontein described by Mr. Horwood. We have their close similarity with the Van Ryn reefs of the Far East described by Mr. Olver and Mr. Graham Bell. We have their equally close similarity, silently yet eloquently, witnessed by the specimens from Langerman's Kop and Reitfontein which I have brought here to-night, to compare with the specimens of

the Van Ryn reef of the Far East Rand and with the specimens of our gold-bearing blanket reefs at Heidelberg identified with certainty by us as the Van Ryn, and erroneously although dogmatically called Kimberley by Dr. Rogers. We have located and are opening up these reefs in the Southern Van Ryn mine, and on Tulipvale and Klippoortje for Houtpoort, Ltd., and on Boshfontein for the Nigel Transvaal Goldfields, Ltd., and Dr. Rogers calls this gold-bearing Buchshot Reef from there which I hold in my hand—Kimberley! Well, I will remind you that Dr. Mellor calls it Elsburg at Langerman's Kop and that he changed it from Elsburg to Main Reef at Reitfontein, and perhaps in six years or so Dr. Rogers may find that after all our reef bears a similar close resemblance to Van Ryn to that which six years later Dr. Mellor found Reitfontein to bear to that reef. For ourselves, we find that resemblance to-day, not by mere superficial looking but by practical work and practical tests. We have proved an unmistakable similarity in character of these Van Ryn Reef reefs which we have located and opened, and in the gold they carry and in their order of deposition at Heidelberg at the Southern Van Ryn, at the New Modder, at Reitfontein and Randfontein, and at all these places around the Rand where they are exposed—a distance of over 60 miles. Surely statements of facts like these are not to be treated as mere *assumptions*, least of all by one who, however learned he may be, has had only very brief experience of the Witwatersrand system and who admits that on the one main point of Rand geology he has not studied the evidence. As Mr. Olver said, on many points about which they scornfully dogmatise, Dr. Rogers and Dr. Mellor are unsupported by any single geologist of repute. Even the Government Mining Engineer has refused to commit himself on the Reitfontein question.

Conclusions regarding Reitfontein and Van Ryn Deep.

I submit that the reading which alone explains the facts, facts like the great similarity amounting to practically certain identity of Reitfontein with Langerman's Kop, as attested by Dr. Mellor himself, and with the Randfontein and Van Ryn Reefs as attested by everyone, is the simple one that the Randfontein Reefs of the West, the Langerman's Kop Reefs of the Centre, the Reitfontein Reefs of the East Rand, and the Van Ryn Reef of the Far East Rand, and our Van Ryn Reefs of Heidelberg belong to one and the same horizon of the Witwatersrand system and are totally distinct from and much older and far more valuable than the reefs of the Main Reef series of the Central Rand.

S.A. Mineral Springs.

Dr. Drennan, who is an authority on the chemical and medical aspects of mineral springs, made special reference to some of those in the course of a lecture in which he asserted that "South Africa possesses a number of hot springs which are unrivalled anywhere in the world. They are each possessed of special virtues which are of undoubted value to a large group of diseases. They are all deserving of much further investigation and development." This Dr. Drennan (who was addressing the University students at Capetown) proceeded to justify by quoting a list of South African springs which is really astonishing in length and in the qualities which are represented. To take only a few leading examples, the Zongala Geyser, in Northern Rhodesia, has a daily flow of 86,000 gallons at a temperature of 97 C. The Goa Geyser, near Choma Station, has a daily flow of 337,000 gallons. The sulphur springs between Louis Trichardt and Messina have not been tested. Some highly radio-active springs are to be found near Machadodorp. There are springs near Cradock and Graaff-Reinet, which are anti-rheumatic. Lochuivar, in Northern Rhodesia, and Weltevreden, at Beaufort West, are of the cold variety. At Rhodes' Drift there is a spring with strongly purgative water. At the junction of the Sanyati with the Zambesi, the Kapessa hot springs are supposed to have many virtues, and have also the credit for providing immediate relief from malaria.

ENGINEERING SECTION.

The Siemens-Martin Steel Making Process.

By Jonas Bethell, Messrs. Spear & Jackson, Ltd., Steel Makers, Sheffield.

The Siemens-Martin process depends upon producer gas as fuel, and before explaining the actual process I will describe how this gas is made.

Although ordinary coal gas would serve our purpose in every way, the cost of producing same is prohibitive. The system of gas production suitable for steel-making requirements was invented by Siemens, and his method has since been improved and modified by other inventors.

However, the general principles on which they have worked will suffice in my present article.

When a current of air and steam is blown over incandescent coke, the steam is decomposed, and the oxygen out of the air, together with the oxygen from the steam, combines with the carbon in the coke, simultaneously liberating hydrogen from the steam and nitrogen from the air.

Under certain conditions we find a certain quantity of Carbon-dioxide formed. As gaseous fuels, we have Carbon Monoxide and Hydrogen, which are approximately 40 per cent. of the producer gas, the remainder being Nitrogen and Carbon-dioxide, which are not fuels. This is the gas which together with air is admitted into the furnace, each having separate ports, the gas ports being lower than the air ports.

Diagram showing General Construction and Method of Tapping Metal.

(1) Charging Door. (2) Gas Ports. (3) Air Port.
(4) Tapping Spout.

The furnace itself is stationary and the method of tapping the metal out of the furnace has very often been a puzzle to the non-technical man. The diagram will fully explain this point and also give you a rough idea of the general furnace construction. Pig iron, scrap and iron ore are the materials used as base for this steel, and the pig and scrap are charged into the furnace first. As soon as this charging is finished, the charging doors are closed and the gas and air turned on. The charge soon melts and a slag is formed by the oxide of iron combining with the silica of the sand which is always found adhering to the pig iron, also perhaps with part of the silica from the furnace lining.

Five or six hours from the time of charging the material will be in the molten condition, and we now commence adding the iron ore, in small quantities and at short intervals, the whole charge being thoroughly mixed during these additions. The slag increases in quantity and very soon the "boil" commences. The boil is due to the formation of gases which find their way through the steel and the slag giving the appearance of boiling to the molten mass. Iron ore is still added and the boil subsides, after which samples of metal are taken from the furnace and rapid analyses made. These samples are very often fractured, and a skilled man is able to determine the percentage carbon present from the appearance of the grain. As soon as the carbon is low enough the steel is ready for tapping and the tap hole is opened by driving a crowbar through the furnace bed and the steel flows down into the ladle, being quickly followed by the slag, although only sufficient slag is allowed to run into the ladle to prevent the chilling of the molten steel. The Ferro-Manganese for the addition of the necessary carbon is usually added in the molten state into the ladle during the tapping of the steel. It also removes the gases in the steel, although the quantities of these are decidedly less than in the Bessemer. The impurities, Sulphur and Phosphorus, are practically the same after the steel is made as at the commencement in the raw material in the acid process, and therefore we have in Siemens-Martin steel comparatively high quantities of impurities which ought to be eliminated.

I explained in my last article that in the basic process the Phosphorus could be reduced, but in practice the results are almost the same for the base metal used in this process is usually 0.20 per cent. Phosphorus contents, and they remove perhaps 0.16 per cent., leaving 0.04 per cent. in the finished product. In the acid process low Phosphoric irons are used and the average analysis of the two processes are as follows:—

	Acid Process.	Basic Process.
Manganese ...	0.30 to 0.70 per cent.	0.30 to 0.70 per cent.
Silicon ...	0.05 to 0.20 "	0.05 to 0.20 "
Sulphur ...	0.03 to 0.05 "	0.03 to 0.05 "
Phosphorus ...	0.03 to 0.05 "	0.02 to 0.05 "

The capacities of the Siemens-Martin furnaces range from 25 to 100 tons and the cost of production is low. The casting ladle, which was invented by Bessemer, is the type still in use, and as I have mentioned the ladle and given a small diagram of same in my last article, I feel that a short description of this will be useful. The ladle is the distributor of the molten steel to the moulds and is of steel construction lined with refractory bricks. In the bottom of the ladle after each cast a new nozzle is put in, and it is through this nozzle that the steel flows. The flow can be regulated by the rod which is covered with silica sleeves and at the end of which is the plug which fits the nozzle. This rod is lowered and raised by means of a lever on the outside of the ladle. As a rough idea of the ladle, imagine a teacup with a small hole in the bottom, slightly away from the centre, into which a pencil would fit perfectly. By lifting or lowering the pencil any liquid in the cup could be allowed to flow out or be kept in the cup. Attached to the ladle is mechanism which will tip the ladle, pouring the steel in the same way as pouring tea out of a cup.

Economical Working of Boiler Plant.

The Fuel Economy Committee of the Federation of British Industries are engaged in extensive propaganda with a view to securing an increase in boiler efficiency throughout industry, and in this connection are publishing a series of Fuel Economy monographs, from No. 1 of which we give the subjoined particulars:—

The efficient working of boiler plant may be considered as consisting broadly:—(1) In utilising the heat of the fuel as completely as possible, and delivering it to the boiler heating surfaces in the form best suited for heat transmission. (2) In securing the best possible transmission of this heat through the plates or tubes of the boiler for the generation of steam. (3) In avoiding, as far as possible, losses of heat from the boiler plant; and (4) in using steam as economically as possible for the requirements of the boiler plant itself, in order to leave the maximum proportion available for external purposes.

In the following notes the boiler plant is generally considered to consist of Lancashire or water-tube boilers, hand-fired with bituminous coal and working on chimney draft. Many of the notes and suggestions may, however, be directly applied to boilers of other types or to other methods of firing.

that the spacing of the firebars should be as regular as possible and should be suited to the size and coking properties of the coal burned. When using the slice bar this should not be used to lift the clinker into the fire, but should only be run along the grate to break up the clinker and detach it from the bars. (2) Careless cleaning of the fires may result in large wastage of fuel, this being particularly likely to occur when the boilers are heavily forced. It is not good practice to burn down the fires too completely before cleaning, but reasonable care should be exercised to ensure that the fuel remaining is not discharged with the ash and clinker.

With reference to the production of smoke and incompletely burnt gases. The production of black smoke in abnormal quantity is usually an indication that the firing of the boiler is irregular and unsatisfactory. Smoke may be reduced to a minimum by careful firing of the coal in small quantities and by proper regulation of the draft. The method known as "side" firing or "right and left" firing is useful in maintaining high furnace temperature and promoting the complete combustion of the volatile matter. After a fresh charge of fuel, the air checks in the furnace doors should be opened, and then, as the volatile matter burns off, gradually closed.

Diagram indicating the chief sources of Waste or Loss of Heat in Steam Raising (for guidance of Boiler House Staff).

To utilise the fuel as completely and effectively as possible complete combustion of coal must be secured by (a) avoiding wastage of coal or cinders in clinker and ashes; (b) avoiding the production of smoke or incompletely burnt gases. The most effective means of conveying this heat to the boiler surface results from (c) burning the coal in the furnace with the minimum excess of air; and (d) thereafter avoiding inleakage of air to the flues or setting.

These conditions may be considered in greater detail.

Regarding wastage of fuel in clinker and ashes, this loss is frequently large, and may amount to over 5 per cent. of the heat of the fuel. To obtain a rough idea of its magnitude, an average sample of ash and clinker should be quenched in water immediately after cleaning the fire and the pieces of coke picked out by hand—or the proportion may be more exactly ascertained by chemical analysis of average coal and ash respectively.

The more frequent causes of loss are:—(1) An abnormal wastage of cinders may occur through the firebars, due to these being too widely spaced for the fuel burned, or to the wrong method of using the slice bar. It will be obvious

It is impossible in practice to burn coal with the theoretical quantity of air, but large and unnecessary excesses are often used and cause serious wastage of fuel. Among the contributory causes may be mentioned:—(1) The draft may not be properly regulated by the dampers. (2) The grate area may be too large for the quantity of coal burned. (3) The grate may not be properly covered with a level fire. (4) The size of coal and/or depth of fire may be unsuitable.

The regulation of the draft and proportioning of grate area to the quantity, size and other properties of the coal burned are of the highest importance in reducing the amount of the excess air passing through the fire.

It is important to avoid dilution of the furnace gases with cold air as to burn the coal efficiently on the grate. In both instances, the object is to maintain high temperatures in the furnace, and to avoid the excessive loss of heat in the chimney gases which occurs when large quantities of air are heated to the chimney temperature. In practice it is frequently found that such heat loss may, on the one hand, amount to over 35 per cent. with careless firing and leaky

settings, whilst, on the other hand, it may be reduced to 20 per cent. or less by careful firing and proper attention to the brickwork.

As regards the best transmission of heat to the boiler, the conditions which enable the most effective heat transmission through the plates or tubes to be obtained are:— (a) That no bye-passing shall take place in the flues or through the baffles, and (b) that sufficient clean heat-transmitting surface shall be provided for the required evaporation.

Any "bye-passing" or "short-circuiting" of the gases in the flues or through the baffles allows a portion of the gases to leave the boiler at an unnecessarily high temperature, in consequence of incomplete contact with the heating surface. Bye-passing results in a higher outlet temperature in the flue gases than would otherwise be found, and may be located by a careful internal inspection of the flues and baffles. In Lancashire boilers such bye-passing often occurs either at the seating blocks or at the partition walls in the down-take flue. At the latter place the effect of repeated expansion and contraction in the boiler is, frequently, to cause cracks and spaces to develop in the brickwork.

It is obviously necessary under most favourable conditions for heat transmission, *i.e.*, with the heat-transmitting surfaces clean, that the areas provided must be proportioned to the quantity of heat to be transmitted, or in other words that the forcing of a boiler beyond a certain point reduces the efficiency. It is therefore advisable that the output from boilers shall not be increased above a certain efficient maximum, and the quantity of coal burned should obviously be limited by this consideration. Apart from forcing the presence of soot or scale on the heating surfaces prevents the easy passage of heat from the gases to the water. Whilst it is impossible to state in general terms how frequently boilers should be cleaned, the average thickness of scale should never be allowed to exceed 1.8 in., and, with hard scale, not more than 1.16 in.

Summary of Recommendations.

Furnace Conditions.—(1) Avoid unnecessary wastage of cinders in the ashes by cleaning the fires carefully and by providing suitable firebars. (2) Avoid the production of unnecessary smoke or incompletely burnt gases by regular and frequent firing of coal in small quantities, and by keeping a proper depth of fire. Open the air checks in the furnace doors only after firing, at other times keeping the checks closed. (3) Regulate the draft by the damper to burn the coal with a minimum excess of air. Try to obtain 12 per cent. CO₂ in the furnace gases, and, if necessary,

reduce the grate area to secure this result. (4) Keep the grate covered, the fires level and free from holes. Use the rake when necessary. (5) Carefully examine the setting and stop all inleakages of air.

Boiler Conditions.—(1) Keep the heating surfaces free from soot and fine dust. (2) Keep the internal surfaces free from scale. (3) Do not force the boilers unnecessarily. (4) Examine flues and baffles carefully. Repair when necessary to avoid bye-passing.

Heat Losses from Plant.—(1) Efficiently lag the boilers and steam pipes (including flanges). (2) Do not blow down the boilers unnecessarily. (3) Keep the boilers filled to the working level by a continuous and steady feed. (4) Avoid leakages of steam from boiler fittings, drains, etc.

Use of Steam.—(1) If steam is used in pumps or auxiliaries, use the exhaust for pre-heating the feed water. (2) If steam jet blowers are used, keep the jets in good condition by renewal as necessary and regulate the pressure on the jets to the minimum necessary for the load.

Efficiency.—(1) If economisers are provided record the temperature of water entering and leaving. (2) Make periodical measurements of CO₂ in, and temperature of, flue gases leaving the boiler under average conditions, to estimate the approximate boiler efficiency.

THE STABILISATION OF THE CURRENCY.

Prof. Cassel's and Mr. D. C. Greig's Schemes Criticised.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Enclosed is a contribution to the discussion you have invited in your article "The Stabilisation of the Currency."

Gold is the fundamental money of the world, and as such never alters in value. This is the very essence of international finance. The so-called premium on gold is non-existent! America, as is reported with nearly every quotation, takes all the available supplies of gold from London, because she is the only country the currency of which is at par. The price she pays is fixed at the mint value—20.6714 dollars per ounce—less an amount varying little from one-half per cent. to cover charges, insurance and freight. When the gold is paid for in London the 20.6714 dollars is converted into British currency at the ruling rate of exchange. Thus, when the exchange rate is 3.65 dollars per £, an ounce of gold fetches £99½ per cent. of 20.6714 ÷ 3.65, or 112s. 9d. in paper—not sovereigns. The basis of the par rate of exchange is the amount of gold in the gold coinage of each country, and the value of the number of coins containing an ounce of gold in any country's currency is of exactly the same value as the number of coins containing an ounce of gold in any other country's currency.

Mr. Greig's scheme.

Mr. Greig suggests selling gold forward at say, 112s. 9d. per ounce. This really means that, to suit the gold mining industry, the rate of exchange must remain at 3.65 dollars per £ over a fixed period, despite the various factors, outside that industry, which govern the alterations of these rates. Mr Greig's chief concern is not to stabilise currency, but to obtain the greatest benefit for the gold mining industry, and his anxiety to sell forward is founded on the gradually increasing rate of exchange between Britain and America.

The same object can be attained by a much simpler method. There is now a reserve of roughly 2,000,000 ounces of gold held against gold certificates. The custodians seem unwilling to make any profit on this gold themselves, but if some of this gold were shipped to London, the mines could hand over their gold to the authorities here and an equal weight could be released in London for immediate sale. As no risk is run, the charge for this accommodation need be very small, and the industry would obtain a measure of relief in a falling market.

Prof. Cassel's Scheme.

From your article, Professor Cassel's scheme seems to be that the Mint should issue a new coin, the gold contents of which should be equivalent to the value of paper money. Again assuming that this value is 3.65 dollars per £, the gold value of paper would be 3.65 ÷ 4.8665 or 75 per cent. The gold contents of the sovereign would then be cut down by 25 per cent. and the new coin—worth 15s.—in gold—would come into common circulation. Remembering that gold is only necessary in international dealings and is not necessary to carry on a country's internal trade, what would happen if the rate of exchange fell below 3.65 dollars per £? The same position arose before, and all gold coinage was withdrawn from circulation. But in the more likely event of the rate rising above this figure, paper money would be of greater value than the new coinage. Can any country be expected to accept payment by means of these coins at their face value? The scheme does not, therefore, seem feasible, and the original question remains unanswered, "How are we to stabilise our currency on a gold basis?"

The Only Way.

The only way to do this is to raise the value of paper to the universal value of gold. Britain was on the high road to accomplishing this, for the exchange rate rose from 3.60 dollars on January 5th of this year to 4.00 dollars on May 13th, when the unfortunate coal strike took place and wiped out this increase, the rate falling to 3.56½ dollars on August 2nd. The only cure is in the hands of those self-same classes which won the War. The British labouring classes have never failed their country yet, and will save her again.

British manufactures must take their old place in the world's markets. The labouring classes must see that this comes about as quickly as possible, by increasing output, greater efficiency and lower costs of production, so that British goods through their quality will attract and hold foreign attention, and so that they can be sold at a price that will command sales and ensure further orders. Here lies the solution of the problem. Can you induce those who so much desire our currency to be stabilised on a gold basis to come forward with practical suggestions as to the best means of bringing home to the working classes the necessity of every shoulder being at the wheel? The first step seems to be to educate the leaders of trade unions and to convince them that it is their duty to avoid petty strikes and the fostering of 'canny' methods. The British workman is honest at heart and loyal to his country, and once he realizes the great issues involved he will be the first to demand the dismissal of those few parasites among his trade union leaders, whose aim in life is to keep themselves in the limelight and to line their own pockets.

Most employers would derive the utmost benefit from a liberal education on the same subject.

"X."

AN INTERNATIONAL CURRENCY CONFERENCE?

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Apropos of your article on the above in last week's issue, may I draw attention to the following from the last issue of the *Statist* to hand:—

"These considerations lead us to examine more carefully existing ideas concerning the welfare of the nations. In the first place, as regards the question of the gold standard, it has frequently been insisted upon by this Journal that while the restoration of a gold anchor for values is eminently desirable, yet any attempt to reintroduce it on the part of one country is useless unless equally vigorous measures to the same end are made by other nations. In other words, to have any practical value a gold standard, or indeed any other monetary standard, must be universal or nearly so, and sacrifices made by nations acting independently for the sake of a metallic standard of value are made in vain if the majority of other nations choose to continue under the régime of an inflated paper currency. The deflationist campaign pursued in this country as well as in the United States would have placed us in a healthier position if it had been accompanied by similar sacrifices elsewhere. As it happened, however, it has gained us nothing. It is true that the price level has been reduced by over 40 per cent., and to that extent we have approached nearer to "normalcy," but an unprecedented trade depression is the price paid for this mythical advantage. "Normalcy," in fact, which a year ago was regarded as the *summum bonum*, has proved the bugbear of national prosperity. Turning again to the United States, we find that part of the movement towards "normalcy" in that country consisted of a net import of gold during the past twelve months amounting to 512,000,000 dollars. This has, indeed, consolidated the financial system of the United States on a gold basis, but the gold standard there has proved unable to perform its most important function of stabilising prices, while the huge inflow of the metal has obviously made it more difficult for other countries to place their currencies on a gold basis.—Yours faithfully,

"INTERESTED."

AMERICAN versus BRITISH RAILWAY PRACTICE.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Your article of the 20-11-20 and 18-9-20, entitled "American and British Railway Practice," noted with much interest from many angles. The writer concludes that the discussions pro and con are a rehash of the battle of the gauges. You discuss the direct versus alternating current for heavy rail transportation, and the three-cornered fight between the machine tool builders, tool makers and electric drivers, each trying to "knock the other out," rather than co-operating. The Canadian and American (States) practice is designed to meet a "rough and tumble" condition inci-

dent to a new country similar to team and cart in a mining camp or on a farm. The States follow Canadian practice and can "vice versa." The writer has noticed that the British-owned roads of Brazil and Argentina are following Canadian practice as the best adapted for a pioneer road, and also are switching Australia and South Africa, notwithstanding that the practice here and in Canada have their defects, namely, the track is too light, rails loose on the sleepers. Running gear under freight equipment 50 years behind the times in view of the load and speed. Also the writer has been converted to plate frame, or what is known in Winnipeg as the "slab frame," of which the C.P.R. is the "beau ideal" and "joy forever" of the British Empire, and it will be noted that the Grand Trunk abandoned its English design in the forties. As to our adhering to the bar locomotive frame, a little digression may not be out of place. In pioneer days, when we had 20 miles of road to one locomotive, it was necessary to "take Mohammed to the mountain," i.e., make the locomotive flexible. It was found necessary to put equeasezers (compensators) connecting the spring between the rails or bars of the frame, combined with the links, straps, and eccentrics. However, the driving base was then short, and broken frames were found to increase with the increase of the driving wheels. The weakness of the bar frame is augmented by boring large bolt holes. The flanges riveted to the plate give it flexibility similar to the chords of a bridge which better enables it to resist lateral stress due to curvature of the track. Furthermore, the bar frame rendered itself to clamping and keying to the saddle better than the plate frame. Your mention of cylinder and half saddle cast in one piece has been diverted from the Penn. R.R. in that the saddle is cast in one piece with the cyl-bolted to the saddle, with the front end "slab" section of the frame sandwiched between. This recalls that the latest British practice has adopted the saddle on heavy locomotives.

The brick arch is a good investment, which is a "half brother" to the baffles in water tube boilers in stationary practice. The arch supports give the ideal circulation of the water, drawing the dead water from the bottom and "water leg." The baffling flame prevents unburned coal being shot out the stock and consumes the gases. If more baffling could be accomplished it would be a move in the right direction. Water heaters are a movement in the right direction. To pump cold water in the boiler is like "raising yellow dogs and shooting them" in wasting fuel, also setting up unequal stresses in the boiler. Superheaters speak for themselves. Power reverse gear is a necessity on heavy locomotives as much as in marine. Also it enables the driver to pump the water and wet steam out of the cylinder, giving the locomotive the power to start the train similar to the "wire engine." The electric headlight is, in the estimation of the writer, wasted effort on the part of the electric manufacturer, which should be outlawed. The driver that would keep an electric headlight burning through a yard should be indicted. The writer had a narrow escape from being killed on two occasions, due to lights being "drowned" on parallel tracks. Numerous wrecks occurred here due to the signal lights being drowned by electric headlights. The fact that they are a "fad" is shown by the fact that there are none on British railways. However, what is needed is more powerful signal lights and reinforced by reflectors, and lights of the same intensity; as is often the case, the farthest light can be seen before the nearer one. The electric headlight is due to the electric man "breaking into the railway game." Oil is the ideal fuel if it could be obtained. Some day it will be uncovered in South Africa. For compounding the French claim economy on long runs, but its utility is doubtful on short runs. Power sanders are essential; choking can be overcome by placing the box on top of the boiler and keeping the sand dry. All the above appliances are on the Canadian roads, of which the conditions are the same as in South Africa. The Canadian roads have to contend with snow. On the Cascade range on the Pacific side the wet snow slides down the mountains, bringing down trees, boulders and mud, so it can be seen, the writer trusts, equipment with "frills" would be out of place. The writer has noted South African roads contemplate wiring out of Cape Town and from Durban to Maritzburg, and the old question is creeping up as to what current and voltage, also the method of mounting the motors on the running gear, whether the locomotives will be designed on the line of exaggerated tram-cars, thereby counter-balancing any economy on fuel. Trusting the above

is comprehensive, otherwise I will be pleased to give further details.

JOHN FRANCIS.

New York.

THE OUTSIDE DISTRICTS.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—In handing you my report on the Golden Valley Co. to peruse and publish, not only is it with the sanction of the owner of the property, who has it under offer abroad, and is slightly indifferent as to when it is disposed of to a company, as the value cannot disappear, but it is my earnest desire, as it always has been, to acquaint the world of the fact that South Africa is not dependent entirely on the bankets of the Witwatersrand geological age for its gold supply. For, as I have often written you, it has three other five-mile-thick auriferous ages to fall back upon. The one to which this report alludes is the most widespread of them all, and is common to the whole world. The others appear to be a special gift by Nature to this glorious country, to which she has also given the finest climate imaginable.—I am, etc.,

SCOTT ALEXANDER,
Rand Stratigraphist.

Johannesburg, August 29, 1921.

THE SOUTH AFRICAN RED CROSS SOCIETY.

Mine Ambulance Competitions.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—The ninth annual mine ambulance competitions for the surface and underground workers' shields (presented by the Chemical Metallurgical and Mining Society of S.A.) will be held on Sunday next, the 11th September. Both competitions will be held, by kind permission of the directors and Mr. W. C. Mossop, the manager, at the Wolhuter Gold Mine, Ltd. A Red Cross flag will fly from the nearest head-gear to denote the spot. Teams representing the following mines (the name of the captain being given against each) have qualified to compete in these final competitions:—Surface (holders: Village Deep): Wolhuter (Fletcher), Village Deep (Hand), Luipaardsvlei East (Emerton), Knight Central (Butler), E.R.P.M. (Berge), New Kleinfontein (Denneby), Modder B G.M. (Paterson); shield holders, Village Deep (Arkley). Underground (holders: Crown Mines): City Deep (Sinclair), Crown Mines (Walker), Consolidated Main Reef (Hippert), Luipaardsvlei Est. (Jackson), E.R.P.M. (Noake), E.R.P.M. (Love), Geduld Mines (Morgan), Brakpan Mines (Clark).

Notice to Competitors.—The competitions will commence at 8.30 a.m. sharp, and teams are requested to be on the property ready to start at 8.15 a.m., at which time captains of teams must report to the undersigned to draw for the order of competition. Suitable clothing to be worn by all teams. Underground teams must bring their own lamps. Competitors will not be permitted to see the work of other teams, and are reminded that *they will be disqualified should they have any communication with those who have already competed, or with persons who have seen the competition.* Each member of each team will find a copy of the rules enclosed, with which they must be familiar. One reserve man of each team will be required for the purpose of supervising one other team.

The management has kindly invited the officials and competitors to lunch, for which tickets will be supplied, the accommodation on the mine being very limited. For the convenience of others coming from a distance, it is notified that dinner can be obtained at the Manor House Hotel, within easy distance of the mine, at a charge of 2s. 6d., and those desiring dinner there are requested to telephone 'phone No. 2189 Central not later than Saturday to reserve accommodation.

Those interested in first-aid are cordially invited to be present, but only a limited number can be allowed underground. V.A.D. members are invited to witness the surface competition, at which there will be ample accommodation.—Yours faithfully,

FRED ROWLAND,
Secretary.

The Week in the Sharemarket.

INCREASED BUSINESS—QUOTATIONS LOWER—DIAMONDS BETTER.

The market has been disappointing this week owing to the recurrence of labour troubles on the Far East Rand, the lower gold premium, and the absence of any confirmatory announcement regarding ex-enemy shares. The trouble at the Van Ryn Deep was not settled until Thursday, and its prolongation caused some uneasiness. The August returns from the mines are, however, most satisfactory, and even if gold does not rise beyond its present figure the December dividend is promising. Something is always turning up to damp the hopes of those who are anticipating a good market. Taken individually, and analysed on their merits, shares of several Rand mining companies can be shown to stand at attractive levels. But the incidence of general or common factors, such as labour, cost of stores and explosives, and price of the product, cannot be left out of the reckoning, and they have a way of unexpectedly rendering all calculations futile. Mine "lives" and development and ore reserves remain, of course, considerations of cardinal importance, but they tend more and more to be overshadowed by the bigger questions indicated. The General Mining proposal to adopt a profit-sharing scheme to save the Roodepoort United will be watched with interest, though the shareholders seem to have small say in the matter. In the diamond market the tone is much better all round on slightly more favourable reports from London. Tin shares are quiet, but African Oils had a welcome spurt during the week.

PORTABLE CONVEYORS

THE Robins Standard Portable Conveyor combines many unusual features with rugged construction, simplicity of parts, economy of operation and upkeep and low first cost.

Equipped with petrol engine or electric motor. Length 25 ft. or 30 ft.. Capacity 35—40 tons per hour.

We make many other types and sizes to suit special conditions.

ROBINS CONVEYORS (S.A.), Ltd.

Engineers, Founders, Machinists
Conveying & Hoisting Machinery

TENDERS

are invited and will be received by the Undersigned up to and including Friday, the 30th day of September, 1921, for the purchase of the following Immovable Properties—

1. Certain piece of ground, being portion of freehold farm Kookfontein No. 57, called "HOPEFIELD," in extent 825 morgen 262 square roods.
2. Certain piece of ground, being portion of the freehold farm Kookfontein No. 57, called "SPRINGFIELD," in extent 2,229 morgen 258 square roods.
3. Certain piece of ground, being portion of the freehold farm Waldrift No. 92, called "BEACONSFIELD," in extent 1,305 morgen 511 square roods.
4. Certain piece of ground, being portion of the freehold farm Waldrift No. 92, called "GARFIELD," in extent 691 morgen 114 square roods.

The above are contiguous, and are situate in the District of Heidelberg, Transvaal, Ward Klip River.

The Farms are traversed by the main railway line to Johannesburg and by the Klip River. Water is brought on to lands by means of furrows.

The well-known Waldrift Coal Mine is situate on the farm "Springfield," the coal seam extending to the farm "Beaconsfield." Excellent clay deposits are also known to exist on the farms.

The farm "Beaconsfield" adjoins the Vereeniging Commonage, and the distance from Johannesburg by road is only about 35 miles.

With the exception of a small portion of the boundary, the farms are fully fenced, and some of them divided into paddocks.

There are three dwelling houses and the usual out-buildings on the farm "Springfield."

Tenders may be for any one or more portions of the above.

The highest or any tender not necessarily accepted.

Intending purchasers may inspect the properties on application to Mr. C. H. McKay, Kookfontein, P.O. Meyerton Station, Transvaal.

Further particulars may be obtained from

J. J. T. KING,

Secretary, Griqualand West Board of Executors, Trust and Agency Co., Ltd.

EUSTON B. BROWN, Executors Testamentary.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS SLIGHTLY BETTER—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—ELECTRICAL GOODS—EXPLOSIVES—OILS AND COLOURS—UNION'S IMPORTS AND EXPORTS FOR JUNE AND FIRST HALF OF 1921—RAILWAY DEFICIT—COAL CONDITIONS IN BRITAIN—EUROPEAN TRADE CONDITIONS WITH AMERICA—METAL MARKET.

General Review.

Business this week has been of a more encouraging nature. The Commercial Exchange has exhibited more activity than has been witnessed for some time past, inquiries being much better and becoming more normal. Several lines are beginning to become scarce as compared with two or three months ago, and, although bigger losses are being made now than ever before, merchants are of opinion that normal levels are within measurable distance. Prices of materials remain much about the same, but there is a likelihood of corrugated iron advancing in price shortly, as quotations ruling recently have been well below replacement value on the Home markets, and prices will, it is expected, from now on show more and more a tendency to keep on a level with those obtaining oversea. This means, of course, that an advance in prices all round may soon be seen. As regards timber, there are good stocks in the country, and advices from the Baltic are not such as to warrant the expectation of any fall in prices for some time to come. As soon as our trouble in the matter of the building wages dispute has been removed—the consensus of opinion in commercial circles is that a satisfactory arrangement will be arrived at before the 16th inst.—the probability is that building materials will harden all round. The gold premium has declined again this week, but if no further great fall occurs between this and the end of the year the position of our lower-grade mining propositions seems to be assured for that period at least. It is as well to reiterate the fact that our gold shares are attracting more and more attention on the part of European investors and likely to increase in favour, which is bound to give an impetus to commercial activity generally by the influx of money badly needed for the opening up of very promising mining propositions. New mines want everything from A to Z and usually get their many requirements before starting.

Iron and Steel.

Business has been livelier during the past few days than for many weeks; inquiries are stronger, and everything points to the fact that the lowest depths have been reached and that we are now heading, slowly perhaps, but surely, towards higher levels. The Commercial Exchange during the week has shown unwonted activity.

Latest quotations:—Dunswart, 29s.; Union Steel Corp., Ltd., ordinary sized rounds, flats and squares, 36s.; angles, 37s.; small angles, 38s. 6d.; small flats and rounds, 37s. 6d.; imported iron and steel flats, small, 40s. to 50s.; larger sizes, 38s. to 55s.; $\frac{1}{2}$ in. and 5-16 in. rounds, iron and steel, 45s.; $\frac{3}{8}$ in. iron, 38s.; steel, 7-16 in., 44s.; mild steel, 43s.; $\frac{3}{4}$ in. iron, 37s. 6d.; steel, 39s. 6d.; $\frac{7}{8}$ in. to 2 in., rounds, 39s.; larger sizes, 45s. to 57s. 6d.; $\frac{1}{4}$ in. square iron, 55s.; $\frac{3}{8}$ in., 47s.; $\frac{1}{2}$ in. to 2 in. square iron, 38s.; larger sizes, 44s. to 50s.; square mild steel, $\frac{5}{8}$ in., 41s.; $1\frac{1}{2}$ in. to 3 in., 40s.; larger sizes, 52s. 6d. to 59s.; channels and joists, 47s. to 48s.; shafting, $\frac{5}{8}$ in., 10 $\frac{1}{2}$ d.; $\frac{3}{4}$ in., 10d.; 1 in., 8d. to 9d.; $1\frac{1}{2}$ in. to 2 in., 7d. to 8d.; larger sizes, 8d.; steel plates, 1-16 in., 24s. to 25s.; $\frac{1}{8}$ in., 32s.; 3-16 in., 32s.; $\frac{1}{4}$ in., 21s. to 22s. in all sizes up to 8 x 4; 30s. to 32s. 6d. for the larger sizes; spring steel

flats, 8 $\frac{1}{2}$ d. to 9d. per lb.; bolts and nuts, $\frac{3}{8}$ in., 1s. to 1s. 2d. per lb.; $\frac{1}{2}$ in., 65s. per 100 lbs.; $\frac{5}{8}$ in., 62s. 6d.; $\frac{3}{4}$ in., 60s.; nuts, $\frac{3}{8}$ in. and $\frac{1}{2}$ in., 87s. 6d.; fish plates, bolts and nuts, $\frac{3}{8}$ in. and $\frac{1}{2}$ in., 8 $\frac{1}{2}$ d.; $\frac{1}{2}$ in., 6 $\frac{1}{2}$ d.; $\frac{5}{8}$ in., 6d.; $\frac{3}{4}$ in., 6d. per lb.; dog spikes, 35s. per 100 lbs.; rivets, $\frac{1}{4}$ in., 1s. 3d. per lb.; $\frac{3}{8}$ in., 10d.; $\frac{1}{2}$ in., 50s.; $\frac{5}{8}$ in., 50s. per 100 lbs.; tool steel, 3s. 6d. to 3s. 11d. per lb.; brass rods, $\frac{3}{8}$ in., round, 1s. 7d.; $\frac{1}{2}$ in., 1s. 5d.; $\frac{5}{8}$ in. and upwards, 1s. 4d.; brass sheets, 2s. 2d. per lb.; 2s. 4d. for the lighter gauges; copper sheets, 2s. 2d. to 2s. 4d. per lb.; fire box copper, 2s. 9d. per lb.; phosphor tin, 3s. 3d.; ingot tin, 2s. 7d.; drill steel, 7d. and 8d.; hollow, 9d.; $1\frac{1}{4}$ in., 9d. to 10 $\frac{1}{2}$ d. Wire nails, 35s. to 47s. 6d.; shovels, 60s. to 65s.; wheelbarrows, 52s. 6d. to 55s.; picks, 37s. 6d. to 67s. 6d.; pick handles, 35s.; barbed wire, "Iowa," 66 lbs. 14 gauge, 20s. per coil; "Iowa," 98 lbs. 12 gauge, 24s. 6d. per coil; "Shorthorn," 69 lbs. 13 $\frac{1}{2}$ gauge, 21s. 6d. per coil; plain galvanised fencing wires, No. 8 gauge 100 lb. coils, 25s. per coil; No. 10 gauge, 100 lb. coils, 27s. 6d. per coil; No. 12 gauge, 100 lb. coils, 30s. per coil; Bulb Tee fencing standards, 14 lb., 27s. 6d. per doz.; 12 lb., 24s. per doz.; black babing wire, 14 gauge, 20s. per coil 100 lbs.; screening, 3s. to 9s. 6d. per square yard; copper tubes, solid drawn, $\frac{1}{4}$ in., 3s. 9d. per lb.; $\frac{3}{8}$ in., 2s. 11d. per lb.; 7-16 in., $\frac{1}{2}$ in. and 9-16 in., 2s. 9d. per lb.; $\frac{3}{8}$ to $1\frac{1}{2}$ in., 2s. 6d. per lb.; $1\frac{1}{2}$ in. to 2 in., 2s. 3d. per lb.; $2\frac{1}{2}$ in. to 3 in., 2s. 6d. per lb.; $3\frac{1}{2}$ in. to 4 $\frac{1}{2}$ in., 2s. 8d. per lb.; copper rods, $\frac{3}{8}$ in., 2s. 5d. per lb.; $\frac{1}{2}$ in., 2s. 4d. per lb.; $\frac{5}{8}$ in. to $2\frac{1}{2}$ in., 2s. 2d. per lb.; cyanide for outside mines, 1s. 6d. to 1s. 7d.; zinc shavings, about 1s. per lb.

Second-hand Machinery.

The market this week has not been very strong in second-hand machinery; many of the smaller second-hand machinery dealers are very pushed and endeavouring very hard to get rid of their stocks, owing to want of cash, and are very anxious to dispose of their goods preparatory to a bigger drop. Many articles can be obtained from them on the bargain principle. The bigger dealers are not disposed to bargain, although selling in many instances under cost. The mines are not purchasing so freely as a few weeks ago, and are reducing economy to a very fine art. As, for instance, welding up all their short hand-power drills, machinery drills, and generally short lengths of bar iron. The great heaps which are accumulated are in many cases turned over daily with a view to economy. Years ago these articles were thrown into the tailing heap or buried, but to-day use is made of practically everything on the mines, such as old heads being converted into shoes and dies, the old broken cam shafts being converted into stems. Mine hammers are also being made from the residue or parts cut off of a head, this material being made of the best cast malleable steel. Tappets and small heads and worn-out shoes and dies are sent by the companies to Vereeniging or the Robinson Smelting Works and made into fresh shoes and dies. All this stuff was unusable years ago; thousands and thousands of tons of it were sent out of the country and eventually found its way to Hamburg, to be flung back at us afterwards in the shape of "Jack Johnsons," "Black Marias," etc. Old rails, instead of being thrown into the dump heap, as in the past,

are now being converted into grizzly bars and gratings. There is a use for everything except for broken castings, which are sold to foundries. Old truck wheels, which were previously buried, are now sent to Vereeniging and Dunswart by the thousand.

Engineering Shops.

The position of the engineering shops as a whole shows that things, although by no means booming, are still keeping going, and if people with a little capital, more particularly those in touch with the mining industry, would endeavour to realise that the liberation of a few thousand pounds would mean a lot to the engineering industry, business would run smoothly. Nobody expects to make money in these times, but everybody wants to keep going until things right themselves, and the lessening of conditions of stringency would enable works to go ahead and allow people to make money. One thing which would be of the greatest possible advantage to everyone concerned would be for the mining groups, railways, etc., to endeavour to have their requirements satisfied on more direct lines by establishing buying sample rooms. The great cry to-day is reduction of expenses in every direction. To take the mines as an example, it is costing them, said a well-known merchant, thousands of pounds per month in the shape of expensive motor cars, travellers, waste of time entailed upon their various staffs, etc. Of course the motor cars are the property of the individuals and firms catering for the mines, but indirectly the mines are paying for them. Surely, he said, samples, drawings, and sketches could be concentrated in some buying sample room, of free access to the public, at a purely nominal cost, and be assured of purchasers supplying goods on a competitive basis at lowest costs. At present, he said, John Smith, reef traveller, calls at the mines, buttonholing the manager, or whatever members of the mine staff he could lay hold of, talks sixteen to the dozen, books an order for £10 worth of

goods for £20, comes into town, chases round to two or three manufacturing places, secures his requirements for £7 10s., and so on it goes. No doubt one of the hardest worked individuals on the reef is such a traveller, but surely not a necessity for such a highly specialised industry as the mines. A sample room need not preclude the management of a mine from purchasing its requirements from John Smith if it wants to do so, but if it were made a standing order that a mine's requirements were duplicated and called for in a sample room, then such mine management would at least have the benefit of competitive prices. Vendors of new special goods, or any article suitable for the mining industry, could exhibit their products, no doubt gladly paying for the privilege. The Commercial Exchange, he said in conclusion, is a perfect institution for the merchant importer, but probably not so many South African manufacturers find it to their advantage to belong to it.

Further signs of revival of industry in Britain are shown in the announcement that Palmer's huge steel works, which were closed early in the coal stoppage, have restarted, while two more ironworks in the Cleveland district have restarted, involving the re-opening of the ironstone mine at Ayton.

The American representative of big financial interests, Mr. W. Ingram, who arrived here in June last, left for home last week, having inspected the whole of the Messina interests. He is understood to have expressed himself as thoroughly satisfied with the properties, and will arrange to work the financial part of the business on a large scale. It is much to be hoped that this will mean the beginning of vigorous development in the Messina district, which is so badly needed. The financial markets of the world have been in a stagnant state recently, and business men are now apparently on the look-out for good things, in which this country abounds. With a little encouragement to the prospector and the financier, this country's development is assured.

Timber and Building Materials.

Timber maintains its price fairly well and there are no changes to report this week. 3 x 9 deals, 1s. 1d.; scantlings, 1s.; beaver board, 5d.; floorings, 7d. to 7½d.; ceilings, 5¼d. to 5½d.; Oregon, 7s.; pitch pine, 7s. 6d. to 8s.; corrugated iron, 9½d. to 10½d. Business remains fairly good, but there are signs that it will become very brisk as soon as the present building dispute has been settled. Consignments of timber are coming in freely from Europe. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality; 14s. 9d. for seconds at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 3d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cubic ft. at mills, Rhodesia; Honduras mahogany, 30s. per cubic ft.; American yellow pine, 1s. 9d. per ft. of 1 x 12, here; American pine shelving, 1s. per ft. There is no change to report in bricks, which are ruling at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed, per 1,000 at yards; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp, course and roofing, 37s. 6d., 47s., 55s. 3d. for 1-3 ply.

Second-hand Iron and Timber Yards.

These are still in the doldrums pending a decision in the building trade dispute regarding wages; iron is unchanged at 5d. to 6d.; timber, 10d. to 1s.

Electrical Goods.

Business remains very quiet in town and country. Apart from tubing reported last week, there are no reductions to announce as yet, although a general fall in prices is not unexpected shortly. Consignments of electrical wares continue to arrive steadily from Britain, and more slowly from the Continent and America. Britain appears to control shipping arrangements as regards the Continent, for while shipments from England take as a rule about three weeks, these from Germany occupy from seven to eight weeks from date of drawing upon merchants here.

Explosives.

The British South African Explosives Co., Ltd., announce that the price of nitrate of lead has been reduced from £65 per ton less 5 per cent. to £60 per ton less 5 per cent., and that the price of detonators has been reduced by the Modderfontein factory from 57s. 6d. less 2½ per cent. to 55s. less 2½ per cent. There are still very large stocks of explosives in the country—amply sufficient for six months' supply—and these must of course be worked off before any benefit can be derived by the mines from lower costs of materials and falling freights.

Wakkerstroom Oils.

Mr. Arthur Pratt, presiding at the meeting of shareholders of the company on August 25th, stated that they had definite proof that in regard to Mavriestad, with an area of 3,127 morgen, they had an asset of remarkable value. According to their experts they had a seam of shale proved on the property varying from 4 ft. to 6 ft. 6 in. in width, carrying values exceeding 20 gallons to the ton, which seam in the opinion of their experts, contains an area of 6,000 acres, with upwards of 93,000,000 tons of shale containing oil, on a valuation basis of 3s. per gallon of a total value of £295,000,000. This, on an estimated total cost of recovery of £1 per ton, should leave a profit of some £187,000,000. The chairman anticipated satisfactory results would accrue from the prospecting operations now being conducted on their other properties. He personally was satisfied that the establishment of an oil shale industry in this country would come to pass in the near future.

Union's Imports and Exports for June and First Half-Year.

These show big decreases compared with last year, but June month shows more encouraging figures as regards exports. Imports in the first six months of the present year show a drop of nearly £12,000,000, the falling off in June being £1,700,000. The reaction this year is not surprising when the flood of imported goods last year is borne in mind. It may be assumed, in view of reduced stocks, that the second half of the year will see the figures mount again. Exports

for the six months showed a decrease of nearly £21,000,000 compared with last year. Diamonds fell over £6,000,000 and wool by nearly £11,000,000; coal, however, increased by £360,000, the total export for the half-year being £1,000,000. Food and drink showed an increase of £1,700,000 for the six months. June exports alone were valued at £4,879,812 drop of £620,000 as compared with June of last year. In June our wool export increased to 19½ million lbs. against 5½ million lbs. in the corresponding month of 1920. The general opinion is that the figures for the second half of the year will show a big improvement on the first.

Railway Deficit.

The gross expenditure on the railways and harbours has risen from over £14,000,000 in 1911 to over £28,000,000 in the last financial year. Wages and allowances which in the former year amounted to £5,821,096 have risen to £16,358,562. Revenue has of course risen owing to increases in rates and fares, but the limit in this direction appears to have been reached, and any further increase would only have the effect of curtailing development and frightening away new enterprises. But notwithstanding increases in rates, revenue falls much below expenditure, and the railways showed on July 31st last a deficit of £3,361,000. With such facts to face it is only reasonable to look upon the present retrenchment policy of the railways as not only necessary but right. The Premier, in his speech at Capetown last week, predicted a great recovery in the Union within the next five years. In view of this expected advance in expansion, the railways and harbours must be ready to handle the traffic. At the present time the General Manager reports a serious shortage of engine power, which would take a considerable time to restore to normal. The fact remains that the present equipment of the railways could not cope with any considerable increase in traffic, and in view of the predicted increase it is to be hoped that the activities of the railways will not be too drastically curtailed. To-day's efficiency must not be lowered in view of probable future demands.

Coal Conditions in Britain.

During the last week of July 4,592,000 tons of coal were raised, compared with 4,277,200 tons during the week before the coal strike. During July 15, 223,500 tons were raised as compared with 179,000 tons during the three months' stoppage, which shows that the industry is about on pre-war footing. In South Wales house coal has been further reduced by 10s. a ton from September 1st, making a reduction of over 17s. in a month. The retail price is now 53s. 6d. per ton.

Germany's Foreign Trade.

The United States Secretary of Commerce, Mr. Hoover, states that German competition in the field of foreign trade is showing signs of weakening. Germany it seems is experiencing difficulty in handling orders obtained by cutting prices, and is unable to produce goods equal to pre-war quality. Lately the Germans have abandoned steel contracts owing to their inability to deliver the steel.

German Dyes.

It is announced that from September 1st the price of German dyes for silk piece goods has been advanced 300 per cent., making 1,200 per cent. over pre-war rates.

European Trade Conditions in Relation to America.

The tariff now being enacted by Congress, says a well-known American bank president, will prevent the importation of many goods needed there, and will hinder economic readjustment internationally, which foreign trade is the most direct and satisfactory way of hastening. If foreign goods are shut out of America, European countries, he said, would have no way of establishing a credit there. There was no question about America needing many of the things manufactured in foreign countries, and the latter in turn need credit, which shipment of their goods to America would set up. He stated that after a visit to Europe he was positive that France would "come back" all right, although the rehabilitation work is progressing very slowly. The devastated areas need, he said, between 200,000 and 300,000 new homes. Labour troubles, he stated, had left England in a bad plight, and he declared that all the nations must economise, reducing extravagance to the minimum and thus reducing the heavy burden on business.

Modder "B" Dispute.

The Modder "B" dispute has been settled by the reinstatement of the mine captain, and the strikers have resumed work.

Strike at Van Ryn Deep.

A long-standing dispute between the reduction workers and the management has culminated in a strike at the battery, impeding the operations on the mine very considerably. The dispute is in regard to the position of shift leaders in the battery. The matter is now being discussed between the Chamber of Mines and the South African Industrial Federation.

Financial.

The South African Reserve Bank's ratio of cash reserves to liabilities to the public on September 3rd was 80.6 per cent.

Metal Market.

The metal market has shown an improved tendency during the past week, due to the re-opening of works in Britain and to better financial relations obtaining in America. A revival in copper is expected shortly; tin and lead are also expected to advance. Latest quotations: Standard copper, £68 19s. 6d. cash, £69 11s. 3d. forward; electrolytic copper, £71 10s. cash, £73 10s. forward; Straits tin, £156 15s. cash, £159 2s. 6d. forward; English lead, £23 7s. 6d. cash, £22 15s. forward; bar silver, 38½d.; fine gold, 109s. 8d. per ounce.

Year's Work of the Union Geological Survey.

DIRECTOR'S REVIEW OF PROGRESS DURING 1920.

The following is the annual report for 1920 of the Director of the Geological Survey (Dr. A. W. Rogers):—

Geological mapping was done in Heidelberg, the Olifants River valley, and near the Crocodile River in Rustenburg. A considerable portion of the time of the staff was taken up by the examination of mineral deposits of actual or potential economic value.

During the year the staff was increased by the appointment of Mr. Haughton, Dr. Krige and Mr. Nel, two of whom took up their work late in the year and one after its close.

Geological Museum.

The Geological Museum in Pretoria has been reopened after an interval of six years, during which the space destined for it was in the use of the Defence Department. Much of Mr. Hall's time was spent in preparing exhibits and in making the extensive changes required to bring the collections shown up to a condition as representative of the mineral resources of the country as possible with the material in the possession of the Survey. The stratigraphical collection and that of the intrusive rocks have also received very considerable attention.

The office accommodation in Pretoria and Cape Town is insufficient for the present staff. It is impossible so to arrange periods of field-work that some geologists occupy offices while others are in the field. The space required by one of the staff on returning from field-work must be sufficient to hold his maps and specimens so that he can refer to them without continual packing and unpacking. At present some officers have to be accommodated in the exhibition room and library, which entails unavoidable disturbance and loss of time.

Another matter which closely concerns expenses and the welfare of the staff is the want of proper accommodation for the wagons when they are not in actual use. The yard in which they are now stored in Pretoria does not protect the wagons from the weather nor from becoming verminous; the results are heavy repair bills and complaints from those who use the wagons for field-work.

Heidelberg Geology.

In the Heidelberg district the area lying north of the Sugarbush Fault was almost completed and a considerable amount of work was done south of that fault. It has been demonstrated that the thickness of each major subdivision of the Witwatersrand system is reduced as compared with the thickness of the same subdivision on the Rand, and no evidence of unconformity within the Kimberley-Elsburg series nor at the top of that series was found between the Klipriversberg and the Malans Kraal—Tweefontein escarpment. The importance of these results lies in the confirmation they afford of the mistake in correlating certain conglomerates in the Kimberley series in Heidelberg with the Van Ryn reef. The mistaken correlation has given rise to very greatly exaggerated expectations of profits to be got from mining certain reefs in Heidelberg. The results of the detailed geological survey of the Witwatersrand and Heidelberg districts made between the years 1910 and 1921 prove that the reefs in Heidelberg, which have been wrongly called "Van Ryn," are in the Kimberley series, and that the Nigel reef is on the horizon of the Van Ryn.

Coal in the North-West.

In September the Director made a journey in the north-western Transvaal with the Government Mining Engineer and the Inspector of Mines, Pretoria, for the purpose of seeing the country where coal has recently been discovered through boring operations of the Irrigation Department. The route lay north-westwards from the Rooiberg tin mines through Buffelshoek on the Crocodile River and across the Matlabas River into the wide sand-covered country north-

west of the Waterberg, where coal had been struck by percussion drill on the farms Hooi Kraal No. 1687, Grootgeluk No. 1360, Leeuwdrift No. 1370, and Enkelbult No. 1361 at various depths ranging from 30 to 330 feet. The results got by rotary drilling since our visit prove that the region contains coal seams that may be of considerable value in the future, though the extent and degree of continuity of the seams are at present a matter for conjecture. On the south side of the coal-bearing area the Karroo beds appear to rest upon pale and dark-striped grits of the Waterberg system, which crop out on Zontpan No. 1238, and are exposed in wells as far north as Kringatspruit; similar rocks occur on the Matlabas River lower down the river than the typical red grits of the Waterberg system, and this type of rock forms the lower beds of the same system in the hills fringing the northern edge of the Palala plateau on Kaffirboom No. 560 and adjacent farms. On the left bank of the Matlabas, near the police station, red Waterberg grits are separated from coarse red granite by aplite containing fragments of the grits. On the north side of the belt of Karroo beds, which is perhaps eighteen miles wide on the west side of the Pongola River, there is gneissose granite containing bands of altered limestone with abundant lime silicate minerals. The Karroo beds stretch from the western side of the Crocodile River to the Palala River, where only outliers remain. The base of the formation is seen to rest on coarse red granite on Buffels Kraal No. 401, Kroonstad No. 365, and Kaapsvlakte No. 368. At the base there is a thin conglomerate, not a tillite, though on the eastern side of the prominent tafelkop on the right bank of the Palala this conglomerate rests on a striated surface of the granite; the general direction of the striae is E. 30 N. The Karroo beds apparently form a wide syncline of which the axis is inclined westwards, so that the area they occupy widens towards Bechuanaland.

The red granite of the Bushveld type is in contact with the much older gneissose granite on Clermont No. 1109, but the actual contact was not seen. Eastwards, unaltered red Waterberg grits appear to rest upon the red granite on the farm Rietvley No. 783, and the grits are overlain by felsites on Goedgedacht No. 786 and Murchison No. 472; the felsites occasionally contain angular pieces of pale quartzite. The Waterberg quartzites which form the north edge of the Palala plateau apparently rest upon the felsites. There are dykes and sills of quartz-dolerite in the Waterberg beds of this area as well as along the Matlabas. Quartz-dolerite is also seen to be intrusive in the red granite on Hellem-Bricksteen No. 2102, where it becomes very fine grained at the contact with the coarse red granite. On Elandsfontein No. 594 there is a wide belt of rocks ranging from very dark norite to anorthosite, including bodies of magnetite-rock, though no pyroxenite was noticed, lying between coarse red granite on the west and the ancient gneiss of Matal's location on the east; the junction is near the eastern beacon of the location.

Mr. A. L. Hall's Work.

Mr. A. L. Hall, Assistant Director, spent the first half of the year in the preparation of comprehensive descriptions of the mica and corundum deposits of the Union, and several months on the establishment of the Geological Museum, a work which has been referred to in the preliminary remarks of this report, and which has been described at length in a recent number of the *Journal of Industries*. The steadily increasing number of inquiries about base metal resources made it necessary for Mr. Hall to visit a number of the deposits; the more important of these were the interesting nickel and tale deposits of the Scotia tale mine near Sheba Siding, and several mica and corundum deposits. Near the latter two valuable deposits of felspar were examined in detail and the material was submitted to technical tests, with satisfactory results. This information is an addition

to what has been already published, and its accumulation will enable the previous publications to be brought up to date when occasion demands it. The results of some of the work, together with information got in other ways, is being co-ordinated with a view to a comprehensive investigation of the clay and felspar resources of the Union.

Dr. Wagners' Activities.

Dr. P. A. Wagner was engaged on various deposits of economic importance, including those of the Olifants River tin fields, the iron ores of the Crocodile River and those near Pretoria, the Pretoria salt pan, vanadinite ores, lead ores, chromite, and fluor. He read papers on the origin of the salt pan, vanadinite of the Marico district, and the Crocodile River iron ores before the Geological Society of South Africa. His memoir on the Olifants River tin fields was sent to the printers on October 5th, but it has not yet been issued on account of delay in its return from the printers.

Mr. Wybergh examined limestones near Robertson, Hermanus and Malagas during the year, and the second volume of the Memoir on the "Limestone Resources of the Union" prepared by him was issued, but most of his time was occupied by an examination of the coalfields of the Transvaal and Orange Free State with the view of preparing a general report of coal resources.

Office Work.

The following publications were finished and published during the year:—

- Memoir No. 13 (Mica), in May.
- Memoir No. 11 (Limestones, II.), in November.
- Memoir No. 15 (Corundum), in December.
- Sheet No. 14 (Transvaal), in November.
- Sheet No. 15 (Transvaal), in November.
- Sheet No. 28 (Cape), in November.

Other work in progress was the preparation of the large-scale map of Heidelberg district; the Johannesburg Sheet No. 52, which was sent to the printers in November; Cape Sheet No. 35; Cape Sheet No. 5 (Laingsburg); Transvaal Sheet No. 19 (Barberton); Sheet No. 68 (Piet Retief) and Sheet No. 102 (Vryheid); Memoir No. 16 (Olifants River tin fields), sent to the printers in October.

Many labels and notices were prepared for the Museum.

A compilation of the published and unpublished analyses of South African rocks was commenced for convenience of reference.

Laboratory Work.

Mr. Gardthausen, Assistant Curator, made twelve analyses during the year for members of the staff, twenty-nine assays, 275 determinations of minerals sent in by the public, and many rock sections and determinations for the staff.

Several analyses of rocks and minerals were made for the staff by the Government Analyst.

The staff of the Survey is the following:

Director, A. W. Rogers, Sc.D., F.R.S.; assistant director, A. L. Hall, B.A., F.G.S.; senior geologists, S. H. Houghton, B.A., F.G.S., and L. J. Krige, Ph.D., M.A.; junior geologist, L. T. Nel, M.Sc.; curator, the Assistant Director; chief clerk, L. B. Yardley; chief draughtsman, E. H. Banks; assistant draughtsman, L. S. Goldsmith, M.C.; assistant curator, C. C. Gardthausen, F.C.S.

Temporary Officers.—Geologist for Mineral Survey, P. A. Wagner, D.Eng., B.Sc., F.G.S.; geologist, W. Wybergh; field assistant, A. K. Parrott; clerical assistant, Miss Scott.

ENGINEER, A.M.I.E.E., with 15 Years ELECTRICAL and MECHANICAL experience chiefly on commercial side, recently representing LEADING ENGINEERING CONCERN open for immediate engagement.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

V.

By Arthur Stenhouse.

In 1886, across the barren veld daily I tramped, prospecting for gold and gathering specimens of quartz by the way; and in the evenings, dusty and tired, arrived at my solitary tent on the Witwatersrand. After a simple meal I panned the specimens, many of which gave excellent results. At sunset I laid myself down to rest, lazily watching the Kafir boy cook his "mealie pap" on one of the numerous ant-heaps.

Pioneering was not all beer and skittles, but during the daytime I lived in hope, and at night recalled memories of the days of 1883-4 in Western Canada, the home of the beaver and the bear, the moose and the elk, when I dwelt in a one-roomed framed house on the prairie, and ploughed the land, reaped the hay, fed the pigs, and tended to the cattle. I also recalled memories of other days spent in the City of Winnipeg, in the almost arctic winter time, often 30 to 40 deg. below zero, when the earth was covered with a mantle of snow, and the charming girls, cosily wrapped in their sealskins and furs, drove in their sleighs, with jingling bells, through the freezing, sunlit air. These memories kept me company on the Witwatersrand, beneath the starlit sky.

To-day, 1921, the refining influences of ladies' society in Johannesburg is not half appreciated. In 1886 there were no angelic beings to soften and elevate the lives of the early pioneers. Later on a lady appeared, "Coekney Liz," and naturally she had a very good time.

In 1887 I was fortunate in obtaining accommodation at "Heights"—the first hotel erected on the Witwatersrand, a building composed of sundried bricks, with an iron roof; thin wooden partitions sub-divided the bedrooms, the partition in my room consisted of canvas only; but after a tedious journey on horseback I was thankful to obtain a "shake-down" anywhere. The late Mr. Height had a charming private residence at Doornfontein, and doubly I can recall the beautiful grounds with a miniature lake and willow trees in the foreground.

In 1888 the gold was not smelted, but retorted only, and the "puddings" of gold were deposited in the bank and were of all shapes and sizes. On one occasion the manager of the "Jumpers" Mine was dissatisfied with the appearance of the "pudding" from the battery, so placed it on a shovel and held it over the blacksmith's fire at the mine to get rid of the sulphurous fumes.

Before the advent of the railway, employees of all mines were paid in notes and gold and not by cheque; the banks charged 5 per cent. for silver coin and 1 per cent. for gold, to cover the cost of transport from the coast ports. Once a week I conveyed the gold from the "Jumpers" Mine to the bank and drew large sums for payment of wages. The Standard Bank (when Nitch and Gardner were general managers) overpaid me at various times, over £1,000 in gold. On one occasion the teller at first refused to take back £500 in gold which I returned next day, as his cash account balanced! However, I persuaded him to retain the money, and shortly afterwards the secretary of another mine called in and stated that he had been underpaid £500, so the matter was amicably settled.

In 1888 city life was very exciting, so in the words of the poet Pringle:

"Afar in the desert I love to ride,
With the silent bush-boy alone by my side."

The Need of Currency Stability.

"THE ONLY TRUE REMEDY"—PROFESSOR CASSEL'S PROPOSAL TO RE-ESTABLISH A CURRENCY SYSTEM BASED ON NEW RATIO OF GOLD.

At the recent Congress of the International Chamber of Commerce held in London, an important resolution was brought forward on behalf of the Finance Group Committee. This declared that "whereas the resumption of international commercial relations was hampered by the dislocation of the normal rates of exchange, and especially by their instability, Governments should pursue a strict policy in regard to taxation and to departmental economy: inflation of paper currency should be stopped and progressively decreased: a study should be made, and a plan of action decided on, with regard to the solution of the problems raised by the question of Inter-Allied debts: the disarmament laid down in treaties should be carried out in order to bring about a reduction of Budgetary expenses: the creation of national and international organisations for export credits should be actively undertaken by private enterprise, with the support of Governments: the Governments of countries with depreciated rates of exchange should avoid as far as possible contracting new external debts: and the greatest possible liberty should be granted in all commercial and financial transactions."

Commenting on this, "Barclay's Bank Review" says: "In many ways this resolution was strikingly reminiscent of the conclusions reached at the Brussels Conference and adopted by the representatives of thirty-nine different nations. Unfortunately, in only too many instances, the Governments concerned have been content with a theoretic rather than an actual adoption of certain of the principles agreed to, and this not only where these principles are in the nature of a counsel of perfection, but in cases well under their own control.

The Need of Stability.

"With regard to the question of deflation, Professor Cassel moved an amendment striking out the words 'and progressively decreased' in the sentence 'the inflation of paper currency should be stopped and progressively decreased.' He claimed that the only true remedy was to restore stability immediately, and he reminded the Conference that last year he had issued a special warning against deflation, principally in the United States. That warning had, he thought, been justified, for one of the main causes of the serious depression of trade and the unparalleled degree of unemployment, was the efforts which had been made to increase the internal value of money and to force prices down. In a period of inflation, credit should be restricted, and at a time like this, when prices were falling, every effort should be made to stop that movement and give confidence that bottom had been reached.

An Opposition View.

"Sir Felix Schuster disagreed with Professor Cassel and thought that the countries which had departed from their pre-war gold standard must aim at deflating their currency

gradually, so as to inflict the least injury, but with one object in view—a return as soon as possible to a pre-war gold standard. He admitted that this policy might be carried out too rapidly, but felt there could be no stability of exchanges, stability of trade and harmonious commercial relations until all currencies were regulated upon the basis of a common standard and that standard at present could only be gold.

"It is important to remember that, although at the present time it is not possible for this country, or indeed for most countries, to establish a standard of currency consisting of gold, or of paper backed by one hundred per cent. of gold, yet a gold standard can be established by the maintenance of an adequate percentage of gold in support of any existing volume of currency. This method does not, of course, provide the same convertibility, but properly regulated it provides an efficient gold standard system.

Too Drastic Deflation.

"Professor Cassel is probably right in his attributing some portion of the serious present depression in trade to too drastic attempts at monetary deflation, for the forcible pursuance of this policy in America compelled this and other countries to take similar steps in order to preserve a relative approximation of price levels. These efforts are no doubt in part responsible for the precipitate fall in prices, which in turn is responsible to a considerable extent for the prevailing lack of confidence. In reality it is more practicable to increase the ratio of value supporting existing currency and credit than to aim at substantial monetary deflation.

"Apart from deflation, however, there are other important factors, which, although difficult to measure, have yet exercised a considerable influence on the trade position. Amongst these are the lack of political stability on the Continent; the lack of a real peace; the lack of harmonious working between labour and capital and the inability of certain Governments of Europe to balance their Budgets and so avoid inflating their currency.

Sound Currency a Necessity!

"Professor Cassel has rendered a public service by emphasising the need for stability and the danger of too drastic deflation. The true position seems to be that there can be no stability of exchanges, stability of trade and harmonious commercial relations without sound currency. This does not necessarily involve the return to a pre-war gold parity—or to a hundred per cent. gold basis—in point of fact such a return would in many cases be impossible of achievement. It does, however, involve the restoration of political stability, the collection of taxation adequate to meet national needs without recourse to the printing press, an increase in productive capacity, and the establishment of a currency system regulated by value and based on a ratio of gold."

Principles of Gold Refining.

The completion of the Gold Refinery at Germiston lends interest to the following brief review of the principles of gold refining, with special reference to the process in vogue at the London, Sydney, and the old Pretoria Mints.

The gold produced from mines in general is associated with a greater or smaller amount of impurities. These impurities are usually present on account of their existence in the ore from which the gold has been produced, but they are also included in the gold from external sources during the course of extraction. They usually consist of the precious metals: silver, platinum, and other members of the platinum group of metals, and the more common base metals such as copper, lead, bismuth, arsenic, etc. Rand gold is no exception to the rule, and we find that it is associated with about 10 per cent. of impurities in the case of mill gold, and even more in the case of cyanide gold.

Refining then has as its object the removal of these foreign substances, which so often have a very injurious effect upon the physical properties of the gold, and render it unsuitable for coinage and other uses.

Briefly, refining methods can be considered under three heads, namely, wet, electrolytic, and dry methods. Past

the gold and most of the other metals go into solution, but on account of the low current densities used, only gold is deposited on the pure gold cathodes, thereby producing gold which is seldom under 999.8 parts per 1,000 fine.

In the dry processes of refining the gold bullion is treated when in the molten state. The principle adopted aims at treating the bullion with some substance which only reacts with the impurities present, and leaves the gold unchanged excepting for slight mechanical losses. The number of substances which can be used to achieve this object are numerous, and attention will only be confined to one process which has been in use on gold approaching Rand gold in composition, and which will probably be adopted at the local refinery at Germiston. The process is called Parting by Chlorine Gas, or the Miller Process.

The process was proposed in 1838 by Lewis Thompson, but was not practically applied. In 1867 it was introduced by F. B. Miller with various important improvements at the Sidney Mint for refining and desilverising gold on the large scale. It has also been employed at the London Mint for gold refining, and was also in use from time to time at the Pretoria Mint in the time of the late Transvaal Republic.

The Miller process depends for its action on the property of chlorine gas of converting the silver as well as the base metals contained in the bullion into chloride, whilst not

Gold Refinery at Germiston nearing completion.

practice has chosen to call these methods by different names, such as inquartation, parting, and refining, but as they all have the same object in view ultimately, it will be sufficient to call them methods of refining in this account.

As the composition of gold produced from various parts of the world varies greatly, it follows that several methods of refining have resulted from this cause. The processes briefly treated here will be those which appear to be applicable to local conditions.

The wet processes can hardly be said to comply with the reason just stated, as it has been found that they work with greatest efficiency on bullion in which the ratio of gold to silver is much smaller than that in which it occurs in Rand or South African gold. Its adoption would entail the addition of much silver to the gold, a circumstance which can be avoided by adopting more applicable processes.

In the electrolytic process we have one which could readily be applied to Rand gold. It is suitable for treating gold alloys in which this metal is in large excess over the other constituents. It is a method which was developed at the North German Refinery in Hamburg. Briefly, the process is as follows: The anodes are made of sheets of the impure gold alloy or bullion, and the cathodes of pure sheet gold. The electrolyte is a solution of gold chloride mixed with an excess of hydrochloric acid, or a solution of any salt like sodium chloride (common salt) which forms double salts with gold chloride. The electrolyte is kept up to strength by the occasional addition of gold chloride. During electrolysis

attacking the gold. The base metal chlorides escape as a gas, as they easily volatilise, while the silver chloride collects as a liquid on the surface of the gold.

The refining is conducted in clay crucibles enclosed within graphite crucibles to avoid loss of metal in case of a crucible cracking. The clay crucible is glazed internally with borax to prevent the chloride of silver penetrating into it. Chlorine is passed into the molten gold by means of a clay pipe which passes through a loosely fitting clay cover. The chlorine is generated from oxide of manganese and hydrochloric acid in a stoneware vessel.

The refining process is conducted as follows: The gold is charged into previously heated crucibles, and when molten 2 to 3 ounces of borax added. The clay pipe, the end of which has been heated, is then lowered into the metal and chlorine admitted. The base metal chlorides are immediately given off as vapours, which disappear when these metals have been removed. The chlorine now combines with the silver present. When the silver has been removed a brownish deposit appears on the clay pipe, and the parting is completed. The crucible containing the gold is removed from the furnace and the gold allowed to solidify. The silver chloride still remains molten, and is poured off. The solid gold is cleaned and re-melted. Its fineness is now from 991 to 997 per 1,000. By repeating the operation more silver is removed. Of the gold present in the alloy, 98 per cent. is recovered, while 2 per cent. goes to the silver chloride removed. This loss is recovered from the chloride by subsequent treatment

Our Iron Industry.

A YEAR'S PROGRESS.

In the course of his annual report, the Government Mining Engineer reviews the iron and steel industry in 1920 as follows:—

The Union Steel Corporation (of South Africa), Ltd.—The works of this company produced during the year 12,245 tons of a total value of £323,604, comprising 9,903 tons of open-hearth steel from scrap, etc., the saleable value of this product being £253,026, and in addition the 3½-ton Heroult electric furnace had an output of 2,342 tons, of value £70,578. The average labour employed consisted of 190 white persons (including staff) and 340 coloured persons. A new 25-ton Siemens open-hearth furnace is now in course of construction and the works buildings are being extended.

The Transvaal Blast Furnace Co., Ltd., has ceased its experimental work at Vereeniging and has gone into liquidation.

The South African Iron and Steel Corporation, Ltd. (late Pretoria Iron Works).—The erection of the plant for this industry has not yet been started, the financial conditions not being favourable at present for raising the further capital required. Meanwhile the drawings for the lay-out and the construction of the plant are being proceeded with. The experimental blast furnace was working for six months of the year only. During this period 1,508 tons of pig, of value £15,080, were produced. The average labour employed was 22 whites and 105 natives.

The Dunsward Iron and Steel Works, Ltd., worked at full capacity for the whole year. The output of bar, rod, and angle iron was 7,034 tons, of value £175,850, and the labour employed averaged 40 whites and 240 coloured persons. Additional plant is now being installed.

The Witwatersrand Co-operative Smelting Works, Ltd.—No further additions have been made to plant during 1920. Since ferro-manganese, ferro-silicon, and ferro-chrome have been obtainable, a higher quality of steel is produced, while the total output of shoes and dies was over 1,200 tons. The life of the liners has also been increased, as much as 120 tons net of castings being obtained from one liner. The total output of shoes and dies was 1,201 tons, of value £24,020. The average labour employed was 3 whites and 31 natives.

The Newcastle Iron and Steel, Ltd.—The plant of this company is still under construction; its completion is anticipated by August next. An average of 30 whites and 150 coloured persons was employed.

Summarising the operations particularised above, it is found that 21,988 tons of iron and steel goods were produced in the Union during the year 1920, the value of the product being £538,554, as compared with 20,314 tons of value £405,798 during 1919. The industry gave employment to an average of 285 white persons and 866 coloured persons during the year.

Swazi Tin.

The following are the results of the operations of this Company for the month of August, 1921:—Concentrate recovered, 20 tons; estimated loss for the month (taking tin at £160 per ton), £168.

The East London City Council intend to borrow the sum of sixty thousand pounds (£60,000) to provide for the purchase and installation of the undermentioned machinery, etc., and work connected therewith, in the West Bank Electric Power Station:—One water tube boiler, complete with mechanical stoker, economiser induced draft plant and smoke stack; one 1,500 K.V.A. three-phase 6,600 volts steam turbo-alternator complete with condenser and auxiliaries; one 300 K.W. rotary converter; necessary E.H.T. three-phase switch gear for alternator feeders and rotary converter.

The World's Gold and Silver Output.

In a recent number (16th July) the *Commercial and Financial Chronicle* of New York gives its usual estimate of the production during 1920 of gold and silver throughout the world, with comparative figures for earlier years. The following statement reproduces the summary figures for both metals. In the case of gold the coining value is given, in the case of silver the commercial value in sterling currency:—

Year.	Gold.		Silver.	
	Quantity. Fine ounces.	Coining Value. £	Quantity. Fine ounces.	Commercial Value. £
Average of 1901-1905	15,628,111	66,385,090	167,449,613	18,181,731
Average of 1906-1910	20,981,757	89,126,308	197,587,326	21,797,930
1911	22,352,095	94,947,029	225,372,844	23,094,547
1912	22,565,697	95,854,568	224,310,654	26,198,781
1913	22,265,198	94,578,208	223,907,843	25,714,416
1914	21,413,701	91,021,119	160,626,019	16,941,026
1915	22,752,229	96,646,927	178,850,500	17,605,596
Average of 1911-1915	22,269,784	94,609,570	202,613,572	21,910,873
1916	21,895,494	93,007,679	161,177,900	21,029,686
1917	20,491,176	87,042,417	168,258,600	28,639,016
1918	18,563,016	78,851,979	197,537,637	39,112,452
1919	17,663,057	75,029,131	174,517,414	41,449,848
1920 (estimated)	16,790,367	71,022,121	175,714,504	47,589,282
Average of 1916-1920	19,080,622	80,990,665	175,441,211	35,564,057

The level of yearly production of gold had, before the war, reached somewhat over 22,000,000 ounces, and in 1920 the total fell below the pre-war average by about 25 per cent., and was 10 per cent. less than the 1919 total. The figures given by the *Chronicle* for the sterling equivalent of the gold whose weight is shown in the table represent, not the market value of the gold, but the number of sovereigns which could be struck from these quantities. As is shown in the interesting and instructive article from which the figures are taken, at the close of the year 1919 the market price of gold was 109s. 8½d. per ounce fine, and by 5th February it had risen to 127s. 4d., or a premium of slightly over 50 per cent. on the coining value of 84s. 11.45d. per ounce fine.

From this point a steady decline brought the price to 102s. 7d. on 2nd April, and an upward movement set in from that date. On 8th November the price stood at 122s. 4d., but dropped to 116s. 1d. by the close of the year. The average price for the year is given as 112s. 11.52d., making the market value of the year's production in sterling currency about £10,000,000 greater than the coining value stated in the table.

The movements of the price of silver, as traced by the *Chronicle*, are also important. From the opening at 76d. per ounce, the price advanced to 89½d. on 11th February, and from this, the highest price on record, the general tendency was downward. The lowest point of the year, 38½d., was touched in December, and at the close the price was 40½d. The year's average was 55d. per ounce.

It will be seen that the quantity of silver produced in 1920 was about equal to the average output of the last quinquennium, and about 49,000,000 ounces, or 22 per cent., less than the annual rate reached in the years immediately preceding the war. For 1920 the outputs of the principal producing countries differed little from those reported for 1919.

In the case of gold the United States was the country showing the greatest falling off from 1917 to 1920, the reduction being 524,000 ounces (18 per cent.) as compared with a reduction of 225,000 ounces (2.4 per cent.) in Africa (including West Africa) and 133,000 ounces (10.5 per cent.) in Australia.

Springs Mines.

The following cable has been despatched to the London Office for publication:—"Owing to breakdowns of Rock Hoist No. 2 Shaft it is anticipated that the tonnage milled for the month will be reduced by 4,000 tons; repairs expected to be completed to-night (12th instant); publish immediately."

Sampling, Analysis and Classification of Coal.

The following is a summary of an article on the above subject appearing in a recent issue of the *Journal of the Chemical, Metallurgical and Mining Society of South Africa*:

Sampling.

The sampling of material, whether it consists of coal, ore, or any other product, is the most important feature in aiming at a true value of the material. In the case of coal which has been mined, one has an aggregate of coal, shale pyrite, and perhaps other impurities ranging in size from several inches down to particles of microscopic size. The breaking up of the coal and its impurities into these different sizes depends entirely upon the physical character of the

On a Transvaal Colliery.

various constituents which make up the aggregate. In the sampling of such a mass it is therefore important that each constituent be correctly represented in the sample. The bigger the range in size between the various pieces which make up the coal, the greater must be the sample in order that it shall be truly representative. The bulk of the sample cannot be reduced unless the size of the pieces is correspondingly reduced. Hence in order to reduce a sample to laboratory size, each quartering down must be preceded by a reduction in size of particles. The errors introduced by incorrect sampling are much greater than those possible by slip-shod chemical analysis.

Analysis.

The determinations usually made in the analysis of coal are: (1) Calorific value, (2) moisture, (3) volatile matter and fixed carbon, (4) ash, (5) sulphur.

In the determination of the calorific value various calorimeters are used, but the most reliable and useful is the Bomb Calorimeter.

The moisture present in coal can be grouped under four heads, namely, superficial moisture due to pit water on freshly mined coal, associated moisture which is included

in the coal substance, water composition or crystallisation, water of reaction due to combination of hydrogen of the coal with oxygen in burning.

Volatile matter is usually driven off coal by heating in a closed crucible at a temperature of about 900° C. The coal is weighed before and after the process and the loss repre-

A Scene on a Natal Colliery.

sents the volatile constituent. Ash is found by burning a previously weighed portion of powdered coal in an open crucible at about 750° C. till all carbon has been removed.

The sulphur determination consists in converting the sulphur present into a soluble sulphate which is afterwards precipitated by suitable re-agents and weighed. Attempts at classification have up to the present resulted in numerous systems, each of which is based on some or other chemical or physical property of the coal. Each system has its advantages when looked at from the point of view of its exponents, and can be put to useful purpose if viewed in the correct perspective.

Zaaipplaats Tin: August Results.

The Zaaipplaats results for the month of August were as follows:—Mill ran 4½ days; concentrates won, 11 long tons; capital expenditure, nil; estimated loss for August, 1921, excluding Government taxes and directors' fees, £300. The Manager reports: During August it was found that a certain belt of granite starting near the Power House and extending up the hill in the direction of No. 13 carried tin values from ¼ per cent. to 1½ per cent. over an area of roughly 300 feet long by 15 feet wide. The tin bearing granite passed under the track from the ore bin to No. 13. A small quarry was started on the side of the track where pannings showed values of ½ per cent. to ¾ per cent. black tin. By the 31st the quarry was 15 feet long by 6 feet wide by 4 feet deep. From 2 feet below the surface to a depth of 6 feet pannings have shown a steady 1 per cent. black tin. Two assays of an average of eight samples from a depth of about 7 feet were made, the results being 1.55 per cent. and 1.31 per cent. metallic tin respectively. The prospects of opening up a large body of 1 per cent. ore are hopeful.

The Failure of State Railway Control.

PROPOSAL TO HAND OVER THE S.A.R. TO PRIVATE ENTERPRISE—LABOUR'S IMPOSSIBLE DEMANDS—RAILWAYS RUN AT A BIG LOSS.

(From a Correspondent.)

Without trenching upon politics it is almost impossible to touch on any matter connected with the life of this country. Anyone advancing views that do not coincide with those of the people in control will at once be called archaic, but in face of the possibility of being called reactionary I will venture to picture certain conditions which appertain here and which if continued must according to the results being obtained here and in other countries lead to further trouble and confusion. Let me draw attention to the railways. It needs no words of mine to show the terrible condition this country is drifting into under the present Government's administration. Not only have the producers of this country been placed in an impossible position, but at the moment produce is being held up, and although men are invited to go on to the land, and officers of the State are busy in England picturing all the advantages of South Africa, yet the possibility of numbers of people buying land

hands, and the Portuguese port of Delagoa Bay with Hollander manipulation was the pawn that was played off against Natal and the Cape Colony.

The miner, the man of commerce, and the farmer are those most interested in the development of the country. The workman and others are more concerned in the welfare of themselves. The merging of all railway lines destroyed any hope of competition. Natal can no longer compete against East London or Delagoa Bay; and the Cape, a thousand miles away, with a long railway, only comes home on the game of averages. When all the systems were merged into the railways of the Union, citizens were led to believe economy and order under one administration would give them ideal transportation and would lead to untold developments. That, however, was not taking into consideration the unskilled labourer, the rights of white labour, and the demands that would curtail the use of Kaffir

This shows how the Coal Trade of the Country is hampered by the Railways. No Trucks at a Colliery—"Boys" idle.

and not being able to send their produce to market is dangerously apparent. The other matters in connection with our railways generally I will allude to later in this article.

Railway Beginnings.

When railways were first built in South Africa, their true purpose was to enable travellers and producers to overcome the difficulties of the slow and antiquated systems of transportation of the period. As the lines lengthened, their extensions served to open up the backveld for the farmer, the discovery of diamonds necessitated quicker communications, and ultimately the great gold field of the Rand, which was forced to use ox transportation in its earliest stages, demanded its connections with the various systems and the coast. It was not without considerable political misunderstandings that it was carried through. Each State had its own railways, there was a question of tariffs, and an *impasse* nearly brought about war as the last links neared their destination. The Transvaal has always been most concerned about its end. Built originally by Hollanders, it was at its inception completely in their

labour. The early demands for Government lines kept out joint stock companies. One or two small lines were built by companies, but the principle of having none other than State-run railroads has always been observed. This jealousy was at first purely political in its sentiment, but latterly was continued, fearing that private enterprise would benefit to the detriment of the State. It seems never to have occurred that by encouraging enterprise and competition a great benefit would accrue.

Anomalous Position To-day.

To-day one sees the spectacle of a country held in the thralls of continuous demands. The wheels of progress run at the dictates of white labour. Unfortunately, to-day they run disconcertedly. There does not seem to be a single section of the community that is satisfied with the working of the Union railways. It is unnecessary to ask farmers, merchants, coal miners, or any of the users of the various lines. Then there is the interminable delay and uncertainty of delivery. The machinery in the hands of a State should simplify and not complicate, and this leads one to consider whether the railways of this Union are not being run as a charitable institution for indigents and for the

benefit of white labour more than for the good of the State. The present financial condition shows that in order to meet labour demands, they are run at a serious loss. The sight of one of the most able controllers of labour struggling with all his wits to bring reason and economy to bear on impossible demands is what we see to-day, but having made it an institution for the relief of labour, skilled and unskilled, and with its years of conciliation-building, can the anomaly be rectified to-day? Will the huge loss on working on this system diminish, or, with the continuous demands of its labour, will it increase? Already the various proposed lines have all been relegated to a too distant future. Many of them may not have their demands considered for a generation. It is not always that trunk lines produce the most—sometimes a branch line develops and pays more than the great long trunks. The Witbank line, the Natal coal lines, and the suburban line at the Cape are all instances of this. The Free State line and the long line to the Cape are occupied to-day largely in carrying coal. I should like to know what the profits on those lines are? The trade of the Cape as a port of coal delivery has been made impossible. Years ago the late Mr. Francis Oats pointed out the profitable impossibility of conveying coal overland to the Cape. Again, I should like to know the profit and loss for coal consigned from the Transvaal to that port over the last ten years? If a mine finds its grade of ore too poor to pay, it leaves that ore in the mine, for it would be madness to work non-payable ore; but does the same businesslike attitude pertain to railways? Recently the Governments of Great Britain and America took over their railways, which, during the War time and after, for purposes of convenience and necessity, ran under Government aegis, but to-day they are being handed back to the companies, and we have still to hear with what results. Having seen the working of competitive railways on the great American continent, one's commonsense tells one that, without competition, rates would have constantly risen and travelling and goods conveyance become impossible.

Question of Capitalisation.

The development of whole States by irrigation schemes where millions of acres were placed under water—one alone in Alberta 300 millions of acres and ditches several hundreds of miles long, by private enterprise—shows the capitalisation of our railways need not frighten us. There are many companies in America alone that earn dividends equal to those of our gold and diamond industries combined; and a billion dollar capital is just a fair concern. It is a question of principle and a question of whether for some political reason we should run railways at a loss that most probably in the hands of companies would be run at 25 per cent. or 30 per cent. less than any Government can do it. It is a question whether coal that should be rushed to the nearest ports and conveyed to the Cape by sea should be dragged unnecessarily 1,000 miles overland, thereby using

up material necessary for the other purposes? It is a question whether the internal development of this great country is not at present being retarded through every branch line having to be set aside for financial purposes. The disposal of the railways to companies would almost free this country from debt. It would enable it to develop numberless industrial propositions vitally necessary. In the hands of companies numerous avenues of wealth would be opened up and new populations settled. It is to my mind a matter of regret that the coal interests of this country are not sufficiently advanced to take over the railways. I should like to see them run with the same energy and activity that has been devoted to some of our gold mines. I am sure it would be an object lesson to those who have muddled the railways so long in the past. Regarding the present hold up in coal, let me reiterate that instead of the Cape being placed in a most favoured position, it is made impossible. A very good object lesson for this Government is the case of Sir Richard Whittington, thrice Lord Mayor of London, and the most important thing in his success was his "cat." I may explain that his "cat" was the ship that brought coals *by water*, from Newcastle to London and thereby made Dick's fortune. This country wants a Dick Whittington; it wants many Dick Whittingtons. It wants competition in railways, systematic arrangement for running the coal by sea and saving friction on land. It wants release from unnecessary financial strangling. The realisation of assets that must continuously depreciate under political sentiment, and official mismanagement. To be more clear, officials in themselves are not to blame, but the vulnerability of a Government concern through the weakness of ministers makes it impossible to carry out the service the country demands from it. One looks back to the recent action of ministers when they virtually placed the citizens of Johannesburg in the hands of Labour agitators and forced its freedom to submit to demands that should have been fought out and perhaps never conceded; one sees men receiving wages that are out of all proportion to what the work can honestly be done for; when railways pay men about half the salaries of Ministers, and whilst all this rich wage developments proceeds, the farmer gets half for his produce and insolvencies become the order of the day. It is not surprising that there is discontent and that wherever one goes one hears nothing but continuous murmurs of disappointment. The various producers of the country have suffered in many ways. Then, if I am wrong in my conjectures, if the railways are not run on political or sentimental lines, if the object of this country is to run railways purely for their commercial value, then let me suggest that some 160 million pounds are involved, and the return is a loss of nearly four millions a year with the prospect of its being possibly ten or twenty million a year if the demands of labour keep on increasing in their past ratio.

Nationalise the Diamond Mines.

With this prospect in view, would it not be a better proposition to consider the nationalisation of the country's diamond mines? There at least is a far better commercial proposition. The capital would be vastly less and, viewing the world's capacity for buying diamonds, we see that one-half of the world the last three years has sold the other half its century-old accumulated store of cut diamonds, and the diamond retains its value. Would it not be wiser to

nationalise all diamond mines and have every stone cut in Johannesburg? It would mean selling some 50 or 60 million pounds of cut diamonds, instead of only 10 or 12 millions of rough stones. It would mean that the Government of this country finds it is more dignified and profitable to carry out its development by controlling this solely, and that its policy is not to associate itself with diamond dealers. If the world's insistence upon buying cut diamonds is so great as the actual purchasing described recently indicates, if Sir Bernard Oppenheimer could cut with the returned soldiers in England, if the natives in the tropical forests of Borneo can mine and cut the produce of their diamond mines, surely the Dutch starving in this country have a right, their birthright, to demand as much as natives and soldiers can do outside this Union? Johannesburg selling 50 millions of cut diamonds and 30 millions of gold a year would become as important a city as many in Europe. The condition of things would change. The world would come to our doors to obtain the manufactured article. Am I not right in recommending the sale of the railways to companies and obtaining the return of all that capital that is losing interest and only being used to advance the interests of labour and making the railways more and more a haven for the destitute and a paradise for labour?

Broadening the Market.

Perhaps the most important point in the whole of this suggested programme of reconstruction would be the building up of new markets, markets which do not exist to-day. For instance, supposing that the railways were owned by joint stock companies, there would be some two hundred million of preferent and ordinary shares added to the share lists of this country. It might be said that there is that amount of Government stock to-day, but there is a vast difference in dealing in Government stock with about 1/3 commission and railway stock which at times would be extremely active and remunerative both to brokers, jobbers and arbitrage dealers. Besides there would always be a borrowing Government. For if the Government were to succeed in getting railways properly administered and its capital released, it would very soon be making State advances for internal development, and possibly there would be little loss to the markets in the exchange. As to the railway rates, they need disturb no one. If countries like England and America can arrange their rates, surely this country could. Lastly, it might be said that no body of financiers would dream of landing themselves with our railways. That, I think, is wrong. If shrewd business men can acquire a going concern that can be worked for perhaps one-third less, and if they are enabled to build all the new lines on fair margins of profit, it is not unreasonable to

expect business, not to-day perhaps but when money becomes easier and prospects brighter. In America investors always want to know whether the goods are there. Well this country has got the goods and plenty of them, but does it handle them rightly? They say in the States, "I come from Missouri and I want to know."

Swazi Tin.

A YEAR'S RESULTS.

In the course of the annual report, Mr. T. Kelly, the Manager of Swazi Tin, shows that the working profit for the year was £10,825 2s. 10d. The quantity and quality of the ground cut were practically the same as those of last year. A comparison of the year's results with those of the two previous years is as follows:—

	1920-21.	1919-20.	1918-19.
Cubic yards treated during year	916,787	957,906	1,091,531
Cubic yards treated, average per month	78,899	79,826	90,961
Lb. Concentrate recovered per cubic yard	0.710	0.695	0.75
Grade of Concentrate per cent, Metallic Tin ...	69.7	70.6	70.7
Lb. Metallic Tin per cubic yard	0.495	0.491	0.531
Average value realised per cubic yard	9.015d.	13.694d.	11.683d.
Average cost per cubic yard	6.271d.	8.700d.	8.254d.
Average profit per cubic yard	2.744d.	4.994d.	3.429d.
Average Metal price realised per ton	£186.607	£299.775	£241.055

(The costs given include all General Charges and Head Office Expenses.)

It will be noted that the working costs show the big reduction of 2.429d. per cubic yard. The year's cost is also 0.326d. lower per cubic yard than our previous best year, that of 1914-15, and £34 6s. 11d. per ton of dressed concentrate less than 1919-20. This big reduction is partly due to the fact that, having purchased the adjoining Indimba Concession, we controlled an ample supply of conveniently placed water under sufficient pressure to raise gravel the required height in our Lower Mbabane workings—the main workings this year—and thus substitute hydraulic for the three mechanical elevators in use last year.

Anomalous State of Labour Conditions on the Rand.

MR. M. FERGUSSON'S OUTSPOKEN VIEWS.

Mr. M. Fergusson, the Inspector of Mines, Krugersdorp District, is noted for the outspoken views he contributes each year in his annual report to the G.M.E. His report this year has the following noteworthy passages.

Most of the mines in this district are low-grade mines, and the majority of them have been on the verge of closing down for some time past on account of the increased costs, due largely to enhanced cost of stores, increased wages paid workmen, diminished output resulting from shortage of native labour and strikes, reduced hours worked, and general inefficiency.

These mines have just managed to keep going by reason of the inflated price of gold, the premium averaging about sufficient in value to offset the increased costs. Certain of them, however, have been forced to abandon development and are gradually working to a standstill. One great stumbling-block in the way of progress in these poor mines is the difficulty of adapting the white supervision to suit the requirements in connection with the employment of the native labour to the best advantage and at the same time keep within the letter of the law and avoid falling foul of the Unions.

Treatment of the Native Worker.

Under existing conditions the natives enter the mines between 5 and 7 a.m. and are all waiting to start work by the latter hour, the official time for commencing shift. The white men follow the natives, and before work proper is started certain preliminaries have to be observed, such as examination and making safe of working places. Consequently many natives, although they are in the mine at perhaps 5 o'clock, cannot get started until 11 or even later, thus losing over half the shift in idleness whilst awaiting permission from their white supervisor to commence. The native must be paid for his shift, so the only loser is the company employing him. At the same time the native would much rather be doing his job, which is often a set task, the completion of which releases him for the day. Any attempted relaxation of the regulations in order to enable the natives to start earlier is jealously resisted by the unions, who dread the least suspicion of a native being permitted to lift a hand without the formality of a white supervisor's authority. The Unions contend that certain work is skilled work and therefore must only be performed by white men, presumably on account of their superior knowledge, experience, and sense of responsibility, yet white youths who hold no certificate, and who have only been in the mines for a few months, are permitted to take control of gangs of natives on the night lashing shift, for instance, where the services of an experienced miner are particularly necessary in judging the safety of the ground in places where such gangs have to work. It does not appear logical that because a man is white he should be able to become a skilled miner within a few weeks or months, and if he is a black man a lifetime's experience in the mines does not enable him to gain sufficient knowledge to form an opinion as to the safety of himself and his fellow-workmen. If all the white men employed in responsible positions in the mines were qualified miners, capable of using their knowledge and experience to the best advantage in obtaining the highest results from the gangs under their charge, there might be a lot to be said in favour of the existing conditions of labour, but where large staffs of highly paid white men—many of whom are of no benefit to the company—have to be employed simply because the law or the unions demand it, many mines will be rendered unpayable which, if worked on a purely economical basis,

would continue for many years to carry on operations at a profit to the shareholders and to the benefit of large staffs of employees.

High Wages and High Working Costs.

High wages do not necessarily mean high working costs, as was proved in America before the war. In that country wages in many industries were higher than in any other part of the world, and yet by reason of the great efficiency of the workmen and the systematisation of the work, America was able to send her products abroad and compete with all foreign markets. In this country the high wages exist, but it is to be feared that to a very large extent the other factors mentioned are lacking. As has been pointed out on previous occasions, the white workmen on these fields may be divided into two classes: (a) the skilled workman, and (b) the unskilled or partially skilled workman. Those included in the first class know what is expected of them and know how to calculate the cost of their labour and the value of the product. Very little is ever heard of them. They perform their work in a thorough and conscientious manner and give satisfaction to themselves and their employers. Such men are naturally in great demand, and there is a tendency to secure their services by offering them substantial rewards for their labour in the form of big wages or highly remunerative contracts. Those included in class (b) are more difficult to deal with. They do not always understand the work, and in some cases do not attempt to learn it. Their whole object in coming to the mines is to obtain the highest wages possible without considering the value of the work which they give in return. Where these men are concerned it is

PHONE 4673 BOX 3162

 SHEFFIELD & JOHANNESBURG.

frequently found that they are merely lookers on whilst the more intelligent natives amongst their gangs are doing the skilled part of their work. They see men included in class (a) drawing big cheques and they agitate for increase in pay, because they consider they are entitled to as much as anybody else. Certain duties become irksome because they do not understand how to perform them, and consequently they are inclined to dictate to the managements what work they shall do. Such men are extremely difficult to control, and where they have a difference of opinion with one of the officials they endeavour to use the whole weight and influence of their Union to obtain their individual ends. This is made easier for them by the fact that it is not always that class (a) men can be found to take office in the Unions' services, their time being generally too valuable to spend in listening to the numerous complaints which they would be required to investigate. It is generally accepted that there are a number of men working on the mines to-day who are neither experienced nor industrious; consequently it is surprising to find that any attempt on the part of the employers to get rid of such incompetent persons is often strenuously opposed by the body of workmen.

A One-sided Argument.

Several mines in this district have been faced with the alternative of closing down completely or retrenching a proportion of their white employees, and where such retrenchment has taken place strong representations have been made by the Unions, and acquiesced in by the heads of the industry, that every endeavour shall be made to absorb in other mines all those discharged. This agreement is difficult to understand, since one would naturally expect that the incompetent and unsatisfactory men would be the first to be dismissed, and the result of the above agreement is that some men who have proved themselves to be incompetent at one mine are given a guarantee of re-employment at another. There can be little doubt that numbers of men were attracted to the mines during the past few years by the high wages easily gained without the necessity for any preliminary knowledge or training. Such men are not like old miners who have spent their lives at the one occupation, and are consequently unable to adapt themselves to any other calling. Many of them have been mining for so few months that it would be no hardship to send them back to their original occupations. That the position is as here stated is proved by the fact that mines which have retrenched 20 per cent. or more of their white complement are producing just as great a total tonnage per month as formerly at a considerably less cost. It certainly seems unreasonable that because a man has once obtained an engagement in a mine he should expect to be clothed, housed, fed, and have his pockets kept filled with money for the rest of his life, irrespective of what he gives in return. Some of them seem to forget that there are two sides to every bargain, and since wages are standardised, and consequently must be paid in full, the employer must have the right to balance the account in some other way, such, for instance, as choosing his workmen.

At some of the mines attempts appear to have been made to force the management to agree to an arrangement whereby any vacancy occurring shall be filled by an employee of the mine engaged in a lower class of work. For instance,

if a stoper is required, the manager is not permitted to engage a stoper from outside, however good his record in that class of work may be. The vacancy must first be filled by some one working in the mine, say, a trammer. If that trammer has had no experience of stoping before, it makes no difference; he must be given the opportunity. Consequently he is put into the stope to show what he can do. If he gets the place into bad shape and proves himself incompetent, he may be removed, but must be replaced by the next in seniority, and so on. How anyone can expect efficiency under such conditions passes all comprehension.

Mine officials charged with the safety and control of workmen have not yet recovered from the shock which they sustained during a previous period when a conflict between themselves and a body of workmen almost invariably resulted in the discomfiture of the official, whatever the merits of the case. Consequently it frequently happens that one finds offenders against the rules of safety or health are not dealt with in a disciplinary manner, the official whose duty it is to note such often preferring to ignore the irregularity and risk the danger rather than face the possibility of being reported for officiousness by the Grievance Committee. This attitude is naturally reflected in the accident rate, which, as will be noted from the section dealing with accidents, shows a step backward.

TRANSVAAL GOLD MINING ESTATES.

The following are the particulars of the output for the month of August, 1921, in respect of the above company:—
Central Mines: Tons crushed, 12,000, yielding 3,583 fine ozs. Elandsdrift Mine: Tons crushed, 1,500, yielding 774 fine ozs. Vaalhoek Mine: Tons crushed, 1,800, yielding 625 fine ozs. Estimated value of month's output, £27,271; estimated profit for month, £5,414. The month's results are based on value of gold of £5 9s. 9d. net per fine oz.

H.E. Proprietary.

With its report for 1920 the H.E. Proprietary (New), Ltd., is in the pleasing position of being able not only to make a start of dividends with a distribution of sixpence per 10s. share for the past year, but also to announce an interim payment of like amount for the current year. The profit and loss account shows a surplus of £18,230, against £12,450 for 1919, and after payment of the 1920 dividend of sixpence there will be £4,522 to be carried forward. The directors state that in their opinion the aggregate value of the assets on a conservative estimate exceeds the total of £324,000 appearing on the liabilities side of the balance-sheet in respect of share capital, creditors and balance of profit and loss account. Active development of the Farm Klippoortje on the Far Eastern Rand is postponed until conditions on that field have become more favourable, both as regards labour and working costs.

The Rise of the Trade Union in South Africa.

HISTORY OF THE GROWTH OF THE MOVEMENT DESPITE MANY SETBACKS.

An important volume of social and industrial statistics has been issued by Mr. C. W. Cousins, the Director of the Census. It provides a valuable survey of industrial organisation in South Africa and a record of real historic interest of the growth of the Trade Union movement in this country, particularly in connection with the mining industry. From the survey we take the following:—

Until comparatively recent years trade unionism did not figure largely in South African life and conditions. In an earlier period the organisation of labour on trade union lines was practically confined to carpenters and joiners, engine drivers and firemen, the engineering and printing trades and occupations on the Witwatersrand gold mines. The Amalgamated Society of Carpenters and Joiners was established in South Africa in 1881; the Iron Moulders' Society in 1896; and the S.A. Typographical Union and the S.A. Engine Drivers' and Firemen's Association in 1898. For some years prior to the constitution of the Union, organised workers on the Rand were represented by the Witwatersrand Trades and Labour Council. In 1911, the Transvaal Federation of Trades was established, and this organisation, to a large extent, assumed the function of the Council, eventually doing so entirely. Following on the industrial troubles of 1913 and 1914, the S.A. Industrial Federation was brought into being. Thus the growth of the trade union movement is reflected in a most interesting review published by the Government, in addition to the usual details concerning rents and the cost of living.

Federation Recognised.

In 1915, for the first time, the Chamber of Mines conceded practical recognition to the Federation on direct representation by the Minister of Mines and Industries. The Federation had much to do with the inauguration of the shop steward movement on the mines, in the power stations and railway workshops. In 1917 the first trade union congress held in this country was held in Johannesburg, being organised by the Federation. Smaller bodies, representative of various occupations, were then linked up, under the name of the S.A. Industrial Federation Industrial Union. As a result of the Labour Charter of Versailles, a reconstitution of the Federation took place under a system of National Industrial Departments. The recent tendency has been towards the affiliation of various organised bodies of workers with large industrial organisations.

132,000 Trade Unionists.

Figures of trade unions and other associations of employees show there are seven mining unions, with a membership of 22,516; seven State service unions, with 44,647 members; five teachers' services, with 4,912 members; eight engineering and metal working, with 11,369; and six building unions, with 9,404; or a total of 90 unions, with a membership of 132,784 as at December 31, 1920. In some cases, craftsmen and others are members of more than one union, and these duplications have not been accounted for in the above figures. Most skilled mechanics in the service of the Railway Administration are members of craft unions and not of railway unions. These are not included in "State Services." A glance down the list shows a great variety of trades included in the list of the 90 unions. A few statistics are also given with regard to employers' associations. These include the Transvaal Chamber of Mines, with 80 members; 61 chambers of commerce, with 2,878 members; and six manufacturers' associations, with 421 members.

Hours of Labour.

The hours of labour worked by Europeans in the Union in various branches of industry show, we are told, a tendency to uniformity, and during and since the War a ten-

dency to reduction. In the gold mining industry of the Rand the weekly hours worked by surface hands in 1896 and some ten years after were 56. By 1910 these had dropped to 51, while the 48-hour week was started in 1915. Underground employees on the gold mines were working a 60-hour week in 1896, 57 hours in 1910 and 48½ in 1918. Underground workers on coal mines were doing a 57-hour week in 1902. This was reduced to a 54-hour week early in 1920, and to 51 and 48 respectively later in that year. On the railways the principle of the 48-hour week was accepted as from December 26, 1919. In engineering trades a 54-hour week was the rule, a 48-hour week being introduced in some cases in 1916. In 1920 48 hours was the rule, with a few exceptions of 44 hours. In electrical trades 47½ hours is the average. In the building trade the 48-hour week, which had been in existence for some years, was reduced to 44 hours in 1919. In 1895 printing employees worked a 50-hour week. In 1914 this became a 48-hour week, except for typesetting machine operators on day work, who have worked a 45-hour week since 1910, and, on night work, a 42-hour week. The present working week consists of 46 hours for day workers (except typesetting machine operators, who work 43 hours) and 40 hours for night workers. The hours of labour in manufacturing industries, except for furniture makers and craftsmen in other woodworking trades, have been generally longer than those obtaining in the other skilled trades. Under the Union Factories Act, the maximum number of hours that may be performed by persons over 16 years is 50 hours per week. Shop hours vary from 48 to 50 hours. "In many occupations, e.g., clerical callings, and those of hotel employees and similar workers, the hours worked are so varied as to render it impossible to determine even an approximate average working week," says the report.

Wages in Building Trades.

A comparison of wages paid in the building trade in South Africa with those in other countries shows that at December, 1920, 16s. 9d. was paid in South Africa; 16s. 4d. in Canada, and 10s. 10d. in the United Kingdom, the purchasing power of the sovereign being 11s. 11d., 12s. 11d., and 14s. respectively, making the "real" wages 1011, 1121, and 728, and proving that Canada has a slight advantage, while Union conditions compare very favourably with those of the United Kingdom. Some figures as to the industrial disputes show that the first of any size was the strike on the Rand gold mines in 1907, which lasted six weeks, and cost £250,000 in wages. In 1910, conciliation boards were appointed under the Transvaal Industrial Disputes Act. After describing briefly the disputes of 1913 and 1914, the report states that two disputes occurred in 1915, 10 in 1916, 22 and 23 in 1917 and 1918 respectively, and 47 in 1919, involving 24,000 workers. The increase in the cost of living is assigned as a reason for this increase. A feature of the 1919 troubles was the number of coloured workers concerned. Thanks to the machinery provided for settlement, none of the disputes lasted long. The action of the Chamber of Mines in utilising boards of reference was also an important factor in maintaining industrial peace. In 1920, voluntary arbitration was applied in several important disputes, apart from the mining industry.

Willoughby's Consolidated.

How substantially the position of Willoughby's Consolidated has improved may be gathered from the following facts. On January 1, 1918, the debenture debt stood at £152,000; to-day it is £71,000. The cattle were valued at that date at £70,000; to-day the valuation is £100,000. At the end of 1917 the figure against creditors was £47,250; at the end of 1920 the figure is £7,500. The profit on land sales to be recovered by instalments on December 31, 1917, was £8,580; at the end of 1920, £16,376—practically double the amount—and in these three years the company has written down its shares in subsidiary companies by no less than £54,000.

THE DAVIS SLIDE RULE

WITH CELLULOID FACINGS—
FOR ALL TECHNICAL CALCULATIONS

THE calculations that may be performed by the aid of the slide rule are endless in number. In addition to the ordinary process of multiplication, evolution and involution, it may be used for a variety of technical calculations, in which its use effects an enormous saving of time. Thus, the engineer may compute the strength of beams, moments of inertia, horse-power of engines, hydraulic formulac, areas of circles and ellipses, cubic contents, weights, conversion of British into metric and other systems of measurement, without putting down a single intermediate quantity. The electrical engineer may solve all problems involving the application of Ohm's law of the relation between current, electro-motive force, and resistance. The surveyor may plot surveys by rectangular co-ordinates and set out curves.

This Davis-made 10-inch Slide Rule can be supplied from stock.

THE GOVERNMENT AND MINING DEVELOPMENT.

Some welcome signs of a more progressive spirit are traceable in the annual reports of the Secretary for Mines and Government Mining Engineer, issued this week. The latter report particularly is a monument to the Department's passionate zeal for statistics, but it is doubtful if the cost and trouble incidental to their compilation are justified. The average man will scan both reports mainly with the object of finding some practical evidence of special recognition of the need for encouraging the development of the mining industry of the Union. It is this often-forgotten aspect of the activities of the Mines Department that is, to our mind, of chief importance, and the whole tendency of events of late has been in the direction of emphasising this fact. Of course, allowance must be made for the unavoidable interval that must elapse between the actual writing of

the reports under review and their publication in book form. Against this must be set the fact that, in practice, the directions in which the public body, the Government, are rendering aid to the threatened gold mining industry are familiar, if not "hardy annuals," and the recent troubles of the industry have merely brought them more into the spotlight. We refer, of course, to such long-urged reforms as amendment to the Gold Law, reducing claim licences, and direct State encouragement to mining and prospecting. By their recognition of the need for these things, we purpose here to judge the reports of the heads of the Mines Department before us. It is a big step forward that Mr. Warrington Smyth, the Secretary for Mines, in his report, frankly admits the need for substantial amendment of the Gold Law. After all, the Secretary for Mines has the ear of his Minister and of the Government in regard to Parliamentary matters, and if he is satisfied that the Gold Law should be improved, he has the remedy almost in his own hands. "With the changing conditions on the Witwatersrand, due to the gradual exhaustion of the reef underlying proclaimed areas and the urgent need of such land for housing and industrial purposes as well as for small holdings, it has become apparent that considerable modifications of the provisions of the Gold Law have become necessary in order to meet the new conditions," he writes. "It became apparent during the year under review that these and other questions in regard to the use of the surface of proclaimed ground on the Witwatersrand were assuming considerable importance, and, as the whole subject is one of much complexity, affecting as it does the reversionary rights of the freehold owner, a Committee was appointed to enquire into these difficulties and to draft provisions amending the Gold Law in such a way as to meet the changing conditions on the Witwatersrand." We can but suggest that when the Gold Law is thus in the melting pot, advantage ought to be taken of the opportunity to make it a measure designed to encourage mining expansion in every possible manner. The inspectors of his own Department who have during the past year written such excellent articles on the "Ideal Mining Law" can furnish the Secretary for Mines with all the details necessary under this head. Indeed, under a section of his report dealing with "Minerals reserved to the Government," Mr. Warrington Smyth himself admires certain important reforms and mentions that the Departmental Committee has now submitted a Draft Bill for the consideration of the Government. The only comment we have to make regarding this is that it is a pity to tackle the matter in piecemeal fashion: The Gold Law, as a whole, should be amended in accordance with the spirit of the times, the crying needs of the country, and the opinions of the more progressive officers of the Mines Department itself. What those opinions are may be seen from the following extract from the report of Mr. Tudor Trevor, the Inspector of Mines for the Pretoria district, who has always been noted for his plain speaking. He writes: "As before stated, the mining industry in this district has, notwithstanding the setback due to the war period, advanced 67 per cent. in the past decade. I fancy that no such increase has taken place in any other inspectorate. Apart from the increase in the value of the coal and diamond output, I believe I can fully claim that this growth has been largely due to the assistance given by the Government through this Department and the Geological Survey. I would strongly submit that this assistance be continued and expanded, as has been constantly advised in other reports. The increase has been entirely due to the activity of small men, buoyed up by optimism, but usually extremely ignorant of their subject. They rely entirely for technical advice on the scientific brains of the Government Service, and that reliance has been justified, and the cost of those services is proving an excellent Government investment, although there is still room for great expansion." This, we submit, is the spirit that should pervade the whole Department, if it is going to be of real assistance to the cause of mining advancement. The attitude of the Government towards agriculture and the minor industries is one of wholehearted enthusiastic support, which we would like to see extended to mining. Too long has this last been the Cinderella of South African industries and the

Departmental attitude towards it a cross between that of a policeman and an unsympathetic big sister. Mining enterprise must be encouraged at least in the same generous measure as other industries are encouraged, and the restrictive provisions of the present Gold Law must all be removed with the least possible delay in order that the industry may realise its full possibilities.

Notes & News.

New Union Loan.

The fact that nothing has lately been heard of a Union loan has attracted comment. Sir Thomas Smartt threw light on the matter at an election meeting at Capetown last week. "There are great possibilities of industrial development in this country," declared the Minister, "but, however much you howl about it, you must have capital, and to get capital you must have a stable Government. I have reason to believe, from the position which South Africa now occupies, that we shall be able to float a loan shortly which will very materially assist us in the development of our industries."

Globe and Phoenix.

An official report from Rhodesia gives the estimated ore reserves of the Globe and Phoenix Gold Mining Co., Ltd., as at June 30 last, at 89,491 tons, containing 136,026 ozs. of gold, or an average of 30.39 dwts. per ton. This represents a further falling off from the figures at December 30 last, namely 93,852 tons, containing 145,321 ozs. of gold, or 30.9 dwts. per ton. Moreover, at that time—and no doubt it is still the case—nearly half the reserves, namely 46,472 tons, were locked-up in pillars and therefore not available for treatment until the levels these pillars support are abandoned. On the current basis of treatment the reserves are only about fifteen months ahead of the mill, but apart from the prospect of further discoveries on the ground the company is at present working, there is a good chance, as announced at the Rhodesia Exploration Company's meeting, of an arrangement being come to with the latter concern for the working of a number of claims which it owns in the vicinity of the Globe and Phoenix.

Inflation in Germany.

The London Daily Telegraph of August 17 contains the following:—There was another sensational fall in the sterling value of German marks, which at one time touched 342 to the £, and the closing rate of 332 only showed a moderate recovery. Early in March last year 365 was reached, which has been the record so far, but from that point there was a rapid improvement, until 120 was touched in May, 1920, when depreciation once more commenced. But there is a wide difference between the rate of 169, which was ruling about this time last year, and the present rate of 332. Reparation payments undoubtedly explain a good deal of the movement, in addition to which Germany has been making large purchases of wool, but over and above these causes there is the constant increase in the note issue, by which alone the national finances are made to balance. A comparison of some of the principal items in the returns of the Bank of Germany is instructive:—

	(000's Omitted.)	Aug. 6, 1921.	Aug. 7, 1919.
		M.	M.
Gold		1,091,554	1,108,010
Discounts and Treasury bills...		75,129,862	28,545,490
Note circulation		77,654,680	28,856,004
Private deposits		7,482,129	8,322,242

It will be seen that within the last two years the note circulation has risen by 49,000,000,000 marks, and has, in fact, more than kept pace with the increase in bills discounted, which are almost entirely Treasury bills. The country is therefore being run by the printing press, and the only question is how long the process can continue before the inevitable crash occurs.

A New Crusher.

Our representative was present at the trial run of a crushing machine of an entirely novel character which was shown by Mr. Stockman, one of its inventors, at Messrs. Wright and Boag's yard during the week. It will run again at the same place on Monday, the 19th, at 2.30 p.m. Messrs. Bleloch and Stockman extend an invitation to any one to attend there, who is interested in the reduction of ore, whether in a small or large way. This invention aims to do away entirely with the use of gravitation stamps and the effective crushing capacity of the small machine which was shown is most remarkable. A fuller description of it will appear in a later issue.

International Chamber of Commerce.

The first meeting in London during the past month of the new International Chamber of Commerce was an occasion of great interest and importance. In spite of the present unfortunate condition of international trade, we believe that no moment could be more propitious for such a gathering (says the "Empire Mail.") The more business men of all nations put their heads together to find some common plan for healing the economic wounds from which the world is suffering as a result of the War, the sooner will the vigour of financial and commercial health return to all countries alike. The late War taught us many lessons, but none more clearly than the need for international co-operation. In no department of life is that co-operation more necessary than in business. Trade in the modern sense is a world-embracing process, and nation depends on nation for the fulfilment of its needs and the enrichment of its coffers. Those who have been responsible for the organisation of the International Chamber of Commerce are fully aware of these things and they have determined that so far as in them lies they will foster common action in regard to the matters that intimately affect international trade. A perusal of some of the principal decisions arrived at by the Conference is in itself a proof of the immense value of such a body at a time like the present. If those decisions can be translated into practical measures for the alleviation of the world's existing financial and commercial troubles, no peoples will be more grateful than those of the British Empire.

Ex-Enemy Shares: Official Announcement.

Sir Walter Hamilton Fowle, K.B.E. (Custodian of Enemy Property), Mr Charles Pienaar (Government attorney) and Mr. S. Y. Eales (of the Custodian's Department) are proceeding to England on September 23 to discuss the ownership of enemy shares held by the Public Trustee in England and the Custodian of Enemy Property in South Africa, and to settle any doubtful points. An official announcement on the matter was issued this week. It says: "As the result of discussion in London between the Prime Minister of the Union and Imperial Government representatives in connection with ex-enemy mining shares in companies in which both the Custodian of Enemy Property and the Public Trustee have holdings, certain principles with regard to the allocation have been agreed upon, and it has also been agreed that arrangements should be made for dealing jointly with such shares. Representatives of the two Governments will meet at an early date in London to settle the jurisdiction under which certain of these enemy shares fall—the ownership of which is in doubt as the result of dual vesting, etc. This investigation will prevent possible over-lapping. The Union Government is well aware that in present circumstances the market cannot rapidly absorb large blocks of shares and that it would be difficult to raise the capital required to finance the carrying of such shares pending their absorption. Accordingly, in any arrangements which may be made for the joint disposal of the shares held by the Public Trustee in London and the Union Custodian, due regard will be given to this aspect of the question, and it is hoped as far as possible to avoid any action which may have the effect of unfairly depressing the values of these securities."

The Tin Position.

As in the case of copper, a drastic reduction in the world's output of tin has so far failed to bring supplies below the rate of consumption, which would naturally raise the price and start the desirable process of wiping out accumulated stocks. At the end of July the total visible supplies of the metal are estimated by one authority at 19,438 tons and by another at 19,852 tons, in both cases representing an increase of nearly 3,000 tons on the month. Since the Armistice the high level of visible supplies was nearly 24,000 tons in October, 1919. But whereas during the year ended July, 1920, the supplies which came forward totalled 95,500 tons, in the past twelve months they have been, according to Messrs. Ricard and Froivald, only 55,400 tons. The considerable stocks bought at high prices and held up by the Federated Malay States and Dutch East Indies Governments are not included in the statistics. The gradual restarting of the Welsh tinplate mills should help to improve the position, but there will not be a real revival until the United States is in a position to buy largely. Meantime only high-grade or exceptionally cheaply-worked tin mines can at present produce at a profit, and that is assuming they can sell the whole of their output regularly.

* * * *

Oil in Angola.

While there are many and varied mineral resources in the hill districts of Angola, the chief interest at the present time centres in the accessible oil area near the coast, where river, as well as railway, communications are available for transport to Lobito Bay, the port of shipment. The existence of oil in Angola is no new discovery, for Portuguese official reports as far back as 1844 referred to extensive deposits of petroleum, almost all of which were stated to be situated at points near the coast or near navigable rivers. But prospecting was slow, perfunctory and ill-directed, with the result that operations were carried on much too far to the north. There was a revival of prospecting by American, Belgian, and other capitalists prior to the war, but little was done in the way of systematic survey till the American Petroleum Company struck a very promising area just north of the Benguella Railway and started active exploitation. Till recently it had seemed that British enterprise was either indifferent or uninformed, but it is reported from London that an important concession, favourably reported on, has been acquired by British interests. It is a huge concession comprising an area of 107,000 square miles from the coast inland, with a coastal extension of 250 miles from the Benguella Railway southward to Port Alexandria.

* * * *

The Mining in the F.M.S.

Last year's export of tin from the Federated Malay States amounted to 34,935 tons, valued at £10,316,737, compared with 36,935 tons in 1919 valued at £8,736,474. In 1918 the exports amounted to 37,370 tons. In his annual report, Mr. A. R. Mynott, A.R.S.M., Acting Senior Warden of Mines, F.M.S., states that at the opening of the year the price of tin on the local market was 167.50 dollars per pikul, with the market rising. The rise continued rapidly, until at the end of February the unprecedented high price of 212 dollars was reached. Thereafter a reaction set in, and the price began to decline. With the exception of a slight rally about the middle of the year, the fall in price continued until, at the beginning of December, it stood at 90 dollars per pikul. The position at that time became so critical that to save a large number of the mines from closing down, and the consequent dislocation of labour that would ensue the Government decided to purchase. From December 14 the Government were purchasing at 110 dollars per pikul which price was raised on December 21 to 115 dollars and that was the position at the close of the year. The highest price reached was 46 dollars per pikul above that attained in 1919, and the lowest price touched was 10 dollars below the similar figure for the previous year.

The fluctuation was 122 dollars in the year under review, as compared with 66 dollars in 1919. On the London market the highest three months' price reached was £123 10s. per ton and the lowest £200. From March onwards, a rapid decline in price was experienced. The market eventually collapsing towards the end of the year, the average price for the year being £297 5s. 11d. The extraordinary rapid rise in the price at the beginning of the year was due chiefly to the operations of speculators, and the reckless buying was no doubt due to the erroneous deductions that a falling off in production was anticipated, with consequent reduction of supplies, that the Central European Powers would be in a position to assimilate amounts approximating their pre-war requirements, and that consumption in the United Kingdom and America would increase. The slump at the end of the year was due to a variety of causes, chief among which was the reduced consumption demand, the unexpected unloading of stocks of Dutch tin on the London market, liquidation of large stocks of Chinese tin which had been held up in Chinese ports owing to the high price of silver at the beginning of 1920, the disorganisation of the Welsh tinplate industry towards the end of the year, the instability of exchange, and the general labour unrest. The outlook at the end of the year was not encouraging, and general conditions were bad, and no improvement in the market could be anticipated while the depressing influences mentioned above were in evidence.

* * * *

The Banking Position.

The quarterly statements of the banks as at June 30th last show that the downward trend in deposits, which has been in evidence since the second quarter of 1920, still continues. The following table gives the totals for each quarter since the maximum was reached in March, 1920, and it will be noticed that the fall has been more rapid during the last quarter than in any previous period:—

Date.	Total Deposits.
March 31, 1920	£117,311,183
June 30, 1920	110,159,379
September 30, 1920	104,452,391
December 31, 1920	102,331,940
March 31, 1921	99,570,923
June 30, 1921	91,405,750

The total advances of the banks continued to increase until September, 1920, since when they have continuously declined, but the ratio of advances to deposits shows little change, and the high figure of approximately 87 per cent. is evidence of the efforts made by the banks to finance the country through difficult times. The totals since March, 1920, are as follow:—

Date.	Total Advances.	Percentage of Deposits.
31st March, 1920	£87,634,741	75
30th June, 1920	89,698,887	81
30th September, 1920	94,399,028	90
31st December, 1920	91,138,022	89
31st March, 1921	86,355,100	87
30th June, 1921	79,263,799	87

Bank notes in circulation at £8,978,869 show a reduction of £282,109 compared with March last, the decrease probably being due to the prevailing condition of trade. Cash on hand, which now includes gold certificates and the balances of the commercial banks with the Central Reserve Bank, totalled £14,144,680 at June 30th, as against £13,016,750 at the end of March. Under the Currency and Banking Act, passed last year, all banks in the Union are compelled to maintain with the Central Reserve Bank fixed percentages of their deposit liabilities and the total of the Commercial Bank balances with the Reserve Bank at the 30th June last was £5,697,100. Gold certificates held as part of the cash balances at the same date amounted to £3,967,259.

Metal Market Report.

In the metal market last week's improved conditions continued until the middle of this week, when the markets became reactionary. Satisfaction is expressed at the trade returns for August, which show some improvement. The monetary conditions are easy. Trade reports from Germany are fairly satisfactory, but the violent speculation on the Berlin Bourse cannot fail to have a harmful effect. Copper was steady during the week. The recovery of American consumption had an important effect on the sentiment. German purchases contributed to the improvement, but the depreciation of the mark stopped buying from that quarter. Tin advanced on influential buying for Eastern smelters and the reluctance of sellers and on an increased demand from the Continent. However, the immediate outlook is not encouraging for the English tinplate industry. As regards lead, the general position is unchanged. The opinion is expressed that in view of the short shipments the revival of the home demand in the near future will quickly influence the market. The Continental offerings of spelter were very limited, and the demand was small. However, there are indications of an improvement in the galvanised iron trade.

The ordinary general meeting of the Chemical Metallurgical and Mining Society of South Africa will be held in the Scientific and Technical Club, 100, Fox Street, Johannesburg, on Saturday, the 17th inst., at 7.45 p.m.

The Gold Law and Mining Areas.

"With the changing conditions on the Witwatersrand, due to the gradual exhaustion of the reef underlying proclaimed areas and the urgent need of such land for housing and industrial purposes as well as for small holdings," says the Secretary for Mines in his annual report, "it has become apparent that considerable modifications of the provisions of the gold law have become necessary in order to meet the new conditions. The many existing buildings on worked-out mining ground, the surface of which is mainly occupied under permissions restricting its use for purposes of, or incidental to, mining, have now become practically valueless to the former mine owner, unless he be also the owner of the freehold of the land. It appears necessary to provide some machinery whereby these buildings may be made use of for other purposes by the owners of the buildings, subject to the rights of the freehold owner. As the law stands, when a mine becomes exhausted the mine owner, unless he is also the freehold owner, is confronted with the prospect of selling valuable buildings at their break-up value. Heavy penalties are provided in the gold law, in the event of these buildings being used for any purposes other than those connected with mining, but if the mine owner is also the owner of the freehold he has, of course, only to await the deproclamation of the land to obtain unrestricted use of them, and of the surface of the land generally. It is, therefore, at this stage that the question of deproclamation arises, *i.e.*, freeing the land from the restrictions imposed upon it by the gold law, and it would appear that, as a preliminary, some machinery should be provided to protect the owners of the numerous dwellings and other buildings, regard being had to the rights of the owners of the soil. Considerable areas of proclaimed land on the Witwatersrand have also been utilised for many years for municipal and other purposes under permissions granted in terms of the gold law and it should be possible for the Legislature to provide some equitable means for the continuance of these occupations after deproclamation where necessary."

The Week in the Sharemarket.

A SET-BACK—PRICES LOWER AND BUSINESS LESS—WAITING A LEAD FROM LONDON—S.A. ALKALIS AND ROOIBERGS.

The cessation of buying from London has led to a set-back in business during the week, and at the time of writing prices have receded and business has fallen off considerably. The official statement regarding the ex-enemy shares means more delay under that head, and has been a little disappointing. It is clear, however, that the Prime Minister now recognises the necessity for finally settling this matter, and has instructed the Custodian of Enemy Property accordingly. The settlement of the labour troubles on the Far East Rand mines, the Modder B and Van Ryn Deep has been followed by the threat of a railway strike. This could hardly be a protracted affair, and the Railway Administration seems to have no option but to enforce its programme of economies. The Government has decided to issue a substantial loan for development purposes almost immediately, and this should help to brighten the general business position. The August gold output figures are very satisfactory, and the month was quite the best from the profit-earning point of view for the year. Nevertheless, the spurt in gold shares has not been maintained, though the price of gold continues to stand in the neighbourhood of 110s. per oz. Diamonds likewise are easier, after some activity, particularly in smaller priced shares. The reports from the diamond centres continue to be most favourable, but it is thought that no great change for the better can take place before the end of the year. The news of the wild speculation in Berlin is not encouraging, and there is no doubt that all markets, ours included, are suffering from the exchange and currency chaos. Until something is done in this direction, it is held in authoritative quarters that markets nowhere can improve very much. Apart from gold and diamonds, there is little to report locally. Shale oils are firmer on better reports from the African and Wakkerstroom properties. Tins are quieter than ever, and Rooibergs contemplate further restricting their already limited operations. S.A. Alkalis are said to be about to issue £50,000 debentures, which are to be taken up by Sir Abe Bailey, and the shares have been easier as a result. Colliery shares remain quiet with Natal Navigations and one or two others firm.

Rhodesia Exploration.

The Rhodesia Exploration Company holds a half interest in coal rights on 18 farms in the Middleburg, Carolina, and Ermelo districts, valued by Mr. C. L. Kessler, a director of the Tweefontein Colliery, at £145,000. It is also concerned in the Far East Rand to the extent of holding a five-sixths interest in the farm Maraisdrift, comprising 4,570 acres, as to which Mr. G. A. Denny made an exhaustive report a year ago. Further investigations conducted during the past year tend to confirm the broad conclusions stated by Mr. Denny, and the board considers that this asset will prove to be one of great importance and value. The company's interest in asbestos and chrome is represented by shares and debentures in Rhodesia Base Metals, Ltd. Up to date the investment has cost £27,000. Mr. Denny, who has just returned from Rhodesia, states that the chrome property covers an area of about 7½ square miles on the Umvukwe Range, Mashonaland. Several separate beds of chrome are found on it in a trough-shaped formation on which extensive prospecting stripping work on the outcrops has been carried out. From the outcrop stripping several thousands of tons of chrome ore have been accumulated, and bulk supplies up to several hundreds of tons in weight have been sold. The average contents of the whole of the ore so far won exceeds 50 per cent. chromic acid. The demand for chrome steels is world wide, and increases with the expansion of the steel industry. The world's deposits of high grade ore are few. "This deposit in its extent, regularity, and average high grade ore," Mr. Denny says, "may claim to be potentially one of the most important ever discovered." He adds that it is bound to become one of the great producers, to satisfy the enormously growing demand which there is for high grade ore, a demand which only waits the cheapening of manufacture to grow to proportions now hardly thought of.

The August Output in Detail.

AN INCREASE OF £88,010—BETTER NATIVE LABOUR FIGURES—BEST MONTH'S PROFITS OF THE YEAR.

An increase of 21,971 ozs., value £88,010, is shown by the Transvaal gold output for August, which was declared by the Chamber of Mines on Sept. 10. The totals for the past two months are as follows: August, 711,526 ozs., value £3,966,757; July, 689,555 ozs., value £3,878,743. The value of the gold produced in August was taken at £5 11s. 6d. per ounce, as against £5 12s. 6d. for July.

For the first time for many months the native labour figures show an improvement, the number of boys employed on gold mines in August being 169,008 compared with 166,999 in July. The native labour totals for the past three months are:—

	June.	July.	August.
On gold mines	168,152	166,999	169,008
On coal mines	14,704	14,688	14,446
On diamond mines	1,317	1,246	1,207
	184,173	182,933	184,661

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to devine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837,
PRETORIA.

Geology of Heidelberg—V.

MR. BLELOCH REPLIES TO DR. ROGERS—THE VAN RYN AND NIGEL REEFS.

Dr. Rogers' "Bird Amygdaloid."

In the time at my disposal I can only deal with this question in the briefest manner. As I have said in a previous contribution to the discussion, Dr. Rogers based his conclusions that these two reefs are identical although totally dissimilar in appearance and character, because he has found an amygdaloidal diabase which he calls the "Bird Amygdaloid," extending over a long line of country in the Heidelberg district, and he correlates this amygdaloidal diabase, which he has proved to have been a contemporaneous lava flow, with certain amygdaloidal diabases which occur in horizons above the Van Ryn Reef over considerable areas of the Far East Rand. I submitted in my brief address at the earlier meeting of the Society that Dr. Rogers had presented no definite evidence that his so-called "Bird Amygdaloid" in the Heidelberg district is the same as the diabases found in horizons above the Van Ryn Reef in the Far East Rand. Dr. Rogers, in an important footnote at the end of his paper, states the "Bird Amygdaloid" to be a contemporaneous lava interbedded with the quartzites between the two uppermost thick groups of slate in the Witwatersrand System, and he recognises it as an important rock in the determination of horizons in boreholes and shafts where the beds do not crop out. That is No. 3 of his material points. That being so, I submit that he must bring the clearest evidence forward for such a material point on which his correlation of the beds mainly rests. Where is his evidence that the "Bird Amygdaloid" of Heidelberg is the same as the amygdaloidal diabases of the Far East Rand? On page 33 Dr. Rogers speaks of the distribution of the "Bird Amygdaloid" east of Boksburg, etc. Why the singular number? In most of the shafts and boreholes of the Far East Rand the amygdaloidal diabase sills are two, three, or even four in number, and I cite the Government area shaft sections especially, as giving definite evidence that the diabases found above the Van Ryn Reef on that mine are sills and not contemporaneous lava flows. These shaft sections completely bear out Mr. Horwood's view, that the diabases there are intrusive. That is my view, and I submit that all the shafts of the Van Ryn Reef Mines on the Far East Rand without exception show these diabases to vary both in number and position from shaft to shaft, and the Government area sections show them to cut across the sedimentary beds. Dr. Rogers in his address at the last meeting of the Society again failed to deal with this question. He brought forward no evidence that his "Bird Amygdaloid" of Heidelberg has any connection whatever with these diabases of the northern Far East Rand. Dr. Rogers, too, has quoted from my book, *The Far East Rand*, in a way which I submit is remarkable for a Doctor of Science to adopt. He says: *In Mr. Bleloch's book it is stated that "the evidence in every case of several boreholes in the Heidelberg district showed that the igneous rock was intrusive and that it invariably traversed the bedding planes of the sedimentary rocks. This statement is made of the amygdaloidal diabase as well as of diabase without qualification. It is certain that the observations of Mr. Bleloch's book are wrong!"*

I submit that anyone who has not read my book on reading this quotation would think that I was the author of the statements made in it. That, however, is not so. I would not have described the facts revealed by the boreholes quite as the words quoted imply. The words are the words of Mr. C. J. Tutt, an independent contributor to my book, and the observations are Mr. Tutt's observations, not mine, although I do not think Mr. Tutt was far wrong. Moreover, Dr. Roger's chief, the Rt. Hon. the Minister of Mines and Industries, rightly demands that the views of his officers when referred to should at least be correctly stated. One would expect that his own officers would be careful to keep to that standard; yet in the first place we find Dr. Rogers

quoting the passage in such a way as to leave the impression that the statements were mine, while my book shows clearly that Mr. C. J. Tutt was the author of the words quoted; and, secondly, he quoted the words incorrectly, for Mr. Tutt referred to several boreholes in the Nigel and Heidelberg district, not in Heidelberg only. Further, Dr.

Sequence of Bedding now established around the East and Far East Rand, at New Rietfontein, New Modder, Southern Van Ryn, and at Heidelberg-Tulipvale-Klippoortje (Houtpoort, Ltd.) and Boschfontein (Nigel Transvaal Goldfields). The Amygdaloidal Diabase is an interbedded lava flow (Dr. Rogers' "Bird Amygdaloid"), but it occurs at Rietfontein, New Modder, Southern Van Ryn, Heidelberg, and elsewhere as shown in the section below the Van Ryn Reef and not above it.

Rogers very carefully ignores the most important and definite material point made by Mr. Tutt—that in regard to the diabases revealed in No. 7 borehole and No. 1 shaft of Daggafontein, Mr. Tutt says: "Compare sections of No. 1 shaft and No. 7 borehole on Daggafontein mine; they are less than 100 feet apart. The shaft section shows two bodies of igneous matter while the borehole shows three, and these are at different horizons." Here we have two closely neighbouring sections in question, and I submit that if Dr. Rogers had given an explanation showing how two sheets of interbedded amygdaloidal diabase can become three and change to different positions in the short distance of 100 feet or so it would have been a stronger argument than misquoting Mr. Tutt and putting his words on to me. I am preparing a diagram of sections showing the varying number of the diabase sills in some of the shafts and boreholes of the Far East Rand for presentation with this discussion. Will Dr. Rogers tell me why he speaks of "*The Bird Amygdaloid*," implying that it is one body which does not vary in position when the facts presented in these shaft and borehole sections show that there are several bodies and that they occur in varying positions.

The Contemporaneous Lava Flow is below the Van Ryn and above the Nigel.

To-night I can go further and state to you that I quite agree with Dr. Rogers that the amygdaloidal diabase he has found lying conformably below a grit bed and outcropping over long distances on Maraisdrift and other farms in the Heidelberg district represents a contemporaneous lava flow, truly interbedded in the Witwatersrand System. As a matter of fact, we found what I believe to be this same amygdaloidal diabase immediately below what appears to be the same grit bed in both our boreholes on the Southern Van Ryn Mine, and we duly investigated the possibility of the grit bed being the Nigel Reef and decided many months ago that it was not that banket body but that the presence of the interbedded lava in both the boreholes bore out that we were correct in identifying the reef in our Nigel Van Ryn Mine as the Nigel Reef.

Our Van Ryn Reef in the Southern Van Ryn Mine, which lies above this interbedded amygdaloidal diabase, was certainly never cut in the upper levels of the Sub-Nigel shaft, where the Far East Rand Kimberley reefs were passed through at less than 500 feet, and no reef like our Van Ryn Reef has ever been found in the so-called Kimberley Series of the Far East Rand, and now that this contemporaneous lava—the "*Bird Amygdaloid*" of Dr. Rogers—in the Heidelberg district has been proved by our Southern Van Ryn boreholes to lie between our Van Ryn Reef there and the Nigel Reef, it affords further strong evidence, as I will shortly show that our Southern Van Ryn Reef is the true Van Ryn, and if, as Dr. Rogers states, such a contemporaneous lava bed lying immediately below a grit bed has been found above the reef mined at a depth of 4,000 feet in the Daggafontein Mine, I would take this fact as very strong evidence that the Daggafontein Reef is the Nigel Reef, *and not the Van Ryn Reef, which lies above the truly interbedded diabase and not below it*, and I am strengthened in this statement by the following confirmatory data which, if he will deign to come with me, Dr. Rogers can see for himself.

Some years ago Mr. Knox, the owner of the claims north of the Van Ryn Reef of the Far East Rand which figured in the Knox Arbitration Case, on my advice opened the Nigel Reef at this outcrop on his claims north of the New Modder Mine, and found it to be identical in appearance and character with the Nigel Reef at the Nigel. About three weeks ago I inspected the section between the Nigel Reef exposed on Mr. Knox's claims, and the outcrop of the Van Ryn Reef there at the New Modder Mine, and in that section I found an outcrop of a grit bed lying on an igneous rock which, although much decomposed, gives evidence of being amygdaloidal diabase. I have no doubt it is the same interbedded lava as that found by Dr. Rogers on Maraisdrift and called by him "*Bird Amygdaloid*." But I can present still more conclusive evidence, because I have found north of the Reitfontein Reefs on the Reitfontein Mine, now accepted by

both Dr. Mellor and Dr. Rogers as the Van Ryn Reef, seeing they class them both as Main Reef Leader, a definite outcrop of an interbedded amygdaloidal diabase overlain by a grit bed lying in the same relative position to the Reitfontein Reefs *above* it, as the igneous rock I have described as occurring north of the New Modder Mine lies to the Van Ryn Reef there. And in the same relative position to that of the amygdaloidal diabase with the grit bed above it lying below the Van Ryn Reef on the Southern Van Ryn Mine and above the Nigel Reef there. I present for your inspection specimens of the rock from New Reitfontein and specimens from the Southern Van Ryn both from a shaft and from a borehole, and specimens from the outcrop on Maraisdrift described by Dr. Rogers, and you will, I think, say they appear to be the same. The occurrence, therefore, of a truly interbedded amygdaloidal diabase representing a contemporaneous lava flow with a grit bed immediately overlying it in the position described by Dr. Rogers instead of being evidence that the banket bed lying on a shale in the succession which occurs below it, is the Van Ryn Reef turns out on the contrary to be very definite and concrete evidence that the banket bed which lies below it in the succession is the Nigel Reef, *and that the banket beds which lie above it in the succession are those of the Van Ryn Reef Series.*

That is the series of gold bearing reefs identical in sequence of bedding, appearance, composition, and gold-bearing character with the Van Ryn Series of the Far East Rand which have been located and opened up on the Southern Van Ryn Mine, by Houtpoort, Ltd., on Tulipvale and Klippocrtje; by Dr. Sauer on the Heidelberg Townlands, and by the Nigel Transvaal Goldfields on Boschfontein. At all these places our Van Ryn Reef carries gold values like those to be found at the outcrops of the Reef on the Modder B, New Modder, Van Ryn, and Kleintfontein mines.

To show that there is the highest geological authority for the views in regard to these igneous rocks which I have presented, I will quote one more brief passage from Sir Archibald Geikie, as follows:—

"The relative date of an intrusive rock can only be certainly affirmed with reference to the rocks through which it has broken. . . . An interbedded or contemporaneous igneous rock has its date precisely fixed by the geological horizon on which it lies."—*Text Book of Geology*, page 522.

That is our method of identification, and it is exactly the opposite of Dr. Rogers' method, which is to fix the date of the sedimentary rocks by means of the igneous rocks intruded into or interbedded with them. I feel safer in following Geikie as my geological guide.

The Position of the Nigel Reef at Heidelberg.

Dr. Rogers has stated that I am six miles in at one point on my line of the Nigel Reef in the Heidelberg district. I say in reply that on the contrary, owing to his erroneous identification of the Molyneux or Government Reef as the Nigel, it is Dr. Rogers who is six miles out. To place my views clearly on record I will state that the sub outcrop of the Nigel reef has been proved close to the eastern boundary of Boschfontein, that is several miles in from his spurious outcrop of the treacherous and misleading Molyneux or Government Reef. Another actual outcrop exposure of the Nigel Reef is that of the small banket reef lying on a shale footwall on Poortje just east of the Tulipvale Boundary near the old free stone quarry. We have evidence of the interbedded diabase, Dr. Rogers' "*Bird Amygdaloid*," overlying it on Tulipvale. The Reef and its shale footwall has recently been well exposed by a cutting put in by the road party in repairing the Main Road from Heidelberg to that high veld. Dr. Rogers knows the outcrop I refer to; on his map he has marked it Kimberley-Elsburg, and I may say that we have opened up the Van Ryn Reef with Van Ryn Reef gold values, nearly a mile on its dip! Measured in terms of miles, the difference between us may be as Dr. Rogers says, six; measured in terms of mining progress and the means of livelihood for thousands of people and indeed of financial security for the State, the difference between us may run into tens of millions.

Shaft sections shewing varying numbers and varying positions of the Amygdaloidal Diabases found in sinking to the Van Ryn Reef in the northern areas of the Far East Rand, affording strong evidence that they are later intrusive sills and not contemporaneous lava flows. -

The Van Ryn Reef at Wilgepoort.

I must further ask Dr. Rogers why he has left out Wilgepoort No. 244 in the Balfour district from his mapping. He has mapped the farms on two sides of this very important farm. I am informed that Dr. Rogers spent a lot of time on Wilgepoort, where he knows that Mr. Thorburn has opened up a reef for the Corporation Syndicate, Ltd., of which company Mr. Harry Graumann, M.L.A., is chairman. I submit that the reef on Wilgepoort has been opened up in the true geological position of the Van Ryn Reef that is, below the Far East Rand Kimberley or South Reitfontein Reefs and above the Nigel Reef. All three reef horizons, the Far East Rand Kimberley, or South Reitfontein, the Van Ryn and the Nigel, are exposed in the Wilgepoort section. The Van Ryn Reef there is just like our Van Ryn Reef on Tulipvale, Klippoortje, Heidelberg Townlands, and Boschfontein, called Kimberley in the Government cables and now again called Kimberley in Dr. Rogers' present paper. Development on this Reef on Wilgepoort has disclosed payable gold values. This is what Mr. Thorburn, who found the Van Ryn there, says about it:—

“Development by the Coronation Syndicate has been steadily proceeding on the Van Ryn Reef Series of this property (Wilgepoort), disclosing highly payable values in two reefs of the series. The Reefs are quite different in appearance and bedding to the Nigel Reef.”

On the other hand, what has Dr. Rogers to say about this important farm—the only farm in the Balfour area where active development has been going on during the period of his study of the Heidelberg geology. Exactly nothing! Could he not have spared a little time from his study of the igneous rocks of the district and given it to this all-important event in the economic geology of the Balfour district, the discovery and identification of the Van Ryn Reef. But no; Dr. Rogers avoids all reference to this farm and its reefs. I would like to know why? I am informed that Dr. Mellor has stated that the Wilgepoort reef is certainly Van Ryn. Does Dr. Rogers agree? I submit that in view of the extraordinary action of his department last year in advising the people of England so urgently by cable about these reefs it is Dr. Rogers' public duty as Director of the Geological Survey and as one responsible for these cables to say definitely what his conclusions are about that important and payable Wilgepoort Reef. Is it Kimberley or is it Van Ryn or Nigel or “Main Reef Leader”?

If it is Kimberley, why does Dr. Rogers not get the Minister busy with a cable to the good people of England warning them to withhold their money? If it is Nigel or Main Reef Leader, why is not a cable sent advising them to get in, so that our mining industry may be pushed ahead? These are questions which I submit cry out for an answer, and I will be mistaken if an answer is not demanded in no uncertain way by the people's representatives during the next session of Parliament.

Heidelberg Geology: A Correction.

Owing to the omission of a line, the article by Mr. Bleloch, in our last issue, was made to do an unintentional injustice to Dr. Rogers. The correct reading of the passage in question is as follows:—“Dr. Rogers admitted that he had not even examined the South Reitfontein Series, and that being so, I submit, he has not yet had sufficient experience to justify him in making dogmatic pronouncements on Rand geology before this Society or in the form of cables to the High Commissioner in London. Can anyone here justify geological dogmatism in that form?”

British Turbo-Electric Locomotive.

Great secrecy is being observed regarding the turbo-electric locomotive which a leading British engineering firm is building for trial on a main line British railway. It can, however, be stated that the principle adopted is similar to the system of electric ship propulsion which was first patented in Great Britain. The prime mover is a high-speed turbine coupled direct to an electric generator; this generator supplies current through controllers to motors which drive the wheels through some form of gearing. The advantage of this arrangement is that it combines the great efficiency of the high-speed turbine with the flexibility of electric speed control. If the trials are successful they will probably lead to the conversion of many express steam locomotives to the electric drive. This turbo-electric locomotive is not to be confounded with a new type of “thermo-electric” locomotive which another leading British firm is building for experimental purposes. In this case the prime mover is an internal combustion engine of a novel and economical design, which can utilise any kind of crude oil. In countries overseas where there is a deficient water supply along the routes of railways there is a magnificent field for an internal combustion engine locomotive which proves to be really efficient.

ENGINEERING SECTION.

A Water Power Scheme for Railways and Iron Industry.

PROPOSAL TO HARNESS ORANGE RIVER TO DEVELOP POSTMASBURG IRONFIELDS AND ELECTRIFY RAILWAYS.

In the course of his latest annual report, the Inspector of Machinery for the Kimberley district writes:—

Under this heading I took the opportunity last year to remark on the possibility of the construction of a generating station at Vierfontein Colliery, the ultimate object of which was the development of the iron fields near Postmasburg. I am still confident that such a scheme as then outlined would prove of enormous benefit to the State, but now realise that, owing to the conflicting interests involved, it has little chance of being undertaken in the near future. To still pursue the original object, would it not be possible to develop the iron fields from the west instead of the east? To me it seems that nature, though withholding coal from the Postmasburg areas and supplying an abundance of iron ore and the Aughrabic or King George Falls in the distance, almost pointed to the means of developing these fields. The falls are approximately 160 miles west of Postmasburg, and if harnessed are capable of generating an abundance of power, not only to develop an iron industry, but to run the present and any extension of railway within that area. As gaugings of the river or the falls are not available, I am not in a position to state definitely the power capable of being developed at the period of lowest river. Four years ago the writer was in Kakamas at the time when water ceased to flow in the irrigation furrows there—the first time since Kakamas Settlement was established, so I was informed by Mr. Conradie, the superintendent—and there was then a considerable volume of water flowing in the lower channels of the river, which if it reached the falls would, I estimate, be capable of developing from 8,000 to 10,000 horse-power, which is ample for the requirements of the scheme at present outlined. The maximum power capable of being developed is only limited by the size of any conservation scheme that may be decided upon. At present I am not interested in this phase of the scheme. In the past there has been no great incentive to utilise the potential power that has been running to waste from time immemorial; but now that the development of a great iron industry is possible within a comparatively short distance of the falls, it would be a great injustice to the country to allow this waste to continue. With such a scheme in active operation, the lack of coal from which this particular area suffers would be more than compensated for by the cheap power available and consequent industrial expansion that would follow. The falls are 400 feet high and are within 40 miles of the Upington-Windhoek railway system. It will be readily understood that a river such as the Orange, the catchment area of which is about two-thirds of the whole Union, with falls 400 feet high, in the vicinity of which latter there are practically no vested interests, must offer great inducements to any one interested in the industrial development of the country. The construction of a hydro-electric installation would be the means employed to convert the power of the falls to power easily transmitted to any point required. The initial stage

of the scheme would only necessitate a comparatively small installation, which, as necessity demanded, could easily be augmented; and the power generated could be used to electrify the De Aar-Windhoek railway and later any branches that may be built from the present system. In the near future a line must be built within the area under consideration, and were I to offer a suggestion, it would follow the route Upington-Griquatown, at which point the system would open out into two branches, viz., Griquatown-Campbell-Douglas-Belmont and Griquatown-Postmasburg-Kuruman-Mafeking. With such a system in operation it would bring the real object of these remarks within the realms of possibility. The power, by whatever electric system the railways will be operated, will be within reasonable distance of the iron fields, and thus place them in a very favourable position with regard to their economic development. Electricity would, of course, be the motive power employed to develop the iron fields, from "grass" to the finished product. The lack of coal and the inaccessibility of the iron fields to a railway has unduly delayed their development, whereas if they had been more favourably situated, they should have proved a strong factor in the establishment of a permanent and lucrative industry. That the ore must be of good quality and practically unlimited may, I think, be accepted, if only for the reason that the late Mr. Francis Oates, I believe, seriously considered the exploitation of these fields, even in face of their adverse situation. Could one visualise Postmasburg, say, fifty years hence, with this scheme in operation, it is possible that it may compare favourably with the cities of the world that owe their present position to the successful exploitation of their iron-ore resources. At present there are few industries requiring power within the area under consideration, but there is little doubt that, with the development of the iron industry, the opening out of the area by means of railways, and plenty of cheap power available, there will be no lack of demand for power to supply the requirements of the many industries which, under such stimulus, will spring into being. The recently discovered galena deposits near Griquatown, if, on development, the silver content proves as valuable as rumoured, is a likely consumer of power, as are also the diamond mines near Postmasburg. These latter—although favourably impressed with what I saw during my last visit—do not enter seriously into this scheme, except for the reason that they are situated close to the iron fields, and thus may add support to the point I am endeavouring to make. My reason for apparently discounting the importance of the diamond mines is not that I think them unpayable, but simply for the reason that I don't think that any addition to the diamond mines at present producing can add to the stability of the State or the diamond industry. In fact, were it possible, I should, in the interest of the State, prohibit the exploitation of any new diamond mines. The asbestos propositions in the district would certainly benefit

to a considerable extent by reason of the shorter distance that that commodity would have to be transported by road to rail; and, in addition, the fact that cheap power would be available might induce those interested to open out the mines more in accordance with modern practice than is the case at present. The pastoral interests, too, would benefit by being placed within easy distance of a railway, and therefore making reliable markets easily accessible. The part of the country through which the suggested branch railways would pass is one of the greatest stock-raising districts of the country, its full development in the past only having been retarded by its remoteness from any railway station. There is no need to dwell further on the saving that would be effected or the benefits accruing to those enjoying the service of such a scheme; its possibilities are so vast and its potentialities for good of such magnitude that, if carried to a successful issue, it might prove the means of inaugurating a wave of industrial development which would make itself felt beyond the confines of the Union.

To summarise the benefits in order of importance, I suggest the following:—

1. Supply of cheap power to operate present railway system and any extension within the area De Aar-Upington-Windhoek, etc., Upington-Griquatown-Campbell-Douglas-Belmont, etc., Griquatown-Postmasburg-Kuruman-Mafeking, etc.
2. Supply power necessary to develop Postmasburg iron fields and later operate furnaces, rolling mills, etc.
3. Impetus given to stock-raising within the area served by the railways and the development of agriculture in general, where the conditions are suitable, by giving access to important markets.
4. Means of developing all mining ventures, present and prospective.
5. Supply of power to farmers for irrigation and other purposes.
6. By opening up a part of the country, the full development of which is being retarded owing to lack of railway facilities.

Ball and Roller Bearings.

As a result of a request received from the British Ball Bearing Manufacturers' Association, a full representative conference, called by the British Engineering Standards Association, met recently at the Institution of Civil Engineers, under the chairmanship of Col. R. E. Crompton, to discuss the standardisation of ball and roller bearings covering the requirements of the engineering industry as a whole, the purpose of the enquiry being to ascertain, before proceeding further, whether there exists a consensus of

opinion favourable to the work being undertaken. It was quickly evident that there was no doubt in the opinion of those present as to the desirability of the proposed standardisation, the only points upon which there was any discussion being in connection with the actual types of bearings to be included. A resolution was unanimously passed recommending the setting up of a sectional committee of the B.E.S.A. to undertake the work, and such a committee will no doubt be formed as soon as circumstances permit. This sectional committee will not, we understand, supersede the existing B.E.S.A. committees dealing with ball bearings for automobile and aircraft purposes, but will co-operate with them.

* * * *

Underground Loco. Costs.

At a meeting of the West Virginia Mining Institute, E. E. Boon, manager of the coal and oil section of the Westinghouse Electric and Manufacturing Co., in a paper on "Storage Battery v. Reel Type Gathering Locomotives," presented the following table of relative costs:—

	Trolley cable-reel.	Trolley rope-reel.	Storage battery.	Combination.
First cost	100	105	122	139
Total installation cost	150	160	165	195
Interest and depreciation	16	17	26	27.5
Yearly maintenance	9.5	6.2	5	7
Power	1.2	1.2	1.1	1.2
Attendance	1.0	1.0	1.5	1.5

The author said that the power used by the cable reel and rope reel locomotives, though generated during the day, was charged at the same rate as that used by the storage battery locomotives, which was generated during the night, and that used by combination locomotives, which was generated partly in the night and partly by day. In consequence, the figures showing the relation that exists when all power is regarded as equally expensive would be modified so as to give a better rating to the storage battery power if the hour at which the power was produced were duly considered. One anthracite company the power plant of which is already overloaded by day, is ordering its superintendents to requisition for storage battery locomotives whenever they can be used and is doing this for the express purpose of cutting down the day load, which is excessively high. Several speakers stated that they had found the cost of mule haulage less than that of locomotives. L. C. Ilesley called attention to the fact that the Bureau of Mines had established schedule 15 under which storage battery locomotives were being examined for approval. He stated that one locomotive had already been approved and that three others were under examination.

Eighteen Years of Progress.

THE BUILDING OF THE BARTLE BUSINESS.

At the time the Bartle business was established, eighteen years ago, the offices, show-rooms and stock-rooms combined, occupied but one comparatively small room and that was located in the Main Street section of the New Club Buildings. Mr. J. O. Bartle, founder, was his own manager, salesman, as well as office-boy. In other words, his was, at its commencement, a one-man business in the truest sense. To-day, the staff of the entire Bartle organisation numbers nearly three hundred. Any attempt to tell in detail of the firm's small beginnings or to outline the big and rapid strides that have been made on the road to bigger things, would be to tell a long story though one full of meaning.

Eighteen years ago—at New Club Buildings.

The progress of the undertakings was greatly accelerated in 1906 by the advent of Mr. A. R. Callow (now managing director of the firm). Mr. A. R. Callow lost little or no time in getting behind the wheel of affairs, and from then on the business which was at that time characterised by its large supply of enthusiasm, determination and ability rather than by a stock of supplies usually associated with an undertaking

Loveday House—Head Offices of Bartle & Co., Ltd.

catering for the mines, moved ahead at great pace, never looking back, and soon developed into a business of considerable standing. Shortly afterwards, a partnership was formed by Mr. Bartle and Mr. Callow. The business was then carried on under the title of Bartle & Co., Mr. J. M. Jackson, who had represented the firm for a considerable time, becoming a director. The new era of prosperity into which the undertaking passed after the formation of this alliance is clearly reflected in the following short account of its growth.

The year 1907 saw the firm as sole South African representatives for a fairly large number of well-known British and American manufacturers, and the rapidly growing business was already demanding bigger ways of doing business. Extensive yards with suitable storerooms were secured, and this allowed of the carrying of much larger and more varied stocks than had hitherto been possible. In 1910 Loveday House, at the corner of Loveday and Marshall Streets, was acquired, and the Bartle business was immediately transferred from the New Club Buildings to its new home. In the following year the firm became a limited company—Bartle & Company, Limited, as it is known to-day.

A year or two later found Bartle's interesting themselves in the motoring business, and it was not long before several very important agencies in this connection were added to their then long list of sole agencies for leading manufacturers in the engineering world. It was soon after found necessary to control these motor undertakings as a distinct side to the business, and within the comparatively few years that have followed, direct branch businesses for the handling of motor and allied lines have been successfully launched in each of the eight leading centres. To-day the Bartle Motor Organisation are leaders in their line and second to none; but that is another story.

Returning, then, to the Bartle engineering business, let us but add that, as year has followed year, so has success followed success. And to-day, after eighteen years of rapid and consistent progress, the House of Bartle's holds an

Mr. A. R. Callow, the Builder of the Bartle Business.

enviable position in the vanguard of South Africa's biggest commercial undertakings, and is firmly placed with the leaders in its particular class of business. Of such businesses, that of Bartle's is as big as any and bigger than most.

Nothing short of a personal visit to the firm's extensive yards and warehouses at Marshall, Mooi and Polly Streets can give one any adequate idea of how surprisingly vast and varied are the stocks carried. And, large as the staff employed is, the continual despatching of supplies of any and every kind to all parts of the Union and adjoining territories, together with the constant arrival of fresh shipments, make every day a busy day at the stores. In addition to the Johannesburg stocks, the value of which runs well into hundreds of thousands of pounds sterling, further large stocks are, it should be remembered, carried at the firm's Kimberley and Durban branches.

With such large and assorted stocks on hand at all times it means that, when it comes to the needs of the gold or tin mine, the colliery, or engineering requirements of any general character, few indeed are the supplies of which Bartle & Company, Limited, cannot offer immediate delivery at right prices, and if it comes from Bartle's it is reliable—always.

Letters to the Editor.

SUBSIDIES FOR THE LOW-GRADE MINES.

A Criticism of the Commission's Findings.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Regarding the report of the Low Grade Mines Commission of 1920, paragraphs 76 and 77, dealing with the suggestion to subsidise the low-grade mines, paragraph 76 makes a good *prima facie* case against achieving the desired object by subsidising these mines, but on analysis it will be found that the grounds on which this suggestion is turned down are utterly worthless; clearly this suggestion, which is economically unassailable, has not been dealt with on its merits at all by the Commission. To analyse paragraph 77. It is true that "the gold mining industry is not peculiar in contributing indirectly to the coffers of the State. Every other branch of productivity which puts money into circulation has the same result." These remarks have absolutely no relevance to the point at issue. Had it been clearly established by a previous enquiry that in the case of all other industries than that of gold mining that the granting of subsidies was economically unsound, this alone could have justified this reference to these facts. Replying to the specific instance taken of a copper mine, it should be obvious that when it was shown that subsidisation of gold mines was to the benefit of the State, the same would also apply to a copper mine. In the case of the boot factory, the Government has already responded to the demand for subsidisation of this industry by granting it that very uneconomic and costly form of subsidy known as protection.

Again, dealing with the statement that "it would be difficult to resist the demands for subsidies to other industries." Firstly, it is not proved that such demands should be resisted, and, secondly, *were* it found that such demands should be resisted, it is conceivable that this difficulty of resisting these demands should be faced rather than shirked, in view of the extreme importance of the issue at stake.

Replying to the next sentence, "it is true that a gold mine, once closed down, may remain closed for ever, and that thus its potentialities of production may be lost for good and all, but this seems hardly a sufficient reason for differentiation," I would remark that this may be so, but that the Commission was appointed for the express purpose of giving a definite finding on such points (or of ascertaining whether this were so or not). This same remark may be taken to apply to the next sentence *re* theoretical economics. I think I have said enough to show that the suggested remedy of subsidies for the salvaging of the low-grade mines was very inadequately dealt with by the Commission appointed to enquire into the matter, and that the country should therefore demand that this question be re-opened. As an economist, I beg to state that subsidisation by relieving the unpayable mines of such portion of their present burden of taxation as is requisite to enable them to pay their way (within the limits hereinafter stated) is a sound economic solution of the problem. It is, of course, out of the question to go fully into the matter here, but I will put the matter briefly as a simple business proposition.

The Government gets—according to official estimates—some 9s. 3d. per ton crushed from the mining industry in *direct and indirect taxation* and in railway rates and harbour dues; now the actual out-of-pocket expenses to the Government for the services which it renders to the mines is probably only some 2s. or 3s. per ton, the balance being for overhead charges on railways and in Government offices, interest on capital in railways, harbours, buildings, telegraphs, and for defence and police, and so forth; thus the difference of some 6s. or 7s. may be regarded as profit, and thus a rebate on taxation (or subsidy) of anything up to this amount per ton could be given without the State losing, and any amount less than the total of this profit would be a gain to the State as compared with closing the mines down. In some cases a rebate of only 6d. per ton might be sufficient to keep a mine running; again there might be

some in which, if the State sacrificed the whole of its profit on taxation, there would still be a loss; in such cases the mines should, of course, close down.

To put the matter in another way; the giving of a rebate in taxation is analogous in its operation to the recognised principle in railway economics of adjusting the rates to "what the traffic will bear," under which valuable ore such as copper may pay several times as much per ton per mile as less valuable ore, such as chrome or iron. I would here suggest to the consideration of the Government that the adjustment of taxation by means of rebates in the principle of "what the traffic will bear" is one that may be found on investigation to be susceptible of wide application with beneficial results.

Some four weeks ago I wrote to the Minister of Mines and Industries pointing out how ridiculous were the reasons given in paragraph 77 of the Low Grade Mines report for turning down the suggested remedy of subsidies, and indicating that, in view of the supreme importance to the State of saving—if possible—the low-grade mines, that consideration of this remedy of subsidies should be re-opened; three weeks afterwards I received a reply which contained no reference to the subject matter of my letter. On coming to Johannesburg I saw Mr. Nixon, M.L.A., who, being impressed with the importance of my case, introduced me to some of the ministers, to whom I explained my views. Sir Thos. Watt expressed himself as greatly interested; the others, including the Prime Minister, appeared—perhaps naturally enough—to be so staggered by my temerity in attacking the findings of a Government appointed Commission that they were unable to give me serious consideration.

In conclusion I will point out that it is not a case of whether the Government is justified in subsidising these mines in order to keep them open; it is clear that no Government could justify itself in *not* subsidising such mines under the circumstances.

Clearly, Commissions appointed to inquire into economic matters should be composed of men with at least some knowledge of economic science.—Yours faithfully,

ARTHUR M. LAWS.

Talc and Fluorspar.

The following, taken from recent publications of the Imperial Mineral Resources Bureau, is of interest:—

Talc.—Talc is a hydrated silicate of aluminium, and has a characteristic soapy feel. A compact variety is known as steatite or soapstone; it is usually grey in colour and extremely soft. When mined the mineral is subjected to careful sorting, and dressing operations usually consist of crushing, grinding, and grading into sizes. About 90 per cent. of talc mined is ground to flour and used in the manufacture of paper, moulded rubber goods, and foundry facings. The world's production of talc in 1919 amounted to about 226,000 tons, of which the United States contributed 168,000 tons and South Africa 788 tons. Talc mining is an industry which is conducted on a very small scale in the Union, although the mineral is widely distributed in the older rocks of the country. The chief producer is the Verdite Mine situated in the Barberton district. The following figures represent the sales of talc in the Union:—

Year.	Sales and Shipments.	
	Quantity. Tons.	Value. £.
1915	39	218
1916	118	586
1917	701	1,962
1918	598	1,713
1919	676	3,102

Fluorspar.—Fluorspar is composed of calcium fluoride. It usually occurs in well-defined cubic crystals of purple, green, yellow or white colour. It is used chiefly as a flux, especially in the manufacture of steel, and also enters into the manufacture of glass. Up to the present South Africa has not exported the mineral. What small occurrences that are known are mined and used locally and at the works of the Union Steel Corporation. In 1918 the output was valued at £360.

General Review.

The improvement in business reported in our last issue, slight though it was, has been maintained this week, and merchants report a bigger turnover and brighter prospects than have obtained for months past. An increase in activity has been witnessed on the Commercial Exchange during the past fortnight. Of course, nobody expects a big improvement this year, but competent judges are of the opinion that we have at long last turned the corner; and, provided no further set-backs occur to retard the smooth running of industrial concerns, gradually improving conditions may be anticipated. The building dispute has been settled, although, it is said, the workers are not altogether at one with their Executive in accepting on their behalf the 10 per cent., or 5d. per hour reduction in wages, which brings their earnings down now to 3s. 10d. per hour. It is hoped that with this reduction of wages and no further considerable fall in costs of material to be expected for some time at least, building operations will be prosecuted vigorously. In this connection a well-known and influential merchant, when asked his opinion as to the immediate future of the building trade, replied that now the dispute in regard to wages had been settled, merchants were looking forward to favourable developments. A great deal, he said, will depend upon the financial position. A number of people are preparing to start building operations provided they can raise money on reasonable terms. Should anticipations be realised, there is every likelihood that the building trade will revive. The gold premium has declined slightly during the past week, but it is generally thought that no big fluctuations will occur between now and the end of the present year, which should enable the mining industry, including the lower grade propositions, to carry on for that period at least. Prices of materials generally during the week under review have been well maintained. Corrugated iron, which we mentioned in our last issue as being firmer, has since gone up another one-halfpenny per foot. A satisfactory feature in connection with the future trend of things is the fact that at last week's wool sales in London the tone was firmer, prices generally showing an advance of from 10 per cent. to 15 per cent. on those of July, which in their turn were a decided improvement on previous purchases.

Iron and Steel.

Business this week has continued to improve and transactions on the Commercial Exchange have been of an encouraging nature.

Latest quotations:—Dunswart, 29s.; Union Steel Corp., Ltd., 30s.; imported iron and steel flats, small, 40s. to 50s.; larger sizes, 38s. to 55s.; $\frac{1}{4}$ in. and 5-16 in. rounds, iron and steel, 45s.; $\frac{3}{8}$ in. iron, 38s.; steel, 7-16 in., 44s.; mild steel, 43s.; $\frac{3}{8}$ in. iron, 37s. 6d.; steel, 39s. 6d.; $\frac{7}{8}$ in. to 2 in., rounds, 39s.; larger sizes, 45s. to 57s. 6d.; $\frac{1}{4}$ in. square iron, 55s.; $\frac{3}{8}$ in., 47s.; $\frac{1}{2}$ in. to 2 in. square iron, 38s.; larger sizes, 44s. to 50s.; square mild steel, $\frac{3}{8}$ in., 41s.; $1\frac{1}{4}$ in. to 3 in., 40s.; larger sizes, 52s. 6d. to 59s.; channels and joists, 47s. to 48s.; shafting, $\frac{3}{8}$ in., 10 $\frac{1}{4}$ d.; $\frac{1}{2}$ in., 10d.; 1 in., 8d. to 9d.; $1\frac{1}{2}$ in. to 2 in., 7d. to 8d.; larger sizes, 8d.; steel plates, 1-16 in., 24s. to 25s.; $\frac{1}{8}$ in., 32s.; 3-16 in., 32s.; $\frac{1}{4}$ in., 21s. to 22s. in all sizes up to 8 x 4; 30s. to 32s. 6d. for the larger sizes; spring steel flats, 8 $\frac{1}{2}$ d. to 9d. per lb.; bolts and nuts, $\frac{3}{8}$ in., 1s. to 1s. 2d. per lb.; $\frac{1}{2}$ in., 65s. per 100 lbs.; $\frac{5}{8}$ in., 62s. 6d.; $\frac{3}{4}$ in., 60s.;

nuts, $\frac{3}{8}$ in. and $\frac{1}{2}$ in., 87s. 6d.; fish plates, bolts and nuts, $\frac{3}{8}$ in. and $\frac{1}{2}$ in., 8 $\frac{1}{2}$ d.; $\frac{1}{2}$ in., 6 $\frac{1}{2}$ d.; $\frac{3}{8}$ in., 6d.; $\frac{1}{4}$ in., 6d. per lb.; dog spikes, 35s. per 100 lbs.; rivets, $\frac{1}{4}$ in., 1s. 3d. per lb.; $\frac{3}{8}$ in., 10d.; $\frac{1}{2}$ in., 50s.; $\frac{5}{8}$ in., 50s. per 100 lbs.; tool steel, 3s. 6d. to 3s. 11d. per lb.; brass rods, $\frac{3}{8}$ in., round, 1s. 7d.; $\frac{1}{2}$ in., 1s. 5d.; $\frac{5}{8}$ in. and upwards, 1s. 4d.; brass sheets, 2s. 2d. per lb.; 2s. 4d. for the lighter gauges; copper sheets, 2s. 2d. to 2s. 4d. per lb.; fire box copper, 2s. 9d. per lb.; phosphor tin, 3s. 3d.; ingot tin, 2s. 7d.; drill steel, 7d. and 8d.; hollow, 9d.; $1\frac{1}{4}$ in., 9d. to 10 $\frac{1}{2}$ d. Wire nails, 35s. to 47s. 6d.; shovels, 60s. to 65s.; wheelbarrows, 52s. 6d. to 55s.; picks, 37s. 6d. to 67s. 6d.; pick handles, 35s.; barbed wire, "Iowa," 66 lbs. 14 gauge, 20s. per coil; "Iowa," 98 lbs. 12 gauge, 24s. 6d. per coil; "Shorthorn," 69 lbs. 13 $\frac{1}{2}$ gauge, 21s. 6d. per coil; plain galvanised fencing wires, No. 8 gauge 100 lb. coils, 25s. per coil; No. 10 gauge, 100 lb. coils, 27s. 6d. per coil; No. 12 gauge, 100 lb. coils, 30s. per coil; Bulb Tee fencing standards, 14 lb., 27s. 6d. per doz.; 12 lb., 24s. per doz.; black baling wire, 14 gauge, 20s. per coil 100 lbs.; screening, 3s. to 9s. 6d. per square yard; copper tubes, solid drawn, $\frac{1}{4}$ in., 3s. 9d. per lb.; $\frac{3}{8}$ in., 2s. 11d. per lb.; 7-16 in., $\frac{1}{2}$ in. and 9-16 in., 2s. 9d. per lb.; $\frac{3}{4}$ to $1\frac{1}{2}$ in., 2s. 6d. per lb.; $1\frac{1}{2}$ in. to 2 in., 2s. 3d. per lb.; 2 $\frac{1}{2}$ in. to 3 in., 2s. 6d. per lb.; 3 $\frac{1}{2}$ in. to 4 $\frac{1}{2}$ in., 2s. 8d. per lb.; copper rods, $\frac{3}{8}$ in., 2s. 5d. per lb.; $\frac{1}{2}$ in., 2s. 4d. per lb.; $\frac{5}{8}$ in. to 2 $\frac{1}{2}$ in., 2s. 2d. per lb.; cyanide for outside mines, 1s. 6d. to 1s. 7d.; zinc shavings, about 1s. per lb.

Mr. Lavenstein, the Managing Director of the Union Steel Corporation, Ltd., in announcing the reduction of their products to an all-round rate of 30s., states that the Corporation are getting a great amount of support and sympathy from the consumers of their goods, that they have now got their steel industry firmly established and are out to meet all comers, and are not at all afraid of fair foreign competition. The quality of the goods supplied by the Union Steel Corporation, Ltd., is giving the greatest satisfaction to their customers; the plant has been improved and extended, and the men of this country, who have been trained during the war, are now reaping the benefit of their efforts and have become skilled workers. There is an increasing demand at the moment for the Corporation's goods.

Second-hand Machinery.

There has been practically very little business done this week in regard to second-hand material, and the orders from the mines have been very scarce, particularly in battery spares, as many of the mines took advantage of those companies which have closed down, and replenished their stocks of spares for several months from those sources. Second-hand pitch pine will become a scarce commodity within the next month or so when all has been absorbed from the above-mentioned defunct mines, and the price will rise, as well as that for other essentials required by the industry. When all the second-hand material has been used, prices for new stuff will be maintained. Merchants in town have complained a good deal in recent months of a lack of business, on account, presumably, of the large quantities of second-hand mining material thrown on the market, and they are hoping to see better times and prices within the next two months; especially will this benefit those merchants with decent stocks, as the majority have been chary of indenting for large quantities for some considerable time, and

we do not blame them. It must have been most disheartening to merchants importing goods, particularly mining material, to see mines closing down and selling off their second-hand machinery, which other mines took the advantage of by purchasing at lower prices to restock their own mines. Indeed, the merchants' lot has not been a happy one of late.

Engineering Shops.

Business is brightening, more orders are coming to hand, and the tendency is undoubtedly upward, the shops now finding work for all their men. There are this week no special features to report.

Iron and Steel Factories in Germany.

An extraordinary recovery of German industry is shown by the September report of the Prussian Ministry of Trade. It states that the Rhenish and Westphalian iron and steel factories are refusing further orders for fulfilment this year.

Sir Arthur Trevor Dawson, Chairman of Vickers, after a visit to Germany, says that the engineering and electrical works there are very busy, and that the works are perfectly equipped. The output was high and labour working without hitch. Wages there, he said, are 3d. per hour, compared with 1s. 9d. of similar workers in England.

Timber and Building Materials.

There is no change to report in these this week, prices being well maintained, with no immediate prospects of their declining below present levels, 3 x 9 deals, 1s. to 1s. 1d.; scantlings, 1s.; beaver board, 5d.; floorings, 7d. to 7½d.; ceilings, 5½d. to 5¼d.; Oregon, 7s.; pitch pine, 8s. to 8s. 6d.; corrugated iron, 9½d. to 10½d. Business remains fairly good, and with the dispute settled regarding the wages of building operatives, should improve shortly. Consignments of timber are coming in freely from Europe. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality; 14s. 9d. for seconds at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 3d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cubic ft. at mills, Rhodesia; Honduras mahogany, 30s. per cubic ft.; American yellow pine, 1s. 9d. per ft. of 1 x 12, here; American pine shelving, 1s. per ft. There is no change to report in bricks, which are ruling at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed, per 1,000 at yards; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp, course and roofing, 37s. 6d., 47s., 55s. 3d. for 1-3 ply.

Blue Hydraulic Building and Plastering Lime.

Business in this section has been fairly steady, but the tendency of those about to build is to wait until costs have come to a lower level. Prices rule now at 3s. 9d. a bag for the building lime and 4s. 9d. a bag for the plaster lime, which is particularly low. Big producers have considered it advisable to bag their lime in bags branded with their name to avoid cheaper substitutes being sold as their manufacture. This is a move in the right direction, as it protects the contractors as well. The works recently erected outside Krugersdorp have gone into liquidation, the main cause being the huge amount of capital invested and the poor output returned. Shortage of houses continues to remain acute, and with the settlement of the dispute between the master builders and the building trade employees, a demand for blue lime is bound to be created.

Second-hand Iron and Timber Yards.

Business is still very quiet in these, but dealers are hoping for better times shortly. Iron is ruling at 5d. to 6d.; timber at 10d. to 1s.

Electrical Goods.

Although there is not much doing at the moment, dealers, now that the building dispute has been settled, are looking forward to improved business conditions very soon. As predicted in these columns, there have already been

some reductions during the past few days, viz., in lamps, from about 1s. 9d. to 2s. to 1s. 6d. to 1s. 10d. per dozen. Adapters, lampholders, switches, ceiling roses, etc.: these have been reduced by from 7½d. per cent. to 10 per cent., with the probability of a further drop shortly. Goods now arriving from Britain are, however, showing no declines, but rather the reverse, but local merchants have been obliged to realise some of their accumulated stocks in view of the possibility of a decline occurring oversea.

Agricultural Implements.

Business merchants report as rather slow at the moment, the present financial stringency operating against farmers and preventing them from many needed purchases. It is generally expected that things will improve after the recent rains and the expected advent of more shortly.

The mine profit-sharing scheme proposed by Mr. Leopold Albu, managing director of the General Mining and Finance Corporation, and chairman of the Roodepoort United Main Reef G.M. Co., Ltd., regarding the future working of the latter company, seems, in view of the present plight of that gold mine, a step in the right direction. The importance of such a co-partnership between the company and the workers is very great and deserves the greatest possible consideration on the part of the mine employees and their unions.

Penrol (S.A.) Ltd.

The provisional directors announce that, owing to the difficulty in obtaining the whole of the capital offered in the prospectus issued recently, they have reconsidered estimates. The initial working capital is to be £20,000. In the meantime, until the capital necessary has been acquired to erect a plant for the manufacture of alcohol from maize or other products, the board proposes to purchase alcohol to the required strength for the manufacture of Penrol and to undertake such manufacture, so that all that would be required would be such plant and containers as are necessary for the conversion of the spirit into Penrol and the handling and distribution of same. It is proposed to start business with a capital of £80,000, and it is anticipated that results will be such that development of the company's business will be rapid. It is stated that Penrol has made a highly favourable impression in Australia, where a parent company has recently been floated. The former Chief Government Chemist in the Commonwealth, in an analytical report, gives it as his opinion that Penrol is better than any other alcohol mixture on the market.

Oil.

An agreement has been arrived at between representatives of the American oil interests and the Mexican Minister of Finance, which means the immediate resumption of oil-producing operations in the Tampico region and the lifting of the Government embargo on oil now in storage. This agreement is expected to lead to a final settlement of all American petroleum problems in Mexico.

British Trade Ships.

The scheme for a specially designed steamer, named "British Industry," is receiving very considerable support from British manufacturers, and the movement will, it is expected, command support from all authorities in the Empire. British manufacturers will thereby be able to offer their goods where local effort is still unable to meet the demand. There will be every commercial facility for banking and cabling on board the vessel. The "British Industry," which will have a displacement of 20,000 tons, will, it is expected, leave England in the summer of 1923, visiting South America, South Africa, Australia, New Zealand, Japan, China, the Straits Settlements and India. During her cruise she will probably cover 43,000 miles in 18 months. The vessel will contain four huge floors for exhibits and accommodation for 300 trade representatives.

Coal Prices in Britain.

Prices of coal in London are being reduced by from 1s. to 4s. per ton. The best Waalsend remains at 68s. per ton, while other descriptions range from 57s. to 62s. In the

Welsh anthracite coal trade there is a boom; most of the pits are in full swing and some are working double shifts.

German Trade.

There is no doubt that, owing to the exchange, Germany is recapturing her pre-war trade, especially in respect of chemicals, which she is in a position to sell at prices with which British firms find it impossible to compete. Stocks of chemicals are now arriving here from Germany at prices which will cause tremendous losses to merchants holding large stocks imported during and after the war, because with such lower quotations in favour of the Continental goods, it is only human nature for people to buy the cheaper article regardless of country of origin. It is true that the Allies have imposed a stiff tariff against German goods, but as German exporters are subsidised by their Government to the full amount of such tariff, it is nugatory in effect.

Shipping.

The Port of London was considerably busier last year than in 1919; the net tonnage of incoming and outgoing vessels was, according to the annual report, 32,758,604 tons in 1920, compared with 26,335,191 tons in 1919.

Canadian Government Shipping Line of Steamers.

By the end of the present year the Canadian Government will be in the possession of some 63 ships, with a dead weight of 390,000 tons, carrying Canadian produce to all parts of the world. These vessels are the last word in ship-building science, and are equipped with every modern device and some with cold storage space. They have all been built in Canadian shipyards. The ships, in spite of the big slump in freights, have been active and have been operated at a substantial profit which, in view of the millions of tons of shipping lying idle in the United Kingdom and the United States, is a very satisfactory result. Voyages have been made to all parts of the world, and the outlook for the immediate future is, it is said, very promising. The policy of the Canadian Government steamers is to open up new trade routes with the help of existing steamship organisations and no competition in the matter of rates. Joint freight services have been established with the Blue Funnel Line, across the Pacific to China and Japan, and across the Atlantic to India, Ceylon and the Straits Settlements with the British India Steam Navigation Co.—Messrs. Mitchell, Cotts & Co., of Capetown, are looking after the Canadian Government Merchant Marine, Ltd., in South Africa.

Municipal Wages.

Under the conditions of the Lucas award, and in view of the figures supplied by the Director of Census, showing that the drop in the cost of living in the last nine months amounted to 23 per cent., and the fall in the April-June quarter, upon which period the October-November wages are based, calculated at 11.7 per cent., the municipal employees have agreed to accept a reduction in wages of 5 per cent. as from October 1. This reduction will, it is estimated, effect a saving of £20,000 to the town. On the other hand, the Council's grading scheme for increasing staff salaries of the Municipality will, if accepted by the Council, add an extra £9,000 to the rates.

British Trade in August.

The Board of Trade returns for August show big reductions. Imports amounted to £88,500,000, compared with £153,000,000 for August, 1920, and exports to £51,000,000 compared with £115,000,000. The largest decrease in imports was in raw materials and manufactured articles. The reduction in the value of exports was almost wholly confined to manufactured goods.

Unemployed in Britain.

The unemployed in Britain now exceed 1,500,000. That this problem is one of the most urgent facing the Government is indicated by the serious rioting in many parts of the country. With winter approaching and fewer chances of any large proportion of this unemployed army being absorbed in trade occupations for months to come, the situation has become aggravated.

Proposed New Thames Tunnel.

A scheme is on foot to construct a new railway tunnel under the Thames between Gravesend and Tilbury at a cost of £5,000,000, to improve road facilities from Essex into London. In the northern manufacturing areas, as well as in the south-east, it is hoped that the tunnel will eventuate in the not too distant future.

Dye Industry.

A Swiss Professor states that Germany before the war controlled 95 per cent. of the dye industry. Since then other countries had entered the field. Synthetic indigo, he said, could equal natural indigo if made sufficiently pure.

Writing by Wireless.

It is reported that a French scientist, M. Belin, has discovered a way of transmitting written messages by wireless. After smaller experiments in France, the experiment was conducted between Paris and New York, a distance of 3,000 miles, and resulted in a big success. What this discovery, fully developed, will mean to the world goes without saying.

Wireless Telephony.

Berlin reports very successful experiments carried out in wireless telephony between Berlin and Copenhagen.

Financial.

London reports that with Treasury Bills selling at 4 per cent. discount there is a growing inclination to take up short-dated securities.

The Bourses in Berlin, Hamburg, Frankfort and other German centres have recently been the scene of wild speculation consequent on the exchange on London going to 369 marks to the pound.

New Australian Loan.

Melbourne cables that three-quarters of the new loan of £10,000,000 has been subscribed, and that the period for subscription is being extended for a few days.

Metal Market.

Latest London quotations:—Standard copper, £67 5s. cash, £68 5s. forward; electrolytic copper, £72 cash, £74 forward; Straits tin, £156 7s. 6d. cash, £158 15s. forward; English lead, £23 7s. 6d. cash, £22 17s. 6d. forward; bar silver, 38½d. per ounce; fine gold, 110s. 1d. per ounce. Copper was steady during the week, tin advanced on influential buying, but the outlook is not encouraging for the English tinplate industry.

KROONSTAD COAL ESTATE COMPANY, LIMITED.

TENDERS

are invited and will be received by the Undersigned up to and including Saturday, 1st October, 1921, for the purchase of the **MACHINERY, PLANT, EQUIPMENT, MINE STORES, TOOLS, ETC.** lying for disposal at the above Company's property at Vierfontein, O.F.S.

Tenders must be for the whole of the above, and the successful tenderer will be required to remove same at his own expense and risk within one month of the acceptance of the tender.

The highest or any tender not necessarily accepted.

Lists and further particulars may be obtained from

Successful Year with the Hume Pipe Company.

GOOD PROFITS EARNED—SOUND FINANCIAL POSITION—EXCELLENT OUTLOOK.

A very satisfactory showing was made at the fourth annual meeting of the Hume Pipe Co. (South Africa) Ltd., held on September 14. Those present at the meeting included Lieut.-Col. C. L. Anderson, O.B.E., Messrs. W. Wolstenhohne, J. R. Leisk, C. A. Wentzel, M. C. Bird, F. H. Wallers, E. M. Geard, P. Lange, and A. C. Smith, secretary. Altogether 153,161 shares were represented out of 250,000.

Mr. John E. Orr presided, and in moving the adoption of the report, said:—Gentlemen, the continued ill-health of Sir J. Percy Fitzpatrick has, I regret to say, prevented him from being present to preside over this meeting. The report of your directors and the statement of accounts for the year ended June 30, 1921, have been in your hands for a sufficient time to enable you to become *au fait* with the position of the company at the end of its last financial year, and it now remains for me to supplement the information already in your possession. The chairman at the last annual meeting referred in his address to the proposed acquisition from the Germiston Municipality of additional industrial sites so as to facilitate the company's operations. Certain formalities as between the Municipality and the Townships Board, however, have not yet been completed, and it may be some time yet before the Municipality will be in a position to deal with the area which it desires to lay out as industrial sites. During the year your company purchased a stand adjoining its ground, and this additional space, together with other space made available by temporary arrangement, has eased matters considerably, and we have been enabled to carry out our work without inconvenience. As you will have seen from the balance sheet, the factory buildings, machinery, plant, etc., account, which stood at the beginning of the year at £58,882 0s. 11d., was increased during the year by £41,711 9s. 7d. This is the expenditure forecasted at the last annual meeting, and the position now is that, with very little further capital expenditure, your factory at Germiston can cope with all reasonable demands which may be made upon it in the future, only a certain amount of erection and completion work remaining to be done.

Increased Stocks of Pipes.

Another item in the balance sheet which perhaps calls for some comment is "Manufactured Stocks on Hand, £49,582 13s. 8d." This is a considerable increase on the figure shown last year. The increase is accounted for by the fact that we had an increased stock of pipes at Germiston seasoning, and awaiting delivery owing to the larger volume of business transacted during the year, an increased stock of pipes against orders requiring delivery from stock, an increased stock of pipes held in terms of our contract against orders from the Administrator of the Transvaal and, further, a stock of pipes held at the new factory at Bellville, as well as a fairly large quantity of bricks made and in course of manufacture at the Brick and Tile Works, Bellville. The value of stock on hand for firm order was £19,122 15s. 2d., and the value of stock made without definite orders having been received therefor was £30,418 18s. 6d., over £7,000 of which being held against contracts.

Anticipating Orders.

It has been found from experience that it is necessary to manufacture certain types of pipes in anticipation of orders so as to avoid delay in delivery when the pipes are urgently required, also that with a longer period allowed for seasoning there is less liability of breakage during delivery by rail and transport. The absence of a sufficient reserve stock has on occasion been responsible for the loss of small orders. Your board is of the opinion that the manufacture of pipes for stock is sound policy, although it, of course, recognises that such stocks must not be unduly large. As was done last year, the stocks on hand have been taken

into the books on a very conservative basis. The desirability of this policy will, of course, be demonstrated in succeeding profit and loss accounts.

The Weekly Output.

During the year 1919-1920 the output of concrete pipes at the works reached 85 tons per week; during the year under review this output had been increased from 85 tons to over 400 tons of concrete pipes per week. Amongst new developments is the manufacture of an entirely non-reinforced pipe made on the Hume principle.

You will also have noted that sundry debtors stand in the balance sheet at £60,517 4s. 1d.; this large amount is due to the fact that the company has had to give extended terms of payment to certain municipalities and other public bodies, which policy was necessary in order to introduce a practically unknown and unproved product. Your board has now decided that the time has arrived to make more stringent terms of payment, and anticipate that the current year will see this figure largely reduced.

Profit for the Year.

At June 30, 1919, a loss of £10,583 13s. 8d. was carried forward to the following year, and at June 30, 1920, this loss had been increased to £11,188 9s., the loss for the year ending on the latter date having amounted to £3,604 15s. 4d. Had it not been for the fact, however, that certain non-recurrent items were charged out, there would have been a profit on actual working for that year of a little over £2,500, so that it was apparent at that time that the company had entered upon the profit-earning stage. From the accounts now before you, you will have seen that your profit for the year under review amounted to £37,714 4s. 5d., and, after wiping out the loss of £11,188 9s., to which I have just referred, there now remains at the credit of our profit and loss account a sum of £23,525 15s. 5d., a result which cannot be regarded as other than satisfactory. Your board has given very careful consideration to the question of disposal of this amount, and has arrived at the conclusion that the interests of the company will be best served by deferring in the meantime any distribution by way of dividend. In forming this opinion, your board has been influenced by the circumstances that very recently several tenders have been made by the company for contracts involving large amounts. It is considered a reasonable assumption that the company will secure a fair proportion of these contracts, and, should this assumption prove to be justified, it will be necessary to provide for fairly heavy outlay on materials and wages, the returns in respect of which will not be available for several months after commencement of the contracts. The tenders referred to are either now being considered or will be considered at an early date.

Fully Equipped.

During the year the Hume Pipe factory at Bellville commenced manufacturing operations, and has already supplied a fair quantity of pipes to complete a sewerage scheme in the Cape Province. The results from our brick-making operations have been very satisfactory, and, with the increased output which it is expected will be produced in the current year, your board anticipates an improvement in the profits from this source. As I have already indicated, your factory at Germiston industrial sites has been enlarged sufficiently to permit of the execution within a reasonable time of any contract, no matter of what extent, which your company may secure in the Union, and the position to-day is therefore that your company is practically fully equipped for its purposes in its present sphere of operations, and, with the improvements and progress which have been, and are being, constantly made as the result of experience gained and of experiments carried out, it can, I think, look forward with confidence to continued success.

The Industrial Depression.

During our financial year the wave of industrial depression which all countries have experienced was not felt by your company until late in the year under review. Since March we have experienced shortage of orders, principally due to the financial straits of the Government and municipalities, who are amongst our largest customers. I am pleased to say that there are signs of improvement in this respect, but I anticipate that it will be some time before trade conditions again become normal.

Before closing my remarks I should like to record our appreciation of the loyal and valuable services that continue to be rendered to the company by its officials and staff.

I now beg to move that the directors' report and the balance sheet and accounts for the year ended June 30, 1921, be received and adopted.

The report of the directors and the balance sheet and accounts were unanimously adopted.

The appointment of Mr. M. C. Bird as a director was confirmed, and Mr. E. G. Izod, M.B.E., and Mr. T. W. Reynolds, the retiring directors, were re-elected.

The meeting then concluded.

Industrial Respirators.

Before the War respirators specially designed for use in industry were, practically speaking, non-existent. Experience with respirators as protection against poison gas during the War, however, has been turned to good account from the industrial point of view, and Dr. Leonard Levy recently, at a meeting of the London section of the Society of Chemical Industry, gave an account of the latest developments in this connection. Improvements have been made in the facepiece of respirators over the type used in the Army, but the canisters employed are unused small box respirator

canisters of the type used in the Army, which it has been found difficult to improve upon, and, moreover, they happen to be readily obtainable in large quantities. The fillings of the canisters, however, are quite different from the Army fillings. For industrial purposes there are now ammonia respirators, which find extensive application in cold storage plants, and for which the most satisfactory absorbent has been found to be crystalline copper sulphate. The next type gives protection against neutral vapours, such as hydrocarbon fumes in oil fields, cleaning out oil tanks, etc., and here the best results have been obtained with a filling of highly activated vegetable charcoals. A third type of filling is designed to deal with acid gases, such as hydrochloric acid, chlorine, sulphuretted hydrogen, phosgene, sulphur dioxide, nitrous fumes, hydrocyanic acid, etc., and in this case it has been found that a uniform mixture of alkaline granules and charcoal has the longest life. The alkaline granules made use of by the author are slaked lime, kieselguhr, ferric hydroxide, and activated charcoals. Finally, there is the carbon monoxide respirator, which has presented many novel problems, because there is no known absorbent suitable for use in a respirator canister for the removal by chemical absorption of carbon monoxide from an atmosphere contaminated with that gas. An effective method, however, is by the catalytic oxidation of the carbon monoxide by the oxygen of the atmosphere, using certain special mixtures of oxide, such as finely divided manganese dioxide, copper oxide, cobalt oxide and silver oxide. Moreover, as carbon monoxide gives no indication of its presence, it is necessary for a detector to be embodied in the respirator, so that the wearer can be warned if the respirator has accidentally failed.

Mr. L. D. Normand, late manager of Landau Mine, has been appointed general manager of the Tendega Collieries, Natal.

The Late Major Clem D. Webb, M.C.

PASSING OF PROMINENT PIONEER AND PROPRIETOR OF THE "S.A. MINING AND ENGINEERING JOURNAL"—SKETCH OF THE CAREER OF A PUBLIC-SPIRITED CITIZEN, A GOOD SPORTSMAN, AND A BRAVE SOLDIER.

With the deepest regret we have to record the death of the proprietor of this journal, Major Clem D. Webb, which took place early last Monday morning. The late Major Webb had been ailing since last June with head trouble, and successive operations had proved ineffectual. He went for a change to his farm in the Northern Transvaal in July, and was forced to go into the Messina Mine Hospital for treatment. From there, after everything possible had been done for him by the doctor to the mine, he returned and entered the Park Lane Nursing Home, which he was fated never to leave alive. The very best medical and surgical skill was powerless to save him, and after an operation to his head on Saturday last, followed by another in the early hours of Monday morning, he succumbed after a plucky fight for life. Fortunately, his end was without pain, and he passed peacefully away in the presence of his family on Monday morning. Owing to the day fixed for the funeral happening to synchronise with a review by the Acting Minister of Defence, it was not possible to arrange a military funeral, but the obsequies were attended by a large and representative gathering on Tuesday

troubles of those days. His forbears had more than their share of fighting blood. His grandfather, John William Webb, an old English squire, came from England in the good ship "Belle Alliance" with the 1820 settlers, accompanied by seven children. One of these, Frederick Charles Webb, who was born in England and came out at the age of seven, turned out to be a prominent leader in these early days. His wife was Mary Stuart, a direct descendant of the Royal house of Stuart. He was commandant at Fort Peddie, and during a big rebellion Commandant F. C. Webb led a body of men against the rebel chief, Macomo, captured him, and among other booty seized a seal that had been presented to Macomo by Queen Victoria, which bears the inscription "Vincit arna Pax." It is to-day a treasured possession of the Webb family.

Mr. F. C. Webb married the sole surviving daughter of Colonel Llewellyn Davies-Ap-Davies, of an old Welsh family, and of the Royal Engineers. As she was the last remaining member of the family—her only brother, Captain Llewellyn Davies, being killed in the early wars—Colonel Davies re-

Hon. Secretary.

that testified to the widespread respect and esteem in which the deceased was held. Messages of condolence were received from relatives and friends from all parts of South Africa, and the floral tributes at the funeral came from every section of the community.

Sketch of His Career.

The late Major Webb was born at Fort Peddie nearly fifty-nine years ago, being the son of the magistrate there. Educated at the Diocesan College, Rondebosch, he was articled to his elder brother, Mr. A. D. Webb, a well-known local practitioner in Queenstown. The latter educated him and acted as a father to him. Indeed he lived with "A. D." until he came to the Rand. In 1886 he was appointed by the Cape Government to take charge of its exhibits at the Colonial and Indian Exposition in London that year, and on his return he came to the Rand at the age of twenty-five, where, though a qualified solicitor of the Supreme Court in Cape Colony, he took up stockbroking for a time. Indeed, it is characteristic of him that he tried several occupations at this time, being successively native labour contractor, stockbroker, and lawyer. Coming of a fighting stock, he was naturally attracted to soldiering at an early age, and he took a prominent part in the Basuto War and in the native

quested her husband to incorporate the name with his own so that it might not be lost. Thus the descendants are properly Davies-Webb. The Davies family came out with the troops long after the arrival of the 1820 settlers.

A Keen Sportsman.

Both at school at Rondebosch and while serving his articles, deceased was a keen, all-round athlete. He was fond of sport all his life, and for two years, in the early nineties, was the amateur heavy-weight boxer of South Africa. He helped to found the Wanderers, Johannesburg, and never lost his interest in sport.

The Reform Movement.

In the strenuous and exciting days that preceded the Raid and the Boer War he played a prominent part, and he assisted in the formation of the S.A. League. Indeed, his life at that time was bound up with the history of the movement for freedom of the Uitlanders, and the story of his activities is written in the chronicles of the period.

The following extract from *Black and White* of February 18, 1899, sketches the rise of the S.A. League and shows the prominent part he played in it. The photos of the four leaders of the movement, of which he was one, are reproduced:—

"The recent riots in Johannesburg showed that the spirit of the Uitlanders is far from dead, and the South African League has been working quietly and steadily to maintain this spirit of independence. Some information about the leading members of this League may be of interest to our readers.

"The President of the Transvaal province of the South African League is Mr. Wilfrid Wybergh, who has already been called upon to make substantial sacrifices for the sake of his sturdy political principles. Mr. Wybergh is of good Cumberland stock, and won a Foundation Scholarship at Winchester College. For three years he studied mining engineering at the Freiberg Royal School of Mines in Saxony, and then in 1890 went up with the pioneers to Mashonaland, where he remained till 1893. Thence he went to the Witwatersrand, and was consulting engineer to the George and Mary Company on the West Rand during 1894, a post which he left to join the staff of the Consolidated Gold Fields of South Africa. As soon as the South African League began to take a prominent part in the agitation against the intolerable condition of British subjects within the Transvaal, Mr. Wybergh's connection with that powerful corporation abruptly ceased.

is a solicitor and notary public of the Supreme Court of the Cape Colony. He was sent by the Cape Government as a representative of the colony to the Colonial and Indian Exhibition held in London in 1886, and had the honour of lunching at Windsor Castle, where he was presented to Her Majesty. Going in 1888 to Johannesburg, he was one of the early members of the Stock Exchange and Rand Club. For some years he has been closely associated with the *South African Mining Journal*, and is the general manager of the company publishing that paper. During the time of the imprisonment of the Reformers, Mr. Webb and four others started the South African League in the Transvaal. He is still on the executive, and is the Vice-President of the Transvaal Province and Chairman of the Johannesburg branch.

"Mr. Tom Dodd is a Northumbrian, and was for ten years mining at home. He was a member of the Northumberland County Council, and was asked to stand for Parliament in the Liberal interest. In 1895 he went to South Africa, and has worked energetically for the cause. He is hon. Secretary of the South African League in the Transvaal, is one of the finest orators in Africa, and is white all through."

Major Webb (in centre, front row) with a group of Pioneers of the Transvaal Goldfields. Photo taken at the inaugural meeting of the '87 Pioneers of the Transvaal Goldfields, presided over by Mr. W. P. Taylor.

"The first President of the South African League in the Transvaal was Mr. Charles Kimber White, who still is one of the most valiant champions of British rights. Mr. White is of blood well known in the country of Somerset, but has for over sixty years been identified with the history of South Africa. In 1838 he took part in the stirring Kafir war on the eastern frontier of the colony. In recognition of his pluck he was granted a farm at Cathcart. Ever since then he has been where history was being made—Kimberley being for some years his residence. During the British occupation of the Transvaal he was appointed representative of the people to the Legislature under the Lanyon Government, upon which he made his memorable onslaught by reason of its delay, its nepotism and its broken promises. After the Retrocession following upon the Boer War, Mr. White and a Dutch colleague of loyal proclivities spoke throughout England for redress for those who were ruined by that great betrayal; but, of course, ineffectually. As a member of the League, however, he has done much good work in the struggle against Boer misgovernment.

"Mr. Clem D. Webb was born in the Eastern Province of the Cape Colony, and is a descendant of the British settlers who went to South Africa in 1820. By profession he

The Edgar Case.

From the *Standard and Diggers' News*, of December 26, 1898, we take the following sidelight on the political turmoil on the Rand at the time, and the part played by the late Major Webb in what was known as the Edgar case:—

"In preparation for the public demonstration which had been announced to take place on the Market Square on Saturday afternoon, a very large crowd congregated at the Post Office end a long time before the appointed hour of 3.30. It had then been decided by a small committee, principally members of the South African League, to place a petition before the British Vice-Consul, for despatch to Her Majesty Queen Victoria, setting forth the facts of the case of the Edgar shooting tragedy, and alleged partial treatment of Police Constable Barend Stephanus Jones by the Public Prosecutor, in releasing him on bail without waiting for any magisterial enquiry, and reducing the original charge of murder to that of culpable homicide. The current of public feeling ran very strong, and an interested crowd gathered about the Square waiting for the first orator.

"While this was going on an open carriage was drawn up, which contained Mr. Clem D. Webb, Advocate Foster,

and J. Dunn. This arrival was the immediate signal for cheering and an enthusiastic reception. Some climbed on to the seat, others on to the wheels, while the body of the vehicle groaned under the weight of a few journalists who suffered discomfort for the gain of 'copy.'

"Mr. Webb then rose, amidst a perfect din of applause, and addressing the assembly in a loud voice, said:—Gentlemen: You are all aware that public and open-air meetings are not allowed in this country. (Hooting and groans.) I don't want you to do that; I want you to respect the law, and to understand that it is the intention of the British subjects to go down in a quiet and orderly manner to the British Vice-Consul, to emphasise the gravity of this particular instance, and to formally protest against what has

murder. For God's sake, let us ask for justice, and go down to the Vice-Consul's in an honest, manly way and show that we have done our duty. (Applause.) Will you please follow the committee and thereby signify your willingness to the petition that is going to be presented. The British Vice-Consul has sent up a message to say he is ready to hear what we have to say. (Deafening cheers.)

"With frantic enthusiasm, the crowd gathered still closer round the carriage. Some insisted on outspanning the horses and drawing the vehicle along themselves. During this operation one man was badly bitten by the horses. The carriage was dragged down Loveday and along Commissioner Streets, followed by an enormous crowd, singing "Rally Round the Flag, Boys," "Freedom for Ever," and other

THE OLD QUEENSTOWN BOYS.

The above is a picture of pioneers from Queenstown (Cape Colony), taken at Johannesburg in 1887 by Alfred Dugmore, photographer. At the present day a good many of those appearing in the group are dead, and some have left the Rand, but a fair proportion, including several prominent men, are still residing here. The late Major Webb is seated on the right of the picture, with pipe in hand. Seated third on his right is Sir Abe Bailey.

taken place. (Cheers.) It is not the intention of anybody associated with me in this affair to do anything of which we need be ashamed. (Cheers.) We are here as British subjects, and are prepared to stand the brunt of what we are going to do. (Loud applause.) What we intend to do is that those who desire to accompany us in a quiet and orderly manner, should go down to the British Vice-Consul's office in the Standard Bank Buildings, and there the Committee which has been formed will present a petition to the Queen—(cheers)—protesting against what has taken place in connection with the Edgar murder case. Gentlemen, let us give the police and detectives, which I see around us, no chance of saying that we have done anything of which we need be ashamed. (Cheers.) At the same time, I would say this, that for God's sake as British subjects let us show that we are not afraid to emphasise our objections to this brutal

similar patriotic ditties. It was noticeable that in spite of Mr. Webb's remarks, there was not a policeman to be seen in uniform at any part of the route.

"Preceded and followed by a huge crowd, the carriage at length arrived at the Consulate, which was swarmed by an enormous crowd. The members of the committee and some fifty others presented themselves before Mr. J. Emrys Evans and advanced on to the balcony, where the petition was read by Mr. T. R. Dodd, as representing the British subjects of Johannesburg."

The ending of this *cause celebre*, of course, is written in the history of the Transvaal.

The Boer War.

When the war broke out he, with other well-known colonists, assisted to form the Imperial Light Horse, which was a

corps d'elite of the time and which distinguished itself particularly in Ladysmith. Under Colonel Scott-Chisholm, in that regiment served, with Captain Webb, as he was then, such well-known fighters as Colonel Sir Aubrey Woods-Sampson, Major Karri Davies, Colonel Creswell, Captains Fowler, John Orr, Barnes, and dozens of others of the fine flower of South African manhood. With no mishap beyond a severe bout of illness in Kimberley Hospital, Major Webb came through that struggle, and being one of the first back to the Rand, he held several important official positions under the military *régime*. He commanded the Fire Brigade and held other posts under the Health and Sanitation Committee, which was afterwards merged into the Town Council. Later he took an active interest in politics, and contested Marico as an independent unsuccessfully. He sat for Yeoville in the Provincial Council since Union, but the deliberations of that phlegmatic body soon lost interest for him. Farming, which had always exercised a fascination for him, occupied his attention at intervals, and he was never happier than when he could throw off the cares of running the *Mining Journal*, and retire for a spell to the country.

The Great War.

Although well over military age, he was not to be denied participation in the Great War, and after several ineffectual attempts to go in any capacity, he secured, through the good offices of his friend, General Byron, the post of Transport Officer to the 5th S.A. Infantry in German East. Both Generals Beves and Byron, under whom he served at this period, speak highly of his personal bravery and devotion, and he won the M.C. for an act of conspicuous bravery in the field. About the same time his eldest son, Stuart, won the same coveted decoration in France, and this emboldened his old friends on the Rand to send him the following unique testimonial:—

An Unique Tribute.

The message was couched in the following terms:—

To
CAPTAIN CLEM D. WEBB, M.C.,
Section 8, A.P.O., B.E.F., France.

"We are guilty in the conventional sense, but we have not forgotten. We did not know your whereabouts. We admire and envy your achievements, which are worthy of you, this being apart from heroics. Continue for the benefit of us who would be glad to have the opportunity of doing likewise to deserve the distinction which has been won by father and son."

"Everyone is the son of his own work."—*Don Quirote*.

This was signed by the following:—J. Beatty, P. D. Dyer, Wm. Beachy Head, P. A. Ogilvie, C. Tremer, Percy Greathead, J. M. Buckland, C. F. Tainton, Emrys Evans, Richard Currie, R. G. Rimer, G. W. Ogilvie, Frank Emley, W. G. Stevens, John R. Williams, W. B. Knox, Sir T. M. Cullinan, Sir A. Bailey, Arthur M. M. Cooke, Oswald Fletcher, H. A. Green, J. Spranger Harrison, W. P. Taylor, Sir A. Wood-Sampson, H. S. Harger, Wm. Stayt, E. H. Danckwerts, H. C. Fletcher, J. A. Vaughan, T. A. R. Purchas, J. Dobson, G. D. Masey, E. W. Buxton, W. K. Tucker, H. Solomon, L. B. Chesterton, J. Frank Brown, Claude Sampson, J. C. Burchmore, E. A. "Barborton" Halliwell, Harry S. Head, Cato Miller, J. V. Blinkhorn, C. J. Watson.

A Padre's Testimony.

The following interesting account of a forgotten incident of the fighting in German East is from the pen of a padre attached to Major Webb's regiment, the 5th S.A.I. It is taken from a vivid pen picture of the fighting contributed by the padre to the *Cornhill*:—

"Scarcely had the firing begun when another sort of crackling sound broke out quite near us, and increased forthwith in intensity. It was a sound I had never heard before and hope never to hear again, the sound of animals stampeding, or trying to stampede, through dry elephant grass. A moment more, and they were upon us, horses,

mules, all our first-line transport, their heels flying wildly in all directions, their distracted leaders hanging on for dear life to the bridles. And with animals came men, helmetless in some cases, and all of them beating the air wildly, and apparently quite distracted. Someone shouted 'wild bees,' and almost at once they were on us too, swarms of them, stinging viciously, and attacking every living thing they came across. Meanwhile the situation was growing every moment more critical. A panic is at all times a formidable peril, but who can calculate the effects of a panic precipitated down an elephant path two feet wide, into an advancing regiment and a large train of native porters? One of the machine-gun mules had already been lost, and we seemed in a fair way to losing the remainder, let alone the fact that the rifle fire from in front still continued, and the arrival of the enemy might at any moment put the finishing touch to what threatened to be a grave disaster. Fortunately, we had in the 5th S.A. Infantry a very remarkable man, a man of many and varied accomplishments, and of very wide experience. He had been, I believe, a member of the Johannesburg

The late Major Webb (left centre) with friends, taken in London in 1886, when he was 26 years of age.

Reform Committee at the time of the famous Raid, and besides being a politician, he was also a mining expert and a journalist, an agriculturist, a hunter, and an authority on native customs. He could also charm snakes, and frequently carried poisonous varieties about with him in his kit-bags. Presumably, he was accustomed to deal with desperate situations: at any rate he dealt with one on this occasion in a truly masterly manner. In a few moments, as it seemed to me, he had hewn out a new path through the elephant grass, and was diverting the stream of tortured men and animals down it, and, by a detour made to avoid the bee area, round to the front again. This officer, a few months later, received the Military Cross for gallantry displayed on another occasion, and no decoration, in my humble opinion, was ever more richly deserved. The episode proved what the South African civilian soldier could do on an emergency. He may sometimes have fallen a little short, in his views of discipline, of the ideals I had been accustomed to with the Guards, but he displayed on occasion a resourcefulness which even the Guards themselves might have envied."

After the successful close of the East African Campaign, Major Webb secured a company command in the Native Labour Contingent that went to France, and one well remembers his gratification on the receipt of a personal message from General Botha commending the natives to his care and consideration and emphasising the importance of the trust imposed on him by the Government. It is not too much to say that Major Webb was overjoyed at the opportunity of getting to France, and only with difficulty was he kept from seeking adventure in the danger zone. When towards the end of hostilities he was allowed to visit the firing line as the guest of the Commander-in-Chief, he tried hard to be allowed to remain near the actual theatre of war. A spell in hospital, however, led to his being sent back to South Africa in charge of a draft, and before he could return the Armistice was declared. It was a matter of the greatest satisfaction to him that he was able to take part in the Great War, and that he was able to give to the service of the Empire four stalwart soldier sons, all of whom distinguished themselves and won commissioned rank and were mentioned in despatches.

Preceding the interment in Brixton Cemetery, a brief impressive service was held in St. Mary's Church, Plein Street, by Canon Harrison Thompson. The coffin, borne by four sons of the deceased, with Captain Fowler, D.S.O., and Mr. A. Child, was covered with the Union Jack. There was a mass of floral tributes.

The chief mourners were the widow (Mrs. Clem Webb), Mr. and Mrs. Howes (daughter), Mr. and Mrs. Guy Webb, and Messrs. Stuart and Clement Webb (Godwan River), Mr. Dodd Webb (Johannesburg), and Mrs. Helen Driver (sister, Pretoria).

The gathering in the church and subsequently at the cemetery, where Canon Thompson conducted the final service, included, among others, Col. A. Woolls-Sampson, Col. Bettington, Col. J. Donaldson, Major Jenner, Senator Kidger Tucker, C.M.G. (representing the 1820 Memorial Settlers Association), Messrs. H. Adler, S. C. Black, W. B. Taylor, W. Webber, M.L.A., J. E. Nixon, M.L.A., W. Grey Rattray, H. Head, Colin Watson, J. Mackie Niven (representing the old Unionist Party), W. Bleloch, A. E. O'Flaherty, Samuel

Officers of the Imperial Light Horse, including Col. Scott-Chisholme, Col. Woolls-Sampson, Dr. W. F. T. Davies, Major Karri Davies, Captains John Orr, Barnes, Fowler, D.S.O., and Lieuts. Clem Webb (first figure on left, standing), F. H. P. Creswell, P. Norman and Brabant.

His Family.

The late Major Webb married, in 1889, Miss G. E. Pretorius, a descendant of the late General Pretorius and of the family of the late ex-President Pretorius of the South African Republic. There are six sons, Stuart, Guy L., Clement, Dodd, Herbert and Owen, and three daughters, Ellen, Mabel, Roma Gladys and Lorna. The sympathy of the whole community will go out to his family—particularly the younger members—on the loss they have sustained of a fond and affectionate father.

Rand Pioneers and W.A.S. Activities.

Amongst his other activities he was for several years on the executive of the Rand Pioneers, and he was also on the general council and executive of the Witwatersrand Agricultural Society to the day of his death. He was also a foundation member of the Rand Club and a life member of the Royal Colonial Institute.

The Funeral.

The funeral on Tuesday was a fitting ending to a varied and adventurous career. Every class and section of the community was represented, and the wide range of his sympathies was reflected in the attendance.

Evans, J. Lang, S. R. Potter (*Mining Journal*), Harry Smith, C. Hewitt, R. H. Sawyer, J. Gill, J. W. O'Hara, M. B. Gardiner, H. S. Lyons, R. Fielding, S. C. Black, Frank Hilner, John Martin, Murray Roberts, L. L. Feltham, W. Blaine, and W. J. Dold.

Floral Tributes.

Floral tributes with expressions of deep sympathy were sent from Sir Abe Bailey, M.L.A., Sir William and Lady Dalrymple, Stuart, Clement and Dodd; Harriet, Constance and Ivan; Guy and Glory, Alice and Sydney, "Chum," Vinny, Nell and Arthur; Vinnie, Harriet and Helen; Herbert, Roma, Lorna and Owen; the Webbs of Bulawayo; "Your godson and old comrade's son" (Almoth Clement O'Flaherty), the chairman and directors of the *Daily Mail* and *Sunday Times*, staff of the *South African Mining and Engineering Journal*, directors of the Central News Agency, Ltd., directors and staff of the Argus Company, Newspaper Union of South Africa, directors and staff of *Mining Journal*, Major and Mrs. Warby, Julius Jeppe, Mr. and Mrs. W. Ross, Mr. and Mrs. J. H. L. Manisty, Mr. and Mrs. J. H. Dinwoodie, Major and Mrs. H. A. Rogers, Mr. and Mrs. Moseley Brady, Richard R. Hollins, Mr. and Mrs. A. H. H. Grant, Mr. and Mrs. C. J. Kleudgen, Mr. and Mrs.

Kilgour, Mr. and Mrs. C. Meintjes and family, Mr. and Mrs. E. L. Bateman, Mr. T. Lloyds Ellis, Mr. and Mrs. Edward Blinman, Mr. and Mrs. Stayt and family, Committee and members of the Witwatersrand Commercial Exchange, Harold Mayer, H. H. L. Feltham, R. T. Ford, M. A. Zoccola and family, T. W. Becket and Co., J. Cyrus Milbourne, Chairman and Directors of the Rand Mines, Ltd., the Ladies' '89 Pioneer Club, the Directors of E. H. Adlington, Ltd., Captain C. H. Fowler, Jack Hartdeger, Hugh Grosvenor, Capt. and Mrs. Childe and family, Harry W. Smith and family, Mr. and Mrs. Dowling, Major and Mrs. S. Munnik, Mr. and Mrs. Frank Donaldson, Deputy chairman, committee and members of the United Party Club, Professor and Mrs. J. G. Lawn, T. P. E. Butt, Mr. and Mrs. A. N. Clogg, J. G. Fitzpatrick, C. E. Nelson, T. G. Currey, Carr Hammett, Transvaal Branch of the 1820 Memorial Settlers' Association, Union Club of South Africa, Rand Pioneers Incorporated, S.A. Party Club, Mr. and Mrs. A. Murray Roberts, Mr. and Mrs. Chas. Jenner, Mr. and Mrs. Henry Adler, Mrs. Kusel and family, Committee and members of the Witwatersrand Agricultural Society.

The funeral arrangements were carried out by Messrs. J. A. Hobkirk, Ltd., Bree Street.

A Personal Tribute.

By W. P. Taylor.

"Your brother is dead and you do not weep." "My brother is dead and I do not weep. Would all the tears that I could shed bring him back to life? My brother is dead and I do not weep." These were the words spoken at the grave of a noble Greek near on two thousand years ago. They were recalled to me by one who to-day is no more. They were brought to my mind by his own words when last I saw him in life. They were recalled to me by his noble bearing, his utter indifference to death. Perhaps I was one of few who realised his danger, and it was only the long years of friendship, unbroken friendship, that permitted me to venture so deeply on the danger of his physical trouble. In the good old days when we were all much younger, how often had I seen him in the white flannels of gymnasium. I had seen him in the ring with the gloves, and whether on bars or where it was, in that garb he was the true type of the figure loved by that great man whose embodiment of physical energy has been placed as an outstanding emblem on the slopes of the hill at "Groote Schuur." The Hermes of Praxitiles at Olympia in Greece, said to have all moods of human expression, and pouring all human beauty and strength, I saw near its bed, where for near two thousand years it had rested, and as my eye fell on its beautiful outlines, I thought of a face that had filled my mind with the same forces away in Africa's veld. I thought of the face of my friend, Clem Webb, and I said to myself, "there are other Hermes living." I have known him in sport and in the field—a lover of fair play and hard fighting, gentle as the moods portrayed by that dead sculptor twenty centuries ago, a living embodiment of life in its best aspect. He accepted death as those do whom the Gods are pleased to call. "My brother is dead, and all my tears will not call him back to life."

Another Pioneer Gone.

By Alfred Stenhouse.

The pity of it! There cannot be more than 300 or 400 real Pioneers now amongst us. Men who laid the foundations, in 1886, of the greatest gold mining industry the world has ever known. Soon we shall know them no more.

Cannot there be a last reunion of these Pioneers in the garden of "Arcadia"? Our first thought every morning should be "First seek ye the kingdom of Heaven." Our friend Clem Webb superlatively possessed the greatest of all virtue, "absolute unselfishness." At the final bar of justice rich and poor alike will toe the line on an equal footing, and by our deeds shall we be judged. Life is short, but once our mission on earth is accomplished, may we also, with every confidence, endorse the farewell song of the meteoric stars:

"O Grave, where is thy victory?
Oh, Death, where is thy sting?"

An Old Comrade's Tribute

By Capt. C. H. Fowler, D.S.O., late I.L.H.

Life was a vivid reality to Clem Webb, and he lived it fully. Athletic and virile, he revelled in the vigour and abundance of it. An all-round sportsman who put the game above the prize, he believed passionately in fair play. He had strong convictions and stood to them strongly, but in thirty years I heard no malice or uncharitableness from him. His good fellowship, his sense of humour, his anecdotes, his optimism, made him an attractive and most lovable man, and the basis of his character was a wide and deep sympathy. He loved his country; he loved his fellows, and he loved children. Though his business kept him in town, he was an out-of-doors man, and his heart was in the calling spaces of veld and bush and berg, where God keeps open house. His heart was very near Nature.

His record of active service began with the Basuto War in the seventies, when he got into trouble for joining too young. It ended on the Western Front when peace was declared in 1918. A fighting man; he got to every war he could reach. He was a valuable officer in the Imperial Light Horse through Ladysmith in the Boer War, and in East Africa was awarded the Military Cross for a signal act of cool gallantry at the age of nearly sixty. He believed fervently in his Race and its cause. He was a Crusader from his youth up.

He represented South Africa at the Colinderies Exhibition in London in '86. He was identified with every form of sport. He played his part in the troublous nineties in the Transvaal, including the Johannesburg movement in connection with the Jamieson Raid at the end of '95, and was especially prominent over the Edgar case in '99. He acted as a head of one of the branches of the municipal service of Johannesburg after the military occupation of the town in 1900, and he represented Yeoville in the Provincial Council about 10 years ago. This is not meant to be a list of his activities, but merely those that occur to me as I write.

Natives trusted him implicitly. His fondness for animals was remarkable, and their response extraordinary. The only horse in the Imperial Light Horse that came out of Ladysmith in decent condition was his "little mare." He dug roots for her. She followed him like a dog. I wish that someone who knows about his horse "Jerry" from personal experience in East Africa would tell the story.

Stevenson says finely, "Every heart that has beat strongly and cheerfully has left a hopeful impulse behind it in the world, and bettered the tradition of mankind." It was thus he lived. He was very human. He was a rare companion; he was a chivalrous opponent, and he was a strong and a sincere friend. He was a pioneer of the Rand, and dated from '88. He did his level best. He pulled his weight; he played the game. This place is the poorer by a great and loyal heart, and many, many miss "a friend that sticketh closer than a brother." The heartfelt sympathy of his friends goes out to those near and dear to him.

An Appreciation.

By Colonel R. A. Bettington.

Seeing that my old friend and I used to exchange experiences covering a period of no less than forty years, I did not hesitate in accepting the Editor's courteous request to put down a few personal recollections of the dear old fellow. His military career has already been dealt with at length, so I will limit myself to saying that he was of the best type of officer—of the men who do things and say nothing, who infinitely prefer speaking of what others have done, and when pressed for personal details relate amusing incidents of which they have been witnesses. Unlike many officers of irregular forces, who so often consider themselves immeasurably superior to their professional brethren, he had a profound admiration for the real thing. I recollect his telling me how in France he attended a gymkhana managed by some of the old "Contemptible" cavalry officers. He turned to his companions and said, "These be officers." "So are we," somewhat indignantly. "Oh, yes, but we can't look like them." "You know, Bettington, our fellows can fight with the best, but it's no use, we can't carry our uniforms like those fellows, even if we have them made by the same tailors; it takes years to walk as they do." For all that, there was not a Guardsman in the British Army who would have denied Clem Webb the right and title of an "officer and a gentleman."

His prowess as an athlete and a boxer have already been mentioned, but never was that mighty hand of his raised save in justice. While we were connected with that financial failure, the *Sunday News*, we had planned a series of articles on extended education for those who had to work for their living, and also on the native question, on which he held the soundest views. When the town and reef were all agog over native outrages, he told me that his old Zulu servant said: "Baas, if this matter was left to us Zulus, we would stop it very soon; we don't like it." It is a pleasure to remember that over the long term of years never one angry word or thought passed between us. His wife must be comforted by the knowledge that she has four gallant sons to carry on the tradition of his own fine record. Righteous people may say, "God rest his soul." It is the last thing he would have wished. As I am writing, I know that my friend is living and doing good work with increased vigour and ability. For "the souls of the righteous are with the Lord." And he is no idler.

Au revoir, my friend.

By Scott Alexander.

The demise of Major Clem Webb, M.C., the proprietor and managing director of your esteemed journal, leaves a blank file in the dwindling ranks of the early and worthy pioneers of the Rand, but those of his pals who are left, like good men and true, knowing that they also will soon have to face the inevitable, in all reverence bid him "au revoir," but not good-bye. His life's history the newspapers all over the country have given, and you will elaborate; but kindly allow me, sir, an old friend and admirer of so noble and charming a character, to add Wordsworth's words as my humble tribute to his memory:

"That man who is from God sent forth,
Doth yet again to God return;
Such ebb and flow must ever be,
Then wherefore should we mourn?"

Some Reminiscences.

By C. J. Lever.

My recollections of Clement Davies Webb extend back for 41 years. When I went to the Diocesan College in 1880, I found him there, and a more handsome specimen of man-

hood it would be difficult to find anywhere. He was then about 19 years old, but well-grown and splendidly developed. He was a particularly good gymnast and boxer, and well to the fore in any kind of sport going. When I first met him he was Senior Lieutenant of the Diocesan College Cadet Corps, and shortly after was promoted Captain Commanding vice Frank Molteno, who was leaving the College; and I can assure you that Clem looked particularly smart in his dark blue uniform with white facings. He left College at the end of 1880 and went to his home at Queenstown, where, as it happened, I too went in 1882. For the four years of my stay there I was constantly in touch with Webb, not only socially but in connection with football, etc. He and I were members of the Queenstown Swifts Football Club, and we have played together in some hard fought contests against Kingwilliamstown, East London and the C.M.R.

I left Queenstown in 1886 for Pretoria, and soon after heard that Clem had come to the Witwatersrand to try his luck. His career here is so well known that I need not touch upon that, except to say that he always took a keen interest in sport of most kinds.

His service in the Anglo-Boer War is well known. During the late War I met him on board the *Professor* at Dares-Salam, and we journeyed to Durban together, where he was invalided out of the 5th S.A.I. Later, in 1917, when I went to France, I had the honour of serving under him in the S.A.N.L.C., in which he was one of the most popular and efficient officers.

Clement Davies Webb was a gallant gentleman, kindly, courteous and debonnaire, and his keen sense of wit and humour always made his society charming and entertaining, and I, and others who knew him so well, will miss him sadly.

"Clem Webb of Ours,"

By A. E. O'F.

It didn't seem to be Clem Webb's turn—not yet. Our people have been marshalled in legions through the wide gates of Death and the most grievous sacrifice has been taken of the young. We are benumbed by unseasonable death: and the epitaph is complete with a date and a number. Yet the closing of Clem Webb's life has suddenly shocked us all again. We measure time by our own shadows; and Webb cast so little shadow that his day seems to have ended in the meridian. I know now what this quality of his was. He took an interest in living—the first quality in a journalist, in the philosopher, and here I see him smile—in this religious man. "Behold that which I have seen to be good and comely is for one to eat and to drink and to enjoy good in all his labour wherein he labour-eth under the sun all the days of his life which God hath given him . . . and to rejoice in his labour: this is the gift of God. For he shall not much remember the days of his life: because God answereth him in the joy of his heart." That "vitality" of his interest caused us all, too, "not much to remember the days of his life," and so he has left us with the pang that belongs to the death of a boy.

It is more than a quarter of a century since I inherited Webb as a friend; and to review the memories of him in those momentous days of South Africa is to walk again in the paths of youth. None of us would claim now that the "patriotic" things we did were right in themselves, but I can safely make the claim for Webb that the spirit in which he did them took away this essential evil—as it seems now—of his deeds. What the unseen forces were which swept Boer and Briton into unnatural and futile conflict none then guessed. For Webb it was not only the high call of patriotism and duty, but a demand which no man of honour could shirk. Idealist in everything, the ideal of England was for him what, I suppose, the Cross was to the Crusaders. It is true that he returned from two such crusades with thoughts severely chastened. He learnt to call himself an Afrikaner

and to feel a genuine friendship for that section of us who first took a pride in the name. It was in their interest he founded *The Farm News* and he looked forward to end his days as an oprechte boer. Yet it was very largely due to this fiery zeal of Webb and Dodd—another idealist—that the turnouts of Johannesburg provided the occasion which the politicians turned to war. His influence was neither oratorical nor literary. His courage vitalised the men around him and his gaiety overbore reflection. Perhaps nothing could more vividly have evidenced the sincerity of his regard and reconciliation with "the Dutch" than his candidature for the Parliamentary representation of Marico. In this he was admirably supported by the beautiful girl he had romantically wooed and won as wife in the years before the turbulence. His instinctive humanity made it easy for him to resume kindly relations with old German friends in spite of the propaganda of hate; and he told me with perhaps a touch of emotion on his return from the battlefields of Flanders that he had found a more cordial welcome from the Germans here than he had from his own. Perhaps it was because it touched his chivalry he felt it so much.

Perhaps the most surprising characteristic of Webb was his modesty. It suited well with his broad shoulders and manly bearing. It made him under-rate his own capacity. He would have been an admirably straight-forward speaker was he not always made shy by a sense of unproficiency, and the *Mining Journal* would have been strengthened had he written more of it. What is remarkable is that while the Journal had as editor many of the most brilliant men of the time, Webb's own personality always made it his paper. I suppose that in no newspaper office in the world was the blue pencil of "the management" so little used; but his editors had a regard for Webb's friendships, and on the whole it had the effect of sound policy.

Behind the apparent unanimity of what is known to the public as the "Mining Houses" there have been intense and even fierce personal rivalries and animosities. In a place like Johannesburg the journalist writing on public themes knows, if he knows his work, that he is also dealing with the crucial affairs of men he is meeting every day. "Detachment" is only got by effort and the "elimination of the personal equation" is hard and, perhaps, not always sound. Webb, however, was no sycophant and criticism of the "Houses" has appeared in the Journal that would not have been permitted by one who only regarded his advertisement pages. In this, however, he proved to be the best friend of his friends, and none can say that "small men" or "new propositions" have been cold-shouldered or repressed or excluded by the *Mining Journal*. Wherever there is a live newspaper the editor's office is a live place. No thrilling thing of his many thrilling things this land has felt since Kimberley reached out to the Rand was long of reaching "the office." Whether it was a new current pushed from outside into the South African League, a new direction about to be imparted to our politics from outside the politician, a new event in this mining or social world, it was earliest and most fairly canvassed in Webb's office. It would be out of place here to record these: over his grave should be preserved the urbanity that distinguished all his dealings. His idealism was tempered with the scriptural counsel: "Be not righteous overmuch." Perhaps that is why all the manly padres liked him. He was most at home with the Catholics, I think, and his national respect for holy things and gay courtesy were always charming.

I seem to have been at Church services very often with Webb. Some of them are vivid now. All but one were for the consecration of a soldier's cause. They grow fewer who recall the last Church parade in Maritzburg, when Scott Christolme read the lesson. Fewer still who recall the rest on the arms reversed when we committed that fine soldier to the grave in the Ladysmith twilight, of which John Stuart wrote so well. I recall the solemnity of the Imperial Light Horse in St. Mary's and some firing parties elsewhere. But none of such things could be more cut into memory than his last Church parade. The soldiers were all engaged with the Minister of Defence and no one had leave to grace his passing with a soldier's farewell, such as

he had a right to. Well, they treated Lukin's arrival here with the same unconsciousness. But his four strong boys in uniform carried their gallant father's body up the aisle and from the altar attended it for the last salute at the grave. The best soldier's funeral I have known.

To them is committed, I suppose, to carry on the *Mining Journal* and the *Farm News* in the same spirit of bright faith and balanced sincerity as illumined their happy father's work and life.

Frater, ave atque vale.

A. E. O'FLAHERTY.

Mozambique Portland Cement.

In the course of a long and detailed report, Capt. H. Pooley, Jr., B.Sc., A.M.I.C.E., F.G.S., one of the consulting engineers to the Mozambique Portland Cement Co. Ltd., states that the company was fortunate in securing its plant at so reasonable a figure, as if quotations were obtained afresh, he thinks that the price would be increased by some £30,000. He concludes his report as follows:— "There is little need for me to say much to you in connection with the prospects of a cement company. At the present time in Africa the field for cement is practically unlimited; cement is being used more largely as time goes on in connection with all manner of constructional work, and I see no reason to doubt that larger quantities still will be required in the future. I feel sure that, before long, you will be wise to consider the duplication of your plant, because the opportunities of your company are unique, and when the factory is in running order, you can look for very substantial returns on the money you have invested."

South African Carbide and By-Products.

At the first annual general meeting, held at Winchester House, Old Broad Street, E.C., Sir Cecil Partridge, K.B.E., the chairman, in moving the adoption of the report and accounts, said that circumstances had arisen since the last meeting over which neither the directors nor the various contractors employed by them had had control, by which the company's programme had been considerably retarded. The directors had determined to push on with the greatest possible speed the carbide side of the company's business, and, in order that production might be secured as early as possible, the consulting engineers had been requested to concentrate upon the construction and equipment of the carbide factory and power station, and it was confidently expected that these sections would be in full working order in six or eight months' time. The progress made in connection with the producer and low temperature section led the directors to anticipate that a portion of this plant would be in operation at an early date.

The increases in the cost of labour and materials since the formation of the company had been reflected in the cost of the company's works and equipment, but the actual expenditure would not be so high as was at one time feared. The estimated commitments were now £292,933. Ten per cent. of the total cost of the plant was not payable until the plant had been operating for three months, and it was hoped that at the expiration of such period the company would be in receipt of revenue sufficient to meet current expenses. The market price of carbide in South Africa had very much increased, and, although working and transport costs had shown a similar tendency, the directors anticipated that the profits accruing to the company would exceed their original estimate. Sir Dennis Bayley, who had recently returned from a visit to South Africa, reported that, considering the unavoidable delays caused by the moulders' strike and the serious congestion on the South African Railway, he was pleased to find the work on the carbide and by-product factory at Ballengeich so well in hand. In his opinion, a very good contract had been made for the building of the factory.

Asbestos in the Pietersburg District.

Early Days at Kimberley.

DIAMOND BUYING METHODS—SOME NOTABILITIES—GUN-RUNNING—SOCIAL AMENITIES.

(By W. P. Taylor.)

These sketches of early diamond fields life are entirely from memory. One or two friends who trod that same soil in those days have corrected impressions and recalled events. I may be guilty of repetition, but with all this risk I venture to show things as I saw them when a boy of 13. Although the country was flat at first, it was not long before we had our mountains. They did not rise to 30,000 feet, but we had our Mount Ararat, Mount Frames, and mountains at the West End, and dotted about were numerous kopjes, all made out of the siftings and sortings from the mines. When I am asked to-day where streets and avenues are, I don't know. I wasn't brought up with streets. We had our Main Street, Dutoitspan Road, and one or two other places you had not dare to forget, but our points of direction were our mountains of debris. Alas, the debris washers came and destroyed all early attempts at scenic beauty, for in order to get the diamonds left by the early sorters, they were all put through the washing machine, and the town returned to its early flatness. When men first came in, it was seen that our discovery was something unique. In America, in earlier days, there was a general movement across a great continent. The Red Indian and the bison had their centuries old sanctuaries invaded. Mormons usurped Utah, and over the great Rockies and their divides Europeans were laying the foundation of that great Republic that already counts over one hundred million souls. In Australia the red-shirted digger had sunk paddocks upon alluvial beds at Bendigo and Ballarat, and from these places there were men whose love of adventure had brought them all the way to Kimberley. There were men just out of the great American Civil War, and later. There were several that had experienced the Siege of Paris and fought at Metz. There were men from Ceylon and India, sugar planters from Mauritius, tea tasters from Mincing Lane, and diamond cutters and others from various vocations. There was a man called "Lying Watson." He found his way to Natal with a shipload of Australians that were induced to come and work alluvial gold. Watson had "pitched the tale," and his ideas were immense. From the first he never took any interest in diamonds. Gold was his dream. He would harangue a crowd of Australians and loudly maintain that the Transvaal was the greatest gold field on earth. Ballarat and Bendigo would be nothing compared to it. His mates would fill him with brandy and he would go to sleep saying "Bendigo, Ballarat—faugh. I know the, the, the—why, damn it, of course—the, the, why this country's full of it, full of it; I know." Strangely enough, old lying Watson was quite right.

The man that you constantly saw peddling diamonds was a Dutchman. The soft yellow ground suited him. He got up early, and directly after breakfast he turned up with a stone. He sold anything he found, just as quick as it turned up: a chip for 10s. or a stone for £50. Up to winch and bucket he had a great time, but the blue ground knocked him silly. When his pick would not bite the blue, he was done. His hasty conclusion was he'd struck the bottom, and selling his claims he returned to his farm. Blue ground had to be weathered. This entailed lots of things. It entailed borrowing money. Two to three per cent. per month was the customary rates. The banks—Marais Bros., L. H. Lyons—and others did a great trade in money lending.

My friend, Mr. Henry Adler, tells me he bought the first diamonds from Dutoitspan and Bultfontein. The early profits were fabulous, inciting London to send out large sums to purchase diamonds, with the result that they were over supplied and lost heavily. In the early scramble to buy

diamonds the Port Elizabeth firms came first—Mackay, Dunn & Co., Hill & Paddon, Mosenthals, Lipperts, Prince, Vincent, and others were very early in the field. Charles Meige, (Sir) Julius Wernher, Bordineks and Faleke, Schwabacher, Max Gammius, (Sir) S. Neuman, Litkies, S. Neales, S. Sacke, Von Beek, Petersen and Dreyfus were, with others, the first foreigners. Then there was Sir Joseph Robinson, J. C. Rimer, James Ferguson, J. T. Phillips, F. T. Gervers, John Birbeck, W. Corbridge, H. B. Webb, C. J. Posno, Barnatos, Harrises (Sir David), Morris, Pickler, Pittiar, Levenson's representatives, English and Yankee Wilson, and H. J. King's Americans. The great Paddon family had the West End to themselves. Amongst the earliest brokers were my father (T. R. Taylor), T. G. Glyn, the Anells, A. Bain, Count Platé, the two Bowleys, Harry Harris, W. Heckrath, Parsons, King, Kopje Smith, W. Else, W. Norris, Arthur Davis, H. Barnsley, and various others that I cannot remember. It was wonderful how we all pulled together. Somehow or other, we did not get in one another's way. With slight exceptions there was an honourable camaraderie that has lived to these years, for I never meet one of the old brigade without some recollection of the old days being revived. It was a sunny time. Most of the years we dressed in white flannels or drill, and it was a religion to have a helmet to match. If you saw a man in white at any time, he was one of the diamond brigade. It was an easy life, the hours being from 9 to 1 and from 3 to 5. It was no good trying to bring in an eight hours day; the buyers only looked at goods when the light was right and the day cool. There weren't many fortunes made in those days. Life was an easy problem, and those that had talent distinguished themselves in music, and others with histrionic ability on the stage. My father was an actor of no mean ability. There are those who will remember his rendering of such parts as Shylock, Fouche in "Plot and Passion," or his Triplet in "Masks and Faces." He had acted over a long period, formerly having introduced the first opera company and the first circus to the Cape. He also introduced the first sewing machine and the first daguerreotype (photograph); that was very long ago, in the fifties, I think. He never was a rich man, but his efforts in those days procured more for charity than those of half the community among whom he lived. He was ever ready to do a service, and the first man to be called upon. Probably there are still some who have not forgotten his wonderful talent and versatility. The present picture shows are destroying the old arts. Local personality is supplanted by American films; our playgoers are no more. The farce, comedy, drama, tragedy and burlesque are not now followed

GOVERNMENT EXAMINATIONS.

METAL MANAGERS EXAM.: Last examination (May, 1921), 15 Metal Certificates were granted in South Africa, and of this number our students secured 10 certificates. Previous examination we secured 7 certificates from 8 entries, and in two other recent examinations 15 passes from 19 entries.

REMARKABLE AND CONSISTENT RESULTS.

COAL MANAGERS EXAM.: Last examination (May, 1921), we secured 3 certificates from 6 entries.

OVERSEAS EXAM.: 21 certificates secured 1920, and 14 certificates to date, 1921.

SURVEY EXAM.: We have secured practically all the certificates granted by the Mines Department during recent years and have obtained 60 certificates to date.

and the renderings of favourite actors registered. As time goes on, reality will fade, and from our midst there will be no entertaining geniuses unless it is from the schools of music and singing. But in those good old days we fell in love with our talented actresses, and the girls went to see Dave and Charlie and all the other young heroes that came out of the diamond market.

Now I come to a wonderful little man with a soft dark beard and a pair of piercing bright eyes. When in action he was coatless and had a lovely coloured shirt, diamond studs, a white helmet, clothes from Peole's, and last, but not least, his buttoned boots, cloth and patent leather, and the heels, just to make him a bit bigger, were actual high heels. In his hand was a white ox tail, and on his signboard A. A. Rothschild—otherwise the Baron. When his various natives rang their bells, Von Bressendorf, the postmaster, donner-wettered and cursed, but the whole street succumbed to the baron. Long rows of tables were laden with miscellaneous goods, and a merry crowd surrounded the wizard and were taught to bid. He made auctioneering an art, and he made a fortune as well. Old Martel was kept busy for years with great ledgers full of figures, and the irrepresible little baron never tired of selling. There was no article he could not fix a tale on to, and sometimes his embellishments were so effective that his customers veritably fought to get the worthless thing. I cannot remember his poetry, yet I can still scent the far-off rose leaves, the very incense and myrrh of his prose, and if in his ecstasy he rose to untold heights, the warmth of his story brought sublimity never too low to entice a buyer, and withal he was loved, and Kimberley lost a bright little pillar when the baron descended from his pedestal and closed his portals.

Wild mobs rushed beside Mount Ararat to burn out canteen keepers. There was the conflagration of canvas and burning liquor. If three-quarters of the liquor sellers had been burnt out, it would have done good. They were getting all the principal diamonds; but without certain evidence things were going too fast. The canteen keepers did not make fortunes; they were a la forchete, for if they did not sell cheap to the buyers they were in danger of being denounced to the mob. It was the buyers who made the money. On Monday mornings certain brokers sold large parcels for certain buyers. The brokers who sold for the legitimate buyers had thin parcels. This sort of thing became so obvious that it attracted the serious attention of a certain gentleman named Cecil John Rhodes. The first thing he did when he returned to Africa after having eaten his dinners and being called to the bar, was to frame a new diamond law. He did it well and truly, with the assistance of other skilled lawyers, and after that John Fry and Izdebsky and others were kept busy, and the big parcels of heavy diamonds were not so apparent on Monday mornings.

The first natives that came to work were most intent upon having guns. There was no law to prevent gun-running, and long rows of Kafir stores sold coloured blankets, old military coats, tunics and trousers, and old military rifles. The muzzle-loading Enfield was not rifled. Equipped

with powder flask, bars of lead and moulds, and garbed in the tunic of a guardsman or the red serge of a foot soldier, thousands of Makatees from the Northern Transvaal, and Shangaans from further on, trailed back with these rifles. How incongruous natives looked in their attempts at European dress. They had come into camp in loin cloths and loose waist adornments, and then they would wear a white paper collar, sometimes that was their one article of European refinement. Coloured tunics and no trousers was quite ordinary for a time. Afterwards dress regulations came in, military sales were stopped, and the colourings sobered down. The early efforts of natives to reach the mines must have been great. They marched from six hundred to near on a thousand miles. Many died on the way, and those that survived were in many cases mere skeletons. It was wonderful to see how quickly they revived and fattened. It was interesting to observe how they settled down to their work, and once they understood their master and what was wanted of them, they carried out the routine and gave little trouble. Well, routine is so easy when once understood. The mules were trained afterwards to trot from the machine to the floor and back again to the machine, without drivers; but when Chicer came, that is, the one o'clock whistle, they had to look slippy, for the mules put their ears back and bolted for their stables.

During all these years there was constant prospecting for new mines. There was St. Augustine's Mine, Taylor's Kopje, Otto's Kopje, the Jagersfontein and Koffyfontein groups. Diamonds were found in impossible places. People rushed about and made a picnic of the occasion until they learnt that an ostrich, a turkey, or a fowl could swallow diamonds and retain them in their crops. They had been too ready to believe in new discoveries. The largest diamond I heard of being found in a fowl's crop was a 14 carats, worth £100.

There was no telegraph, only one post a week, no telephone, no electric tram, and no motor car. It cost 10s. to drive to the river for a week-end. There were yellow fish and barbel. The world was young. What could one wish for more?

Simmer & Jack Prospects

The operations on the Simmer and Jack during the year ended 30th June, 1921, resulted as follows:—A comparison of the results obtained during the last six years is as follows:

Year ended 30th June, 1916: Tons milled, 797,900; yield per ton, 5.288 dwts., value 21s. 11.236d.; costs per ton, 14s. 8.854d.; profit per ton, 7s. 2.382d.; total profit on working, £227,184.

Year ended 30th June, 1917: Tons milled, 765,300; yield per ton, 5.125 dwts., value 21s. 4.865d.; costs per ton, 15s. 5.619d.; profit per ton, 5s. 11.216d.; total profit on working, £227,184.

Year ended 30th June, 1918: Tons milled, 685,400; yield per ton, 5.518 dwts., value 23s. 1.289d.; costs per ton, 17s. 4.902d.; profit per ton, 5s. 8.387d.; total profit on working, £195,304.

Year ended 30th June, 1919: Tons milled, 605,900; yield per ton, 5.224 dwts., value 21s. 11.746d.; costs per ton, 19s. 10.960d.; profit per ton, 2s. 0.786d.; total profit on working, £62,575.

Year ended 30th June, 1920: Tons milled, 621,300; yield per ton, 4.933 dwts., value 26s. 1.780d.; costs per ton, 22s. 9.007d.; profit per ton, 3s. 4.773; total profit on working, £105,550 (including premium on gold).

Year ended 30th June, 1921: Tons milled, 702,900; yield per ton, 4.581 dwts., value 25s. 4.559d.; costs per ton, 21s. 11.788d.; profit per ton, 3s. 4.771d.; total profit on working, £119,253 (including premium on gold).

Mr. G. A. Chalkley, the Superintending Engineer, writes: "From the figures given in the manager's report it will be seen that the premium obtained on gold during the year ended 30th June, 1921, amounted to £211,766 2s. 11d., and was equivalent to 6s. 0.399d. per ton milled. The tonnage milled during the year amounted to 702,000 tons, with a yield of 4.581 dwts., as compared with 621,300 tons, with a yield of 4.933 dwts., for the year ended 30th June, 1920. Working costs per ton were approximately 9d. lower than for the preceding year, the decrease being due chiefly to the adequate supply of native labour, especially during the latter part of the year, and the reduction in the number of white underground workers. The average number of natives employed was 3,803, as compared with 3,396 during the previous year. The development accomplished amounted to 4,266 feet, of which 1,227 feet were sampled. Payable reef was exposed over a distance of 594 feet, with an average value of 13.7 dwts. over a reef width of 33 inches, equal to 452 inch-dwts. During the year the tonnage hoisted through the Rhodes Shaft increased from 9 per cent. to 48 per cent. of the total tonnage. The sinking of the Rhodes Incline Shaft has been completed to the 39th level, and the installation of the engine and shaft boxes is being proceeded with. Through this shaft will be hoisted the ore from the claims taken over from the Simmer Deep and Jupiter Companies, the workings of which are now being opened up. The outcrop section of the mine produced 12 per cent. of the total tonnage at a profit of £1,300 per month, and a further twelve months' supply of rock is in sight. Owing to the closing down of the Simmer Deep, Jupiter and Knights Deep mines, and the dismantling of the central pumping plant at the Lohse shaft of the Knights Deep, the water from these mines, and also from the Simmer and Jack, is now accumulating in the workings of the Simmer Deep below the southern boundary of your property, and it will be necessary to instal new pumping plant to deal with the water before it endangers the working of your mine. The ore reserve fully developed at 30th June, 1921, is estimated at 1,081,000 mine tons of an average value of 5.71 dwts. per ton over a stopping width of 76 inches. I wish to place on record my appreciation of the work performed by your manager and his staff during the year."

Simultaneously with the revival of the diamond trade, merchants at Antwerp have opened a new palatial diamond exchange, work on which was begun in 1913 but was interrupted by the War.

"Stabilising the Exchanges."

It is reported from Washington that Treasury officials there "are considering the question of assembling an international congress of financiers, possibly coincident with the coming disarmament Conference, to discuss the stabilisation of the foreign exchanges." What exactly is proposed is not yet clear, but apparently in financial as well as in political affairs, the United States is beginning to realize that an attitude of "aloofness" is impossible in the present interdependent condition of all countries in the world. If so, this is a satisfactory development. It is suggested that the Conference may consider the question of settlement of some forms of commercial indebtedness along the lines of international bonds, instead of in actual currency, but it is clear that if exchanges are to be gradually stabilised, to put their currencies on a gold basis, however reduced the ratio of gold to paper, something must be done to help the more necessitous countries.

EDITORIAL.

THE LATE MAJOR CLEM D. WEBB, M.C.

Although we all recognised the dangerous nature of the illness from which the late Major Webb was suffering, his death on Monday morning came as a painful shock. Knowing his indomitable spirit, his wonderful power of resistance, and his magnificent physique, we continued to the last, hoping against hope, that he would win through. But though he had the very best medical and surgical help available—indeed, the surgeons fought for his life with rare and wonderful perseverance—coupled with the loving care of a devoted wife and family, the trouble had become too deeply rooted to allow of his life being saved. We who have served under and with him through years of stress and strain, ups and downs, of anxious change and ever-varying conditions are left to mourn a good man gone—a broad-minded, generous, big-hearted friend, who was at once a leader and a comrade. Other pens in other parts of this paper pay tribute to his worth as a man, his personal bravery as a soldier, his steadfastness in face of trouble, and his unflinching high courage that marked a life full of action and endeavour. In a brief and inadequate sketch of his career printed elsewhere in this issue, we have tried to illustrate the many-sidedness of his interests and the surprising cheerfulness with which he encountered "the slings and arrows of outrageous fortune." His were in full measure the difficulties that invariably beset the path of the adventurous and the pioneer. But he refused to let them daunt his brave spirit, and it is not too

much to say that few men would have survived with such unbroken serenity the trials he underwent during the thirty-three years of his connection with the Rand. Though Fortune denied him the favours lavished so bountifully on many of his pioneer contemporaries, he enjoyed the substantial compensations of a devoted wife and family and a wide and warm circle of friends drawn from many walks in life. His large-hearted generosity was his most pronounced quality. No appeal of a fellow-creature in distress could he resist, and he was never happier than when "helping a lame dog over a stile." He was known among the needy from far and near, and it is not too much to say that the extent of his private benefactions was out of all proportion to his means. As the history of his career so clearly shows, fighting was in his blood, and his happiest days were spent on the veld with horse and gun. In the world of sport he held a record to be proud of, and the fame of his prowess extended far beyond the confines of South Africa. As a soldier, we have the sincere and enthusiastic testimony of all who served with him to the effect that he was brave almost to the point of rashness and a born leader of men. In civil life, perhaps, his naturally modest—almost shy—and unassuming nature prevented him from taking the prominent part his talents would otherwise have rightfully commanded, and also mitigated against his success in politics. In private life his lovable attributes of comradeship and cheerful good fellowship made him a host of friends and warmly endeared him to them. If we may introduce a personal note, it may be added that no one was easier to work for or with when once his trust and confidence had been gained, and he had in a remarkable degree the capacity for drawing forth the best efforts of all associated with him. Indeed, his personal magnetism and the uncommon devotion he inspired in his colleagues and associates was perhaps, in practice, his most valuable asset. His memory will long be cherished by those of us who were privileged to serve him, through the not always easy years, as that of one who fought the good fight, maintained his spirit in the face of many trials and discouragements, and who left behind an honourable and enviable record in private life, as a loving father, husband and brother, and, in public life, as a loyal and generous friend to many.

DEATH OF MAJOR McCORMACK, O.B.E., M.C.

With deep regret we have to record the death, which took place suddenly this week, of Major M. McCormack, O.B.E., M.C., Manager of the Union Corporation, Ltd., and a member of the Executive of the Chamber of Mines. The late Major McCormack was born in Ireland fifty years ago and came to South Africa in 1898. He served through the Boer War in Kitchener's Horse, attaining the rank of captain and paymaster. In 1902 he came to Johannesburg, and joined the railway service, in which he held the position of assistant accounting officer, New Construction Department. In March, 1905, he was appointed accountant to the Rand Water Board; in March, 1906, he became acting secretary, and in October of that year he was appointed secretary and treasurer to the board. This post he held until June, 1920, when he resigned his service with the Board in order to take up the important position of manager in South Africa of the Union Corporation, Ltd. This position he was occupying at the time of his death. In February, 1915, when the campaign in German South-West Africa was in progress Major McCormack was appointed D.A.Q.M.G., Northern Force, and held that position until the end of hostilities in the territory, receiving for his services the Military Cross. In August, 1917, he went overseas and was gazetted to the "Queens" (Royal West Surrey Regiment). He was then placed on the staff at the War Office, becoming later Assistant Controller of National Aircraft Factories, and for some time being Acting Controller. At the termination of this service in July, 1919, he received the O.B.E. To his sorrowing widow and family we extend our deepest sympathy.

Notes & News.

Machavie Prospects.

Tests of the tailings at the Machavie Mine made by the Minerals Separation people have given favourable results, and it is hoped that, like the Afrikander, which is to be re-opened soon, the Machavie may be given another chance.

* * * *

S.A. Alkali.

A reference in the share market notes in our last issue to the forthcoming debenture issue by the S.A. Alkali has been misinterpreted as reflecting on the guarantor of the issue. What actually it was intended to convey was that the fact that the company had found it necessary to make an issue of debentures had unfavourably affected the shares. After all a debenture issue is a loan and a first charge on the assets of a company, and no matter who the lender may be, the transaction is bound to depress the quotation for the shares.

* * * *

Rand Refinery.

It is officially announced by the Chamber of Mines in regard to the Rand Refinery, Ltd., that it is expected operations on a small scale will commence at the Refinery during the month of October, and that early in the New Year the whole of the production of the Witwatersrand gold mines will be able to be refined. A staff of some seventy employees will be engaged. A photo of the Refinery appeared in a recent issue.

* * * *

Birthday Asbestos.

The Willoughby's Consolidated Company issues the following announcement with reference to the Birthday Asbestos Mine, in which it has a 40 per cent. interest: "Willoughby's Asbestos Pool is taking advantage of the slump in the asbestos market, and its improved financial position, to cease producing from its Birthday mine for six months in order to bring the plant up to date, instal grading machinery, and further develop the mine, the recent reports from which are highly satisfactory." The Birthday Asbestos mine is in the Shabani district of Rhodesia in the neighbourhood of a block of claims belonging to the Rhodesian and General Asbestos Corporation. The Chicago-Gaika Company also owns a 40 per cent. interest in the Birthday mine, while the remaining 20 per cent. is held by the Surprise Gold Mining Company.

* * * *

The Afrikander Redivivus.

We understand that the old Afrikander, in the Klerksdorp district, may soon be re-opened by a syndicate composed of well-known Johannesburg mining men. The property, of course, is owned by a company, the Afrikander G.M. Co., Ltd., and the new syndicate is in negotiation to tribute the mine. It is generally agreed that they have embarked on a profitable enterprise, and it is hoped that their success will encourage others to undertake the working of other dormant "propositions" in the "outside districts." The company was registered on March 10, 1905, in the Transvaal, and acquired 306 prospecting claims and 62 diggers' claims on farms Wolverand No. 383 and Rietkuil 626, together with a freehold portion of farm Kafirskraal, 18 morgen in extent, twenty machine stands and two water rights situate in the Klerksdorp district, about 10 miles west of Johannesburg, Transvaal, and formerly owned by the New Afrikander Gold Mining Co., Ltd. The vendors received 150,000 fully-paid £1 shares. During March, 1910, the entire Wolverand Mynpacht was acquired equal to a further 364 claims. Some of the claims have been abandoned, leaving total area now held

656 claims (404 reef-bearing), in addition to freehold property, water rights, etc. Three shafts have been sunk, the Main Eastern Incline, Central, and the New West, the last named being about 3,300 feet west of the Incline and 1,500 feet from the Wolverand boundary. Development work was in progress up to December, 1910, when, owing to exhaustion of working capital, operations were suspended. The ore reserves at the time of suspension were estimated at 227,088 tons, value 8.2 dwts. per ton, and 158,893 tons value 2.6 dwts. per ton.

* * * *

A Rhodesian Reconstruction.

The scheme for the reconstruction of the Bwana M'Kubwa Copper Mining Company, which owns an extensive concession in Northern Rhodesia, has now got to the underwriting stage. The present company has an authorised capital of £600,000 in 1,200,000 10s. shares, of which 925,053 were issued at the date of the last accounts. It is understood that the shares in the new company to be offered to existing shareholders will involve a liability of 2s. 6d. each. At the meeting last December the Acting Chairman summed up the then position as follows:—"We have a mine already showing 3,000,000 tons of ore, assaying 4 per cent. to 5 per cent. copper, and a probability of many more millions of tons with development. Hitherto we could not extract the copper without exorbitant expenditure for treatment plant, but the Minerals Separation have now found a process which will not require such a heavy outlay, and have carried out a practical test at the mine which has been entirely successful. To develop and equip the mine for a plant of 1,000 tons a day capacity and to pay the £26,000 we owe will require £300,000. An option has been given to reconstruct the company and to guarantee the necessary funds, and, subject to your approval, the option will be exercised if railway rates can be arranged, and so soon as there is anything definite to put before you we will call you together to consider it." Assuming that a satisfactory arrangement has now been come to as regards railway rates, it would not be surprising if such also benefited the Rhodesia Broken Hill Development Company, whose lead-zinc property is situated about 100 miles south of the Bwana M'Kubwa mine.

The Future of Copper.

News of the formation in the United States of a Copper and Brass Research Association, including representatives of the copper, brass, and copper alloy interests, mining, manufacturing and commercial, is pretty clearly one outcome of the slump in copper values. The aim of the association is to revive demand by stimulating the use of brass and copper products. In this as in other directions the reaction has swung too far. Copper, in any event, may be relied upon to come into its own again, for it is much too remarkable and useful a metal not to have a wide application in industry. The American Association already includes an imposing array of names, individual as well as corporate, and it has set out on the right line in seeking to link up science with manufacture. But if the report from Laporte, Indiana, turns out correct, that a young inventor named Buntun has rediscovered the ancient and long-lost secret of tempering copper, and that the invention has been bought by the United States Steel Corporation, then the Research Association looks like having stepped in after the event. There seems to be little doubt, looking at the fine grain and tensile strength of the metal, that the tempering of copper to a high degree of hardness is a scientific possibility. Nobody, at all events, can safely lay down the limits of the possible in science. The question that arises is how far the tempering process now said to have been rediscovered affects the tensile strength of the material. If it does not, then for a great many purposes copper will be superior to steel, and its uses will be multiplied in all those directions where now its qualities are off-set by its one defect of softness. In that event neither the Research Association nor anybody else need trouble themselves about the demand. The only fly in the ointment will be that the Steel Corporation will have got in first. Most probably the secret is really very simple. Nearly all epoch-making discoveries are.

South African Asbestos Mines, Limited.

A representative of this paper visited the property of the S.A. Asbestos Mines, Ltd., last week-end, and contributes the following interesting account of his visit.

The South African Asbestos Mines, Ltd., was floated in September, 1920. The directorate consists of:—

Chairman: Mr. A. B. Sumner.

Managing Director: Mr. Hugh J. Orr.

Consulting Engineer: Mr. H. Rose-Martin.

Directors: Messrs. J. Cohen, E. A. Johnstone, J. Norman, C. J. Williams, W. M. Taylor.

With a capital of £50,000, divided into 100,000 shares of 10s. shares, the company holds 3,590 base metal claims lying 65 miles by road south-east of Pietersburg, the nearest railway station.

The only means of communication which exists between the company's holdings and the town of Pietersburg is the road by which the property was reached, and this is in a very bad state of repair. Unless serious attention is paid to its upkeep its state will become much worse as soon as the property has to dispose of its full output.

Property.

The country in the neighbourhood of the claims is very mountainous, and well timbered and watered. A good supply of cheap timber and water is an asset which greatly enhances the value of any mining proposition. The claims lie between two parallel ranges made up by a very prominent ridge of dolomite, and an equally prominent ridge of succeeding quartzites. Both these rocks belong to the Transvaal system. Between these two prominent ridges there occurs the banded ironstones of the same formation, and it is in these that the several layers of asbestos containing rock is to be found. The formation of the country strikes roughly east and west, and the dip lies in a southerly direction. The Olifants River valley also lies to the south of the property, hence all streams run south, with the result that the property has been cut transversely to the strike by a series of vallies no less than six in number. The result of this erosion is that the formation which dips 20 to 25 degrees south has been exposed by these valleys, which are down to 2,600 feet in depth. The asbestos veins which occur in the banded iron stones are thus exposed over the entire property, which has a length of eight miles. This asbestos belt extends in the direction of strike of the country rock on either side of the property, and aggregates over a hundred miles in length. It is opened up on the west on the property of Mr. MacBean, and on the east at Penge, which lies to the south of the Olifants River. Asbestos of two varieties is to be found in this belt, namely, blue asbestos (crocidolite) and white asbestos (amosite).

The white asbestos is to be found both below and above the horizon of the blue asbestos in this locality, and the latter occurs in numerous lodes or groups of veins. Prospecting and mining operations have been concentrated chiefly on two valleys known as McPie valley and Waterkloof. The lodes have, however, been traced at outcrop over the whole length of the property. In the McPie valley no less than 12 lodes of blue asbestos are to be found, and several are to be seen at Waterkloof. A waterfall exists in the latter valley, and will when harnessed provide a cheap source of electric power. A good supply of water is to be found in both valleys, and greatly adds to the value of the property.

Mining.

Mining operations are being confined to the McPie valley, where the treatment plant has been erected, at present. Attention is paid only to one lode, which has been opened up from the base of the valley to the tops of the slopes on either side. The lode is mined to a width of 5 feet, and over that stopping width contains about 11 per cent. of asbestos varying in length from 2 inches downwards.

No shafts need to be sunk at present, as sufficient tonnage of ore exists above the base level of the valleys to

supply the works for a considerable time to come. Preliminary mining expenses are thus cut down to a minimum, and all work done results in the production of ore. The lode will be attacked by drives at various levels connected by stopes. As the treatment plant is situated some distance up the hill side, ore from the opposite side will be brought to the crushers by means of an aerial rope-way. The rope-way will be secured to the hillside, and ore brought to it from above by means of a chute. Expenses incurred by conveying ore will thus be exceedingly low.

Ore Treatment.

The treatment to which the ore is subjected is as follows: It is first of all hand-cobbed in the mine. This process consists of breaking off from the ends of the asbestos any pieces of waste rock. It is conducted by boys by hand, and it follows that its scope is limited by the length of fibre. Short lengths are difficult, and become impossible to cob, and have up to the present been rejected as waste, while the cobbed asbestos has been bagged, after sorting into sizes varying with fibre length, and sold. The method of treatment to be adopted here aims at the following improvements:—

1. Utilisation of the material which has been rejected as waste.
2. The further removal of waste rock from hand-cobbed asbestos in order to reduce the weight of material to be transported.

The treatment plant thus has as its object the recovery of every particle of asbestos which is mined; and the large tonnage of waste which usually accompanies the old method is entirely eliminated.

The mined ore has now been reduced to hand-cobbed asbestos and waste. The waste is crushed in a Blake crusher and then passes a set of rolls. It then passes into a sizing trommel which grades it approximately according to its fibre length. The graded products each pass in turn to edge-runners, which further break off any waste rock adhering to the asbestos. A fan superimposed on the edge-runners removes by suction all the fibres of asbestos, and deposits them in a suitable cage, from which they are removed and bagged. The hand-cobbed asbestos is sorted into sizes or graded, and each length in turn sent through the centrifugal disintegrator. All adhering waste rock is removed, and the disintegrated fibres bagged for export. The fines produced are deposited in the settling chamber, while the shorter fibres discharged with the waste rock are removed subsequently. Each different length is treated similarly.

The mined asbestos has thus been reduced to waste free products varying in length from about two inches down to asbestos dust. Several grades of product are produced, and each marketed as such. The fines produced form an excellent binder for asbestos-cement products.

The economy brought about by this method of treatment is noteworthy. On hand-cobbed asbestos the weight of product is reduced to one-half and one-third of the original, while the saving of the asbestos in the waste rock represents an indisputable gain.

Transport.

Transport represents the only serious problem with which this venture is burdened. At present the only mode which exists is by means of ox-waggon over the 65 odd miles to the railway at Pietersburg. The cost of this transport amounts to 50s. per short ton of asbestos. This cost of transport clearly shows the urgent need there is to this industry as well as others in the neighbourhood for a more adequate means of transport. A railway which would pass through this locality would greatly assist any undertaking of an industrial nature by removing the chief obstacle in the road of development, namely, uncertainty of transport. However, the venture is one with immense possibilities, and the management is to be congratulated on the large amount of progress achieved in an exceedingly short time and under the most trying conditions.

It is also noteworthy that the mine employs several miners suffering from silicosis and that one of these, who was given six months to live by the doctors, has already been on the mine for nearly ten months, and has gained sixty-eight pounds in weight.

The district of Malips River in which this mine is situated covers the exceedingly fertile valley of the Oliphants River, and although the ground is very sparsely

occupied at the present moment, we are informed by the secretary of the local farmers' association that the district in question is producing 15,000 bags of winter wheat and grows three crops per year on the same piece of land. If served by a railway it would be capable of supporting a very considerable number of settlers and producing at least ten times the quantity of produce at present marketed. There is little or no fever.

Latest Metal Quotations.

On the metal market last week there has been little change in the general situation. European business has been handicapped by adverse exchanges. The new business in copper for the home trade has been disappointing, but the reports from America are more hopeful. The consumption of tin has slightly improved, but is insufficient to influence prices. Production is still restricted. There is enough to meet current requirements, but consumption must broaden considerably if the present prices are to be maintained. In lead there were indications in favour of the continuation of a steady market. There was some demand for spelter, which improved, but it was insufficient to make any decided change in the tendency of the market. Existing supplies are strongly held. Present values are below the cost of production, and a recovery in price may reasonably be anticipated. There was no essential alteration in tins, except in the firmness of the market for wasters, chiefly for the Far Eastern market. There was a more hopeful feeling as regards iron and steel, but dear fuel returns are further restricting idle works. There was a more general disposition to cut prices. China bought silver both here and in New York, while the Indian demand was substantial.

The Tin Outlook and Swazi Tin.

"He would be a rash individual who ventured to-day to foretell the course of the metal market during the ensuing 12 or 18 months. There are many depressing features, such as accumulated world stocks, fall in consumption, high costs of exports and realisation, financial stringency—to mention only a few. On the other hand it is well known that tin is one of the most speculative items of the world's metal markets, and is periodically subject to the most unexpected fluctuations of price. It is therefore not beyond the bounds of possibility that the position a year hence may falsify the somewhat gloomy outlook of the present moment." Thus said Mr. J. R. Leask, C.M.G., speaking at a meeting of the Swaziland Tin, Ltd., this week. In concluding, the chairman said: "The company's financial resources are good, and we are in a position to undertake active development should any fresh discovery or enlarged field for our enterprise be opened up. We are probing these possibilities, and should any reasonable opportunity arise we shall grasp the opportunity of extending our scope of activities and prolonging the life of the company. The first two months of the current year have shown a small working loss, due the low price of metal and to a heavy fall of overburden in one of the paddocks in July. The 39 tons of concentrate won during the two months have not yet been sold, and we hope that a rise in price may yet enable us to reduce the adverse balance when we realise."

Springs Mines.

RESULT OF METALLURGICAL EXPERIMENTS.

An official statement has been issued to the effect that the board of directors has decided, on the recommendation of their technical advisers, that in extending the nominal capacity of the reduction plant, already authorised and in course of erection, from 40,000 to 50,000 tons per month, the stamp battery and plate amalgamation will be discarded, and that all-sliming of the ore and direct cyanide treatment will be adopted.

This decision has been come to as the result of experimental metallurgical work on a large scale which has been carried out on the company's property. The experiments show that the above method of treatment will result in:

- Reduced capital expenditure.
- Probable saving in operating expenses.
- Increased extraction of the gold contents.

The consulting engineer's report sets out the results obtained by the experiments as follows:—

- The elimination of the stamp battery as a crushing unit and the direct tube milling of the product obtained from single stage breaking in gyratory crushers.
- The elimination of plate amalgamation, the pulp from the tube mill plant being taken directly to the slimes plant for cyanide treatment.

Referring to "A." As the result of crushing some 30,000 tons in our experimental plant it has been demonstrated that a standard 22 ft. x 5 ft. 6 in. tube mill can economically handle a much coarser feed than has hitherto been furnished by means of stamps; this coarse feed being obtained by single stage breaking in gyratory crushers, with certain minor modifications from existing practice. It has also been determined that tube milling under these conditions gives a product having a much higher degree of comminution than has hitherto been economically obtainable by means of the operation of the standard plants. It is this which has led to the possibility of the elimination of plate amalgamation and direct cyanide treatment of the pulp.

Referring to "B." As the result of the elimination of plate amalgamation and the direct cyanide treatment on the above lines of approximately 4,000 tons of pulp from the experimental plant, an increased extraction of the gold contents of the material treated has been obtained.

KROONSTAD COAL ESTATE COMPANY, LIMITED.

TENDERS

are invited and will be received by the Undersigned up to and including Saturday, 1st October, 1921, for the purchase of the **MACHINERY, PLANT, EQUIPMENT, MINE STORES, TOOLS, ETC.**, lying for disposal at the above Company's property at Vierfontein, O.F.S.

Tenders must be for the whole of the above, and the successful tenderer will be required to remove same at his own expense and risk within one month of the acceptance of the tender.

The highest or any tender not necessarily accepted.

Lists and further particulars may be obtained from

SALISBURY, BEATON & RAYNHAM,

Secretaries,

Kimberley.

17th August, 1921.

In view of these results, and also because a considerable reduction in capital cost and a probable saving in operating expenses will be effected, I have now to recommend that in the extension of the Springs Mines plant the stamp battery and plate amalgamation be discarded, and that all-sliming of the ore and direct cyanide treatment be adopted."

The Lonely in August.

The following are particulars of gold, etc., from the Lonely Mine for the month of August, 1921:—Mill ran 688 hours; crushed 5,170 tons; fine gold recovered, 1,781.687 ozs.; value, £7,492 7s. 5d.; treated by cyanide, 5,170 tons; fine gold recovered, 3,119.667 ozs.; value, £13,121 14s. 11d.; total fine gold, 4,901.354 ozs.; total value at 84s., £20,614 2s. 4d.; profit, £19,888 13s. 10d. The above profit includes the sum of £12,264 8s. 9d., premium received February-April, and £127 15s. 5d. adjustment on June gold.

The Grootfontein Borehole.

MR. G. A. DENNY'S OPINION.

The secretary of the Rhodesia Consolidated, Ltd., writes:—

"During the past few months information with regard to the progress of the Grootfontein Vogelstruisbult borehole, which has been successfully sunk under the supervision of the engineering staff of the New Consolidated Gold Fields, Ltd., has been communicated to shareholders as received.

"On the 4th instant, it was reported that the main or Van Ryn reef had been intersected at a depth of 3,440 ft., showing a width of 6 ft. 3 in., and the subsequent gold assay value was reported as averaging 1 dwt. The comparatively shallow depth at which the reef has been struck, and its width, are very favourable features.

"To the uninitiated, it is possible that the low assay value may suggest a non-payable deposit, and in order to counteract such an impression the directors have obtained from Mr. G. A. Denny, M.I.M.M., who has had extensive experience in this district, the enclosed report thereon, which explains the position clearly and concisely, and sets out in true perspective the valuable nature of the results so far secured.

"The directors take this opportunity of congratulating the shareholders on the highly satisfactory outcome of the boring operations."

Mr. Denny's Report.

Mr. Denny's report is dated August 12, and is as follows:—

"Diamond drilling on the Far East Rand basin has, in general, been disappointing if considered from the standpoint of value. This is not surprising when you consider that very large patches of poor ground exist in the richest mines, and that the section of the reef produced by the drill measures about $\frac{7}{8}$ in. in diameter, or an infinitesimal percentage of the area of the reef intersected.

"The long experience gained in this region—that is, the area of the reef basin east of a line joining the Van Ryn Mines on the north and the Nigel Mine on the south—of the relationship between the results obtained from boreholes and those subsequently got by actual mine development shows that the latter has always proved to be payable, no matter what results were given by borings. As a case in point the Brakpan Mine borings may be taken. I was responsible for the laying out of the original borehole sites on this property in 1898. The results obtained were most disappointing, but the estimates made of the probable future yield, based on the development of the mines producing in the vicinity, proved to be very accurate.

"Present-day opinion, therefore, does not attach great importance to localised assay values, whether they be high or low, although naturally it is gratifying when they are high. The principal function of a borehole to-day is to determine the depth of the main reef series below the surface and to exhibit at the same time a section of the rocks passed through by the drill.

"The Grootfontein borehole has traversed a normal Far East Rand section, comparable in every essential with the sections disclosed in boreholes and deep shafts all over the area. Development of the great producing mines of the Far East Rand area now covers so wide a field that it is possible to make very safe generalisations respecting the prospective value of any given property, having especial regard, of course, to the producing mine which is nearest to it.

"The nearest producing mine in the vicinity of your borehole is the Springs Mines. Your property lies directly in the line of the ore shutes projected from New Modderfontein through the Springs Mines. The latter company

crushes upwards of 40,000 tons per month, had ore reserves as at December, 1920, amounting to about 2,750,000 tons, assaying 8.76 dwt. over 63 $\frac{1}{2}$ in., and is making a profit of £30,000 to £40,000 per month.

"This is the soundest indication of the prospective value of the reef intersected in the Grootfontein borehole, when that reef has been explored over areas as wide as those in the Springs Mines. I say 'prospective' value advisedly, because there can be no assurance of the actual value without extremely wide development."

Mine Ventilation Committee's Report.

An interim report has been issued by the joint committee appointed by the Government Mining Engineer and the president of the Chamber of Mines to inquire into "dust prevention" in mine development. It contains conclusions which are of considerable importance and interest. The report states: "We have, apart from preliminary tests by the individual members, conducted a series of tests in development drives in the Crown and Springs Mines to ascertain the effect of water-blast and of auxiliary ventilation after blasting. We have come to the conclusion (1) that observance of the water-blast regulations will not necessarily give such a satisfactory condition in developing ends; (2) (a) that the useful purpose of a water-blast is to damp the face and broken rock; (b) that the present water-blast is ineffective in allaying the fine dust which has been projected by the blast; (c) that if the water used is not clear of solid particle the water-blast is likely to increase the dust contents of the development ends; (d) that one water-blast at the face is sufficient to damp the face of broken rock if it is of a type to project the necessary water; (3) that the exact amount of air required to clear development ends has not been definitely determined. From tests conducted it would appear to be not less than a volume of air equal to that of the development end. The exact amount may be dependent upon the rate and method of supply of the air; (4) that the most practicable way of dealing with the fine dust in development ends is by ventilation. Tests are being conducted to ascertain the volume of air necessary under different conditions for ventilation of development ends both during the working shift and after the blast." The report is signed by Albert E. Payn, A. V. Lance, A. A. Coaton, J. Boyd, Chamber of Mines representatives; A. P. Swinburne (chairman), Charles J. Gray, A. J. Pretorius, R. G. Ray, Mines Department representatives.

* * * *

Fineness and Dryness of Pulverised Coal as Fuel.

From a series of extended tests on a 500 h.p. boiler fired with pulverised coal, it is concluded that the grinding and drying of the coal need not be carried to such high degrees as has been considered necessary heretofore, states Messrs. Henry Kreisinger and John Blizard, in a paper before the American Society of Mechanical Engineers. It is pointed out that it has been customary to state that for good results the coal must be powdered to such fineness that 95 per cent. will pass through a 100-mesh screen and 85 per cent. through a 200-mesh screen. Results from coals in which 88.6 to 93.2 per cent. passed the 100-mesh and 64 to 74 per cent. passed the 200-mesh screen indicate that extremely fine grinding is not necessary for efficiency or good combustion. The completeness of combustion seems to be more a matter of a proper furnace and burner design and the right way of supplying air, than of the fineness of the coal. The losses due to coarseness of coal would be shown by the greater percentage of carbon in the refuse. The average loss due to that cause for the tests with the coarser coal is 0.7 per cent., as against 0.6 per cent., with the finer coals, the averages of the efficiencies being nearly the same. The ability to use the coarser coal efficiently means increased capacity of the pulverising mills and decreased cost of preparing the coal. Another statement generally accepted is that pulverised coal must be dried to about 1 per cent. moisture in order to be burned successfully. Test made with undried coal, however, showed equally good combustion.

Spontaneous Combustion of Coal in Mines.

The subject of the spontaneous combustion of coal has lately been investigated by a Commission in South Africa, and the following summary of the findings of the British Departmental Committee has an important bearing thereon.

The Report of the Departmental Committee just issued is divided into four main sections, and the introduction calls attention to the fact that the committee was appointed by the Home Secretary in August, 1912, "to enquire into the circumstances in which spontaneous combustion occurs in mines, its causes, and the means of preventing it, or of dealing with it when it occurs." It further relates that in December, 1913, the committee presented an interim report, which dealt particularly with the measures necessary to safeguard the lives of persons employed in mines subject to the occurrence of spontaneous combustion. It is stated that the war interfered with the publication of the final report, that two members died during the war period, that one member resigned, and that a further appointment was made. The number of meetings held was 28, of which 26 were devoted to the taking of evidence.

Early theories are discussed, the antiquity of the subject is indicated, and prominence is given to an account by Dr. Plott in 1686 of the occurrence of spontaneous combustion of coal both on the surface and in underground workings. At that remote period and well into the nineteenth century, the commonly accepted explanation of the phenomenon was that the heat evolved by the oxidation of the pyrites in coal was the primary and principal cause of the initiation of spontaneous combustion. The history of the gradual refutation of this long-established theory is carefully traced and supported by numerous quotations from various writers on the subject. The most prominent of the nineteenth century investigators were Richters (a German chemist) and Fayol (a French mining engineer), and they independently came to the conclusion that pyrites had little or no effect on the spontaneous heating of the coals examined by them. The "pyrites" theory was replaced by others, such as "absorption of oxygen by the coal substances," "bacterial action," "moisture," etc., but none of these was generally accepted as a solution of the problem.

In view of the divergent theories held as to the occurrence of spontaneous combustion, the committee decided to investigate the subject in the light of the most modern scientific research. To this end many of the most eminent mining chemists and palæobotanists of England were invited to give evidence. Definite scientific experiments were made at the request of the committee, the results of which are embodied in the report and appendices. Complete unanimity was not obtained on all these points, but, after careful consideration had been given to the evidence, the committee arrived at the conclusions here quoted in full:—That the self-heating of coal is not in any way due to the presence of bacteria; and bacterial action, even if it occurs in coal, does not account for even the initial stages of self-heating. Some small amount of heat may be developed by the oxidation of pyrites when it occurs as an amorphous form of marcasite; but as pyrites is present in coal in such small proportions as compared with the coal substance proper, which is a bad conductor of heat, the effect of this heat is negligible. The chief part played by pyrites when present in an unstable form is that of a disintegrator of the coal, so rendering the latter more permeable by air, and exposing a greater area of coal substance in oxidation. The presence of moisture in coal has an accelerating effect on its oxidation, and consequently coals high in hygroscopic moisture absorb oxygen more readily than those of low moisture content. The self-heating of coal is mainly due to the absorption of oxygen by the coal, resulting in the generation of heat. Though coal absorbs both oxygen and nitro-

gen in a physical sense as well as in a chemical sense, the absorption, in so far as heating effects are concerned, is a chemical and not a physical process; the chemical process is mainly one of attachment of oxygen to molecules of high carbon content, but subsidiary to this, and playing an important part in determining the actual spontaneous ignition of coal, is a chemical interaction between the oxygen thus loosely held by the carbon-like molecules and other atoms in these molecules or other portions of the coal conglomerate.

The conclusions arrived at by the committee as to the causes, from the practical point of view, of the spontaneous combustion of coal, and their recommendations, are reproduced in the report, and it is said that probably all bituminous coal is liable to spontaneous combustion in some degree; but the fact that there is greater liability to self-heating of the coal in the seams of some coalfields of the United Kingdom than in others is due to several causes other than the chemical composition of the coal.

The committee recommend that mining engineers should consider the application of the cementation process to combat fires that have occurred in main roads, ribs, and pillars; but do not recommend the establishment of regulations additional to those brought into force in July last, which were based upon their interim report, and which they regard as sufficient under present circumstances.

Shamva Mines Position.

The Shamva Mines Company issues its quarterly report to 30th June:—Tons crushed, 164,150; ounces fine gold won, 7,720; tons cyanided, 163,547; ounces fine gold won, 16,346; total yield fine gold (ounces), 24,066; value, taking gold at £5 5s. per ounce, £126,346! working costs, £87,384; working profit, £38,962; total ore reserves at 30th June, 1921, value 4.1 dwts. (tons), 1,831,000. The tonnage crushed is 71,800 tons higher than in the March quarter, when operations were suspended owing to the strike of employees. Compared with the last normal quarter (December) the increase is 16,850 tons. The whole additional plant is in commission and has given full satisfaction. Two sections of eight stamps each in the mill have been dismantled and put in good repair. The fall in the gold premium did not allow the mining of much from the lower-grade sections, which are outside the calculated ore reserves, in consequence of which these were decreased by 96,000 tons. Development was again curtailed, there being no machine development. The new air compressor was completed and put into commission at the end of July. Working costs, compared with the last normal quarter, are the same at 10s. 8d. Development redemption was calculated at 1s. per ton up to the end of May and at 9d. for June, averaging 11d. for the quarter. An adjustment to 9d. per ton will be made from the 1st January, 1921, under this heading. The anticipated fall in the price of stores has not yet materialised, many lines, including cyanide and explosives, actually showing an increase. No benefit is now derived from bank exchange, which will account for a rise of 2d. per ton in general expenses compared with the December quarter.

Concerning Mines and Men.

Mr. James Leisk, C.M.G., has been appointed Chairman and Managing Director of the National Bank of South Africa, Ltd.

Mr. Arthur French, * Manager * of the * General Mining and Finance Corporation, Ltd., has returned to the Rand after a six months' visit to England.

Mr. H. C. Fletcher, of Messrs. Johnson and Fletcher, Bulawayo, has been visiting the Rand, on his way back from East Africa and the Kilo goldfields of the Congo. Mr. Fletcher was much impressed with the vastness of the great Kilo fields, and is one of the few British subjects who have been privileged to visit them.

Geology of Heidelberg—VI.

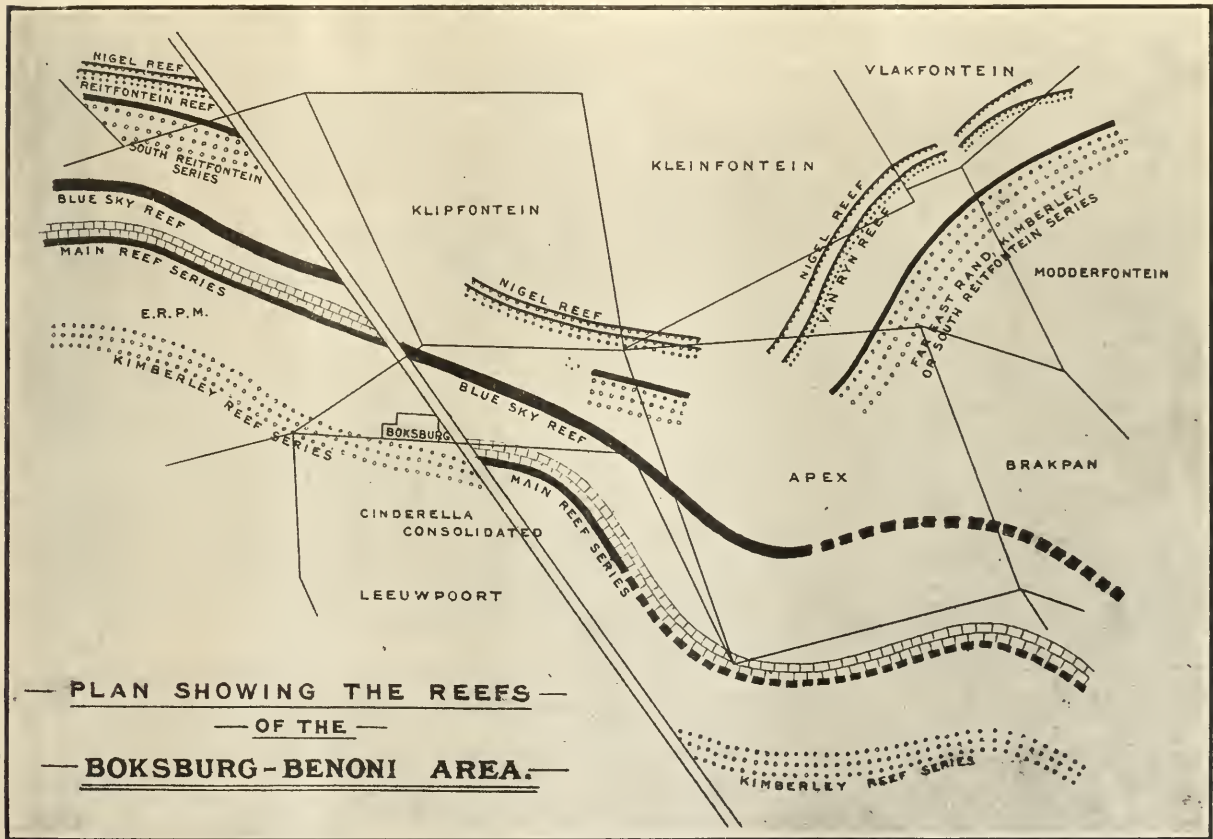

MR. BLELOCH REPLIES TO DR. ROGERS—OTHER REEFS.

The Blue Sky Reef and the Main Reef Series S.E. of Boksburg.

Seeing Dr. Rogers has referred to my views on the true extension of the Main Reef series of the Central Rand beyond the East Rand Proprietary Mines, I think it is necessary, in order to make the position clear, to present with this paper a sketch plan of the area which I have prepared to show the position of the outcrops and sub-outcrops of the reefs there. The sketch plan will convey my views of the position and identity of these reefs.

Before Boksburg is driven into rapid decline by the closing down of the East Rand Proprietary Mines, I hope that the Mayor and Town Councillors will come out with me to see and examine the outcrops, and that after seeing them they will insist that the shafts and drives on the Main Reef Leader and South Reef in the old Leeuwoort G.M.

Perhaps the reason for this is a feeling of delicacy towards his predecessor, Dr. Mellor. The Tatham Reef is a most distinctive large pebble reef, carrying payable gold, whose geological position is at the base of the Nigel shales and at the top of the Government Reef quartzites. The Reef has been supporting the Modder West mine with gold from its mill only and without cyanide works for many months. It has been opened too on the West Rand and it was one of the underlying markers from whose position the important borehole on Luipaardsvlei south of Randfontein was located by Mr. J. A. Thorburn a few months ago. That borehole was located to cut the Randfontein reefs. The borehole has been successful and the west reef carrying high gold values has been intersected. The sectional diagram I have presented in No. V. shows the relative positions of the Government Reef, the Tatham Reef, the Nigel Reef, and the Van Ryn-Reitfontein Reefs. The diagram shows the sequence

Company's workings will be de-watered so that they may be sampled and assayed, and I feel sure that the results will cause development to be proceeded with. On reflection, I think Dr. Rogers did well apologise for reiterating all these points concerning "mistaken correlations." He was correct in saying there was nothing new in his arguments. They are the same old obstructive ill-founded arguments which have been gradually closing up the Rand mining industry. Again I ask, why the determined opposition to putting these views to the test, why should not these reefs on Leeuwoort be sampled and assayed?

The Tatham Reef.

Dr. Rogers in the course of his paper has never mentioned this reef—the reef mined at the Modder West mine.

of beds occurring below the Van Ryn now established right round the Rand syncline from Randfontein to Nigel and beyond. Why does Dr. Rogers ignore the Tatham Reef? Is it because Dr. Mellor gave evidence on oath in the Knox Arbitration Case that the Tatham was not a reef at all. In his evidence in that case Dr. Mellor said: "I should not call Tatham's a reef." "I did not go down Tatham's shaft, I simply viewed it from the surface." "It was not necessary to pan." "It is apparent to the eye." "I have never seen portions of the Main Reef like it." That evidence and other similar and incorrect evidence resulted in an unjust and wrong decision against Mr. Knox, who lost the £3,000 he had paid in claim licences, his claims, and his costs. As I have mentioned above, the Nigel Reef had since been opened by a shaft on three claims which on my advice

Mr. Knox retained. It is worth noting that Mr. Knox recently lost even these three claims because he was 10d. short in his remittance for the licences and fines due on them. He had forgotten to pay in time, so for 10 pence the Government sacrificed a steady revenue on these three claims of 9 pounds per annum! I will say, too, that Dr. Rogers ignores the Tatham Reef, and the above facts relative to it, although he has been clearly informed of them by me, and as a matter of fact the existence of the Tatham Reef is to-day common knowledge; yet on page 50 of his paper, referring to Dr. Mellor and myself, he says: "I am thus in a position to compare the results of the methods of the two men." Well, my conscience is clear: I have never given evidence on oath that a reef was not a reef, on which there are now tens of thousands of tons of pay ore actually developed to witness that my evidence, bringing ruin in its train, was hopelessly and manifestly wrong.

"Errors of Correlation."

Dr. Rogers accuses me of making "errors of correlation which give rise to public expectations which are not otherwise justified." Here again my conscience is clear: I have never put forward the poor and unpayable Blue Sky Reef, with £5,000,000 of money against it, lost by the misguided shareholders who found the money to develop it on the faith of its official correlation with the "Main Reef Leader." I have never correlated an unpayable reef like the Molyneux with the "Main Reef Leader," a correlation which when publicly made by the Director of the Government Survey is extremely likely "to give rise to public expectations which are not otherwise justified."

I will tell Dr. Rogers, too, that I have never ruined thousands of innocent shareholders by inspiring an ill-advised Minister to cable to London condemning the great pay reef we have found in the Heidelberg district—the true Van Ryn Reef of the Far East Rand, the pay reef of our richest goldfield by calling it Kimberley in spite of the fact that our reef has the appearance, the character, the footwall, and the gold of the Van Ryn Reef and not of the Kimberley, thereby preventing the much-needed and the only possible expansion of the Far East Rand mining industry; stopping a round million of new working capital in these times of unemployment and falling State and railway revenues, and in very fact endangering the financial future of the country which pays him. For the Molyneux Reef—the reef he identifies in the Heidelberg district as the "Main Reef Leader"—has been known and proved in many shafts for twenty years past to be unpayable.

Has Dr. Rogers in the whole course of his paper informed you of that simple yet all-important fact? Has he informed the Minister? Evidently not, for on the contrary Dr. Rogers says (page 32): "The Molyneux mine, where a conglomerate lying directly on slate and, I am informed, another thin conglomerate 40 feet higher up in the quartzite were successfully worked some years ago." Dr. Rogers, by putting these words in his paper—an important State paper—practically gives the warranty of the Government to mining enterprise on the Molyneux Reef. The future may

show how "public expectations" raised on that statement will be realised. I would ask Dr. Rogers what authority has he for saying that "the conglomerate lying on slate in the Molyneux mine" was ever successfully worked and who informed him that the conglomerate 40 feet up was also successfully worked? Did he trouble to verify the statements of his informant by looking up the records of the Mines Department? It appears that he did not, because if he had done so he would have found that no mine on the Molyneux Reef or Government Reef—the reef he refers to as identified as the "Main Reef Leader"—has ever been successful. That is the pity of it; that he, the Government authority, should not only make an erroneous correlation, but in addition pass on statements which may "give rise to public expectations which are not justified."

In the last issue of the *South African Mining and Engineering Journal* Dr. Rogers is reported to have stated in reference to our Van Ryn Reefs at Heidelberg, "the mistaken correlation has given rise to very greatly exaggerated expectations of profits from mining certain reefs at Heidelberg." I challenge Dr. Rogers to find any leading mining engineer of the Rand mining houses who will confirm the opinion that the Molyneux Reef, his "Main Reef Leader" at Heidelberg, to which he has in the words quoted above given the imprimatur of the Government, is a payable reef. Yet he has the assurance to encourage "public expectations" on that reef while at the same time he goes out of his way to condemn the true Van Ryn Reef which we have found, which has always justified the greatest "public expectations" in every mine where it has been worked and whose actual outcrop and borehole values in the Heidelberg area give the greatest assurance of justifying public expectations there too.

Ill-advised Assurance.

Dr. Rogers has the ill-advised assurance to lecture me about reefs which I have known and studied for half a lifetime, and on which I have done more practical and costly research work than he is ever likely to do, work done too, not at the country's expense as with him, but to the country's immense gain, because merely to be licensed to do that work there has had to be paid into the State coffers not less than a quarter of a million pounds. He has the assurance to put forward as a final and closed judgment, not to be questioned, that a reef which for long has been proved to be economically worthless and unpayable is the representative in the Heidelberg district of the greatest and most valuable gold reef the world has ever known—the Van Ryn Reef of the Far East Rand. He shuts out all other Heidelberg reefs, no matter how unmistakably one particular series of them may agree in sequence of bedding, character and in gold values with the Van Ryn Reef. His reef being unpayable, he yet has the assurance in this way to bang the door on any expansion of the Far East gold

S. T. GEEN & Co., —HATFIELD HOUSE,—
PRESIDENT - STREET,
JOHANNESBURG.

mining industry and thus to seal the economic and industrial doom of this mining community. That and nothing less is what Dr. Rogers's paper comes to. That and nothing less, too, is what the dogmatic identification of the worthless Blue Sky Reef with the Main Reef Leader, east of the E.R.P.M., comes to. There, too, the door is banged and no one may try to develop the reef which we submit is the true Main Reef series on Leeuwpoot, except at the peril of being denounced by Dr. Mellor and Dr. Rogers and the Mines Department, and to such lengths will dogmatic tyranny go, that an attempt may even be made to get the man who tries it into jail. Meanwhile, the town of Boksburg is in decline and thousands of workers are in danger of being thrown out of work. I ask, why this banging of doors? Why should the Mines Department by means of the Geological Survey and cables to the High Commissioner prevent these reefs being developed and their gold values being tested and proved? Why not rather encourage capital to do the necessary work to put them to the test? Such colossal assurance which goes so far as even to imperil the livelihood of whole communities on the strength merely of an opinion based on the uncertain and accidental occurrence of an igneous rock is surely extraordinary even on the part of the most autocratic Mines Department or on the part of the most learned geologist.

Dr. Rogers's predecessor, Dr. Mellor, said that the Tatham Reef was not a reef, although he did not take the trouble to go down an 80 ft. shaft to see it. Dr. Rogers is silent on the matter! and follows faithfully in Dr. Mellor's footsteps. He is silent, too, in regard to the Minister's statement that it was not his (Dr. Rogers's) opinions but those of Dr. Mellor, at that time the technical adviser of the Corner House, which were sent last year in these Government cables—opinions which I submit I have proved to have been based on "errors of correlation"—cables which ruined for the time being not one but several mining enterprises on whose success the future welfare of this community and indeed the financial stability of this country greatly depends.

He is silent, too, although he must know that these cables were excused in Parliament the other day by the Rt. Hon. the Minister of Mines and Industries by the accusation that I had used his (Dr. Rogers's) name or the name of Dr. Mellor, forsooth, as supporting my geological views and for company promotion purposes. Gentlemen, that accusation made in Parliament by the responsible Minister, on the written authority, he said, of Dr. Rogers, was a false accusation. Will Dr. Rogers repeat that accusation? I say to you that neither the Minister nor Dr. Rogers, nor any one else, can bring forward one sentence of mine written or spoken to justify it even in the remotest degree, and I have respectfully requested the Minister to order an inquiry into the whole of the circumstances which brought it forth.

I submit that the sooner the Government and people of this country realise that the dogmatic but erroneous correlation of the Molyneux Reef in the Heidelberg district as the one and only "Main Reef Leader," the condemnation of all other reefs there, and the interference with mining enterprise by Government cables has shut out all hope for the present of any expansion of our most profitable gold field. That expansion can, I submit, only take place on the reef that carries the gold—the true Van Ryn Reef which we have found and opened up, and it can never take place on the unpayable Molyneux Reef put forward as the "Main Reef Leader" by reason of a deplorable and tragic "error of correlation."

Sir Robert Hadfield's Plea for Unity.

In the course of an arresting article contributed to "Unity," Sir Robert Hadfield, Bart., who as metallurgist and inventor enjoys a world reputation, makes a powerful appeal for industrial peace as the only alternative to national disaster. To the workers whose wages have not much more than kept pace with increased cost of living, except in certain cases where they were scandalously low before the War (says Sir Robert Hadfield), the wage-cut now imposed by circumstances sounds the knell of the hopes they had of a better standard of life in the country for which they fought. They may bow to the logic of facts because they have no alternative, but unless some permanent edifice of conciliation and co-partnership is reared on the foundation of the present agreements the peace for the present attained will prove but a hollow truce. Renewed prosperity will bring renewed demands, in all probability ill-timed and impatiently urged, and we shall traverse the whole "vicious circle" again. "I would suggest to all employers," Sir Robert concludes, "that now is the time to meet all the workers in full and frank discussion of all the conditions of their common industry, to lay the cards on the table as to the state of the order books and the conditions under which contracts may be obtained, the profits and losses made during recent years, and to discuss, with a view to arriving at a permanent scheme, the question of unemployment; in a word, to dissipate the great cloud of suspicion and mistrust which is poisoning all relationships, hampering the recovery of the country, and giving the extremists who wish to overturn the whole social and industrial system their best chance. It is no business of mine to preach to Labour, but I do venture to ask this: that the workers should believe that the majority of employers are really and sincerely endeavouring to find a path to a better world of industry; that our ears are opened to reasonable suggestions; that the War in which our sons sweated and froze and fought and died together has not left us callous. And, as a consequence, that Labour should, in this new spirit of trust, put forth its best efforts to regain that measure of prosperity without which the best laid schemes of future prosperity are bound to 'gang aft agley.'"

Letters to the Editor.

THE GOLD QUESTION.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—I have read with much interest Mr. Speak's article on the real value of gold. He states in the first paragraph that "gold differs from all other commodities, except silver, in that the demand for it is almost entirely for money purposes." I remember some years ago that the chairman of the London City and Midland Bank stated at his annual meeting that India absorbed an enormous quantity of gold annually. It would, I am sure, be of great interest to your readers if Mr. Speak has in his possession any data showing approximately how much of the world's gold production is absorbed by the arts and industries, including the amount hoarded in the form of raw or wrought gold, or minted coins in the East, annually. This question is rarely dealt with, and I feel sure that Mr. Speak will be glad of the opportunity of giving us any information he has on the subject.—Yours,

ENGINEER.

IS THERE A FREE GOLD MARKET?

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—I notice from the Home financial papers that all the gold we send over goes to U.S.A. Is there really any competition at all? We are told that there is a world hunger for gold. Then surely with open competition between Continental countries, India and China, some of the gold would be taken by other countries than America. Then, again, the price is often reduced by varying amounts, no matter whether there is any gold in the market or not, and thus we get prices wired out here to South Africa as being the price of gold, when really there was no gold to sell in the market. Another thing I can't understand: Imports from America at this time of foodstuffs are very heavy, and on the top of that there was all the coal we imported during the strike which should have helped considerably to put the exchange against England, and yet we have the fact of the sovereign improving in value day by day and the premium disappearing. How is it?—Yours, etc.,

"CURIOUS."

Salisbury, Rhodesia,
13th September, 1921.

THE FINANCE OF THE MODDER EAST.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Allow me to express through the medium of your valuable paper my approval and appreciation of "Mere Shareholder's" suggestion of a scheme for the financing of Modderfontein East Gold Mining Company with funds sufficient to put up its own plant, and at the same time reduce its £2,000,000 capital to a more reasonable figure.

I, as a shareholder, who looks upon an investment in sound mining shares as upon a business proposition with its risks and chances, have been following keenly all the stages of the opening up of this property, and I am convinced that the hitherto failure of the financing scheme was due mostly to external causes, like the sporadic conflagration in Europe, from the Irish to the Caspian Seas, local financial strain caused by the fall in prices of the principal South African products, in addition to the heavy capital (authorised though not yet issued).

All these causes helped to overthrow the past schemes. As the financial strain is now becoming easier, a scheme whereby the company's capital could be reduced by 25 per cent. is bound to meet with success, and I think every shareholder will see to making it a success.

I will try here to sum up what Modder East is losing through not having her own plant. At present it crushes about 320,000 tons per year at a profit of £160,000, losing £80,000 in transport and rent for the Apex plant; interest on £110,000 invested in the Simmer Deep plant at 8 per cent. is £8,800; total, £88,800, which is would-be profit lost: whereas with a 50,000 to 60,000 tons plant the company will crush about 720,000 tons, at 10s. per ton, equalling £360,000; plus saving on rent and transport at 5s., £190,000; profit per annum, £550,000—sufficient to pay off the debentures when these are due, or in case debenture options are exercised, a thing which is very likely to happen. Then a dividend of over 30 per cent. can be paid in 1922, and such a result would be the best reply the "Controlling House" could give to the unscrupulous and foolish suggestion of a Government inquiry about the affairs of the company.

It seems people are always keen in looking for some one to put every blame on, so in the Middle Ages heretics were accused of droughts, rinderpest or failure of crops, etc. In our new democratic times it is fashionable to ascribe any trouble or crisis to the "vile" capitalist, as if a corporation who ably controls the technical and financial affairs of the mining industry is to be blamed for any trouble caused by a De Valera, Corfanty, or falling wool prices, things which, incidentally, upset the plans of an over zealous speculator unintentionally, and which are as uncontrollable as a drought, flood or any natural outbreak.—Yours, etc.,

AN INVESTOR.

FAILURE OF STATE CONTROL.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—With reference to your remarks under this head in your last issue, may I state the following facts:—

According to the Brisbane correspondent of the *Melbourne Argus*, Queensland has more than £1,500,000 involved in State enterprises. It is the richest State in Australia so far as resources are concerned. Yet it has had an increase of unemployment in six years of 117 per thousand registered unionists. The greater part of the £1,500,000, the above-named authority goes on to say, is locked up in the 23 State farming stations, which comprise about 31,000 square miles of excellent grazing country. In 1919-20, the best pastoral season Queensland ever had, the State stations, allowing for undue inflation in the value of stock on hand, paid less than 2 per cent. in profit. At the same time the Government was paying 7 per cent. to the Bank of England for a temporary loan, which it is now trying to redeem by monthly instalments. It is contended that even in that year the stations were in reality worked at enormous losses, since the Government pays neither State nor Federal taxes, and if the original lessees had not been disturbed the State would have obtained many thousands of pounds more in income, land taxes and stamp duty than it claimed as profit, whilst the Federal revenue would have benefited similarly by income and land taxes. The results for the last financial year have not been made available, but even Ministers admit that they have been "very disappointing"; in fact, says the correspondent, there is good reason for believing that the loss has been staggering. The Queensland Government, it is further stated, has followed the policy of not gazetting a business as a State enterprise till all development work has been paid for from the consolidated revenue or loan fund. The Warra coal mine, for instance, was closed with a dead loss of £47,000. The State trawler, which cost £32,000, was laid up after costing £10,676 to catch fish valued at £1,583. The Baralaba and Styx River coal mines have cost some thousands of pounds in development work, yet neither of them is treated as a State enterprise. The losses on enterprises that have been closed are charged against consolidated revenue, and the development work on other enterprises is charged against that fund or the loan fund. Perhaps the most pronounced failure of all, says the writer of the article under notice, was the lime-crusher, which cost approximately £15 4s. a ton to crush lime, although the price in the open market was

£1 2s. 6d. a ton. That, too, was charged against revenue. "The experience in Queensland is that the enterprises have had a discouraging effect on industry; they have decreased employment, and they have developed into a thoroughly bureaucratic and centralised administration, 'soaking up' public funds, and are condemned even by some leading Labour supporters." Western Australia, too, is affirmed to have had a surfeit of State enterprises, and the present Ministry is represented as anxious to rid itself of the obligations in this respect which it inherited from its Labour predecessors. The Premier (says the *Melbourne Argus*) wishes to sell out as soon as it is possible, and invest as much of the money that he can get back in "more profitable directions." This after a trial of many years, and the expenditure of no less a capital sum than £2,000,000. "When the idea was first conceived the attraction held out was that the people would obtain meat and other foodstuffs at cheaper rates than the ordinary market price." It is now declared on responsible authority that commodities are "not a penny cheaper" as the result of State trading, and although it would be too much to assert that such enterprises can never be successful, some of the Australian object-lessons, if the facts are as represented, would appear to have been attended by distinctly discouraging results.—Yours faithfully,

"STUDENT."

THE FAILURE OF STATE RAILWAY CONTROL.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Apropos of your article on the above, it is only necessary to contrast Canada and Australia and the results of Government administration in the two countries. One part of the picture: New South Wales, Labour ridden till its withers are wrung. Its debt is three hundred and sixty millions. England had to come to its rescue and lend it six and a half millions a year for three years.

That place and its Government railways, run by labour conditions, will show exactly what is happening and will continue to happen here. In order to get political support and in order to please parties, the Government of this country may venture to experiment, but we must never forget that our conditions are entirely different. In order to conciliate white labour, the Government may do many things, but it must not forget that although it may be threatened by skilled labour and appealed to by indigent whites, the major part of this country's population is black, and although black labour has so far not combined and appointed its leaders, yet, as one that has seen conditions for two generations, I venture to say that at the rate of advancement of the black man, his majority is not going to remain a dead letter much longer, and if white labour's programme is to make South Africa as impossible a country as New South Wales, it will be the native and its overburdened white citizens that will have to come to its relief. The present system of slavery in mines will have to give way. The native is entitled, at least, to the same conditions that slaves were before the world's philanthropists released them to what is to-day a worse slavery than was ever endured under the early Dutch. If the needs of this country points to the sale of its railways and introduction of foreign capital and companies that will run them on competitive lines and thereby enable the population of this country to avoid being placed in bankruptcy by white labour. Is it possible to continue on a wild, downward course, determinedly ignoring our great black population? Can we ignore that, without his aid these fifty years, little would have eventuated in this country? For although the white skilled labourer may have his co-operations and associations and their combined effect may have immediate destructive results, as we evince with daily apprehension at every hour, yet this is but a terrible destructive weapon. The true builder up and the only reliable resource offering is the hand of the black man. As we see white men placed upon the veld, so do we see natives, for land is purchased and natives located on it, just as continuously as white settlers. Are all these settlers, black and white, to be led

into the same conditions as New South Wales, in order to pander to labour unions?

We are on the verge of Rhodesia entering this Union. There is a long railway line. Its traffic is on a par with the Cape's, and added to the present lines it will become a heavier millstone round our neck. Investigations will probably show that that line may have to be taken down and added to the Messina line, which serves richer districts and lessens length. Whatever may have to be done, it would be wise to interest the present owners in railways. It would be wise to even tempt them to take wider interests; in fact, it would be wiser still to sell them all our railways and regulate the rates by agreement. If not, and our native population keeps on increasing, and our debts as well, the time is not far distant when, through poll-taxing this man, it will become necessary to take a plebescite of the country, black and white, upon the continuance of running our railways under white labour and Government direction, or under joint stock companies and competition. Make no mistake, the native is being placed upon the land for a purpose. He is constantly improving his position. He is already reading, writing, clothes himself and his women in European clothes. He uses the latest plough and agricultural implements. He is invited to become a producer. He is to incur fresh taxation, and he is either to be ignored for the purposes of labour unions, or he is to be consulted and have his say. I am not saying he will have a white vote and enter a white Parliament, but his built up position will advance probably as fast, if not faster, than the labour unions will, and for the purposes of regulating his political position, he will have his native councils, and I venture to say soon, and through them he will have his right to say something not only upon railways but upon the condition of suppressed black labour.—Yours, etc.,

The Week in the Sharemarket.

BUSINESS RESTRICTED—PAUCITY OF ORDERS—WAITING A LEAD FROM LONDON.

Business has been dull and quiet this week, awaiting a lead from London. The stagnation affected the whole market, and is disappointing in view of the higher price of gold and the cessation of labour troubles on the mines. An erroneous impression exists in some quarters that Germany might sell scrip now that she is again free to deal. In point of fact, either the Public Trustee or the Union Custodian of Enemy Property has either vested with him, or has a tight grip upon, virtually all the pre-war enemy holdings in South African gold and allied companies. Company secretaries would probably not recognise the transfer of even bearer warrants by ex-enemies, should coupons be presented for dividend payments. The pre-war property of the last named in the Allied countries is held, under the Peace Treaty, as security for debts to Allied citizens. The former German owners have to look to their own Government for recompense for the securities and other properties which have been sequestered and already, in many cases, realised. Thus the Germans—or other ex-enemies, for the matter of that—can have no substantial blocks of Rand shares to sell, and they would be very courageous if they tried to open bears just now, even did our current system of dealings allow of it. Despite the good profits being earned by the mines, London is not giving much attention to South African shares, and it is now thought that there will be no great activity until the ex-enemy shares question is disposed of. Oil shale shares after a spurt on rumours that the Shell people were favourably impressed with the prospects of African oil, have become quiet again. Tin shares are still stagnant, on the outlook for the metal, which was dealt with by Mr. Leisk at the Swazi Tin meeting this week. Colliery stocks may be written down as dull, but industrials have been a little more active, notably Hume Pipes, which firmed up during the week. In some quarters the statement in this column last week has been misconstrued which dealt with the reported issue to Sir Abe Bailey of £50,000 debentures in S.A. Alkali. What it was intended to convey was that the very fact that it was found necessary to raise further capital by means of a debenture issue had depressed the price of the shares. A debenture issue is, of course, but another name for a first mortgage on a property, and however good the name of the mortgagee may be, the depressing effect on the ordinary shares is just the same.

General Review.

These notes would be incomplete without some reference, however slight, to the gloom caused in commercial and other circles by the untimely decease on the 19th inst. of the founder of this journal, Major Clem Webb. The sad event is referred to in another part of this issue, and it only remains to be said in regard to the commercial community that the deceased had endeared himself to all by his sterling personality. The writer of these notes, having had the privilege of knowing him since 1888, is well assured that he could never possibly have had one single enemy. *O si sic omnes!*

There is no important change to report this week in general business. The most satisfactory feature, of course, has been the final settlement of the building trade wages dispute. It is naturally full early to look for any great improvement in the building trade, but now that wages have been reduced and materials are as low as they are likely to be for some time to come, developments may, it is thought, occur shortly. As is well known, there is a tremendous amount of building work to be tackled, and there seems nothing to be gained by postponing operations in the hope of lower costs. Labour, of course, represents about two-thirds of the building cost, and while a 5 per cent. reduction is after all not a very big matter, it still means about £50 reduction in the cost of an average house, and so is in the right direction. The gold premium has advanced to 110s. 10d. per oz., and authorities consider that there may be even further advances within the next few weeks. However hard for Britain as regards the pound sterling, the upward exchange can only be viewed as a blessing by us on the Rand. The pendulum will, of course, sooner or later, swing the other way, but in the meantime our lower grade propositions may take heart of grace. Apart from forced sales, there are no changes to report in prices generally, but it may at once be said that the improvement of the past fortnight has not been maintained and has given place to the lethargy prevailing during past months. However, optimism is in the air, and these relapses are generally compared by the commercial community to the ebb and flow of the strength of a convalescent—after each relapse a fresh accession of strength. Better conditions are confidently expected to rule even during the present year.

Iron and Steel.

Business has been very quiet during the past week, the improvement noticeable during about a fortnight not being maintained, and the volume of dealings has relapsed to recent levels. On the Commercial Exchange forced liquidations have again been the order of the day. The present financial stringency, while leaving firms of big financial resources comparatively cool, is undoubtedly causing some merchants, without such financial strength, a rather warm time.

Engineering Shops.

Business is still improving, and there is this week quite an optimistic tone in engineering circles. During the slack time experienced by the trade, brains have been busy in inventing and adapting several money-saving devices, which are now approaching the practical stage, and to which we hope very soon to revert to and report upon.

Second-hand Machinery.

The market in second-hand machinery has made no improvement since our last report, possibly on account of the unsettled state of the railways and the farming community and outside mines delaying purchases. There have been during the past few days fairly large purchases of boilers and engines for industrial purposes in the Northern Transvaal. In view of the flotation of one or two big companies on new discoveries, there is likely to be a big demand for machinery very shortly. Local orders are very scarce, although there are still a few to keep dealers going. The

mines will not purchase any large quantities as they used to do, and are only buying from hand to mouth. The management of a mine to-day is a fine art, and expenses are cut very fine; every department is well supervised, and before a big order is placed it has to go through several departments before the final decision is arrived at—not as in the early days, when the heads of each department had the authority to order on their own responsibility; in fact, the managers in those days left everything in the way of purchasing entirely to their subordinates; to-day we have a very different system before a purchase is made. There have been several orders for second-hand steel plates lately for certain cyanide tanks which have come down to £10 10s. a ton; the better class is fetching up to £14 a ton. Several mines of late, to economise, have even collected all their short drills and welded them together, making them as serviceable as new—quite a contrast to a few years ago, when these drills were buried in the dump, as well as short pieces of bar iron and other commodities. Things have undoubtedly changed in respect of the economic working of our mines.

The iron and steel industry in Britain is still suffering from the high price of coal, which, although cheaper than during the strike, is still too high to admit of general profitable workable conditions, in view of the keen Continental rivalry. Hitherto British manufacturers have been able to sell considerable quantities of high-speed steel to the United States. Until recently it was possible to place British steel, containing 18 per cent. of tungsten, on the American market at £483 per ton, inclusive of duty (£63), plus the cost of freight and insurance, representing a difference in favour of Britain as against America of nearly 300 dollars per ton. Under the new tariff systems to be adopted by America, which will render imported goods liable to duty on their American values and not on the value in the exporting country—representing about 30 per cent. increase on present duties—Britain will be unable to sell her products at a profit. It is feared that the new tariff will prove prohibitive to British importations. It is stated that the industrial boom in Germany, especially in iron and steel and cognate industries, is largely due to orders from England, Holland and the United States. There is at the moment a large English demand for German half-finished iron and steel.

Coal prices are still falling in Britain, with the result that an increasing number of iron and steel works are resuming work, which is having an encouraging effect in combating foreign competition. Belgian foundry iron is quoted now at £6 15s. per ton, as against the Scotch make of £8 5s. British pig iron is, however, making some headway against Continental quotations. German iron and steel goods prices are advancing rapidly, with big Home and export orders, the explanation of which is to be sought in the continued deterioration of the mark.

Timber and Building Materials.

Things are much about the same as last week, prices are unchanged, and business is only fair. Now, however, that the building trade dispute regarding wages has been definitely settled, the general impression is that we shall shortly see increased activity in the building trade. 3 x 9 deals, 1s. to 1s. 1d.; scantlings, 1s.; beaver board, 4½d.; floorings, 7d. to 7½d.; ceilings, 5¼d. to 5½d.; Oregon, 7s.; pitch pine, 8s. to 8s. 6d.; corrugated iron, 9½d. to 10½d. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality 14s. 9d. for second at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 3d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cub. ft. at the mills; Honduras mahogany, 30s. per cub. ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks, in the absence of any activity in the building trade, are unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 37s. 6d., 47s. 6d., 53s. 3d. for 1 to 3-ply.

Second-hand Iron and Timber Yards.

Business in this section, although at the moment practically much as it was, has an undercurrent of firmness, which is expected to eventuate in activity within a few weeks. With the settlement of the building dispute, there is undoubtedly a better outlook, and dealers with full stocks are looking forward to more prosperous times. Iron is ruling at 5d. to 6d.; timber at 10d. to 1s.

The **BANK** is in close touch with **TRADE** and **INDUSTRIAL CONDITIONS**, both local and overseas, and special attention is given to **COMMERCIAL ENQUIRIES** from customers.

EXECUTOR and **TRUSTEE** business undertaken.

Over 460 Branches and Agencies in Africa.

Agents and Correspondents throughout the World.

MAGNOLIA
ANTIFRICTION METAL

"FLOWER" BRAND.

HAS THE LOWEST CO-EFFICIENT OF FRICTION.

KEEPS down the bill for lubricants, making **BEARINGS** smooth as glass and keeping them **COOL** under heaviest pressures and highest speeds.

Manufactured and Sold By—

THE MAGNOLIA ANTI-FRICTION METAL CO. OF GREAT BRITAIN, LIMITED,
48, QUEEN VICTORIA STREET, LONDON, E.C.

Agents for South Africa: **FRASER & CHALMERS, Ltd.,** Johannesburg, Bulawayo and Salisbury

Electrical Goods.

Dealers admit that it is yet too early to look for any radical improvement in business, but they are sanguine that, notwithstanding the present dullness, better times are in front of us. In the meantime they report that inquiries are now much more numerous than of recent months and that the tendency is better. No further reductions have to be reported than those given during the past fortnight, but notwithstanding the unbending of British prices up to the present, it is generally thought that by about the beginning of October a few more reductions may occur—not warranted, they state, by the general position, but by the continued financial stringency, which compels merchants to reduce heavy stocks at a sacrifice notwithstanding the world's position as regards raw materials. A satisfactory feature to report is increased inquiries, not orders, but which may eventually lead to business, from the country. The Springs, Kimberley, etc., are now more enterprising than they have been for some months. In short, electrical goods merchants are now in quite a cheerful mood regarding the immediate future.

British Trade in August.

This shows some revival both in imports and exports, amounting, as compared with July, to about £8,000,000, while business in foreign and Colonial goods showed an increase of about £10,000,000. During August over 3,000,000 tons of coal, valued at £5,000,000 sterling, were exported; £19,000,000 sterling worth of raw materials were imported, compared with 15½ millions sterling during July; £18,000,000 sterling worth of manufactured goods were imported during July and August, but during the latter month the exports of manufactured goods amounted to £40,000,000, an increase of £3,250,000 compared with July.

British Revenue and Expenditure Returns from April 1 to September 10.

These show receipts of £400,000,000 and expenditure £449,000,000, in comparison with £541,000,000 and £456,000,000 respectively for the corresponding period of last year.

Union Railway Earnings and Expenditure, 1914-1921.

The expenditure on railways has increased from £14,491,696 in 1914 to £28,348,563 in 1920-21, or 95.62 per cent. The position is best disclosed by giving the imports and exports in 1914 alongside of those of last year, viz.:—

	Imports.	Exports.
1914	£30,162,000	£38,495,000
1919	46,712,000	95,803,000
1920	93,404,000	70,799,000

Taking, however, the exports of wool, hides and skins, corn, grain, meat and mohair, the position is:—

1914	1919	1920
Tons.	Tons.	Tons.
227,058	575,671	187,354

which shows that notwithstanding an increase of expenditure since 1914 on railways of 95 per cent., our products exported are less in 1920, which calls for increased economy in the working of our railways.

Pretoria Portland Cement Co.

Mr. James R. Leisk, C.M.G., presiding at the annual general meeting of shareholders last week, had the pleasant task of announcing that the company's profit for the past year amounted to £195,231, an increase of nearly £50,000 on the preceding 12 months. The capital of the company had been increased during the year by £270,000, bringing it up to £630,000. Two dividends, each of 15½ per cent., had been declared during the year.

Oil.

The Karoo series of oil shales is reported upon very favourably by a well-known engineer. He says that the area known to be covered by these beds is very large, the thickness of the beds varying from a few inches to three or four feet. The value of the content seems to vary from 12 to 50

gallons per ton, the possible average being 20 gallons. It is estimated that the costs of running and refining will be covered by 20s. to 25s. a ton, so that 20 gallon shale should show a profit of 35s. to 40s. a ton. In his opinion a plant to treat 500 tons per day could probably be fixed up for less than the cost of a 100-stamp gold mining mill. A point in favour of producing oil in the Union would be the capture of the South African market for oil and lubricants. Regarding the estimated value of these shale areas, he stated that, based on data of the best authorities, and allowing amply for contingencies, the profits to be made would be greater than those presently obtained from the gold and diamond industries. In his opinion, the structural geology of the country precluded the probability of gushers being found. He thought that the oil shale proposition in the Union was one of the biggest economic chances South Africa had ever had, and that it should be exploited without the help of the great oil groups, who might possibly queer the pitch.

Oils and Colours.

White lead in oil, small sizes, 1s. lb., 41s. per 50 lb kegs; red lead, 1s. per lb. in 6½ lb., 12½ lb. and 25 lb. kegs; 10 lb. in 50 lb. kegs; dry white lead, 1s. 6d. lb.; linseed oils, raw or boiled, small bottles, 1s. 9d. each; 7 lb. tins, 8s. 6d. each; 4 Imperial gallons, 42s. 6d.; spirits of turpentine, small bottle, 2s. 6d. each, 10s. 6d. per 83 Imperial gallons; turpentine substitute, 6s. 6d. per tin, each 5-6 Imperial gallons; finest linseed oil putty, in 100 lb. drums, 5d. lb.; English putty, in bladders, 7½d. lb.; colours ground in oil, 1s. 6d. to 4s. 6d. lb.; dry colours, 6d. to 4s. 6d.; colours ground in water, 1s. to 2s.; in turpentine, 3s. to 10s. 6d. lb.; ready mixed paints, 1s. 6d. lb.; 70 lb. drums, 1s. 4d. lb.; roof paints, 1s. 6d. lb. in 14 lb. tins; 1s. 4d. per 70 lb. tins; varnishes, 25s. to 47s. per Imperial gallon; red oxide, ground in linseed oil, 50s. per 100 lb.; alum, 9d. lb.; creosote, 4s. 6d. per 5-6 Imperial gallon; methylated spirits,

USE

“PORPOISE”

BRAND

ANTIFRICTION GREASE

Used for years by the majority of Mines all over South Africa.

National Bank Chairmanship.

The board of directors announce with regret that the Hon. Hugh Crawford has decided to relinquish his position at the end of the present year, Mr. J. R. Leisk, C.M.G., accepting the chairmanship from the beginning of 1922. The Hon. Hugh Crawford has been connected with the National Bank of South Africa since its inception in 1890-1.

Settlement of Strike at Messrs. Hubert Davies & Co.

This has been satisfactorily made; the strike is off and all employees have resumed work.

A lock-out of boiler-makers is threatened in the Mersey ship-repairing yards in connection with the restriction of the use of "burners." The "burner" is a mechanical device entailing a big saving of labour, to which the Boiler-makers' Society object.

Transmission of Power.

The General Electric Company of America make the important announcement that for the first time in history it has generated and transmitted an excess of a million volts pressure by transformer equipment designed along standard lines, with current at ordinary household efficiency of 60 cycles per second. They claim the feasibility of using considerably higher voltage in the transmission of power and that the extent of long-distance transmission has advanced tremendously.

Australian £10,000,000 Loan.

The Treasurer of the Commonwealth, the Right Hon. Sir J. Cook, announces that the success of the New Australian loan is now assured.

Radium.

It is announced that a British company has concluded an agreement with the Czecho-Slovak Government, virtually amounting to a monopoly of the output of radium in the producing mines at Joachimstal, which is the only European State producing this valuable metal. The mines are expected to produce three to four grammes yearly. The company will not sell, but hire the radium for medical and research purposes.

Gold Cathodes in place of Platinum.

An American chemist is making apparatus out of gold instead of platinum to save money. His expedient grew out of his need for several cathodes in making electrolytic tests for copper. To avoid the large investment for platinum, he stated, cathodes of 24-carat gold were tried. They

proved to be, to all appearances, the equal of platinum, at one-tenth the price. He has had since then several open cylinder cathodes of the same dimensions as the platinum cathodes in constant use with perfectly satisfactory results. He states that he still has to use platinum as anode, but with the precaution in using the gold cathode when igniting to remove any traces of grease, these cathodes seem to be the equal of platinum.

Bwana Mkubwa Copper Mine Reconstruction.

This company, which owns extensive concessions in Northern Rhodesia, is now in course of reconstruction.

London Share Market.

Latest quotations: Standard copper, £67 13s. cash, £68 13s. 9d. forward; electrolytic copper, £72 15s. cash, £74 forward; Straits tin, £154 7s. 6d. cash, £156 10s. forward; English lead, £23 2s. 6d. cash, £22 15s. forward; bar silver, 39½d., and fine gold 110s. 10d. per oz.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

VI.

(By Arthur Stenhouse.)

In 1886-7 the Market Square of Johannesburg was one vast dusty plain, partly surrounded by tin shanties. Towards the evening, and all night long, the Boer farmers with their ox wagons laden with pigs, produce and poultry, would trek in from every quarter and camp upon the Square, and the Boers would sleep beneath the wagons. It was a weird and imposing spectacle watching the camp fires burning, and listening to the lowing of the cattle in the silence of the night.

In 1888-9 there was a tremendous boom in gold mining shares. The Stock Exchange was situated in Simmonds Street, facing the Corner House. Traffic between Commissioner Street and Market Street was "barred" by iron chains. Share gambling was universal, and, daily, after the closing of the Exchange, the space between the chains was densely packed with brokers and their clients. Miners trooped into town after completing their shifts on the mines, and joined the noisy throng. The sharebrokers' clerks were often occupied in the offices throughout the entire night. Share gambling was a mania.

The proprietors of the "Star" newspaper were very enterprising. Hourly editions, containing the latest quotations, were published, and eagerly purchased by an excited crowd. The local bars did an enormous trade, and champagne flowed like water. Appropriately was the Stock Exchange named the "Kafir Circus"; it only required a brass band to complete the picture!

Away from the crowd, on the silent hills behind the town, overlooking the treeless valleys, towards the blue mountains surrounding Pretoria, placidly I recalled happy memories of leisurely wanderings through the lovely gardens attached to the Villa Pallavicini—the loveliest in Italy, viewing the noble cathedrals at Genoa, containing paintings and pictures of priceless value; exploring the marble palaces of the Duke de Galleiria, the Palace Durazio, and the Doria Palaces; admiring the pictures by Raphael, Corregio, Titian, Perugino, Guido, and other celebrated masters; and by easy stages travelling along the Mediterranean shore to Monte Carlo, with its world-famed terraces, and resting in the lovely gardens attached to the Casino beneath the palm trees shade.

In the pioneer days we wandered afar in quest of gold. Crossing the Zambesi River we trekked through an almost mythical country, passing by the way enormous ant-heaps sufficiently large to inset a double line of rails. From the summit of a lone mountain, half hidden by bush, we gazed down upon an extinct volcano, which resembled a great cup, the bottom of which had subsided to a level floor. A weird and impressive scene; somehow there was an indefinable feeling that the crater might at any moment burst forth into flame and envelop us with molten lava. Hurriedly we descended, and once more freely breathed the balmy air beneath the welcome sky.

Romance figured largely in the solitude of our sub-tropical surroundings in those days of long ago.

We take the following from the *Pretoria News*: Mr. Geo. Jackson Kirby, of New York, who is taking a great interest in South Africa (mines and minerals), informs us that he is prepared to present the Government, or Pretoria, with the finest site on Capital Park (15 or 20 acres), on the ridge overlooking the Magaliesberg valley and range, for the purposes of a college or similar building, provided that such building as was found desirable and was approved, was commenced without unreasonable delay.

Facts of Management

ONE WAY OF REDUCING WORKING COSTS

With operating costs what they are to-day, purchases in your plant which were once considered matters of routine have come up for sharp executive scrutiny.

Take the matter of steam lubrication. The executive whose mind is keyed to to-day's conditions knows that:—

1. There is a correct steam engine for his power needs.
2. There is a correct steam cylinder oil for that engine.
3. Either a poorly-chosen engine or incorrect steam cylinder lubrication involves a definite money loss.

The steam cylinder oil for the lubrication of your steam engine should be chosen with great care to meet the operating conditions of that engine.

There are five factors which influence the service value of an oil used for the lubrication of steam engines and cylinders and valves. These five factors must be taken into consideration before the correct selection can be made. They are

1. The size of the engine.
2. The speed of the engine.
3. The load carried by the engine.
4. The pressure of the steam.
5. The quality of the steam.

We are able to offer oils which will meet any combination of the foregoing conditions in operation, and satisfy all the requirements of correct lubrication of steam cylinders. We shall be glad to prescribe the correct oil if you will consult us.

Consolidated Building, Johannesburg.

ENGINEERING SECTION.

The Crucible Steel-Making Process.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Steel Makers, Sheffield.

This process, as its name implies, is carried out in crucibles which are (in Sheffield practice) made from a mixture of refractory clays together with a little coke dust. Two crucibles are placed in each melting hole, and they are heated to redness in an annealing furnace first. When in the melting hole they stand on a fire clay stand. The lid is placed on the crucible and the fire drawn up in the usual way until the crucible and stand are brought to a good heat when a small quantity of sand is thrown into the crucible to frit (join) the crucible to the stand. Crucibles when made have a hole in the base like a plant pot, and the sand fills this hole and fuses, fastening the pot and stand together. The first method used was simply to melt carburized iron and cast into ingots. However, this has been superseded by melting a quantity of wrought iron or ordinary scrap steel, together with either charcoal or white iron, which act as carburising agents, i.e., they add to the steel the necessary carbon content. This process is purely and simply a melting of the mixture put into the crucible, and it has no purifying effect on the material as charged. In other words, if you want a pure steel, you must commence with pure irons. When the crucible is at a good heat and is well fritted to the stand, the metal is charged through the "charger," which is an iron funnel made to fit the mouth of the crucible. The lid is placed on the crucible again, and more coke added, and after $3\frac{1}{2}$ to 4 hours the charge is clear melted. We now have to keep the steel in a molten condition until it is dead melted or killed, which are terms used for the elimination of the gases in the steel. The crucibles are now pulled out and the steel cast into ingots. As the crucibles only hold 56 lbs. of material the usual practice is to make ingots not exceeding 56 lbs. each, although very large ingots have been made from crucible steel by various methods, such as the using of the ordinary steel ladle, or by a relay of teemers, the flow of

metal being kept continuous until the ingot is made. The pots are put back into the furnace and another charge added of less weight than the first. The reason for this is, the slag which floats on the surface of the steel attacks the crucible, and on examination you can clearly see the slag line, which shows that at this particular place in the crucible we have a weak spot, and if the same height of steel for the second heat as for the first was used, the action of the slag would be in the same place and would break through the walls of the crucible. Some pots have done as many as four separate heats, but the present practice in Sheffield is two heats only, not due to the fact that the crucible will only do this amount, but the working day of eight hours is in vogue, and therefore two heats is called a working day and is approximately $7\frac{1}{2}$ to $9\frac{1}{2}$ hours, according to circumstances. Once the crucible becomes cold it is of no further use.

As I have already said, this process is essentially a melting operation, and the chemical changes in the steel are very small. The carbon may gain slightly, obtaining carbon from the crucible, to which you will remember coke dust is added in the course of manufacture. The Silicon increases considerably, this also being obtained from the crucible, which is dependant on silica for its refractory properties. The phosphorus, a deadly impurity, is practically unchanged. The manganese is reduced by about 40 to 50 per cent., and this is due to the oxygen in the molten steel combining with it. The sulphur, another impurity, is actually increased, due to the sulphur in the coke forming sulphur dioxide, penetrating the walls of the crucible and being absorbed by the molten steel. This is the theory put forward, but how it does happen is yet to be proved, for experiments in this direction are very difficult. Suffice it to say, however, that the increase in the sulphur content in crucible steel is entirely due to the poor quality of coke we now have in Sheffield, and although you may use the best irons as base metal, the resulting product is high in sulphur. It is very obvious to all that steel of high chemical purity is the first essential, method of casting, etc., following in importance, and it is for this reason that Swedish irons have for many years formed the base of the best Sheffield crucible steels. A few days ago I was asked to explain why crucible steels differed from Siemens steels when the analysis of each steel was practically the same. I pointed out that this was very rarely the case, as the manganese in the Siemens was invariably higher than the crucible, in some cases more than double, and in fully explaining I quoted H. Brearley's "Heat Treatment of Tool Steels," in which this question is so ably dealt with.

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to devine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

A point of comparison between Siemens and crucible steels which is often insisted upon when both are used for tool making is that Siemens steel does not withstand so well the re-hardening operation, the reason commonly expressed being that the former does not contain so much "body" and loses its "nature" more easily than the latter. This explanation is a remnant of the time when the manufacture of tool steel was purely an empirical art and the influence exerted by the essentially different composition of Siemens steel had not been clearly realised. These terms "body" and "nature" have no precise meaning; they refer to nothing which can be measured or weighed; they do not even belong to that class of appearances such as fractures and the position of a crack, which can be appreciated as reliable indications though they cannot be expressed in any scale of units. They belong rather to the primitive jargon of a craft, and may be taken to-day to reflect something of experience, something of prejudice and a semblance of commercial astuteness. There is greater danger to begin with that a tool made from Siemens steel will break on hardening. This is consequential to the fact that the steel contains more streaks of non-metallic impurity, such as slag and manganese sulphide, and is generally less homogeneous, because it has been cast in larger ingots under conditions of casting somewhat remote from the ideal. The main reason why Siemens steels are different, when equally sound as crucible steel, is that they contain almost invariably larger amounts of manganese than crucible steels, and on this account harden more intensively and to a greater depth, which may be an advantage or otherwise. This obviously increases avoidable stresses if it hardens those parts where hardness is not required, e.g., at the roots of teeth, and at the same time **lessens the resistance of the material to stress.**

If a tool, for the reasons stated, is more apt to crack at the first hardening, it is still more apt to do so on the second hardening, because on re-heating, the stresses, already larger than usual, are in greater danger of being increased to breaking point. The explanation of this relative behaviour lies not in some mysterious property conferred by a melting process, but in the choice of material well or ill suited for its purpose on account of its chemical composition.

The first point you will see, therefore, if any trouble is experienced, is the question of using the correct chemical composition of steel for the purpose, and Sheffield manufacturers are always willing to advise on any point such as this.

British Engineering Standards Association.

The British Engineering Standards Association held its third annual meeting on Thursday, the 14th ult., at the Institution of Civil Engineers, when the chairman (Sir

Archibald Denny, Bart) presented his annual report, and made a review of the position. The meeting was well attended, some 80 members being present, and a number of useful suggestions were made. The chairman's address once again showed the vastness of the work undertaken by the association, and the economical manner in which it is carried out. There are now more than 1,500 engineers who give their time and experience to this national work, but the business community is not as impressed as it should be with the commercial value of standardisation, otherwise the association would not have so much difficulty each year in raising the comparatively small sum required for this work, which is of such value to the trade and commerce of the country. Last year £15,000 alone was expended, of which the industry of the country contributed about £10,000, the remainder being in the nature of grants from H. M. Treasury and the Indian and Dominion Governments. The chairman emphasised the progress made in regard to the revision of the steel sections, the standardisation of railway materials, the work in connection with a British specification for girder bridges, the extensive programme of standardisation of details in the construction of ships and their machinery, and the important development in the electrical work. He mentioned that the chemists and chemical engineers were now making use of the organisation, and that their work was bound to have a beneficial effect on that branch of British trade. He also referred to the satisfactory working agreement which had been arrived at with the various research associations, which will enhance the already cordial collaboration between those engaged in research and the standards organisation, the line of demarcation of which is sometimes none too easy to draw. In glancing at the work abroad, he mentioned that there are now 11 local committees actually at work. These committees are continually making valuable suggestions to the home committee, and from their vantage point of experience in local conditions are in a position to offer most welcome advice. He also mentioned the question of international standardisation, and the proposals which are to be put into effect in order, with proper safeguards, to assist in guiding along right lines the trend of international agreement in engineering matters generally. A number of suggestions were made by those present, the more important of which were the advisability of giving greater publicity to the work of the association, and the question of assisting purchasers to ascertain without difficulty the names and addresses of manufacturers who are prepared to work to British standards. These suggestions will be considered by a publicity committee recently nominated.

Otavi Mines Scheme.

Authoritative particulars are now available of the scheme for converting the Otavi Mines and Railway Company (the Otavi Minen-und-Eisenbahn Gesellschaft) from a German undertaking registered in Berlin to an undertaking registered in South-West Africa, with its capital in sterling instead of marks. As reported recently, the company has now been duly registered as a foreign company in the South-West African Protectorate. An extraordinary general meeting has been called for the purpose of passing the necessary resolutions for the conversion of the mark capital into a £ sterling capital, the exchange of the old shares and Genussschein (deferred shares) for new shares in English currency, and the raising of further working capital. The Union of South Africa having assumed the Protectorate over South-West Africa and introduced sterling currency there, it becomes necessary, especially in view of the great fluctuations in the mark, to free the capital of the company, which naturally has to operate under the influence of the new currency, from such fluctuations. After the occupation of South-West Africa the funds required by the local management had to be procured in sterling by means of bank loans, which now have to be covered.

In order to eliminate the not very fortunate distinction regarding dividend rights between shareholders and Genussschein holders—a distinction which had its rise in the historical development of the company—it is intended in future that Genussschein holders shall be enabled to acquire full rights as shareholders, including the possibility of acquiring new shares. In exchanging old shares for new ones a cash amount of 20 marks will be paid per share.

The new working capital will be applied chiefly to paying off the bank loans contracted during the war, extending the machinery and dressing plant for oxide and carbonate ores, constructing a new dressing plant for sulphide ores, and putting down a new main hauling shaft.

The bank loans have been chiefly employed in developing a further 500,000 tons (approximately) of new ores. The extension of the existing dressing plant for oxide ores and the construction of a new plant for sulphide ores are urgently required to deal with the large quantities of low grade ores—particularly the aplite ores—now on the dump.

During the past year the ore output is stated to have been satisfactory, and, with the introduction of piecework, pre-war figures will, it is hoped, be reached within a reasonable time.

The exportable ores resulting from the output of the current and the next financial year are sold firm, and the management hopes later to reach a figure of exportable ores in excess of the quantity sold.

Trans-Zambesia Progress.

According to the latest advices received in London, track has been laid on over 100 miles of the Trans-Zambesia Railway, which is to connect Beira with the railways of Nyasaland. The earthworks are completed to the 140-mile post, and the rails are expected to reach the temporary terminus on the south bank of the Zambesi, opposite Chindio, before the end of this year. Borings at the proposed site of the bridge, which will be erected when general conditions are more favourable, have not yet been completed, but the results obtained indicate that there will be no difficulty about finding a rock foundation at Mutarara, some thirty miles up the river from Chindio. As the bridge will cross nearly 1½ miles of water, in addition to a sandbank about 1¼ miles wide between the two arms of the river, it will be an expensive structure. How long it will be before it is put in hand must depend largely on the trend of prices for bridging material and the possibility of raising the necessary capital at a reasonable rate of interest.

ENGINEERS will do well to study the cost of Flake Graphite Lubrication. Are you certain yours cannot be reduced? If cheaper and more dependable service can be had from engines and compressors because of better lubricated parts, then you should decide if any possible economies have been overlooked in your plant.

SMOOTH valve action and uniform steam distribution are assured when you use DIXON'S FLAKE GRAPHITE. Scoring of cylinders is prevented, blowing reduced, oil eliminated from the exhaust and the life of the packing prolonged. The cost of cylinder lubrication can be reduced by half.

AIR COMPRESSOR LUBRICATION.

WHEN used in compressor cylinders, oil is prevented from getting into the air lines and receivers and discharge valves do not carbonize or clog. In mines where the air supply of the miners is chiefly the exhaust from rock drills, it is most desirable to avoid tainting the air with the fumes of lubricating oils; this constitutes one of those side lights on the subject of air compressor lubrication that deserves thoughtful consideration.

DIXON'S TICONDEROGA FLAKE GRAPHITE is known the world over as the ORIGINAL FLAKE GRAPHITE.

The Richest Gold Mine in the World!

The New Modder, illustrated above, has had a record year in point of output and profit. The tonnage milled, the amount of gold recovered, and the working profit earned are the highest yet obtained during the history of the Company, and exceed by 114,500 tons, 27,691 fine ounces, and £205,207 the records established in the previous year. Included in the working profit of £1,699,052 is an amount of £751,427, equal to 44.2 per cent., representing the amount realised above standard price for gold sold.

The Roodepoort U.M.R.: Proposed Co-Partnership

SUB-COMMITTEE OF M.W.U. INVESTIGATING—PARLOUS POSITION OF THE MINE—RECENT HISTORY OF ITS STRUGGLE TO KEEP WORKING.

Early in the month the Rand was startled by the offer of the Albu Group to the employees of the Roodepoort U.M.R. to introduce a co-partnership scheme to obviate the closing down of the mine. The doubtful merits of co-partnership applied to mining are discussed in our leading columns, and we here set out the particular case of the Roodepoort U.M.R.

Of all the low-grade mines of the Rand now being kept alive by the gold premium, the Roodepoort United Main Reef is in the most precarious position. Its financial history in the past couple of years is briefly as follows:—From January to July, 1920, the company made a working loss of £21,296. In the middle of that year, it will be remembered, the employees were called together and the impossible nature of the position explained to them very fully and frankly. A retrenchment scheme was then agreed upon by the management and men, and as a result the following six months, working on that basis, resulted in a small profit of £17,731. With the drop in the gold premium the position changed again, and for the period to August, 1921, a net working loss of £11,953 resulted. The company, it may be recalled, is burdened with a debt of £380,000, on which, of course, interest must be paid. The Albu group, it must here be said, have all along made a brave struggle to keep their low-grade mines alive, and the present proposal at the R.U.M.R. is simply a last desperate expedient to keep the mine going at all costs. There are 164 white employees on the property, and in order to save them from being thrown out of work at a time like the present, the directors, as a last resort, decided to put forward the co-operative scheme explained in the following letter from the chairman, Mr. L. Albu. That letter was dated September 8, and is as follows:—

"In accordance with the promise which I made to the representatives of the various Workmen's Unions and Officials' Association, at a private meeting held in this company's office on Saturday, the 3rd instant, I now beg to place before you a recapitulation of the terms on which this company is prepared to continue working.

"1. That all employees of the company be guaranteed one-half of the standard wages ruling on the mines of the Rand, from time to time, during the period of this agreement.

"2. That the revenue which accrues to the company from gold mining operations (not including any revenue derived from sale of plant and stores) shall be utilised as follows:—

- (a) To cover the working expenditure, including the cost of shaft sinking and development, and such capital expenditure as may become necessary in future.
- (b) To payment of interest on the loan, at present, approximately, £2,500 per month.
- (c) To payment to employees to bring them up to the standard wage, as defined under (1).
- (d) Any balance which may remain over after (a), (b) and (c) have been provided for, to be distributed equally between the company and the employees.

"3. This arrangement to be in force for a period of two years, provided, of course, that circumstances do not render it necessary for the company to suspend operations prior to that time.

"The principal reason which influences me in making this offer is that I am firmly of the opinion that it is only want of efficiency in the various departments of the mine which has brought this, and other low-grade mining companies, to a position where they have either to close down altogether or to continue the struggle under extremely adverse conditions. I feel confident that if the Unions will only remove all artificial restrictions and allow free play to the most economic method of working that the carrying out of these proposals will prove to be for the benefit of the employees as well as of the company. I feel also that the fact that the prosperity of the company will be shared by employees will give them an incentive to work such as they have never had before on the Rand, but I reiterate that to give this experiment fairplay the men must be allowed full scope for their productiveness.

"As explained to you, this company is heavily in debt, and as the bank is pressing for a settlement of its liability, I shall be obliged if you will let me know at the earliest possible moment whether you are willing to lend your support to the scheme outlined above."

To this a reply was sent by the Secretary of the S.A.I.F. last week stating that the Unions concerned had been communicated with, but that all had not replied, and that, as the scheme was quite a new departure to the workers, it was essential that they should be allowed time to consider and discuss it, as any hasty decision might be a means of eventually wrecking a scheme of this description. In these circumstances it was hoped that the directors would bear with the seemingly unnecessary delay.

Need for a Decision.

To this communication the following reply from the Secretary of the Board of Directors was received:—"I am instructed by my Board to acknowledge receipt of your letter of September 22 in reply to mine of September 21, stating that you do not anticipate being able to reply to our chairman's letter of September 8 until towards the end of the coming week, notwithstanding the fact that the matter has been put before your Federation for consideration for quite a considerable time. This my directors very much regret, as it is essential that a decision should be come to at once, and I am therefore directed to inform you that unless a satisfactory arrangement has been arrived at before the end of the month, my directors will be reluctantly compelled to take steps for the immediate closing down of the mine."

This letter was considered at a meeting of representatives of the joint Trades Unions on Monday evening, when it was decided to reply to the effect that the Federation would require at least another month before it could come to a decision, and expressing regret if, in the meantime, the mine was closed.

The position is now that a sub-committee of the S.A. Mineworkers' Union—not, as the "Rand Daily Mail" has it, the Reduction Workers—has been appointed by the executive of that body to investigate the whole matter, and that while the company is anxious for their decision by the end of September, there may be some further delay in view of the importance of the subject. Some general considerations bearing upon it are discussed in our leading columns.

New Detector for Fire-Damp.

Fire-damp is the great enemy of the collier, and it is peculiarly insidious inasmuch as it collects without giving any sign to the senses of its presence. Many attempts have been made to devise a reliable detector, and it is interesting to learn that very promising experiments have been carried out by the British Ministry of Mines with a new form of instrument for this purpose. This instrument relies for its operation upon the expansion of liquid in a glass tube. It is now undergoing extensive trials underground, and the final result will be awaited with keen interest.

Distillation of Oil Shale.

An exceedingly interesting and instructive article on the above subject by David E. Day appears in the "Mining and Scientific Press" for August 20, 1921. In view of the South African oil shale activities, this article should prove of great value to those who are interested in the industry. Extracts from this instructive article are reproduced hereunder.

The major operations in a plant producing oil from shale are: (1) mining and crushing the shale, (2) treating the shale to recover the oil, and (3) refining the oil into marketable products. The first and last of these operations present no new features.

There remains only the problem of producing the oil from the shale—a problem that does not present any serious difficulties, but one that at present retards the operations of those who believe that the time for oil-shale development has arrived. Except in isolated instances, the only commercial method of recovering oil from shale is by means of a carefully regulated heat treatment. Although the condition in which the oil-producing substance exists in shale is not definitely known, it is almost certain that it is an exceedingly complex hydrocarbon. It cannot readily be dissolved and extracted by solvents; it adheres too closely to the shale to permit mechanical separation. There remains only the method of vaporising this hydrocarbon, and condensing the vapors formed. In all probability, the original hydrocarbon is so complex or so tightly bound in the shale pores that it will not distil without "cracking." Assuming that this theory is correct, and that a "cracking" distillation is the only method of recovering oil from shale, the problem resolves itself into the controlled-heat treatment of a fragmentary material.

By the principles of retorting shale for oil is meant those that are involved in producing oil as the main and most important product. The factors governing the efficiency and economy, and oil-recovery of a retort, considered from the standpoint of the retort alone and ignoring the factors introduced by the type of shale or its preparation before retorting, are as follows:—

- (1) Factors affecting efficiency:
 - (a) Thin shale layer.
 - (b) Mechanical agitation.
 - (c) Complete heat control.
 - (d) Efficient application of heat.
 - (e) Efficient furnace design.
 - (f) Simple mechanism.
 - (g) Large unit capacity.
- (2) Factors affecting economy:
 - (a) Continuous operation.
 - (b) Minimum number of moving parts.
 - (c) Maximum use of automatic machinery.
 - (d) Minimum fuel requirements.
 - (e) Accessibility of parts.
 - (f) Mechanical strength and endurance.
- (3) Factors affecting the quantity and grade of oil recovered:
 - (a) Temperature control.
 - (b) Even heat application.
 - (c) Progressive heating.
 - (d) Protection of vapors from abnormal temperatures.
 - (e) Free passage of vapors.
 - (f) Freedom from dust.

Factors Affecting Efficiency.

Thin Layer of Shale.—The necessity for a thin layer of shale in the retort is due to the insulating qualities of the spent shale. Because of its high porosity and carbon con-

tent, spent shale is one of the best of insulating materials. A thickness of ten inches of spent shale is equal in insulating qualities to a two-course wall of firebrick.

Mechanical Agitation.—The agitation of the material as it passes through the retort is important, both from the standpoint of heat efficiency and operating efficiency. It is obvious that a greater shale layer may be retorted with the same amount of heat and in the same time, provided that it is constantly stirred and agitated, than would be possible if it remained stationary. Furthermore, most rich shales tend to coke in the retort unless they are subjected to constant agitation.

Complete Heat Control.—The importance of complete heat control is so obvious as to require little discussion. If too little heat is applied the time of retorting will be increased, with a loss in retort efficiency. If too much heat is applied, some of the oil will be lost as permanent gas, and heat will be wasted, thus reducing both operating and heat efficiency.

Correct Applications of Heat.—Not only must the heat be under complete control, but it must be correctly applied. To achieve high efficiency, shale should be heated progressively to higher and higher temperatures; the greatest heat should be applied at the discharging end of the retort, and should decrease gradually toward the charging end.

Correct Furnace Design.—Too little attention has been given to the furnace in which the retort is placed. This furnace should not only be designed to regulate and apply the heat as discussed under the last three headings, but should also be designed with attention to the general principles of furnace efficiency.

Simple Mechanism.—The simpler mechanism, the lower the cost of installation and of upkeep and operation. Many retorts that produce good results in the laboratory are totally unfitted for commercial operations because of the complication of their mechanism.

Large Capacity.—In designing an oil-shale retort, or in considering the adoption of a process, the primary consideration should be the adaptability of the retort to large-scale operations. The oil-shale industry is fundamentally a low-grade mining enterprise. To be commercially successful it must handle large tonnages at low costs. For this reason any successful retort must not only be adaptable to large-scale development, but must be capable of attaining this development without too great a duplication of units.

Factors Affecting Economy.

Continuous Operation.—Continuous operation is essential, not only from a standpoint of efficiency, but to secure economical operations. No matter how ideal a batch type of retort may be from an efficiency standpoint, it can never be as economical as a correctly designed continuous retort. The time required to empty and recharge a retort of the non-continuous type is a total loss. A non-continuous type of apparatus cannot be made as nearly automatic as a continuous retort, and consequently requires a greater labour and superintendence charge per ton capacity.

Minimum Number of Moving Parts.—The number of moving parts required should be kept at a minimum not only for the reasons discussed under efficiency, but also for reasons of economy.

Maximum Use of Automatic Machinery.—The effect of automatic machinery on the economy of operation is too well known to require discussion.

Minimum Fuel Requirements.—It is obvious that to obtain operating economy, fuel requirements should be kept at a minimum. For this reason full use should be made of all possible heat applied (1) by designing an efficient furnace, (2) by controlling the heat applied, and (3) by recovering some of the heat at least from the spent shale and the vapors.

Accessibility of Parts.—The entire retort should be completely accessible. Shale may tend to coke or clog the retort, or carbon may form on the walls. Consequently, access to the interior should be provided so that the walls may be scraped or cleared if necessary.

Mechanical Strength and Endurance.—The last and, possibly, the most important factor is the mechanical strength and endurance of the retort. No matter how sound and perfect a retort may be from a theoretical point of view, it is worthless unless it can withstand continuous service without excessive repairs and replacements.

Factors Affecting the Quantity and Grade of Oil Recovered.

Temperature Control.—If the theory that oil is produced from shale by "cracking" complex hydrocarbons, already existing in the shale, is adopted, the importance of complete temperature control is at once evident. Experiments have proved that radically different results are obtained when shales are treated at different temperatures. When high temperatures are used a large amount of light oil is produced at the expense of a lessened total recovery. When low temperatures are used, a maximum amount of oil is recovered, but this oil has a small percentage of low boiling hydrocarbons.

Even Heat Control.—Inasmuch as the use of different temperatures will result in the production of different grades of oil from the same shale, similar heat treatment must be given to each particle of shale in order to produce an even product and to avoid losses. This will necessitate:

- (1) A thin layer of shale.
- (2) Mechanical agitation.
- (3) Continuous treatment.

The thin layer of shale avoids over-heating of the shale nearest to the retort wall in the attempt to heat sufficiently the shale further removed. Mechanical agitation further reduces the effective insulating property of the shale layer, and makes even treatment of the individual particles possible. Uniform heating conditions can only be maintained by continuous treatment.

Progressive Heating.—Experimental work and research have shown that to obtain a maximum yield of the most desirable product, the shale must be heated progressively. In practice the temperature of the shale should be increased gradually to the point at which oil vapors are formed, and then increased uniformly until all the oil is driven off.

Protection of Vapors From Abnormal Heat.—Shale vapors as formed are composed of complex molecules which are easily dissociated if exposed to temperatures higher than those at which these vapors were formed. Some of this breaking down or "cracking" may be desirable for the production of light oils, but in any case it must be carefully controlled. In general, it seems essential to withdraw the vapors as rapidly as formed, and to protect them from high temperatures. If, on the other hand, the vapours come in contact with a layer of relatively cool shale, and are condensed and re-vaporised, a large loss will result, and undesirable hydrocarbons will be produced. Except in special cases, therefore, the vapors should be withdrawn without over-heating or re-distillation.

Free Passage of Vapors.—One of the most essential factors in obtaining the result discussed above is a free passage for the vapors, not only in the retort itself but also from the retort to the condenser.

Freedom From Dust.—Although, as already discussed, mechanical agitation is essential to successful retorting, this agitation should not produce dust by grinding the shale, nor should it tend to stir up the dust that may be present with the crushed shale. Shale dust, if given the opportunity, will go over into the vapor lines and condenser with the vapors, and will absorb oil to form a thick paste, which not only clogs the lines and causes countless mechanical difficulties, but also wastes a large amount of oil.

The Retorting Apparatus.

The determination of the factors just discussed indicated certain features essential to the retorting apparatus. It is directly evident that the retort should be continuous, it should be capable of complete temperature control, it should agitate the shale, it should treat the shale in a thin layer, it should heat the shale progressively, it should avoid dust, it should be simple mechanically, it should be of large capacity, and it should be strong and durable. It also indicated that the retort should be vertical because of the mechanical difficulties involved in externally heating a horizontal retort. In a vertical retort, the stresses all act downward on a firm basal support, whereas in the externally-heated horizontal retort, these stresses are balanced only at the points of support and the unbalanced stresses between these points cause the retort walls to sag and to twist out of shape.

The Day-Heller Retort.

The retort is composed of three main parts: (1) the retort-shell, which may be made of cast-iron, cast-steel, or refractory material, (2) the vapor-manifold, and (3) the furnace.

Mechanically, the retort is extremely simple. There is only one moving part—the vapor-manifold—and this is strong and durable. It moves slowly, encounters no stresses acting directly against its motion, and is insulated from the heat. Access may be had to the complete retort by lifting the vapor-manifold out through the top. This can readily be done by unbolting the cover plate, by lifting the upper brace bearing from its lugs, and by removing the gear and bearing from the lower end of the manifold pipe. With the manifold removed, the retort is open for inspection and clearing. All the parts are standardised, and are interchangeable with similar parts in other units, so that by keeping a few spare parts on hand a large plant may be operated continuously without serious shut-downs and delays.

The furnace is designed particularly for high efficiency, economy, and complete control. The greatest objection to a vertical furnace is the difficulty of efficient heating. This has been overcome in this retort by using horizontal annular flues, which are separate and independently controlled by dampers. The retort has a high capacity compared to its bulk and to the ground space occupied. Thus a single unit 25 ft. high and 10 ft. in diameter, including flues, will have a capacity of from 100 to 250 tons per 24 hours, depending on the type of shale treated.

Mineral Occurrences in the Namib Desert.

Our knowledge of the mineral wealth of this country is continually being added to by valuable contributions in papers, and the short account of a portion of South-West Africa, read by Dr. P. A. Wagner before the Geological Society, is not without interest. Dr. Wagner shows that, excepting for certain superficial deposits, the area under review consists of ancient crystalline rocks belonging to the Fundamental Complex of South-West Africa. It comprises all manner of schists, metamorphosed sediments, granites of several ages, and various types of composite gneiss. The iron deposits in this neighbourhood are situated about 10 to 16 miles south-east of Walvis Bay. The ore is of very variable character, and is usually made up of iron-rich and iron-poor layers. The average grade of the ore is poor and far below the value for an iron ore. Precious metals have been reported to be present in these ores, and assays have shown up to 1.3 dwts. of silver and 3.5 dwts. of gold per short ton of ore. Other samples, however, have shown no values whatsoever. The precious metal content is thus scattered and patchy, and of little economic value. Other minerals to be found are cordurite, garnet, sunstone, beryl, felspar, and phlogopite, a variety of mica. The last-named mineral has been systematically opened up, and is of excellent property both as regards splitting and electrical properties.

Cheap Pig Iron.

By G. H. Blenkinsop.

In this article the author, a well-known authority, declares that it will be possible for the Union to export pig iron to Europe at much less than the cost of production there.

A few months ago, at the request of the editor of *The South African Mining and Engineering Journal*, I enquired into the prospects of the establishment of an iron and steel industry in the Union of South Africa. My conclusions were that the erection of blast furnaces for the manufacture of pig iron was not a commercial proposition inasmuch as the Union lacked a supply of coking coal in commercial quantity. Since then I have become possessed of data which render it imperative that I should revise my conclusions.

A process known as "froth flotation as applied to the washing of industrial coal," the invention of Minerals Separation, Ltd., has been investigated by Messrs. Ernest Berry, Walter Broadbridge and Alfred Hutchinson at the works of the Skinninggrove Iron Company. The results of their investigations are embodied in a paper read before the Institution of Mining Engineers, Manchester, 15th September, 1920. Suffice it for my purpose to say that in some instances the percentage of ash in the original coal was reduced from 20 per cent. to less than 4 per cent. Colliery dumps and washery waste also showed remarkable results, the percentage of ash in some instances being reduced from 60 per cent. to less than 7 per cent.

The percentage of colliery smalls produced at the South African Collieries is very high; it is a soft coal, the thro' and thro' containing quite 50 per cent. smalls. This colliery small costs sixpence per ton to dump, and it could be put in truck at the screens practically free of cost.

I will, however, in my calculations take the cost at one shilling per ton f.o.r.

In addition to the results achieved by the "froth flotation" process, I have read the results obtained in "The Carbonisation of coal at low temperatures." See paper read before the North of England Institute of Mining and Metallurgical Engineers on August 6th, 1921.

For details of these tests see *The Iron and Coal Trades Review*, 12th August 1921. These trials have proved that a bright hard coke having a crushing strength of over 400 lbs. can be manufactured from a coal containing a moderate percentage of volatile matter such as the South African coals contain. I may mention en passant that these data have only just been in my possession.

Cost of Raw Materials.

In the investigations which I carried out at the request of the Editor of *The South African Mining Journal* I arrived at the following figures as to the cost of the raw materials delivered at a suitable blast furnace site. The Union possesses large resources in high grade acid iron ores and also in high grade basic iron ores containing, say, 0.25 to 0.30 per cent. phosphorous. These latter cannot, of course, be considered basic ores per se, but when dealt with on the lines which I propose they are eminently suitable. In a number of instances these occurrences of high grade iron

ores, both acid and quasi basic are situated on farms containing an abundance of coal.

Iron ore containing 60 per cent. metallic iron and upwards, 1 ton pig iron=5s. 0d. per ton, say 34 cwt.

8s. 6d. per ton pig iron	...	8	6
Dolomite for flux, say, 7 cwt., 2s. 6d. per ton (CaCO ₃)			
MgCO ₃ pure limestone not being available	...	10	½
Labour "boys" wages, 2s. 6d. per day	...	3	½
Coke from Colliery Slack, say, 22 cwt. at 5s. per ton		5	6
Overhead charges	...	2	0

Total (per ton) 17 2

In taking the cost of coke at 5s. per ton I have not taken credit for by-products. I have carefully checked my figures and I am satisfied that the cost of producing a ton of pig iron should not exceed, say, seventeen shillings and sixpence per ton. In addition the Union also contains a large quantity of high grade iron ore having a phosphorous content in excess of the acid steel limit.

At these figures it will be possible for the Union to put pig iron in the United Kingdom and the Continent at much less than the cost of production in those countries.

"W. P."—(1) No. (2) Unknown here.

Electric Welding by the Wilson Plastic Arc System.

The application of electricity to welding processes has not made such rapid strides as one finds in its application in other directions. The term electric welding implies the joining of metals, salvaging defective castings, repairing of cracks or breaks, etc., by means of the electric current. Until recently various difficulties have existed which have retarded the growth and application of the process. These have been successfully overcome in the Wilson Plastic Arc system of electric welding. A trial run of the plant was conducted at Wright and Boag's engineering works on Thursday, the 29th. A very instructive display of the work the plant was capable of doing was given, and even the welding of cast iron, formerly thought to be impossible, was successfully demonstrated. A detailed account of the plant, as well as remarks on the quality of the work done by it, will be given in next week's issue.

Simmer and Jack Prospects.

The future of the Simmer and Jack is, of course, bound up with the maintenance of the gold premium. That, and the possibility of a reduction in working costs, govern the existence of the mine. Mr. D. Christopherson presided at the annual meeting of the company last week and showed that it was only the so-called premium on gold which has enabled the company to show a profit on working of £119,250. During the year under review the average price per fine ounce at which gold was realised was 110s. 9d., with the result that revenue from gold was the greater by £211,766 as compared with what would have been the case if gold had only realised par value. "This fact," Mr. Christopherson said, "makes it evident that a substantial reduction in the cost of working must be effected if this mine is to work at a profit when exchange conditions become such that gold will only realise its normal value, as an improvement in grade can hardly be expected. It is perhaps somewhat encouraging to note that for the first time since 1916 the working costs per ton for the year show a decrease as compared with the previous year, not that this decrease is great, it being only represented by 9d. per ton, but still we hope it indicates the turn of the tide so far as costs are concerned."

ENGINEER, A.M.I.E.E., with 15 Years ELECTRICAL and MECHANICAL experience chiefly on commercial side, recently representing LEADING ENGINEERING CONCERN open for immediate engagement.

The "J.C.I." Year.

GOLD PROFITS AND PREMIUM.

BETTER DIAMOND PROSPECTS.

The "J.C.I." Co., Ltd., has issued an excellent report for the year ended June last.

After providing for depreciation, English and Colonial Income Tax, and other charges, the profit for the year, including £191,453 8s. 4d. brought forward, amounts to £579,411 13s. 8d. On the 23rd June the Directors declared a dividend of 10 per cent., free of Income Tax, payable to Shareholders registered as at 30th June, 1921. This distribution (excluding provision for Income Tax) absorbs £395,000, leaving a balance of £184,411 13s. 8d. to be carried forward to next account. The financial position of the Company continues to be very satisfactory, and as opportunity occurs the Company's interests are being extended and developed.

Mining Interests.

The usual Reports issued by the various gold mines under the Company's control afford all necessary detail as to their position. The following general information, however, is given:—

Government Gold Mining Areas (Modderfontein) Consolidated, Limited.—This property continues to make excellent returns. The tonnage milled for 1920 amounted to 1,515,000 tons, which was an increase of 154,000 tons, and the number of fine ounces of gold recovered was 603,239, an increase of 33,857 fine ounces when compared with the previous year. In view of the Company's large ore reserves, amounting to over ten million tons, the policy of the Company is to maintain the ore reserves at this figure.

Van Ryn Deep, Limited.—The ore reserves are over three million tons of an average value of 9.7 dwts. over 72 inches; both tonnage and grade showing an improvement as compared with the previous year. The development of the Western section of the mine shows improvement.

Randfontein Central Gold Mining Company, Limited.—The scheme for the re-organisation of this mine is now nearing completion, but progress has been retarded by strikes and other obstacles beyond the control of the management. It should be borne in mind that the work which required to be undertaken has been practically equivalent to the opening up of a new deep level proposition at the bottom of the former workings. There is every reason to anticipate that substantial benefits will shortly accrue from the re-organisation of this property.

The taking over of the Randfontein Deep, Ltd., property, referred to in last year's Report, has been completed, and mining operations in this area have been carried on for the last twelve months. It is anticipated that ore from the Randfontein Deep section will be sent to the mill at an early date.

Randfontein Estates Gold Mining Company (Witwatersrand), Limited.—In the Company's previous Report reference was made to an action successfully brought by the Randfontein Estates Company against Sir Joseph B. Robinson, which resulted in the Randfontein Estates Company being awarded £215,000, plus interest at 6 per cent. as from February, 1907. In respect of this judgment a payment of £391,155 11s. 6d. on account has been made to the Randfontein Estates Company. The latter's solicitors have since been served with notification that Sir Joseph B. Robinson has applied for permission to appeal to the Privy Council against this judgment.

New State Areas, Limited.—The work of sinking the two shafts on this property is now completed, the south shaft having been sunk to a final depth of 4,071 feet and the north shaft to a final depth of 3,768 feet. The reef intersected by the south shaft gave the extremely high average value of 89.8 dwts. over 18.9 inches. The reef intersected by the north shaft was found to be faulted and disturbed by numerous quartz intrusions, and therefore no reliable assay

value has yet been possible. Development is rapidly proceeding and there is every reason to anticipate that the New State Areas will prove a most valuable property.

Working Costs.

It has for some time been obvious that existing circumstances no longer justified a continuance of the high scale of wages paid to the miners in South Africa. It is therefore satisfactory to report that an amicable arrangement has been concluded between the Transvaal Chamber of Mines and the Trade Unions concerned resulting in an immediate reduction of wages, with the probability of further reductions in the near future.

Gold Production.

The value of the gold produced by the Company's Group of Mines during the year under review amounted to £9,926,943, the average price obtained being approximately £5 11s. 0d. per fine ounce.

Coal Interests.

As mentioned by the Chairman on the occasion of the Company's last annual meeting, the Company has acquired considerable coal interests in South Africa. The equipment

The Johannesburg Headquarters of the "J.C.I."

of the mines is nearing completion, and they will be capable of producing a large quantity of coal. The Directors are hopeful that the Company will eventually derive material benefit from this new enterprise, more particularly when the necessary railway facilities have been obtained.

Diamond Mines.

Regarding the Company's interests in the leading Diamond Mines of South Africa, it may be mentioned that during the period under review the falling off in the demand for stones has been met by a drastic curtailment of production. This is no new feature in the history of the diamond industry, and it is confidently anticipated by those who control the policy of the diamond mines that an improvement in the position may be expected in the near future, and of such improvement indications are already apparent.

New Modder Year.

**RECORD PROFIT—GOLD PREMIUM MEANS EXTRA
£751,427.**

The New Modder has had a record year in point of output and profit. The tonnage milled, the amount of gold recovered and the working profit earned are the highest yet obtained during the history of the Company, and exceed by 114,500 tons, 27,691 fine ounces and £205,207 the records established in the previous year. Included in the working profit of £1,699,052 is an amount of £751,427, equal to 44·2 per cent., representing the amount realised above standard price for gold sold. Development operations show a further substantial increase in footage accomplished. Very satisfactory values were obtained in the western section of the mine, where active development has been resumed; the eastern section continued to fulfil expectations. The average price realised for gold during the year was 112s. 7d. per fine ounce, as compared with 102s. 3d. per fine ounce for the year ended 30th June, 1920. The ore reserve was re-estimated at 30th June, 1921, and at 8,884,600 tons of 8·4 dwts. shows a small increase in tonnage, with no change in value. The crushing capacity of the Company's reduction plant has been increased to 105,000 tons per month by the addition in May last of eight Nissen stamps to the mill at the circular shaft. The balance of the working expenditure and revenue account for the year shows a net profit of £1,720,202 17s. 4d. This amount, together with the balance of £344,025 13s. 0d., unappropriated at the commencement of the year, and £763 12s. 9d. in respect of forfeited dividends, making a total of £2,064,992 3s. 1d., has been dealt with as follows:—Capital expenditure.—Equipment, less sales of plant, £50,672 13s. 7d.; annuity in respect of undermining rights leased from Government, £17,310—£67,982 13s. 7d.; less amount received under Bewaarplaats Money's Application Act, 1917, £7,789 10s.—£60,193 3s. 7d.; Government and Provincial taxes, £297,950 9s. 5d.; dividends Nos. 29 and 30, £1,400,000—£1,758,143 13s.; balance unappropriated at 30th June, 1921, represented by cash, investments, and cash assets, less liabilities, £306,818 10s. 1d.—£2,064,992 3s. 1d. This balance is made up as follows:—Shares and interests in co-operative and other concerns, £33,024 10s.; stores, materials, etc., £115,980 12s.; sundry debtors and payments in advance, £26,908 7s. 11d.; Rand Mines Power Supply Company, Limited, compressor account, £56,280 4s. 5d.—£232,193 14s. 4d.; net cash and investments, after allowing for liabilities, £74,654 15s. 9d. Two dividends, Nos. 29 and 30, of 57½ per cent. and 42½ per cent. respectively, absorbing £1,400,000, were declared during the year.

In the course of his annual report, the consulting engineer, Mr. H. Stuart Martin, writes:—Comparative figures of the leading features for the last three years are as follows:—Tons milled, 1919 920,500, 1920 968,500, 1921 1,083,000; yield per ton milled, 1919 10·485 dwts., 1920 10·321 dwts., 1921 9·741 dwts.; yield per ton milled at standard price of gold, 1919 43s. 10d., 1920 43s. 2d., 1921 40s. 11d.; working costs per ton milled, 1919 20s. 2d., 1920 21s. 11d., 1921 23s. 5d.; working profit per ton milled at standard price of gold, 1919 23s. 8d., 1920 21s. 3d., 1921 17s. 6d.; working profit at standard price of gold, 1919 £1,089,891, 1920 £1,029,188, 1921 £947,625; revenue derived from price of gold above standard, 1919 nil, 1920 £464,637, 1921 £751,427; total working profit, 1919 £1,089,891, 1920 £1,493,845, 1921 £1,699,052; total working profit per ton milled, 1919 23s. 8d., 1920 30s. 10d., 1921 31s. 5d.; ore reserve, 1919 8,854,300 tons; 1920 8,869,700 tons, 1921 8,884,600 tons; ore reserve value, 1919 8·5 dwts., 1920 8·4 dwts., 1921 8·4 dwts. The yield obtained in fine dwts. per ton is slightly below that of the previous year, and working costs increased 1s. 6d. per ton milled. These were, however, offset by the improved price obtained for gold, the difference showing an improvement in the profit per ton of 7d. The average native complement for the year has been 6,162 natives, and the average number employed 5,390, or 87·4 per cent. On this account it has not been possible to

derive full benefit either from the large and accessible ore reserve or from the full capacity of the reduction plant, which at the close of the year had been increased to a capacity of 1,200,000 tons per annum. Development operations were extended, the total linear footage being 2,716 feet more than in the preceding year. An important feature has been the disclosure of high grade ore over a large stoping width in the area west of No. 2 Shaft between the 12th and 13th levels. The tonnage developed here amounted to 302,800 tons of 9·7 dwts. value over 82 inches stoping width. Nothing of this character has hitherto been found in this section of the mine. Results on the eastern side of the mine have continued to fulfil expectations. The payable reef disclosures for the year average 669 inch-dwts. on the footwall leader only; allowing for the additional reef disclosed by prospecting in the hanging wall, the figure becomes 803 inch-dwts. The total payable ore developed for the year amounted to 1,234,100 tons of a value of 10·5 dwts. per ton. The ore reserve, re-measured and re-valued at June 30th, 1921, was 8,478,700 tons valued at 8·5 dwts. over 68 inches stope width, this being exclusive of 405,900 tons of 6·8 dwts. value consisting of boundary and shaft pillars temporarily unavailable. There is very little alteration in the above figures when compared with the preceding year. The value of the ore stoped was again somewhat over the average value of the reserve and approximated more closely to the value of the year's development. Capital expenditure for the year was on account of the additions to reduction plant, additional housing, and measures for safeguarding the water supply for the reduction plants. The commitments for the current year are very small and are to complete the last two items. During the current year, sand-filling operations will be taken in hand with the object of recovering valuable pillars (not included in the ore reserve) from the upper levels of the north-eastern section of the mine, and of controlling the movement of the hanging wall. The re-equipment of No. 2 Incline with heavier rails, skips and winding equipment, will enable development and stoping to be carried on in the western section of the mine with greater effect. The general position of the mine is all that can be desired, and given sufficient labour, the output for the year can be increased a further 200,000 tons as compared with the past year. The manager, Mr. E. Miles Sharp, and, during his absence on leave, Mr. M. O. Tillard, together with the staff, have accomplished a first-class year's work.

Southern Rhodesia Geological Survey.

Recent issues by the Southern Rhodesia Geological Survey have come to hand. The reports are as follows: "The Geology of the Diamond-bearing Gravels of the Somabula Forest," by A. M. Macgregor, B.A. The work embraces much valuable information on the various aspects of the mineral deposits found in the area under consideration. The history of the discovery as well as the previous geological work done on it is mentioned. A noteworthy discovery made during the examination of the area is the presence of fossil plants which has led to the determination of the age of the beds. The result is to put the prospecting for similar diamond-bearing beds of like age in a totally new light. Of the economic minerals present, the most important is the diamond. A discovery of platinum caused some interest, but attempts to verify the reports were very discouraging, and showed only very small amounts of that metal. "Short Report No. 11" makes public a summary of the field work carried out during the last field season in the Bembesi basin. "The Provisional Table of Geological Formations in Southern Rhodesia," compiled by H. B. Maufe, gives a list of all the formations to be found in Southern Rhodesia. Their equivalents in the Union are mentioned as well as the igneous intrusions and earth movements which have at times affected them. A list of the economic minerals found in each formation is also given and should prove to be of great value to the prospector.

Consolidated Main Reef.

INCREASED WORKING COSTS OFFSET GOLD PREMIUM.

The outstanding fact at the Consolidated Main Reef last year was that the increased working costs more than offset the gold premium. With practically the same tonnage milled as for the previous year there is a slight reduction in the yield per ton. Owing to the increased price obtained for gold there is an improvement in the revenue of 2s. 1d. per ton, but, on the other hand, working costs rose by 3s. 1d. per ton, the net result showing a decreased profit of 1s. per ton.

The average price realised for gold during the year was 112s. 4d. per fine ounce, as compared with 102s. 2d. per fine ounce for the year ended 30th June, 1920.

The value and tonnage of the ore reserve remains practically the same as last year.

To the working profit for the year of £199,124 17s. 6d., which includes credit adjustments on gold realised up to 31st March, 1921, has been added £5,820 7s. 10d., representing the difference between sundry items of expenditure and revenue detailed in the working expenditure and revenue account, making a total profit of £204,945 5s. 4d., which has been carried to appropriation account. This amount, together with £193,562 19s. 5d. unappropriated at the commencement of the year, and forfeited dividends £192 16s. 5d., making a total of £398,701 1s. 2d., has been dealt with as follows:—Capital expenditure (net), £24,513 5s. 8d.; Government and Provincial taxes, £29,775 13s.; dividends Nos. 25 and 26, £155,950 5s.—£210,239 3s. 8d. Balance unappropriated at 30th June, 1921, represented by cash, investments and cash assets, less liabilities, including Mine Development Suspense Account £11,328 6s. 6d., £188,461 17s. 6d.—£398,701 1s. 2d. This balance is made up as follows: Shares and interests in co-operative concerns, £19,231 16s. 10d.; stores and materials, etc., £66,292 3s. 7d.; sundry debtors and payments in advance, £19,134 8s. 3d.—£104,658 8s. 8d. Net cash and investments, after allowing for liabilities, including Mine Development Suspense Account £11,328 6s. 6d., £83,803 8s. 10d.

Mr. A. J. Brett, the Consulting Engineer, writes:—Tonnage milled, 1919 570,710, 1920 557,500, 1921 561,800; working costs per ton, 1919 26s. 3d., 1920 29s. 2d., 1921 32s. 3d.; revenue per ton at standard price of gold, 1919 29s. 6d., 1920 30s. 6d., 1921 29s. 3d.; profit per ton at standard price of gold, 1919 3s. 3d., 1920 1s. 4d., 1921 loss 3s.; working profit at the standard price of gold, 1919 £93,715, 1920 £38,256, 1921 loss £83,599; additional revenue due to gold being above standard price, 1919 nil, 1920 £188,779, 1921 £282,724; total working profit, 1919 £93,715, 1920 £227,035, 1921 £199,125; total working profit per ton milled, 1919 3s. 3d., 1920 8s. 1d., 1921 7s. 1d.; development footage, 1919 15,798, 1920 22,962, 1921 22,815; ore reserve tonnage, 1919 1,200,900, 1920 1,186,000, 1921 1,176,500; average value of ore reserve—dwts. per ton, 1919 7.6, 1920 7.6, 1921 7.5; average strength of coloured labour force, 1919 4,301, 1920 4,412, 1921 4,573. The result of the year's work, measured in terms of the profit earned, must be considered satisfactory, albeit not quite so favourable as that of the preceding year. One of the most noticeable and, at the same time, disquieting features to which attention must be drawn, is the further heavy increase in the cost of operating the mine. During the preceding financial year—at a time when costs were considered abnormally high—the total working expenditure was £812,362. In order to treat practically the same tonnage and carry out the same amount of development work during the year under review, however, no less than £905,952 had to be expended, an increase of £93,590, representing 3s. 1d. on every ton milled, of which stores and materials were responsible for 1s. 5d., white wages

10d., coloured wages 7d., and other costs 3d. The reason for the further large increase in the cost of white labour was that the all-round increase in wages granted in November, 1919, only affected a portion of the year ended 30th June, 1920, while, of course, it was in force during the whole of the year under notice. The yield per ton declined slightly owing to the fact that much more stoping was carried out in the latter part of the year in areas where the reef is very narrow and the gold distribution very irregular; under these conditions the difficulty of valuation of ore reserve tonnage is increased and considerable fluctuations in grade may be expected. The small decrease in the yield, however, was more than counterbalanced by the higher average price obtained for gold throughout the year, the result being that the revenue per ton was 2s. 1d. above that of the preceding year. The net effect of these factors was to reduce the profit per ton by 1s. and the total working profit by £27,910. Development operations were continued vigorously, and sufficient ore was added to the reserve to replace that mined. Work under this heading was confined in the main to an area in the centre of the property, bounded roughly by No. 4 incline shaft on the west and No. 3 incline shaft on the east. This area has been the most promising for some time past, hence it will be understood that the results achieved during the year were due to a considerable extent to selective development, and are probably by no means representative of what development throughout the whole of the property would show. Prospects of encountering considerable bodies of ore which would be payable with present working costs, to the west of No. 4 incline shaft, do not appear promising.

Consolidated Main Reef Headgear.

but some encouraging values have been disclosed in the area east of No. 3 incline shaft, referred to last year; it is intended to explore each of these districts by extending drives at various intervals in depth, as it is important that every effort be made to find some extension of the present central zone of payability. Should no further areas be found which will yield a reasonable proportion of payable

ore, and the tonnage that can be obtained from reclamation in worked out areas decrease, as it must necessarily do within a year or so, the position will become difficult. With the present percentage of payability and the limited number of faces available for development in the areas selected, it will not be possible to maintain the tonnage in the ore reserves, and a reduction in the scale of operations will have to follow, unless the proposed skeleton development mentioned above reveals other areas of promise, or a considerable reduction in working costs renders payable tonnages at present classed as unpayable. The question of the most suitable method of exploiting the deep level ground in your property received further consideration during the year. While it was recognised that the best means of attacking this ground would be afforded by sinking a new deep vertical shaft from the surface, it was felt that the values and percentage of payability found in the lower levels of the mine did not justify the heavy expenditure which would have to be incurred were such a policy adopted. It was accordingly considered advisable to equip No. 3 incline shaft in such a manner that it could be used as a main artery to its utmost limit in depth, while the other two inclines, Nos. 2 and 4, would be continued as long as necessary. The ore standing in reserve in the mine at the end of the financial year was estimated to be as follows:—Main Reef leader, 1,171,800 tons, average value 7.5 dwts. per ton, average width 49 inches; South Reef, 4,700 tons, average value 8.7 dwts. per ton, average width 48 inches; total, 1,176,500 tons, average value 7.5 dwts. per ton, average width 49 inches. The present rate of yield should be maintained during the ensuing year, but, given a satisfactory supply of native labour and freedom from industrial troubles, the profit to be earned will be determined mainly by the selling price of your product.

Nourse Mines.

BIGGER TONNAGE CRUSHED.

At the Nourse Mines in the twelve months ended June 30 last there was an improvement in the tonnage milled compared with the previous year. The yield obtained in fine dwts. per ton was slightly below that of the previous year, but owing to the improved price obtained for gold there is an increase in the recovery value of 2s. 5d. per ton milled. On the other hand working costs increased by 1s. 5d. per ton, the net result showing an increase of 1s. per ton in profit, which totalled 4s. 8d. per ton. At the standard price of gold and on the basis of working costs obtaining during the past year there would have been a loss of 4s. 4d. per ton. Development operations resulted in a little over half a million tons being added to the ore reserve, the re-estimation of which shows little change compared with the previous year, the tonnage being slightly more, but the average value .1 dwt. per ton less. A further 539 feet were sunk in the south-eastern shaft, making its total depth 3,296 feet. The working profit for the year, which includes credit adjustments on gold realised up to 31st March, 1921, amounted to £118,347 6s. 8d., from which has to be deducted £546 13s. 11d., being the difference between sundry items of revenue and expenditure enumerated in the working expenditure and revenue account, making a total profit of £117,800 12s. 9d., which has been carried to appropriation account. This amount, together with the balance of £134,037 1s. unappropriated at the commencement of the year, and £163 2s. 2d. in respect of forfeited dividends, making a total of £252,000 15s. 11d., has been dealt with as follows:—Capital expenditure (net), £62,306 4s. 9d.; Government and Provincial taxes, £11,341 6s. 1d.; dividends Nos. 31 and 32, £62,086 11s. 6d.—£135,734 2s. 4d. Balance unappropriated at 30th June, 1921, represented by cash, investment and cash assets, less liabilities, £116,266 13s. 7d.—£252,000 15s. 11d. This balance is made up as follows: Shares and interests in co-operative

concerns, £14,730 7s. 6d.; stores and materials, etc., £36,432 18s. 6d.; sundry debtors and payments in advance, £17,125 8s. 10d.—£68,288 14s. 10d.; net cash investments after allowing for liabilities, £47,977 18s. 9d.—£116,266 13s. 7d. Two dividends Nos. 31 and 32 of 5 per cent. and 2½ per cent. respectively, absorbing £62,086 11s. 6d. were declared by the directors during the year, free of income tax.

In his annual report Mr. H. Stuart Martin, the Consulting Engineer, writes:—The tonnage milled improved 31,400 tons, whilst the yield at 6.310 dwts. was .146 dwts. lower than in the preceding year. Based on the standard price of gold, the yield was worth approximately 26s. 6d., against average working costs of 30s. 10d. per ton milled. The amount realised above standard on the sale of 160,499 fine ounces of gold was equivalent to 9s. per ton milled, thus converting a loss of £110,568 into a profit of £118,347. In other words, the sum realised for gold above standard price was £228,915. Development operations were well maintained throughout the year, resulting in the addition of 502,340 tons of 6.9 dwts. value to the ore reserve, which at June 30th, 1921, was re-estimated as follows:—Main Reef, 62,690 tons, value 5.6 dwts.; Main Reef Leader, 853,590 tons, value 7.2 dwts.; South Reef, 672,750 tons, value 6.7 dwts.; total and average, 1,589,030 tons, value 6.9 dwts., the estimate being based on stoping widths averaging 54, 49 and 53 inches respectively. Compared with the previous year, the position shows little change. A total of 47,520 tons valued at 6.7 dwts. previously included in the ore reserve, situate in isolated small blocks in the old Henry Nourse area, has this year been excluded from the reserve, owing to their doubtful value under present circumstances. The general condition of the mine is satisfactory, and there are no new features of special interest. The south-eastern shaft of the South Nourse was sunk a further 539 feet to a total depth of 3,296 feet, and the major portion of the capital expenditure incurred was on account of the sinking and equipment of this shaft. During the current year development from this horizon should make fair progress. In view of the probability that the price of gold will gradually revert to standard, it is scarcely necessary to emphasise that the future of the mine is dependent on a reduction in working expenditure. The manager and staff have operated the mine with keenness and attention to the difficult conditions which prevail.

Review.

“Concentration by Flotation.” By T. A. Richard. 692 pages. Price 42s. net. London: Messrs. Chapman & Hall.

The field held by the flotation process has been widened to such an extent within the last few years that it has been an exceedingly difficult task for the person interested in it to keep in touch with its latest developments. The long-felt need for a work which is up to date in this exceedingly interesting process has been supplied in this book. It is a compilation of articles which have appeared during the years 1915 to 1920 by various authorities on the subject. The process is studied from all possible points of view, and a chapter devoted to the flotation of gold and silver mineral should be of special interest in connection with the Rand mining industry. Differential flotation is also treated by itself, and a study of the methods should throw light on the problems met with in the lead and zinc ores of Rhodesia.

The glossary of flotation is a very useful addition to the work, as it explains the more uncommon terms used in the work, without which reading would be difficult to those not acquainted with them.

Modder East.

A YEAR'S RESULTS—INCREASED ORE RESERVES.

The year's results at the Modder East have been considerably benefited by the gold premium. Calculated on the basis of pay limit adopted in the preceding year, the ore reserve shows an increase of 191,900 tons, but a decrease of 5 dwt. in value. Based on the existing restricted scale of milling operations and prevailing working costs, the ore reserve is estimated at 1,611,700 tons of 7.7 dwts. over a stopping width averaging 57 inches. Whilst development operations during the year have not disclosed further high grade blocks such as that adjoining No. 1 Incline Shaft, they have proved the existence of extensive areas of medium grade ore at Nos. 2 and 3 shafts. Milling operations continued throughout the year at the Apex plant. 297,800 tons were crushed, yielding 118,938 fine ounces of gold and a working profit of £209,790, equal to 14s. 1d. per ton milled. Working costs averaged 30s. 5d. per ton milled. The average

profit of £174,338 17s. 10d. After deducting the loss on working for the period 23rd April to 30th June, 1920, viz.: £696 1s. 8d., the balance of £173,642 16s. 2d. has been dealt with as follows:—Profits appropriated during the year for capital expenditure, £16,286 11s. 7d.; premium on debentures, £20,538; Government and Provincial taxes, £3,826; consideration payable to Government in respect of mining lease, £6,069—£46,719 11s. 7d.; balance unappropriated at 30th June, 1921, represented by cash investments and cash assets, less liabilities, £126,923 1s. 7d.—total, £173,642 16s. 2d. The unappropriated balance is made up as follows:—Shares and interests in co-operative and other concerns, £1,057 4s. 6d.; stores, materials, etc., £21,726 1s.; sundry debtors and payments in advance, £11,357 3s. 11d.—£37,140 9s. 5d.; net cash after allowing for liabilities, £89,782 15s. 2d. The loan of £400,000, appearing in the balance sheet,

View at the Modder East.

price realised for gold during the year was 11s. 5d. per fine ounce. It is explained in the consulting engineer's report that the conditions under which milling operations were carried out during the year necessitated a certain amount of overmining of the ore reserve in order to obtain the results achieved. Working capital available at the beginning of the year, viz.: £46,156 6s. 8d., was increased during the year to £363,293 0s. 5d. by the issue of the following shares:—186,692 shares issued in respect of 3 year options exercised at 21s. 3d., £198,360 5s.; less amount received prior to 30th June, 1920, in respect of 3 year options exercised for which shares had not been issued at that date, £65,193 18s. 9d.—£133,166 6s. 3d.; 235 shares issued in respect of 4 year options exercised at 22s. 6d., £264 7s. 6d.; 61,582 reserve shares issued at par, £61,582; 122,121 new shares issued at par, £122,124—£317,136 13s. 9d. As the net capital expenditure during the year, viz.: £379,579 12s., exceeded the working capital available, the balance of £16,286 11s. 7d. has been met out of profits. The working expenditure and revenue account for the year shows a net

will be utilised towards the redemption on the 31st July, 1921, of 6½ per cent. Debentures outstanding on that date: the 5 per centum premium due on redemption, amounting to £20,538, has been charged on the appropriation account now submitted.

The report of the consulting engineer, Mr. H. Stuart Martin, states:—Milling operations proceeded without interruption throughout the year, the average tonnage crushed being 24,816 tons per mensem. Transport arrangements between the main ore bin on the mine and the Apex reduction plant worked smoothly in the hands of the South African Railways and the Kleinfontein Company, at a cost to the Modderfontein East Company of 1s. 9½d. per ton hauled. The value of the ore mined from stopes has exceeded the average value of the ore reserve, this being more marked in the first half of the year and gradually being reduced as the mine opened up and working facilities improved. Taking into consideration the large percentage of output of low grade ore from development faces and from surface dumps, the high working costs due to the limited

scale of operations, the cost of transport and rental of the reduction plant, it will be clear that a certain amount of over-mining is essential in order to obtain sufficient working profit to meet the cost of an extensive development programme. Hoisting facilities at No. 2 and No. 3 Shafts have so far only permitted a limited amount of stoping in the areas which they serve; additions now in hand will remedy this defect. Effective arrangements have been installed to enable waste rock and the lowest grade product from development faces to be handled separately and conveyed direct to the waste dumps on the surface. Development operations were gradually increased from a total of 981 feet in July, 1920, to 2,363 feet in June, 1921. Whilst no new important high grade blocks of ore have been developed, the existence of extensive areas of medium grade ore at No. 2 and No. 3 Shafts has been established. The continuation of development in depth at No. 1 Shaft has been somewhat delayed; the indications, however, are that the limit of the relatively high grade area in the neighbourhood of No. 1 Incline has not yet been reached. The following statement sets out the payable reef disclosures by linear development from the inception of the Company to June 30th, 1921:—

No. 1 Shaft—Footage advanced, 46,444; footage on reef, 29,239; payable footage, 13,932 feet, 47·6 per cent.; reef disclosures, width 23 ins., value 21·2 dwts., 487 inch dwts.

No. 2 Shaft—Footage advanced, 11,031; footage on reef, 9,085; payable footage, 5,370 feet, 59·1 per cent.; reef disclosures, width 25 ins., value 15·6 dwts., 389 inch dwts.

No. 3 Shaft—Footage advanced, 11,194; footage on reef, 8,185; payable footage, 5,445 feet, 66·5 per cent.; reef disclosures, width 28 ins., value 12·7 dwts., 355 inch dwts.

Total and averages—Footage advanced, 68,669; footage on reef, 46,509; payable footage, 24,747 feet, 53·2 per cent.; reef disclosures, width 25 ins., value 17·5 dwts., 437 inch dwts. The above figures are exclusive of vertical shaft sinking and the work done by the Modderfontein B Company. The ore reserve position at June 30th, 1921, calculated on a similar basis of pay limit as in the preceding year, amounted to 1,950,300 tons of an average value of 7·2 dwts. over 57 inches of stoping width, this being in comparison an increase of 194,900 tons and a decrease of 5 dwt. in value. The above figure includes 338,600 tons of 4·8 dwts. value which under circumstances already explained cannot be regarded as profitable at present. The blocks constituting this lower grade tonnage are as a rule favourably situated and will be distinct assets when the Company is producing on a larger scale. The ore reserve position estimated on the basis of the present limited scale of operations is, therefore, as follows:—No. 1 Shaft, 763,100 tons, value 9·2 dwts., stoping width 57 ins.; No. 2 Shaft, 373,900 tons, value 6·3 dwts., stoping width 55 ins.; No. 3 Shaft, 474,700 tons, value 6·2 dwts., stoping width 58 ins.; total and averages, 1,611,700 tons, value 7·7 dwts., stoping width 57 ins. The capital commitments for the current financial year, apart from development, are mainly in connection with additional housing and compound accommodation. I am desirous of emphasising the fact that the mine is still in a transition stage, being a concern which is carrying on an extensive development

programme in conjunction with a limited and expensive milling policy. This being the case, the mining policy has been adapted to circumstances, and it can only be gradually placed on a more normal basis when conditions permit, these conditions being an increased ore reserve and a larger reduction plant, situated on the Company's own mining ground. The development of the mine and its management have been handled well by Mr. W. C. Coe, who has been acting-manager from the inception of the Company to the end of 1920, and by Mr. E. Pam, who succeeded him, and the staff of the mine.

Only Forty Years of Natal Coal.

GOVERNMENT INSPECTOR DESCRIBES NATAL COAL RESOURCES AS "VERY LIMITED"—OTHER MINERAL PROSPECTS.

"The impression, so largely held in Natal and elsewhere, that the supplies of good coal in Natal are inexhaustible, is, on present information, anything but correct.

"The known supply of high-grade coal, such as the majority of that now exported, is very limited, and even at our present rate of production it will probably be exhausted in our children's lifetime. If production increases, as it must do, the exhaustion of the best Natal coal will be complete in a few years, say, forty to fifty years.

"In 1920 Natal produced 3,321,594 tons of coal, while in 1913 Great Britain produced 287,000,000 tons, so that our present known reserves of good coal would be exhausted in less than a year if we produced on the scale that Great Britain does."—Inspector of Mines, Natal.

"Towards the end of the year there was a tremendous boom in coal properties in Natal, and if only half the properties taken up develop into collieries the coal industry will be largely increased.

"I can only reiterate my remarks of last year that it is of the greatest importance for the welfare of the Natal Province that the coalfields should be thoroughly examined

it—and a plausible story, known to many victims on the Rand as the "Commissioner Street Prospector," comes in for a little attention.

The Inspector says:—

"The present method of encouraging prospectors by swallowing the most incredible yarns will never lead to anything, as those persons who are taken in once are afraid to put money into what sounds an ordinary mining venture."

"When such stories as that of a spring of mercury in the Berg are swallowed with avidity, the honest prospector can expect little encouragement."

Mr. Vaughan says: "Considerable interest in Metalliferous mining propositions has been shown during the year, and many claims have been pegged. Interest has chiefly centred in oil shale and asbestos. The country still requires prospecting, and valuable propositions will not be discovered by the present haphazard method of prospecting, which is chiefly done by amateurs in their spare time."

"It cannot be said that any discovery of marked value was made during the year."

In his general remarks the Inspector says:—

"Now that the Rand is on the down grade it would seem high time that attention was devoted to the mineral possibilities of Natal and Zululand.

Where to Search.

"Between Durban and Maritzburg the Umgeni River has carved out a valley for itself through the older rocks

Coal at Dumbe and Makatees Kop, Northern Natal.

and mapped by the Geological Survey, and then systematically proved by boring, so that we have full knowledge concerning our coal supplies."

The report contains much that is of interest in regard to other mineral possibilities of the Province. The absence of systematic prospecting—such as is carried on in the Transvaal and Rhodesia—is commented on. The Inspector says:—

"Considerable interest in metalliferous mining propositions has been shown during the year, and many claims have been pegged. Interest has chiefly centred in oil shale and asbestos."

The Wrong Encouragement.

The gentleman with a piece of road metal in his pocket, an unkempt beard, "hat and shirt to match"—as the lady "frocks and frills" reporters of weddings would have

of the country, and it is in a district such as this that important mineral discoveries should be made. Yet, so far as I can ascertain, not a single prospector has tried his luck in this area, the Inanda and Indwedwe Locations.

"Large areas of the country, close to the railway, are neglected and have probably never been inspected or prospected by either a competent geologist or prospector. Prospectors, when they make discoveries, usually seem to do so in the most out-of-the-way spots, but the Inanda Location is bounded for a long distance by the main line from Durban-Johannesburg and is within one hour's run of Durban by car. Gold, tungsten, graphite and iron have been found on the borders of the location, but no discovery has been made in the location itself, simply, I believe, because no one has tried to find minerals there.

Another big location close to Durban which is worth the attention of the prospector is the Umlazi Location. Copper

has been found there, and there is no reason why other minerals should not be.

"The locations, as a rule, consist of mountainous and broken country, and are ideal places for prospecting; but prospectors apparently prefer fossicking in the wilds to examining country which is comparatively close to large towns."

The following are extracted from the Inspector's notes on the various minerals:—

Iron.—Iron propositions were in demand, but little prospecting was done on those which were taken up, and it would appear as though they were held in the hope of off-loading them at a good profit to overseas' speculators.

Mr. J. K. Eaton continued the erection of his blast furnace and accessory plant at Newcastle, and pig-iron should be produced in the coming year.

Asbestos.—The Natal Asbestos Company and the Buffalo Asbestos Company continued prospecting on the farm Tugela Randt, near Krantzkop. Numerous promising veins of asbestos were opened up, and there is little doubt that an almost unlimited supply of this mineral occurs in the neighbourhood.

is held under claims. The syndicates occupied themselves in extracting from 50 to 100 tons of oil shale to be sent to Great Britain for test purposes.

Nickel and Copper.—The Mount Ayliff Syndicate started prospecting operations by driving along the contact between the norite and the shales. Mr W. H. Goodchild, the consulting engineer, holds the theory that where the norite touches the shale there will be a chilled facies, and that the richest zone for the platinum, nickel, and copper deposits will be found a few feet above. Up to the end of the year 118 feet had been driven in cross-cuts, 186 feet in drives, and 148 feet sunk in winzes. At the lowest depths promising ore was encountered, and the rocks exposed afford good evidence of the feasibility of Mr. Goodchild's theories. As the workings get deeper there is an increase in the copper and nickel values, and it is hoped that this concern will eventually turn out to be a sound low-grade nickel and copper proposition.

Tungsten.—A discovery of wolframite was made near Sitoku's Kraal, in the Melmoth District, Zululand. The first sample gave 15 per cent. of tungsten, and other samples averaged 3 to 4 per cent.; further prospecting giving only

The Hlobane Colliery in the Vryheid District.

Galena.—Very promising samples of galena containing high values in silver were submitted by Zululand prospectors, but, strange to say, no attempt to work the deposit was made. This is remarkable considering the high prices touched by silver.

Gypsum.—The Natal Gypsum Company continued operations on a small scale and produced 1,007 tons of gypsum, as compared with 1,000 tons in 1919. The company closed down at the end of the year. Owing to the increasing overburden, the cost of obtaining the gypsum increased, and as the Pretoria Cement Company were able to obtain gypsum at 13s. a ton less than the Natal Gypsum Company could supply it for the cement company refused to renew its contract.

Mercury.—Wild tales were spread of a discovery of a spring of mercury in the Drakensberg in the neighbourhood of Bergville, and a large number of claims were pegged on the strength of the rumours. No cinnabar was found, and, needless to say nothing came of the reported discovery.

Oil Shale.—Much attention was devoted to the oil shale in the Drakensberg, in the Loteni and Unkomaas Valleys. Numerous syndicates started, and practically all the ground blast furnace of the Newcastle Iron and Steel Works.

disappointing results, the venture was closed down and the claims abandoned.

Glass.—The Union Glass Works completed the erection of their furnace and works at Dundee. The buildings and plant are of the most up-to-date type, and everything has been done to secure the erection of a first-class bottle-making factory. The capacity of the furnace is 120 tons, and at present the output is almost entirely confined to the manufacture of beer bottles of the capsule and screw-neck type.

The output at the end of the year was 30,000 bottles per week, and it is hoped to put this up to 80,000 per week.

As was only natural, a few difficulties were experienced when the plant started, but these were soon overcome, and at the end of the year the plant was running efficiently.

Practically nothing but coloured labour is employed in the making of the bottles.

Fire-clay.—302 tons of fire-clay were mined at the Parkside Colliery, near Newcastle, and made into fire-bricks. The bricks were said to be of excellent quality and have been used for lining the interior of the top portion of the blast furnace of the Newcastle Iron and Steel Works.

EDITORIAL.

PROFIT-SHARING ON RAND MINES.

The Rand was started at the beginning of September by the announcement of the offer of a profit-sharing scheme by the directors of the Rodepoort United Main Reef to their 164 white employees. Details of the scheme and the history of the negotiations to date are given in another part of this issue, and we purpose here merely to deal with some general considerations affecting the proposal. Credit must at the outset be given to the originators of the scheme for what we believe to be a sincere and well-meaning attempt to save a body of mine employees from unemployment. Probably it would prove far more advantageous to the company in every way were the mine to be closed down without further ado, and time, money, and trouble would doubtless be saved to the controlling house were that course adopted.

However advantageous co-partnership may be in practice, the moment, moreover, would seem inopportune to apply it on the Rand. Conditions, chiefly in regard to wages and the colour restrictions, are far from what may be called normal or settled, and the introduction of a new and far-reaching principle such as co-partnership would only serve to postpone or render more difficult a settlement of these vexed questions. It is true that there is a great deal to be said for the application of co-partnership to mining, and as far back as 1906 we advocated in these columns its trial on these fields. In December, 1906, we cited the case of the Levant Mine in Cornwall, where the simplest and crudest form of profit-sharing had just been introduced, and we advocated its adoption on more approved lines—as an experiment—on the Rand. We quoted the successful example of the South Metropolitan Gas Company, and reproduced a thoughtful letter on the subject from the author of that scheme, Sir George Livesey, to Mr. J. Q. Braidwood, the well known Rand mining engineer. It must be admitted that a fair hearing was given at that time by the leaders of the industry to the merits of the proposal, but for reasons inherent in gold mining, it was "turned down." The possibilities of co-partnership are, of course, enormous, though the history of its application to industries in other countries shows a very high percentage of failures. Fortunately, we have available a large volume of data drawn from actual experience of the causes and circumstances which make some profit-sharing plans fail and others succeed. From a multitude of opinions expressed, covering alike well-tried and recently-adopted profit-sharing schemes, in the main satisfactory results are indicated. Both the general objects, such as co-operation and loyalty, and specific objects, such as reduction of labour turnover, economies of material, greater productive efficiency, avoidance of industrial disputes, and the promotion of thrift, are being achieved to a greater or less extent with profit-sharing plans. Indeed, these plans seem to be uniformly successful in producing general co-operation, and loyalty and stabilisation of the working force. One interesting result, which would doubtless be very marked on the Rand, is the elimination of the inefficient, due to the refusal of the better men to work with men of low intelligence and ideals. Another important point observable is that there has been a consistent opposition to profit-sharing by organised labour and by trade unionists generally. From a detailed analysis of past and present profit-sharing plans, the following authoritative conclusions are drawn:—(1) Judged purely on the basis of their longevity, profit-sharing plans are a doubtful expedient, since but few of the many plans put in operation have survived a long period of trial. (2) A critical examination of individual experiences, however, indicates an encouraging degree of temporary success. In conclusion, we may quote the following pertinent passage from an important American research report on the subject: "Profit-sharing is no panacea. It cannot be offered as a solution of the wage problem. But properly understood and utilised, it possesses valuable features. Of greater importance, however, than any mechanism for securing co-operation and loyalty, and necessary to the real success of any plan, is the influence and personal touch of a wise management." We cannot say that a survey of the experiences of profit-sharing, as applied elsewhere throughout the industrial world, encourages us to believe in its beneficial adoption, in the present circumstances, by the mines of the Rand.

MR. H. O. BUCKLE'S QUARTERLY REVIEW.

Mr. H. O. Buckle's speech at the quarterly meeting of the Chamber of Mines on Monday was remarkable more for what was left unsaid than for what was said. Thus, there was no reference to the question of the gold premium, or ex-enemy shares, or the mine co-partnership proposals, or the new co-operative gold refinery. As all these questions are still under discussion, and as Mr. Buckle is much too direct a speaker to be able to talk round a subject without telling us something about it, he no doubt was justified in maintaining an attitude of silence on those vital industrial

questions. Instead, he confined his remarks to labour matters, white and black, and his speech resolved itself into a review of what had happened under these heads during the quarter. As our readers are familiar with the history of the two recent strikes on the Far East Rand, we need not follow Mr. Buckle's summary of these events. He regards the settlement of the white wage question as "a matter for congratulation, as it disposes for a while at least of the necessity of frequent discussion of a very thorny subject." He also welcomes the action of the Mine Workers' Union in regard to the February strike which began at the Consolidated Langlaagte, as showing "a degree of courage and a sense of responsibility which they should welcome as a good augury for the future." He emphasised the fact that "the effect of the break in service caused by the dismissal of the strikers had been entirely wiped out, at a cost to the mines of something like £100,000, which must be admitted to be a very substantial recognition of the union's treatment of the principal offenders." As regards the recent relaxation in mining regulations in regard to natives working underground, he said that though "they did not go so far as the Chamber would wish, or indeed so far as they ought to go, in relieving the industry of the many and onerous burdens under which it laboured, tardy and meagre as the small relief had been, it was none the less welcome, if only as an indication that some notice had been taken of one at least of the recommendations of the Commission." He anticipated an improvement in the native labour supply to the mines in the near future, particularly from the East Coast; and here again Mr. Buckle avoided any reference to the contentious question of the agreement with the Mozambique Government. For the same reason that the monthly public gatherings of the Chamber were abandoned in favour of quarterly ones—viz., the inadvisability of making public pronouncements on matters under discussion—it would seem that the quarterly meetings of the Chamber might without much loss be given up in favour of half-yearly ones.

Notes & News.

The Late Major Clem Webb.

We are indebted to many readers for expressions of appreciation of our Special Memorial Number to the late Major Clem Webb, M.C. The issue was sold out at the Central News Agency early in the week. A printer's error crept into the account of the parentage of the late Major Webb. It should be made clear that his grandfather, John William Webb, married Mary Stuart, and that their son, F. C. Webb, married Miss Davies, who was the mother of the late Major Webb.

General Byron's Tribute to the late Major Webb.

In the course of a letter written to Mr. Mackie Niven on receipt of the news of the death of the late Major Webb, General J. J. Byron writes: "By one of the curious coincidences of life we were discussing Clem Webb at the homestead (not being aware that he was seriously ill then) the evening before his passing over. We recalled his great personal gallantry in action, his unabated cheerfulness under the most exhausting and depressing circumstances, and his wonderful power of inspiring optimism in others. We always reckoned he was well worth his place in any unit for the above qualities alone—and he had many other good ones."

Metallurgical Developments at Springs Mines.

In last week's issue of the *Journal* the official statement of the adoption of the new metallurgical process at the Springs Mines was reproduced. In this connection readers are reminded that a metallurgical development of that nature, and embracing most of the points mentioned had been fully treated in the July 30, 1921, issue of the *Journal*. In an article entitled "The Elimination of the Stamp Mill from Rand Metallurgy," the various aspects of the question were fully dealt with. The scope of the article extended

only as far as crushing to the tube mill circuit was concerned, and elimination of amalgamation after tube milling, and all-sliming were not discussed in that connection. As far as primary crushing goes the conclusions arrived at in the article are identical with those mentioned in the official statement, although the two crushing processes differed in detail only. In the previous article breaking by means of Blake crushers and rolls was described, while the Springs plant will employ single stage breaking in gyratory crushers. The fundamental principle underlying both processes is the same. Figures on operating expenses reproduced in the article clearly show that expenses in that direction will be cut down. Whereas an estimate for crushing by this means only amounted to 14 pence per ton, figures for stamp mill crushing amounted to 26 pence per ton. Mention is also made of the saving in capital cost, but as this appeared to be self-evident the question was not laboured.

Stabilising Gold.

Dealing with the question of the desirability of stabilising the price of gold, the *Westminster Gazette* says that it is easier to state objections than to formulate a scheme whereby this could be effected. But with the goodwill on the part of the South African and Home Governments and the Transvaal gold producers, it is obvious that the difficulties should prove surmountable. If the mechanical difficulties can be overcome, the still more formidable problem will arise in regard to fixing a price at which gold ought to stand. It is already suggested that 110s. per ounce as a minimum and 120s. as a maximum price might be regarded as reasonable, and somewhere between these two figures the basis for a compromise might be reached. It is proposed that the arrangement should last for two years.

The Decay of Gold Mining.

In a statement regarding the gold-mining industry made lately, Mr. E. C. Dyason, president of the Chamber of Mines of Victoria, described the present condition of the industry "as a patient that was being kept alive by the precarious oxygen of the gold premium." To his mind it was surprising that the industry had survived the blows it had received. Costs and charges had increased 25 per cent. in the last decade, and the increase in the price of gold, which was quite recent, had been only from 25 to 35 per cent. Mr. Dyason, after dwelling upon the shocks the industry has received, asserts, for the benefit of posterity, that the obliteration of mining in Victoria is economic, not geological. He contends that hardly any of the goldfields of the State have been exhausted, and believes that, even though the industry may be stopped now, it will some day revive. He states that there are 100 years' work in Bendigo under more favourable conditions, and avows that other fields of the State have similar prospects.

Diamonds in New South Wales.

News from New South Wales is to the effect that an attempt is to be made to revive mining for diamonds on the Bingara field. An exchange states that the diamonds so far found there have been small, but they are exceedingly hard, and have had a value because of their use in polishing other diamonds. Mr. Dickens, a representative of some Victorian capitalists, has spent two or three weeks in making an inspection of the locality, and claims as a result of his investigations to have made discoveries, one of which is that the locality has revealed at least one creative point of the diamond. The geological conditions, he states, appear suitable for the existence of the already much searched for volcanic pipes of kimberlite (the matrix of the diamond), similar to those of South Africa. This, he says, is supported by an examination of some decomposed "blue ground," which revealed the existence of the minerals usually associated with the diamond. Mr. Dickens has returned to Melbourne to report, after first lodging an application for an extensive area of mineral lease. Very close search has been made in the district by the geological officers of New South Wales for the sources of the diamonds, but it has generally been understood that they have not been successful.

Boring on Luipaardsvlei No. 10.

We understand that boring on Luipaardsvlei is proceeding very satisfactorily, a depth of 450 ft. having been reached. The drill is dolomite, and it is expected that it will reach the Witwatersrand beds early next month.

T.G.M.E. Meeting.

Mr. Max Honnet presided at the annual meeting of the T.G.M.E. last week and reviewed the prospects of the property in detail. The dividend question was discussed by several shareholders, and the official announcement cabled to London on the subject after the meeting will be found elsewhere in this issue.

August Mineral Statistics.

The following statistics have been issued by the Department of Mines and Industries for the Union of South Africa:

	August.		Totals for 8 months from Jan., 1921.	
	Output.	Value.	Output.	Value.
	ozs.	£	ozs.	£
Gold	715,538	3,039,413*	5,337,227	22,671,100
Silver	72,971	10,946	529,677	80,626
	Carats.		Carats.	
Diamonds ...	48,275	175,608	614,914	2,420,384
	Tons.		Tons.	
Coal	1,035,494	448,048	7,671,401	3,460,219
Metallic Tin & Concentrates	77.2	7,347	1021	101,801
Other Base Metals	—	10,407	—	£98,451
Totals		£3,691,769		£28,835,415

*Gold valued at par.

It is gratifying to note that advances in both output and value have been made in all the cases considered. The following figures fully bear out this statement:—

Increase of August over July in—

	Output.	Value.
Gold (ozs.)	19,617	£83,328
Silver (ozs.)	304	45
Diamonds (carats) ...	1,528	107
Coal (tons)	73,161	27,218
Tin (tons)	21.2	2,104
Base metals	—	841

De Beers' Industrial Interests.

A feature of interest in the review of developments in the Cape inspectorate included in the annual report of the G.M.E., is the reference to what is being done by De Beers Company in the matter of industrial development, through the medium of the establishment of a fertiliser factory at Somerset West, in which connection the following details are given regarding the position as at the date of the report: "Hitherto the supplies of fertilisers have been limited to the local product, which consisted largely of bone meal, the output of a few small factories, and to importation from other countries, which latter amounted in 1913 to £188,431 and in 1915 to £175,336, and it was to meet this demand that De Beers decided to launch out on a big scale and hope to be in a position in a few months' time to be able to supply the whole fertiliser requirements of the Union, which are said to be about 100,000 tons per annum. The material for erecting a huge building, 700 feet long and 75 feet high, which is to house the main portion of the fertiliser plant at Somerset West, has arrived, and all the foundations have been prepared, and it is hoped that the plant will be operating by June or July. Eight subsidiary buildings in addition to the main one will complete the installation, and the plant, as a whole, will be capable of turning out 100,000 tons of fertiliser per annum on a single eight-hour shift. Every kind of fertiliser will be sold by the company, and those, such as basic slag, which cannot

at present be produced here, will be imported. It will be the policy of the company to aim at large production with small profits, rather than small production and large profits, and the prices charged will depend on the demand, and the question whether the Union will have cheap fertilisers depends largely on the farmer himself, as the incidence of the heavy capital charges will diminish as production increases, and the saving resulting from increased production will go to the benefit of the farmer in the shape of lower prices. The factory, when complete, will be not only the most modern, but also one of the largest in the world, and will be operated by modern mechanical devices which will reduce supervision to a minimum." The report also gives details showing how De Beers Company are extending the uses to which in the past reinforced concrete has been put, and are manufacturing many articles and applying them to many purposes where previously iron, wood, or masonry were used. The reinforced hollow concrete brick is one direction, and the result, the report anticipates, will be eventually to entirely supplant the ordinary clay brick. Towers for electric power lines, sleepers for railway and tram tracks, beaver setts for mining purposes, and water-tanks for all purposes are named as but a few of the other uses to which reinforced concrete is now being put by De Beers. Reference is also made in the report to the possibilities of developing the iron fields.

Far East Rand Mining Problems.

In the course of his annual report, Colonel Bottomley, Inspector of Mines for the East Rand, writes:—"There is nothing of a special nature to report regarding the progress or development of the mining industry during the year. The expansion of the Far East has, if anything, received a slight check owing to the stoppage of most of the development ends on the Daggafontein Mine and the poor results of the development in Springs West. The results so far achieved on these two outlying mines are distinctly discouraging, and are certain to influence opinion in connection with the long looked for expansion of the Far East and the development of the large unworked areas between Springs and Nigel. It is apparent that the zones of enrichment or lenses are further apart and the reefs narrower going south from Springs. On the other hand, we have the splendid example of the Nigel, which was a prominent producer and dividend earner for many years. The mine is situated eight miles to the south of Springs, and it is more than probable that similar large patches of rich ground should be found between these two points. The difficulty lies in their location. The deep shafts on the Springs West, New State Areas, Brakpan, and Geduld, have now approached the Main Reef horizon, the New States having actually encountered the reef, and the coming year will witness a programme of development hitherto unprecedented on these fields. Owing to the large claim areas involved, first consideration is being paid to rapid and easy transportation of ore by laying out the drives and main haulages on capacious lines. The question of ventilation, as is only natural in this enlightened age, is receiving every possible consideration, and the wide drives already mentioned will materially assist in this direction. It is satisfactory to note that the North Shaft of the New State Areas was sunk to the reef—a depth of 3,760 feet—without a single fatal accident. It has been decided that the two circular shafts of the Brakpan Mines which are now in their last stages—No. 4 having already encountered the reef—are to handle the work during the development period without their permanent equipment. This means that wire guides will continue to be used without any other steadying factor than their own weight and what is added to them for stabilising purposes. I cannot help feeling that the extra tonnage hauled will be a severe test on the conditions mentioned. The sinking of the two shafts has been a nightmare to the managers up to the present, and it is more than likely that their troubles are not yet over. It is felt that there is insufficient data available in connection with the handling of a large tonnage on rope guides over a shaft depth of 4,000 feet.

Concerning Mines and Men.

Mrs. Clem Webb and family desire to thank the numerous friends who have extended sympathy in their recent sad bereavement.

Mr. G. A. Keene, director of Sandycroft, Ltd., is on a visit to the Rand.

Col. Bartley, O.B.E., of Messrs. Sykes & Co., Ltd., has returned to the Rand.

Major T. D. Stoward, of Messrs. Sykes & Co., Ltd., has returned to the Rand, after a two years' stay in England.

Mr. W. S. Saunders, of the "C.M.S." group of companies, has returned to the Rand, after a six months' holiday in England.

Mr. P. Rouillard, Consulting Engineer to the Mauritian Group of Natal Collieries, has been on a visit to the Rand this week, on a mission regarding railway rates.

The Bailey-Jeppe group of companies is now engaged in moving into Farrar Building, which has been renamed Clewer House, in Sir Abe Bailey's honour. The W.N.L.A. have moved into the new Chamber of Mines building, which is rapidly nearing completion.

Gold Producers' Association.

We learn from the Australian Press that no sales of gold were made by the Gold Producers' Association, Ltd., during May. On 20th May fine gold was quoted at £5 2s. 8d. per oz., and the board considered it advisable to hold the available gold for a better market. During May and June quotations varied between £5 2s. 8d. and £5 10s. 5d. per oz., this being the gross price, without deduction of insurance, freight, and other realisation charges. The quantity of gold disposed of by the association in June, including local sales for the June quarter, was 184,769 oz. standard. The average net price obtained was £4 19s. 1d. per standard oz. equal to £5 8s. 1d. per fine oz. All but 45,000 standard oz. of the total gold production available for sale during the past half-year has been sold. The board expected to dispose of this remainder before the end of July.

Geology of Heidelberg—VII.

MR. BLELOCH REPLIES TO DR. ROGERS—CONCLUSION—DR. ROGERS' MATERIAL POINTS.

Dr. Rogers admits there is nothing new in his arguments and apologises for reiterating them. He naively says "some of them have been greatly strengthened by the detailed mapping." That fond delusion must have been comforting, for Dr. Rogers seems to have realised how weak are his arguments and how sadly they needed strengthening. Now that the detailed mapping has been shown to be a new source of weakness instead of a source of strength these temporarily stimulated arguments will have to relapse again among their weaker fellows. In an important footnote on page 52 of his paper Dr. Rogers states: "The material points are:—

"1. No unconformity within the Kimberley-Elsburg series south of the Rand.

"2. The absence of an unconformity at the top of that series south of the Rand.

"3. The 'Bird Amygdaloid' is a contemporaneous lava interbedded with the quartzites between the two uppermost groups of states and as such is an important rock in the determination of horizons in boreholes and shafts in areas where the beds do not crop out. These conclusions were very clearly set forth in the papers by Dr. Mellor referred to on previous pages especially in the upper Witwatersrand system published as long ago as 1915."

Just so! Dr. Rogers and his predecessor have both got into the same boat and they eventually persuaded the Government Mining Engineer and the Rt. Hon. the Minister of Mines and Industries to get in too. Unfortunately for them all, the boat has sprung a leak and they now find themselves in a sorry and desperate plight, and none of the professional brethren of the three experts are showing any ardent desire to come openly to their assistance.

When the notorious cables were dispatched to destroy confidence in the reefs we have found and identified as the Van Ryn series in the Heidelberg district, and to spoil the financial arrangements for developing them, and to stop a million of new working capital from coming to open up the only possible extension of our Far East Rand goldfield, it was never for a moment dreamt that these cables would have a far wider effect than they were intended to have. It was not foreseen that the cables would not only spread doubt and uncertainty about the new mines under our control but that they would put doubt and uncertainty into the minds of the speculative investor in regard to the whole Rand mining industry. People rightly and naturally thought that if a Government goes out of its way to send a warning about the reefs of its greatest goldfield there must be something radically wrong. Not only, therefore, was Dr. Sauer's company wrecked, but the big mining house enterprises, too, came under suspicion. Not only did more or less unsatisfactory properties like Modder Easts and properties like Daggafontein working the Nigel Reef instead of the Van Ryn suffer, but even established mines on the Far East Rand like Springs and Brakpan, the old and new State Mines, West Springs, and all have come in for a no small amount of suspicion and uncertainty, duly reflected to-day in the graveyard quietude of the Stock Exchange. It was not foreseen that the cables would bring about a situation which, unless it is relieved by a public withdrawal and repudiation by the Government itself, must preclude any hope of more capital being forthcoming for new mines, either in the southerly extensions of the Far East Rand under our control, or on the Government's own remaining deep level areas in that field.

A Blacked-out Future.

The Government apologists say that unemployment and depression are not to be laid at the door of the Cabinet—that it is the result of world conditions—but no country that I know of has ever cried out "Stinking Fish" by cable and warned people against investing money to expand its

greatest and most profitable industry. The Government itself, therefore, by these cables has brought about decreasing State and Railway revenues and by its own extraordinary act inspired by Dr. Rogers—so the Rt. Hon. the Minister informed Parliament—it has undermined and impaired the very credit of the country. Popular indignation is rapidly rising against the conditions of poverty and unemployment reigning in the midst of inexhaustible but un-get-at-able wealth, barricaded off and locked up by the permanent heads of the Mines Department. The Rt. Hon. the Minister of Mines and Industries who apparently acted on incorrect and misleading representations which were made to him by his officials, set his seal on the locking up by authorising the cables, and now he looks around at the present consequences of his act and contemplates the blacked-out future of the industry he administers. He must be experiencing a sinking feeling of dismay.

The Points Refuted.

To bring these criticisms and reflections on Dr. Rogers's paper to an end, I will briefly remark on his material points.

Point 1.—In regard to this point I submit that except Dr. Mellor and his school, of which Dr. Rogers proclaims himself an adherent, I do not know of anyone who puts forward that there is unconformity within the Kimberley-Elsburg series. Certainly I have never done so. Only those who say that Langerman's Kop beds, although so like those of Reitfontein that Dr. Mellor once said they must be classed together, are nevertheless overlapping Elsburg beds faulted down, imply such an unconformity as Dr. Rogers denies. The experts who say that belong to Dr. Rogers's school, not to mine.

Point 2.—I submit in regard to this point, that with cited and verifiable facts, I have proved Dr. Rogers to be wrong, and I have shown that at Heidelberg as elsewhere the Ventersdorp system is manifestly unconformable to the Witwatersrand system. I have supported that matter of fact evidence with the testimony of geologists and engineers experienced in Rand Geology some of whom have gone to other lands and others—among them some of the ablest—are, alas, now dead and gone.

Point 3.—I submit that on this point, too, I have proved Dr. Rogers to be wrong, and my proof is again in the form of cited and verifiable facts. I have shown that the amygdaloidal diabases occurring in the horizons above the Van Ryn Reef on the Far East Rand are mostly probably intrusive and that in any case Dr. Rogers has brought forward no evidence to prove that his interbedded lava of Heidelberg has any connection whatever with the diabases encountered in the shafts and boreholes put down to the Van Ryn Reef on the Far East Rand. On the contrary I have brought forward matter of fact evidence which shows that Dr. Rogers's "Bird Amygdaloid" of Heidelberg almost certainly belongs to an altogether earlier period, for just such an interbedded lava flow as that which he has described in the Heidelberg district did take place in the period *before* the Van Ryn Reef was laid down on the Far East Rand, and this rock is to be seen in the neighbourhood of both the New Modder and Reitfontein Mines outcropping north of the Van Ryn Reef on these mines: proving that just such a truly interbedded amygdaloid as Dr. Rogers described as occurring in the Heidelberg district is there in position at New Modder and Reitfontein, but it lies *below* the Van Ryn Reef and not *above* it as it would be if Dr. Rogers's correlation were correct. I may also add that even below the Nigel Reef there is another amygdaloid, and there is still yet another below the horizon of the Molyneux Reef. In view of these facts, how can Dr. Rogers take any of these amygdaloids as the sole reliable markers by which to identify the banket beds which lie above or below them. By doing so, he successively identified three entirely

different reefs—the Van Ryn, the Nigel, and the Molyneux—as all one and the same “Main Reef Leader” and so has brought about his tragic “errors of correlation” with all their disastrous consequences.

In regard to points 2 and 3, I do not believe that Dr. Rogers will find, barring Dr. Mellor, any two geologists to support him. I submit that they constitute the false premises on which his errors of correlation are founded, and on these as a top storey Dr. Rogers has built up a fantastic but unstable edifice of assurance. I further submit that, sooner or later, the Government will have to repudiate and withdraw the sweeping and unwarranted cables banning all the reefs in the Heidelberg district except the unpayable Molyneux: that Cockoo reef of which Dr. Rogers in succession to Dr. Mellor has now become the foster parent.

Closing Up the Rand.

I submit that until Dr. Rogers deals with the facts I have cited bearing on the fundamental questions of Rand geology, like those of Reitfontein and Langerman's Kop, of the unconformability of the Ventersdorp system to the Witwatersrand system, and of the amygdaloidal diabases in relation to the sedimentary beds in which they occur, it is dangerous for the Rt. Hon. the Minister of Mines and Industries to take it for granted that Dr. Rogers is justified to dictate either by cable or by any other way as to which reefs can or cannot give rise to public expectations which are justified. I submit to the Prime Minister that the Government should immediately institute an impartial inquiry into the whole question and that it should meantime order the withdrawal and repudiation of the notorious cables which it now appears were instigated on statements, in regard to my addresses and lectures in London in 1919-1920, which had no foundation in fact. I again repeat my statement that these grave errors of correlation and deplorable errors of judgment are *closing up the Rand*. That they are causing unemployment and poverty and creating chaos and deficits in the finances of the nation.

In addition to the quotations and references made in the body of this paper; for the information and convenience of my readers and of the members of the Geological Society of South Africa I append a further number of brief statements by independent authorities on the questions at issue.

In addition, too, to the diagrams presented with the text, I am able by the kindness of the *South African Mining and Engineering Journal* to present a new geological plan of the Witwatersrand system (1921) illustrating the conclusions regarding the gold-bearing reefs of the system as described in the text.

Brief Statements by Independent Authorities.

“Dear Mr. Bleloch, I thank you very much for the copy of your paper on the Rand with the map. I have read the paper and studied the map with considerable interest. I quite agree with you about the Far East Rand, I also think that portion of the basin too shallow to give enough space for such a great thickness of the strata of the Witwatersrand System as would include the Main Reef. I also expect lower Witwatersrand beds there.” *Dr. G. A. F. Molengraaff, Professor of Geology, Delft University, and formerly State Geologist to the Transvaal Government. 2/11/10.*

Note by W.E.B.—In this, in effect, Dr. Molengraaff states that he is in agreement with me, and that it is his opinion that the reefs mined on the Far East Rand, which produce nearly 70 per cent. of the total profits of the Rand goldfield, are in the lower Witwatersrand beds, and are quite distinct from the less profitable Main Reef series of the Central Rand.

“Certainly the Van Ryn Reef was not the Main Reef, and had not anything to do with it.”—*H. S. Denny, Financier Report. May 17th, 1919.*

“This reef (Van Ryn) outcrops throughout nearly the whole length of these properties.”

“The facts, old and new, set forth in this report are open for all to see, and I can say at once that in my opinion they leave no room for further controversy. How any man with eyes to see, after carefully observing these reefs in position all round the Rand, can declare that the Nigel Reef is the same as the Van Ryn, or that either of these reefs is the same as the Tatham, or the Kimberley, is beyond understanding.

“I am prepared to go with the Government Survey Officers, or with any independent Engineers or Geologists, and check off the several beds shown in these sectional profiles, bed for bed, at each of the places around the Rand to which they refer.”—*W. T. Hallimond, Report, Houtpoort, Ltd., 11th December, 1920.*

“The Reef now being mined from the No. 1 Incline Shaft in the northern section of your property (The Southern Van Ryn) is the true Van Ryn Reef of the Far East Rand. I also confirm that the Nigel Reef is a separate and distinct pay reef which is being mined in the South-East section of your property.”—*W. T. Hallimond, M.I.M.M., M.I.M.E., Report, Southern Van Ryn Reef G.M. Coy., Ltd., 17th December, 1920.*

Nigel Reef.—I am mining the Nigel Reef in the Nigel Van Ryn section of our property (The Southern Van Ryn). The average assay value is 7.25 dwts. over a stoping width of 24 inches.

Van Ryn Reef.—Seventy per cent. of last month's development on the Van Ryn Reef from No. 1 Incline Shaft averaged 9.8 dwts. over 24 inches. Values like these will enable me to send ore to the mill of an average grade of, say, 8.5 dwts. per ton, that is nearly as high a grade as that of the New Modder Mine, and higher than the grade of a medium value mine like Brakpan.”—*C. J. Tutt, Consulting Engineer, Southern Van Ryn Reef G.M. Coy., Ltd. Report, 14th December, 1920.*

“I have seen the three reefs—Tatham, Nigel and Van Ryn Reef in their sequence exactly as shown in your brother's sections and exactly similar in character and sequence as they occur at the Southern Van Ryn Mine.”—*W. Marshall Philip, Mining Engineer. 5/5/20.*

WRIGHT'S ROPES

H. ALERS HANKEY - - - Sole Agent.

(1) The Main Reef as worked on the Central Rand is cut off in the neighbourhood of Boksburg, beyond which point it has not been exploited.

(2) The reef known as the Van Ryn belongs to a much lower horizon of the Witwatersrand System than the Main Reef of the Central Rand.

(3) The Nigel Reef underlies the Van Ryn, and is exposed north-east of Boksburg.—*E. T. Tenby, F.G.S., M.I.M.E., January, 1915.*

"After having examined the evidence and seen the Reefs, I say that no man can say that there is only one reef, or that the Nigel is the same as the Van Ryn."—*A. Danks, Mining Engineer, Special Commissioner, South African Mining Journal, August, 1920.*

"When I went as Manager to Government Areas I was struck by the resemblance between the Van Ryn and Rietfontein Reefs, and also by the total absence of the characteristic features of the Main Reef Series in the Central Rand. As the result of 2½ years' experience in development work on Government Areas—during which period about 70,000 feet of development was done—I came to the conclusion that the Van Ryn Series was the Rietfontein Series, and not the Main Reef Series. I see by the recent published cable report that your latest development results on the Southern Van Ryn are excellent. I hope that you are now entering one of the payable zones of the Van Ryn Reef, which will establish the value of your properties in that district."—*Graham Bell, 2nd March, 1920, Mining Engineer, formerly Manager of the New Rietfontein Estates Mine and the Government Areas, Modderfontein.*

"I cannot understand how any man who professes to know anything about the Main and Van Ryn Reef Series can possibly say that the Nigel is a Main Reef proposition."—*F. E. Rivas, 26th July, 1915.*

"In view of all the evidence, deductive and positive, the most reasonable conclusion is that the Nigel is not Main Reef Series."—*J. T. Carrick, M.I.M.E., Ph.D., 11th July, 1904.*

"I know the Nigel Reef and the Van Ryn Reef. In my opinion the Nigel is not the Van Ryn. I cannot understand how anyone could identify Nigel Reef with Main Reef Series."—*The late Joseph Storey Curtis, Mining Engineer and Geologist with 25 years' experience on Rand, put down first borehole on Main Reef Series. Formerly on Geological Survey Staff, United States of America. From evidence on oath, Knox Arbitration Case.*

"I reported to Rhodes that the Van Ryn Reef had no correlation with the Main Reef but that it was very much more probably an extension of the du Preez (Rietfontein) Series. The Van Ryn Reef is incomparably the most valuable reef in the system.

The Nigel and Van Ryn Reefs are different and distinct."—*Dr. Hans Sauer, Special articles in "The Financier," 1918.*
 "It is quite distinct from the Nigel and from the Van Ryn. The Nigel Reef is distinct from the Van Ryn."—*John Dampier Green, M.I.M.E., F.G.S. Evidence on oath, Knox Arbitration Case.*

"Certain of the facts and showings I saw with my own eyes were of a startling character."—*R. R. Mahson, Special Commissioner for "The Statist."*

"Since then development by the Coronation Syndicate has been steadily proceeding on the Van Ryn Reef Series on this property (Wilgepoort), disclosing highly payable values in two reefs of the series. The reefs are quite different in appearance and bedding to the Nigel Reef."—*J. A. Thorburn, Mining Engineer, with 30 years' Rand experience. 19th March, 1921.*

"I state most emphatically that the Van Ryn Reef of the Van Ryn Series worked in the Van Ryn Mine on the Far East Rand, has no connection with the the Main Reef Series of the Central Rand, and lies stratigraphically far below that series. I may also add that the reef exposed in your No. 1 Shaft of the Southern Van Ryn Gold Mine is the same reef as that worked in Government Areas (Modderfontein), Modder B. etc."—*Scott Alexander, Rand Stratigraphist. 17th March, 1921.*

TO INVESTORS AND SPECULATORS.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

VII.

By Arthur Stenhouse.

On the 3rd September, 1886, I arrived in Pretoria from the United States of America, and was met by the manager of Robey & Co., who at once advised me that Mr. Samuel Marks's carriage was outside the hotel, and he had been sent in specially to take me out to his beautiful home "Zwartkopjes." As I had never met Mr. Marks, I naturally protested, but Mr. Clench insisted that I should accompany him. Reluctantly I consented, and was driven out to "Zwartkopjes," introduced to, and warmly welcomed by, Mr. "Sammy" Marks, who insisted that I should take up my residence there as his guest. Soon afterwards he went to Barberton by coach, and I was left in charge of Mrs. Marks and the baby, and here for a month I resided and enjoyed Mrs. Marks's unbounded hospitality.

Oftentimes we would drive into Pretoria and have lunch at Mr. Nelnapius's residence. At the Pretoria Club I was also warmly welcomed, and happily entertained. On one occasion, when dining at the Club, the late David Benjamin (one of the earliest Pioneers) arose from the table and, referring to the writer, remarked "that the fame of our goldfields had travelled afar. Here," said he, "was the first mining man to arrive from the four corners of the globe to exploit our goldfields"—a prophecy that has long since been fulfilled.

On the lower side of Church Square (Pretoria) there was a charming white-washed, thatch-roofed bungalow, the residence of the late Mr. Nelnapius, the verandah shaded by honeysuckle and sweet briar, and the garden one mass of colour. The owner was a great personal friend of Paul Kruger, and a most hospitable and kind-hearted gentleman. Oftentimes I would drop in to lunch, or to dinner, without notice, at his hospitable home, and was at all times warmly welcomed. Occasionally the house party would drive away into the country for a picnic, and go a-fishing at the swiftly-flowing river at the Powder Factory. Pretoria at that time was crowded with visitors, and the hotels were packed. Visitors willingly paid one pound a day for the privilege of sleeping on the floor, or anywhere inside the building. There was a peculiar fascination about those Pioneer days. New developments were occurring day by day. We lived at a time of great possibilities, and in an age of universal optimism. The seriousness of business was unappreciated: the combination of pleasure and business at that time would be unrealisable to-day. Individual interests were identical; class distinctions almost unnoticed in the one general aim of the Pioneers to work harmoniously together for the advancement of the gold mining industry. Boer and Briton took a lively interest in each other's welfare; intense heartiness characterised both our work and our pleasure. At a semi-public banquet at Hatherly Distillery, where over 200 guests sat down, I was the honoured guest and sat at Mr. "Sammy" Marks's right hand. What a contrast to my experiences in America, where I earned my livelihood as a farm labourer at a wage of \$15 a month, and where the playful little pigs were my chosen companions! Interesting are the varied experiences of the early Pioneers, and it behoves us to place them on record.

T.G.M.E.: 24th Annual Meeting.

The following cable was sent from the head office to the London secretaries in regard to the T.G.M.E. meeting: "At the annual meeting held to-day the Chairman announced no dividend 30th September, but since desired financial reserve now attained, dividends will be resumed next half-year and onwards as permitted by profits earned."

NOTE.—To arrive at an approximate Distributable Profit, the following items require to be deducted from the "Estimated Gross Profit" (which will consequently reduce % on Capital), viz.:-
 Profit Tax (average about 9% of Gross Profits). Interest on Debentures (if any).
 Extra War Tax. Interest on Advances (if any).
 Capital Expenditure (if any). Assessment for Miners' Phtthisis.
 Redemption of Debentures (if any). Government Annuities (if any).

It is impossible to arrive at an average percentage of these items. The calculation most commonly used to arrive at a very approximate "Annual Distributable Profit," is to multiply any one month's profit by ten, thus allowing two months' profits for all appropriations.

In the case of Govt. Areas, Brakpans and Springs, the Government share of profits must be deducted to arrive at the "Distributable Profit."

No Unworked Claim area is given, exact figures being unobtainable.

The occasional discrepancies between "Working Costs" plus "Working Profit" and "Yield" may be accounted for by such items as Sundry Revenue, etc., not shown.

Questions of "life," debentures and Government annuities are dealt with from time to time in our columns in the annual reports of the companies concerned.

Sunken Treasure.

During the war many vessels containing valuable stores were sunk by submarine or by mines. Among them was a liner which contained amongst her cargo 20 bars of gold, each worth about £1,500. An enterprising effort is being made by British salvage ships to recover this treasure in spite of

the fact that the ship was so badly broken up that the gold was buried under many tons of wreckage. This wreckage has to be blasted and carried away to another part of the ocean. So far only seven bars of gold have been picked up, but it is hoped that eventually the skill of the British divers will secure the recovery of the whole amount.

Malaria and "Outside" Mines.

THE RED CROSS SOCIETY'S ACTIVITIES.

The East African Campaign brought home the evils of malaria to thousands in South Africa, who had never previously realised the danger of the disease to the health of the individual and the community. Yet for years past the disease has been rife in many parts of the Transvaal, Zululand and adjacent areas. In many districts of the countries referred to, with the passing of the winter months and the advent of the rainy season, the malarial mosquito awakens to life with the inevitable consequence that, where the necessary precautions are not taken, large numbers of the residents, both whites and natives, go down with malaria. Malaria is a disease which can both be prevented and eradicated. The work accomplished in Panama, Italy, Spain and in many other countries amply proves that where adequate precautions are taken to screen dwellings effectively, this alone has considerably lessened the incidence of the disease; and where steps have been taken to rid malarious districts of the anophles mosquito, malaria has been practically wiped out.

The Anti-Malarial Association.

In South Africa, much excellent educational work has been carried out by the S.A. Anti-Malarial Association in bringing a knowledge of the preventive measures necessary to combat the disease to the population in malarious areas. For various reasons the work practically lapsed during the war, and it was recently deemed advisable to dissolve the association and to hand over the carrying out of its activities to the S.A. Red Cross Society (Transvaal). Malaria was one of the many problems dealt with by the great medical conference which preceded the formation of the League of Red Cross Societies, and it is only natural that the Society, as a member of the League, should be the body entrusted with the propaganda work essential towards the eradication of the disease. The Council of the Society has appointed a special anti-malaria committee, amongst the members of which are the heads of various interested Government departments, including the Public Health Department, as well as representatives of the Transvaal Land Owners' Association.

Organisation.

This Committee, under the chairmanship of Dr. A. J. Orenstein, C.M.G., a recognised and well-known authority on the subject, is taking active measures to continue and

extend the educational propaganda hitherto so well carried out by the Anti-Malarial Association. One of the immediate objects in view is the formation of local committees in the various districts where malaria is at present endemic. The work of these committees is to assist in educating the people to a sense of the real dangers of the disease, and the best means to be adopted to prevent and eradicate it. In country places where it is not possible to form local committees, the Red Cross Society is anxious to have the help and co-operation of individuals who will assist in furthering this educational work among their neighbours. Thanks to the late Association, the Society is in possession of a quantity of literature in English, Dutch and Native languages, which is available for immediate distribution, while the committee is also prepared to arrange for lantern and bioscope lectures on the subject. Applications will be welcomed from persons resident in malarial districts, who desire to avail themselves of any assistance which the Society can give. Correspondence on the matter should be addressed to the Secretary of the Society, P.O. Box 3266, Johannesburg.

New Anti-friction Metal.

There are many special alloys for the purpose of lining the bearings of machinery so as to reduce the friction to a minimum. The objection to most of these is that if from any cause they should become hot the metal melts and runs out. This drawback is avoided in a new metal which has been tested in Great Britain with very satisfactory results. In these tests the metal became very hot without showing any signs of melting, and when forced lubrication was used the bearings showed no sign of wear or flow even with a load of over 1,000 lbs. per square inch.

ENGINEERING SECTION.

George Ellison's Electrical Specialities.

(From a London Correspondent.)

Unique among the big engineering concerns of the British Isles stands the Perry Barr firm of Mr. George Ellison. Essentially a "one-man" organisation, it is also a working demonstration of sustained effort and organised concentration.

Established about a quarter of a century ago to manufacture control panels for induction motors, the firm has not once deviated from the clearly defined industrial path it was founded to tread. Even during the war, when many manufacturers made radical departures and turned, almost literally, ploughs into swords, Ellison's only speeded up output to meet the national demand for its specialities. Changes there have been, but these come as developments in directions indicated by scientific research. Of the wisdom of this policy there is abundant proof. Ellison control gear has gained a world-wide reputation.

When I was at the works a day or so ago, 700 employees were completing orders destined for despatch to near and distant lands. After hearing so much of idle benches and silent lathes, it was decidedly refreshing thus to confront a scene of intensified industrial activity. As for the works themselves, they are, as one would expect, the last word in modernity. A single-storied, glass-roofed building covers an area approximately 600 feet by 250 feet. The view from end to end is unobstructed. A job commenced at one extremity will probably pass from stage to stage and from hand to hand through the entire length of the building until, as the finished article, it ultimately reaches the packers and then the loading deck of the motor lorry. The poetry of systematised efficiency could hardly find more eloquent exemplification.

In making my round of the works I had as guide Mr. Ellison's general manager, Mr. Robertson, who told me much concerning the methods of his firm. It was interesting to

learn that to them strikes are almost unknown. Mr. Ellison controls his employees by methods as original as those upon which he has developed his business. Each employee, each member of the staff, is an individual, and as such is treated. The human element enters largely into the routine at Perry Barr. Mr. Robertson, who spent some of his earlier years in South Africa, tells me that Mr. Ellison may shortly be contemplating a visit to the chief industrial areas of the Union.

The following technical descriptions concerning three main lines of Mr. Ellison's manufacturers are of special interest to South African mining undertakings:—

Oil Break Star-Delta Starter.

These starters are similar in appearance and construction to the oil-break circuit breakers, and are suitable for the same industrial purposes. The contacts are mounted on a slate base in a cast-iron case, and take the form of a change-over oil-break switch. Full automatic releases are fitted, with time lags on the overload trips; thus the starters contain all that is necessary to start, stop and protect squirrel-cage motors. They are mistake-proof in operation, being fitted with a patent "Gradatum" device which ensures that the handle is moved in a proper sequence, with a pause at

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to divine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

the starting position and quick change over to the running position. The overload trips are operative only in the running position, and the time lags permit reasonable overload trip settings, whilst preventing the starter opening by the current rush caused at changing over from start to run. The Oil Star-delta Starters are made for currents up to 200 amperes working load. A series-parallel starter of the same design is made for two-phase induction motors.

Drum type controllers are made for A.C. and D.C. motors for cranes, or for any purpose requiring frequent operation, where an ordinary starter intended for operation at long intervals cannot meet the conditions of service. Experience and experiment over a number of years has resulted in designs which have proved their suitability for onerous conditions. The barrels have contact segments which are readily accessible and replaceable when worn. The fingers are of

" Unit " Type Switchgear.

Unit type switchgear is made for all industrial applications and intended to cover the field between the ordinary switch and fuse distribution board and the elaborate cellular switchboards for large power stations. The standard oil-break circuit breakers and starters lend themselves to the building up of quite complicated arrangements, yet each part is of simple robust construction. The units are supported by cast-iron stands, and are bolted together to form a compact, totally enclosed, weather and mistake-proof switchboard which safely withstands the roughest use. The breakers are bolted to a steel-plate chamber which contains the isolating switches and bus-bars, and carries the necessary instruments. Interlocking devices are provided between the isolating switches and the breakers. The illustration shows a seven-unit switchboard which was installed in a mill to control a group of five slip-ring motors, each driving a section of the mill. An oil-cooled rotor starter is included in each unit, mechanically interlocked with its circuit breaker. All the units are electrically interlocked to ensure that the various sections are started up in correct sequence, and if one section is stopped, the others dependent on it are automatically shut down. Many of these switchboards have been installed in mines, where they have been subjected to very hard wear and tear, and have withstood falls of roof without causing interruption of the supply.

Drum Type Controllers.

patented design, adjustable for wear, and with renewable tips. The arc shields are effective and magnetic blow-outs are fitted to the D.C. pattern. The illustration shows a D.C. controller with cover removed and arc shields and blow-outs withdrawn for inspection. The contact fingers are disposed radially to the barrel and have roller tips, which are pressed on to the barrel contacts by spring. This design is a departure from existing types and has several advantages. The roller is mounted so that it can rotate, oscillate and lift, and consequently beds perfectly on the segment. The barrel contacts are shaped to prevent the possibility of an arc being blown inwards and spreading from finger to finger, a trouble which is sometimes present with a magnetic blow-out field parallel to the barrel. The handle lever is very strong and fitted with a device shaped to set itself correctly, so that no matter how the handle is left, it always comes to the right position to arrest motion, and cannot be moved from "forward" to "reverse" accidentally. Controllers are made in practically every type for series, shunt, and compound D.C. motors and for squirrel-cage and slip-ring A.C. motors.

An Electrical Pioneer.

A link with the great Faraday, who was the scientific founder of the electrical industry, has been broken by the death recently in England of Mr. S. A. Varley at the age of 90. Varley received his first inspiration from the lectures of Faraday at the Royal Institution, London, and he played an active part in the laying of the first Atlantic cable. During the Crimean War he laid, for the first time in military history, a field electric telegraph for war purposes. He was also the originator of the time ball at Greenwich Observatory and elsewhere, for giving time signals visible to the public. Still more important was his invention of the compound wound dynamo.

Electric Welder for Large Work.

The process of spot welding, as it is called, has been employed extensively for small work such as fixing handles to pots, but until the recent invention of a British machine it was not applied to large articles such as the ventilating cowls of steamships. The process consists in pressing two pieces of metal together by electric terminals through which a current is passed, thus melting the metals together at the spot between the terminals. In the new machine, the metal is supported on a long rigid arm carrying one set of electric terminals and the other set is pressed on the metal from above. Very large sheets of metal can thus be handled with great facility and expedition.

The Electric Steel-Making Process.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Etna Works, Sheffield.

There are several successful types of electric furnaces now in use, and in all cases they are capable of being tilted. The furnaces are of sheet steel and lined with refractory materials. The material used for melting may be any kind of scrap, its chemical composition does not matter, as the electric furnace refines or purifies the steel. This refining can be carried out so that the finished steel contains only traces of sulphur and phosphorus. Whatever kind of steel scrap be used as a base for melting, it is first of all melted under a slag of lime and oxide of iron (iron ore, mill scale, etc.). This slag is an oxidising one, and by allowing it to float on the surface of the molten steel in the furnace it picks up and removes the phosphorus, carbon, silicon and manganese, the phosphorus being converted into phosphate of lime, which floats on the surface of the metal as slag. When dephosphorisation has been carried out to the desired extent, the slag is raked off and the metal is now almost pure iron containing some sulphur and considerable quantities of oxide of iron. A calculated quantity of anthracite coal is next thrown on to the bare surface of the metal so as to give the desired carbon content. A new slag is then formed by throwing into the furnace lime mixed with fluorspar and sand. These all melt and form a fluid slag. On to this slag small quantities of powdered coal and ferro-silicon are thrown so as to produce a reducing and desulphurising slag. A reducing slag is one which tends to remove oxygen from the molten metal. When first melted this slag is quite black, but as the refining proceeds it gradually becomes lighter in colour, until at the finish it is almost snow white. This white slag indicates that the steel is in good condition and that everything is proceeding satisfactorily.

If additions of special alloys such as ferro-manganese, ferro-chromium, ferro-vanadium, etc., be now made, they can be added in the theoretical amounts, as no loss occurs through oxidation. In all other processes of steel making, considerable and unavoidable losses of the special alloys take place, due to the oxidising conditions present, so that large excess is always added to allow for this. From time to time the melter examines the steel by withdrawing a small quantity from the furnace by means of an iron spoon, and the steel is not cast until it is quite sound and at the right temperature. The composition of the steel is controlled by taking samples and analysing as often as necessary, suitable additions being made to bring the steel to the right analysis. A few of the advantages of electric steel over other steels are as follows:—

1. The chemical composition of consecutive heats, most notable when handling easily oxidisable metals like vanadium, chromium, silicon and manganese, can be held more closely to a standard than with any other process.
2. Successful heat treating is improved accordingly as composition can be controlled.
3. Electric steel is usually chemically purer than any other steel.
4. The segregation of sulphur and phosphorus are not to be feared as they are practically absent.
5. Low sulphur in electric steel usually indicates a prior reducing condition favourable to complete deoxidation, sound ingots, freedom from blow-holes and resulting seams.
6. Alloy additions may be made in the furnace itself rather than in the ladle, which increases the probability of thorough assimilation, diffusion and homogeneity.
7. Results indicate that electric steel is less easily injured by overheating than other steels. It has a wider heat range, will withstand variations in forging and heat treating without injury.
8. Electric steels are always free from slag and non-metallic inclusions than Bessemer and open hearth steels.

For the production of castings the electric process has very many advantages over other processes. The electric process is the only one of all processes of steel making where the temperature can be controlled at will, and the metal can be got as hot as required for the particular kind of casting being made. As all electric furnaces are capable of being tilted, it is not absolutely necessary to pour all the steel from the furnace into the ladle at once, and if required only a small quantity need be used at a time. When working any other process with, say, 2 or 3 tons of steel, the whole of

Electric Steel Furnace.

the steel must be poured into a ladle from which the casting is done by taking small quantities in small laddles from the larger ladle. It will be perfectly obvious with this way of working that the steel first used will be very much hotter than that used when the ladle is nearly empty and the steel has had time to cool. The importance of correct casting temperature cannot be over-estimated, particularly when large numbers of the same type of casting are being made and where uniformity is vital.

One may sum up the advantages of electric steel castings as follows:—

1. Great purity of steel and consequently no segregation of impurities.
2. Good, clean castings, due to correct casting temperature.
3. Freedom from blow-holes, giving sound castings.
4. Increased toughness, due to the almost complete absence of dissolved gas in the steel.
5. Castings of any composition can be made.

Oil Fuel for Ships.

At a recent engineering exhibition held in London, many forms of oil burners for marine and land purposes were exhibited, thus reflecting the rapid progress which has been made in converting coal-using British ships to oil burning. The pre-eminence which British engineering firms have secured in this field is illustrated by the fact that a large French liner has been equipped with oil burners by a British firm which, by the way, began its experiments in oil burning no fewer than 40 years ago. A special feature of the equipment is the means taken to ensure so efficient a mixture of oil and air that combustion is complete and the furnaces remain perfectly clean.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

DULL BUSINESS WEEK—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—ELECTRICAL GOODS—PREMIER ON RAILWAY POSITION—RAILWAY EARNINGS FOR WEEK ENDED SEPTEMBER 17—WHITE'S CEMENT CO. AND CRUSHING RAILWAY RATES—UNION'S IMPORTS AND EXPORTS. JANUARY-JULY, 1920-1921—OIL FUEL IN BRITAIN—UNION'S £5,000,000 LOAN—LATEST METAL QUOTATIONS.

General Review.

The past week, being the last in the month, has, as is usually the case, been a poor one as regards business activity. August, like its predecessors, started well owing to the demands from the mines, and showed indeed better promise of improvement than has been witnessed for many months, merchants being fairly busy during the first week or ten days. Business, however, gradually slackened off and left things much in the same position as before. Owing to the depreciation of prices the total of sales is very small—probably about one-half for the same amount of material disposed of as compared with the corresponding period of last year. The general business outlook at the moment is not too bright, nor has the position been improved, but rather the reverse, by the recent speech of General Smuts on the financial position of the country in general and of the railways in particular. As a matter of fact, there has been a feeling of depression this week in commercial circles, contrasting greatly with the optimism ruling about a fortnight ago. The financial stringency appears to be as acute as ever, and is apparent in every direction. In former times the farmer could and did come to the storekeepers and obtain six to twelve months' credit. To-day he is unable to obtain these facilities because the storekeepers have to pay cash for what they buy, and are therefore unable to accommodate their clients as heretofore. The banks to-day are not encouraging speculative business of any kind whatsoever, and business everywhere is languishing. The present commercial atrophy may, however, be relieved to some extent when the £5,000,000 loan now being raised in London shall have been effected and diverted to the purposes intended, viz., to develop as far as may be our railway and harbour resources, irrigation and P.W.D. works throughout the Union. At any rate, this loan (which is understood to be the first instalment of a much larger one) should be a good "kick-off." There are no especial reductions in material to report (apart, of course, from forced liquidations). Stocks are being gradually reduced and getting to normal, and very few merchants are at present indenting. In the opinion of one authority this country will, within a month or two's time, be short of goods for a period, which will have a stabilising effect on prices. The general opinion is that no big revival in general business here can be expected until conditions in Europe become more settled. Merchants say that business (turnover) is undoubtedly better than it was, say, three to four months ago, but this means only that to-day goods can be realised at a price, whereas previously they were unsaleable at almost any quotation. But the present sacrifices! Next week's Jewish holidays are also tending to depress things. Altogether the past week's activity has been characterised by extreme dullness.

Iron and Steel.

The volume of business transacted during the past week has been exceedingly small. On the Commercial Exchange there have been further forced sales at prices below standard. The improvement noted in the early part of last month has quite vanished, and the financial pressure seems to have become more acute. With few exceptions, however, merchants anticipate a turn for the better about the end of the year.

African Iron and Steel Products Co., Ltd.

We understand that Mr. W. Martin, late resident engineer of the Simmer Deep, has been appointed business manager, and Mr. D. R. MacLachlan secretary, to this company. The organisation of the company is proceeding apace and things should shortly be running smoothly. One of the directors remarked that the Government are very keen about the establishment and development of iron and steel industries in the Union, but said that deeds rather than words were necessary if the Government were really anxious to establish such industries which mean so much to the country. A little more sympathy, he said, is required on their part.

The Board of Trade Journal predicts large developments in the production of pig iron and steel in the Union, which it thinks will lead to an industrial revolution in South Africa. The conditions in the way of skilled European labour and the low standard of unskilled labour may, in its opinion, limit our advance for a time, but our development should

go on increasing gradually. But, as pointed out by Dr. H. J. van der Bijl, the expert adviser to the Government Board of Industries, such development must be built upon sound foundations, and must be built upon the country's own resources. Melting down scrap was, on the face of it, unsound, and it was impossible to establish a big iron and steel industry in this country upon such insecure foundations. Dr. Van der Bijl pointed out the three essentials requisite for the making of iron: (1) the iron ore; (2) coal that could be coked; and (3) the flux. All three the Union possesses in abundance in the Pretoria, Rustenburg and other districts of the Transvaal, in Natal (Newcastle and Dundee), and in the Cape Province. The Transvaal and Natal deposits are close to coal measures where a good coking coal is mined close at hand. For flux, dolomite, and even the poorer limestone are found in the immediate neighbourhood of the iron ore beds. In Mr. Van der Bijl's opinion there was no reason to assume that the unskilled whites of this country, judging from past experiments by the Pretoria Iron Works and the Union Steel Corporation, Ltd., Vereeniging, among others, were lacking in ability. As far as native labour was concerned, he said it had been proved on the gold mines that the native could be trained to do fairly complicated work without much difficulty. The great trouble, of course, was their habit of leaving at short intervals and others having to be trained in their place. But practically the only great difficulty was capital. The erection of an iron and steel-producing plant is an expensive matter, but if that were surmounted he saw no reason why a steel works should not be able to supply South Africa with the (approximate) 200,000 tons of rough iron and steel manufactures which we are at present importing, and saving thereby about £1,500,000. He thought a further 50,000 to 175,000 tons could be absorbed annually by local manufacturers, such as agricultural, mining and railway machinery, pipes and pipe fittings, galvanised iron, etc. Coal and iron were the foundation not only of an iron and steel industry, but was the key industry upon which many other industries would be built. Cheap iron and steel would benefit the whole country in many ways at present unrealised.

Engineering Shops.

There is nothing new to report this week; business remains fairly good, and the tendency, judging from recent inquiries, is towards gradually improving conditions.

Surplus Brass War Stores.

Negotiations between the Government and the British Metal Corporation are proceeding regarding 180,000 tons of brass surplus war stores.

Timber and Building Materials.

Business, in the continued absence of any forward move in building operations, has been quiet this week. The biggest drawback at present to increased activity in this direction is of course the prevalent financial stringency. Merchants are unanimous that as soon as money becomes easier, with the accumulated arrears of building to be made good, a very busy time should be witnessed here. 3 x 9 deals are ruling at 1s. to 1s. 1d.; scantlings, 1s.; floorings, 7d. to 7½d.; ceilings, 5½d. to 5¾d.; beaver board, 5d.; pitchpine, 8s. to 8s. 6d.; Oregon, 7s.; corrugated iron, 24 ft. gauge, 9½d. to 10d.

Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality 14s. 9d. for second at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 3d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per eub. ft. at the mills; Honduran mahogany, 30s. per eub. ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks, in the absence of any activity in the building trade, are unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag; blue lime, 3s. 9d.; blue plaster line, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 37s. 6d., 47s. 6d., 55s. 3d. for 1 to 3-ply.

Second-hand Iron and Timber Yards.

Owing to the Jewish holidays next week business is rather quiet, with, however, a good undertone. Prospects are now brighter than they have been for many months. Iron is 5d. to 6d., timber 10d. to 1s., with a firming tendency. Dealers in second-hand material report that the only drawback to increasing activity is the continued financial stringency, which is causing would-be builders still to hang back, pending more favourable conditions.

Electrical Goods.

Dealers report that more inquiries are coming to hand and that the tendency of business is decidedly better, although failing any great activity as yet in the building trade, orders are not very numerous. Prices generally remain much about the same, but it is generally expected that the present month will see some further declines. Electrical materials are arriving regularly from Britain, America and the Continent. Trade at the moment with Germany is rather slack, but orders in one or two lines for that country are still being taken. Of course, wherever the raw material for wares cannot be obtained in Germany and has to be obtained from the Allies, the price of such goods is going up, but where indigenous to that country, quotations are conversely much below other competitors, particularly with regard to porcelain manufactures, where the price is very low indeed.

The Premier on the Railway Position.

General Smuts, in replying to the deputation of civil servants which waited on him last week in Pretoria regarding the extinction of the war bonus, made a masterly though gloomy survey of the general financial position of the Union. In regretting his inability, in face of the grave financial position of the country, to be able to accede to the withdrawal of the war bonus, he referred, *inter alia*, to the most vital of the public services—the Railways. The Premier said that for years past the administration of the railways had resulted in deficits, which had accumulated by the end of last year to £2,500,000. Although railway rates had been continually raised, the expenditure on railway services had risen more rapidly. The revenue had fallen far below the estimated figures, and from April 1 to September 10 had declined approximately £500,000 below the estimate. During the first four months of the financial year the railways had built up an additional deficit of £737,000. If one compared the position to-day with that in pre-war times, when the railways showed a surplus and were one of their finest assets, one could see the parlous plight in which they were. The total expenditure for this year was estimated at £28,348,000 as against a total expenditure for 1913-1914 of £14,491,000, showing an increase over the war period of £13,800,000, or 95 per cent. Of this increase £7,250,000 represented salaries, wages and allowances, apart from cost of living allowance, since the beginning of the war. The cost of living figures were £2,900,000. Increased cost of stores and material amounted to about £3,000,000. Much of the item of £7,250,000 was attributable to the introduction of the universal eight hours day. They could not contemplate indefinitely raising railway rates. The increase as compared with pre-war rates was approximately £7,000,000. They were coming to a state of affairs in the country when railway traffic would not bear any further increase in rates. On the contrary, remissions had to be made, more especially in connection with the coal traffic, without which certain foreign markets which South Africa could supply would be lost, and even with such remissions they were losing the coal market to a large extent. Railway rates could not be raised beyond a certain limit, especially in a time of depression, when produce prices had fallen without killing traffic. If they were raised, foreign markets could be cut off and things brought to a standstill. General Smuts pointed out that, after the abolition on the railways of the remaining 50 per cent. of the war bonus, the position of the railwaymen would still be much better as regards substantive pay than it was in pre-war days.

South African Railways and Harbours Earnings.

These during the week ended September 17 were £407,746 as compared with £454,008 during the corresponding week in 1920. The total earnings from April 1 to September 17, 1921, were £10,036,251 as against £10,583,705 last year. The revenue from harbours during the week ended September 17 was £21,215, against £32,749 during the corresponding week in 1920. The total earnings of the harbours between April 1 and September 17 amounted to £472,727 compared with £673,143 during the corresponding period of 1920.

White's S.A. Cement Co.: Crushing Railway Rates Crippling Cement Industry.

Mr. William Pott, the chairman of this company, at a meeting at Ventersburg Road last week of the employees met to talk over the position of the concern, explained why it had been necessary to curtail the company's operations and consequently reduce employment. Mr. Pott said that for months past they had been manufacturing more cement than they could sell, caused principally by German and Continental cements being delivered at coast towns cheaper than their company could deliver it, because while freight from European ports was 17s. 10d. per ton, their railrage for 446 miles was 41s. 10d. This rate, due to the absurd railway labour demands, is, he said, iniquitous and is killing local industries such as theirs. The railway labour bill had increased 181 per cent. since 1912, and £10,000,000 a year more is paid for no compensating gain of revenue. The second cause was the altogether inadequate protective duty levied on British and Continental cement of 5s. and 6s. 3d. respectively per ton. Other local industries had the benefit of a duty of from 15 per cent. to 20 per cent. ad valorem as against their less than 7 per cent. He hoped that if the Government, either by a reduction of railway rates—which to-day are 250 per cent. higher than pre-war rates—or by increase of duty against Continental cements, would assist in restoring trade, the company would be able to resume normal manufacture. A committee of employees was appointed to consider the retrenchment scheme proposed by the company.

Union's Imports and Exports, January to July, 1920-1921.

The comparative totals for the seven months, January to July, are as follows:—Imports, 1921 £30,985,347, 1920 £49,768,378; exports, 1921 £31,214,228; 1920 £52,970,712. The factors in the big fall in values of export are that the value of diamonds fell by seven millions compared with last year; wool by 10 millions; 3 millions in hides and skins; and 2 millions in gold. With regard to imports, the more noticeable declines were 3½ millions in cotton manufactures, 1 million in iron and steel, 1½ millions in hardware, cutlery and leather goods, and 1½ millions in motor cars and motor cycles.

Oil Fuel in Britain.

As illustrating the development of oil fuel for many purposes in Great Britain, large storage depots are being constructed at various points. In one of the latest, on the Tyne, there are two tanks of 8,000 tons capacity each, together with one of 4,000 tons capacity, forming the first instalment of a very large depot. The tanks have been erected near the jetty, with which they are connected by means of pipe lines, and vessels requiring supplies of fuel will berth in deep water alongside the jetty. Following on this development in oil storage, there is at present a remarkable advance in the production of oil-engined ships in British yards, and some of these oil-propelled steamers have achieved most marked economic results in working.

Union Loan.

London announces the successful flotation of a 6 per cent. Union of South Africa Loan of £5,000,000 at the price of 96 per cent., redeemable in 1940, for the purpose of railways, harbours, irrigation works, land settlement and other public works. The "Morning Post," in referring to the loan, considers that it will be a most attractive one.

British Engineers & Shipbuilders: Withdrawal of War Bonus.

The negotiations between the engineering and shipbuilding employers and men on the question of the withdrawal of the war bonus on October 12 have broken down. The intervention of the Minister of Labour has been sought to prevent the dislocation of industry.

Cornish Tin Mines Closed.

In consequence of the industrial depression, it has been found impossible to work at a profit, and every Cornish mine has been closed down. The mines are now being flooded, and the miners are starving.

Reported Gold and Silver Discoveries in America.

It is reported from Los Angeles that the gold strike in the Santa Monica Mountains, Southern California, is a very rich one, yielding, it is said, £15 to the ton. There are stated to be millions of tons of this high-grade ore. A rich silver-bearing area is said to have been discovered in the Yukon 1,000 square miles in extent, assays of which vary from 200 to 700 ozs. to the ton.

Metal Market.

Latest London quotations: Standard copper, £67 16s. 3d. cash, £68 11s. 3d. forward; electrolytic copper, £72 cash, £74 forward; Straits tin, £156 6s. 3d. cash, £158 6s. 3d. forward; English lead, £22 15s. cash, £22 10s. forward; bar silver, 41½d.; and fine gold, 110s. 9d. per oz.

DAVIS-MADE MEANS HIGHEST GRADE.

**HERE IS THE
DAVIS - BIRAM
ANEMOMETER.**

It is constructed on the principle of the revolving fan, and offers several advantages over its predecessors. The air enters, as usual, from the back of the instrument, and instead of passing in a straight line through the protecting ring, is deflected outwards by a cone through port-holes. The friction of the air passing through the instrument to the outer air is practically nil. So constructed, it is possible to bring the instrument in front of the operator, and experiments have proved that, if held 18in. from the body, there is no hindrance to the free current of air, and that the accuracy of the readings is not interfered with. Thus, what was previously considered impossible has been achieved. The Davis Biram Anemometer has several other distinct advantages which places it ahead of all others. May we send you full particulars?

CONDENSITE CELORON.

A Remarkable Waterproof Insulation Material.

CONDENSITE CELORON, made from a fabric base or a base of Diamond-Fibre (genuine vulcanized fibre), thoroughly impregnated with water-resisting Condensite, possesses the high dielectric properties of the well-known Condensite products, together with the physical properties of Diamond-Fibre.

CONDENSITE CELORON for insulation and insulating parts is especially valuable for service under damp or moist conditions. It will not warp, shrink or swell through exposure or age. It can be readily machined and is therefore adaptable for many purposes. It is insoluble in all ordinary organic solvents.

CONDENSITE CELORON is made in sheets, rods and tubes. From these are machined panels, frames, bases, spool heads, coils, handles, levers, wireless apparatus and innumerable other insulating parts. **CONDENSITE CELORON** is also used for noiseless gears.

Diamonds in Arkansas.

Diamonds are not usually enumerated among the products of the United States. From a correspondent of *The Literary Digest*, Miss Ruby E. Livingston, we are in receipt of the following information regarding the Arkansas diamond field: "From the surface of the ground, with the crudest of working materials, already more than 2,000 diamonds have been taken, submitted to every known test by diamond experts, and pronounced the equal in quality of the diamonds of South Africa. The diamonds have also been worthy of note in size, the largest weighing eighteen carats. This stone was found on top of the ground. The field of peridotite was discovered some thirty years ago by Dr. J. C. Branner, then State geologist, later president emeritus of Leland Stanford University, and now a resident of Arkansas; but no diamonds were found until a few years ago. An effort was made to interest London financiers, who agreed to help in developing the field, provided that they were given controlling interest; this the Arkansas promoters refused, for fear the field would be kept closed until the South African supply is exhausted. Recently, London bankers have financed a 10,000,000-dollar corporation; modern machinery, identical with that used at Kimberley, has been installed, being completed in October, and work has begun in earnest. I recently had the pleasure of holding in my hand a rare canary diamond in the rough, which would cut about two carats, which had been found by one of the officials in September. As to their abundance, we can only conjecture, but a diamond mine gets better with depth (?). John T. Fuller, former manager of the Du Toit Pan Mine, of the De Beers Consolidated, Kimberley, in his report of the field, says: 'We may therefore, with a large degree of confidence, expect to be limited in depth only by economic and engineering conditions, and not by a failure of continuity of deposit.'

The British Manufacturers and South African Technical Education.

Mr. W. G. Wickham, H.M. Senior Trade Commissioner in South Africa, has done an excellent service to education in this country, and possibly an even greater service to British industry, in his report to the Department of Overseas Trade for last June. He draws pointed attention to the fact that very important developments, particularly in regard to University education, are in progress in this country, and says that in the case of both the new Cape Town and Johannesburg University buildings excellent opportunities are afforded to British manufacturers of being first in the field with donations of apparatus, machinery, and other equipment for scientific work and engineering training. "There is," he writes, "probably no form of advertisement—to put it on its lowest plane—so remunerative as making sure that the rising generation of chemists and engineers are taught as household words the names of the makers of plant and apparatus, Optical instruments, laboratory supplies, assay apparatus, testing machines and in-

struments, engines, machine tools of all kinds, all find a place in such educational institutions, and the makers of such who are fortunate enough to obtain a place for their makes in college laboratories have an obvious advantage over their rivals in all succeeding years, as young chemists and engineers go out into the world with the names of those manufacturers as familiar as those of standard editions of Greek and Latin authors are to classical scholars. On a higher plane it may be said that special scope for generosity is afforded by these institutions, and it is to be hoped that the excellent precedent of recent gifts of machinery towards technical education in Nottingham will be followed in the case of South African Universities and other educational institutions throughout the Dominions. It is indeed lamentable to find instances of British manufacturers demanding the full retail price for such equipment . . . when American and German manufacturers are presenting their makes free of charge.

The Museum of the Union Geological Survey.

BRIEF DESCRIPTION OF THE WORK OF THE SURVEY AS EXEMPLIFIED IN ITS VALUABLE COLLECTION OF MINERALS, ROCKS AND FIELD MAPS.

The following account of the Geological Survey's valuable and interesting Museum at Pretoria has been specially written for this journal, as the result of a visit paid by our representative.

The Geological Survey Museum forms the Department of Geology and Mineralogy of the Transvaal Museum, and is accommodated in a single gallery, 115 x 60 feet in size, forming the first floor in the northern wing of the New Museum in Market Street, Pretoria.

Systematic State-aided geological investigation in South Africa began in 1895, when the late Geological Commission of Cape Colony was instituted. This was followed almost at once by the appointment of a State geologist to the South African Republic. In 1902, when the Geological Survey of the Transvaal became organised, a substantial nucleus of the present collection of minerals was already established.

About the same time arose the Geological Survey of Natal and Zululand, which was maintained for several years, and gave a further impetus to the investigation of the mineral resources of South Africa.

Owing to the gradual extension of field work and the increasing number of donations from mining men and others, the material brought together at Pretoria began to increase at too uncomfortable a rate for the limited space available. As a result of Union, the Geological Commission of Cape Colony and the Transvaal institution became merged into the Geological Survey of the Union, with Pretoria as its headquarters. The survey of Natal and Zululand had ceased a few years before Union.

New Accommodation.

The necessity, since this amalgamation, of illustrating the stratigraphy and mineral resources of the several provinces severely accentuated the lack of exhibition space in the old building, but the difficulty was solved by the completion of the New Museum Buildings in Market Street, to which place the offices of the Survey and its collection were transferred in 1913.

The main objects of the collections are to illustrate as fully as possible the geology and mineralogy of the Union, including the leading characters of its different formations, as well as the various occurrences of economic mineral deposits and examples of articles manufactured from them. In short, the ideal is aimed at to build up a complete museum of theoretical and applied geology.

Some Uses of the Museum.

The value of an institution of this nature to the prospector and student of geology need hardly be mentioned. It furnishes the former with examples of all the minerals occurring in the country, and the forms in which he is likely to find them when in the field. Very often valuable mineral occurrences are passed over simply because they may be obscured by some external cause unknown to the prospector. As an example of this nature may be quoted the number of different rocks which contain gold from the northern and eastern Transvaal. The student of ore deposits is well aware that there is nothing so instructive as having a particular deposit represented by a large series of rocks for comparative study. In this connection a special collection (comprising some 500 exhibits) represents the stratigraphical series arranged in order of age and drawn from all parts of the Union. In another collection the minerals are arranged in the order in which they are mentioned in Dana's Mineralogy, and form an exceedingly valuable collection for comparison when identifying unknown minerals.

Geological Survey Maps.

The many maps published by the Geological Survey are arranged in continuous series on the walls, and furnish valuable evidence of the field relationships of many ore deposits. The boundaries of all the formations are shown, and prospectors can obtain valuable information regarding the localities where certain minerals are most likely to be found. Photographic enlargements of views of particular geological and mining interest are also arranged around the room.

Collections of special interest from their economic point of view are arranged in the following groups:—

Precious Metals Deposits.—Gold Reefs, Diamonds, Diamondiferous Deposits, Precious and Semi-precious Stones.

Base Metal Deposits.—Ores of Silver, Copper, Nickel, Chromite, Cobalt, Lead, Zinc, Mercury, Manganese, Antimony, Arsenic, Iron, Tungsten, Molybdenite and Vanadium.

Non-Metallic, Earthy Deposits, etc.—Fluorspar, Felspar, Monazite and other rare earth minerals, Kaolin, Kieselguhr, Phosphates, Glass Sands, Asbestos, Corundum, Cement-making raw materials, Ornamental and Building Stones, Gypsum, Salt Deposits, Mica, Magnesite, Saltpetre, Coal and Oil Shale, Graphite, Moulding Sands, Barytes, Limestones, and Tale.

Some Special Features.

Some outstanding features of the collections are the corundum and asbestos exhibits to be seen. The former mineral is represented by several hundred exhibits, including

ruby-coloured and sapphire-coloured corundum. South Africa now includes the largest corundum fields of the world (some 1,800 square miles in the Zoutpansberg District and south of Leydsdorp), and their output between 1912 and 1918 rose from 111 to 3,875 tons. Here may be seen many commercial samples of crystal, boulder and reef corundum ranging from a fine gravelly deposit up to the tremendous crystal weighing 335 lbs. from the neighbourhood of Leydsdorp.

Asbestos is well exhibited by some 110 specimens, which demonstrate the three principal varieties, namely: Cape Blue or crocidolite; Amosite, a new variety from the Lydenburg and Pietersburg district; and Chrysotile from Carolina, Barberton, etc. The visitor is immediately struck by the magnificence of the exhibits representing the three varieties, and more especially the last named. An example of this kind from Kaapsche Hoop in the eastern Transvaal has the remarkable fibre length of $4\frac{1}{2}$ inches.

The mica exhibits from Leydsdorp also form an exceedingly interesting collection. The district produces a very fine quality of muscovite.

Industrial Exhibits.

Various industrial activities such as the manufacture of cement, brick and pottery works, and glass manufacture, are represented by well laid-out specimens of the raw materials used in each case as well as the various stages passed through and the final products obtained.

To further aid in the industrial development of this country a corner of the museum has been walled off where the enquirer can examine his mineral or rock undisturbed, and, if he so desires, carry out some simple tests. A small collection of the commoner minerals for the public to handle and examine is also provided. The publications of the Geological Survey and a bibliography of mineral resources are

also available for consultation. The museum also provides facilities for the assaying and analysing of minerals at a moderate charge.

An object of historic interest to the mining world which strikes the visitor on entering the museum, is a primitive ore grinding mill. It was used at the Erstelingen Gold Mine near Pietersburg in 1868, and consists of a huge dolerite boulder weighing 1,100 lbs. This boulder was placed on a natural rock foundation, and ore crushed by placing it under the boulder and rocking it to and fro by means of iron bars secured in the boulder. The rocking motion crushed the ore between the boulder and stone floor.

A complete and appropriate description of the work of the Geological Survey as exemplified by the Geological Museum is a most difficult if not impossible task. To those who are interested in the immense mineral wealth of South Africa a trip to the Capital would be amply repaid by a visit to the Geological Museum.

American Trade Increasing.

The foreign commerce of the United States, both exports and imports, is on the increase, according to cable advice to the American Trade Commissioner, Mr. P. J. Stevenson, from the American Department of Commerce at Washington. August exports to British South Africa were \$1,600,000, an increase of \$200,000 over July, while imports from British South Africa were \$355,000, a drop of almost \$100,000 as compared with July. Since imports on the whole are increasing, the effect on trade with South Africa should soon be reflected in the statistics. The general tone of business has been quiet during September, with wage reductions still continuing. Conditions in the steel industry have been marked by sagging prices and a slight improvement in production.

Cornish Miners for the Rand.

THE QUESTION OF PRE-DISPOSITION TO MINERS' PHTHISIS—PRELIMINARY EXAMINATION IN ENGLAND.

Last week the Minister of Mines and Industries received a deputation from the Cornish Association of the Transvaal, consisting of Messrs. A. Gribble (president) and W. Jenkin (past-president). There were also present Sir Robert Kotze (Government Mining Engineer), Dr. Watkins Pitchford (Director Phthisis Medical Bureau), and Mr. H. Warrington Smyth (Secretary general Department of Mines and Industries).

The deputation presented the following memorandum relative to the medical examination of miners overseas:—

"May we draw your attention to a serious matter arising out of the application of the present Phthisis Act?"

"It is provided that no person may be employed underground in a schedule mine who, in the opinion of the Phthisis Medical Bureau, is suffering from a disease of the respiratory organs, or whose general health," etc.

"With the Act, or the Medical Bureau's interpretation of the clause, we have no quarrel. On the contrary, we endorse the principle and the Bureau's decisions.

"The matter which we wish to bring to your notice is that miners are arriving in South Africa and coming to the Witwatersrand who, after presenting themselves for examination by the Medical Bureau, are informed that they have failed to pass the necessary standard of health required by the Act, and consequently may not work underground in a schedule mine. These men are then faced with the problem of how to exist, and, in many cases also, how to support their wives and families. Their small capital spent in the expense of travelling, they are dependent on their friends or charitable organisations; subscriptions lists may be opened, and they eventually return to England, broken in spirit and penniless.

To Obviate Hardships.

"To obviate these hardships we suggest a medical examination overseas by doctors approved by the Medical Bureau, Johannesburg. The Director might arrange with one of the London hospitals—say St. Thomas's—to make the examinations, the Bureau supplying specimen X-ray photos of the minimum standard acceptable at Johannesburg, and also a diagnosis of general health, certificates granted by the London hospitals to be subject to review by the Bureau at Johannesburg.

"But we suggest that, in the case of unsatisfactory review, the applicant be granted a six months' provisional certificate by the Bureau. We think that the percentage of unsatisfactory reviews would be small, and that in any case the defect would not be tuberculosis.

"Consequently the Bureau, in granting a certificate, would not be prejudicing the health of the holder's fellow-workmen. The six months' period would allow of his earning the return passage money or making some arrangement for the future. Several instances have come to our notice of men being accompanied by their families; consequently, in these cases there are three or four or more persons to repatriate.

"The reports of recent speeches made at mining company meetings regarding the efficiency of miners have been published in Cornish papers. There are some 4,000 unemployed miners in Cornwall, and naturally the men, on reading the reports, are fired with a desire to go to South Africa, especially as in some of the mining news reports there were suggestions that they would be welcome.

Association's Duty.

"We do not wish to be a party to preventing miners coming to South Africa, but on the other hand it is our duty as a county association to warn our fellow-men of the possibility of not only being unemployed, but unemployable. The Cornish Associations of London, New York, Boston,

Detroit, South Australia and Vancouver will be notified of any arrangements made. In asking for your favourable consideration of the suggestion, at your earliest convenience, we would point out the urgency and seriousness of the matter.

"For the purposes of this suggestion a miner may be any person employed underground. The suggested examination may apply to any person proceeding to South Africa with a view to employment in the Witwatersrand mines."

After discussion, the Minister expressed his acceptance of the memorandum in principle, with the reservations that the examination must be voluntary on the part of the applicant, that the expense of the examination must be borne by the applicant, that the examination must be regarded as preliminary to the examination at the Medical Bureau, Johannesburg, and that no certificate granted shall have precedence over the Bureau's certificate, and that the provisional certificate for six months is a matter for Parliamentary decision.

Further, the Minister promised that, on the Medical Bureau having drafted the procedure of the overseas examination, it should be forwarded to the association for distribution to the associated Cornish Associations and the Press.

Coal and Cheap Power.

Coal and the possibilities of its scientific use formed the text of the address given by Sir John Cadman to the Institution of Mining Engineers in mail week. The speech contained some valuable reminders. Ours, the new president of the institution told his hearers, is a coal civilisation, and coal, the foundation of Great Britain's manufacturing advancement, is still its mainstay. What of the future? In the opinion of Sir John Cadman, one of the prizes held before the Old Country by science, if bold enough to seize it, is "a smokeless Britain, possessing the cheapest power resources in the world." It sounds a tall order, but, on the other hand, while Germany before the War raised 70,000,000 tons less coal a year than Great Britain, she produced twice as much coke, 16 times as much patent fuel, and one and a half times as much ammonia sulphate. It is clear, therefore, that there is ample room for improvement, and that Great Britain is on the wrong road in thinking that lack of science, sense and care can be made up by Acts of Parliament. Sir John Cadman looks for the salvation of the industry to the mining engineer and the chemist. Legislation has already been overdone. In 1900 the British production was 290 tons a year per person employed, in 1913 it had dropped to 253 tons, and in 1920 to 183 tons. With fall in output went a falling off in grading and quality and a huge advance in cost. Reduction in output, increase of cost, fall in quality—these are not good omens for a "coal civilisation." Past mistakes, however, are beginning to cure themselves through their own consequences. Coal is a wonderful product, capable of being resolved into a hundred by-products of the widest usefulness in manufacture, and yet of being employed as much as now as a heat source. Past waste has been beyond calculation. There is no great point in complaining of hard times when the "mainstay" is treated in such a fashion. As to increase of output by the greater use of mechanical means and electrical energy, the progress, the president of the Institution of Mining Engineers thinks, will, if steady, be, in the face of prejudice, inertia and economic ignorance, slow. No doubt but the problems of coal are no longer looked upon with common indifference, and it is "up to" the mining engineers and chemists to show the way.

Natal Colliery Outputs. Flotation on Rand Gold Ore.

COAL AND LABOUR RETURN.

The official coal and labour return for Natal Province for August, 1921, is as follows:—

The Statistical Summary of the Mineral Industry of the British Empire and Foreign Countries.

Reliable information on the production, exportation and importation of minerals and metals is of very great assistance to mining men engaged in the flotation of mining companies. It furnishes statistics on what has been done in the past in the particular proposition with which they are engaged, and also shows how demand stands in relation to supply. The work under review very fully covers all the above points, and deals in detail with no less than 39 different minerals and mining products. The production, amounts imported and exported, by each of the leading countries between the years 1913-1920 are carefully tabulated. The statistics on gold production, etc., are very carefully set out and should afford valuable material for the student of the gold premium. It is interesting to note that the contribution of the Union of South Africa to the world's gold output has progressively increased since 1913 as follows:—South African percentage of total in 1913, 38 per cent.; 1914, 38.2 per cent.; 1915, 39.8 per cent.; 1916, 42.2 per cent.; 1917, 43.7 per cent.; 1918, 45.6 per cent. Although the annual gold production of the world has been falling since 1913, the South African output has not been falling at the same rate. This accounts for the gradual increase in the Union's contribution to the world's total. Other minerals dealt with in this work, and of importance to South African producers, are Asbestos, Chromite, Coal, Copper, Lead, Magnesite, Mica, Silver, Tale, and Tin. Copies of this valuable work are obtainable from H.M. Stationery Office, Imperial House, Kingsway, W.C.2.

Attention is directed to an article on the above subject which appeared in the September 3 issue of this journal. The article was based on a paper read before the Chemical and Metallurgical Society by Mr. F. Wartinweiler. A discussion by Dr. W. A. Caldicott on that paper throws further light on the subject of concentration practiced on Rand ore. An extract from the discussion is reproduced hereunder:—

Flotation concentration, as described in the previous article, produced the following concentration on pulp from the Ferreira Deep:—

	Gold value, dwts./ton.	Percentage Recover., by wt.	Percentage Recover., by value.
Cyanide pulp before flotation	2.4	—	—
Concentrate from pulp	36.2	5.81	87.5
Tailing from pulp	.32	94.19	12.5

In this case 87.5 per cent. of the gold in the pulp is accounted for in the concentrate, while by the old method of concentration only 31.8 per cent. was recovered.

Although the old method of treating gold ore tailing by means of concentration has long since died a natural death, in view of the much greater recoveries which can be obtained by flotation concentration, the subject becomes one to which considerable importance can be attached.

It is somewhat remarkable that so many years should have intervened before further progress, since early in this century the important subject of gold distribution in blanket ore products was investigated in some detail by means of other classification methods.

In considering the relative proportions of gold and pyrite separated by oil flotation, the fact that the author crushed all sand samples to pass a screen of 150 meshes per linear inch is of great importance, an effective oil segregation being thereby rendered possible of the gold and pyrite released from attachment to larger quartz particles. It does not, however, follow that the pyrite carried the gold, as galena does silver, in the original ore or sand grains, but merely that the fine crushing set free from the siliceous matrix many individual and separate gold and pyritic particles, and thus rendered the former available for amalgamation, or capable of separation together with the pyrite by oil flotation. This consideration is of great importance as it explains the failure of attempts in earlier years, accompanied by very large capital expenditure, to profitably employ, on blanket ore tailing, concentrators of the vanner and Willey type.

From a report by Messrs. W. Bettel and J. H. Johns, published by the Witwatersrand Chamber of Mines on 2nd September, 1896, upon concentration by vanners in the Ferreira Mill, the following results are calculated:—

Products.	% Pyrite.	Dwt. Gold per ton.	Dwt. Gold per 1% Pyrite
Tailing pulp before vanners	2.178	11.37	5.22
Tailing pulp after vanners...	0.825	7.75	9.39

Hence the vanners recovered 62.1 per cent. of the pyrite, but only 31.8 per cent. of the gold.

T.G.M.E. September Output.

The following are the particulars of the output for the month of September, 1921, in respect of the above company:—Central Mines: Tons crushed 12,00, yielding 3,470 fine ounces; Elandsdrift Mine: tons crushed 1,520, yielding 966 fine ounces; Vaalhoek Mine: tons crushed 1,925, yielding 726 fine ounces; estimated value of month's output, £27,998; estimated profit for month, £6,009. Note.—The month's results are based on value of gold of £5 8s. 3d. net per fine ounce.

Light in the Mine.

ITS BEARING ON ACCIDENTS AND REDUCED COSTS.

The mine casualty list is said to be on the up-grade during this present year. Moreover the economy in the use of stores is more pronounced than ever before on the mines of the Witwatersrand. Is it not just possible that there may be some connection between these two occurrences, that a too severe economy in the use of mine stores may conceivably lead to a heavier accident roll and as a consequence to an increase and not a decrease in the actual cost of mining? This is not by any means a plea for relaxation of control in the allotment of mine stores, nor for the issue of such stores without full and careful inquiry as to the necessity for such issue. It is more particularly the purpose of this article to consider whether, in the desire to cut down mining costs it may not be possible to proceed too far in such a direction and thus to defeat the end in view. We have all heard of the man who tried a restrictive diet on his horse and what became of it. It may be equally useful to consider whether in the matter of illumination the desire for economy has not resulted in an addition to, and not a subtraction from, the costs of mining.

Given that other things are equal, the better the light is the better is also the work performed. We all know that in fiery coal mines the need of safety lamps with their feeble lighting effects has resulted in the creation of a new industrial disease known as astygmatisis, an affection of the eyes which prevents miners from following their occupations. It was proved in Great Britain that where mines changed over from open lights to locked lamps the accident rate was also raised and that the cost of mining was increased; this was conclusively proved by statistics published by the Home Office; and it also affected the rates of pay given for coal cutting, a higher price per ton being paid to the collier when using safety lamps than when using open lamps or candles, because it was found that the earning power of the miner was directly affected by the absence of light in his working face.

There has never been a thorough investigation into the minimum amount of light essential to safe and economical working of the Witwatersrand gold mines. It is scarcely too much to assert that the adequate lighting of the mine has not figured in any inquiry relative to working costs. In most cases the prominent factor has been how to reduce the consumption of candles and carbide so as to make an apparent reduction in cost of stores, and this without any reference to the vital bearing on costs of the absence of a sufficient amount of light throughout the mine.

We hear much about organisation as applied to the working of the Rand mines, but where is the organising power which takes no account of the lighting factor in mine costs? As an actual fact it does not exist. Each mine is a law unto itself so far as its arrangements for lighting are concerned. We know that a co-ordinated plan exists for the watering of the working faces, etc., in each mine, and as this is enforced by statute it may be assumed that it is fairly efficient. Lighting is in even a worse plight at present. Owing to the causes referred to above, *i.e.*, the absence of statistical records on lighting efficiencies, the apparent conflict of good lighting with cost of working—it is only reflected at present in lower costs of candle and carbide—we have no evidence on record of the evils of our neglect of this matter. Indirectly, however, there is abundant evidence on the subject, and this of such a nature as to make the need of investigation a matter of urgency.

It would be very interesting to know, for instance, which mines are most and least economical in the consumption of candles and carbide. Coupled with this should be appended tables showing their relative accident records. Of course, one would necessarily allow for circumstances which would

operate in favour of or against any such mine—such as age of mine, its general layout, the amount of electric light installed, and such like.

One fact, however, stands out unchallenged, and that is the supreme importance of adequate lighting as a necessity for efficiency.

How many daily cases of minor injuries are treated in the mine hospitals, entailing a small expenditure in materials and possibly in time lost by the native labourer or possibly the white man? This time lost is a real addition to working costs, since the person injured does no more work for the shift in most cases, and there is always the disruption of the routine work, if only for a few minutes, but which in the aggregate is a factor in the actual working cost of the mine. The native with his candle, or sometimes a half-candle, is apt to overlook the element of danger due to his being unable to see clearly his surroundings. In the hammer gang he may have shattered and loosened rock above his head hidden from him in the darkness, his time is occupied with his task, the rock falls and he is injured more or less severely. The lashing boy cannot see clearly many yards around him, he himself is only a dim shadow to others. Without being in the least blameworthy, he may quite easily cause injury to himself or others through his being unable to see clearly the surrounding objects.

The tramping boy is very often the cause of injury to himself or others for the same reason. Coming along in the dark or with his candle throwing out a feeble beam, he is unable to see clearly what lies ahead of him. Usually he is lucky and pulls through, sometimes he is not; and then the resulting accident may incapacitate himself or others for a time. All these are routine cases which are considered inseparable from and incidental to mine work, and call for no comment from anyone, but are taken as a matter of course.

Inadequate light is further responsible for the fact of much time and labour being wasted in many directions owing to the need of concentrating several lamps or candles on an important piece of work, or perhaps because it is dangerous and light is essential to show a quick means of escape if needed. It is surely high time that special efforts were made to supply a better illuminant than the ordinary candle or carbide lamp. For one thing the extension of the arrangements already in force for lighting shaft bottoms, engine chambers, pump houses, and such like, should be extended very considerably. In some of the newer mines long stretches of main haulages are lighted, with manifest advantages to efficient working and comfort in travelling. What is wanted is the extension of the system to the working faces generally.

The cost need not be excessive in the first instance, and that is at any rate partly balanced by the saving in candles and carbide possible.

Cables could be run along the drives with coupling arrangements at convenient points from whence small cables coiled on drums to be worked by hand and with attachments on the cables at suitable intervals for lamps would radiate. These cables would be unwound at the commencement of the shift and be carried up through the stope face and connected where necessary. The lamps, suitably protected, would be attached, and in this way a flood of light could be obtained which would undoubtedly make for safety, comfort and efficiency of those workers concerned. If such a method were in operation there would certainly be a far better chance of detecting bad ground in the stopes and of minimising the risk of accidents due to the condition of semi-darkness of the workers. The working face could be examined more closely, likewise the hanging wall and the general state of the stope. If the miner were further furnished with an electric torch of suitable pattern, he would then be able to supplement the general examination of the working face by a particular examination of the hanging wall and thus, so far as is humanly possible, ensure the safety of himself and his gang. The drives would have sufficient lighting power to enable tramping to be carried on under the best possible conditions and with the least

fear of accidents. Similarly with regard to the lashing, timbering and waste packing gangs. One must not omit the fact of better supervising results, since the officials and supervisors would each be so much better able to see exactly what the workers were doing.

Altogether we may assert that the advantages accruing from a proper and sufficient supply of light would not only offset the actual first increased cost of installing the system, but would enormously increase the comfort of the workers, improve their efficiency, better the supervision, and reduce the accident rate very materially. The result of such a combination of improvements would necessarily be a reduction of working costs in the mine, and this would be reflected in additions to the profits of mining and in an extension of the lives of the mines of the Rand with mutual benefits to the workers, the shareholders, and the community.

W. H. JONES.

Accidents Due to Rock Falls.

G.M.E.'s VIEWS.

The following extract from an article appearing in *The Reef*, by Sir Robert Kotzé, is of special interest. The question of falls of hanging is one which has occupied the minds of mining men all the world over, and one which appears to affect Rand mining to a greater extent than mining in other parts.

During the year 1920 falls of hanging accounted for 582 accidents on the Witwatersrand and 161 deaths. The percentage death rate was 33·13 of all deaths, and represented 81 persons killed for every 1,000 employed as against a total death rate from all causes of 2·45 per 1,000. This class of accident therefore accounted for the deaths of one person out of every three who met their death by accident on the Witwatersrand mines. The next highest class, falls of material, accounted for 16 per cent., or 79 deaths, and the two together are the cause of half of the fatalities on these mines.

During the six months January to June, 1921, there has been a large increase in the number of deaths due to falls of ground, the total being 117 for the half year as compared with 161 for the whole of the year 1920. This alarming increase is fortunately compensated for by a reduction in the number of deaths from all other sources, but it draws renewed attention to the need for care in guarding against accidents from this source of danger.

An analysis of the time at which fatal accidents occurred is shown in the following figures:—

Time of Day.	Fatal Accidents.	Deaths.
1—6 a.m. inclusive	1	1
7 a.m.	2	2
8 a.m.	7	8
9 a.m.	10	10
10 a.m.	15	18
11 a.m.	12	14
12 a.m.	11	24
1 p.m.	10	26
2 p.m.	12	3
3 p.m.	—	—
4 p.m.	1	3
5—8 p.m.	—	—
9 p.m.	2	3
10 p.m.	1	1
11 p.m.	—	—
12 p.m.	3	4

The distribution according to the hour of day shows that most fatal accidents occur towards 10 o'clock in the morning. Accidents of which each causes the death of a number of persons are more numerous about noon. One is inclined to infer from these results that immediately after the early morning examination working places are comparatively safe, but that progress in movement in the hanging takes place. Within a few hours the danger has unnoticeably increased, leading apparently to the maximum of small falls about 10 o'clock, and later on to the maximum of heavier falls about noon or after. No doubt a further increase in falls takes place after that time also, but, owing to the gradual withdrawal of men from the working places, fewer persons are exposed to risk and the number of fatal accidents decreases accordingly.

In all mining countries falls of hanging account for more fatalities than other source of accident. The Witwatersrand is therefore not unique in this respect. But the Rand has on the whole such a good hanging in its mines that one would be inclined to expect that this source of danger would lead to fewer deaths than elsewhere. Such is by no means the case, for on the Rand the accident death rate from falls of hanging alone is more than half that from all sources in the most advanced European countries. Many reasons may be advanced for this unsatisfactory state of affairs, but on this occasion attention is drawn to only one, and that is the false sense of security into which persons are lulled by the very strength of the hanging.

Another example of the way in which one is easily lulled into a sense of security is instanced by what happens when systematic support is provided. This proves so safe that the hanging does not receive the close attention it ought to, and fatal falls take place which would have been avoided if such absolute reliance had not been placed on the systematic support.

The lesson to be drawn from all such occurrences, and one that is especially needed on the Witwatersrand, is the necessity for ceaseless and eternal vigilance. The piece of rock that may be sound or tight in the early morning may become, in the course of the shift, loose and dangerous owing to imperceptibly small movements and vibrations, and may come down unexpectedly a few hours after starting work. Therefore take no chances, but accustom yourself to look upon the hanging as an ever present source of danger which can only be met by constant carefulness.

Tenders for the purchase of the machinery, stores and equipment of the Kroonstad Coal Estate are being called for, and soon there will be no trace of the mine except the dump, which is not advertised for sale, but even that with a series of east winds will soon dwindle away, and nothing will be left except a few yarns and old tins to denote that a prosperous coal mine was ever in existence there.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

VIII.

By Arthur Stenhouse.

In 1887, as agent for Mr. Edward Lippert (the Dynamite Concessionaire), I had leased an old farm house on the outskirts of Pretoria for the storage of dynamite at a modest rental. Soon I discovered that there was a large quantity of this dangerous compound stored promiscuously all over the township, so I at once interviewed the Editors of the various local newspapers and described the situation. Next morning sensational leaders appeared in the papers pointing out the dangers of this proceeding. The "Kruger" Government became alarmed, and at once issued a proclamation that all dynamite must be removed beyond the town boundaries within forty-eight hours. I was prepared for this announcement, and notified the merchants that I would remove the dynamite in ox-wagons and store same in the magazine at a rental of half-a-crown per case per month. Promptly I obtained contracts, and transported the dynamite to the store. It was quite a payable proposition, and at the same time I probably saved the ancient city of Pretoria from total annihilation, and the citizens from sudden death! Years afterwards there was a terrible outcry in Johannesburg about this concession, so Mr. Lippert gracefully retired to his palatial mansion in Germany with about a million pounds in his pocket!

At this period of our history we must confess that the main portion of our time was devoted to pleasure. At Christmas time one of the "belles" of Pretoria graciously requested me to make arrangements for a dance. She said if I did so, all the girls in Pretoria would adore me! How could I resist such a pleasing prospect? At once I set to work, hired the Masonic Hall and got young Albrecht Jeppe to assist me. We engaged a one-legged man to play the piano, and "hustled" around generally. On the eventful night my pianist imbibed too freely, and we had to dispense with his services. However, charming ladies came freely forward, and the dance was pronounced a brilliant success! The true definition of happiness is to make other people happy, and our efforts were amply rewarded.

In the early days there was great excitement when the coaches, with their magnificent teams of ten horses, and with bugles sounding, raced into Pretoria. The excited population rushed to see if any of their friends were amongst the new arrivals, and to obtain letters by the incoming mail! A dense crowd assembled in Church Square to hear the latest news, and to welcome the new arrivals from all the centres, and when J. B. Robinson, Barney Barnato, Beit, Knight and other "big" Kimberley men arrived, their movements were carefully watched. Nearly everyone carried a piece of gold-bearing quartz in their pockets, and we were all prospective millionaires! A vivid contrast to the pessimistic tone prevailing to-day.

Pioneering undoubtedly has some compensations!

Gazing at the motley throng, I recalled the opening stanza of Shakespeare's poem on the seven stages of man:

"All the world's a stage,
And all the men and women merely players.
They have their exits and their entrances,
And each man in his day plays many parts."

Mining in the Outside Districts.

POINTS FROM THE REPORT OF MR. T. G. TREVOR, INSPECTOR OF MINES—VALUABLE REVIEW.

The following are extracts from the annual report of Mr. T. G. Trevor, Inspector of Mines, Pretoria:—

The general progress of mining work in this inspectorate during the year under review has been extremely satisfactory. The value of the mineral output increased from £4,130,688 in 1919 to £5,489,108 in 1920, being an increase of £1,358,420. For the purpose of showing the steady advance made by the industry since 1910, the figures for that year have been included in Section III. under the head "Mineral Output," and it will be seen that the value of the output for that year was £3,290,803, which was exceeded in 1920 by £2,198,305. From the above figures it is obvious that the mineral industry in this inspectorate is advancing steadily in the right direction, and the output for 1920 actually showed an increase of 67 per cent. over 1910, and this notwithstanding the closing down of the great Sheba Mine, the Worcester Mine, etc., and a decline in the output of the Transvaal Gold Mining Estates and several other fairly large producing gold mines. The increase in the mineral output is due largely, it is true, to the expansion of the collieries, but a most satisfactory feature is that in 1910 only eleven different minerals were on the production list, whereas to-day there are twenty. Formerly, very little, if any, attention was given to any minerals save gold, diamonds, or coal, and the general opinion was that the country had been thoroughly prospected and that no fresh developments were probable. The experience of the last ten years has completely negated this point of view. Several very rich, if small, gold mines have been discovered, mostly by accident and in places which were supposed to be worthless. The small attention which has been directed to the base metals and non-metallic minerals has been so successful that I have every confidence that in the future as more attention is paid to the matter the advance of the last ten years will not only be maintained for an indefinite period, but greatly excelled. In fact, the longer experience one has of this inspectorate the more optimistic one becomes of its future. It is a curious fact, however, that the discovery, exploitation, and proving of the value of nearly all the minerals placed on the list during the last ten years, or even twenty years, has been left to private individuals of no or very little financial standing, who have usually received no encouragement, but often have had very severe opposition to overcome before attaining success. It is astonishing to note what little success the big land companies and mining corporations have met with and of what little use they are in the initial stages of the development of any industry.

Gold.—The value of the gold output for the year under review was £569,229, being a decrease of £61,846. The decline of the gold output has been going on steadily during the past ten years, and a comparison of the output for the years 1910 and 1920 shows a decrease of approximately £290,000. However, the diminution has been gradual which is due to the discovery of new and payable mines. The output of alluvial gold remains stationary in the neighbourhood of £5,000 per annum.

Diamonds.—The value of the diamond output has increased by £902,834 over 1919 and by £1,079,842 over 1910. This is due to the increased price of stones, as the actual amount of ground washed is about one-fourth of what it was in 1910 and one-half of what it was in 1919. The output of alluvial diamonds has decreased slightly during the year, and is likely to decrease largely in the near future owing to the difficulty experienced in disposing of the stones.

Coal.—A great advance took place in the value of this output, an advance which will be considerably exceeded during the next year. In 1910 the coal output was valued

at £704,755, in 1919 at £1,380,271, and in 1920 at £1,712,603, being an increase of £1,007,848 and £332,332 over the years 1910 and 1919 respectively. Over and above the actual increase in production of the collieries, coal is now being opened over a vastly extended area in the high veld; good coal has been struck in boreholes in the North Waterberg and Zoutpansberg districts, showing that the extent of our coal measures is very much greater than is usually supposed. With regard to the coal in the northern Waterberg district, this to-day is valueless owing to its position, but the fields lie only fifty to eighty miles from the Rhodesian railway at Pala Road, and it is quite probable that in the future, either near or distant, the construction of a railway from Pretoria to the iron mines at Buffelshoek and its extension to connect with the Rhodesian railways may make this a national asset of great importance. For the fields will be approximately only 480 miles from Kimberley, as against Witbank at 427 miles, and 250 miles from Bulawayo, as against Wankie at 212 miles.

Coke and Tar.—For the first time for some years there was an output of tar, valued at £3,074, and of coke, to the value of £81. These only occurred in the latter months of the year and are an earnest of a regular supply in the future.

Copper.—Notwithstanding the fact that the Messina Copper Mine ceased production in May, the actual output was in the neighbourhood of £190,000. The above company is busy erecting a new plant, and it is believed that the above output will be maintained in the future, although everything depends on the price of the product, which is at the present moment below the economic limit of the mine. No new copper mines started during the year, but good developments are proceeding at Arton Villa, in the neighbourhood of Messina, which may in the near future justify the opening of a mine.

Tin.—The tin output increased from the value of £267,489 in 1919 to £439,823 in 1920, an increase of £172,334, and surpassed that of 1910 by £111,339. The recent great fall in the price of tin may, however, if sustained, cause a corresponding fall in the output for the next year. However, the present prospects, as far as the production of ore goes, are more favourable at Lecuwpoort than they ever have been in the past. At Rooiberg, Zaaiplaats, and Groenfontein, which may be described as hand-to-mouth mines, the prospects are just about the same as in recent years, though perhaps slightly more favourable. No new mines opened nor was any serious prospecting carried on during the year.

Lead.—The value of the lead output was £3,859, a slight increase over the previous year. There was, however, a great boom in properties containing this mineral, especially near Argent, where the Transvaal Silver Mines are developing their properties and equipping a plant on a basis of an output of 500 tons per month metallic lead. As this lead contains approximately 80 to 100 ozs. of silver per ton, this output, if attained, will add materially to the general value of the output of the country. In any case, whether that output is attained or not, it seems certain that the mine will be a success in a smaller way, and that a constant production of lead and silver may be looked for in future.

Corundum.—The output of corundum from the Zoutpansberg district received a rude shock at the end of the European War, when it appeared likely that there would be no future demand for it. It is, however, recovering in a most satisfactory, if gradual, manner, though the output for 1920 was only valued at £1,290. At the present time two responsible parties are engaged in organising a trade in this mineral both in Europe and America, and it appears to me certain that they will be successful and that a regular output of increasing value may be looked forward to.

Arsenic.—The production of arsenic remains constant at a value of about £660 per annum. The Consort Mine remains the only producer. Notwithstanding the demand for the mineral and all our inquiries, we have not yet been able to find a satisfactory deposit of this mineral in the country.

Magnesite.—There is still only one producer of this mineral, but the output increased from the value of £2,723 in 1919 to £3,780 in 1920. The iron companies at Pretoria, Vereeniging, and Newcastle have been inquiring for magnesite properties during the year, but though they have been unsuccessful, there is no reason to suspect that the properties at Kaapmuiden are not capable of supplying all their requirements.

Nickel.—Though there was no output of nickel ores, and though no further developments took place in the Rustenburg district deposits, a very interesting discovery of rich ore was made in a totally unsuspected locality in the Barberton district. This is now being developed, and, as the ore is exceptionally rich and very conveniently situated, it is probable that more will be heard of the discovery.

Graphite.—The Transvaal Graphite Mine in the Spelonken remained the only producer with a small output valued at approximately £2,400.

Mica.—The mica sales, which for the year 1919 were valued at £369, increased to £500. This is an earnest of a considerable improvement which is taking place both in the production and demand for this mineral, and I look forward to a considerable permanent increase in its output.

Talc.—The value of the talc produced remained constant at about £2,000. A new talc mine on the railway at Barberton has developed extremely well, and attempts, which there is reason to believe will eventually be successful, are being made to establish a trade with European markets. There is every reason to hope that this industry will take a permanent place on our lists.

Asbestos.—The asbestos output, which in 1910 was valued at £1,648, had increased in 1919 to £7,699 and in 1920 to £41,193. This extremely favourable result is, however, only the beginning of a great expansion in this industry. The Transvaal mineral (amosite) has now established for itself a recognised place both on the European and American markets. The deposits have developed extremely well and are capable of indefinite expansion. At present, however, the output is strictly limited by transport difficulties. As these difficulties are diminished by the approach of the railway, the output may be expected to increase step by step. It is satisfactory to note (4th February, 1921) that work is now being commenced on the railway extension from Lydenburg. During the year some new deposits, which appear very valuable, of chrysolite asbestos have been discovered in the serpentine underlying the Black Reef formation at the Kantoerberg. These are developing well and may be expected to add to the value of the output in the oncoming years.

Soda.—There was no output of soda from the Pretoria Salt Pan (S.A. Alkali, Ltd.) during the year, but continuous experiments have been going on in the hopes of discovering a process for its extraction from the material of the pan. So far as the natural liquor goes, a satisfactory process has, it is believed, been attained, though some details, more especially the drying on a commercial scale of the decahydrate produced, are giving trouble. It is only a matter of time before these questions will be solved and when an output of very great value will be added to the list.

Manganese.—There has been no output of manganese for the past few years, but the iron mines have secured properties capable of supplying all their needs as they arise.

Iron Pyrites.—Notwithstanding the increasing demands from the Sulphuric Acid Works, which now amount to over 1,500 tons per month, the production of pyrites did not increase, but remained stationary at a value of £5,000. I am confident that good deposits could be found if the gossan outcrops of the bushveld and Barberton areas were systematically opened. No attempt has been made to do this, and

it looks highly probable that we will not be able to supplant the importation of this mineral.

Iron Ores.—The preliminary blast furnace of the Pretoria Iron Mines ran quite successfully for the last five months of the year, producing 2,467 tons of first-class pig-iron. Mr. Delfos, managing director of the company, visited Europe with the idea of getting a certain amount of capital taken up in England and of getting some of the English iron masters interested in the venture. He was not altogether successful in his object, but he received sufficient support to determine the directors to proceed at once with the erection of a plant capable of smelting about 200 tons per day with an appropriate converter and rolling plant for the manufacture of steel. The high class iron ores which were discovered at "Buffelshoek," on the Crocodile River, some ninety miles north of Pretoria, have been acquired by the company. These ores have been geologically surveyed by Dr. Wagner of the Geological Survey, and proved to be of great size and extent, though not so extensive as was originally supposed.

Marble.—The development and exploitation of the marble deposits at Marble Hall still await the advent of a railway, but such work as has been done and all the information we have obtained about the stone is quite up to our most sanguine expectations.

Districts: Pilgrims Rest.—The mining industry in this district remains very much where it was and no perceptible difference is apparent, though the appearance of the country is altering in a surprising manner owing to occupation and tree-planting. Towards the end of the year a departmental committee was appointed to inquire into the water-power question at Sabie. The committee very strongly recommended that a hydrographic survey should be made by the Irrigation Department and the most attractive scheme put up for public tender.

Pietersburg.—Gold mining and prospecting is at an extremely low ebb, if not at an actual standstill. Mr. Ford, at the Ellerton, has an attractive prospect which may develop well and reattract attention to the district. The falling-off of the gold mines is, however, compensated for by the arrival of the asbestos and corundum fields, the output from which will be greater than any ever attained by the goldfields.

Barberton.—Gold mining now takes quite a second place in the economy of this district, its place having been usurped by the farming and citrus-growing industries. However, mining will probably continue on at least its present scale for very many years, for unexpected surprises, such as the Maid of De Kaap Mine and the asbestos mine on the Kantoerberg, continue to turn up and to compensate for those dropping out. The Sheba Gold Mine, after being closed down for some years, has restarted, and in the Zwartkoppies section extremely good ore has been discovered in a short continuation of the original abandoned development. The history of this mine is most extraordinary; every manager works it to a standstill and can discover nothing fresh, and every new manager finds fresh deposits or shoots which give it a new lease of life.

Wit. Deep September Return.

The estimate of results for the month of September, 1921, is as under:—Tons milled, 33,630; gold recovered, 9,717.039 ounces; average of stamps running, 180; stamps running time, 21,289 days; tube mills, 5. The working expenditure, including head office charges for the month, is £12,368, or 25s. 2d. per ton. The estimated working revenue based on an estimate of £5 10s. per fine ounce (less 1s. 6d. realisation charges) is £52,715 or 31s. 4d. per ton. The estimated working profit is £10,347 or 6s. 2d. per ton, from which is to be deducted the capital expenditure for the month of £1,976, leaving a surplus of £8,371.

The Week in the Sharemarket.

LONDON MARKET CONDITIONS IMPROVING—GOLD SHARES STEADY BUT QUIET—DIAMONDS SLIGHTLY BETTER—SILVERS DECLINE.

The market has been very dull and unattractive during the week. Gold shares are very quiet, though steady. Nothing further is known regarding the ex-enemy share question, and the price of gold remains almost unchanged. The September profits of the mines and the excellent annual reports published in our last issue have, of course, been discounted, and the market still awaits a lead from London. According to the latest cables from that side, although there is a general complaint as to the paucity of business, conditions are mending. Despite wide discussion of unemployment problems, there is no doubt trade is quietly and steadily improving. Moreover, the market is free of heavy liquidation. There is a brisk demand for the new Union Loan, which advanced 1 per cent. premium, finally closing at $\frac{1}{2}$ per cent. premium. Industrial shares were disturbed by the passing of dividends by prominent companies. Kafirs have been almost lifeless, but later were rather better on improvement in the price of gold and the absence of selling tendency. They further improved on Paris support and this offset the lower price of gold. Diamond shares fluctuated under Paris influences, but closed stronger. Rhodesian shares are quietly steady. Replying to a communication from the Stock Exchange with reference to the possibility of a return to the fortnightly settlements, Sir R. Horne, while sympathetic, declines to repeal the temporary regulation, but suggests that particulars should be obtained of the total pre-war account still open. That the turn of the tide has come for Government stocks is indicated by the announcement of the immediate issue of 5½ per cent. Treasury bonds at 98 instead of 97 as at present. The feature of the week on the local Exchange was the drop in Transvaal Silvers, which had been firmer on reports that smelting was about to start. Forced liquidation seems to be the cause of the present slump. Tin shares are easier, and Collieries a little better on the railway rate reductions. Two additions to the list under this head are Buffalo and Enyati Collieries, full particulars of which have already appeared in our pages.

SERVICE TO CUSTOMERS

OUR Engineers are always in close touch with our Customers, co-operating with them in securing maximum operating efficiency, in correcting sources of trouble, and in modernizing obsolete equipment.

Their service and advice is the more useful and authoritative, because it places at customers' disposal the designing experience, technical resources, and operating knowledge of a firm of twenty-five years' standing in one speciality—the design, manufacture and erection of materials-handling installations in all parts of the world.

EDITORIAL.

THE EIGHT HOURS DAY IN SOUTH AFRICA.

The Union Government, like the Imperial Government, has found itself unable to ratify the draft Convention regulating the hours of labour, adopted at the Washington Labour Conference. Some time ago the Imperial Government published in detail the reasons for its attitude, and the Union Government has now followed suit. The correspondence issued by the Union Government a few days ago shows that though it is "in sympathy with the general principles laid down," it is unable to give them universal application. In a letter from the Department of Mines and Industries to the International Labour Office, dated 7th June, the provisions of the Convention were discussed in their reference to the four classes of employment to which the limitations of an 8-hour day and 48-hour week, with certain specified exemptions, were applied, viz., mines, manufacturing industries, constructive works of an outdoor

character, and transportation. With regard to mining, the position in the Union is governed by Section 9 of the Mines and Works Act (1911). Under this Act an 8-hour day and a 48-hour week constitute the limit prescribed for underground work in the gold mines by adults. In the coal and base metal mines the general practice at present, as laid down in agreements between owners and workers, is founded on a 48-hour week. Surface work on the gold mines is also carried on under a like agreement. Manufacturing industries are dealt with under the Factory Act of 1918. The limit there laid down is that of 50 hours per week, or 9½ hours per day, for adults. So far, however, as regards the skilled trades carried on in connection with such undertakings, arrangements have been come to between the organisations of employers and workers respectively making the 48-hour week general. The limitation prescribed by the Factory Act constituted in the case of many industries a considerable reduction, and the letter points out that in the less skilled trades, where the rougher classes of coloured labour are employed, it is thought that a further reduction would at present be undesirable. It is also shown that the Factory Act provides for exemptions in regard to hours where the supply of raw material is intermittent or subject to seasonal variations, where raw material is liable to deteriorate if left untreated, or continuous processes are carried on, or where the exigencies of the case at certain periods render special hours necessary. These exemptions, it is felt, comply with the spirit, and almost the letter, of the Convention. With regard to general constructive work of an out-door character, the letter went on to show that a very large proportion of the works included under this heading are carried on in this country by native and coloured workers. A strict limitation of hours under the circumstances applying to these operations, would at present be impracticable. Regarding the transportation services, the letter emphasised the very strong objections presenting themselves in this country to a hard and fast 48-hour week or 8-hour day, owing to the scattered position of the population centres, and the great distances covered by the system. While accepting the principle of a 48-hour week and 8-hour day in the larger centres, where work and responsibility are continuous, the railway administration is unable to tie itself down to the maintenance of an 8-hour day, with the strict limitation of overtime, provided at Washington. In its attitude the Union Government has been guided solely by the practical difficulties that have to be taken into account. That this fact is fully realised by the International Labour Office is clearly evidenced by the nature of its reply. The careful consideration given by the Government, and the interest it is taking in the improvement of labour conditions in South Africa, are there highly appreciated. The International Labour Office, the reply states, recognises that special geographical and social conditions in South Africa complicate the question of giving effect to certain of the recommendations. It notes with satisfaction, however, that the Government generally approves the principles adopted. The following explanatory remarks are added by the Secretary for Mines and Industries:—"It will be seen from the above that the Government of the Union while sympathetic to the principles embodied in the 8-hour day and 48-hour week Convention, and while willing to apply those principles as far as is consistent with practical and economic results has not ratified the Convention, nor has the Convention been ratified by the Parliament of the Union, although the full terms of the whole of the Washington Convention and recommendations were duly placed before both Houses of Parliament in the Blue Book containing the report of the Union Government delegate on the Conference. The practical difficulties in the way of its ratification in all its details are shared by other members of the League of Nations, notably by Great Britain and Canada, whose Governments for the same reason have found it impossible to ratify the Convention." It may be hoped, therefore, that nothing more will be heard of the charges made in numerous Labour speeches of late to the effect that the Union Government had gone back upon any obligations entered into by its representatives and endorsed by the Union Parliament.

SWAZILAND MINERAL LEASES TAX.

Though we are all for penalising holders of dormant mineral rights who refuse to make them productive, we must sympathise with the unfortunate owners of mineral leases in Swaziland who have lately been notified of a new tax of an unusual description. This tax amounts to 5s. per 100 morgen on all mineral concessions in that territory not worked during the previous twelve months, irrespective of how much work has been done in the past. Under the able presidency of Mr. William Pott, of Henderson's, who are the largest concession holders in the territory, the matter has been energetically taken up, and a petition has been prepared for submission to the High Commissioner praying for the repeal of the tax, or alternatively, for the right to surrender those concessions that the holders cannot afford to retain. Mr. William Pott made a very explicit statement of the case for the leaseholders, which has appeared in the papers, and he has since written amplifying his remarks. *Inter alia*, he says: "The holders of many of these concessions, or to use the proper term, leases, spent much money in years gone by in prospecting. I know of the discovery of magnificent iron ore equal to Lake Superior ore, anthracite coal of high value, which discovery was communicated to the Admiralty some twenty years ago, and its importance in time of war pointed out. Gold was found and worked until it petered out. Almost the whole country has been open to private prospectors for years on more generous terms than the Government grant in the Union." Mr. Pott also points out that the present tax means that lessees who had a perfect right to accept the terms of their leases as defining their full liability for the rights leased are now by a legal quibble called on to triplicate or quadruplicate their liability by spending further unlimited sums in finding again each year what they found years ago, or to reprove annually that what they leased the right to work could not be worked because it did not exist. This penalty is imposed for the unexpired periods of concessions, in most cases ten to fifteen years, and the unfortunate holder can neither go back nor forward, as even abandonment of all his dearly bought rights is denied him. Another point made by Mr. Pott is that the new proclamation leaves to the discretion of the Resident Commissioner to decide whether property has been "adequately exploited." The Resident Commissioner is not a mining expert, nor is there any department of mines in Swaziland to provide him with advice and information on such an important matter, yet upon his in-expert decision the tax has to be paid or remitted. We may not have done justice to all the objections raised by the leaseholders, but enough has been stated to show that they have made out a very reasonable case, which, it is hoped, the High Commissioner will favourably consider.

Notes & News.

World's Stopping Record Broken at Van Ryn Deep Gold Mine.

We have received information that during the period September 2nd to October 1st, 1921, the following very fine performance was achieved in Stope 3 East 9, Eastern Shaft, Van Ryn Deep Gold Mine: Working shifts, 26; machine shifts, 78, total fathoms broken, 248; fathoms per machine shift, 3.18; stope width, 69 inches; contractor, B. T. Lellyett; type of drill, "Holman" eradle hammer (C.H. 2); number of machines, 3; steels used, 5 jumpers to set (10 ft. chisels). Next week we hope to publish figures showing the progressive work leading up to this truly remarkable performance.

Engineering Standards.

The South African branch of the British Engineering Standards Association have issued a copy of the British Standard Electrical Pressures for New Systems and Installations, which has been published by the British Engineering Standards Association. These standards have been recommended for adoption in South Africa by the Electrical Section of the South African branch of the Association. In addition to the standardising of electrical pressures, the frequency of 50 cycles per second for all alternating current systems has been recommended.

* * *

Planet-Arcturus.

In the report for the quarter ended 30th June of the Planet-Arcturus Gold Mines, which are at present being operated by the Gold Fields Rhodesian Development Company in order to recoup itself for substantial cash advances made, the following important change of policy is announced:—"As there has been no reduction in the cost of mining material and requisites and working costs having, owing to the increase in white employees' wages, risen far higher than at the date when the lessees took over, they have had to reconsider the policy hitherto pursued, and have decided for the present and until working costs decrease to confine the treatment of ore to such blocks as are considered payable under existing conditions. The estimated balance of ore reserves at 31st March last was 268,004 tons of a value of 11.8 dwts., which, after allowing for the ore crushed during June quarter, would be reduced to 251,034 tons of about the same value. A revaluation of this ore as at 31st May, after leaving out of account ore considered as unpayable under present circumstances, would consequently reduce that figure to 139,600 tons, averaging 13.27 dwts. per ton." From the treatment of 16,970 tons of ore yielding 9.39 dwts. per ton, the report shows that a surplus was earned of £17,173 (including gold premium) in the June quarter.

* * *

Progress at the Falcon.

The interim report of the Falcon Mines for the half-year ended 30th June shows an estimated surplus of £787 from the treatment of 92,312 tons, yielding copper (valued at £63 per ton), gold (109s. per ounce), and silver (3s. per ounce) of an estimated value of £201,550. Working costs averaged 43s. 6d. per ton. The estimated ore reserves at 30th June were:—

	Tons.	Value taking gold at 5s. per dwt. and copper at £50 per ton. £65 per ton.	
		Per ton.	Per ton.
Sulphide ore.....	417,000	44s. 7d.	50s. 9d.
Do., lower grade	52,000	32s. 8d.	38s. 4d.

As mentioned in the annual report in April last, development work in the mine was stopped during March. The working costs given above include the usual charges for redemption of the amounts previously expended on development and broken ore in stopes, but since March little or no expenditure has been actually incurred on development work, and further reductions in the actual expenditure have also been effected by the utilisation of stores in hand, which at end-June had been reduced to the minimum consistent with safety. In addition to the cash savings effected by reason of this advance expenditure and by the consumption of stores, economies have been effected wherever possible, and the white and native labour forces have been reduced to the effective limit. "As the result of these steps the liabilities for debenture redemption and income tax, amounting in April last to some £50,000, have been substantially diminished, in addition to meeting current expenses, and it is hoped under present conditions to discharge the balance of indebtedness in a few months, this being subject to any material rise or fall in the price of copper or gold in the meantime." The realised value of the output for six months to 31st December, 1920, was £212,360, as against the estimated value of £193,626.

Early History of De Beers.

COTTY'S—CECIL JOHN RHODES AND BAXTER'S GULLY—A LADY DIGGER.

(By W. P. Taylor.)

The name Cotty may mean little, or it may mean much. It came from the old country a good many years ago, and there are still a few who remember "Cotty." Cotty and De Beers went together in the seventies, and Cotty was as well known as De Beers itself, for Cotty was De Beers; at least when you went to De Beers you found Cotty. Sidney Cotty was the universal provider of De Beers. He provided the diggers and their wives with practically all they required; he provided the diggers themselves with drinks at "Cotty's Bar," and then he provided John Birbeck with gold, and not only John Birbeck, but all those that ran out on Saturdays, for Saturday was a golden day, not only at De Beers, but everywhere at the mines. The Kafir boy had to get his 10s. on Saturdays, and there was always a rush at the banks. Gold ran to a premium. Men came to town in their best clothes, and those that sold their diamonds late had to be provided with plenty of gold to pay boys, and that's why Cotty was always terribly busy on Saturdays and spent most of his hours counting gold. Cotty was English. He lived English, eat and drank that way, and did sound English as he was born. He never could have competed in the Taal. First of all, he ran on strictly English lines; one of the most conservative of men. After he had been many years in Africa he lost nothing of his English mannerisms or speech; never answered a question without long moments of deliberation; never discarded his black bowler hat. If he could have continued life in his grandfather's collars and black stock, he would never have worn other; but in a white shirt and black tie—a small stiff bow tie, and sound English clothes, Cotty came to stay at De Beers. In course of time he sent £2 for his father, and there was an earlier edition of Cotty: a Gladstone collar, a black stock, and a Gladstone face shaved clean, and under his chin, there, reminiscent of Pegotty, was the old, old fringe of hair that men wore when Charles Dickens wrote his glorious descriptions of British character in the forties of last century. There were other members of the Cotty family; they were all more or less up to the old conservative British standard. Miss Cotty answered to a Dickens maid, who reticently went through life with silent purpose and unchanging garb. She was one of the few who we admired for industriousness, but, I fear, beyond that there was no note of romance. Amongst these Cottys we moved for many seasons. In this atmosphere there were men who responded nationally. There was a Swede, an American, and some Australians, but Cotty's daily course, like a vessel sailing under the Union Jack, had passengers and crew logged British.

It is fitting that I should introduce the chief character that for several years dominated Cotty's. Cecil John Rhodes first took an interest in De Beers when "Baxter's Gully," a long triangular depth cut into part of the mine by one Richard Baxter, was flooded. Baxter worked this claim in De Beers, on shares, for William Dudgeon. The ground was fabulously rich, but a great spring of crystal water suddenly flooded his workings and gave him and De Beers a long rest. It was then that Rhodes became interested. He concluded a contract with the Diggers' Committee, and Johnnie Ramsbottom brought his engines and started to pump out water. There was more water than they thought, and incidentally, there were more diamonds. The contract lengthened, and as the water subsided and the ground became workable, William Dunsmore secured Dudgeon's ground, Rudd and Rhodes bought claims adjoining, and very soon the nucleus of the great De Beers Company came into life. Like all mining concerns, it had its vicissitudes, but its origin was simple and essentially British.

John Birbeck's office adjoined Cotty's Bar. John was a handsome Welshman, tall of stature, and with a great soft beard. If he had lived a few thousand years ago he would have worn the old true Welsh garb and carried a mighty club, but as it was, he showed his nationality in his face, just as a Scotchman does in his shaggy beard and brow, or an Irishman in his tongue's wit. In the mornings the sunshine poured into office and bar, and when the shadows moved to the east a Cape cart invariably brought two men from Kimberley. One was thin and had a scanty beard; he had long been associated with Rhodes, and in the partnership I had marked him down as the silent member. If one heard conversation between Rhodes and Rudd, it was invariably Rhodes' falsetto pressing a point or arguing from various facets. Rudd invariably was silent, but monosyllably answered Rhodes' appeals. The Cape cart stopped at Cotty's, and Rudd and Rhodes walked to the headgear and peered down the mine. I have seen these two men stand silently gazing into the mines of Kimberley and De Beers. Rhodes in a brown coat with white flannel trousers; a characteristic brown bowler hat—it was not a hat that could have come out of the hunting field, but it had never come from the city, or even the West End; it was simply Rhodes' hat, and from what I recollect of it, I should never accuse it of ever having been new. I don't think Rhodes liked new hats. I'm certain he hated new clothes, and like my old master of the pack I hunted with, had no great love for new people. Rhodes, as I knew him, was reminiscent of old-fashioned English county. If he had followed his father and been a parson, he would have stuck to old county fashions. I rode next to an old country squire in the "Old Berks" for several years. He always wore a brown hunting coat; it might have been twenty or thirty years old, and showed its wear, but it showed its historic master in alienable country colouring. Rhodes' coat and hat matched dear old Squire Lenthal's coat. In all the years that I knew Rhodes, he never lost his county colouring. I saw him on the mine, in the town, on the veld, and, lastly, in the House of Parliament at the Cape. Wherever he was there was not only that commanding air that was his throughout, but there was ever a something reminiscent of an English county. All the Rhodes showed public school characteristics, and perhaps none of them more so than Colonel Frank Rhodes.

Cotty's had a yard as well as a bar. In the yard was a quoit pitch. It was customary not to "stand drinks" as we do at the Rand Club. From 4 to 6 the gathering played four-handed quoits for drinks. Captain Stanley Louw, C. D. Rudd, and one or two others invariably looked on, but most of them took their turn and played. William Anderson, Rhodes' partner, had a glass eye. He never played quoits but once. Thinking himself alone at the pitch, he ventured to throw a quoit, and his glass eye, not seeing Myers, who was at the opposite end, caused the direful tragedy of Myers' death, for the quoit fairly caught him on the brain, and he succumbed. In Birbeck's office a good many important matters connected with the early business of De Beers was transacted. Birbeck had Rhodes' confidence, was as close as a clam, and never speculated. I never knew him to own a claim or a share. Rhodes had the greatest regard for Birbeck's judgment and often acted on his advice. As De Beers developed, so did Birbeck's business, for until the company opened its offices in Kimberley, Birbeck bought all its finds. I am afraid I have not given as clear a picture of those days as I should. Some years earlier we sifted and sorted the soft yellow ground. There was a lady, a little lady, who had a table on a high mound of gravel. Every day she would walk to it from her tent, a coloured sunshade shading an old-fashioned print sun-bonnet, old-time mittens covering her hands, and a rather fat King Charles spaniel following in her wake. When too tired to sort, she would peer from the winch, where they hauled up the ground. I often wondered what her dreams were. For although dia-

mond digging serves you with the most delicious dreams, yet one cannot always go on with the same old dream. It was, however, a delightfully quiet life. Sorting for hours and hours, your mind could wander where it would, so long as your eye kept on the spread of gravel that your scraper flung over a clean space. But though our new life has brought every disturbing contraption that science and manufacturers could devise for man's annoyance and mortification, in the seventies we revelled in peace and contemplation and days of dust and gravel. I left the fair lady looking down into the depths of her claim. It was a rich claim; not large, but it served its purpose. She worked it well for several years. John Birbeck bought her diamonds, and whenever she went to sell a parcel of stones, the boys hung around. She had a slim figure; it might have been the waist of a girl of eighteen. I have no intention of disclosing her name, but she was our one lady digger. Many a time have I taken a scraper and helped her sort. Many a time have I walked up and down the little footpath that led from tent to mine. She was not of the modern mining class, nor of its day, and our conversations took us over wide fields. And then, when she was no more, I sold her claim to Alfred Beit. It was the first that he bought in De Beers. I bought many claims for him, but none richer. This purchase was the first rung on his ladder of fortune. It cost little; it was her all. She died without fortune; she died without debt; her mite went to found the fortunes of a millionaire—a little stepping stone such as this has often led to greatness. Faded from memory with the many parting years, and as you fade, little lady, I still see journeying to your claim the mince figure shaded with sunshade, the kerchief's colouring, and your mittened hand. What your heart carried during those years I will not tell. Creditors claimed your all, and they were satisfied. You took your greatest asset with you; it was worth more than the diamonds of all the mines to you, and you kept that wealth. Man may amass gold—mountains of it—and when he dies his soul's aeroplane cannot take even its shadow with him; but a heart that can cherish carries love, and the burden of it is so light that it will travel to eternity, and beyond, with what is called the soul.

Age had not yet marked their brows. In ruddy youth they tossed the quoit. They quaffed with health and mirth. The quoits' clink will sound there no more; the sunshine glinting through the narrow passage will never touch those forms. Think not as you pass by that in these shadows there lurk nought but deadly ghosts. Mercurio's ghost could never be deadly. And those that have gone from that old spot were of his kin. We cannot bring it all back again, but there is a joy in reviving old recollections, and though their sounds are silent, there is in memory the one connection that alone can take you back, and those old friends who still live and remember can glance back to Cotty's and see Rhodes, Dunsmore, Palmer, Maine, Wright, Rowe, Slatter, Robinson, Meyer, Alderson, Rudd, Birbeck, English, Compton, Gardner, Ted Slatter, Breda, Stigling, Rivas, Niekerk, Hull, Shields, Anderson, Wolhuter, Harris, Parker, Gray, and Walter Ward, the mine inspector, on his grey Basuto pony—that flea-bitten grey. His master, with a great wide pith helmet, incessantly cantering over dumps from mine to mine. There were two ponies that had many friends—one was Walter Ward's, the other O. J. Skill's. Dear old O. J.; whenever you met him he said, "You haven't such a thing on you, perhaps, as a match?" Then, when you gave him the match, "Oh, I say, I forgot, you haven't such a thing as a pipeful of tobacco?" Skill and Cator smoked from many pouches.

The certificates issued by the Mines Department for the period ending 30th September, 1921, were as follow:—Mine Overseers (Metalliferous Mines): P. A. Corbitt, E. Marks, C. W. T. Pittendrigh. Mine Surveyors: T. M. Bremner, H. A. T. Child.

Mr. Victor Kent, who has been associated for the past 25 years with Messrs. Geo. Cradock & Co. (S.A.), Ltd., is relinquishing his position in order to start up in business on his own account at No. 31, Ground Floor, Cullinan Building.

Concerning Mines and Men.

Mr F. W. Mills, Chief Electrical Engineer to the South African Railways, has returned to the Rand.

Mr Jonas Bethell, who is writing the series of articles on steel now appearing in this journal, has expressed his willingness to give technical advice and will, to the best of his ability, endeavour to help readers out of difficulties in the heat treatment or handling of steel. Mr. Bethell comes direct from Sheffield, and as a specialist in steel is so rarely among us, we hope that advantage of his generous offer will be taken.

"PAX"

HACKSAW BLADES

NINETY strokes per minute, cutting three inch round cast steel, one cut every seven minutes, with life of blade averaging twelve hours continuous cutting. That is the sort of satisfactory service that PAX power hacksaw blades are giving in some of the local workshops. And what PAX blades are doing for others they can do for YOU

Letters to the Editor.

"THE REAL VALUE OF GOLD."

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—*The S.A. Mining and Engineering Journal* of the 10th instant contains an article by Mr. S. J. Speak, A.R.S.M., M.Inst. M.M., entitled "The Real Value of Gold," the said article taken over from the *London Mining Magazine*.

It is the first practical solution I have yet read, and I have read several suggested solutions of the currency problem. I am quite in agreement with Mr. Speak's suggestion that the price of gold should be fixed at six guineas per ounce. There is just one point in Mr. Speak's article which I should have worded differently. Under the heading of results of the scheme, he says "the immediate results would be somewhat as follows: (1) Wages need be little disturbed for some time. I should have worded it "wages need not be disturbed at all." No one really wants to disturb wages. Certainly not the miners. Certainly not the merchants, storekeepers and shopkeepers. And certainly not the mine-owners and controllers of the mines, for they all have enough money to buy food and drink and cigars and wearing apparel, and any spare time they may have they would rather spend playing golf and doing things like that than spend hours, if not days, at the offices of the Transvaal Chamber of Mines debating why wages should be reduced.

People who have written and spoken on the currency question may ask on what grounds I claim to be an authority on a subject like "The Real Value of Gold."

So, Sir, I suppose I must give my credentials. I assisted in the production of gold which was sold in London through Messrs. Sharp and Wilkins at the price of 84s. 7½d. per ounce "fine."

I went to Swansea early in the year 1875 in the employ of Messrs. Vivian and Sons, who at that time smelted more than 75 per cent. of the gold and silver ores produced throughout the whole world, including the United States of America. The whole time I was in the employ of Messrs. Vivian and Sons I acted as assistant to the general manager, the late Mr. James Nettell.

I left Messrs. Vivian and Sons' employ some time about 1883, to become managing director of the South Wales Smelting Co., Ltd., at the Landore Silver Works (Gioth Bach).

As a mine-owner I have been the sole owner of a copper mine out of which I made money.

The sole owner of a colliery, where I lost money, and the sole owner of an iron ore mine, where I also lost money. Every mine does not yield profits; to quote an old South African sporting saying, "One cannot make every post a winning post." I have also been a director of several other mining companies, my co-directors being leading men in Paris, Rome, Florence, London, etc. my London co-directors including men like Mr. Edmund Davies, Mr. Edward Jekyll, the late Mr. Percy Tarbutt, and others.

I also claim to understand English, French, Italian and Spanish workmen, for I have performed manual labour with all four.

I have fought a Cornish miner in Cornwall, in a skittle alley, and a Welsh collier at Llangefelach Fair, near Swansea. I have been a large employer of labour practically all my life, or have had the supreme direction of mines and industrial concerns employing labour. These are my credentials. Sir, for claiming to speak "as one having authority," for I can quite understand the questions between the mine-owners and the miners from both standpoints.

Personally, I would like to be in a position to pay any miners I employ five pounds per day, and the mine-owners and controllers of the Johannesburg gold mines, not being

fools, would no doubt like to be in a position to do the same, for in practice it would mean more money for them and no trouble and annoyance by strikes and industrial disputes.

It may also be said that a lot of what I have just written is irrelevant, but it is not; it is material, and very material to a proper understanding of the present-day position.

When the amiable and highly-respectable old gentleman or gentlemen fixed the price of "fine" gold no workman in any part of the world received a "living wage"; they lived under appalling conditions as regards housing, food, raiment, etc. The younger generation have read of these things, but I also speak from my own knowledge.

We are now told that according to the laws of political economy the price of gold must remain at 84s. 7½d. per ounce "fine," and that wages must come down and the standard of living be reduced.

We are not living in an age of superstition and people nowadays will not do a thing or submit to a thing because an amiable and highly-respectable old gentleman in days long gone by said so-and-so; put up a monument to the dear old soul in the market place by all means, if it so please his worshippers, and I will contribute my "mite," but for gracious sake do not let superstition and veneration for the learning and authorities of a dead and gone past, whose circumstances and conditions bear scarcely the slightest resemblance to the surroundings and level of thought of to-day, cause us to try to perpetuate such a monument of folly as keeping the price of "fine" gold at 84s. 7½d. when, except in the case of a few rich mines, it costs more than one hundred shillings (100s.) per ounce to produce it.

I am not trying to pose as a modern Jonah crying "woe" in the streets of Ninevah, but if it is attempted to reduce wages and lower the standard of living, as the political economists and the 84s. 7½d. gentlemen desire, there is going to be trouble, and lots of it.

Some authorities say agriculture is the backbone of every country and that the gold mines will die, that even Methuselah died; quite true, my friends, but if the price of gold is fixed at six guineas per ounce "fine" South Africa will be producing gold in large quantities when aeroplanes are as plentiful as natives on push-bikes in the streets of Johannesburg.

Of course everything in this world is a matter of comparison. When authorities speak of South Africa as an agricultural country I agree with them to the extent that it is an agricultural country when compared with the southern part of Patagonia and places like, but it is not an agricultural country when compared with England or France or Italy. Do not get on your hind legs until you have looked up the Government agricultural statistics. If you call a country an agricultural country which has an average yield of two point two (2.2) bags of mealies per acre and 4.3 bags (four point three) of wheat per acre, I do not. Save perhaps Natal (the garden Colony) and a few spots in the western part of Cape Province and parts of Zululand, South Africa is a ranching country, and not too good at that.

In the early days the country which is now the Union of South Africa could have been described as a good ranching country, for the Boers fed their flocks on the high veld during the summer and trekked with them to the low veld during the winter.

The Union of South Africa, with the exceptions mentioned, will remain and be only an indifferent ranching country until the scheme of Professor Swartz to bring the waters of the Zambesi into the Union is "un fait accompli."

South Africa is a rich mining country. I am speaking from my own knowledge, for I have travelled the Union from north to south and from east to west. It is not an unsupported statement.

The Government mining engineers say the Transvaal is the richest mining country in the world.

South Africa will be a rich mining country when the present rich American mines have followed our old friend Methuselah.

I, like thousands and thousands of others, am anxious to see ex-officers and men comfortably settled in life. Well, follow Mr. S. J. Speak's advice and make the price of gold six guineas per ounce, and there are hundreds of spots in the north of the Transvaal and Rhodesia that would give them something more than a comfortable living and be the means of greatly increasing the general prosperity of the country. It is by sound practical suggestions like that of Mr. Speak that normal conditions and the general prosperity of the world will be restored; it will not be restored by leagues and conferences and clinging to ancient shibboleths. We people of the year 1921 require money to buy food and drink and wearing apparel and smokes and things like that. Some people have money, but many more haven't, and those that have not intend getting it and being in the great majority, who is going to stop them? If the battle cry at the next election were increase in the price of gold and no reduction of wages, General Smuts would have no alternative but to visit his friend, Lloyd George, and I bet that those two very able gentlemen after luncheon would do more to settle the currency question and in consequence the unemployment question than all the leagues, conferences, ancient shibboleths and superstitions between Timbuctoo and Mesopotamia.

To revert to the demand for a reduction in wages and a reduction in the standard of living, I remember a different standard of living among workmen to that which obtains to-day.

At a Board meeting of the South Wales Smelting Co., Ltd., Mr. Joseph Gordon Gordon, one of the directors, asked me the rate of wages we were paying the various workmen. My answer was: Blast furnace or Cupolo furnacemen 4s. to 5s. per day, reverberatory furnacemen the same, Calciner men 2s. 6d. to 3s. per day. Mr. Gordon, who is a nephew of the late Sir William Siemens, and who at that time was acting as managing director of the Landore Siemens Steel Works, said: "I am paying furnace forehands six pounds per week and others in proportion." Then he turned to me and asked: "Cannot we improve our rate of wages, which I consider disgraceful."

I replied that I agreed with him, but that our rate was somewhat higher than that paid by the other smelting works and that unless we altered our system of smelting it was impossible to improve the rate of wages.

Mr. Gordon then asked if it was possible to do so. I replied I was certain it was, but that it would require more capital. He answered: "You work out the system and I undertake to find the capital."

If the furnaces and calciners of to-day had been at my disposal we could have paid our furnacemen and calciner-men one pound (20s.) per day.

Unfortunately at that time the price of silver was on the down grade. When I went to Swansea in 1875 the price of standard silver was sixty pence per ounce and had been so for quite a long time. At sixty pence per ounce for standard silver the intrinsic value of the shilling is one shilling. I am speaking of the shilling minted a few years ago, not the debased thing of to-day. I do not suppose the Chancellor of the Exchequer gleefully debased it, but in the words of the old saying, "Needs must when the devil drives."

When we commenced smelting at the Landore Silver Works the price of standard silver was fifty pence (50d.) per ounce. When we closed down the price of standard silver was less than thirty pence (30d.) per ounce. This fall in the price of silver upset all my plans for improving our methods of smelting, for who would provide capital on a falling market?

If Mr. Speak's suggestion is adopted, the currency question and the question of the low-grade mines will both be solved, and very satisfactorily solved. Johannesburg will continue to increase in size and prosperity.

To enable the practically unlimited quantities of low-grade ores in South Africa, I say South Africa and not only Johannesburg, to be worked at a profit, miners' wages must

be reduced at least ten shillings a day; that is, if the price of gold remains at 84s. 7½d.

By low grade gold ores I mean ores containing only 3 dwts. of gold, the mineral mentioned by Mr. Samuel Evans at the last meeting of the Crown Mines, Ltd.

Is there any sane man in the whole length and breadth of the land who believes for a moment that the miners of the Rand would accept a ten shilling per day reduction in their wages without a long and bitter strike, which would mean disaster not only to Johannesburg, but to the whole of the Union?

I also ask does any sane man dream that the controllers of the mining industry or that the Government would allow such a state of affairs to come to pass?

So-called high wages and so-called high living have come to stay just as natives and push-bikes have come to stay.

I am afraid that some of the good people who write and speak on the currency question and political economy and things like that remember only what they have learnt in their youth.

"The times are changed, my masters"; these are the days of raising up, not levelling down.

It is no more possible to go back than it is to "raise spirits from the vasty deep."

The controllers of the mines know it as well as the labour leaders, the man in the street knows it also, but he does not possess the special knowledge to enable him to write on such a subject as "The Real Value of Gold," but all the same he is thinking what I am now writing.

Is there any modern intelligent man who can give intelligent reasons why Mr. Speak's suggestion should not be adopted?

Political economists, exchange and currency experts do not get stranded on the bank; move with the times and let us have the benefit of your knowledge and experience, or I fear the pendulum will swing to the other extreme. The people, that is the voters, can fix the price of gold at ten pounds if they so decide, and make it a serious criminal offence to be possessed of a bank note or bill; there would then be such a demand for gold as the world has never seen and the price of ten pounds per ounce would not be too high to enable the demand to be satisfied.

Well, before I conclude there is another matter connected with the gold industry which I must mention, and one that will provide employment for a large number of men, viz., the working of mines containing so-called refractory gold ores.

When I came to South Africa about twelve years ago I first heard the expression refractory gold ores. I had, of course, heard of complex gold and silver ores, that is gold and silver ores containing also copper, arsenic, antimony, zinc, etc. I have smelted thousands of tons of such ores and I like them, for these are the ores that give smelters their profits. To a smelter such a thing as a refractory gold or silver ore does not exist. I have been called refractory and other things when I was a boy, but I never heard the word refractory used in any other sense until I came to South Africa. I am informed, and I also know from my own knowledge, that there are large quantities of so-called refractory ores in Rhodesia and the Transvaal. These ores have a good commercial value. The owners and shareholders in properties containing the said ores are at the present moment regarded as having been unfortunate in their speculations. This is not my view. Again, I speak as "one having authority." I will endeavour to express my meaning so that the non-technical man who is the owner of such properties may understand me. I will take a gold ore containing, say, one ounce of gold per ton, also antimony, arsenic and copper. The copper may, of course, be any figure, the more the better, and the antimony and arsenic may be as much as 30 per cent.

For such an ore on the basis of "fine" gold at five pounds (100s.) per ounce I could pay f.o.r. at a smelting works £2 10s. (twenty shillings) per ton. For higher gold

contents I could, of course, pay more money. Antimony, arsenic, etc., have nothing to do with the case. I would also pay for all copper contents over 2 per cent. (2%). The price per unit of copper would depend on the market price of copper and also on the percentage of copper contained.

In concluding, permit me to say, as a mining engineer and geologist of over forty years' experience in various countries, the last twelve being in various portions of the Union, including the South-West Protectorate, that you have in South Africa a very old country from a geologist's point of view, but a very young country from a commercial point of view. As a place for immigrant workmen it has a life of less than fifty years.

Speaking metaphorically, it is for miners and men of good physique "a land flowing with milk and honey." I have been in several countries, but I have never been in one to come near it in the matter of commercial mineral occurrences.

You have the richest gold occurrences in the world with a practically indefinite life. They have scarcely been scratched yet. You have practically a monopoly of diamond occurrences; you have important coal fields and oil shale deposits, and I say with a due sense of responsibility and after close and careful investigation and study that you have the largest and richest copper deposits the world has ever seen.

As far as I know, after the great American mines are exhausted, Africa, and particularly South Africa, is the source from which the world's supply of copper will come. Only in exceptional cases can a copper mine be brought to the commercial or producing stage in less time than three years, and, generally speaking, to do so, requires the employment of a considerable capital. There are other minerals, but those I have mentioned are the ones of leading commercial importance.

Permit me in the penultimate portion of my letter to say: Give up worrying about trifles and don't have sectional disputes and strikes; they cost you and others money and cause discomfort, and who in a young country like South Africa, where everyone must hustle, can remember, say, in six months, what the trouble was about.

If Mr. Speak's suggestion is adopted and the price of "fine" gold fixed at six guineas, there will never be a general strike.

To the port towns and the farming districts I would say: Your prosperity, nay, your very existence, is dependent on the mining industry.

Do not be pessimistic at the present moment: your social conditions and material conditions are better than in any other country in the world, and there is none to compare with you in future prospects.

Recently it has been suggested to me that I should select a site, design the works and furnaces, etc., and act as managing director of a "Customs" smelting works having also its own mines to ensure a regular tonnage for the furnaces.

So-called refractory gold ores, copper ores and other ores will be purchased there for cash. Immediately the ores in question have been weighed, sampled and assayed, the cash will be at the seller's disposal. Think the matter over and try to realise what a difference such a works will make to the whole of the Union!

The "small" man will only have to purchase a few picks, shovels, explosives, etc., and engage with a Boer farmer to transport his output or production to the railway. There will be no occasion to erect batteries, etc., or to wait months for his money while his produce is being realised in Europe or America.

If necessary, we shall establish subsidiary works in districts that justify such a step.

At these works the mineral will be concentrated; that is, partially treated and the product sent to the main works.

If the suggestion had been made, say, three months ago, I should with pleasure have agreed to it.

Since then some friends, on my recommendation, have purchased two farms which I consider contain mineral occurrences of great commercial importance.

I have undertaken to test these properties and, without their freely given consent, I shall confine my attention to these properties until I feel justified in engaging assistance to carry on the development.

I very much regret the suggestion was not made three months ago, for smelting is not only a part of my profession; it is one of my "hobbies."

I would mention that a smelting works cannot be established at or near Johannesburg or any other residential centre, for the furnace fumes are principally sulphurous and arsenic gases; the former would destroy all vegetation within a wide radius, and the latter is detrimental to animal life.—I have the honour to be, sir, your obedient servant,

G. H. BLENKINSOP.

CONCRETE PIPES.

To the Editor, *S.A. Mining and Engineering Journal.*

Sir,—As a news item we think the following will be of interest to your readers:—In connection with the City of Kimberley new sewerage and drainage scheme, which is giving relief to many unemployed, and for which a large loan was recently raised by public subscription, it is interesting to note that the first contract for concrete pipes has been awarded to the firm of J. Wright & Sons, Ltd., of Jacobs, Natal, and this on open tender and against keen competition.—Yours faithfully,

J. WRIGHT & SONS, LTD.

WITBANK COAL AREAS.

To the Editor, *S.A. Mining and Engineering Journal.*

Sir,—On page 137 in your second special Coal Number, July, 1921, is a map showing the principal coal areas of the Witbank district. Wakefield Siding is shown as being on the farm Elandsfontein, when it is actually on Rondebult and *not* on *Elandsfontein*. I enclose plan of the farm Rondebult, on which you will see the position of Wakefield Siding.—Yours faithfully,

W. HAMPSON.

FAR EAST RAND GEOLOGY.

To the Editor, *S.A. Mining and Engineering Journal.*

Sir,—Would Mr. Bleloch, through your journal, enlighten me on the geology of the Far East Rand, that is as far as his correlation of the different reefs is concerned.

First, Mr. Bleloch states: Langerman's Kop, Reitfontein and Van Ryn Reefs are one and the same, leaving Langerman's Kop out of it. How does Mr. Bleloch account for Reitfontein Reef underlying Hospital Hill formation, and Van Ryn Reef overlying Hospital Hill formation?

Second, placing Central Rand and Reitfontein Series back into position before faulting, would this not put Reitfontein to correlate with Orange Grove—its true position? Central Rand would be in place near Reitfontein Station and correlate with Modder West, and our great mystery, the Van Ryn, would correlate them with the upper Bird Livingstone Series.

Why this correlation, which is mine, on the Far East Rand? We are practically undisturbed, and the Central Rand, having been pushed forward about a mile, would then leave Central and Reitfontein to be picked up further north-north-east of the Blue Sky. When this break occurred, which, no doubt being at one with the upheaval at the back of Reitfontein, a dyke went through the country from Reitfontein through Blue Sky and continued south, Central Series would then have been standing far above the Far East Rand Series, allowing the coal area to come in and bank up against this wall; hence no coal formation west side of dyke. The Hospital contorted beds may be found two miles north of Benoni Township, and the large pebble reef overlying Reitfontein is to be found at this point underlying the contorted beds. Van Ryn is certainly not Central Main Series and certainly not Reitfontein. Can Mr. Bleloch put forward any other theory? Is Langerman's Kop not the portion of country connecting Reitfontein with Orange Grove carried in on top of the diabase. I wonder?—Thanking you,

MINER.

THE "PASSING" OF THE GRAVITATION STAMP.

To the Editor, *S.A. Mining and Engineering Journal.*

Sir,—In the *South African Mining Journal* of October 1 appeared a paragraph which foreshadowed the "passing" of the gravitation stamp in the new economy of the Springs Mines, Ltd. Well, everything and everyone in this world must come to an end; even Methuselah died. No

longer will "Cousin Jack," when he awakes in the still night, hear the batteries roar reminding him of the roar of the ground sea beating on the western shore of his native Cornwall. Like a great many institutions in Johannesburg, the gravitation stamp has long outlived its day of usefulness. It has died a hard death, the final agony being prolonged by professional jealousy, which refused to recognise that simpler and cheaper methods of crushing must take its place. It's the old, old story, "history repeats itself." Even the Transvaal Chamber of Mines discovered this when they threatened to oppose an application for a patent on the part of Mr. G. H. Blenkinsop, on the grounds that the process in question had been described in a book entitled *Agricola's "de re Metallica"*, published in 1556 (Hoover's translation). The opposition was not proceeded with. Maybe the Transvaal Chamber of Mines, on full consideration, decided that an opposition founded on this hoary publication might fail, and they therefore refrained from calling on this testimony of a bygone age. The Transvaal Chamber of Mines clearly thought that the process described in the venerable publication of 1556 bore a resemblance to the one for which I had applied for a patent. On the face of it no doubt they were right, but my patent agents are of opinion that my application of the process constitutes a distinct novelty.

The process, briefly, is this. I heat the ore or mineral under treatment to a maximum temperature of 600 C. and then plunge it into cold water. The expansion caused by the heating and the contraction caused by the sudden cooling render the mineral extremely friable, in fact so much so, that two pieces of Rand blanket from a depth of, say, 3,000 feet, can, after being subjected to this treatment, be crushed in the hands as easily as two walnuts. This simple test can be made by anyone with the aid of the kitchen fire. This process does away altogether with the gravitation stamp and makes the all slining of the ore and the consequent improvement in extraction a positive certainty. Like the new system foreshadowed at the Springs Mines, it does away with plate amalgamation with its heavy losses caused by pilfering.

In addition to the increased gold recovery, there will be a further substantial gain in the matter of increased duty to be obtained from the tube mills. I do not think I am over-estimating the gain under this head when I put the increased duty as 3 to 1. This process will be a boon to the "small" man of Lydenburg and Barberton. It will no longer be necessary for him to impoverish himself, his friends and relations for funds wherewith to erect a five-stamp battery. An outlay of a few pounds will provide for the construction of an efficient heater, and a mortar mill will efficiently do the crushing or slining.

I propose to charge only a nominal royalty for the use of the process. In the case of mines treating a tonnage equal to the average Rand mine, I propose to charge a royalty of one halfpenny per ton. This small amount of royalty would scarcely pay the cost of collecting in the case of small mines, and in such cases, as the extraction would also be increased by, say, 2 dwts., I propose to charge a royalty of threepence per ton.

Every mine on the Rand that adopts this process will at once lessen its crushing costs to the extent of from two shillings to half-a-crown a ton, and they will at the same time increase their gold extraction to the extent of from one to two dwts.

What have the low-grade mines to say to this? No intelligent reason can be advanced why this very simple process should not be adopted. Now that the Springs Mines have shown the way in a tentative fashion, will not the low-grade mines take their courage in both hands and show the consideration due to their shareholders and the mineworkers by adopting a process which is simplicity itself and will give practically immediately beneficial results. In the interests of all concerned, it would be better if the heads of the mining industry relied more on their own intelligence and less on that of their technical advisers. If they had done so, the superstition which has so long preserved that primitive symbol of early metallurgy, the gravitation stamp, would long ago have been swept away.—Yours, etc.,

G. H. B.

AN APPRECIATION OF THE GEOLOGICAL SURVEY.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—I should be pleased, through the medium of your valuable paper, to be allowed to express an opinion on the various comments appearing in the journal on Witwatersrand geology. The various letters and articles are interesting, but the disrepute the Government geologists are put in is very unfair. Having an intimate knowledge of the Witwatersrand system of rocks and the accompanying reefs, I can speak with some knowledge of the system, and also of the method in which way the geological surveys have been carried out. The work done by Dr. Mellor in mapping the Witwatersrand area has been done very accurately, and he has also given the correct reading of the system. I have carefully examined Dr. Mellor's map and find the work thereon is a true representation of the outcrops as one sees them in the field. Dr. Rogers' work I do value in the same measure as Dr. Mellor's. Though I am not acquainted with the entire Heidelberg district, I find Dr. Rogers' work there in the areas I know to be accurately mapped. His description of the Witwatersrand rocks from that district is in agreement with the system here on the Rand. The series of the upper system I know from depths as well as the surface outcrops, and were there any inaccuracies they would easily be detected. It is regrettable that the services of geologists of the high training and experience of both Dr. Mellor and Dr. Rogers have not been more fully appreciated. Their work is a great credit to the geological survey and a lasting benefit to the community.

PETER MACADAM, JUNR.

Review.

MINERAL OIL PLANT.

At a time when widespread interest is being centred in the oil shale industry, publications on the technology of oil shales and plant required in their treatment are of great help to the parties concerned. The catalogue issued by A. F. Craig & Co., Engineers, of Paisley, Scotland throws much light upon the subject of mineral oil plant.

Their connection with the mineral oil industry for over forty years has enabled them to keep in touch with all the advances made in the oil shale industry, and has resulted in their producing a most up-to-date and efficient plant. Their well-illustrated catalogue gives the principal parts of oil plant manufactured by them. Their oil shale retorts are of the Pumpherson type erected in ovens of four retorts each. The capacity per retort varies with the quality of the shale treated, but on an average shale yielding, say, 20 to 30 gallons of oil to the ton, the throughput may be taken as about 3½ tons of green shale per 24 hours per retort.

GOVERNMENT EXAMINATIONS.

METAL MANAGERS EXAM.: Last examination (May, 1921), 15 Metal Certificates were granted in South Africa, and of this number our students secured 10 certificates. Previous examination we secured 7 certificates from 8 entries, and in two other recent examinations 15 passes from 19 entries.

REMARKABLE AND CONSISTENT RESULTS.

COAL MANAGERS EXAM.: Last examination (May, 1921), we secured 3 certificates from 6 entries.

OVERSEAS EXAM.: 21 certificates secured 1920, and 14 certificates to date, 1921.

SURVEY EXAM.: We have secured practically all the certificates granted by the Mines Department during recent years and have obtained 60 certificates to date.

TYPIST,

Box 2075, Johannesburg.

September Gold Output : Group Returns.

CENTRAL MINING/RAND MINES GROUP.

Results of crushing operations for the month of September, 1921:—

Company.	Tons crushed.	Yield in Fine Gold Ozs.	Estimated Value.	Estimated Profit.	Estimated Working Costs per Ton.
City Deep	89,000	35,729	£193,831	£69,526	27/ 11
Cons. Mn. Reef ...	50,000	17,719	96,125	19,399	30/ 8
Crown Mines ...	193,000	58,984	319,988	83,443	24/ 6
Dur. Road. Dp. ...	24,350	9,502	51,349	7,797	35/ 9
E.R.P.M.	124,000	33,652	182,560	19,607	26/ 3
Ferreira Deep ...	32,200	10,296	55,857	16,068	24/ 8
Geldenhuis Dp. ...	49,526	12,686	68,717	3,564	26/ 3
Knight Central ...	27,600	6,473	35,118	3,966	22/ 6
Modder B.	59,000	30,736	166,745	92,289	25/ 2
Modder East ...	25,000	9,791	53,034	11,087	33/ 6
New Modder ...	101,000	46,994	254,942	142,939	22/ 2
Nourse Mines ...	41,200	15,062	81,712	11,888	33/ 10
Robinson G.M. ...	40,000	7,701	41,780	2,599	19/ 7
Rose Deep	54,000	13,676	74,193	15,445	21/ 9
Wolluter G.M. ...	32,200	7,939	43,071	5,956	23/ 0
Village Deep ...	48,100	15,308	82,941	14,042	28/ 7
Tls. & averages ...	990,176	332,248	£1,801,963	£519,615	25/ 10

General Note.—The valuation of gold has been taken at £5 8s. 6d. nett per fine ounce, being 1s. 6d. per ounce less than previous month.

CONSOLIDATED MINES SELECTION GROUP.

The following are the results of operations for the month of September, 1921:—

	Stamps Working.	Tons Milled.	Working Costs per Ton Milled.
Brakpan Mines	120	57,500	25/ 6.183
Springs Mines	80	36,250	31/ 1.179

Totals and averages 200 93,750 27/ 8.086

	Value of Gold declared.	Yield per Ton.	Working Profit based on stand-ard value of Gold.	Working Profit per Ton.
Brakpan Mines	£93,217	32/ 5.081	£19,861	6/ 10.898
Springs Mines	67,874	37/ 5.375	11,509	6/ 4.196

Totals & averages £161,091 34/ 4.393 £31,370 6/ 8.307

	Estimated Premium taking Gold at £5 10s 0d. per fine oz. less exchange on remittances.	Total Estimated Profit.
Brakpan Mines	£26,199	£46,060
Springs Mines	19,212	30,721

Totals and averages £45,411 £76,781

Notes.—Brakpan: Placed to gold reserve, 1,602 fine ounces; total reserve at date, 7,818 fine ounces.

Springs: The profit for the month was adversely affected through the breakdown of the winding engine at No. 2 Shaft, which resulted in the mill tonnage being reduced by 5,000 tons, with a consequent high standard of costs, which is accentuated by the inclusion of expenditure on repairs.

Glynn's Lydenburg.

The following are the particulars of the output for the month of September, 1921, in respect of the above company:—Tons crushed 3,675, yielding 1,321 fine ounces; estimated value of month's output, £7,162; estimated profit for month, £1,314. The month's results are based on value of gold of £5 8s. 3d. nett per fine ounce.

UNION CORPORATION GROUP.

Particulars of operations on the producing mines of this group for the month of September, 1921:—

Company.	Stamps.	Tons Crushed.	Fine Ozs.	Revenue (Including Sundry Total)	Rev Per ton
Geduld Prop.	100	45,000	16,185	£89,667	39/ 10
Modder Deep	70	43,000	23,355	127,070	59/ 1
Totals and averages	170	88,000	39,540	£216,737	49/ 5

Company.	Total Costs	Per Ton.	Profit Total (Incl. Sundry Rev.)	Per ton
Geduld Prop.	£51,442	22/ 10	£38,225	17/ 0
Modder Deep	46,227	21/ 6	80,843	37/ 7
Totals and averages	£97,669	22/ 2	£119,068	27/ 3

The above results are arrived at by calculating the gold produced at £5 10s. 0d. per fine ounce. Realisation charges in excess of normal are debited direct to revenue.

GENERAL MINING & FINANCE GROUP.

The September operations of the producing mines of this group were as follow:—

Company.	Tons Crushed.	Total Cost.	Cost per Ton.	Total Revenue.	Profit.
Aurora West	10,800	£13,953	25.84	£15,229	£1,276
Meyer & Charl. ...	13,200	17,360	26.30	12,367	25,007
New Goch	17,000	18,912	22.25	20,379	1,467
Roodepoort Un. ...	22,600	25,153	22.26	23,133	*1,720
Van Ryn Est.	31,630	42,570	26.92	50,588	8,018
West Rand Un. ...	32,000	43,112	26.94	48,125	5,313

127,230 £161,060 25.32 £200,421 £11,081
Less loss 1,720

* Loss.

In calculating the revenue, gold has been taken at a value of £5 10s. 0d. per fine oz., less estimated realisation charges.

WHY PAY SHOP PRICES?

Write for Furnishing Guide at once as the prices quoted WILL SAVE YOU POUNDS.

We are prepared to accept payment by Six Monthly Instalments. Our Prices will not allow for any longer term. ALL GOODS are CARRIAGE PAID to any Railway Station in the Union.

S. T. GEEN & Co.,
—HATFIELD HOUSE,—
PRESIDENT - STREET,
JOHANNESBURG.

ENGINEERING SECTION.

The Wilson Plastic Arc System of Electric Welding.

Electricity as a means for the joining of metals in repairing cracks or breaks, salvaging defective castings, and for metal cutting purposes, all included under the general heading of electric welding, although comparatively simple in theory, has been slower in development in this particular field than in any other service in which it has been applied. This slow growth is probably due to two causes—the scarcity of skilled operators who could manually control the arc, and reliable apparatus suitable for performing the actual operation of controlling the heat at the weld and relieving the operator from holding a fixed arc length. During the last five years, however, arc welding has made great strides, and undoubtedly a great stepping-stone, by means of which it has obtained greater prominence and the confidence of the engineering world in general, was through the successful welding of the damaged parts (principally of cast iron) of the German ships interned in American harbours at the outbreak of the War between the two countries in the spring of 1917. The work that was done on the engines of the damaged German ships demonstrated to the engineering world in general that electric welding could be depended upon to make permanent repairs, no matter how large the part to be welded, or the character of the metal. In the past cast iron has been a stumbling block for welding engineers. The welding together of many of the more ductile metals, such as wrought iron, boiler plate and parts, etc., has been accomplished successfully, in fact easily, as compared with the difficulties encountered in welding cast iron.

The Wilson Plastic Arc Welder, which was exclusively used in repairing these ships, is of the constant potential automatic control system type. It is designed to work on a voltage of 35, thus limiting the operator's arc and ensuring accurate results. A distinct advantage of low voltage at the arc is that it becomes impossible for the operator to draw out a long arc between the electrode and the work, thus eliminating oxidation of the molten metal by the air, and ensuring the metal being deposited in the correct place. With a low voltage supply, the external appearance of a weld is a certain guide to its value, and it can be safely reckoned to be free, internally, from any dangerous slag or oxide inclusions. The low voltage used also ensures better penetration of the original metal by the concentrated arc than is the case when a longer diffused arc of the higher voltage systems is used. The Plastic Arc System, by means of a special flat compound 35 volt generator feeding a special automatic constant current control panel, delivers and maintains a critical degree of heat at the weld, and thus ensures proper fusing of the original and added metal. The automatic current control of the Plastic Arc panel eliminates guesswork or fluctuating heat at the weld. Thus it is claimed that the Wilson Welder complies with all the requirements for successful welding of all classes of work to an extent which no other system has been able to approach. Demonstration plants have been imported by Messrs. Bellamy and Laubie, and a skilled demonstrator from the English works is in Johannesburg to carry out the demonstrations.

A trial run on a plant of the above description was conducted at the engineering works of Wright Boag and Co., Ltd., last week, and the claims made for the plant were

fully demonstrated. The plant was of the portable type, built to be independent of an external source of power. The welding current was generated in a specially constructed low voltage direct current dynamo. The dynamo was driven by a petrol-driven internal combustion engine. The generator delivered current at 35 volts, and the current after passing through the automatic control system was led by insulated cables to the spot where welding was conducted. In a direct current arc metallic ions are continually being carried from the positive pole to the negative, and being deposited on the latter. This effect, combined with the melting of the electrode due to the heat generated at the arc, makes welding by the electric current possible. In practice the best conditions for the deposition of the electrode metal on the part to be welded are those which will subject the deposited metal as well as the article welded to the least amount of chemical change. Internal homogeneity at the weld is essential, otherwise the join is a spot of weakness, and places a doubtful safety factor on the welded article. Over-heating during the process of welding is undesirable, as it produces structural changes in the article welded. The inventor of this system of welding has successfully coped with these difficulties by employing the short low voltage arc produced in his plant. A short arc minimises the risk of oxidising the deposited or electrode metal, due to the shorter distance it has to travel through before deposition. A short arc also concentrates the operation on a smaller area, resulting in more rapid working. This means that the metal welded is subjected to the intense heat of the arc for a much shorter time, and is thus less liable to structural and chemical change. The composition of the electrode or metal deposited can be varied to suit the article welded. This gives the plant a very large range of application, and the welding of cast iron has been made possible thereby. During the demonstrational run several articles were welded in a very short space of time, and work on cast iron was conducted with as little trouble as on wrought iron. During welding the deposition of metal is controlled by a skilled operator, who holds the metal to be deposited in a special holder by hand, and watches the operation through a specially prepared glass light filter.

Underground Electric Loco. on the Rand.

Heat Treatment of Steel.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Etna Works, Sheffield.

The heat treatment of steel covers the following: Annealing, normalising, hardening, tempering, and case-hardening.

Annealing.

In annealing the steel is sometimes heated below the lower critical point, sometimes to a temperature between the upper and lower critical points, and sometimes above the upper critical point, according to the objects in view (usually retained at the maximum heat for, say, 3 hours for a single bar up to, say, 6 hours for a furnace full), and is cooled very slowly (12 to 18 hours) in the furnace. Annealing is used: (1) To remove internal stresses and/or to induce softness; the maximum temperature may be above or below the critical points according to the degree of softness required. (2) To refine the crystalline structure in addition to the above, in which case the temperature must exceed the upper critical point (to secure a complete diffusion) as in normalising. Annealing is necessary before and after machining high carbon tool steels, high speed steels, air hardening nickel chrome steels, etc. High speed steels should also be annealed before forging. Some steels are first normalised to refine the structure, then allowed to go cold, and then annealed at a lower temperature.

Normalising.

In normalising the steel is heated to a temperature of 20 to 50 degrees Centigrade above its upper critical point (for, say, 15 minutes) and allowed to cool freely in air. Normalising is used to bring all bars of a batch (which have left the rolls at different temperatures and consequently vary) to a uniform condition to refine the structure (and consequently toughen) and to relieve the strains set up in rolling, etc. It has very little softening effect and is employed chiefly on the ordinary alloy steels for aircraft and motor work, etc. (All such steels should be normalised before hardening.)

Hardening.

This operation consists essentially of heating and cooling with the object of producing in the cold condition the hard constituents of the steel. There are many types of furnaces used for heating, the blacksmith's hearth, the muffle gas furnace, the flat hearth gas furnace, the salt bath, etc. In this country the blacksmith's hearth is almost in general use, but for intricate work this is without doubt the worst type of furnace in existence. However, for the general class of work done here it answers the purpose and is very cheap. The application of the heat is a very important factor; regular and uniform heating can be obtained by turning the tool constantly in the fire. Sharp edges and corners always tend to heat up more quickly than the mass of the tool. To equalise, withdraw the tool from the fire

at intervals and hold for a second or two, when the corners will rapidly lose their heat and become the same temperature as the mass. To learn how to harden steel correctly take a short piece of steel, say 12 in. long by $\frac{1}{4}$ in. by $\frac{1}{2}$ in. and nick this fairly deeply at intervals of about $\frac{1}{2}$ in. Heat this in the fire so that one end is considerably over the correct hardening temperature, the heat gradually tapering off to the other end, which is much below the correct hardening temperature. Withdraw from the fire, study the hot bar carefully, and note at which notch you consider the temperature is about correct for hardening. Quench the bar and break off the notched pieces one by one. At the over-heated end the fracture will be very crystalline and of a "sugary" appearance, gradually becoming less so and finer, until a beautiful fine and silvery fracture is obtained, which indicates the correct temperature. Repeat the experiment until you find you can regularly judge at which notch the correct fracture will occur. Then repeat again and again, now trying to get the whole bar the correct temperature; break off the notched pieces as before, to test whether correct by the fineness of the grain.

I will deal with tempering and case-hardening in detail in my next article, and would wish to point out that although hardening and tempering are often confused by workmen and others they are essentially two different processes of heat treatment.

A Correction.

The photo of the headgear and crusher station on page 123 of our last issue was incorrectly described as that of the New Modder. It should have been the Modder "B."

Masticon and Flexolac.

There are to-day on the market two interesting new asbestos products, Roofing and Rust Plastic Compounds. These materials are British manufactured by the Industrial Engineering, Ltd., Poland House, 167, Oxford Street, London, W.1.

Masticon is a plastic asbestos repair compound for making leaky roofs permanently waterproof, and is guaranteed for 10 years. It is made of the finest South African asbestos impregnated with plastic gums, and is, therefore, imperishable and indestructible. The asbestos fibre gives to these plastic gums the same interlacing strength as steel bars to reinforced concrete. It is very easily applied by any handyman with the aid of an ordinary plasterer's trowel, tar brush, or putty knife. For general purposes it is laid $\frac{1}{4}$ in. thick. It adheres immediately and permanently to any surface, whether corrugated iron, concrete, zinc, felt, glass, slate, asphalt or lead, and expands with heat and contracts with the cold, always ensuring perfect contact with the joints.

Rust and Its Prevention.

Flexolac.—The terrible ravages of rust have been forcibly evident ever since the application of iron and steel to constructional and industrial purposes. Since the life and strength of these metals depend on their not rusting, the introduction to the engineering world of a material which will efficiently prevent oxidation or rusting will be welcomed. Iron and steel rust in varying degrees upon exposure to atmospheric moisture, sulphurous fumes or saline matter, much depending upon the condition of the metal surface, rough surfaces rusting much more rapidly than smooth or burnished surfaces.

Wherever moisture (oxygen and water) is found, rusting takes place, and since our atmosphere contains moisture we find rust everywhere. Under this influence a combination of iron and oxygen is formed and the metal is stated to be rusted. Several paints and other compositions which are termed rust preventatives only fulfil their mission in a

limited sense and under a limited type of conditions—their life is short. Flexolac is a material designed to protect the metal parts of constructional work from all known actions which give rise to rust. It is actually a rust-resisting paint which maintains its purpose for many years. It is therefore eminently suitable for the preservation of all types of metal roofs, chimneys, ridges, piers, railings, fire escapes, pipes, etc., etc. It is a scientifically prepared compound. Its base is fibrous asbestos rock as it comes from the mines in South Africa fire-proof and imperishable. This indestructible fibre is impregnated with plastic waterproof gums producing an adhesive, penetrating, durable and elastic coating which is unaffected by climatic conditions and which will not crack or peel as the result of heat or vibration. It never sets hard enough to become brittle, yet it dries hard enough to eliminate all possibility of its being washed or rubbed off. This is due to the fact that it sets by chemical action and not by evaporation. This is why water has no effect on it.

The South African agents are Messrs. Sedgwick & Luckhoff, Box 978, Capetown; and the distributors are Messrs. Hunt, Leuchars & Hepburn, and Rogers Jenkins & Co., Durban, Johannesburg and Capetown.

Oil Fuel in Great Britain.

The development of the use of oil fuel for many purposes in Great Britain is illustrated by the construction of large storage depots at various points. In one of the latest which is being constructed on the Tyne, there are two tanks of 8,000 tons capacity each and a similar one of 4,000 tons capacity forming the first instalment of a very large depot. The tanks have been erected near the jetty, with which they are connected by means of pipe lines. Vessels desiring to obtain supplies of oil fuel will berth in deep water alongside the jetty. Along with this development in oil storage there is proceeding a very active production of oil-engined ships in British yards, and some of the ships have achieved remarkable economic results. One of them on her maiden voyage across the Atlantic consumed only 130 tons of oil. This was 200 tons less than the amount which the engineer had calculated would be necessary.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

A QUIET OPENING—HOLIDAYS RESTRICT BUSINESS—COAL TRADE PROSPECTS—LOCAL METAL PRICES—OVERSEAS IRON AND STEEL OUTLOOK.

Business on the Commercial Exchange was even quieter this week than last. The holidays and the beginning of the month made for inactivity, and there is really little to report. The reduction in the railway rates on coal is hailed as a good augury for a revival in the colliery trade, which lately has been drooping.

The Coal Trade Outlook.

The prospects of the Union's coal trade are, of course, of vital interest to business men. If our coal industry survives the conflict successfully, the outcome will certainly be a vastly increased volume of traffic over our railways, a greater influx of shipping at our ports, and an all-round improvement in railway revenue, which will leave the Administration relatively much better off than before the present rate reductions were made. The railway rates on coal are still, however, about 250 per cent. above pre-war level. Between 1911 and 1921, for example, the railway rate from the Transvaal collieries to Delagoa Bay soared from 6s. 1d. per ton to 36s. per ton—an increase of 500 per cent. At the time the last rise was made, world conditions were abnormal; coal was selling at famine prices, and the industry could well afford to let the Railway Administration have a lion's share of the profits, which it well deserved. But at the beginning of 1921 the boom burst; prices avalanched downwards. The Union collieries, which at the end of 1920 jumped their pithead price for 1921 export contracts to 17s. 6d.—the price in 1910 was about 4s. a ton, and at the end of 1919 13s. 6d. a ton—got caught on a slumping market, and for some weeks the export trade ran a real risk of disaster. But pithead prices soon slumped, too, and successive reductions of railway rates to 300 per cent. above the 1911 level successfully tided things over till the recent coal strike in Great Britain, which once more gave the South African coalowner the opportunity of regaining a sound footing in the Eastern markets. And now, just in time, Mr. Jagger has consented to the rate reduction essential to enable our coal to compete with the British article, under post-strike conditions.

The Johannesburg Chamber of Commerce announces that as a result of further representations to the Union Government, it has been arranged that permits for travellers to Portuguese East Africa will in future be available for any number of journeys during a period of one year from the date of issue. It is hoped that this extension of the validity of the permits will remove to a very great extent any inconveniences suffered by British subjects who have to travel frequently to the adjoining territory. With regard to the Portuguese visa, it is understood that the Portuguese authorities do not insist on these permits being vise-ed, except when the holder lives in a town in which a Portuguese Consul resides. The Government points out that the conditions in South Africa are different from those obtaining in France, Belgium, and other parts of Europe, inasmuch as there is a strict police surveillance of all travellers on the Continent which is absent in South Africa, and also in most countries in Europe there is a systematic registration of all persons at police offices.

Trade and Finance.

The general managers of the Standard Bank of South Africa, Ltd., have received the following cable advices from the London office of the bank:—The following views are expressed in financial circles: There is much complaint about trade depression and the number of unemployed is still very large. There are, however, signs of improvement because the collieries are working freely and prices are still falling. Economies of many kinds are being practised by manufacturers with the result that contracts are possible where before they seemed to be out of the question. The August trade figures are distinctly in advance over those of July, and it is evident that business is improving, but only to a moderate extent. Much depends upon further economies in productive costs. Meanwhile disordered exchanges tend to complicate the position. The money market has been very easy because the poverty of the Exchequer caused considerable borrowings on ways and means. Another fall in the bank rate is expected, although there may be some pressure for money just before the end of this month. Until the last day or two day-to-day loans have been fluctuating between 2 per cent. and 4 per cent., whilst the rate for additional Treasury Bills has been lowered to 3 $\frac{1}{2}$ per cent. This caused ordinary discount rates to rule between 3 $\frac{1}{2}$ per cent. and 4 $\frac{1}{2}$ per cent.

American Trading in East Africa.

America seems to be making determined efforts to capture the East African market—a fact which should engage the serious attention of South African firms engaged in the export trade. According to the *Board of Trade Journal*, H.M. Trade Commissioner in East Africa reports that in his area a large amount of commercial propaganda is being carried on by United States firms. Many East African firms regularly receive free copies of United States trade journals, but some United States firms, notably those engaged in the hardware and motor accessories trade, are writing to East African houses offering the sole agency of their products on the following very liberal terms, provided that a certain amount of business is contracted for, viz., 30 per cent. approximately on imports direct to the agent and 10 per cent. on imports in the area other than those on account of the agent. Commenting on these facts, the *Journal* remarks that the interest displayed in the East African market by the United States firms is worthy of note, but that whether the condition imposed can be accepted in that market, where prosperity is dependent on a variable agricultural production, remains to be seen.

H.M. Senior Trade Commissioner for South Africa advises us that the settlement of the coal dispute has not so far resulted in a general resumption of work in the iron and steel trades. Up to the present only two or three blast furnaces have been restarted and the output from these is not intended for the open market but is reserved for associated steel plants. Pig iron producers feel that it is useless to resume operations until fuel costs have fallen to a level which will permit of iron being made and sold at a profit, and it would appear, therefore, that some weeks must elapse before a general restarting of the furnaces occurs. In the meantime, stocks of Cleveland foundry iron are becoming still more scarce, but No. 4 and mottled iron, grades for which there appears to be no demand at present, are available in considerable quantities.

A few of the finished steel works which, when stocks of fuel were exhausted had uncompleted orders on their books, have restarted, but a feature of the stoppage has been that there has been no accumulation of orders, and makers are now disposed to defer a resumption until such time as the state of their order books makes it worth their while. How long a period this will be depends upon the time it will take for production costs to fall to the point which will enable British steel material to be sold in competition with the products of Continental works, and here again the principal

factor is the price of fuel. At the present time the world's price for iron and steel is fixed by the Continent. There has lately been a tendency for quotations to become firmer, and it is reported that the French and Belgian producers are considering closing down rather than continuing to manufacture at rates which, they state, yield them no profit. It is said that the Germans, who appear to be taking the greater portion of the business at present offering, are selling for export at figures below the cost of production, even allowing for the depreciated German exchange.

There would thus appear to be some grounds for assuming that higher prices all round for Continental material will be seen before very long.

Tinplates.—A number of South Wales mills have restarted and plates are being offered for delivery. The demand, however, is still very weak, and there is some disappointment that the big curtailment of production during the stoppage has not created a better market.

"Wake Up, South Africa": Plea for Mining Development.

FAR WEST RAND POSSIBILITIES—THIRTY NEW MILES OF REEF—CORONATION POSSIBILITIES—
EXAMPLE OF THE AFRIKANDER—GOLD MINING STILL OUR PREMIER INDUSTRY.

In the following eloquent appeal, Mr. W. P. Taylor, voices his support of our efforts to re-arouse interest in the vast dormant mining possibilities of the country. He re-states many of the accepted facts of the position, and argues from the case of the Afrikander, the Coronation, and the Western Rand Estates, that there are still great undeveloped mineralized areas in the country.

I have recently been asked why I have not written further on the active prosecution of gold mining here. This at least is an indication that my articles have been read with some interest, but the fact that they have been taken over and circulated to the millions of people in Great Britain is perhaps more significant. My desire is that they should become far-reaching, because the matter is of importance, as I have said, not only to mining men here, but to everyone interested in the development of whatever nature in this great country. There is to-day in Johannesburg, and perhaps throughout the country, a regular hang-dog, rotten, despairing attitude amongst a lot of the people which should not be there. General Smuts is perfectly right in his continual optimism, the country is dead right, it has got the goods, every time, but it is a question of the handling. Now, where we are all going wrong is in getting away from our main business. The idea of neglecting to develop gold and harassing a poor old Dutchman with a tax on growing tobacco is absolutely drifting from civilisation to the ante-diluvian. Such drivel will never appeal to me. What is wanted here is some good sound sense and honest co-operation, and it won't be long before men will be holding up their heads and saying "This is God's own country"! Well, it is God's own country. Although engineers and geologists may say there is no more gold worth looking for in the strata of this Rand, beyond the Main Reef series, I cannot help saying they are wrong. There is any amount of gold to be found, and a good deal of it will be worked very soon. The results of the Coronation Company's second borehole will be made within a few months, and it should add, they say, eight miles of reef at once to the Rand. If the Western Rand Estates were compelled to work, it should, probably, assist with twenty more, and if boreholes were put further west, another Rand of greater dimensions might be proved within a year. This is infinitely more interesting than worrying my friend the tobacco farmer for his useless mite. Did the brains that conceived that tax realise that if it were collected, citrus, cotton, maize, wool, sheep and cattle would all have to be taxed, and such perniciousness would have changed supporting S.A.P.s into Nationalists without number? As I have said before, I in no way desire to embarrass the Government, but I cannot get away from what is so perfectly obvious. Now, Cecil Rhodes loved globular figures; so do I. There are endless globular figures of quite a long string in what I am writing about, but it requires an enterprising mind to follow the lines. All over the Transvaal—Witwatersrand, Heidelberg, Potchefstroom, and Klerksdorp—there is gold in reefs, white reef and black reef, all low grade except in places on black reef. In the Northern Transvaal there are numbers of low-grade properties. In the Lydenburg, Barberton, and Carolina districts there are fields of low-grade ores. All the above statements are accepted by mining men to be more or less correct. Recently two new appliances for reducing ore have been tried successfully so far. It is not impossible that in the near future, with such an innovation and the use of oil separation, instead of cyanide, that thousands of small concerns will produce gold all over this country. If one

looks at the list of producing companies to-day and sees that it has dwindled down to some fifty concerns or less, you can at once realise the significance of such an innovation. Spread all over the country's surface, opening up local markets, buying produce at the farmer's door. Can anything be more ideal? Since I last wrote advocating co-operation to carry out development in the Potchefstroom district, three of the Rand's most prominent engineers have taken up the Afrikander mine at Klerksdorp, and it will very soon be producing gold; but there should be many Afrikanders, miles of them, and look at the resurrection that will take place. Why, Klerksdorp is already smiling. Anyway, it is the individual who will come to the rescue, for there is much more money to be made out of gold mining than growing mealies at 6s. 6d. a bag! I do not desire to belittle agriculture, but in this country, at present, it is putting the cart before the horse to put it first. I can quite understand love of country, sentiment, and perhaps political necessities pushing men, clever men, to do all sorts of things, but in the eyes of the practical man, the mechanic, the miner, all this is bumble puppy. It is getting away from the first true work of the country. It is gold that we have to centre on. It is this stretch of auriferous strata and the scattered gold, to take up the appliances put before us, to test it all and put it to work at once and have a renewed industry which can lend agriculture and industry its support to all the great things we should mightily dream about. The watchword of "Wake up, England" did a lot. We certainly want waking up here.

The Position at the Transvaal Silver Mines.

NOTHING WRONG WITH THE PROPERTY—PLANT AND EQUIPMENT ALMOST COMPLETED—EXCELLENT PROGRESS MADE.

What's wrong with Transvaal Silvers? was the question of last week on the Rand. and we are glad to be able to show in the following article that everything is all right at the mine and that the splendid reduction plant and equipment are nearing completion. Shareholders will be reassured to know that whatever may have depressed the quotation for the shares, the trouble, at any rate, is not at the mine.

The property of the Transvaal Silver and Base Metals, Ltd., was the subject of a long and detailed account published in the June 11 and 18 issues of this journal. The technology and the prospects of the company were very fully treated, and the development reached by the beginning of the month of May was given. Since then several additions have been made to the plant, and considerable underground development achieved.

Situation.

The property is situated a few miles to the north-west of Argent, a station on the Springs-Witbank line. This proximity to the railway is a feature of not inconsiderable economic importance to an industry of this nature. The cost of transporting raw materials, supplies and products from and to the railway is thus reduced to a very small figure. In comparison with other successful mineral propositions, the Transvaal Silvers have been greatly favoured in this respect.

Mineral Occurrences.

The outcrops of the silver-lead bearing lodes have been traced at surface for considerable distances. The following figures give the lengths proved:—

Main lode	7,000 feet.
Main cross lode	1,000 "
East lode	3,000 "
Brakfontein lode	5,000 "
Spies lode	3,000 "
Le Grange lode	2,000 "
Boschpoort lode	800 "
Total					21,800 "

The extent of the ore deposits is thus immense, and should provide ore reserves lasting for very many years. Underground exposures of the lodes have been made in the case of the main lode as well as the Brakfontein lode, and ore of high grade exposed. The workings at Brakfontein were under water at the time of the writing of the first account, but since then work there has resulted in the unwatering of the first level. Sampling along this level proved ore of high grade to exist. This confirms the conclusions drawn from the appearance of the lode at surface in this neighbourhood. The following cablegram despatched by the company to its London offices bears out the facts

stated:—"Brakfontein workings unwatered and lodes exposed; first level sampled distance 130 feet, of which 70 feet is payable, containing 12 per cent. lead and 12.6 ounces silver per ton, value 97s. 10d. per ton."

From the last quarterly report of the company we have recorded:—Total footage accomplished, 3,219½ feet, of which 750 feet were payable, and averaged 13.2 per cent. lead and 12 ounces silver per ton, and 1,450 feet were unpayable and averaging 1.5 per cent. lead and 1.4 ounces silver per ton.

Plant, Lay Out, etc.

The property has been laid out on ground which lends certain natural facilities to the disposal and transportation of products. It is situated conveniently close to a stream of water, which supplies the boilers of the power plant. Housing accommodation has been conveniently arranged for both married and single employees, and a supply of domestic water is obtained from a well.

The assay office has been completed, and samples need no longer be sent to Johannesburg for assay. The electric generating plant has been completely installed and is in working order. The reduction plant has been completed in all respects excepting for the concentrating units, which are under erection. It is hoped that these will be completely installed before the end of the year.

Considering the short time that has elapsed since the publication of the last article, when the only evidence of the presence of a reduction plant was the excavations and some foundations of the smelting house, a considerable amount of work has been accomplished under most trying conditions. A close study of the flow sheets published in the May 7 and June 18 issues of this journal will furnish the reader with an idea of the amount of work in connection with the erection of the plant.

The crusher house and its equipment is completed, as well as the conveyor belt for transporting the crushed ore to the wash trommel. Ore from the mine can be treated up to the hand-sorting stage at present. The further additions cannot come into commission till the erection of the concentrating units has been completed.

The roasting plant is in operation and running satisfactorily on hand-picked ore. The first unit of the smelting plant has recently been started up and is now producing lead bullion from the desulphurised ore.

METALS, MINERALS, DIAMOND PIPES AND FISSURES,

I have invented an instrument to devine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

Some Facts Regarding the Victoria Falls and Transvaal Power Company.

In view of the controversy regarding the Municipality of Johannesburg taking a supplementary supply of power from the V.F.P., the following facts regarding the latter undertaking are of interest.

The Victoria Falls and Transvaal Power Company, Limited, was formed in 1906 with the object of supplying electrical energy to the gold mines and other consumers in the Witwatersrand area, excluding the Johannesburg Municipality. In the year 1908 the largest group of mines, now controlled by the Central Mining and Investment Corporation, Ltd., decided to electrify its mines and to purchase all its power, both electric and compressed air,

50,000 h.p. air compressors; Simmerpan, 56,000 h.p. electric generators; Brakpan, 40,000 h.p. electric generators; Vereeniging, 58,000 h.p. electric generators; Robinson, 24,000 h.p. electrically-driven compressors; total capacity of plant installed, 302,000 h.p.

Cycle of Operations.

The cycle of operations resulting in the finished product of electrical energy is as follows: The raw material, coal, is delivered in S.A.R. trucks, which are shunted on to a number of sidings outside the power stations, from which the coal is off-loaded. There is a gallery underneath each of the sidings in which a bucket conveyor and elevator work. The buckets are filled automatically and convey the coal to the overhead bunkers above each of the boiler houses, the coal not being handled by hand at any part of its journey. From the overhead bunkers the coal is discharged, also

View of a Victoria Falls Power Supply Station, whence, it is urged by competent authorities, that the town should take a supplementary power supply.

from the Rand Mines Power Supply Co., Ltd., a subsidiary company of the Victoria Falls and Transvaal Power Co., Ltd. There are, therefore, two separate power companies working under separate licences granted by the Government in terms of the Power Act passed in 1910, but both concerns are controlled and operated by the same management and staff. Capital: Ordinary shares, 1,000,000 (issued as fully paid); preference shares, 2,000,000 6 per cent. cumulative and participating; debentures, 3,000,000 5 per cent. first debentures, 1,650,000 5½ per cent. second debentures; total capital, £7,650,000. Power stations installed capacity: Rosherville, 64,000 h.p. electric generators; Rosherville,

automatically, into a chute which conveys it to a hopper or receptacle at the front of each boiler, from which it is again automatically fed on to the stoker grate. This consists of an endless chain of links conveying the coal from the front to the back of the boiler during which it is consumed and discharged as ash into a receptacle at the back of the boiler, where it falls through a door at intervals into a hopper, from which it is again discharged into cocopans or trucks which are handled by natives in the basement of the boiler house and afterwards hitched on to an endless rope haulage and taken up to the dump at a short distance from the station.

The Rosherville Power Station.

The Rosherville Power Station is typical of the other three power stations. The boilers are of the marine water-tube type. Forty of these are installed at Rosherville, each capable of evaporating about 40,000 to 50,000 lbs. of water per hour into steam. The normal steam pressure is 220 lbs. per square inch and it is superheated to a total temperature of about 340 degrees centigrade. A special form of induced draft is used, known as the "Pratt ejector draft" system. Steel chimneys in the form of an inverted cone are used as being necessary with this type of plant. The electric generating and air compressor plant is all steam turbine driven, the five electric generators being each of a capacity of 9,600 kw. (12,800 horse power), five compressors, each of 4,000 h.p., and three compressors, each of 10,000 h.p. The steam turbines driving the electric generators and the air compressors are of the "impulse" type and revolve at 1,000 revs. per minute in the case of the electric generators and 3,000 r.p.m. in the case of the compressors. The steam, after doing its work in the turbine, passes into the condenser, where it is condensed and returned as water to the hotwells or feedwater tanks, from which it is pumped back into the boilers. The condenser consists of a large cylinder filled with brass tubes through which cold water circulates, the steam passing over the outside being condensed, and as a consequence a vacuum being produced. All the circulating water and feed pumps are steam driven, the turbines being of the "impulse" type and run at 1,400 to 1,500 revs. per minute.

Air Compressors.

The five 4,000 h.p. air compressors, at the time they were installed, were much the largest in the world. The three 10,000 h.p. compressors, which were added at a later date, are to-day the largest units of their kind in existence. The air is compressed to a pressure of about 120 lbs. per square inch and delivered through the pipe network to the mines over an area extending about 15 miles east and west.

Electric Generators.

The electric generators are direct driven by the turbines and generates 3-phase alternating current at a pressure of 5,000 volts. This is transformed to a pressure of 20,000 and 40,000 volts for distribution by the overhead lines and underground cables to the consumers' sub-stations.

Water.

The circulating cooling water is obtained from the Rosherville dam, on the banks of which the station is built. This dam contains at the present time about 900,000,000 gallons of water. Canals are cut leading the cold water to the pump suction. After doing its work in the con-

densers the water is discharged into the outlet canal from which it again passes into the dam, the cooling taking place by natural evaporation.

Network.

The main transmission lines of the company extend from Randfontein on the west to Sub Nigel on the east, a distance of about 56 miles and 36 miles due south to the Vereeniging Power Station. Transmission pressures are 80,000, 40,000, 20,000 and 10,000 volts. The mileage of main transmission line circuits is: 80,000 volts overhead, 136 miles; 40,000 volts overhead, 82 miles; 20,000 volts overhead, 93 miles; 10,000 volts underground cable, 49 miles; 10,000 volts overhead, 40 miles; miscellaneous low tension circuits, 21 miles; pilot and telephone cables, 202 miles; telephones overhead, 55 miles.

Auxiliary Power.

The auxiliary power used at this station in the way of steam and electricity is about 11,500,000 units per annum, which is, roughly, equal to the whole of the sales of electricity in the City of Capetown. It will be noted that there are no reciprocating steam engines in this station, all the auxiliary plant being driven by steam turbines or electric motors.

A Few Interesting Facts.

Approximately 837,000,000 units, or 1,120,000,000 h.p. hours were sent out of the generating stations in the year 1917. This involved burning over 1,000,000 tons of coal, a large proportion of which consists of duff, and is a by-product from the collieries. The Victoria Falls and Transvaal Power Co. is the largest power undertaking in the British Empire. The year's operations involved the heating and evaporating into steam of about 6,500,000 tons of water and this quantity was passed through the turbines and condensed in the surface condensers, which required the circulation of approximately 78,000,000,000 gallons of water. The total number of units sold for lighting, power and tramways by the Public Utility Companies and Municipalities of Greater London for the year 1916 was approximately 450,000,000 units, or about 40 per cent. less than the units sold by the Victoria Falls and Transvaal Power Co., Ltd., to the mining industry on the Witwatersrand. The compressed air supply is much the largest in the world. During the year 1917 no less than 2,000,000 tons of air passed through the main pipe network from the two compressor stations to the mines for use in driving rock drills, etc. At the time of maximum load each day air is delivered at the rate of about nine tons per minute. Approximately 20,000,000 tons of air were passed through the boiler furnaces and up the smoke stacks in the year 1917.

Small Gold Producers.

A YEAR'S RETURNS.

The following list of gold concerns run by small syndicates or private individuals is given by the G.M.E. in his annual report. The returns made to this office show the following comparative figures from gold mining concerns on which less than ten stamps were run:—

	1919.	1920.
Number of concerns which produced during year	45	49
Average number of whites employed during year	109	100
Average number of coloured employed during year	1,770	1,518
Average number of stamps dropping during year	111	87
Tons of ore treated	88,230	78,442
Gold won: fine ounces	21,022.070	19,275.381
Value of gold won at £4.24773 per fine ounce	£102,039	£81,877

Taking all the concerns which may be considered as run by small syndicates or private people, the following comparisons are arrived at for the two years:—

	1919.	1920.
Number of concerns which produced during year	60	63
Average number of whites employed during year	232	196
Average number of coloured employed during year	3,376	2,901
Average number of stamps dropping during year	236	*197
Tons of ore treated	232,812	186,108
Gold won: fine ounces	60,419.583	48,883.833
Value of gold won at £4.24773 per fine ounce	£256,646	£207,645

*In addition, 1 Whittaker Pan mill and 1 Huntingdon mill were in use.

Rouxville Diamonds.

THE POSITION TO-DAY.

Mr. G. A. Chalkley, the Superintending Engineer of the Consolidated Goldfields, has written a very complete report on the position of the Rouxville diamond mine to-day. We take from it the following:—The total number of loads mined during the year amounted to 15,545, and in addition 17,241 loads of surface gravels were removed to dump.

Number of diamonds recovered was 3,488; weight in carats was 4,405½.

If reference is made to the Superintending Engineer's report of last year it will be seen that he draws attention to the richness of portions of the black conglomerate, and refers particularly to the phenomenal results obtained from a wash on the 9th of September. The material for this wash was taken from the south-east corner, which was by far the richest area in the pothole, and from this point in every direction the values in the black conglomerate decreased. By the middle of October practically all the black layer originally stripped had gone through the plant, and from this date it became necessary to remove the overburden and underlying layers in benches, and to treat the thick brown layer before reaching the black conglomerate. The yield of diamonds from the brown bantam layer proved to be considerably less than had been expected, and the few loads of black conglomerate available also gave disappointing returns. These facts, taken in conjunction with the considerable drop in the price of diamonds in February, 1921, made it impossible not to feel uneasy as to the future of the venture. Following on the poor results obtained from the upper or brown bantam layer, the pothole was thoroughly tested, and the results obtained can be summarised as follows:—At the south-east corner the footwall of the pothole was found to dip very steeply up towards the dyke, and further rich discoveries at this point under such conditions could not be expected. On the west wall, although the bantam layers looked promising, the diamonds were few and small in size. Equally poor results were obtained from tests made in the neighbourhood of the north wall and also of the south wall. It was thus realised that it was impossible to even meet the cost of working, in view of the low price offered for the output of this class of diamond, and it was therefore decided to close down the mine until the price of diamonds or other circumstances might justify the re-opening. The dump of diamond-bearing conglomerate oversize from the trommel was put through the plant during the months of April and May, and work was finally suspended on the 24th May, 1921. The whole of the staff were paid off with the exception of a caretaker.

Mr. Hoover, Secretary for Commerce, addressing the American Export Manufacturers' Association, said national industry during the early spring underwent a recovery, having entered a period of easier credits which was marked by a rise in price of bonds and a decrease in the federal reserve and interest rates generally. It must not be thought, however, that the country was on the threshold of a boom and the return of economic stability was still remote. There was little hope of foreign trade between America and any other country becoming normal, while violent fluctuations in the foreign exchanges continued. Steps to secure some stabilisation of the German mark must take priority before the stability of any European country was possible.

Barberton Asbestos.

DEVELOPMENTS IN THE DISTRICT.

At the monthly meeting of the Geological Society, held last Monday, Mr. A. L. Hall, the Assistant Director of the Geological Survey, gave an account of the chrysotile deposits near Kaapsche Hoop in the Barberton district. The deposits occur in the serpentines of the Jamestown Series and lie from 12 to 15 miles from Godwan River Station. The fibre line extends from the eastern slopes of the Drakensberg eastwards for some three miles and is up to 15 feet thick. The seams are distributed both along the contact between two varieties of serpentine or in a green rock immediately underlying a thin quartzite. The principal development work has so far been done on Joubertsdal No. 99, by the Amianthus Mines, Ltd., and in Messrs. Myburgh and Munnik's workings on adjoining Government ground. The most striking feature on Joubertsdal, where the fibre line is opened up continuously for 800 yards along the strike, is the association of a very large number of almost strictly parallel seams over a width of from 5 to 15 feet, with occasional seams up to 7 inches thick. The fibre has that peculiar snow-white fleeciness and high tensile strength combined with the delicate olive green tint of fibre lumps, characteristic of superior quality chrysotile. A plant for milling and screening is now in working order, and furnishes seven grades of fibre down to a quarter of an inch, while the proportion of spinnable fibre (three-quarters of an inch and over) is uncommonly high.

Mr. Hall concludes as follows:—

1. Within the serpentine belt of the Jamestown Series near Kaapsche Hoop chrysotile deposits are found in payable quantity and quality.
2. These deposits extend roughly for some 3 miles along the strike and follow a horizon generally corresponding to the contact between two varieties of serpentinous rocks, and through a thickness of up to 15 feet.
3. The seams are crowded together in large numbers and are as a rule almost strictly parallel to one another and to the contact plane, so as to produce a "banded" or "ribbon" type of distribution, in which the occurrence of 30 parallel seams per linear foot is not uncommon. This type of deposit leads to rocks with up to 40 per cent. of fibre.
4. While the number of seams per linear foot decrease away from the contact plane, there is a tendency towards a progressive increase in seam width in the same direction.

5. The economic importance of these deposits lies in the large quantities of ribbon rock available, in the high flexibility and general superior quality of the fibre, and in its high proportion of spinnable length.

6. The origin of the chrysotile horizon probably depends upon the association of two varieties of serpentine, and the general appearance of the seam distribution recalls that of banded agate and is probably due to the principle of rhythmic precipitation.

7. Development has not proceeded far enough to give any definite indications as to persistence of fibre in depth, but the field relationships favour the view that the fibre formation does not depend upon changes within the belt of weathering.

Northern Transvaal Progress.

A PROSPECTOR'S NOTES.

A journey from Johannesburg to the Rhodesian border is one of luxury compared with the old transport wagon or coach of bygone days. Thanks are due to the Messina

Two Views of the Messina Copper Mine to-day.

copper mines for the change that has taken place adjoining the railway line. Farming with all its different branches, from cattle raising to citrus growing, houses and orchards, beautiful reservoirs, well-fenced lands, happy children, make one wonder if this is the veld we knew a few years ago.

A pleasing incident that helped to secure the firm footing now enjoyed by these people of the north happened during the war. As beginners with limited capital, their participation in that struggle was in the profitable production of corundum ores, which local agents readily bought and shipped to different destinations, where they were used by the Allied Powers as abrasives. There are still available enormous supplies of excellent quality situated along the line between Pietersburg and Sandrivierspoort. The production of this commodity, like copper and many other base metals, has had a restricted output by conditions of world-wide depression prevailing. However, it may be safe to conjecture, when the clouds clear and the world's markets again open to take supplies, that good times for producers will be restored. There is also graphite of good quality and workable quantities known to exist within easy access of rail, which should in time prove an asset to residents near the localities of occurrence. Towards Messina, some distance further and eighteen miles from that place, we arrive at the Liliput coal pits situated on the Sand River, where the copper mines of Messina have secured an unlimited supply of fuel. This is the only coal mine opened up on this formation. Adjacent to the Messina ground and near the siding is Potash Hill, yielding a high and uniform percentage from extensive bodies owned by the Dominion Syndicate.

Again, nearer to Messina is the Messina Extension Syndicate, where considerable work has been accomplished and their claim holdings carry promising copper values. In the district chrome iron, asbestos, limestone of high grade, salt, etc., also occur. From the Rhodesian border the Messina copper mines are distant seven miles, and form the terminus of the railway in the Northern Transvaal.

Letters to the Editor.

THE REAL VALUE OF GOLD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Under the above heading a long letter appeared in your last issue, over the signature of G. H. Blenkinsop, who was so particularly anxious to be accepted as an authority on the subject that he favoured your readers with a very interesting autobiography. I have always been of the opinion, considerably strengthened by Mr. Blenkinsop's letter, that currency and exchange, never having been reduced to an exact science, has baffled all those economists and others who have endeavoured to understand and expound its intricacies and vagaries; the war and its aftermath have clearly proved this. And so we are witnessing the collapse of those theories so dear to economists who would have us believe that they *do* understand what they lay down in their "Wealth of Nations" and other volumes of a similar esoteric nature. But one may still hope. Where all the orthodox economists have failed Messrs. Speak and Blenkinsop are going to rescue the world from financial chaos by—of all remedies in the world of imagination!—increasing the price of gold permanently to £6 6s. per fine ounce (why the odd shillings?). Let us put this precious remedy to a simple test: In 1914, and well on into the war period, an ounce of fine gold could have been exchanged for coins to the value of £4 4s. 10d.; to simplify the illustration and to eliminate the decimals, 10,000 ounces of fine gold could have been exchanged for 42,116 sovereigns. Does Mr. Blenkinsop really think that by increasing the value of gold to £6 per ounce that he would get 60,000 sovereigns in exchange for 10,000 ounces of gold, or, in other words, that he would get, roughly, 50 per cent. more gold in the form of coin than the amount of rough gold deposited?—ridiculous. Why fix the increase at £6 6s.? Why not at one jump double the value of gold and thus simplify the conjuring trick; our sovereign would then become £2 and the half-sovereign would take the place of the pound piece; but how much would these coins buy. Why just as much as they buy now—no more, no less. Your correspondent asks—one can almost hear the triumphant note—"Is there any modern intelligent man who can give an intelligent reason why gold should not be six guineas per ounce? Well, sir, here is one very intelligent and cogent reason: To-day America holds 80 per cent. of the world's gold and would hold the other 20 per cent. if the allied nations were able to liquidate their indebtedness to that country; is it not apparent to the densest intellect that a gold premium spells ruin to England and France should America demand a settlement of her account? America holds £1,000,000,000 in gold. Mr. Blenkinsop's proposal would mean that this amount would be increased, by a stroke of the pen, to £1,500,000,000 without increasing the wealth which the sum is supposed to represent. It is nothing short of madness to delude our workers with a vision of the millenium by the mere fixing of a gold premium, and any proposal to tamper with our currency is a chimera. I would remind Mr. Blenkinsop and those who think with him that "money is the article agreed upon as a common demonstration of value, in terms of which all commodities may be expressed with a commensurate amount of which any commodity may be purchased, for a commensurate amount of which any commodity may be sold. Gold being the standard governing the exchange of all commodities, it must follow that its value cannot fluctuate, and it also follows that whether an ounce of gold is minted into four or eight coins it is not the number of coins but the quantity of gold contained which fixes the price of commodities. In conclusion, Mr. Blenkinsop should know that England is in a very bad way financially, especially as regards her indebtedness to America, and any permanent increase in the price of gold,

that is, making it more difficult to get gold, would result in enormously adding to the trials and tribulations of England and her allies.

Yours faithfully,

LEWIS WATKINS.

INCOME TAX RELIEF TO RESIDENTS ABROAD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—It is quite apparent, from the information constantly reaching me, that many individuals not resident in the United Kingdom fail to claim the reliefs from British Income Tax to which they are now entitled. This failure to claim repayment of tax doubtless arises through lack of knowledge of the nature of the reliefs, the chief of which are:—(1) Exemption in respect of dividends on certain British Government securities where the beneficial owner is ordinarily resident abroad. (2) Exemption in respect of interest or dividends on Foreign or Colonial securities, stocks, etc., owned by a person not resident in the United Kingdom. (3) Reduction or exemption from tax on income from sources within the United Kingdom in the case of a British subject, Crown servant, ex-Crown servant, widow of Crown servant, employee of Missionary Society, resident of the Isle of Man or Channel Islands, or resident abroad for sake of own health or health of a member of the family. (4) Reduction of tax where Income Tax has also been paid on the same income in another part of the Empire. I shall be glad to reply to inquiries from any of your readers who consider they may be entitled to claim repayment of tax suffered.—Yours faithfully,

W. R. FAIRBROTHER,

Income Tax Specialist.

The Gold Basis.

By R. E. Barker.

The currency and credit problem is now under almost ceaseless discussion, and, however much the real issues involved in its solution may be side-tracked or disguised, the matter is probably the most important which this generation has to consider. In South Africa there is, under its circumstances, a pardonable bias towards reversion to the gold basis as an objective of national policy. And, although the conflict of opinion as to how this purpose can best be achieved is often bitter, men of all parties seem persuaded that the anchorage of currency to gold is essential to the proper functioning of production, distribution, and exchange. The implications of this doctrine are sometimes curious. Mr. Tielman Roos, for an example, defines "capital" as a "mixture of money and credit on a gold basis," and, as a means to restoring the gold basis of our currency here, advises Government to prohibit the export of gold. Seeing, however, that nearly half the world's annual supply of the metal comes from the Witwatersrand, it is clear (though not to Mr. Roos) that, were such a prohibition applied, the return of other countries to the desired basis would be retarded or made impossible; and the amount of their "capital," on Mr. Roos' definition of the term, would shrink proportionately. No doubt this may be flattering to our sense of importance, as it involves the admission that the narrow crescent of reef between Heidelberg and Randfontein is the spinal-cord of the world's industry, and that if an earthquake ruptured it civilisation would immediately dwindle or collapse.

Politicians and the Question.

The views of Colonel Creswell and Mr. Kentridge, even if in complete alignment with one another, are certainly in opposition to the measures which either the Government or National Party favour for restoring the gold basis. Yet they agree that a gold basis is desirable, but recommend a State Bank as a substitute for private credit institutions. Bankers in all parts of the Empire continue to affirm their faith in gold as the right foundation of credit and currency, and are deflating to restore it. The unity of opinion, touching this one matter, expressed by such different schools of thought, must be gratifying to conservative economists. If the world is unsafe for democracy it should, apparently, be safe enough for gold, when the Socialist echoes the financier in applauding it as the rock upon which money and credit must repose. "To get back to a gold basis we shall gradually deflate," says Sir Felix Schuster. And Mr. Kentridge across the ocean, and Heaven knows what sundering gulfs of philosophy, answers him: "The evil of inflation could be checked by the restoration of the gold standard." Such concord is charming; and is, perhaps, the prelude to that "co-operation of all classes" and "pulling together" which, we are told, is the first step towards healing the wounds of humanity. In the meanwhile it is well to subject the term "inflation" to a brief analysis.

Deflation.

Bankers and, it seems, communists too, consider that the currency is inflated when the monetary tokens available exceed the gold, into which they are convertible on demand, by more than a certain proportion. Hence, in the words of Hawtry: "Deflation is the weapon the banks use to protect their gold reserves." If currency were tied to wheat, it would be inflated when, for instance, there were 10,000,000 notes in circulation each carrying the right of conversion into a bag of wheat when the banks had only 1,000,000 bags in their possession. Similarly, if financial credit, money, buying power—whatever you choose to call it—were based upon commodities in general, both in *esse* and *potesse*, it would be inflated only when it furnished the means to acquire goods more rapidly than they could be produced. Under such circumstances we should suffer from over consumption. And the remedy would doubtless be the raising of price levels. In fact, under an ideal credit system, prices

would fluctuate automatically as the power to produce commodities increased or diminished. But that Utopia is far off. It is obvious, however, that a system, under which the amount of buying power issued is governed by the available supply of any one commodity, does not, and cannot, furnish means adequate to induce the full and steady employment of the world's productive capacity. Financial credit based upon gold can have no scientific relation to commodities in general—to real credit and ability to create wealth.

Whatever the supposed merits of a gold basis may be, it is at the deadly disadvantage that it must always collapse when subjected to the strain of a big war. War initiates a tyrannous demand for commodities, to gratify which huge financial credits are released when, of course, the currency, at once breaks moorings from its bed of gold. So that if, by drastic restriction of credit, the world ever does return to a gold basis, it will only remain there until the next armed conflict between the nations, which the growing competition for foreign markets makes almost inevitable. The vast output of munitions during the recent war period was induced by the issue of more buying power. Because, although prices rose, they were subject to some control. Hence there actually was a great enhancement of effective demand, and consequently of production. It would have been impossible to finance the war on a gold basis. It was financed on the credit of the nation. Now, if a currency and credit system founded upon gold cannot support the intenser national activities during war, we might infer that, even during a peace, it would not be the best possible system to induce the maximum output of commodities. If it is the best, then our prospects are desperate indeed. We must always suffer from the alternating phenomena of inflation and deflation, with corresponding fluctuations in price levels, from under consumption, from booms and depressions—chiefly the latter—from want, destitution, unemployment, and all the rest of it. The gold basis is unable even to assure the stability which its advocates claim as its most conspicuous virtue.

The Douglas Scheme.

There is no attempt here to solve the highly technical problem of how to establish financial credit on a broader and more rational basis. Some scheme has been worked out in detail by an English economist—Major Douglas—but his book on credit power, which embodies it, is not procurable in Johannesburg. Price fixing, however, and the foundation of producers' banks, and the issue by them of financial credit based upon the productive capacity inherent in the machinery development and personnel of the various industries are essential features of the Douglas scheme. Presumably it has something to recommend it, because it is approved by Professor Pigou, the very distinguished successor to M. Daguin as Economics professor at the University of Bordeaux. But whether or no Major Douglas has revealed the road out of our difficulties, some road must be found. In essence, the problem is to devise a mechanism which will bring financial credit into some proper relation to productive capacity. When this is accomplished, as it will be by the next civilisation if not by ours, every advance in progress will be a benefaction and not, as now, too frequently a curse. Surely a system is gravely defective which makes no provision for expanding the means to acquire commodities as improvements are effected in the means to producing them. Yet how is this feasible if the operative force of demand for commodities in general is to be determined by the available supply of only one commodity—gold—and the ratio it bears to the buying tokens? It is not suggested as a remedy for this disease of under consumption which afflicts us, that there should be an unregulated issue of paper money. For such an issue would constitute no increment of buying power, if it provoked an equivalent rise in price levels. But I submit that some device must be found for instrumenting the consumer to acquire and induce an output commensurate with that latent in mankind's splendid productive capacity. Another and far more devastating war will be the consequence of our economic distress; and then it will be too late to find a cure. When a civilisation is in convulsions it is not the best time for calm thinking; men do not see clearly in the blood-shot light of its decline.

Miners' Phthisis.

SOME REASSURING INDICATIONS.

In the course of his annual report for last year, Sir Robert Kotzé has the following on the vital question of miners' phthisis:—

The report of the Medical Bureau for the year 1919-1920 shows that the number of miners who during that year contracted miners' phthisis in the primary or secondary stage was 398, as compared with 319 in 1918-1919 and 153 in 1917-1918. The average period of work was nine years and eight months, as compared with nine years six months and nine years five months for the two preceding years. During the year, the number of cases of men in the anti-primary stage was also determined, but as there was no previous determination, the production rate of this class cannot yet be ascertained. The figures quoted appear to show that there has been an increase in the number of new cases, and it might be concluded that the preventive measures are proving inadequate. The chairman of the Bureau does not, however, consider this conclusion justified, and attributes the increase to the miners who have returned from military service, and who had not previously been examined on any occasion. A considerable number have had silicosis for years past, and they have now to be included amongst the new cases, and thus bring up the production rate. The Bureau considers that the length of the average period of work of the miners who have contracted silicosis is at present a more reliable criterion of the effectiveness of the combative measures, and the slight increase in this period is therefore satisfactory. A far more reassuring indication of such effectiveness is, however, to be found in the evidence of the Chairman of the Medical Bureau before the Miners' Phthisis Commission, and quoted by the President of the Chamber of Mines in his address at the annual meeting on the 31st March, 1921. The figures advanced for the seven months since 1st August, 1920, showed that the production rate since then had fallen off very substantially as compared with the previous two years. I am informed by Dr. Watkins-Pitchford that this decline has been maintained up to the date of writing (June 14th). Of the miners who have passed the initial examination of the Bureau in the four years following 1st August, 1916, 3,592 adopted underground work, but not one had contracted silicosis in a recognisable degree up to August, 1920. This also is a satisfactory feature, but the period is so short that undue weight must not be attached to it. Although the indications support the contention that in the main the combative measures are effective, there is no justification for slackening off in the stringency of the preventive campaign. There are still too many new cases of silicosis, and inspectors' reports prove that slackness is still too prevalent, and that conditions are too often found to be unsatisfactory to permit of any such relaxation.

Machine Drills.—The annual report of the Chairman of the Medical Bureau draws attention to the continued greater evidence of the disease amongst machine drill men as compared to other miners, emphasising the need for still greater attention to the operations in this class of work. Machine drills of which the dry jack hammer is the type, and which clear the hole by passing compressed air only down the hollow jumper, have been prohibited by regulation since 1st March, 1920, but further improvements in the machine drill work generally are necessary. In my previous annual report, I indicated several directions in which this can be effected, and the report of the Miners' Phthisis Commission, now in print, makes recommendations towards the same end. Voluminous evidence on preventive measures was led before the Commission, and its suggestions will no doubt serve as a jumping-off point for the inauguration of improvements in conditions. Attention has frequently been drawn to the faulty features of various types of machine drills. Many of these defects are inherent in the machine, but they are frequently and unnecessarily aggravated by the use of faulty material, such as inferior

hollow steel or by inattention to details in sharpening the steel or in repairing, for which the designers and maker of the machine cannot be held responsible. The remarks of inspectors of mines quoted below will furnish instances.

Miners' Phthisis Commission.—During the year, a commission of five members, presided over by Mr. Justice J. de Villiers, was appointed, principally with the object of devising improvements in the Miners' Phthisis Act of 1919, but charged also with the duty of inquiring into the methods for the prevention of the disease. The Commission has issued an interim report, in which it deals at some length with various preventive measures, but intimates that its work in this direction was still incomplete. The Commission has now been dissolved, so that we are deprived of the benefit of its judgment in several matters on which evidence was presented to it.

Systematic Inspections.—In September the staff of inspectors of mines on the Witwatersrand was strengthened by the appointment of four additional assistant inspectors of mines, mainly with the object of undertaking the systematic inspection of the phthisis mines described in my last annual report. A number of mines have already been thus inspected and reported upon, the intention being to have each mine overhauled once a year if possible. Further work has shown that it will probably be necessary to modify the original scheme in some respects, so as to do the work more expeditiously and to render the inspection more effective. Experience will indicate the weak points of the scheme and suggest improvements, but the knowledge already gained of the conditions on the inspected mines is considerably in advance of anything the department had before. In the course of inspection there is opportunity for discussing every point with the officials of the mine, and rectifying faults wherever possible, and a copy of the completed report is presented to the manager, so that he also is placed in possession of a general review of the conditions, and can give his attention to any matters which the report indicates as being in need of it.

Ventilation.—Comment has been made on a previous occasion on the necessity for improving the atmospheric conditions underground, and especially for suitably distributing the available air supply. It is becoming increasingly clear that the removal of the finest and most dangerous dust is dependent upon ventilation, and that unsatisfactory dust conditions are frequently due not so much to the nature of the work being performed, as to the relative inadequacy of the ventilating currents. Close places through which there is no air-current, and backstops with sluggish currents or stagnant air, are generally found to be unsatisfactory. The dust in the air must be considered and treated like a deleterious gas, and removed like it; that is, by displacement of the air containing it. A corroboration of this contention is to be found in the circumstance that a high CO₂ content is frequently accompanied by unsatisfactory dust results. When the amount of CO₂ is lowered by replacing the foul air by fresh, there is also, as one would expect, an improvement in the dust conditions. During the year returns have been secured of the ventilating systems of all the mines of the Witwatersrand, giving particulars of the system of ventilation and of the quantities of air in circulation. These have been compiled into a tabular statement. The quantities of air circulating have not in all instances been checked by the inspectors, but in the course of the systematic inspections now in hand, such a check will naturally be made. The amount of air called for by regulation is 30 cubic feet per person per minute, and a few mines do not reach this standard, and steps will have to be taken to bring them up to standard.

CO-PARTNERSHIP IN MINING.

Although there is an ominous silence regarding the progress of the Roodepoort U.M.R. co-partnership proposals, of which we wrote some weeks ago, the matter continues to excite so much discussion in mining circles that we may be pardoned for returning to it. Since last we wrote we have been enabled to consult the informative work on the subject of co-partnership by Mr. L. L. Price, and on "Profit-sharing" by Mr. L. V. P. Gilman. We have also had the advantage of perusing the data published in the valuable Board of Trade report on the subject issued just before the Great War. All these works bear out the conclusions already published in these columns, notably the hostility of organised labour to all such schemes and the difficulty of bringing them to successful fruition. For a practical example of co-partnership applied to mining, however, we need go no farther back than the recent settlement of the strike in the British coal industry, and several of the facts brought out

in the discussion of that settlement have an important bearing on the principle as applied to the Rand. For the best examination and analysis of the position in the British coal mines to-day, we are indebted to Mr. W. L. Hitchens, of Messrs. Cammel, Laird & Co., Ltd., who is well known in South Africa. Mr. Hitchens, in the course of a long and closely reasoned paper read the other day before the British Association, shows himself in favour of making some reasonable experiments to reconcile the interests of capital and labour. In this category he reckons profit-sharing, though he thinks it will never solve the problem of the fair distribution of the proceeds of industry between labour and capital. His views on the new agreement in the coal mining industry are worthy of special note. He points out that the objection that under a profit-sharing system there might be glaring inequalities as between one mine and another has been anticipated under this scheme; but he observes that in the first place it is not a profit-sharing scheme in the proper sense of the term, because individual companies may make a loss and yet be obliged to pay the increased wages. In the second place, he believes that the mines in each district will be obliged to amalgamate, in order that the poor mines may not be too heavily penalised by the rich ones, and the range of profit and loss still further accentuated. He is not very sanguine, however, about the scheme as a whole; it is more probable, he thinks, that "there will be no average profits during the next few years, since substantial reductions in the price of coal are essential and inevitable," and that the scheme will prove to be stillborn. Should it, however, turn out to be a vigorous infant, and lead on to district amalgamations, a further consequence, Mr. Hitchens thinks, will be that the miners will make a strong demand for a voice in the control of the industry. This natural consequence of effective profit-sharing he believes to be unworkable, as the ultimate control in any business must always rest with those who bear the financial responsibility. In this respect, it will be noted, he supports the view taken by the directors of the Roodepoort U.M.R. That this may prove to be an accurate diagnosis seems undoubtedly the view held by the majority of those concerned in the management of the British coal industry, and there are grave disadvantages in the method suggested by Mr. Hitchens of "trying out" each such nebulous scheme that the mind of man may devise; every failure inevitably causes disappointment, sours by a suspicion that the workmen have been "had," and we are not sure that this danger does not far outweigh the educational advantages of proof by concrete example, which some of these derelict schemes undoubtedly may give. To the discussion that followed upon Mr. Hitchens' paper, a valuable contribution was made by a well-known employer, Mr. A. Hopkinson, M.P., who said that profit-sharing, from his own experience, as a solution of industrial troubles, was not of very great direct importance, although indirectly he had found it important. The introduction of profit-sharing into his own works had turned the works into a school of economics for trade-unionists. After a year's experience, a small finance committee, which consisted of men experienced in trade union finance, went through the balance sheet with him, and one of them suggested extending the works. When he explained that money would be needed for the purpose, they wanted to know where the money had come from when the works had been extended previously. The money had been provided out of profits, whereas the men were under the impression that the employers had squandered it all. When this was explained to them they were taken aback, and gradually a few men began to realise that to keep a business healthy some of the profits must go back in the form of new capital. The few workers, therefore, came to the logical conclusion that it would be better if the employers took more profit year by year. He appealed for the provision of more capital by labour itself, which would result in raising wages and reducing the capitalists' share of profits. If the money which went to bookmakers and publicans were saved for a few years, companies should be able to get capital at 2 per cent. or even 1½ per cent. It may be a far cry from the debates of the British Association pundits on profit-sharing to the modest scheme proposed at the R.U.M.R., but we believe the points we have quoted have a very direct and practical bearing on the problem at our doors.

MONEY AND MINES.

The past few days have been unusually prolific in suggestions from politicians of the Nationalist and Labour Parties in regard to economic matters. In one quarter is advocated the creation of more paper currency, in another the declaration of a moratorium, in another the prohibition of the export of gold. It is a little difficult to discuss these bucolic nostrums with patience after all that has been said and written in regard to them in the past few years. An inflated paper currency can but add to our difficulties, and bring down on South Africa the troubles under which the paper-ridden countries of Europe are now groaning. A moratorium is, of course, but another name for bankruptcy, and bad as the position in the country districts may be, it scarcely warrants the adoption of that expedient. The last suggestion is perhaps the most foolish of all. If the product of the mining industry is not to be exported, imports cannot be paid for, trade must come to a standstill, and, bereft of supplies, the mining industry must close down. If there is a shorter cut to bankruptcy, we certainly don't know of it. As it is, the position, quite apart from these desperate expedients, is bad enough. The renewed discussion in London on the question of cancellation of war debts has had the effect of depressing the dollar exchange value, and as a consequence reducing the premium on gold. Nothing could better illustrate the delicate nature of the latter. Already Presidents Wilson and Harding have set their faces against war debt cancellation, but it seems possible that the coming disarmament conference may revive the question. Everyone is agreed that were the war debts cancelled between the American and Allied nations, it would go far to stabilise exchanges and make foreign trade again possible. But public opinion in America does not yet seem educated up to this heroic form of trade restoration, and the gold premium seems safe for a little longer from this danger. As one London contemporary well puts it: "In an attempt to stimulate exports America is said to be contemplating a commission to inquire into the means necessary to stabilise foreign exchanges, but the prospects of success are doubtful. Depreciation in currencies may be said to be due to foreign debts and unbalanced budgets, and no commission can remedy the latter, because it would mean the imposition of fresh taxation, and when local Governments are afraid to do that, recommendations from any commission is apt to fall on stony ground. Nor must it be forgotten that the real purpose of the commission is less to stabilise exchanges for the benefit of the Allies than to find out a way to sell American goods. Further, to stabilise exchange means in effect that a solvent country will be unable to derive any benefit from her improving position, while an insolvent nation, making no effort to cover expenditure by revenue, will be able to disguise her real position for a time. The after effects of stabiliment of exchange would be just as disastrous as other Governments' experiments in interfering with economic laws. It would, however, be a different matter were America to agree to the debts of the Allies being payable at a fixed rate of exchange which would approach normalcy. Outside this country there is very little likelihood of any of the Continental Powers being able to liquidate their American indebtedness while the present New York valuation of local currencies continues. Such a concession might more than halve the face value of some of the loans, but the creditor would benefit quite as much as the debtor, because so long as the debts remain unsettled international business cannot be restored. Cancellation of the debts altogether would be the best way, but failing that the acceptance of payment at normal valuation of currencies, both by this country and America, would be of very material benefit towards the restoration of the world to prosperous peace conditions."

Notes & News.

Rhodesian Diamonds.

Recent issues by the Southern Rhodesia Geological Survey include a report on "The Geology of the Diamond-bearing Gravels of the Semabula Forest," by A. M. Macgregor, B.A. The work embraces much valuable information on the various aspects of the mineral deposits found in the area named.

Blue Asbestos.

Blue asbestos producers in British Bechuanaland have joined hands in the formation of a Blue Asbestos Producers' Association, by which it is hoped to place the industry on a sound and business-like basis. A deputation consisting of Messrs. W. H. Addison and J. P. Frylinck recently waited upon the Minister of Mines and Industries in Pretoria, and the Government, as an outcome, has consented officially to recognise a grader of the fibre appointed by the Association. The latter has agreed upon a standard grading and minimum prices.

A Stopping Record!

Further to our announcement last week of the world's stopping record, which was broken at the Van Ryn Deep during September, we now publish the figures showing the three previous months' work performed by Mr. B. T. Lellyett with Hohman drills:—

Contractor: B. T. Lellyett.

Type of Machine: Hohman H.W.3 and Hohman C.H.2.

Period (inclusive)		Square Fathoms	No. of Mchns.	Length of Steel Chisels	No. of Working Shifts	No. of Machine Shifts	Fathoms per Machine Shift
From	To						
1/6/21	25/6/21	160	4	6 in.	22	87	1.84
27/6/21	26/7/21	207	4	6 in.	26	103	2.01
27/7/21	1/9/21	234	4	6 in.	32	118	1.98
2/9/21	1/10/21	248	3	10 in.	26	78	3.18

Co-operation in Oil Prospecting.

Replies have been received by the Home and Territories Department from several of the State Ministries with reference to the encouragement of prospecting for oil in Australia (says the *Melbourne Argus*). New South Wales decided late last year to increase to £10,000 the reward for the discovery of oil in that State. Applications were also invited for assistance from the prospecting vote to bore for petroleum on approved sites, on the basis of half costs, each case to be dealt with on its merits. In February, the Premier of New South Wales suggested the inadvisability of granting the proposed reward at present as no indication of commercial oil deposits had been found. It was also stated that a reply had been received from Victoria to the effect that the Victorian Government did not consider that any good purpose would be served, so far as that State was concerned, by supplementing the reward offered by the Federal Government. The policy of South Australia is that the best encouragement for prospecting is a bonus on actual production rather than a subsidy towards prospecting operations. Five applications have been received by the Federal Government for the reward of £50,000 offered for the discovery of oil in payable quantities in Australia. Three of these are sending regular monthly reports to the Department of Home and Territories, but no definite indications of large deposits of oil have yet been announced. No applications have been received from prospectors in Victoria. There are two from New South Wales. A Queensland Oil Company has also lodged a claim. One of the other applicants refused to indicate the location of the bore, or to furnish any particulars, though demanding payment of the £50,000. An offer was recently received from an American firm offering to locate oil in New Guinea and Papua by the aid of a divining rod. This offer was not accepted as the Federal Ministry has experts prospecting in those parts.

Important Insurance Deal.

It is announced that Mr. I. W. Schlesinger has, on behalf of the African Life Assurance Society, bought the entire African business of the New York Mutual. This incurs the transference of over one million pounds sterling, bringing the policy reserve fund from New York to the African Life Assurance Society. Thus the sum becomes available for investment in this country. In estimating the value of the deal, so far as South Africa is concerned, it has to be borne in mind that, according to its articles of association, the African Life can only put its moneys in Government and Municipal stocks or lend it on first mortgage. It is rumoured that Mr. Schlesinger has also purchased the whole of the African business of two or three other American insurance companies, which would result in the transference of a further two millions sterling from New York to the African Life. These later rumours, however, lack confirmation.

World's Record and the Rock Drill Hose.

In connection with the world's record established by the Holman rock drill, it is of interest to know that the drill was equipped with the well-known "4810" unarmoured rock drill hose. Records of this character can only be established with absolutely the finest equipment it is possible to procure, and one of the most essential details is, of course, that the air drill hose used should conduct 100 per cent. air. A cheap grade of hose which is susceptible to the action of mineral oil would have been useless, due to the fact that fine particles of rubber would come away from the inner tube and choke up the ports of the drill, materially affecting the drilling speed. "4810" hose is constructed of such material that it is impervious to the action of mineral oil, and the tube will not flake or come away under the severest possible conditions. It is a tribute to the fine reputation of this hose that it should have been selected as equipment for the Holman drill in the establishing of the world's record.

The Afrikander Annual Meeting.

The annual meeting of the Afrikander G.M. Co., Ltd., was held a few days ago, Sir William Dalrymple presiding. *Inter alia*, the Chairman said:—The report of the directors and the accounts for the year ended 30th June, 1921, are before you for consideration. The total expenditure was £1,868; £550 was received on account of sundry revenue and interest, leaving a net expenditure of £1,317 for the period. £1,306 was paid to the Government for claim licences and nuyapacht dues. An amount of £1,074 was realised by the sale of certain stores and buildings, and after allowing for sundry creditors, the cash in hand at the end of the year was £9,188. The property remains in the hands of a caretaker, and all machinery, plant and buildings have been maintained in good order and repair. During the year an agreement was entered into with a tributing syndicate for the treating of the surface ore dumps on the property. This syndicate, however, discontinued their operations, and a 30 days' option has since been given to another syndicate to lease the whole property for a period of six years on a royalty basis agreed upon. This option is still in force. The report was adopted.

Hydro-Electric Power in South Africa.

The above subject formed the basis of an exceedingly interesting paper read by Mr. H. W. Miller before the South African Institution of Engineers on Wednesday night. A full and detailed account of the hydro-electric plant installed by the S.A. Rubber Manufacturing Company at Howick was given, and some interesting discussions arose out of it. Although South Africa is a country which is not well supplied with an abundant and constant supply of water, it does possess potentialities of not inconsiderable importance in this direction. A comprehensive survey of available sources of water power in South Africa has been made by the Irrigation Department, and although numerous cases are brought to public notice, the majority of them are unfavourably situated in the country's present state of development. The harnessing of the waters of the Howick Falls is an excellent example of what can be done with the more accessible of these sources of water power. A more detailed account of Mr. Miller's paper appears elsewhere in this issue.

Victoria Falls and Transvaal Power.

It is noteworthy that the report for 1920 states that in December 31 last the issued share capital amounted to £3,000,000 and the debenture capital to £3,351,870 a further £328,210 of 5 per cent. first mortgage debentures and £63,380 of 5½ per cent. second mortgage debentures having been purchased for redemption during the year. After providing for interest and premium on debentures (£183,895) and for depreciation and income-tax, etc. (£409,941), the net profit is £173,161, and £91,321 was brought in, making £267,482. Dividend of 6 per cent. on preference shares for year, less tax, absorbed £84,000, leaving £183,482. In respect of this surplus the directors on June 16 last declared a dividend of 5 per cent., less tax, on ordinary shares for the year, and as the preference shares are entitled to share *pro rata* with the ordinary shares in the surplus profits distributed until the preference shares have received a total dividend of 10 per cent. for the year in respect of which the distribution is made, the directors also declared a further dividend of 4 per cent., less tax, on preference shares in respect of 1920. These dividends absorbed £91,000, leaving a credit balance of £92,482, which will be carried forward.

* * *

The Silver Position.

Standard silver spurted 1½d. in mail week to 41½d. per oz., which brings it up to virtually the level at which it started this year, after being down to 30½d. on 5th March. Last year's extremes were 89½d. on 11th February and 38½d. on 10th December. Just before the War the metal ranged between just under 2s. and not quite 2s. 6d. per oz. The latest rise is ascribed to further Indian buying and bear covering in a market temporarily short of supplies. In their weekly report on silver Messrs. Samuel Montagu & Co. state that the market preserves a steady tone. Indian sentiment is bullish and purchases have been made freely for cash and for forward delivery, notwithstanding the inquiry for gold which has set in from the same quarter. China has not been an active factor, probably because of the direct shipments of silver which are being made from time to time from the result of the Royal Mint operations in reducing the quality of home coinage. The prospects of silver depend more than anything else upon whether the phenomenal inquiry which has arisen this year in India will be prolonged indefinitely. In view of the fact that silver derived from the partial demonetisation of United Kingdom silver coin is now finding its way to the Far East, there to be utilised as currency, it is not surprising that China is not much in evidence as a buyer. Indeed, it is rather surprising that, notwithstanding the slack movement of goods from that country, exchange rates are so well maintained. The amount likely to be released by the reduction of the quality from '925 to '500 must be very large, but it is not easy to ascertain. A rough guess of 40,000,000 ozs. as the amount likely to be added from this source to the world's supplies during the next year or so is not unreasonable.

Concerning Mines and Men.

Mr. W. T. Anderson, M.I.M.M., has returned to South Africa.

* * *

Mr. Arthur French, Manager of the General Mining and Finance Corporation, sailed for England last week.

* * *

Mr. J. W. Kirkland has returned to the Rand after a business trip of six months to England and America.

* * *

Mr. M. H. Turner, of the "J.C.I." engineering staff, has been placed in charge of the extensive coal interests of that group.

* * *

Mr. Ross Macartney, the General Manager of Rhodesia Broken Hill, has left on six months' leave. His place is being filled by Mr. Barton.

* * *

With deep regret we record the death, which took place last week at Durban, of Mr. J. H. Richardson, the well-known stockbroker. Mr. Richardson was buried at Johannesburg last Tuesday, the funeral being attended by a large and representative body of friends.

London Market Review.

On the Stock Exchange during last week there was a good deal of forced liquidation, notably in oil shares, says the latest cable. This is attributed to commercial and financial conditions in the commodity. The markets are also clearing up the balance of pre-War speculative accounts. Later pressure showed signs of relaxing, some support being forthcoming at the lower level. The best feature of firmness were gilt-edged securities, which is noteworthy in view of the revenue return showing a deficit of forty millions sterling for the half-year. There was also a rush for the new issue of the New South Wales loan of three millions at 6 per cent., price 95½, now being underwritten. Allotments were made of Ceylon issue on the basis of 25 per cent. dealings at ¼ per cent. premium. In Kafirs business was limited to weaker selling, believed to provide funds to meet differences in other directions. The weakness of gold is the reflex of the depreciation of the dollar, which is attributed to the fact that speculators in exchange fluctuations were scared into closing commitments by renewed talk of funding Allies' debts to the United States.

Witbank By-Products.

A SUCCESSFUL INDUSTRY.

Few people are aware with what success tar is now being produced by the By-product plant of the Witbank Colliery. An illustration on this page shows the magnitude of the plant, and the following extract from some views of the manager of the plant (Mr. W. T. Burton), given in our Coal Number, may be of interest:—

Mr. Burton wrote, *inter alia*:—Having been in the country a few months only, one naturally feels at a disadvantage to give a definite opinion on such an important subject. But at the outset it seems to me that the potential value of waste coal which costs sixpence to dump has not up to now been realised with the exception of one of our great mining houses. I know of no other in the sub-continent who have made any serious attempt to utilize any of the

The Witbank Colliery By-Products Plant.

enormous quantity of unsaleable coal which in every colliery is mined daily. When one realizes the fact that tons of tar, wood and iron preservatives and other bitumistic compounds are imported annually and that we have the raw material at our disposal (material which is very often an expensive nuisance), one is given furiously to think. To my mind the non-development of this industry is due to concentration on the gold and diamond industry, whereby other national resources were ignored, and justly so perhaps. But any empire or country which concentrates all its energies and capital on one or two sources of revenue, is in the long run bound to come to a dead end.

Wherever one industry is created, obviously products are required to help in its own particular line to maintain it. In the case of South Africa the position is unique, both in natural resources and, compared with other nations, cheap labour and raw material, and can manufacture any or all of the by-products of coal at a competitive price with the imported article. My short stay in this glorious country has firmly convinced me of this. I feel it would be inadvisable at this juncture to go into technical details. I hope, however, to do so at a future date, and that the by-product industry of South Africa will before long be more than in the experimental stage is my fervent wish.

Technical Equipment for the Rand University.

The desirability of ensuring that supplies of British technical equipment should be available for educational institutions in South Africa has lately been dealt with in these columns, and in this connection we note that Mr. W. G. Wickham, H.M. Senior Trade Commissioner, has the following in his latest annual report. He points out that:—

Capetown is building a university on an ample scale. Johannesburg has converted its School of Mines and Technology into a University College, and is hoping for a charter

to create an independent university. In both cases new buildings and new equipment are involved, and excellent opportunities are afforded to British manufacturers of being first in the field with donations of apparatus, machinery, and other equipment for laboratories, both scientific and engineering. There is probably no form of advertisement—to put it on its lowest plane—so remunerative as making sure that the rising generation of chemists and engineers are taught as household words the names of the makers of plant and apparatus. Optical instruments, laboratory supplies, assay apparatus, testing machines and instruments, engines, machine tools of all kinds, all find a place in such educational institutions, and the makers of such who are fortunate enough to obtain a place for their makes in college laboratories have an obvious advantage over their rivals in all succeeding years, as young chemists and engineers go out into the world with the names of those manufacturers as familiar as those of standard editions of Greek and Latin authors are to classical scholars.

On a higher plane it may be said that special scope for generosity is afforded by these institutions, and it is to be hoped that the excellent precedent of recent gifts of machinery towards technical education in Nottingham will be followed in the case of South African universities and other educational institutions throughout the Dominions. It is indeed lamentable to find instances of British manufacturers demanding not only the full retail price for such equipment, but treating unendowed colleges, which usually have to collect subscriptions before ordering plant, as ordinary customers; and taking orders only for indefinite delivery and charging prices 50 per cent. or more above the sum collected for purchase. It is all the more to be regretted at a time when American and German manufacturers are presenting their makes free of charge.

It would be only reasonable and natural under the circumstances if professors responsible for equipping the laboratories and workshops of universities and technical schools in the Dominions not only accepted all proffered gifts from foreign countries instead of vainly endeavouring to induce British manufacturers to give a discount off their full list prices, but left England out of their inquiries altogether.

British manufacturers may rest assured that were it not for the loyalty of the professors themselves, and for rare instances of generosity on the part of a very few British firms to provide a justification, inquiries would no longer be sent to the United Kingdom except purely as a matter of form.

September Output in Detail.

LOWER TOTAL—LABOUR SUPPLY IMPROVES—CROWN MINES AND GEDULD INCREASES.

In September the Transvaal mines produced 691,096 ozs. of fine gold as against 711,526 ozs. in the longer month of August, a decrease of 20,430 ozs. The value of the September output (£5 10s. per oz.) is estimated at £3,801,028, showing a decrease of £165,729 compared with the August return, which was valued at £5 11s. 6d. per oz. A gain of nearly 3,000 is shown by the native labour returns, the total number of boys employed on the gold mines being as follows: August, 169,008; September, 171,912. The group profits for September show a decrease of £73,007. The following are the individual increases and decreases for September:—

The Week in the Sharemarket.

GOLD SHARES EASIER ON REDUCED GOLD PREMIUM—DIAMONDS AND INDUSTRIALS WEAKER—A WAITING MARKET.

The latest price for gold, dated London, October 11, is given at £5 6s. 9d., and as a consequence gold shares are easier. The explanation given for the drop in gold is that speculators in exchange have closed commitments in view of the talk about cancellation of international debts. The whole market took its tone from gold shares, and both diamonds and industrials were weaker. Colliery shares which have hitherto stood the strain very well also fell away on the depressing news of the coal export trade. Wednesday was a Stock Exchange holiday and on the Call on Thursday prices reached the lowest for some time.

Liquidation on a large scale continued, and prices were marked down all along the line. The decline ranged from 1s. in the case of New Modders at 71s. 6d. sales to 1½d. in Main Reefs at 10s. 6d. sales, and was in most other stocks about 6d. Modder B, however, were steady at 26s. 3d. and 26s. 6d. sales, Nourse Mines unchanged at 9s. 6d. sales, and Coronation Syndicates at 6s. sales. Natal Navigation Collieries were obtained at the low price of 28s., the lowest point for a long period. Consolidated Diamonds were 7½d. lower at 14s. 9d. and 14s. 7½d. sales, and Frank Smiths were easier at 4s. sales and sellers. P.P. Cements were fairly steady at 42s. 6d. and 42s. 9d. sales. Transvaal Silvers easier at 16s. 9d. and 16s. 6d. sales. Hume Pipes and Alkali inactive. Nothing was done in tin shares, and Union Loans were steady but inactive.

In a speech at Kimberley, delivered during the week, Sir David Harris took a more cheerful view of the diamond outlook, and the opinion is gaining ground that there may be a revival by Christmas. As it is, people are content to wait and hope that better news from London, a settlement of the ex-enemy share question, and good dividends at Christmas may make for a better market.

4810 Air Hose

The Air Hose that helped to break the World's Stopping Record at the Van Ryn Deep Gold Mine

3 "Holman" Cradle Hammer (C.H. 2) Drills ; 26 Working Shifts ; 78 Machine Shifts ;
69 inch Stope Width. September 2nd to October 1st, 1921. Fathoms broken 248

— 3.18 Fathoms per Machine Shift. —

Made possible by good Drills, plus good operators, plus the Air Hose that delivers 100% air efficiency, without internal flaking or kinking—Records are possible if you specify "4810" Air Hose.

The Early Days of our Gold Fields.

A PIONEER'S RECOLLECTIONS.

X.

By Arthur Stenhouse.

Vividly, clear-cut against the summer sky, stand out events of 1886—thirty-five years ago! It seems but yesterday when my esteemed friend, Richard R. Hollins (who at the time represented Kynoch's, Ltd. (the gun people), and who was also a director of the first gold mining company registered in the Transvaal, the "Kromdraai"), in exuberance of spirit, persuaded me to accompany him, on "Guy Fawkes' Day, in the mad project of painting Pretoria "red" to enliven the sluggish town. Filling our pockets with dynamite cartridges, we started out on our adventure and carefully placed the cartridges (without caps) on the tops of the fencing poles surrounding the Dutch Reformed Church in the centre of Church Square, also on the stoep of the Standard Bank and other semi-public buildings. When our mines were prepared we set fire, and the whole town was at once brilliantly illuminated. We now thought it time to clear. Richard, being short-sighted, fell into a sluit of clear running water and beneath the kerb stones lay half hidden in the cooling stream. He advised me to make myself scarce also, so I sought safety in flight. The Z.A. Police were after us, so I made for home like a streak of lightning, and was soon in bed, apparently asleep.

Next day there was great commotion in the city! The newspapers, in big headlines, asserted that an attempt had been made to blow up the church, the bank, and other buildings, and the police were on the track of the perpetrators.

Fortunately for us, the mystery was never solved by the ruling authorities. A year afterwards the papers recalled this mysterious occurrence, which had never been solved. Confession is good for the soul, so after a period of 35 years we must confess that we were the guilty parties who woke up the City of Pretoria on that eventful night.

The coach journeys before the advent of the railways were interesting. On one occasion I travelled by coach from Pretoria to the Rand by the first of Hollins & Dow's coaches. The late Captain Dow was a very handsome man, wore a big sombrero hat, and drove the coach himself. I sat on the box-seat beside him. We started late from Pretoria, and it soon became quite dark. Suddenly the team swerved, the captain pulled up, and descended to see what was wrong. He discovered that we had come bang up against a wire fence in the darkness. We had lost the way. Nothing was said to the passengers as we crawled beneath the coach and laid us down to sleep. There were some ladies in the coach, and they inquired why we were not going on! No one replied to their inquiry; we were filled with mirth and hardly dared to breathe! Soon the inmates realised the position and patiently waited for the break of day, when we resumed our journey and eventually arrived at our destination.

To-day (1921) on the hill tops overlooking the fertile valleys and rugged kopjes towards Pretoria, the old Adam dwells with his beloved Eve in their Garden of Eden. Sweet are the memories of joys that are past, but sweeter still is the modest hope of securing two back seats in the pit of a permanent Paradise.

S.A. MINING YEAR BOOK. 1921-22.

The eighth annual edition of this invaluable reference work, the many features of which are too well known to call for review, is now on sale. The Year Book may be obtained from this office, any branch of the C.N.A., or the Argus London Offices.

ENGINEERING SECTION.

Heat Treatment of Steel.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Etna Works, Sheffield.

Tempering.

The object of tempering is to remove the strains produced in hardening and or to reduce the brittleness to a degree suitable for that particular type of tool and the work it has to do. The temper is usually judged by the formation of colours on the surface of the steel, these colours being due to oxidation of the surface of the steel. As soon as the correct colour appears the tool must be immediately quenched out. These colours will not appear unless the steel surface is free from scale, for this is an already oxidised surface, therefore after the initial quenching (hardening) the part to be tempered must be cleaned with a stone to produce a bright surface. In the case of alloy steels, however, the steel must be maintained at the correct tempering temperature so that the heat thoroughly penetrates to the middle of the bar. Another important point is that the tempering furnace must be cooled down as low as possible before putting in the hardened bars and then brought up slowly to the correct heat. If hard alloy steels are placed into a hot furnace they will invariably crack. All nickel chrome steels tempered between 350 degrees and 525 degrees Centigrade must be quenched out immediately after tempering. The furnaces used for tempering are varied. We have the ordinary gas furnace for alloy steels (*i.e.*, nickel-chrome, chrome-vanadium, etc.), the oil bath, fusible salts, lead pot, gas heated hot plate and hot sand bath. For tools such as picks, drills, cold chisels, etc., one heating is sufficient for both hardening and tempering, the heat in the unquenched portion of the tool being sufficient to temper the hardened portion when allowed to run down.

Case-hardening.

Where a hard wearing surface and a tough centre is required such as in the case of camshafts, gear wheels, etc., case-hardening is the method adopted to produce the desired qualities. The operation consists of adding carbon to a low carbon steel, by means of heating in the presence of a compound capable of supplying the steel with the necessary carbon. The outer surface of the steel therefore after carbonisation has a greater carbon content than the core and on subsequent heat treatment, the core is toughened and the case is hardened.

For plain carbon steels the actual process is as follows: Pack the articles to be case-hardened in an iron box, into which a case-hardening compound has been placed, and close carefully with fireclay to make airtight. Heat up uniformly to 900 to 950 degrees Centigrade and keep at that temperature for a pre-determined period, this period to depend upon the depth of case required. The object of this is to add carbon to the steel. Cool the articles either in air or quench out in oil or water. If the articles were quenched out, and fractured to see the grain of the steel they would appear very crystalline and give obvious proof that the steel had been overheated. Therefore to refine the steel, heat up to 870 degrees Centigrade and quench in water. The object of this last treatment is to refine and harden the case. Reverting to the length of time at which the carburising temperature must be maintained, this varies greatly, depending on the depth of penetration required, the

temperature, the packing, the compound used, the analysis of the steel, etc. A point which is very often overlooked is that the articles to be case-hardened should be free from rust, scale and dirt. The question, "Why does steel harden?" is very often put to me, and I am confident that the following few notes will be easily understood by even the non-technical man.

Steel is crystalline—like sugar. Crystals, however, of the same steel when examined under the microscope vary considerably in their size and constitution according to the condition of the steel. The effects of hardening, tempering, annealing, etc., are brought about by alteration of size, form and microconstituents of the crystals. Just as ice when heated to a certain definite temperature becomes water, just so the microconstituents of the steel crystals when heated to a fixed temperature (critical point) change, and if the steel is quickly cooled or "trapped" in that condition the steel is hardened: just as the melting point of ice varies somewhat if it contains foreign substances, so the hardening temperature of different steels varies according to their composition, but it is always the same for the same steel. Unless steel is quenched from above the hardening critical point it will not harden and so long as it is over the critical point there is no advantage (and there are considerable disadvantages) in increasing the temperature. If heated considerably above the hardening steel becomes "burnt" and is spoiled. Steel in the hardened state is too brittle for use and if hardened steel is heated up again, or "tempered" the crystals gradually tend to go back to their original "soft" state. The loss of hardness and increase in toughness varies according to the amount of tempering given.

The Bradbury patent rubber-lined valve is an interesting novelty recently introduced on the Rand. It is manufactured locally and seems well worth a trial.

SOUTH AFRICAN MINING AND
ENGINEERING JOURNAL.

The Howick Falls Hydro-Electric Power Plant.

By H. W. Miller.*

A little while ago, Mr. W. R. Eales read a paper describing the plant of the South African Rubber Manufacturing Company, Ltd., and in the early portion of his paper he mentioned that this plant was operated by means of a hydro-electric installation situated at the base of the well-known Howick Falls. I propose to describe this plant in detail this evening, as it presents, I think, features of interest.

It has been recognised that the Howick Falls are one of the sights of South Africa, and when the authorities gave the company the necessary permission to use the water of the falls for power purposes, they made certain conditions to safeguard the scenic beauties, as well as to control the water supply within reasonable limits. In a very low river, which occurs at long intervals, it would be possible to take so much of the available flow through the turbines as to detract from the appearance of the Falls, and provision has been made to prevent the drying up of the river so far as the crest of the Falls is concerned. The distance of the intake and the discharge into the river from the turbine tail race is so little that there is no danger of any riparian interests below being jeopardised from this cause, but it is obvious that if all the water were diverted and allowed to pass through the turbines during an abnormally dry season, it certainly would affect the scenic beauties, and possibly the interests of the Howick residents, who are naturally interested in the visits of people from all parts of this country. Through the courtesy of the Borough Engineer of Pietermaritzburg, I was allowed to see the records of the flow of the river for a series of years before a specially heavy flood tore away the measuring weir, and a perusal of these figures convinced me that the chances of the river falling to such a low ebb as to prevent the hydro-electric plant being temporarily operated were very remote indeed. In 1903, the readings indicate that this was an abnormally dry year and for 7 days in August, 10 days in September, 28 days in October, and 7 days in November, a total of 52 days, the flow of the river fell to $12\frac{1}{2}$ cusecs, but as the requirements of the company when operating the two units installed on full power amount to 11 cusecs, for 10 hours out of the 24, and when the storage capacity of the pond formed above the falls from which the water is diverted into the intake of the tunnel is considered, it is obvious that the risks of any shortage of water are very remote indeed. Over this period of $8\frac{1}{2}$ years, there were only 52 days when the supply in the river fell as low as the above figures, and in this specially dry year of 1903 there were only 151 days when the supply fell below 40 cusecs, and in 1904 there were 96 days when the flow of the river was below that quantity. For the whole of the remaining period there were only 79 days when the flow of the river was below 40 cusecs, and then for only short periods, aggregating the above length of time, and from this one would infer that this shortfall was due to riparian owners above the Falls being engaged in profusely irrigating their lands. These figures are led to show that the risks incurred by the company in deciding upon this system of power for the operation of their factory were insignificant so far as a shortage in the supply of water in the river was concerned. In a country like South Africa, where droughts are of common occurrence, it is well to have a contingency of this nature well in view before decision is arrived at.

Operations were commenced by the building of a concrete diversion weir above the Falls on the right bank of the river. This caused the flow into the mouth of the tunnel, which pierced the ridge on the right bank of the river and led the water to a suitable point on the flank of the hill, below which it was decided to place the power station. The building of this weir caused silting of the

river, and this choked the mouth of the intake, so a covered channel was built above the diversion weir, with a deep mouth forming a catch sump. At the same time, suitable silt traps were provided at the entrance to the tunnel, this being controlled by a grid of large surface and the necessary sliding sluice gate, operated by a screw-lifting device well above flood water level and available at any and all times.

The tunnel is driven through shales a distance of some 650 feet and comes out on the flank of the hill, on the other side of the dividing ridge through which this tunnel is cut. Advantage was taken of the tunnel being in close proximity to a gorge in the side of the hill, to drive a cross-cut and tap the tunnel somewhere about the centre, thus giving two more points of attack, and enabling the bulk of the spoil to be dumped into the river at a convenient point and where its deposition was not objectionable, as it was obscured by the profuse vegetation characteristic of the spot. From the point where the tunnel emerged, the pipe line that supplies the turbines was led down the hill at a mean angle of 30 degrees to the power house in which the turbines are installed. At the end of the tunnel a suitable silt trap was formed, and here another grating was fixed, with the bars closer together than the one at the tunnel entrance in the river, to prevent any large substances getting down the pipe. An air vent was formed by raising a small shaft through to surface near the entrance to the mouth of the pipe line, but owing to the contractors having made the tunnel of generous dimensions, there is little fear that any hydraulic surges of a dangerous character are liable to be encountered. The fall in the tunnel being about 15 to 16 inches, the velocity of the flow of the water will be so moderate that any silt likely to be brought down in the water will have every chance of being deposited in the tunnel, from whence it can easily be cleaned out at suitable times. Suitable pipes and valves are provided for flushing the tunnel and clearing out any deposit of fine silt that may accumulate, but, as mentioned before, the area of the tunnel is so much in excess of that required for the full power likely to be developed even in the distant future by the company, that there is no risk of silt being a source of danger to the turbines, provided the most elementary precautions are observed.

The pipe line, which is some 600 feet long, is made of mild steel pipes in three sections, to permit of their being nested to effect economy in ocean transport. The first or upper section is 34 inches diameter by 200 feet long, and is connected to the tunnel by special angle bend, cemented into the mouth and well anchored at its end, which connects with the first expansion piece. These are telescopic expansion pipes, with glands packed with suitable grease packing. The next section consists of pipes 30 inches diameter, there being a taper piece between the 34 inch upper section and the expansion piece, which forms the top of the second section. Then another tapered piece reduces the diameter from 30 inches to $26\frac{1}{2}$ inches, the diameter of the third or lowest section of the pipe line. This pipe is connected at the bottom to a very heavy bend that is securely anchored in a massive concrete block, which has to withstand the thrust of the pipe line and its water contents, and in the case of a hydraulic surge, is called upon to withstand considerable stress. Consequently, great care was given to this important anchor, which is heavily reinforced by strong rods and angles.

(To be continued.)

S.A. Alkali.

The headquarters of the S.A. Alkali, Ltd., were changed, as from October 1, to Clewer House, the home of the Bailey-Jeppe Group. Details of the contemplated debenture issue are not yet available.

* From a Paper read before the S.A.I. of E.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS AGAIN RESTRICTED BY HOLIDAYS—UNDERCURRENT, HOWEVER, FIRM—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—ELECTRICAL GOODS—RAILWAY EARNINGS STILL FALLING—BRITISH TRADE IN SEPTEMBER—COAL MINES IN BRITAIN—SOUTH AFRICAN OIL ACTIVITIES—FINANCIAL—METAL MARKET.

General Review.

Owing to the Jewish holidays business this week has again been restricted. On the Commercial Exchange, although the cutting campaign has declined of late, the volume of business has been small. The gold premium has dropped somewhat during the week under review, but in the opinion of authorities most competent to judge, no great fluctuation is anticipated between now and the end of the present year, which means, of course, breathing time for our lower-grade mines and enhanced profits for those better circumstanced. The world conditions generally, as reflected by the Exchanges, are still in a case of flux, and it is difficult to gather an inside view as to the immediate future. Sufficient unto the day is, however, enough; the commercial community, without undue optimism, is unanimous in the opinion that we are on the eve of better things.

Iron and Steel.

The week has been a short one on account of holidays, and even within its limits little evidence of strength was apparent. In the opinion of experts, however, we may expect gradually improving business conditions shortly.

Second-hand Mining Machinery.

Second-hand steel plates are ruling from £10 to £12 10s. Good second-hand loco-type boilers are maintaining their high price; compared with pre-war levels the price is about three times that which it was to-day; those coming in from the country are all being absorbed by industrial concerns; the big difficulty to-day is to procure the exact thing. There is an enormous amount of diamond drilling being done just now all over the country for coal and gold prospects, with a great deal of activity in the Free State for diamonds. All kinds of second-hand machinery are quiet just now, certain classes being unobtainable except new. It is generally anticipated that as soon as the machinery and material from those mines which have lately closed down have been absorbed and the limit of exhaustion been reached, there will be a big scarcity with enhanced prices. The mines are still economising and practically only buying from hand to mouth. Second-hand pitch pine is becoming scarce, at about 4s.—4s. 6d.

Engineering Shops.

The opinion in engineering circles is that business is mending; no great things are expected this year, but that the tendency is towards betterment is undoubted.

Cut in Iron and Steel Wages.

Under the sliding scale adopted by the Board of Conciliation and Arbitration in the manufactured iron and steel trade in the North of England, wages have been reduced 25 per cent., making the total reductions since January 1921 132 $\frac{1}{2}$ per cent. Even with this reduction the present wages scale is 97 $\frac{1}{2}$ per cent. above the pre-war scale. The Villiers Spelter Works at Swansea have restarted operations and are the only spelter works in South Wales working to-day. This has been made possible only by the reduction in wages.

The Humboldt Machine Construction Institute has declared a dividend of 10 per cent. compared with last year's declaration of 6 per cent. The company reports an unprecedented number of orders from abroad. The Offenbach Rubber Works has increased its capital from 8,000,000 to 17,000,000 marks. It is semi-officially stated in Berlin that, owing to the depreciation of the mark, the surcharge on import duties will be raised on October 20 from 900 to 1,900 per cent.

Base Metals and the Prospector's Lot.

In the course of a chat with a well-known prospector, he said that initiative with determination needs a man who weighs with foresight his chances, fights for the place necessary to give him the requisite financial aid to meet expenditure month after month for the carrying on in respect of wages, licences, foodstuffs, etc. Local requirements were, he said, as heretofore, advanced development of the outside mineral discoveries, with all encouragement to prospecting. One's knowledge of mineral wealth in the land we live in is limited to a select circle. The prospector's lot in the Transvaal is not a coveted one; he knows that the race is not to the swift, not to the strong, but to the "slim."

There are too many hindrances in the way of the mineral resources of the country being adequately developed, among which, he said, are the unsympathetic prospecting development laws, with pinpricks of officialdom and no encouragement to the attraction of foreign capital for legitimate progressive mining activity. As a matter of fact, he stated, the opposite law to this is in operation, cooling and killing the ardour of the genuine worker and prohibiting capital being spent, meaning also the cessation of search, doubtful titles, abandonment of promising prospects, loss to the general community, also of concentrated energy of capable, experienced prospectors, and possibly loss of new mines. Town builders, railway makers and farmers are the advance guard pioneers of industry and civilisation. A change, he said, was necessary for courageous action towards a sphere of active work for the sake of all members of the community. This change, he thought, we needed and must have to fill up our vacant and stagnant land. It is through the prospector that we are here, and reversal from the growing deficits in public works and political claptrap to the practical exploitation of our mineral resources is our only cure.

Timber and Building Materials.

Business has been fairly good, but in the slow resumption in the building trade there is nothing of importance to record. 3 x 9 deals are ruling at 1s., 1s. 1d.; scantlings, 1s.; floorings, 6 $\frac{3}{4}$ d., 7d.; ceilings, 5 $\frac{1}{4}$ d., 5 $\frac{3}{4}$ d.; Oregon, 7s.; pitchpine, 8s., 8s. 6d.; corrugated iron, 9 $\frac{3}{4}$ d., 10 $\frac{1}{4}$ d. Stocks of timber are satisfactory; indications from the Baltic as to future prices are more towards a firming tendency than otherwise. Bricks are unchanged in price at 70s. for blue stock, 60s. for mixed, £4 10s. to £5 for wire cuts, and £5 for pressed, per 1,000 at yards; white lime, 7s.; unslaked, 9s. 6d.; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. per bag.

Second-hand Iron and Timber.

Second-hand dealers report a somewhat better tendency than has prevailed for some months past. Although actual business remains much about the same, there are now more inquiries for material, which is the first tentative step towards improving conditions. Second-hand iron rules at from 6d. to 7d., timber 10d. to 1s.

Electrical Goods.

Business in town and along the reef is a little better, not so much in respect of actual transactions, but in the matter of inquiries, which dealers look upon as the prelude to improvement very shortly. In the meantime there are no reductions to report from Britain and the Continent, where it seems that the question of raw materials is making itself more and more felt. Nevertheless, dealers think it not unlikely that a slight fall in prices generally may be witnessed within a few weeks.

Railway Earnings.

According to the latest bulletin issued by Sir William Hoy, the General Manager of the Railways, the loss on the railways for April, May, June and July, after providing for depreciation and interest, was £653,866, while the net loss on the harbours was £46,139. In the same period the working expenditure increased by £43,310 compared with the total for the corresponding months of 1920. As a matter of fact, the actual outlay in this direction was no less than £5,867,534; in other words, notwithstanding economies effected on all hands, the cost of running the system has risen by 74 per cent. It is gratifying, however, to note a revival in the export trade, which it is hoped will continue.

Shipbuilding Slump.

Lloyd's Register records the continuation of the heavy slump in shipbuilding throughout the world. At the moment there are only two million tons actually under construction. The countries most affected by suspensions in shipbuilding are Italy and the United States.

British Trade in September.

Imports during the month amounted to £87,118,507, showing a decrease of £65,638,629 compared with September, 1920. Exports were £55,247,578, a decrease of £62,208,335.

American Cotton Crop.

The Bureau of Agriculture, states a message from New York, estimates the cotton crop of the United States for 1921 at 6,537,000 bales, compared with 12,123,000 last year. The season has been a very disastrous one, August and September alone showing a shortage of 1,666,000 bales, owing to a plague of boll weevils.

Coal Mines in Britain.

Lord Aberconway states that there is little prospect of coal prices falling while wages and working conditions remain as they are, and says, further, that it is a question whether it would not be more profitable for owners to close their collieries and stand the expense of overhead charges from their own pockets in preference to letting the mines run at a loss. On the other hand, it is satisfactory to note that the North Wales Collieries mines have been re-opened.

British Rubber Industry.

According to a bulletin issued by the Federation of British Industries, it appears that the process of vulcanisation and the essential operations of compounding, moulding and spreading have made a very rapid expansion, and during the last twenty years the industry has increased by something like seven times its former dimensions. In other words, the value of the world's consumption of manufactured rubber goods has increased from approximately £50,000,000 in 1900 to £350,000,000 in 1920. In Great Britain the capital invested in india-rubber manufactures totals about £25,000,000, with an estimated turnover of £30,000,000. One specialised section of the india-rubber industry is the making of cycle, motor-cycle, and motor pneumatic tyres. The possibilities of the tyre industry are tremendous and will, under anything like normal conditions, mean a further expansion for the high quality British product.

Oil: South African Activities.

In the matter of crude oil storage in Durban, the Vacuum Oil Company has two huge oil tanks of 9,000 and 9,500 tons capacity; the Anglo-Persian one tank erected and another planned; the British Imperial Oil Company is erecting a complete tank in sections; and the Texas Company is on the point of commencing developments. This oil station will be in a position to handle 50,000 tons of oil, but later on this may be greatly augmented. It is thought that very soon now petrol tanks will be erected and tank steamers requisitioned to meet the growing requirements in motor fuel for inland transport.

Financial.

The Finance Committee of the Johannesburg Town Council has delegated the matter of the £1,500,000 loan offered from America, which has met with a somewhat mixed reception, to a sub-committee with instructions to endeavour to secure a reduction of the proposed rate of interest from 7 $\frac{1}{2}$ per cent. to 7 per cent.

S.A. Reserve Bank.

On October 8 the ratio of cash reserves to public liabilities was 72.6 per cent.

Metal Market.

Latest London quotations:—Standard copper, £67 7s. 6d. cash, forward £70 6s. 3d.; electrolytic copper, £73 10s. 6d. cash, forward £75 10s.; Straits tin, £156 cash and £158 forward; English lead, £23 5s. cash, forward £23 2s. 6d.; bar silver, 12 $\frac{1}{4}$ d. per ounce; fine gold, 109s. 8d. per ounce. No special feature was noticed during the week, but the feeling was that the worst of the trade depression had passed and a recovery could be confidently anticipated. Under the influence of American advices and a better demand from consumers in Britain, there was considerable activity in copper. Tin was steady to fair. September figures indicate an increase in the visible supply of 1,600 tons. Local and American demand has slackened. The lead trade at Home is improving and the export for the Continent has expanded. The spelter market is active. Increasing orders for galvanised sheeting have been placed by India and the East. Gold has slackened off in the Indian demand, but America is taking all offerings.

A Carbon Monoxide Gas Mask.

The development of a carbon-monoxide mask is announced from the United States, and if this device should prove capable of protecting the wearer against deadly percentages of this poisonous gas it will find ready application in many industries. Such a mask will, of course, be of no value where the atmosphere to be respired in addition to containing an actively poisonous gas like monoxide is deficient in oxygen. The possession of a mask protecting men against comparatively small percentages of carbon-monoxide would in many cases have enabled men to escape from fire-damp poisoning after coal mine explosions, as in some cases the atmosphere that killed the victims did not put out the light of oil lamps. There would seem to be possibilities of a self-rescue apparatus in the carbon monoxide mask that one may hope will be further developed. Carbon monoxide, in addition to being a quick and sure poison in percentages exceeding half of one per cent. in respired air, is in smaller quantities a cumulative poison, and if men are constantly exposed thereto deterioration of the blood constituents takes place and is incapable of remedy.

Gas Mask for Carbon Monoxide Perfected.

The first public demonstration of the gas mask for protection against carbon monoxide, manufactured by the Mine Safety Appliances Company, Pittsburg, Pa., and in which is utilised the special mixture called Hoppelite, developed by the U.S. Bureau of Mines and Chemical Warfare Service, U.S. Army, was given on the afternoon of May 26th in the special smoke room of the United States Bureau of Mines, Pittsburg, Pa. The U.S. Bureau of Mines, in its research of various types of gas masks, including the carbon monoxide mask, has a very large smoke room especially adapted for testing purposes, and the courtesy of the use of this smoke room was extended for this demonstration. In addition, the first public demonstration was also given of the U.S. Bureau of Mines gas mask for city firemen, also containing Hoppelite, for carbon monoxide protection.

In this test two men entered the smoke room, which contained 1 per cent. carbon monoxide gas in the air. One of the men carried a canary bird into the room to indicate to the observers the poisonous nature of the atmosphere. The canary bird collapsed in 45 seconds, and it was immediately removed to fresh air, where it was revived with oxygen.

Tests were also frequently made with the M-S-A Carbon Monoxide Detector to show the observers the strength of the gas. The wearers of the mask remained in the atmosphere

for 30 minutes doing vigorous work part of the time, and experienced no ill effects whatever from the poisonous carbon monoxide gas. The gas masks gave perfect protection through the entire period of the test.

The carbon monoxide gas mask is of special interest to iron and steel industries, fire departments, industries using gas producers, illuminating gas plants, coal and metal mines and to all other persons who are apt to encounter carbon monoxide gas in their work.

Carbon monoxide occurs frequently in dangerous quantities around blast furnaces, gas producers, etc., and is a constant hazard because of its poisonous nature. A simple protective device, light in weight, devoid of all complicated mechanisms, has long been needed for the protection of men engaged in such work.

While the gas mask used will give protection in higher percentages of carbon monoxide, 1 per cent. of carbon monoxide will kill a man in a few minutes time. The percentage found in working places where there is ventilation usually amounts to considerably less than 1 per cent.

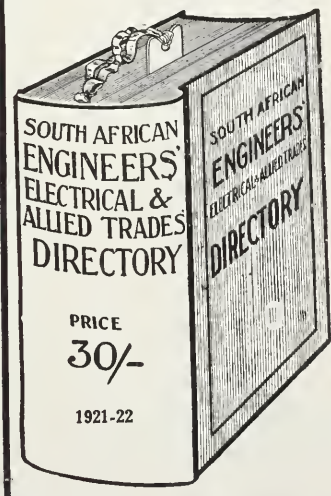

One-tenth of one per cent. of carbon monoxide, however, will seriously affect a man who is working and, therefore, breathing hard in about one half hour's time, while two-tenths will affect him seriously in about 10 minutes' time.

The Metal Market.

According to a Reuter cable dated August 20, the Metal Market during last week was dull, with little confidence anywhere. As regards copper, the immediate outlook is poor. The market relapsed on a large arrival of copper from New York, and cheap offers of electrolytic copper. An American report suggests that some mines belonging to the Anaconda Company will resume operations in September. German competition in manufactured copper is pretty aggressive. Tin declined on selling by tired bulls, while the news that large parcels of tin have been sold in Batavia helped to shake the confidence of operators. On the other hand, the bears took advantage to cover themselves, and the Continent and America were inclined to purchase at lower levels. Lead was dull, possibly in anticipation of an early revival of shipments from Australia. The demand from consumers was quiet. Spelter declined on realisations. The fall in the German mark led to anticipations of increased German offerings, which have not at present materialised. Consumers buy small parcels for immediate delivery. The iron blast furnaces are starting again in every area, but the large majority are still idle. Before any substantial quantity of iron is sold on the open market there will have to be a drastic cut in prices. The position as regards steel at the present moment is most unsatisfactory. Manufacturers are approaching the end of current contracts, which are not being replaced.

The Wolluter.

The report of the directors of the Wolluter for the quarter ended 31st July, 1921, shows: Total development footage, 852 ft.; total footage sampled, 626 ft. The payable reef disclosures were as follow: Main Reef, 12 ft., reef width 32 in., assay value 7.3 dwts.; South Reef, 75 ft., reef width 29 in., assay value 11.6 dwts.; Pyritic Lode, 341 ft., reef width 53 in., assay value 8.4 dwts. Tonnage mined, 105,926 tons; tonnage milled, 97,500 tons; total yield, 24,090 fine ozs.; total yield per ton, 4.942 dwts. Working revenue, £128,470, or £1 6s. 4d. per ton milled; working costs, £113,827, or £1 3s. 4d. per ton milled; working profit, £14,643, or 3s. per ton milled; amount received during current half-year above the monthly valuation placed on gold, in respect of sales realised up to 31st March, 1921, £3,863; total working profit, £18,506; sundry expenditure, £2,015; total profit, £16,491; Government and Provincial taxes, £3,221; capital expenditure, £2,259. The working revenue above mentioned, viz., £128,470, is arrived at by calculating the value of the gold produced at the following prices: May, £5 3s.; June, £5 6s. 3d.; July, £5 11s. 3d. per fine oz., after deducting realisation charges.

The Solution of the Gold and Currency Problem.

IMPORTANT SUPPORT FOR "MINING JOURNAL'S" SUGGESTION—NEW RATIOS FOR GOLD AND CURRENCY—ENLIGHTENED OPINION VEERING ROUND—AN ALTERNATIVE TO DEFLATION.

In our issue of September 3, under the heading "A Real Solution of the Currency Problem at Last," we wrote strongly in favour of the proposals of Professor Cassel and Mr. Samuel Evans that the true solution of the gold and currency problem in countries with depreciated currencies, lay—in the words of the latter—in abandoning paper money for gold, no doubt with units containing far less gold than their pre-war money. Since then no less an authority than "Barclay's Bank Monthly Review" has come out with support for the proposal, and the Chairman of the Federation of British Industries, Sir Peter Rylands, has also put it forward as the only alternative to deflation. "The Statist," by this mail, has a long and closely reasoned article in favour of the idea; and we quote the following passages therefrom giving the arguments in detail for making "the paper currencies of all countries which were formerly gold using, convertible into gold, not at the pre-war gold ratios, but at the values as measured by the actual exchange rate with the United States dollar at the time chosen for taking this step, or the average exchange rate over a detailed period." Needless to add, the net effect of the adoption of this proposal, now backed in such influential quarters, would be to stabilise the "premium" on gold, to the direct and obvious benefit of the Rand gold industry.

Many economists, recognising the impracticability of deflation as a solution for the currency problem, have recently put forward other schemes of reform involving, for the most part, the introduction of an entirely new standard of value (says *The Statist*). These mark a distinct advance on earlier discussions of the currency question, in that they emphasise the international character of the problem. The most prominent of them are admirably planned from the theoretical point of view, but it is open to grave doubt whether in practice it would be possible to adopt a step so revolutionary as the introduction of a new and untried standard of value. In this respect they savour too much of empiricism, and even if the change proved possible it would necessarily take a long time to come about, whereas the currency problem is one of the most pressing urgency. Many of the supporters of schemes of this nature criticise the gold standard as not making for currency stability before the War, but the changes in the price-level caused through the use of gold as a basis for currency and credit were generally imperceptible, except over long periods, and, while admittedly imperfect, the gold standard is infinitely preferable to the present currency regime.

Our Proposals.

We would not, then, favour total rejection of the gold standard. On the contrary, our proposals embody its restoration, without, however, any preliminary deflation of existing paper currencies. In other words, let the paper currencies of all those countries which were formerly gold-using be made convertible into gold, not at the pre-war gold ratios, but at the values as measured by the actual exchange rate with the United States dollar at the time chosen for taking this step, or the average exchange rate over a selected

period. The new ratios between gold and the currency unit would, of course, be made statutory in each country. To illustrate by an example: suppose it were decided to repeal the old Coinage Act relating to gold, and make the £ sterling convertible into gold at the new rate determined by the average level of the New York exchange during, say, last month, which was \$3.656 to the £. The United States dollar is equivalent to 23.22 grains of fine gold. This would make the £1 sterling worth 84.89232 grains of fine gold, as compared with a former equivalent of 113.0016 grains, so that if this rate were adopted the £ sterling could be made convertible into a standard gold coin containing 84.89232 grains of fine gold and 7.71748 grains of alloy. When the new ratio is in force the now undervalued gold in the Bank of England and in the Currency Notes Reserve, instead of, as at present, covering £155,012,000, would cover £206,181,000—that is, its paper equivalent would be increased in the ratio of, roughly, 85:113. The outstanding total of Bank of England notes and Currency notes on the 14th inst. was £421,879,000, so that the gold reserve would form forty-nine per cent. of the note issue, or, after setting aside a reserve of thirty per cent. against notes in circulation, £79,617,000 would be available as a backing for deposits. The new par of exchange with the dollar would be \$3.656 to the £, and when the new system would be fully in operation the rate would vary from this level by only a fractional amount, determined by the cost of shipping gold from London to New York on the one hand and from New York to London on the other. It will be understood, of course, that the figures in this example are selected purely by way of illustration, and are not suggested as those which should ultimately be adopted.

The Principle Involved.

On perusing the foregoing paragraph, which gives the main general outline of our proposals, many questions of detail will doubtless occur to the reader. Before proceeding to discuss these, however, it is necessary to comment on the main principle involved—namely, that Governments which, through the exigencies of War and post-War finance, have allowed the value of their currencies, expressed in terms of gold or commodities (and, of course, the value of their Public Debts), to depreciate by the process of inflation, are to be allowed to fulfil their obligations by repaying them at the depreciated value. In this connection we cannot do better than quote from Mr. Chamberlain's Budget speech of April 25, 1921. Dealing with the question of Debt redemption, he said: "The first observation I would make is that it is obviously desirable that we should redeem as much Debt as we can while prices, though lower than they were, still remain above the level which we expect them to reach in a comparatively short time and to maintain over future years." As far as we are aware, nobody took exception to this statement, which assumes precisely the same principle as that embodied in our proposals. If it were possible to pay off the bulk of our Debt last year, when prices were at the peak, and when, consequently, the commodity value of the Debt was greatly depreciated, it is hardly conceivable that the repayment would occasion a general outcry among the holders, though in reality the Government would be paying back much less than it received. As prices have fallen heavily since 1920, the commodity value of the Debt has increased, and on the same showing it ought to be legitimate to repay the Debt at its present commodity value. We do not suggest, of course, what is obviously impossible—that the Debt should be redeemed in the near future—but if our proposals are carried into effect the real value of the Debt will be more or less permanently fixed, so that the payment of a given nominal amount of the annual interest charge or of the principal would over a number of years represent approximately the

same effort on the part of the Government. Under existing conditions it is impossible to foretell with certainty the course of prices during the next few years. If the present inflationary finance of the Government should, in conjunction with a trade recovery, bring about a rise in the price-level, the commodity value of the Debt would decline, to the disadvantage of the holder. If, on the other hand, prices should fall, the real burden of the Debt would be correspondingly increased. The same applies to private as well as to public debts. The question of debts owing abroad must be postponed.

Price Movements and Public Debts.

The foregoing discussion is closely connected with the question of deflation or inflation, to which we must revert for a moment. It is of the utmost importance to recognise that deflation always entails a sacrifice on the part of the Government no less than of industry, as the real burden of the Debt is being increased while prices are falling. But, it might be argued, as the Government was itself mainly responsible for the inflation which lowered the value of the Debt, it is but just that it should repay to its lenders by means of deflation the same value as it received, excluding, of course, the question of interest and whatever premium on redemption it originally undertook to pay. In strict justice this argument is indisputable, and for this reason *The Statist* originally supported the deflation movement. As already shown, however, while not denying the possibility of rigid deflation in Great Britain, it must be admitted to be practically impossible in the case of most Continental nations, and as no currency scheme is acceptable which does not apply to all countries alike, the point of equity must be waived in favour of the requirements of moment, which demand above all things stable Foreign Exchanges.

Cost of Ventilating Drives and Tunnels.

Mr. Hutton, Inspector of Mines, Germiston, has made a comparison of the cost of ventilating a long tunnel by means of electric fan, compressed air fan, and compressed air direct. The typical case of a drive is taken which is to be 2,000 feet in length, with a cross section of 50 square feet, and the calculation is made for the whole of the ventilation from the commencement to the completion of the tunnel, a period of twenty-five months. The fan ventilation allows for capital cost of fans, of which two will be worn out if they are compressed air fans, for maintenance, cost of 16-inch piping, for power or compressed air, and incidentals. Compressed air cost is taken at the prices charged by the Victoria Falls Power Company—probably the lowest at which compressed air is obtainable on the Witwatersrand. The comparison is as follows:—

Method.	Total Air. Cub. ft.	Cost per	
		Total	1,000
		£	s. d.
(a) Electric fan	1,872,000,000	£638	0.082d.
(b) Compressed air fan...	1,053,000,000	£978	0.223d.
(c) Compressed air direct	224,125,000	£1,077	1.154d.

It will be seen that although the amount of air which is supplied by fan ventilation is many times larger than with compressed air supplied direct the cost is considerably less. The cost per 1,000 cubic feet of air supplied is, of course, greatly in favour of ventilation by fan.

The report of the Labour Department Employment Exchange, Capetown, for the month of September, states:—Engineering Trades: Still very slack, local orders falling off still further. Slight improvement in shipping repairs. The S.S. "Outinequa" is undergoing extensive repairs. These are being executed by Messrs. Tait and Stewart, South African Iron Works. H.M.S. "Thistle" has also been docked at Simonstown for overhaul, and these activities have been giving work to a considerable number of skilled artisans and helpers. There remain still a large number of fitters, turners and blacksmiths unemployed, and for these there appears to be no immediate prospect of work being found. In accordance with arrangements made by the Joint Board

of the engineering trades, a further reduction of 1½d. per hour operates as from the beginning of October. The rate will then be 3s. per hour. Materials are plentiful, costs remain practically stationary, excepting in the case of leather belting. An increase of 15 per cent. in this commodity is noted. Electrical Engineering: Trade fair, good supply of materials, with prices steady. There is considerable competition in quotations for light wiring. Small operators are cutting prices to the lowest point, and are using, wherever possible, materials of Japanese manufacture, the quality of which leaves much to be desired. Motor Engineering: Improvement reported last month maintained, though some of the smaller shops again complain of slackness in trade. A fair number of cars changed hands during the month, chiefly through auction sales. Comparatively small prices were realised. Sheet Metal Works: Slight falling off in trade; materials are plentiful, and show no alteration in prices.

U.K. Profit-sharing in 1920.

The report on Profit-sharing and Labour Co-partnership in the United Kingdom, prepared by the Intelligence and Statistics Department of the Ministry of Labour in 1919, gave an account of the progress of the profit-sharing system in this country up to that date, and of the results of schemes in operation in 1918. Inquiries have again been made this year, relating to the working of such schemes in 1920. So far as is known to the Department, 49 schemes of profit-sharing or co-partnership were started in 1919, and 40 in 1920, by far the largest totals hitherto recorded. Of the 49 started in 1919, 5 have since been abandoned. Since the end of 1920, however, as is usual in times of bad trade, the number of such schemes started has fallen considerably; up to June 30 last the introduction of only 3 schemes has been reported to the Department. Returns received show that at June 30 last 205 firms, with an aggregate of 300,195 work-people in their constant employment, were practising systems of profit-sharing or labour co-partnership. Of these 205 firms, 6 were reported to have two schemes each, so that the total number of schemes of profit-sharing in operation at the above date was 211. In addition to the firms referred to, two firms have schemes which are at the moment in abeyance; while 19 other firms are known to have practised profit-sharing within recent years, but no information is available to show whether these schemes are still in operation. Of the 205 firms practising profit-sharing at June 30 last, 29 (employing 84,832 workpeople) were in the engineering, shipbuilding and metal trades. It should be remarked that the figures given above tend to overstate the numbers of workpeople who are effectively employed under profit-sharing conditions, since in a number of schemes profit-sharing is restricted to certain classes of employees, or is enjoyed only by those employees who choose to deposit savings with the employing firm or to take up shares in the undertaking. Information has been collected by the Department relating the bonuses paid under profit-sharing arrangements in 1920. Of the 211 profit-sharing schemes in operation at June 30, 1921, a considerable number are schemes recently introduced. A further proportion consists of schemes of such a nature that the amount of the bonus, and the proportion which it bears to earnings, cannot be stated. As regards the 151 schemes for which statistics can be given, 109,580 employees participated, or were entitled to participate, in bonuses in 1920. Of these, however, 29,207 were employed under 32 schemes which failed to pay a bonus. The bonuses paid represented an aggregate addition to earnings of over £1,000,000, or £9 17s. 11d. per head; the average ratio of bonus to earnings being 6.3 per cent. These figures represent a very considerable increase when compared with those for 1919, in which year the results of 116 schemes yielded an average addition of £4 18s. 10d. per head, and an average addition to earnings of 4.9 per cent. It should be noted that the figures now given relate to the bonuses paid or credited in 1920; and that, in the great majority of cases, the bonuses so paid were based on the profits either of the year 1919 or of a financial year ending at or before June 30, 1920, and are not, therefore, seriously affected by the depression in trade which began in the latter half of 1920.

Modder East Position.

DEVELOPMENT AND ORE RESERVES.

GOVERNMENT INSPECTOR'S REPORT.

Following closely on the annual report by the Company's own Consulting Engineer, comes the report of the Inspector of Government Leases on the Modder East for the year ended June 30 last. It will be seen that the Government report is substantially in agreement with that of the Consulting Engineer.

Inter alia, the Government Inspector of Mining Leases writes in his annual report on the Modder East for the year ended June 30 last. The ore reserves as at the 30th June, 1921, are estimated by the company at 1,950,300 tons, of an average value of 7.2 dwt. over a stopping width of 56.8 inches. This represents an increase of 194,900 tons compared with the previous estimate as at the 30th June, 1920, when the value and width were 7.75 dwt. over 55.3 inches.

The minimum block value on which the reserve estimate has been based is the same as that adopted in the previous estimation, namely, 4.5 dwt. On the basis of present working costs and the normal or pre-war price of gold, ore of a minimum block value of between 6½ dwt. and 7 dwt. would require to be worked to avoid loss. Under these circumstances and assuming the block pay-limit was fixed at 6½ dwt., only about one-third of the total estimated reserve tonnage would be available. The following table gives the price fine gold must realise per ounce in order to make ore of a reserve block value of from 4.5 dwt. to 6.5 dwt. per ton payable based on present working costs of, say, 32s. per ton, together with the reserve tonnage available at the respective block values:—

Block value (in dwt.)	4.50	5.00	5.50	6.00	6.50
Gold realisation (per ounce)	135s. 7d.	120s. 6d.	108s. 6d.	98s. 6d.	90s. 3d.
Reserve Tonnage available	1,950,300	1,611,700	1,439,200	1,015,500	709,500

Of the total area of the company's property of between 2,250 and 2,150 claims, that portion on the farms Cloverfield No. 12 and Modderfontein No. 6, the boundary of which has been fixed, and to which mining operations by the present company have been confined, amounts to 1,449.42 claims. These claims, so far as is known, are practically all reef-

Modder East: No. 1 Shaft Buildings.

The average value, therefore, shows a drop of 0.55 dwt. and the stopping width an increase of 1.5 inches. The twelve months' development has resulted in a very satisfactory addition to the reserves in the Nos. 2 and 3 shaft areas, but the average grade in these areas is comparatively low. The reserves in the No. 1 shaft area, which average a higher grade, show a decrease. This is partly owing to the major portion of the tonnage mined during the year having been drawn from this area, and partly to the elimination of certain areas which have proved to be, or are now considered unpayable. The distribution of the reserves over the three shaft areas may be taken as follows:—

	Tons.	Value Dwt.
No. 1 shaft area ...	817,900	9.0
No. 2 shaft area ...	471,900	6.0
No. 3 shaft area ...	660,500	5.8
Total ...	1,950,330	7.2

bearing, with the exception of probably from 80 to 90 claims representing dyke. Of these 1,449.42 claims, 15 claims, or a trifle over 1 per cent., have been mined by stopping and development, while the ore reserves of 1,950,300 tons represent an area of 75½ claims, or 5.2 per cent. Compared with the previous year, there was a decrease of 4,806 feet in the total footage developed. The percentage payable of the footage sampled has fallen from 58.5 per cent. to 51 per cent., and the average value from 439 inch pennyweights to 395 inch pennyweights. During the early part of the year under report, which was shortly after crushing operations commenced, a portion of the underground native labour had to be diverted to stopping operations, and at that time the compressed-air supply was inadequate for all requirements, so that development became curtailed. Additions have since been made to the compressor plant, and during the last quarter of the year the rate of development increased considerably. The year's development has been fairly evenly distributed, and the property is being opened

up from those points of attack likely to prove the value of the ground, and although the development has resulted in a substantial increase of the payable ore reserves, yet no highly payable zones of ore have been located beyond that on the southern boundary adjoining the property of the Geduld Proprietary Mines.

MINING.

The rock broken in the mine according to survey measurements amounted to 293,199 tons. The rock broken came from the following sources:—

	Tons.	Percent.	Sampled age.	Dwt.
Payable ore reserves	189,222	64.5	12.5	
Other than payable ore reserves	1,374	.5	4.0	
Development	102,603	35.0	2.8	
Totals	293,199	100.0	9.0	

Average stope width ... 59 inches.
Average reef channel width ... 38 inches.

The average value and width of ore mined from the payable reserves, according to data adopted in the estimation of reserves, as at the 30th June, 1920, were 9.98 dwt. over 57.8 inches, whilst the payable reserves as a whole at that date averaged 7.75 dwt. over 55 inches. Overmining has, therefore, taken place to the extent of 148 inch pennyweights, or approximately 2.5 dwt. over the stoping width. The average face sampling value of the ore stoped on the whole has been considerably higher than the estimated value of the corresponding blocks, the difference amounting to 157 inch pennyweights, or an increase in value of 27 per cent. The areas of some of the blocks are of fair extent, and the values around their perimeters in some instances vary considerably, and in cases the point of attack has been in that portion carrying values higher than the average. Stopping operations are carefully carried out, the width mined being in close approximation to that estimated to be carried. The average width of external waste carried amounted to 21 inches, and a considerable portion of this waste rock is used in support of the workings. The broken ground in stopes is handled by means of winches, and in two instances short footwall crosscuts facilitate the handling. The mine is well ventilated by means of a fan installed in the No. 2 main haulage raise about midway between the Nos. 1 and 2 shafts. The Nos. 1 and 3 shafts are downcast, and the No. 2 shaft upcast. Considerable improvements have been carried out at the No. 1 shaft station, which has been extended. The ore bin has also been enlarged, and provision made for keeping separate the waste from the mill rock. The No. 1 incline has been regraded preparatory to the installation of mechanical haulage, which should shortly be in operation.

NOW READY.

THE S.A. MINING YEAR BOOK

1921—22

By S. E. POTTER.

The Standard Reference Work on South African Mines.

Price 21/- net. Post free 22/6. 250 pp., In Cr. Follo, Cloth, Gilt Letter
Obtainable from the Office of this Paper or from Argus (S.A.) Newspapers, Ltd.
82-85, Fleet Street, London, E.C. 4.

A Recognised Indispensable Work of Reference

For Mining Investors, Mining Engineers, Mine Managers, Bankers, Stockbrokers, Solicitors or anyone interested in the Mining Industry.

A RECORD OF INFORMATION concerning Mining Companies operating in all parts of South Africa. Gold, Diamond, Copper, Tin and other Mines, Collieries, Exploration, and Mining Investment Companies. DATA TWELVE MONTHS AHEAD OF THOSE IN OTHER WORKS OF REFERENCE.

New Kleinfontein.

The report of the directors for the quarter ended 30th September, 1921, shows that the results of development (excluding shafts) were as follows:—Number of feet driven, risen and sunk, excluding boxholes, 2,113 ft.; footage sampled, 1,585 ft.; footage sampled (payable), 760 ft.; mining width (payable), 59 ins.; assay value (payable), 6.33 dwts.

Frank Smith Diamond Options.

An extra-ordinary meeting of Frank Smith Diamond Estates and Exploration Company will be held at Johannesburg on 29th November to pass a resolution extending the option to subscribe for new shares from 23rd February, 1923, either by a period of two years or so long as the mine remains closed down, whichever period is the less.

Ventilation and Miners' Phthisis.

Instructive and interesting remarks on ventilation and miners' phthisis are contained in the annual reports of the Government Inspectors of Mines.

Mr. M. Fergusson, I.M., Krugersdorp, writes:—There is little fresh to be added to what has been said in previous reports with regard to miners' phthisis. The periodical examinations of all classes of underground employees at the Medical Bureau, with the consequent elimination of those affected with silicosis, have without doubt brought home to every person concerned the grave dangers incurred as a result of exposure to dust or blasting fumes, and the majority of men appear now to take a keen interest in using to the fullest extent the appliances provided for dust prevention. Investigations with the komimeter and microscope have been carried out at all mines throughout the year, and it frequently happens that large quantities of extremely fine dust are indicated where the conditions of work would least lead one to anticipate such results. These unexpected results are almost invariably discovered in close places, and one can only conclude that the question of ventilation has a more important bearing on the elimination of dust than had previously been recognised. This, however, is a matter which is being dealt with by a Commission at the date of writing this report, and no doubt the subject will be fully dealt with by that body.

Col. H. Bottomley, I.M., Boksburg, writes:—It is pleasing to record that a tardy but distinct improvement is noticeable in the manner in which ventilation problems are now being met. The improvement is due to a progressive appreciation of the benefits and absolute necessity of a more healthy set of conditions underground, and to the constant pressure exerted by officials of this Department, wherever unsatisfactory features are revealed during the course of inspections. Confidential complaints from miners to this office have been more numerous during the past year than formerly, and although it is felt that such complaints should be made in preference to the management, they are at once investigated, whether by night or day, and the matters complained of adjusted. Faulty conditions in development ends have been discussed in previous reports *ad nauseam*, but, in spite of this, I feel that the subject is of such importance that nothing but unremitting attention will effect any improvement. It is, after all, only natural that managers should hesitate before incurring the heavy cost of numerous fans and tubing, especially where such expense is charged against working costs. Nothing but a legal obligation will bring about the desired results, and at present the Mining Regulations are not sufficiently definite in many instances to enforce compliance. There are many cases in connection with old producing mines where the only effective method of dealing with ventilation costs is by the appropriation of a special vote to cover the desired expenditure, charged to capital. I am pleased to record that this has been done in this district on one or two mines, notably at Brakpan Mines, where the problems were of a peculiarly obstinate nature. There are more long distance development ends in this district than anywhere else on the Reef, owing to the exceptionally large claim areas and to the increasing number of large mines in the development stage, which, owing to the present system of lay-out, entail unusually long drives. In the new mines which have either struck the reef, or which are in the immediate neighbourhood of the reef horizon, the question of adequate ventilation is receiving the close attention which it deserves. As an indication of what is being done, I may mention that the New State Areas have ordered the necessary fans and cables, and have placed an order for 41,000 feet of galvanised iron tubing from 22 inches to 24 inches diameter, made on the Springs pattern. The efficiency and proper maintenance of

this equipment will be the deciding factors in the consideration of the application to blast twice in twenty-four hours. It is apparent from repeated inspections that ventilation conditions on night shift are in need of closer supervision. This shift consists almost exclusively of trimmers and shovellers. The compressed air liberated during the day shift by machine drills is absent, and consequently the air currents are proportionately weaker. The staffs on this shift are not as a rule capable of dealing with ventilation problems, besides which their principal duty is to clean the faces for the oncoming shift and fill the ore bins. Managers rely to a great extent on complaints recorded in the book designed for that purpose, but it is now an established fact that this source of information cannot be relied on. As a general rule, when a trimmer finds smoke in his working place, he prefers to struggle through with his work rather than incur the penalty of being regarded as a "grouser." The obvious remedy is for the higher officials to go underground occasionally with the night shift and make personal

Fan 2,000 Feet below Surface, Village Deep.

investigation. This is done in very exceptional instances, but the practice is not regarded with any degree of favour. The statement issued by the Miners' Phthisis Medical Bureau dealing with the phthisis rate on individual mines is a most interesting document, and one which, in the interests of the mining public, might with advantage be published. The statement gives the degree of phthisis production for every mine on the schedule. It is interesting to note that the mines of the Far East Rand are more free from phthisis than those on the rest of the reef. This is doubtless due to the fact that more slate is mined here than elsewhere. The Far East Rand is a "one reef" area, with a low dip and a soft shale footwall, in which most of the development is accomplished.

New Machine Drill.—A machine called the "Turbo" has recently made its appearance on the mines, which in trials has proved itself superior to any other type at work, in actual drilling time and in steel economy. Like the deadly Leyner, it passes air and water down the steel to the cutting edge, and, unfortunately, appears to create more dust under normal conditions than other types. As an

indication, however, of what good results can be attained under ideal conditions, and under the direction of a careful official, it may be mentioned that at the Modder Deep dust samples were taken at short intervals throughout a drilling shift with one of these machines at work. That result proved that considerably less dust was being produced than is usual. The one departure from the usual practice in this test was the use of a separate water hose for spraying purposes round the hole when the machine was collaring. On this mine all machines are now similarly provided with an extra hose, and I would commend the practice to other managers as being likely to improve conditions. It has been found on a recent investigation that an unaccountable slackness has been the practice in the majority of mine drill shops, in connection with the hollow steel now in universal use for drilling machines. It was found that in most cases the perforation or tube had been reduced in area in welding or sharpening to such an extent as to seriously restrict the flow of water to the cutting edge. The natural result of this would be that air would be depended on for clearing out the sludge produced by drilling, and considerably more dust would be produced.

Mr. C. E. Hutton, I.M., Germiston, writes:—There are three prolific causes of the formation of dust in mines, namely: (1) Blasting operations; (2) shovelling operations; (3) drilling operations.

Blasting Operations.—The very fine dust created by blasting in a mine cannot be allayed, and must therefore be got rid of by means of ventilation. Ventilation is divided into two divisions, general and local. The term "General Ventilation" applies to workings in which a through current of air can be established by splitting and coursing the main air supply, and the term "Local Ventilation" applies to "close" working, such as back stopes and development tunnels. Except in very special cases, when the permission of the inspector of mines has been obtained, blasting operations are only permitted once in twenty-four hours. In a large number of mines the night shift has been abolished, and in other mines a small number of persons are employed on shovelling and tramming during the night shift. These persons go down the mine from four to seven hours after the blast. I may safely say that the dust from blasting operations is removed from all the workings served by the "general ventilating" current in a period varying between four to seven hours, but in many long development tunnels and back stopes, where the "local ventilation" is done by compressed air, the very fine injurious dust from the blasting operation remains in suspension for hours, which fact shows that such close places are inadequately ventilated. The elimination of dust in these places is at present engaging the special attention of a committee of inspectors. The presence of this very fine injurious dust in the atmosphere of development tunnels, hours after blasting, has been detected by the use of the konimeter, whereas the gravimetric method would have shown good results. From the foregoing it will be seen that as soon as the elimination of dust in "close" places is achieved, very little harm can result from dust from blasting operations if a reasonable period be allowed to elapse between shifts. Frequent surprise inspections are made of the stations in main travelling shafts at blasting time, and during the last twenty months no persons were found to be exposed to the fumes and dust created by the blast at the end of the shift.

Shovelling Operations.—If the provisions of Regulation 101, sub-section 2, are not observed to the letter, there is little doubt that shovelling operations may remain a cause of the creation of dust. The regulation may appear to be sufficient, but it would be impossible to obtain a conviction for a contravention thereof unless the ground being removed contained no visible signs of moisture. What is and what is not "effectively" wet would be most difficult to prove in a court of law. It can be said without fear of contradiction that in every mine day after day this regulation is in a sense contravened. Possibly in every instance the ground being moved had been wetted, but had not been kept "effectively" wet, although at the same time it was

not dry or dusty. To prove that in a court of law would be impossible; the offenders are merely instructed to apply more water.

Drilling Operations.—Now that the use of the dry jack hammer drill has been forbidden, and allowing that the Leyner type of drill is kept in proper working order, there should be practically no dust escaping into the air if the provisions of Regulation 101, sub-section 1, are observed.

Underground Fan on a Rand Mine.

It must be obvious that if the devices for dust allaying are properly used, and the regulations obeyed, the creation of dust from drilling would be reduced to an almost negligible quantity. The quantity of injurious dust formed by any sort of machine drill if used dry is so enormous that a few minutes of such drilling is sufficient to contaminate a very large volume of air in the mine. The opinion formed by inspectors is that this offence must be a daily occurrence in more than one working place of any mine.

(To be continued.)

Swazi Tin.

The following are the results of the operations of this company for the month of September, 1921:—Concentrate recovered, 17½ tons; estimated net loss for the month, including credit adjustments on previous shipments (taking tin at £155 per ton), £106.

Grootvlei Options Extended.

The head office of the Grootvlei Proprietary Mines announce that the directors have decided to extend for a further period of two years all options for shares granted in September, 1919, in connection with the issue of 250,000 new shares. Holders of option certificates entitling them to apply for and receive an allotment of shares at the price of 25s. per share up to the 30th September, 1921, are therefore now entitled to this option up to 30th September, 1923, and can have such extension endorsed thereon on presentation at the London office, 34, Bishopsgate, E.C. The Grootvlei Proprietary area is situated on the Far Eastern Rand, slightly to the south-east of the Geduld farm, but separated from the Geduld Proprietary's mine by a block of Government ground which was unsuccessfully put up for tender a few years ago. It was intended to restart shaft sinking on Grootvlei at the end of 1919, but the directors ultimately decided to postpone a resumption of operations until the necessary machinery could be obtained more cheaply. The shafts will have to be put down about 3,000 to reach the reef.

Sampling Analysis and Classification of Coal.

In a recent issue of the journal an extract from a paper by A. Trevor Williams, M.Sc., on the above subject, read before the Chemical, Metallurgical and Mining Society of S.A., was printed. The contribution to the discussion arising out of the paper by Mr. J. Q. Braidwood, reproduced hereunder, contains some noteworthy points pertaining to South African practice.

The first paragraph in the paper is one I take exception to. This paragraph is essentially one of the most important in the paper, as it shows that the value of the paper depends, apparently, on the reliability of the authorities quoted, and not on personal experience and research by the author.

With regard to the reliability or practicability of the methods mentioned by the author of the paper, or their applicability to this country, I am afraid I must disagree to a very considerable extent. I question whether they may be considered as an improvement on methods in use

The South Rand Colliery at Grootvlei.

here in 1908—gradually improved since, and standardised by the South African Engineering Standards Committee* (now the British Engineering Standards Committee, S.A. Branch). A similar but in my opinion unnecessarily elaborated system for commercial purposes with drawings and unnecessary multiplication of operations was published by the Bureau of Mines, Washington, in 1916, about four years subsequent to the South African publication, which gives one the impression that it is the work of a scientific gentleman who has lost sight of the fact that, however accurate a system of sampling may be, there are always small errors due to various well-known causes which make elaborate sampling methods and apparatus, unnecessarily expensive. No good purpose is served by such elaboration, as nothing kills a good idea quicker than unnecessary or high cost.

I must presume, for want of other and more certain knowledge, that the paper in question has been written with a view to assisting us in this benighted part of the world (or so it is generally assumed to be elsewhere); to give us an idea of what is being done in England so that we might gratefully follow the lead of the reliable authorities quoted, who have had one or two years' experience in selling coal on the calorific basis, as against a dozen years here. We are always pleased to know what others are doing elsewhere, but by past bitter experience we have found that

* Report, January, 1912.

to apply home methods here without very thorough investigation and experiment is courting disaster. I find that in the third paragraph of the second column, only English and American research Associations and authorities are mentioned. It is possible that no such remark as attributed to Mr. Sinnatt can be found in the pamphlet entitled "Standardisation of Coal Sampling," published here in 1912, which may be due to the fact that we assume that those entrusted with such work realise their responsibility and the necessity for carrying out intelligently the simple and effective methods in use here, or that they will immediately be replaced by someone who can.

I would like to discuss another quotation near the foot of the second column, "The principle underlying sampling and its possible errors."

"To be truly representative of the whole weight of any consignment of coal a sample should not only contain a portion from every different part of coal, but also the correct proportions of large and small coal, and of large and small pieces of foreign matter and impurities."

The foregoing has many objectionable features likely to cause trouble, particularly if in the hands of a non-technical person, perhaps a buyer of coal. It does not say that this should be, weight in sample, in proportion to quantity of such material present in the bulk, although some such idea is conveyed later with regard to large and small coal. This gives one the idea that all small coal is inferior in

South Rand Colliery—Headgear and Screening Plant.

calorific value to larger coal, which is not always the case, depending as it does a great deal on the friability of the coal and method of mining.

With regard to the engineer mentioned, I can only suggest that what we call a fitter in this country is meant.

I am in agreement with the statement about "errors" being traced "to an under-estimated notion of what the weight of a sample ought to be," yet lower down I note weight of original sample should be 39,000 lbs., and I would like to point out that it is easy to make rules which it would be absurd or impossible to carry out. For example:—If I went out to a mine and suggested that a 39,000 lbs. sample should be taken, it is quite probable that the resident engineer would say, "Why not take the whole blooming truck?" Engineers in this country often sacrifice the more cultured methods of speech to convey an incontrovertible fact in a few words.

From experience, I would say that to assume the smallest weight of a sample to be 1,000 lbs. or half a ton for 100 tons bulk is misleading. Such a large quantity has been proved to be quite unnecessary. Further, to give a sampler of the ordinary human man type instructions such as, "In obtaining the gross sample great care must be exercised to ensure the presence in it of the proper proportions of large and small coal, and large and small impurities" would result in hopeless muddle. I say that it is not humanly possible for anyone to accurately estimate the

quantity of large or small coal or impurities in a bulk consignment; in fact, such an instruction would wreck coal sampling if carried out, also if a coal sample of 39,000 lbs., or even 1,000 lbs., had to be sieved over a $\frac{1}{4}$ in. sieve, the gain would be infinitesimal.

We are told to "Run a shovel along the bottom of the wagon after enough coal has been unloaded to allow the coal to assume its natural shape" (I presume "natural shape" means angle of rest on the resulting slope due to removal of a part of the coal).

I am very definitely opposed to running a shovel along the bottom of the wagon unless I want to get a sample of coal to include any dirt there may have been in the truck previous to loading!

Again we are told that, "When cars or wagons are being dumped a scoop (size and shape are not given) may be held in the stream of falling coal." This, we are told, "essentially means collecting successive small increments from successive parts of the heap, and provided discrimination is used as to the relative quantities of lump and fines, the method has every claim to accuracy."

In my opinion if an accurate result were obtained by this method it would be by accident, as when coal is running, any large lumps will most probably fall off the scoop and an undue proportion of fines will be found in the resulting sample. If coal larger than nuts or peas size is sampled, that is for anything above nuts say from $1\frac{1}{4}$ in. to as large as 18 in. diameter, we must throw this system out.

Under the sub-heading "Mine or Seam Sampling," the author of the paper again quotes Mr. Sinnatt, in what in my opinion is about the most unpractical and excessively and unnecessarily expensive method of sampling a seam that I should think it would be possible to imagine, and I should like to ask the author if this has ever been carried out in practice, or is it only the result of a fertile brain and unlimited spare time? If a specimen of a seam were required for exhibition purposes overseas, where expense, etc., were no object, perhaps one might consider the matter from that point of view, but in that case I would suggest a wider section than 6 in. to show more of the coal as a set-off against the cost of admission to the exhibition.

If the author of the paper has not used a pick underground or has not tried cutting pillars out of a seam, I should strongly advise him to try and make a note of the time required to make a calorific survey of a mine by his method. I particularly mention the use of the pick by the author himself, as experience in handling the pick is a very necessary part of the operation. The usual miners' method of using a pick, or the Kaffirs' for that matter, is quite unreliable. Making an accurate calorific survey of a mine requires considerable experience, and the personal factor and judgment are most important if real accuracy is the object in view, and not exhibition "pillars" packed in straw; this I think I am well able to state from a very considerable personal experience in this work.

In this country the miner mines the coal in quantity according to instructions, but only large stone or shale bands, or some continuous band not suitable as saleable coal, is left underground, the real picking or sorting taking place on the surface on a travelling belt constructed for the purpose, so that the American quotation in first paragraph on page 3 does not apply to the Transvaal. The American system published in 1918 is similar to the system published by the South African Engineering Standards Committee in January, 1912, which I had had in use since 1908, having devised it to suit necessity, and improved it by experience. It is in use to-day with marvellously accurate results at a minimum of labour and expense. It cuts out as far as possible all unnecessary apparatus, and reduces the time required for the operation (and the cost) to a minimum without sacrificing accuracy. This I feel sure has not even been thought of, far less attempted, with the system given us by the author of the paper.

In view of the multitude of things the sampler has to take underground, I think it can be said that here it is simplicity of apparatus and a knowledge of the work, as against multiplicity of apparatus to make up for a want of knowledge of the work as shown in the paper under discussion.

It would seem that the author has written a paper on other people's experiences, or the want of it, and therefore I hope will not bear me any ill will for what I have said, and I trust that if ever he goes to England that he will read a paper on South African methods, and then I think we shall have cleared the slate, and he will have had his opportunity. There is still another little point I would like to mention as showing the impracticable ideas conveyed. I will quote: "A second method is to place the whole of the sample in a thick canvas cloth sheet tarpaulin on which it may be crushed by means of the 'punner' or hammer. I have seen a similar method used for separating mealies from the cob by beating them inside a sack, but to break coal on canvas or tarpaulin would mean that both or one of them must be of practically no value after the operation, as I leave you to guess how

Fan at the South Rand Colliery.

long the operation would continue without holes being cut in the sheeting. In this country we have to buy any canvas or tarpaulin we require.

The system of coning when quartering the coal was early discontinued for large quantities—as the work is not done in the laboratory, nor is the usual sampler of coal in this country a man trained in the laboratory. We substituted after each mixing the following:—With samples of between 200 and 300 lbs. we lay out the coal in a square of 6 in. thick, it does not matter if it be 3 in. thick beyond the fact that it would cover too much space which is often limited; it is then quartered. The quartering is very expeditiously and accurately done by using a cheap quartering apparatus designed by Mr. Thomas, Chief Engineer of the Wolluter Gold Mine, which apparatus I commend to others as a time saver and insurer of accurate quartering in unskilled hands. No royalty I believe is charged for its use, only a grateful letter of acknowledgment is sometimes sent.

I will again quote, "When the weight falls to about 40 lb., samples may be sent to the laboratory or be crushed so as to completely pass through a sieve of four meshes to the linear inch when its weight may be reduced to 15 lb."

I can imagine that if all samples that were sent to the laboratory weighed 40 lb., some of these laboratories would soon be in competition on unfair lines with coal dealers who pay for their coal, besides the fact that the increased cost of storage in town would take a little of the gilt off the small amount of gingerbread allowed for the work. Surely the Home laboratories must have large spaces, cheap assistance in the way of pupils, etc., as well as get a good price for their work.

I cannot quite understand why No. 6 is given as "Nitrogen percentage," No. 7 as "Ultimate analysis," giving the percentage of C.H.O. and N. If N. stands for anything

else than nitrogen, what is it? nitrogen having already been mentioned in No. 6, but it may be only to extend the list and make it look more important.

I would specially commend the part dealing with "associated" moisture and water of composition for discussion between the author and my learned friends the analytical chemists; it is too deep for me in its present form with the time I have at my disposal.

I am afraid the author has given us nothing new; in fact, has lightly touched on a very serious subject, almost to belittle its importance.

So far as accurate determination of moisture goes, I am in favour of the U tube absorption test with dry calcium chloride, or a similar method with sulphuric acid, to determine the error due to the oven method for each class of coal, and so standardise an easy cheap method with an error factor instead of a continuous expensive method whose percentage of accuracy above the corrected one does not warrant the increased cost where large numbers of determinations are done on a commercial basis. This I hope will some day be the case, when the powers that be are converted to the benefits of reducing our results to a definite dry coal basis of sample and return.

With regard to the method of determination of volatile matter in a sample of coal given by the author, I can only say that the results would be quite useless to me in my work, as I make considerable use of the proximate analysis, perhaps new uses, in obtaining information not heretofore associated with chemical analyses.

I have corresponded with the American Bureau of Mines on the subject of the American method of heating the coal at a given temperature for a given period, a method which does not accurately show what the volatile contents are, but shows a result depending on the rapidity with which the coal gives up its volatile, including moisture, in a given time, which is not necessarily a true statement of the volatile contents.

The Agglutination Curve, or hit-or-miss method of determining the coking qualities of coal, does not commend itself to me since it depends on an outside factor or diluent, and since you don't know if the hit was a bull's eye, or the miss only just grazed the target, I think we might devise a better method if we had the money and time to spend on research that the people at Home seem to have.

Mention is made that "authorities" have judged "it essential that all classification of coal should be made on dry and ashless basis, or, in other words, on the pure coal substance."

It will depend a good deal for what purpose the classification is required, and how much use it is going to be when arranged. I am in agreement that all our returns of calorific value should be on the dry coal basis, the hygroscopic moisture being known; but ash is not separable from coal until burnt, a fact that must be considered when classification is considered. What is termed pure coal by the author is known here as combustible matter; pure coal to my mind is a term to be carefully used, perhaps in the future, when we know what pure coal is.

When we consider the great difference in age and composition of the coals of South Africa from those of other countries, it but emphasises my contention that we should do our own research work, lay down our own laws, and determine our own facts, and not blindly accept the dictum of others unknown to us, and unknowing our country, its difficulties and possibilities.

There is reference to a sample of "slack" in which small coal when separated showed 10 per cent. of ash, and the so-called large coal contained 40 per cent. ash; this is followed by the remark, "What would be the worth of the analysis as representing the heap from which the sample had been taken if the proportion of large and small received

in the laboratory had not been representative of the large and small in the heap?" Here follow a number of figures which can be read from the paper and then again I quote, "It will be seen at once that the calorific value as disclosed by the laboratory would vary tremendously in the two samples referred to." There would undoubtedly be a variation in coals having a difference of 30 per cent. ash contents, but if the sample of the whole bulk is properly taken by the method in use here and by a man who has been properly instructed, say, for a couple of hours, there should result a true sample without any unnecessary separation and calculation.

The author would perhaps be surprised if he knew the system in use here, including registration and other checks on sampling coal. Anything in the way of careless sampling is soon detected, errors of labelling and numbering of samples shown up as soon as made, the percentage of errors from any source being a negligible quantity.

Without going into further detail I may say that in my opinion the methods given by the author for sampling coal might perhaps be of use for some other purposes, but for coal in South Africa I must absolutely oppose the adoption of many of them, even in modified form, and would further warn others that there is plenty of "trouble sticking out" for whoever tries to obtain reliable results with some of these proposed methods. Most of the reliable information mentioned may be obtained from text books, but there is much of this that is not applicable to South Africa, and further, I find no hint in the paper as to costs, or who pays. Both are important items, particularly with elaborate and expensive systems.

I would like to take this opportunity of mentioning that the success of the systems in use and mentioned above for the detection of errors, etc., is largely due to the very valuable assistance ungrudgingly given, often under trying and worrying conditions, by the analytical chemists who carry out the work of analysis and sometimes of supervision.

I have often thought that the training of the engineer should include sufficient of the chemist's and physicist's training to enable him to appreciate and discuss the work of the chemist, and likewise that the chemist should be able to appreciate the engineer in the same way, have similar training in engineering, and then the ideal collaboration would result to the benefit of both.

I would mention, for example, the bomb calorimeter, perfect as a physical instrument of a very delicate character, but rotten as to mechanical design and operation; here it is necessary for the engineer to know the apparatus, its use and purpose, before he could design an instrument to embody the necessary strength, accessibility of all parts easy to use, and so nearly perfect in its mechanical parts, as it is in its physical principles.

I wish to anticipate a question that may be asked, that is: Why do I not read a paper on coal rather than use destructive criticism of the work of others? It is a reasonable question, and my reply to this is weak, you may perhaps think. I am the engineer to the Transvaal Coal Owners' Association, as some of you know, and in that capacity I feel that I have knowledge in trust which I could not use except in a general manner, and a general paper is not suitable to the standing of this Society, so that I may do more good as a critic inducing discussion.

I hope I shall have helped to discussion on a large scale, and to the writing of fresh papers on the subject of coal with something South African about them.

I have to propose a vote of thanks to the author of the paper for having opened up a subject that we should have opened up, and discussed ourselves, except for our retiring natures and somewhat shy dispositions. In some of this work we may claim to be pioneers; further, I think that the sale of coal on a calorific basis was better understood here than anywhere, at least up to a few years ago. I hope that shortly we shall keep ahead of the times by meeting again on a larger and more representative board, to revise, discuss, and add to our previous work.

Flotation Applied to Rand Ores.

Sir,—The following results of flotation tests on Rand ore, slimes and sand residues, made at our newly-opened laboratories, Flotation Buildings, corner of Kort and President Streets, may be of interest to your readers:—

1. Crude Ore from Mine: Assay value of ore, 9.9 dwts.; ore crushed to 80 L.M.M.; value of concentrates, 65.9 dwts.; percentage of concentrate caught, 14.8; residues, .42 dwts.; extraction, 98.5 per cent.; cost of reagent, 7d. per ton.

2. Slimes Untreated: Assay value of slimes, 1.34 dwts.; assay value of concentrates caught, 7.2 dwts.; percentage of concentrates caught, 16.4 per cent.; residues, 0.20 dwts.; extraction, 88.1 per cent.; cost of reagent, 4d. per ton.

3. Black Reef Tailings: Assay of crude sample, 2.45 dwts.; assay value of concentrates, 24.6 dwts.; percentage of concentrates caught, 8.6 per cent.; residues, 0.42 dwts.; extraction, 86.3 per cent.; cost of reagent, 8d. per ton.

4. Sand Residues from Rand Ore: (1) The first tests were on sand as received without further grinding. There was no difficulty in concentrating by flotation the free mineral consisting of iron pyrites. The concentrates averaged 10 dwts. in value and were about 6 per cent. of the bulk treated. The original value of sand in this test was 1.4 dwts. and the residues averaged .85 dwts. It was quite clear to us that a large proportion of gold was locked up in sands and could only be floated by further grinding. (2) The next test was made as follows: Assay of crude sand, 1.75 dwts.; concentrates, 12.6

dwts.; percentage of concentrates caught, 10.3; residues, .45 dwts.; extraction by flotation, 71.1 per cent.; crushing, 80 mesh L.M.M.; average cost of reagents was 4d. per ton.

In view of the above results, even allowing for the cost of re-grinding sand, it appears probable that these particular sand residues can be profitably re-treated by flotation.

Flotation Tests on Crude Rand Ore done in our London Laboratory: A fairly large scale test of 1,870 lbs. run in London recently gave a .55 dwt. residue on a grade of ore assaying 22 dwts. If the ore had been of a lower grade, undoubtedly a far lower residue would have been obtained; as it is this result indicates a recovery of from 96 to 98 per cent. From tests done here and in London, it appears probable that on a 4 dwt. ore a residue of .15 to .2 dwts. may be looked for, the residue rising more or less slowly as higher grade ore is treated.

We believe that our process, if applied to current reduction works, would mean a large saving in working costs, and is worthy of most careful consideration. Instead of treating the whole of the crude ore by cyanide, we are fairly confident from the results we have obtained up to date that we can give a 10 per cent. concentrate containing from 93 to 97 per cent. of gold in the ore, and this concentrate can be easily treated by ordinary cyanide method.—Yours faithfully,

E. HOMERSHAM,
Minerals Separation, Ltd.

A disastrous strike at the E.R.P.M. this week was averted at the last moment by the resignation of the employee whose refusal to join the Union was the cause of the trouble.

Glencairn G.M. Co. Liquidation.

A SHAREHOLDER'S QUERIES.

FULL AND SATISFACTORY ANSWERS.

Sir,—I was glad to see from a recent article in your widely read journal that widespread dissatisfaction exists amongst shareholders on your side at the way in which certain liquidations are being carried out. I am interested in most of the gold mining companies now being liquidated but, with the exception of the above company and its stable companion, the Ginsberg Gold Mining Co., Ltd., cannot say that I have any reason to be dissatisfied with the conduct of affairs. Such companies as the Village Main Reef and Knights Deep have given their shareholders all the information possible.

But it is very different in the case of the Glencairn and Ginsberg, both of which were placed in liquidation towards the end of 1920, the former, I think, on the 31st December of that year. Is there any reason why a report and balance sheet should not have been issued for 1920? I should have thought that under the Companies Act (1908) the Directors were bound to issue reports. We shareholders on this side have been kept in complete ignorance as to what transpired at the liquidation meetings, and are not even aware who the liquidators are. We presume they are the late directors.

Another matter of more serious concern to the shareholders is the way in which the whole of the mining property and freehold area, etc., of the Glencairn Company has been disposed of for the paltry sum of £1,500, representing only a fraction of a penny to the shareholders. As the mine closed down some months before the mines were allowed the benefit of the premium on gold, it was only natural that the shareholders expected the liquidators would be in a position to dispose of the substantial amount of ore left in the mine for a fair sum, or get one of the neighbouring mines to work it on a profit-sharing or royalty basis.

The directors of the New Primrose, who, with one exception, were also directors of the Glencairn at the time of the sale, have certainly done a magnificent stroke of business for their shareholders. I understand the New Primrose profits for the months of July and August amount to nearly £12,000, and as its own mine is exhausted, the bulk of the ore must have come from the old Glencairn. What we shareholders on this side want to know is whether the mine, etc., was exposed for sale by public auction, or tenders called for before the sale for the above ridiculous sum took place.

I have made several applications to the Chairman of the London Committee for information, but have been told on each occasion that he is in exactly the same position as other shareholders on this side, and knows nothing. It is rumoured on this side that a large quantity of the mining machinery of the Glencairn and Ginsberg was disposed of to another mine of the same group, viz., the New State Areas, but I have no definite authority for stating it as a fact. Probably some of the shareholders on your side know the facts, and it would be interesting to have their views regarding this matter.

Apologising for taking up so much of your valuable space, I beg to subscribe myself,

DISQUIETED SHAREHOLDER.

London, E.C.,

15th September, 1921.

[With reference to the above, we have made inquiries and find that all the statutory requirements in connection with the liquidation have been complied with. Further, that a meeting of shareholders was duly advertised and held on the 4th August, 1921, when the liquidation accounts were submitted. The chairman of this meeting informed shareholders that the profit from the treatment of accumulated slime to 30th June, 1921, was £6,456 16s. 10d., and that the surplus cash at the same date amounted to approximately £25,000. He further stated that the treatment of accumulated slime continued, and that there remained to be sold the buildings and plant used in connection therewith, and certain houses on the property. Reference was also made at this meeting to the first liquidation distribution of 2s. per share made on the 31st March, 1921, absorbing £55,000.

With regard to the purchase of the Glencairn ground by the New Primrose Company, it was pointed out to shareholders at the meeting held on the 27th May, 1919, that mining operations could no longer be profitably carried out, and that the mine was consequently closed down, and as the New Primrose Company was the adjoining company, and was the only company that could work this ground, negotiations were entered into and the ground sold for £1,500, which, in comparison with the price paid by the New Primrose Company for ground purchased from the May Consolidated Gold Mining Company, Limited, was a fair price. The statement that the New Primrose Mine is exhausted is incorrect; as a matter of fact only a small proportion of the tonnage milled comes from the Glencairn section of the property.

Referring to the remarks dealing with the sale of machinery, we would like to point out that both in regard to the Glencairn and Ginsberg Companies a complete valuation of all machinery and plant was made by a well-known firm of mining and machinery brokers, who, after valuing them, issued a detailed catalogue, and the prices realised were highly satisfactory.—Editor, S.A. M. and E.J.]

The Climax Rock Drill Control Actuated by Water Flow.

In designing this mechanism, the object in view was to prevent a rock drill from working if the water was not flowing, and further, to stop a rock drill from working if the water ceased to flow for any reason. It was decided that the most effective way of doing this was to upset the function of some vital part of the machine, such as the valve, which, in its turn, would prevent the machine from working. In the following description reference is made to the mechanism applied to the valve chest of a "Climax" Cradle Hammer Drill (Joburg No. 3) for which the experimental mechanism was made, but it should be borne in mind that the principle can be applied to all types of rock drills.

Mechanism Described.

The mechanism consists of the body F, the lock nut K, the piston E, the rubber packing G, the spring H and the cap J. The remaining parts shown, namely, the machine valve box B, the machine valve A, the valve chest buffer plate C and the valve rubber buffer D, are all parts of the

against the spring until the head of the piston is clear of its cylinder, and water flows freely past the underside of the piston head into the space L and out through the water outlet to the water tube. When the piston and piston rod are in this position, the holes in the walls of the hollow portion of the piston rod are blinded by the body of the mechanism, and therefore the end of the valve chest is no longer in communication with atmosphere, but is sealed, so that pressure can be set up in the end of the valve chest, which will allow the valve to function in its normal manner, and operate the drill. Assume for a moment that the water tube gets choked, and that the water ceases to flow. The water pressure at the water outlet will then build up until it is equal to the water pressure at the water inlet, and as far as the piston is concerned, these pressures will balance each other. The spring will then take control and depress the piston into its original position, thus placing the end of the valve chest in direct communication with atmosphere, and so stopping the valve and the machine from working as before.

THE CLIMAX ROCK DRILL CONTROL
ACTUATED BY WATER FLOW.

standard machine, and are only shown to illustrate the function of the mechanism more clearly. To enable the valve to operate and so the machine to work, pressure and then release has to be continually taking place in the ends of the valve chest, i.e., in the space between the machine valve A and the valve chest buffer plate C. It will readily be seen that if this space is connected direct to atmosphere, pressure cannot set up, the valve cannot operate, and so the machine cannot work. Assume, first of all, that the water is not flowing. The piston E is then held in the position shown on the sketch by the spring H. The lower end of the piston rod is hollow, and this hollow portion of the piston rod is in direct communication with the end of the valve chest, thus putting the end of the valve chest in direct communication with atmosphere through the holes in the walls of the hollow portion of the piston rod, and the air passages through the body itself. Therefore, when the piston is in this position, the valve cannot operate.

The water connection from the main supply is attached to the part marked "Water Inlet." From the part marked "Water Outlet," a connection is made to lead the water to the water tube. Now assume the water is turned on and that the water pressure is above the minimum at which it is desired that the machine shall work. The piston then rises

It is possible to have pressure without flow, but it is not possible to have flow without pressure. Although pressure enters into the working of the mechanism, it will be readily seen that the mechanism relies solely on flow for its successful operation.

Interesting New Device for Rock Drills.

In the course of his annual report for last year, Mr. C. J. Gray, the Johannesburg Inspector of Mines, says that a device invented some years ago by J. Berry for cutting off the compressed air supply, and thus stopping the drills when the water pressure fails, was tried at the Ferreira Deep during the year. It was not wholly successful, as dirt soon prevented the plunger from working; alteration in design might overcome that difficulty. Towards the end of the year, Mr. S. Fisher, Underground Manager of the Ferreira Deep, made an invention still more directly calculated to get over the difficulty arising from failure of the water feed in machines on the water principle. His device is attached to the machine itself, and stops it if the current of water through the machine falls off for any reason, such as failure of the water supply, reduction in pressure of the supply, or choking of the water tube or drill bit. Sufficient practical trial of the device has not yet been made.

Another Mine Closes.

ROODEPOORT U.M.R. PROFIT-SHARING PROPOSAL FAILS.

As anticipated in these columns last week, the failure of the men's unions to accept the profit-sharing terms offered by the directors of the Roodepoort United Main Reef has led the directors to decide on closing down the mine. Accordingly they have sent the following communication to the S.A. Industrial Federation:—

Dear Sir,—I am instructed by my Board to acknowledge the receipt of your letter of the 29th ult., and to express their regret that the various unions concerned are not yet in a position to notify their acceptance, or otherwise, of the profit-sharing scheme outlined by the chairman at the meeting held on the 3rd September last, and subsequently confirmed in his letter of the 8th idem.

My directors are most unwilling to close down the mine, and add to the existing unemployment, but at the same time they wish to point out to you that the matter has already been under consideration for nearly six weeks, and that in the meantime the mine continues to show heavy losses, which are likely to be increased substantially as a result of the recent fall in the price of gold.

Under these circumstances, since it is impossible to continue operations on the existing basis, they have most reluctantly decided upon a gradual suspension of operations, and instructions are being issued to the management accordingly.—Yours faithfully, (Sgd.) J. V. BLIXKORX (Secretary).

It appears that this decision had been arrived at with the utmost reluctance, but the directors had no alternative. The loss last month was £1,700, and since the beginning of October the price of gold has fallen very substantially (approximately 4s. per oz.), which will mean a still heavier loss for October.

"We feel," said one of the directors, "that even if we got a reply from the unions there would be many outstanding matters remaining to be discussed, and we should probably not be able to reach finality for some months to come; in the meantime the company would be getting still further into debt.

"The mine already has lost £380,000 and the General Mining and Finance Company cannot possibly go on carrying the burden, as they have done for years past, entirely for the benefit of the workers.

"We realise that shutting the mine down immediately—although the men have had very long notice—would throw 164 white men out of work, and that would be a great hardship at the present time, when there is a certain amount of unemployment in the country. Therefore we have decided to try to close down gradually.

"That is to say, we shall first of all immediately stop all development. We shall stop mining work on the lower levels of the mine, retaining one man and a gang of boys

on each of the levels where mining work is stopped in order to reclaim the material and clean up the stopes. In that way we hope to discharge the men gradually over a period.

"It is somewhat of an experiment. Whether it will be successful or not depends upon co-operation from the men who are left on the mine. If they are willing to help us during the struggle of running two shifts in the reduction works, instead of three, operations may continue for another two or three months, perhaps even a little longer, but, of course, if we find we cannot cover expenses on that basis the only thing for us to do will be to close down immediately.

"We want the men to realise the position, and we want them to see that if they do help us in this matter that they are helping themselves by avoiding a large number of men being thrown out of employment at one time."

The Currency Conference.

A conference was opened this week at Union Buildings by the Minister of Finance with reference to the currency question. The Conference comprises Mr. W. H. Clegg (Governor of the Reserve Bank), chairman, Sir David Graaf, Sir Ernest Oppenheimer, Col. Creswell, Messrs. Aiken, E. Chappel, S. Evans, J. P. Gibson (General Manager, Standard Bank), and J. R. Leisk (Managing Director, National Bank). The Conference considered (1) whether the provisions of sub-section 3 of section 7 of the Currency and Banking Act 1920 (whereby the inconvertibility of gold certificates terminates on June 30, 1923) should be carried into effect or amended so as to extend the period of inconvertibility, and (2) in either case what steps, if any, should be taken in advance to avoid undue disturbance of exchange and business.

The "All-Sliming" Process.

Mr. H. R. Whitehead (late mining editor of the *Statist*), who has just returned from a visit to Canada, writes to the *Financial Times* as follows:—"There is, as you say, nothing new in the process known as fine grinding, all-sliming and continuous decantation, but it has great advantages not hitherto recognised on the Rand. Probably you are right in questioning whether the older Rand mines will at this late date discard stamps in favour of less elephantine machinery for secondary crushing, but I do not think it will be very surprising if some of the long-life concerns do so. I learned while in Canada, whence I have just returned after visiting the Kirkland Lake and Porcupine mines, that the management of the great Hollinger mine, which has a mill capacity of 3,500 tons a day, has now decided, after exhaustive experiments, to replace their 100 stamps with roll crushers. Mr. A. F. Brigham, the general manager, was for many years associated with the management of the De Beers mines, and I should imagine his old friends can obtain from him, if they have not already done so, a good deal of informative data on the subject of the advantages of crushing ore without stamps. The Hollinger rock, I know, is relatively friable, but there is to be found the last word in milling without stamps at the new plant quite recently installed at the Wright Hargreaves mines on the Kirkland Lake field, where the ore is very hard indeed.

POSITION WANTED.

MINING ENGINEER, holder of first-class Mine Manager's Certificate, with extensive underground experience in the layout of surface plant of gold mines, and also in management, **SEEKS POSITION AS MANAGER OR POSITION OF TRUST ON UNDERGROUND STAFF, OR WITH CONSULTING ENGINEER**, Mining Machinery House or Importing Firm. Is also prepared to visit properties and report on them and make complete plans for their equipment.

FIRST-CLASS REFERENCES.

Address—

"AB," Box 963,

Care of "Mining Journal," Johannesburg.

CORRECTION.

With regard to the Prospectus of the UNION ASBESTOS CORPORATION (S.A.) LIMITED, published in the last issue of the "Sunday Times," we are requested to state that the reference to Mr. V. GRINDLEY FERRIS as Consulting Engineer of the Company appeared in error, and that his report was made in his private capacity as a Consulting Engineer only.

Old Kimberley Days.

DIAMONDS, BANKERS AND LAWYERS—SOME WELL-KNOWN NAMES.

By W. P. Taylor.

The world has grown hungry; in spots, terribly hungry. In this land of plenty mankind does not realise hunger. Russia and China are the hunger wolf's great hunting ground. There are degrees of suffering, just as there are degrees of temperature. The intense cold of the snow lands lulls the poor hunger-stricken sleeper to an unawakening slumber; but hunger and cold in its deepest degree are unknown here. Yet in this sunshine and plenty there are sufferers; yes, sufferers in their degrees. I could not relate my tale without some pathos. Our family had known poverty ere we reached diamond land. I remember as a very young boy finding my mother terribly nervous and overwrought. She had inflammation in her eyes and could hardly see; but it was not her suffering that agitated her. There was nothing in the house. Father had left early in the day, very worried, and the rent had to be paid that day. He had not returned to lunch, and as it grew late she was afraid. What was she afraid of? She never told me, but I read an awful fear in her face. As I said, she could not see, and I did not see her eyes. I saw her hands move, and I read a message, and without her breathing a word. I said, "I'll find him and bring him safe to you," and then, like a terrier, I was off on my quest. I had a search, and as the hours latened I had a good cry. The dread, the fear, all crowded, and crowded on my little mind. No one had seen him. I need not say how overjoyed I was to find him. How happy he was, whistling his way home, holding my little hand. The rent was paid; mother's eyes got well; poverty was forgotten. Working from hand to mouth, we constantly took chances. Well, chances are taken by degrees as well as poverty is endured that way. We were a happy little group. There was father, mother, five girls, my brother Jim, Rowley the little one, and myself. Then there were the Kafir boys—Shilling, Kleinboy, Springbok, Soldat, Martinus and Engelsman. We took life seriously. It commenced at 5.30, and the day's work ended at dark. We lived under canvas, and dressed in white moleskins and flannel shirts; we had no use for coats. The mine ground was sorted, and we got so accustomed to finding nothing that the poor old guv'ner, who was the banker, kept looking at the fast emptying treasury, and sighed deeper and deeper. As the boys didn't know its condition, they worked confidently, and as my brother and myself hadn't troubled to inquire, we simply worked on, and rose every day with a sure conviction that that day we would find a stone and everything would be all right. How many of us, in those days, were doing the same thing. We got thin on hope, dreadfully thin. The groceries, meat and vegetables were finished, and there was no credit. There were some bags of mealie meal, and we got down to pap, pap, pap. It's only those who have got down to it seriously who know and appreciate what I am writing. There were five girls. We had to keep up our heads. The Kafirs had got to believe we were merry and bright. There was a window, a little window in the canvas side of the frame house. It looked at a dead bush fence. It was a fence without character, or if it ever had a character it had been lost in its deadness. It was a thing without life, an obstruction, and beyond it was the west.

My mother's mother was the wife of a sea captain, as daring a seadog as ever took the sea. He had left her at times with the sails full of wind and darted into the ocean on voyages that lasted months, and then, like Ariadne, she had stood before the lattice searching the sea, and there, at that little window, with the setting sun beyond that rotten dead fence, her daughter stood for hours in silent thought. My mother had a thoughtful face and dark brown eyes. She would wear her silk fichu and cairngorm brooch, and with her basket of work mend for nine. Tired, she would drop her work and look at that dead fence, with the

glinting sun sending her messages through its gables and twisted shapes. Ever and anon her eyes would brighten as some thought flashed by. I have wondered at those thoughts. They were not for me; I never knew them, they never carried a sigh, and yet there were but two bags of mealie meal, six or eight Kafirs, and the family—and she did not sigh.

Down at the mine was a pinched face, sorting in the sand and dust. It was coated with soft, yellow lime, and two dark eyes looked out of their hollows. The boys moved silently at their work. There was no singing. I have often thought that those Kafirs must have thought us awful fools, working for nothing for months. I suppose without religion and belief in a God, no sane being would have gone on as we did; but father prayed, mother prayed, and all the tribe prayed, and everyone of the tribe and their parents felt as certain as we do of the income tax to-day that we would find a diamond and everything would be right ever after. Many a time in those old days did I get into a corner, and always got out of it the same way. God always answered our prayers. I remember on one occasion I found a debris heap. It had every appearance of being good, and I hadn't a cent. There was no one I could go to, and I walked round that debris heap and prayed. At last I went to William Rogers, and he lent me £10, and in a week I found £100 worth of diamonds, but there was the family eating mealie meal, father sighing his heart out, and his wonderful mate as confident as life that he would bring home a stone.

JOHANNESBURG.

And he did. On this occasion it was my brother Jim who found it. The strain at that time was most intense, and our flag was in danger of being pulled down any minute, when the native sifted out a great white diamond, which my brother pounced on and placed in my father's hand. It is near on fifty years ago, but its recollection remains undimmed. It was a happy moment in his young life, and though it is ever so far away, he would not have missed it for untold wealth. "Oh Lord, we thank Thee for Thy bounteous mercies," was the Taylors' prayer. It happened not once, but at other times, and so, working on narrow margins, the pioneers struggled on; it was their very shortness that kept them perpetually busy. That stone fetched £600. It was sold to Messrs. Merriman and Becher, and I believe Mr. R. E. Wallace, father of Stuart Wallace, of this town, was the broker.

Early Financial Experiences.

When I was but 12 my ambitions were about on a par with Cecil Rhodes. I had amassed £100 in buying diamonds, and my safe was a black, tarred, canvas chest that had been one of two on a gun-carriage. They had an iron rail on each side and a strong hasp and staple, for when in action they had carried the black powder for the gun. How they found their way to Kimberley I do not know, but I converted one into my safe, and they both remained the repository of all my worldly possessions for many years. My father was nervous of this constant accumulation of money, and took me to Mr. Sheriff, the then manager of the Cap of Good Hope Bank. I was introduced as a prospective customer, which amused the manager immensely. It was against the rules, as I was too young; but on my father assuming responsibility I was allowed to open an account. I think it was because we had been neighbours at Green Point, near the Cape, and that I was so well known to him, that I was privileged; but all the same, I felt very proud with a cheque book, and it proved a convenience not handling bundles of notes. I banked with them for a great many years. After Mr. Sheriff came Mr. Feltham, and finally, Tommy Ball. Fred St. Leger and Sidney Cowen are the only two that I still see of the old staff. This bank was Cecil Rhodes' mainstay in his dull, dim days, when gloominess nearly overcame his luminous hopes. Let it not be thought that Rhodes' little barque sailed through nothing but smooth water, with full sails and a fair wind. There was a time when Henry Feltham had to come to the rescue—perhaps not only once. There was many a buzzing in his bank parlour. Rhodes always got cash, and with his cash was always a day ahead. I remember when the first De Beers Company was floated there was a big transaction in which Rhodes, Beit, Graham, Stow, Runchman and Dunsmore were guarantors, or rather purchasers, of reserve shares, and when the money became due, De Beers shares had fallen so low that it was impossible to finance. Rhodes, Beit, Graham and Stow financed through. Dunsmore got stuck, and a dear old friend of mine, Joe Deneyx, lent him twelve thousand pounds and pulled him through. (I am sorry to say that when the bank broke and pulled poor old Joe down, Dunsmore did not return the compliment.) Poor Runchman was ruined, and it was indirectly through this

very transaction that Wildegerood committed suicide. So you see, the little barque had to be steered through very troublous waters at times. Ah well, Henry Feltham always retained Rhodes' undying thanks. He became a director of the De Beers and was pensioned for life. A fine handsome man with dark eyes, aquiline nose, and a great soft beard, dark and long, which rested on a white waistcoat. One of the pleasantest of bank managers, he never refused me anything I ever asked him, but I often felt he could refuse advances with the adroit modesty of a lovely young lady who knew how to finish a lover without money. They say, when Mr. Feltham went on pension, they thought it might cost the company five years' pay, and I am glad to say he lived a happy retired life of about thirty good pensions, and this is as it should be, for I honestly believe that he was the man who saved the ship.

Two Genial Lawyers.

Through all our early ups and downs there were two genial lawyers. One was Bob Graham, and the other Selby Coryndon. Now when I say genial, I mean it in its fullest sense, for there never were two more popular men in any town anywhere. Bob lived and died a great, big, loveable thing, and his early death filled many a heart with sorrow. Selby Coryndon was full of character and a sure winner. There were numbers of amusing stories about him. His son is to-day Governor of Uganda. As a native administrator his talent is immense, and his promotion will ever continue. Our Robert Hearle was at Stow's with Henry Russell. Poor old Russell. His father was the great English baritone singer, and he longed to see the world. "If De Beers go to £10," said Fred Stow, "I'll take you round the world." De Beers did go to £10, and Russell was taken, but it was anything but a joy ride. It was a sort of penurious Ford shake about, and the telephone cigar story came back with Russell. Stow smoked the telephone cigar and a down East Yank told him so. One day Mr. Otto swanked into the old Craven Club. He was dressed in immaculate white, with a white helmet and white cow's tail whisk in his hand and a red rose in his button-hole. A handsome man with dark curly hair, cheeks that just showed their redness through his soft, curly beard, and a bright smile for every lady and an ever thankful heart that loved God for his goodness. Just then E. F. Gray met him and said, "I can't think, Otto, how you can sleep at night, owing Litkie £20,000." "Me sleep," said Otto, "oh, I sleep all right; it's Litkie that can't sleep." And so it was.

Barium.

The Imperial Mineral Resources Bureau has issued a booklet on barium. The chief barium minerals are barytes and witherite. The former is the sulphate and the latter the carbonate of barium. Barytes is the more common mineral, and its chief uses are: (1) in a finely ground state as a filler in the manufacture of paint, rubber, linoleum and asbestos goods; (2) as a raw material for the manufacture of barium compounds. *Inter alia*, the work says: Barytes appears to be fairly widely distributed in South Africa, but little reliable information is as yet available regarding the individual occurrences of the mineral. The most important deposits occur in Southern Rhodesia. Since 1918 a large deposit, near Hunter's Road, has been the principal source of supply for the Sienna Paint Company at Durban and two large explosive works in the Union. Another deposit has recently been discovered near Bulawayo (E. 28° 58', S. 20° 2'). In the Union of South Africa, a deposit has been opened up near Riversdale (E. 20° 10', S. 34° 00'), Cape Province, where the barytes is of a pale bluish-white colour and averages 87 per cent. BaSO₄. In the Transvaal, massive barytes occurs in large quantities on the Magalacqueen River (E. 29° 30', S. 23° 15'), 80 miles north-west of Pietersburg, and in the Bushveld to the north-east of Pretoria. It is of a very pure white colour, and apparently well suited for the manufacture of white paints. The chief consumers of the mineral in South Africa are the manufacturers of explosives and paint. The total output for South Africa and Rhodesia up to the present time is only 48 tons.

Early Natal Mining.

A REMINISCENCE.

By James Cumming.

Somewhere about 1886 a young man who, prospecting in Zululand, one day entered the "office" (a grass hut) of the Gold Commissioner (the late Mr. Andrew Muirhead) and asked for a licence for a new discovery he had made—a brass mine! And, right enough, he there and then produced samples of brass he had found.

What he had actually stumbled across was an old Zulu forge, containing scraps of brass—smelted by natives by an admixture of copper and tin ores, and used by them in their manufacture of armlets and leglets. But this young man, in his stupendous ignorance, really thought he had discovered a brass mine.

At about the same time he (the same smart young man) was working a small mine by means of an adit level, on behalf of the late Mr. H— E—, of Natal (and, by the way, the level was as crooked as a maze), and he had a large staff of both whites and natives. He constantly reported in the Natal Press that he was getting good gold values, while on the same line of reef, outside his claims, the quartz was well known to be practically barren. He regularly sent samples to Mr. E— for assay purposes, and the results as published bore out his reports in the newspapers. One ounce, two ounces, three ounces, and more per ton were announced in the *Natal Mercury*, and eventually he acquired a small battery and engaged a man named G— H— to run it.

This man brought his wife and family into Zululand, and received instructions from his "principal" to await his arrival before commencing milling operations. But the "principal" never again materialised on that field, and H— was left stranded and unpaid. But on going through the "stores" at the battery he found two dozen books of gold-leaf and a sugar packet of specimens of quartz, from the honeycomb holes of which it was quite easy to pick out plugs of gold-leaf, when suspicion was aroused.

These "samples," when crushed by pestle and mortar and run through a fine-meshed sieve, gave lovely "tails" of gold, as had those sent to Mr. E—, on panning. Suspicion was first caused by the fact that on one occasion H— panned a sample only roughly crushed and not sieved, with the result that the plug of gold-leaf partly unfolded itself.

The name of that prospector and "owner" of a brass mine and of that "principal" without principle was— well, having regard to the law of libel, knowing that the greater the truth the greater the libel, coupled with the fact that the worthy man still lives, let me content the curiosity of my readers by saying that, as the twig was bent in those long ago days, so does the tree stoop to-day.

Magadi Soda.

The report of the Magadi Soda Company for 1920, issued in mail week, shows a debit balance for the year of £159,327, including £49,342 as provision for depreciation. This makes with the £197,731 brought forward a total debit balance of £357,058. The operations in Kenya have, the report states, continued throughout the present year without material interruption. The directors feel satisfied from the results already obtained from the initial working of the various sections of the plant that the latter is capable of producing soda ash of the finest quality. Shipments of the commodity are being made in increasing quantities, and the reception accorded to them by consumers has been a favourable one. The plant will soon be fully equipped, and the company will then be in the position of producing and marketing largely augmented quantities of soda ash. The directors state that the War Office has definitely refused to recognise the company's claim for compensation for military use of the Magadi Railway and water supply during the War. Dr. W. T. Pauling, owing to absence from England and to pressure of other work, has resigned, and Sir David Yule has joined the board and now offers himself for re-election.

BUYING paint for the protection of metal surfaces from rust and wear is no longer a haphazard experiment. It is an important investment, worthy of serious contemplation.

With the high cost of labour in mind, the "cost per gallon" of paint is not the deciding factor, but how long does the paint last on the job?

DIXON'S Silica-Graphite Paint

has won an enviable reputation for long service with satisfaction in all parts of the world.

GRAPHITE

is not affected by sunlight, heat or cold, acids or alkalis, and it has no equal in withstanding dampness.

SILICA

is equally impervious and is to graphite paint what copper is to gold in a chain or watchcase. It resists wear, and anchors the film. To secure these results, specify

EDITORIAL.

THE REAL VALUE OF GOLD!

Since we wrote a few weeks ago on the gold question, our correspondence columns have testified to the increasing public interest in the matter, and we have printed all sorts of views on the subject from divers sources. It seems to us that as currency and exchange problems have now become the business of world congresses and international conferences, we in South Africa should, in our own interests, best confine ourselves to the study of these questions as they affect us as producers of half the world's annual gold output. If we keep that consideration constantly before us, we can perhaps best judge the value of the multifarious proposals and schemes brought forward by economists, bankers and doctrinaires from time to time. As gold producers, it is plainly our duty to ourselves to make gold an indispensable basis of currency and to support every reasonable proposal that enhances its value and importance in the scheme of things.

Moreover, in the light of the same consideration, it behoves us to oppose every proposal or scheme that aims to make currency independent of gold, or that lessens the importance of the part played by the metal. When, therefore, Prof. Cassel, at the meeting of the International Chambers of Commerce in London recently, declared for a scheme that meant getting currencies back to gold on new ratios of gold to paper, and he was supported by Mr. Samuel Evans, we cordially welcomed the proposal as a simple solution of the currency problem that had the added advantage of fixing a permanent premium on gold to the obvious benefit of our gold mining industry. Since then we have watched for opinions on the point, and, it is most gratifying to note that authoritative and influential opinion in England is coming round to support the proposal. For instance the *Statist* received by this mail, in a long article under the heading "The World's Currency Problem—a Suggested Solution," comes out strongly in support, and nails its colours to the mast on behalf of this solution of the problem. We have quoted freely from the *Statist's* article elsewhere in this issue because it elaborates and explains very clearly the scheme merely sketched by us. Briefly, it will be seen the *Statist* proposes making "the paper currencies of all countries formerly gold using convertible into gold not at the pre-war gold rates, but at the values as measured by the actual exchange rate with the U.S. dollar at the time chosen for taking this step or the average exchange rate over a selected period." That, in other words, is what Mr. Samuel Evans said at the last Crown Mines annual meeting, and what Prof. Cassel said in London and has since repeated in a report made to the League of Nations at Geneva. The latest recruit to the movement is no less than the Chairman of the Federation of British Industries, Sir Peter Rylands. The resolution which the Credits and Currency Committee of the Federation of British Industries, under the presidency of Sir Peter Rylands, sent to the Prime Minister recently, recommending a reconsideration of the report of the Cunliffe Committee—which advised a policy of gradual deflation—is described as re-opening the whole currency question. Sir Peter Rylands, in a covering letter, explains that no criticism of the Cunliffe Committee's report is intended, but declares that conditions have so altered since 1918, when that report was issued, that a reconsideration of the whole matter is imperative. He gives four instances of these changes: (1) The de-control of foreign exchanges; (2) the unwillingness of any other country to incur the loss of a policy of deflation; (3) the continued rise of prices through 1918-19; (4) the already enormous burden of taxation on industry, which would become intolerable if it had to pay back war debts with a pre-war standard of currency.

Sir Peter Rylands suggests that now the Government have had to stop reducing the paper currency note issue, because of trade depression, *the best thing they can do is to fix a new standard of currency by minting sovereigns with a lower standard of gold purity than before the War*, so as to bring them into nearer relation with the currency note, and so stabilise the currency. It is expected that there will be fierce opposition to this idea, and all the old hubbub about risk of provoking spurious coining if we alter the standard; but this is because the standards of anything purely relative and instrumental are always more precious to the departmental mind than the more important standards of national solvency and progress. It is—as one paper puts it—with the economic position as it is with Ireland: people have had so much anxiety, and are having it still, that they are prepared for bold measures and a little risk, rather than for a groovy timidity which condemns the Government to be evasive and the population to despair. No less an authority than the *Spectator* supports Sir Peter Rylands's apparently revolutionary proposal in the following eloquent passage:

"From a theoretic point of view the arguments against deflation seem unanswerable. After all, it does not really matter whether we give few or many tickets for a thing. What does matter is that they should always be of equal exchange value for the same commodity and should be for a

perfectly stable and trustworthy standard against which we can measure the fluctuating values of commodities. The only real harm is done when the value of the currency—the tickets—itsself suddenly changes, and we seem to get all sorts of new values for commodities which have really changed only in price and not in value. We get the sort of result that would be obtained if one tried to measure off cloth with a tape measure which was continually expanding and contracting in length. Hence the essential need in the currency problem is the need for stabilisation, and any measure which necessitates a change in the value of money, even if it is in the direction of deflation, is an unmitigated evil, sure to have the most detrimental effects on trade and industry. Lord Melbourne was wont to declare that it did not matter what the Cabinet said so long as they said the same things. So, with the exchange value of money it does not much matter what it is as long as it is always the same."

Enough has been quoted to show that enlightened public opinion in England is rapidly coming round to the view we expressed as far back as our issue of September 3 last. With some of the great bankers, industrialists and leaders of the Press in favour of the proposal, it is, at any rate, certain to be fully ventilated. For our part, we are satisfied that the suggested solution of the world's currency problem contains in it the solution of the problem of the future of the Rand for the reason that the latter is vitally affected by the scheme to stabilise the price of gold at a substantial premium.

THE WAGES QUESTION AGAIN.

It came as a surprise—almost, indeed, a shock—to the Rand last week-end to learn that the miners' union was seriously considering going back on the wage agreement with the Chamber of Mines of July last, and demanding a reversion to the pre-July wage. The reasons given for this extraordinary decision are not plain, but there seems to be a confused feeling that neither the cost of living nor the gold premium is going down, and that the members of the mine officials' unions have not had their salaries correspondingly reduced. Nothing is said of the deliberate intention to break an agreement solemnly made within a few months of its ratification; and indeed the whole proceeding is so outrageous as to encourage the belief that it is the merest "try on" and not to be taken seriously. If an agreement of this sort only made after months of discussion and debate, is to be treated as "a scrap of paper" at the whim of either party, then the whole system of collective bargaining on the Rand is turned into ridicule. The facts are, of course, that both the cost of living and the gold premium are on the down grade and the pay of all classes of mine employees on the Rand is bound to suffer accordingly. Indeed, ever since the unions expressed their intention of taking another ballot on the matter the gold premium has been falling rapidly, and at 105s. per oz.—the latest quotation available—is perilously near the danger limit for a number of the low-grade mines. From the now historic list prepared last year by the Chamber of Mines, showing the cost of producing an ounce of fine gold, we may quote the following:—

Mine.	Ounces produced	Cost.
	Jan.-Aug., 1920. Ozs.	per ounce Produced. s. d.
Luipaardsvlei	36,466	111 11
New Goch	26,891	109 0
Roodepoort U.M.R.	39,804	109 3
Durban Deep	59,081	106 11
Randtontein Central	290,773	105 11
Aurora West	23,792	105 7
New Primrose	31,118	100 6
Simmer and Jack	101,784	100 3
E.R.P.M.	274,567	99 8

Apropos of these figures, it may be recalled that the Chamber of Mines' representatives pointed out to the

Unemployment Commission that with gold at 105s. per oz., six mines would be unpayable on the July basis of costs. These mines employ 2,457 Europeans and spend £2,250,000 per annum on wages and £1,440,000 in stores. With gold at 95s. the number of unpayable mines would be increased to fourteen, employing 7,295 Europeans and spending £6,053,000 per annum in wages and £3,644,000 in stores, and at the normal price of 85s. no fewer than twenty-eight mines, employing 12,688 Europeans and spending £10,146,000 per annum in wages and £6,471,000 in stores, would be unpayable unless costs were reduced or only ore of a higher grade extracted, which is frequently impracticable if not impossible. It is, of course, true that the causes which would bring about an improvement in the American exchange would also tend to reduce working costs, but any reduction, particularly in rates of wages would take place at a much slower rate than the fall in the price of gold. Since this list was prepared the Knights Deep has closed down, its end being hastened by the burning of the mill; and the Roodepoort United Main Reef is now on the eve of following suit, its directors endeavouring to ensure its gradual closing down in order to save its employees from sudden unemployment. The E.R.P.M., for a reason other than wages, was on the verge of a strike during the week, the men being apparently oblivious of the fact that once closed that property would probably not re-open. Despite all these patent facts, the farce of taking a ballot in regard to reverting to the July wage basis goes gaily on, and it is said that November 5—appropriately enough—is fixed for the return of the voting papers. Exactly what is at the back of this unprecedented manoeuvre we do not profess to know, but the men should know that public opinion is against their action, and in circles outside mining altogether the opinion is strongly held that the mine directors would be justified in declaring a "lock-out" in the face of such conduct. For our part, we can only reiterate that the whole business is too stupid and aimless to be taken seriously, and we hope those responsible for it will recognise the folly of their attitude.

THE GRAIN ELEVATOR CONTRACT.

There has been much discussion lately on the question of the grain elevator contract which has been placed by the Government with an American firm, and although the official statement hints that there is a possibility of the American contractor installing British machines, past experiences have not shown that American firms are exactly keen on putting in British machines. The American tender is said to be between 30 and 40 per cent. lower than the next lowest tender, but there appears to be a marked reluctance on the part of the Railway Administration to publish the actual figures, and we can see no valid reason for this. We understand that a local firm put in quotations for the 34 country elevators, and one would naturally assume that a practical knowledge of local conditions would give them a distinct advantage when tendering, particularly with regard to the constructional work, as admittedly conditions in South Africa, especially in the country territories where these inland elevators are to be erected, are dissimilar from those met with in Australia or America. In addition to this, our information is that the local firm had secured quotations for the machinery section of the contract showing a reduction of 33½ per cent. on the prices quoted by the only other two English firms quoting, and as we understand that the American firm has not received a quotation from this firm, the natural inference, in view of the information given by the Government that English machinery is being installed, is that the successful tenderer is quoting on the higher priced machinery. Therefore, his price, allowing for the constructional work, must be about 60 per cent. lower than that of a firm of experience in this class of work and thoroughly conversant with local conditions. This does not appear to be feasible, and although the Railway authorities may consider themselves amply safeguarded in all respects, we have recollections of similar instances occurring where the body con-

cerned were badly let in. As a case in point, the Cape Town Pier may be mentioned. We can admit the possibility of a strong American firm equipped with a large and efficient plant and using the most modern concentration methods, being able to beat the average contractor by a considerable margin on a large unit such as the Cape Town or Durban terminal elevator, but not in a case where 34 small units are spread over an area of 90,000 square miles, where an expert knowledge of local conditions is imperative. Apart from these points, we doubt if the economic position has been taken sufficiently into account. Money spent in America shows no benefit to South Africa, whereas a contract placed in South Africa with a South African firm ensures the maximum possible of money being retained locally. Surely a firm with its headquarters in South Africa, paying taxes, and employing local labour throughout, should have some preference over a foreign competitor. Further, all customs dues are withdrawn in this particular instance, and the country suffers accordingly. The whole of the material in connection with the reinforced concrete work can be, and is being, produced locally, but if the price submitted by the successful tenderer shows such a considerable difference, then obviously local producers cannot supply at a price to compete. The same remarks apply to the bulk of the structural steel. On more than one occasion recently Mr. Malan, the Minister of Mines and Industries, has lectured the local industrialist on his shortcomings, and the latter naturally feels aggrieved that the Government spokesmen should confine themselves to giving advice that is in the nature of a "counsel of perfection" and ignore their interests when a contract of substantial proportions comes to be given out. Finally, there is the British manufacturers' attitude on the matter. According to the cables, that attitude has been fully ventilated in the London papers during the week. There certainly seems to be cause for complaint when within a few weeks of the Union Government raising five millions in London, a contract for a round million goes to America. More is likely to be heard of this aspect of the matter. In the meanwhile, we would urge upon the Railway Administration the desirability of publishing the actual figures of the contract, and also any other facts that may be pleaded in extenuation of its action.

Notes & News.

Settlement of E.R.P.M. Dispute.

A dispute which nearly culminated in a strike arose last week at the E.R.P.M., due to an engine driver named Lang refusing to become a member of the labour union. The employees on the mine had intimated to the authorities, through their union, that they refused to work with a non-union man, and that work on the property would cease at 4.40 p.m. on Tuesday. Efforts were made between the Chamber of Mines Executive and the S.A.I. Federation to adjust the matter, but no way out of the difficulty was found. The mine management was officially informed by the strike committee that the strike would take practical effect. At the last moment a new development occurred. Lang conveyed verbally his resignation from the E.R.P.M. to the engineer and promised to put it in writing. His resignation was placed in the hands of the strike committee, and this new phase of the situation discussed. After some deliberation the strike was declared off, and work continued as usual.

Commerce in Conference.

The annual congress of Chambers of Commerce, held at Pretoria during the week, produced notable addresses from the Minister of Mines, Mr. Malan, and from the President, Mr. G. A. Fichardt. Mr. Malan gave some sound advice to the assembled business men and reviewed the whole field of commerce and industry, incidentally entering a plea for this newly-constituted Board of Trade and Industries. Mr. Fichardt also covered a multiplicity of subjects in his address, and emphasised the inter-connection of mining, farming and commerce. He ended on an extremely hopeful, not to say optimistic note. There was a general feeling, he remarked, that the bottom had been touched, and he

went on to indicate measures which he deemed necessary for the advancement of the country. He also noted that good roads and plenty of them are required, that railway rates must be so fixed as not to hamper the growth of the various industries, and that a wise taxation policy should be laid down. He also repeated one or two home truths. "If only," he said, "we had less politics and agitation and more solid work in building up commerce, farming, mining and other industries, the country would be better off, and it behoves all to do their utmost to achieve this end. Let us be ready when the time arrives, so that we may take full advantage of the situation and that South Africa may hold the place it should in the world's trade."

The Flotation of Gold Ores.

The success of a metallurgical process of extraction is defined by profits per unit of material treated. Profits depend chiefly on the following factors: Grade of ore treated, grade of tailing or waste, and working costs. Assuming the grade of ore to be constant, then the profits will be determined by the sum of the two remaining factors. If this sum is reduced, then the metallurgist is improving his process of extraction. In present Rand metallurgical practice we find a very low-grade tailing produced with an accompanying cost of treatment. Flotation processes applied to Rand ore have as yet failed to produce such low residues. For the flotation process to be able to compete against standard cyanide practice, it must make up for loss in tailing by reducing working costs to a correspondingly greater extent. The success of the flotation process on Rand free milling ore thus depends entirely on a reduction of working costs. However, when we pass from our free milling Rand ore to the refractory varieties known as antimonial, cupriferos, arsenical, telluride gold ores, etc., then we approach the field of the flotation process. On ores of this description, straightforward amalgamation and cyaniding have in many cases proved to be unsuccessful, and a solution of the difficulties has been found in the flotation process. An example of this nature is found in the Falcon Mine of Rhodesia, where the gold is associated with copper. A metallurgical process which results in an increase in profits, even if only slight, will receive due attention in an industry treating thousands of tons of ore a day. Such a slight increase amounts to a not inconsiderable sum when applied to the total tonnage. Experiments on Rand ores have been conducted by the representatives of Minerals Separation, Limited, at their Flotation Research Laboratory, and the results will be read with great interest by those following the development of flotation. An account of the results appears elsewhere in this issue.

S.A. Mining Year Book.

The 1921-22 edition of the *S.A. Mining Yearbook* has now been issued. The work is in its ninth year of publication and its many valuable features are too well-known to require detailed review. A gratifying increase in circulation has attended each successive issue of this Year Book, and its merits are yearly becoming more widely known and recognised by shareholders in South African companies, resident in this country and overseas. The present edition marks a big advance on former issues in more than one direction. The editor (Mr. S. R. Potter) has again been able to enlist in the work of compilation the fullest cooperation of the Gold Mining Companies, the big Diamond producers, the Colliery Companies and the Banks. The work, therefore, can truly claim to be fully representative of every branch of mining and financial activity in the country, and to enjoy the support of all those responsible for the great industries with which it deals. No annual work of reference produced in South Africa or overseas, concerned with our industries, enjoys these privileges; and the result is that readers and users of the Year Book are assured of the fullest possible measure of accuracy and authority for its contents. The Year Book, which runs to over 250 pages, is bound in cloth with gold lettering. It is beautifully printed and produced by the Argus Co., and may be obtained from the office of this paper, from the Argus London offices, or from any branch of the Central News Agency.

Metal Market Report.

On the Metal Market during the week some disappointment was felt at the fact that the bank rate was not reduced. However, the new loans were remarkably well subscribed, and this money must shortly find its way into industrial channels. Foreign exchanges exerted an unsettling influence.

The copper position is largely dominated by America. In view of the better outlook there it is unlikely that there will be a further serious set-back in the price.

Any attempt to lower the price of tin was restricted. Trade prospects are better, and it is confidently asserted that the price is low enough.

Lead improved on a general demand, the scarcity of the metal for prompt delivery and the indifference of producers.

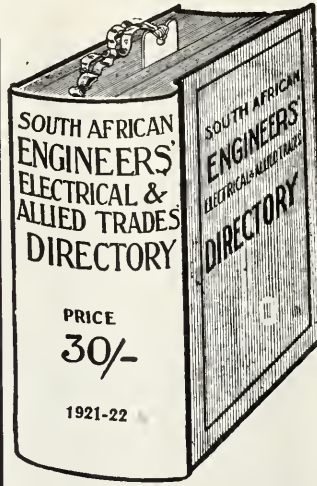

A further advance is anticipated. The spelted market was firm. The demand after slackening improved. Producers abstained from offering here.

The tinplates output is now 60 per cent. of normal. A larger shipment is being made in the East, while home buying is assuming importance.

Silver advanced at 42½d., the chief factor being a demand by China.

Technical Education for Trades.

Last Wednesday night's meeting of the S.A. Institution of Engineers was the occasion for some interesting discussion of Mr. W. J. Horne's paper entitled "Technical Education for Trades." Mr. V. Powers, of the Draughtsmen's Association, discussion was the more notable, and he pointed out the requirements of such an education from the draughtsman's point of view. He went on to discuss the need for the technical training of engineering students, which he thought could also be met by a development of the trades school system. While the sure grounding in technical studies afforded by a "shop" apprenticeship was still essential for the engineering student, it became increasingly difficult to secure this in the ordinary trade workshop, for on the one hand the specialisation of the works or factory no longer admitted of that all-round training which was desirable. Mr. Powers also commented on the lack of interest displayed by craftsmen in their work. Work was no longer done for the satisfaction that accompanied a conscientious expenditure of the best energies of both hand and brain. He thought that the courses described by Mr. Horne had a particular significance as possibly tending to restore this real living joy in work once felt by the craftsmen.

The Week in the Sharemarket.

FALLING GOLD PREMIUM AND LABOUR TROUBLES DEPRESS MARKET—A SLIGHT RECOVERY.

The week opened with the whole market under a cloud owing to the falling gold premium and several distinct labour troubles. Gold dropped sharply to as low as 104s., but seems to have recovered about a shilling since, according to the latest cables. What is going to happen to the premium in the immediate future no one can say, but it is believed that as the prospects of the Disarmament Conference at Washington improve, the effect on the price of gold will be to depress it further. In regard to labour, at the beginning of the week three separate and distinct causes all added their quota to the general unsettlement: the claim of the stationary drivers and firemen to have their wages stabilised until the end of the year, the demand of the Joint Executives that the mining industry should revert to the conditions of July, and that the recent settlement should therefore be swept aside, and, lastly, the more imminent threat of a strike on the East Rand Proprietary Mines because a workman with a conscientious scruple had resigned his membership of a trade union. Fortunately for everybody, the last trouble was settled at the eleventh hour, and there now only remain the two former bones of contention. It is inconceivable that, in the present circumstances, either could lead to a rupture, but the market is in pessimistic mood these days, and all gold shares were marked down in view of the possibility of trouble. The fall in gold premium has rudely shattered the hopes that the price of gold might be stabilised, but it is noteworthy that the overseas press is paying increasing attention to the subject, and the public is being educated up to the need for some such step. Fortunately, as the week wore on, the outlook improved a little. Gold improved a trifle and rather better advices from London caused a slight recovery. This was reflected in the prices on High Change on Thursday morning. Springs were 9d. higher at 38s. 3d. sales, Randfonteins 7½d. at 14s. 6d. sales, Modder Deeps 3d. at 42s. 3d. sales, Modder B 3d. at 25s. 9d. sales, and Anglo-Americans 6d. at 19s. 6d. bid, while Gedulds, State Mines, New Modders, and Van Ryn Deeps all had higher buying bids without business. Bantjes were higher at 6s. sales, Modder Easts had a higher buying quotation, as also had West Springs, etc. Frank Smith Diamonds were steady, Consolidated Diamonds and others, inactive. Nothing was done in tin or industrials, but Witbank Coals were again bought at 37s. The week's quotations are reflected below:—

Concerning Mines and Men.

Mr. Archie Simpson, of the English Electric Co., Ltd., is on a visit to the Rand.

Mr. A. C. Holtby, of the Consolidated Goldfields engineering staff, returned from England this week.

Mr. H. S. Harger, the well-known diamond mining expert, has returned to the Rand after a professional visit to Brazil.

Mr. R. T. Mathison, Chairman of the Union Petroleum Company, Ltd., has resigned from the Board of the company.

Mr. A. F. Mullins, of the Corner House, and Mr. G. H. Beatty, of Randfontein, have returned to the Rand after a six months' visit to England.

Mr. W. Wolstenholme, of Hume Pipes, Ltd., sailed from Capetown for England this week by the intermediate steamer "Gloucester Castle" on a six months' visit.

Dr. Rodgers, Director of the Geological Survey, left Pretoria for the Free State on Monday. Mr. A. L. Hall, the Assistant Director, leaves this week for Brandfort, where an oil indication is reported.

Transvaal Silver and Base Metals Ltd.

Official reports have been cabled to London concerning the commencement of operations on the roasting and first units of the smelting plants of the Transvaal Silvers. The diagrams reproduced hereunder represent: A general plan of the property showing the several lodes, and their relation to the railway at Argent; and a flow sheet of the metallurgical process adopted on the property.

FLOW SHEET No. 1.

The concentration plant has not been completely installed, and operations are being conducted on hand-sorted ore. This passes to the roasting plant, where the excess of sulphur is removed prior to its proceeding to the blast furnace. Addition of the fluxes is also made at this stage, and the ore is smelted in a water-jacketed blast furnace using coke of South African manufacture as fuel. The products of the furnace are: base lead, base bullion, dust and fume, which are retreated, and slag which is dumped.

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to divine any reef lodes of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

NEW PATENTS.

- 862a. George Walter Sharp, P.O. Box 3346, Johannesburg.—Improvements appertaining to the runners of guiding means for skips, cages and other vehicles employed in vertical shafts.
- 862b. Reginald de Robillard, Tongaat Sugar Co., Tongaat, Natal.—Improvements relating to electrolysis.
- 863. William Arthur Caldecott, P.O. Box 668, Johannesburg.—Improvements in tube mills and the like.
- 883. Adam McCracken, Royal Colonial Institute, Northumberland Avenue, London, England.—Improvements in connection with rock drills.
- 890. George Gadda, P.O. Box 41, Potgietersrust, Transvaal.—Reinforced concrete slabs for irrigation furrows.
- 898. Ernest Fraser Jones, Oceana Buildings, Simmonds Street, Johannesburg.—Improvements in fluid control for rock drills.
- 902. 1, David Charles Bowen; 2, John Fairfax Walker, both of P.O. Box 3146, Johannesburg.—Improvements in apparatus for washing ore preparatory to sorting.
- 907. John Herbert Veasey, c/o P.O. Box 7312, Johannesburg.—Improvements in the construction of rock drilling machines.
- 908. Durelec Ltd., Thanet House, Strand, London, W.C.2, England.—Improvements in or relating to reduction of oxides of tungsten and molybdenum.
- 909. James Stephenson, 13 Cranbrook Avenue, Beeston Hill, Leeds, County of York, England.—An improved method of manufacturing railway and like vehicle axles.
- 911. Edwin William Balderson, c/o P.O. Box 3146, Johannesburg.—Improvements in water supplying attachment for hammer drills and the like.
- 917. Samuel Hardman Berryl, V.M.C.A., Market Street, Pretoria.—Water power wheel.
- 919. 1, Joseph Edward Francis Winter; 2, Herman Max Biegel, both of 34a Milligan Street, Perth, Western Australia.—Improved vapouriser for motor engine.
- 920. 1, Andries Johannes van Tonder; 2, Felix Johan Tromp, both of Transvaal University College, Pretoria.—Fuel for internal combustion engines.
- 921. Morris Ellis, Stellenbosch, Cape Province.—Improvements in devices for removing dust and purifying air before inhalation during mining operations, and the like.
- 924. Gerold Francis Dampney, Lynista, Turramurra, near Sydney, New South Wales.—Improvements in concrete slab building constructions.
- 925. 1, Matthew Richard May, William Street, Gawler South; 2, John Albert Blackall Wesley, 37, Alexander Avenue, Rose Park; 3, Henry George Mole, Margaret Street, Walkervilla, All of South Australia.—An improved spring washer nut lock.
- 926. Thomas Greig Ironside, c/o P.O. Box 3146, Johannesburg.—Improvements in the process of distilling oil shales, coal and other carbonaceous materials and in apparatus therefor.
- 927. Harold Wade, 112, Hatton Garden, London, E.C. 1, England.—Improvements in or relating to the treatment of oxidised ores.
- 929. John Wilfred Wickes, Tongaat Sugar Co., Ltd., Tongaat, Natal.—A cane loading or off loading grab.
- 931. Mannes Mannrohren Werke, L-6, Bergenufer, Durseldorf, Germany.—Improvements in tubular masts or poles.
- 932. Robin Seymour Urry, 2073 Brakpan, Transvaal.—Improvements in hand tools.
- 933. William Thomas Hust, 107, Smedley Road, Cheetham, Manchester, County of Lancaster, England.—Improvements in steam separators.
- 939. Otto Tobler, c/o P.O. Box 668, Johannesburg.—Improved process for welding metal.
- 941. John McKay Dixon, c/o P.O. Box 668, Johannesburg.—Improvements in or relating to stamp mills and the like.
- 942. John Herbert Veasey, P.O. Box 7312, Johannesburg.—Improvements in wet rock drilling machines.
- 943. Ernest Fraser Jones, Oceana Buildings, Simmonds Street, Johannesburg.—Improvements in fluid control for rock drills.
- 944. 1, Albert Thomas Harris; 2, Charles Alexander Grant, both c/o P.O. Box 3146, Johannesburg.—Improvements in hose pipe connections and the like.
- 947. 1, Francis John Archibald Courtis; 2, Jules Denis Henri Constantin; 3, Joseph Miller; 4, Albert Rieckhoff, all of P.O. Box 3146, Johannesburg.—An improved device or appliance for use with pans or other similar cooking utensils.
- 949. 1, Walter Penker, 45, Sixth Street; 2, William Henry Hamer, 45, Sixth Street; 3, James Robert Alexander Mills, 51a, Sixth Street, All of Boksburg North.—Haulage dip.
- 960. 1, Neville Charles Thomson Harper, 571, Essenwood Road, Durban; 2, Frederick Lamplough, 25, Victoria Street, Westminster, London, England.—Improvements in or relating to centrifugal filters.
- 955. Thomas Daynes, 31, Categate Street, Norwich, England.—Improvements in or relating to boots or shoes.

Gospel of Safety.

Mr. S. Beaton, manager of the mine, presided at the lecture on "Safety First" delivered by Mr. A. M. Anderson, Ambulance Organiser to the Prevention of Accidents Committee of the Rand Mutual Assurance Co., Ltd., on Tuesday, the 18th inst., in the Recreation Hall at the Nourse Mines. There was a large and appreciative audience which, in view of the inclemency of the weather, was distinctly gratifying. The interest and enthusiasm displayed in "Safety First" on this mine is a fine example as to what can be achieved by the co-operation of all concerned. The lecturer congratulated those present on the fatal accident rate of the mine for the year 1920, which was 1.67 per thousand, and compared favourably with the rate of the Witwatersrand gold mines, which, for the corresponding period, was 2.45 per thousand. This figure, although gratifying, still left room for further improvement, and the lecturer urged his audience to continue to co-operate with the Prevention of Accidents Committee and the management of the mine by conveying the message of "Safety First" to their fellow-workers, in addition to acting upon it themselves. The lecturer then briefly outlined the various causes of accidents, and illustrating each with a series of interesting lantern slides, and referred to striking cases of negligence which had come to his notice, and which had unfortunately cost their victims loss of life or limbs. He also instanced cases where prompt and efficient first-aid had been the means of saving limbs which otherwise would most probably have been lost. He made a special appeal to shift bosses and shop foremen to assist in the movement, as their co-operation was particularly essential. Ladies, he stated, could also help in this campaign, and Mr. Anderson urged those present to take up first-aid and home nursing, as a knowledge of both would be found most useful in the prevention of injuries and illness. Mr. Beaton thanked Mr. Anderson for his interesting lecture, and expressed the hope that what had been said would bear fruit in the further reduction of the mine's accident rate. The lecture was preceded by the "Dust that Kills" cinema film illustrating the various causes of miners' phthisis and the measures employed to counteract them and to ameliorate the condition of sufferers from the disease. This film was recently produced by the African Films, Ltd., at the instance of the Transvaal Chamber of Mines. It is admittedly one of the best mining films ever taken underground and should be of particular benefit to underground workers.

Asbestos.

A rich discovery of fine white silky asbestos associated with pure zeolite has been made on the farm Edendale, a couple of miles from Rayton Station, district Pretoria, by Messrs. J. H. Spohr, E. H. Solomon, and another, of Johannesburg.

Cables: "HOBNAILS."

the stabilisation of the wages of certificated winding engine drivers had been agreed to in February last, the Chamber decided to give those drivers the benefit of that doubt. The representatives of the Chamber who attended the February conference are, however, quite clear that, if any exception was then made in favour of engine drivers, that exception could have applied only to certificated winding engine drivers; and the Chamber cannot agree that there are any sufficient reasons for extending the exception to the other members of the Association and thereby favouring those employees above all the other classes who are now sustaining reductions in pay." The Association communicated to the Press the following resolution, passed at its mass meeting on Sunday: "That the S.A. Industrial Federation be requested to notify the Chamber of Mines that their decision re the stabilisation of wages for stationary drivers and firemen is not acceptable to the members of this Association, and that unless the terms of the agreement verbally made in February last to organised labour under the auspices of the S.A.I.F. are complied with, means will be adopted by the Association to enforce compliance." This resolution will be dealt with by the Executive of the Association as soon as possible. Members are specially asked to observe that nothing has been agreed to between the Chamber of Mines and the Association in connection with the payments made to certificated winding drivers, notwithstanding anything that has appeared in the Press."

SEPTEMBER COMPANY REGISTRATIONS.

The list of companies registered in September is as follows:—

- 6861. Wholesale Distributors, Limited, Winchester House, 87, Main Street, Johannesburg; £5,000.
 - 6862. The Berkeley Rooms, Limited, 148, Jeppe Street, Johannesburg; £2,000.
 - 6863. Universal Stores, Limited, Shop No. 4, Hatfield House, corner Eloff and President Street, Johannesburg; £6,000.
 - 6864. Commercial Industries, Limited, 2-6, Estate Buildings, Fox Street, Johannesburg; £50.
 - 6866. Germiston Dairies, Limited, Provident Buildings, President Street, Johannesburg; £1,000.
 - 6867. Golden Tobacco, Limited, 48a Commissioner Street, Johannesburg; £750.
 - 6868. The Mayfair Land and Investment Company, Limited, 8, Meischke's Buildings, corner Harrison and Market Streets, Johannesburg; £100.
 - 6869. Crouse and Levy, Limited, 61, De Korte Street, Braamfontein, Johannesburg; £6,000.
 - 6870. X.Y.Z., Limited, 213, Permanent Buildings, Harrison Street, Johannesburg; £50.
 - 6873. Matthews & Son and Elswick Garage, Limited, 64, Sivewright Avenue, Doornfontein, Johannesburg; £2,500.
 - 6874. The Silowe Finance Company, Limited, 97a, Commissioner Street, Johannesburg; £25,000.
 - 6875. I. J. Yodaiken & Company, Limited, 29, Sacke's Buildings, 109, Commissioner Street, Johannesburg; £500.
 - 6876. Windram & Fain, Limited, 3-4, Norwich Union Buildings, Fox Street, Johannesburg; £710.
 - 6877. The Globe Furnishing Company, Limited, 85, Delarey Street, Vrededorp, Johannesburg; £6,000.
 - 6878. H. L. Hall & Sons, Limited, Tomango, near Nelspruit, District Barberton; £21,000.
 - 6879. G. H. Winters, Limited, 4, Commercial Exchange Buildings, Main Street, Johannesburg; £3,000.
 - 6880. George Cacaburas, Limited, 35, Bureau Street, Pretoria; £1,500.
 - 6881. Dungor Warehouse, Limited, 65, Delarey Street, Vrededorp, Johannesburg; £5,000.
 - 6882. London House, Limited, 65, Delarey Street, Vrededorp, Johannesburg; £2,000.
 - 6883. The Newlands Brick and Tile Company, Limited, 14, Henwood's Arcade, President Street, Johannesburg; £1,250.
 - 6884. Gilcliff Investment Company, Limited, 57-58, National Mutual Buildings, Rissik Street, Johannesburg; £60,100.
- FOREIGN COMPANIES.
- 6865. Underwriters, Limited, c/o William Thomas Lee, 1-4, B. & T. Buildings, Commissioner Street, Johannesburg.
 - 6871. Ackerman's, Limited, c/o Barnard Joseph Lyons, corner Marshall and Maddison Streets, Jeppe, Johannesburg.
 - 6872. Leenwult Diamond Syndicate, Limited, c/o T. E. Duckles, 119/20, Stock Exchange, Johannesburg.

Letters to the Editor.

THE REAL VALUE OF GOLD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Mr. Lewis Watkins assumes that if the price of "fine" gold were fixed at six guineas per ounce, the Mints would still continue to put more than twenty shillings worth of gold into a sovereign. I think it improbable. That, sir, is my reply to Mr. Lewis Watkins' letter. Now, sir, with your kind permission I would add a few remarks to my letter published in your issue of the 8th instant. We were told by the authorities on finance and political economy that deflation was an infallible remedy for all our commercial ills. Well, sir, the British Treasury has tried it, and look at the position of commerce to-day! We are now told that an infallible remedy lies in the reduction of wages, salaries and the cost of living. Since the days of King Canute, if not before, there have been attempts to put back "the clock of time." This is one of them. Formerly, "the world was governed by monarchs and statesmen," to-day the world is governed by the voters. In the days gone by the saying, "Vox Populi Vox Dei," was very much qualified; to-day it is literally true. The reduction of wages, salaries, and the standard of living is impracticable; then for gracious sake let us try something that is practicable, and make a real attempt to restore normal conditions. The fact that the British currency is ranked among the depreciated currencies is galling to our national pride. The discount on the British paper pound is not a passing phase. Only the revival of industry and commerce can remove the ills from which we are at present suffering. To continue to speak of the increased price of gold as a "premium on gold," and to attempt to reduce wages, salaries, and the standard of living, is travelling on the wrong road. No one at present living will ever see the price of gold back to 84s. 7½d. Does anyone think of asking a manufacturer of lead piping to sell him a ton of his product at £20 per ton when he knows it costs about £30 per ton to produce? Then why expect the gold miner to sell his product below the cost of production? This talk of deflation, reduction of wages and salaries and the cost of living, etc., etc., would be amusing if the consequences of the persistence in such a policy would not be so tragic. The price of gold will remain at a so-called premium. The said premium may vary a few shillings from week to week or month to month, but it has come to stay. Then why not "stabilise" things by definitely fixing an increased "standard" price? I have the honour to be, sir,

Your obedient servant,

G. H. BLENKINSOP.

[This suggestion has all along been supported in our editorial columns.—Editor.]

TRANSVAAL SILVERS.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—We shall be obliged if you will insert in the next issue of your paper a notification to the effect that the following cablegram has been despatched to the London office to-day on behalf of the Transvaal Silver and Base Metals, Ltd.:—"Desulphurising plant working satisfactorily; first unit smelting plant started 13th October."—Yours faithfully,

GENERAL MINING & FINANCE CORPORATION, LTD.,
C. E. FARQUHARSON, Sub-Manager.

WOOD PRESERVERS' SERVICE BUREAU.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir, The Service Bureau of the American Wood Preservers' Association has just been established with headquarters at 1146 Otis Building, Chicago. We are pleased to enclose our announcement, which contains a brief statement of our activities and a list of members. It is our aim

to make the Service Bureau a direct benefit to all users of wood, lumbermen, engineers, architects, farmers, the wood preservation industry, and to everyone interested in the conservation of our forest resources. The cooperation of the *South African Mining and Engineering Journal* is earnestly solicited, and we will appreciate any assistance you can give in bringing our organisation to the attention of the readers of your magazine. If, in return, we can render you any service we shall consider it a pleasure to do so.—Very truly yours,

SERVICE BUREAU,

P. R. HICKS, Secretary-Manager

The objects of the new organisation are explained in the following:—The Service Bureau has been established to promote the use of wood properly treated to resist decay, marine borers, and insect attack, thereby aiding in the conservation of the forest resources of the nation by making one stick of timber do the work of several. Headquarters are maintained which act as a repository for reliable information on the practice of and the results obtained from the art of wood preservation. The value of wood for construction purposes is fairly well understood, but for permanent structures treatment with a standard preservative, such as creosote or zinc chloride, is absolutely necessary. The policy of the Service Bureau is to give the public reliable information on the treatment of timber according to the standards of the American Wood Preservers' Association and the use of treated wood. Publicity will be given to facts relative to treated wood from the standpoint of economy and conservation through the public press, trade and farm papers, and technical journals.

THE REAL VALUE OF GOLD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Referring to Mr. Blenkinsop's delightfully breezy letter in your issue of the 8th inst. on "The Real Value of Gold" (it was so breezy in places that it came perilously near blowing), it is conceivable that voters of like mentality to Mr. Blenkinsop might fix the price of gold at £10 the ounce and prohibit the use of notes, but I doubt whether the country which compelled its mint to give 10 sovereigns containing nearly 2½ ounces of gold for each ounce of bullion, would find in this a very satisfactory solution of the currency problem. 'Tis said that "a little knowledge is a dangerous thing," but absolute ignorance, though it may not be very edifying, would appear to be both innocuous and amusing.—Yours faithfully,

ARTHUR N. LAWS.

Gatooma, 16th October.

PROSPECTING AND THE MESSINA MINE.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—As an old Johannesburger, allow me to thank you for your various articles and letters from correspondents, of late, appearing in your esteemed journal, dealing specially with the decline of genuine prospecting throughout the Transvaal, and also the departure of so many of our pioneer prospectors. These, as pointed out, are not being replaced by the coming generation, and it certainly seems to me, Mr. Editor, that our big mining houses are now entirely resting on their oars in the shape of being quite satisfied with their present production of gold, ignoring to a large extent the importance of new districts, which can only be opened up through the assistance of the genuine prospector. Unfortunately from our Government we cannot expect much help in this direction, their sympathies leaning more towards agriculture, forgetting seemingly that successful mining is the forerunner of agricultural success in South Africa, as well as many other countries. Now, sir, I have just returned from the Northern Transvaal, Messina, having spent over a month wandering around between the Sand and Limpopo Rivers and was much interested in one of your correspondent's letters of last week, from Mr. J. Huitt, speaking of

the possibilities of that district, etc., waiting for development up there. What struck me very forcibly, Mr. Editor, was this: a fine railway built to the Messina copper mine, a rich proposition reputed to have over 3 million tons of copper ore developed, going average 8 per cent. copper, with Vogelsang and Artonville adjoining, which have opened out fine copper lodes, a reasonable Government who has given the Messina Company relief in the way of rebate, on the loss incurred in running the railway. Now, sir, I found the mines practically closed down, soup being dealt out to children in the district, and the few remaining miners keeping themselves going by shooting an occasional buck. I found several small mining syndicates holding ground on the Messina copper belt, who have put in a lot of useful work, with certainly good results, but all complained (rightly, too, I think), whilst the Messina Mines remain closed, our propositions are being killed after (they say with some truth) we have given the copper company an enormous rebate from loss on railway running. Now, sir, my contention is, seeing the Government has helped the company, we, the public, should surely have the right to say either work or allow us (the Government) to work the mine, in these hard times of unemployment, and thus push along a district which I can assure you, Mr. Editor, only wants confidence and capital to open up and give us markets for our labour, commerce and enterprise. Mayhap this will take the eye of some of your correspondents, who, I hope, will take this subject up to our mutual advantage. Thanking you for your courtesy, Mr. Editor, allow me to remain, yours truly,

" LIMPOPO. "

THE GRAIN ELEVATOR CONTRACT.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—An announcement appeared in the *Rand Daily Mail* of the 15th October to the effect that the contract for the S.A. Grain Elevators had been let to a Mr. Menkins, a gentleman of considerable experience and Canadian interests.

Inquiries disclose that Mr. W. A. Menkins is a contractor of purely American interests, whose head office is 321, Broadway, New York. He appears to be backed by another American firm, namely, the American Trading Co., also of Broadway, New York.

In view of the large sum of public money involved, over one and a half million sterling, it would seem that the public, a very large section of which is interested, are entitled to know the following:—

- (1) The amount of Mr. Menkin's tender.
- (2) By what amount was Mr. Menkin's tender lower than the lowest British or South African tender.
- (3) What guarantees the Government have that British machinery will be used and local industries supported.
- (4) Is the money for the scheme to come out of the loan recently raised in London (all good English money) by General Smuts.

Inquiries among local engineering firms elicit the fact that there is an element of mystery surrounding the whole affair. Why should this be?—Yours, etc.,

" ENGINEER. "

[The matter is dealt with in our leading columns.—Ed.]

Transvaal and Rhodesian Estates.

The profit of Transvaal and Rhodesian Estates for 1920 was £22,403. Total outstanding to credit of profit and loss is £86,520, which it is proposed to carry forward. Further reductions have been made in administrative expenses both in London and Rhodesia. Tons milled at Fred Mine totalled 18,950. Yield per ton, 14.75 dwt. Cost per ton, including development redemption, 52s. Cost per ounce produced, 64.55s. Total working profit (before providing for depreciation), £29,324. Ore reserves, 48,350 tons; assay value,

16.2 dwt. Total ounces in reserves, 39,163. Recoverable gold in reserves (90 per cent. extraction and gold at 85s.), £149,795. All figures indicating values are calculated at standard price of gold. The board is advised that there is every likelihood that ore reserve position will be maintained in ensuing year as at end of 1919. The company's interest in chrome and asbestos is represented by shares and debentures in Rhodesia Base Metals. Progress on Nigerian interests has been interrupted and slow. Total of 40 tons of tin were won from Zari properties, but in view of price of tin it was decided temporarily to close down operations. On silver lead properties, in which the company owns 30 per cent. interest, work has proceeded during the year. Large bodies of heavily mineralised ore have been disclosed and partly opened up. Since close of year the company acquired an interest in the farm Maraisdrift, situate in the Heidelberg district. Part of purchase consideration has been satisfied by allotment of 100,000 shares of 3s. each.

* * *

The Power Controversy.

The power question has been the subject of much discussion at recent election meetings. Various candidates have put forward schemes of action and suggestions, but on the whole there appears to be a lack of knowledge concerning the true facts of the case. The position is as follows: The municipal power station is unable to meet the demand for power placed upon it, and the question has arisen of the advisability or otherwise of obtaining extra power from the Victoria Falls Power Company. On what terms such extra power could be purchased from the V.F.P. is unknown to the public, as the Council has refused to make any inquiries into the matter, but a recent letter, by Mr. Bernard Price, of the V.F.P., appearing in the press stated that power could be obtained from that source at less expenditure of time and money than was possible by any other alternative. The cost of connecting up with the V.F.P. has been given by Mr. W. M. Taylor as £5,000, citing Mr. Sankey as his authority. In opposition, Mr. J. A. Clark, however, states that if extra power were available, its distribution would not be possible with the present state of overload under which the present distributing system is labouring. This is so, but by making suitable arrangements with the Power Company it is possible to relieve the overloaded feeders at the necessary points. It is a technical difficulty which is not beyond the scope of electrical engineers to settle. Fortunately, those portions of the town which consume the greater portion of the power lie in the vicinity of the V.F.P. distribution system, a fact which further facilitates the obtaining of extra power from that source. It has been stated that if consumers were dependent on private companies for their power, they would be totally at the mercy of such companies. This is not the case, as such companies will be bound by contract with the Municipality to supply power according to definite decrees. Further, the interests of the public are safeguarded by the terms of the licence granted that company under an Act of Parliament. The fact that the price at which the Power Company has been providing power has not changed for the last ten years of change in all other commodities clearly shows that the interests of the public will in no way be endangered by fluctuations in price.

Gold Premium in Rhodesia.

The Acting Secretary for Mines and Works, Salisbury, has received, the Rhodesia Chamber of Mines notifies, the following cablegram dated the 12th inst. from the B.S.A. Company's London office:—" Rothschild and Sons to-day distributed £1 7s. 3½d. per fine ounce profit on gold realised quarter ended 30th September." For the period from July 25 to December 31, 1919, the profit was 17s. per fine ounce. The gold premium paid for the quarters succeeding December 31, 1919, are as follows:—January 1 to March 31, 1920, £1 9s. 8½; April 1 to June 30, 1920, £1 0s. 9d.; July 1 to September 30, £1 7s. 1d.; October 1 to December 31, £1 13s. 5½d. (the highest figure); January 1 to March 31, 1921, £1 2s. 5d.; April 1 to June 30, £1 0s. 11d.; July 1 to September 30, £1 7s. 3½d.

ENGINEERING SECTION.

The Howick Falls Hydro-Electric Power Plant.—II

By H. W. Miller.*

From this anchored band the horizontal branch pipe passes alongside of and parallel to the power house, there being two branches, each 10 inches diameter, for the two units installed, and the end of the pipe is blanked, but a third connection is provided for a further unit. A 4-inch diameter blow down outlet is provided at the bottom of the branch pipe for emptying the main if necessary at any time. Two other main anchorages are provided for the other two pipe sections, each adjacent to the expansion pieces, and the pipe is carried at regular intervals by massive concrete saddle supports, well anchored by steps into the steep hill side, to prevent any creep of the pipe line down the hill. It was decided to maintain this pipe in a straight line, although it would doubtless have reduced the amount of work entailed if it had been permitted to follow the sinuous course of the ground. A considerable amount of excavation was therefore necessary, as for a comparatively short distance only is the pipe line above the ground. In order to reduce this excavation as much as possible, it was decided to rivet the pipes by means of pneumatic riveters, and this course was adopted, although, provided that good access can be obtained to the pipes below them, hand riveting is the least troublesome method for work of this class and the least expensive. I must pay a tribute, however, to the excellent work performed by the pneumatic riveting tools, that turned out a very fine job.

The upper section of the pipe line, which was 34 inches diameter, was made of $\frac{3}{4}$ inch thick mild steel plates in sections 14 $\frac{1}{2}$ feet long, each section being formed of three plates, the joints being crossed out to form inserted joints where the ends came together. The second section was made of plates 5-16 inch thick and of similar construction, and the lower section was made of plates 7-16 inch thick, each length being made of one plate, double riveted in the longitudinal seams and being made alternatively telescopic male and female joints. The pipes were all single rivetted at the circumferential joints. They were all coated with Dr. Angus Smith's solution. Considerable difficulty was experienced in assembling these pipes, owing to the careless way in which they had been manufactured, for they had certainly not been "tried out" in the works in the careful manner that should have been adopted. The way this difficulty was overcome, I have embodied in a small contribution to the items of practical experience, which I think will prove of some interest to the members. In spite, however, of the difficulties mentioned, the men made a magnificent job of this pipe line, which stands as a monument to efficient workmanship.

The power house is a substantial stone building in random rubble masonry, measuring 60 feet long by 27 feet wide and about 15 feet high to the eaves. The roof trusses are of massive steel construction, specially designed to take the

weights of the largest pieces of the plant to be installed in the house. The light steel angle purlins support the corrugated asbestos roof covering, which helps to keep the power house cool in the hot weather, which is very much in evidence in that part of the world. Ventilators are also provided in the gable walls, as well as in the ridge of the roof.

The power house is made large enough to accommodate three units, of which two have been installed and are now at work. Each unit consists of an impulse turbine, more familiarly known as Pelton wheels, directly connected to an electric generator. Each wheel develops 175 horse power at a speed of 500 revs. per minute, the generating dynamo having an output of 120 kilowatts. The generators are three-phase alternating current machines, made by the Westinghouse Company, wound for 500 volts at 50 cycles, and have their exciting machines directly connected on the same spindles. The generating dynamos are connected to the turbines by means of flexible couplings of the Zoidel-Voith type. To ensure an even torque under irregular loads, there is a cast steel fly-wheel, 5 ft. 3 in. diameter, fitted to each turbine, the wheel spindles being carried in three bearings, there being one bearing support on each side of the fly wheel. The revolving parts are carefully balanced. The turbines are mounted over an arched tunnel, into which the tail water is discharged, and through which it runs away to the river after it has passed through the wheels. The turbines, out-board bearings and generating dynamos are anchored to massive concrete foundations of the most substantial character, and in the event of a run-away speed of even double the number of normal revolutions, there would be no risk of any movement of the plant of a dangerous nature.

Each machine is connected to the main switchboard, which is fixed at the end of the power station and takes the width of the building to accommodate it. There are four panels, two being the receiving panels from the machines and two being the outgoing panels. Each machine has its own independent three-core cable to the switchboard room at the factory, where the current is distributed to the different buildings containing the motors that derive their driving force from it. Space is left on the frame work of the switchboard for the additional panels for the third unit when it is installed. The whole board is of handsome design and pleasing appearance and, with its instruments, is an ornament to the power station.

The running of the wheels is controlled by oil pressure governors made by James Gordon, who is also the designer and builder of the impulse turbines. The governors are of exceedingly sensitive action and control the plant within a very small percentage of speed variation, which is an essential feature in a plant so liable to speed fluctuations as rubber machinery. These governors are sufficiently sensitive that with an alteration in load of 45 to 50 per cent, there is no appreciable variation in the speed. They are capable of being synchronised with alternators operated in parallel, being fitted with a special device for this purpose.

* From a Paper read before the S.A.I. of E.

(To be continued.)

Table Bay Harbour Improvements.

The committee appointed by the Minister of Railways to inquire into and report upon the immediate requirements of Table Bay Harbour and general scheme of dock extension and developments for the future, has issued its report recommending an estimated outlay of three and three-quarter millions on immediate requirements. The report states that in the unanimous opinion of the witnesses and the committee itself, immediate improvements are required, such as the widening of the South Arm to permit of new cargo sheds and the minimum of four cranes. The committee is unanimously of opinion that in the event of a heavy crane being ordered it should be a 50-ton non-propelling floating crane, costing £100,000, in preference to a short travelling crane, but Captain Mathie is unable to agree with the other members that a heavy lift crane is necessary. The committee, with the exception of Captain Mathie, hold that such a crane would obviate the necessity of three 15-ton cranes which otherwise would have to be ordered. Dealing with coaling facilities, the report states that the capacity is 360,000 tons per annum, of which 83 per cent. is dealt with from the shore and 17 per cent. from the water side. After outlining means for expediting the handling of coal, such as adequate craning facilities at all deep water berths, the report says that greater use should be made of the water side, as it would help to relieve the congestion on the railway in the dock area. The committee is in favour of pooling and grading of coal, fixing, as the minimum quantity of coal which should be available, 50,000 tons. In considering the provision of coaling facilities, regard should also be had to the question of increasing the use of oil-fuel, and the report mentions the necessity of low coal prices, as coal will have to compete with oil-fuel.

Bunker Coal.

Dealing with ocean routes and their direct bearing on the route followed, which the cost of bunkers at Capetown, has, the report says "on the relative importance of the English coal prices; it is not necessary to make any further remark than that outward-bound vessels to Australia are at present bunkering in the United Kingdom for the voyage through to Australia without replenishing at Capetown. After full consideration, both from the material and engineering standpoints, the committee states that the breakwater should be extended in its present alignment. As regards the important question of cold storage accommodation, the committee says the necessity for providing additional cold storage accommodation to deal with the

anticipated increased citrus export trade will require careful consideration after the Citrus Exchange (formed as a result of the recent Conference at Johannesburg), has become established. In the meantime the committee has no hesitation in recommending that the Government extend the present accommodation to its fullest capacity of 2,000 tons. Another point touched on was the new graving dock, the committee recommending that provision should be made in any future dock expansion for a large dry dock. Under the heading of the amenities of Table Bay, the report states that it should be recognised that the amenities of the town should be subordinate to any scheme of development. The time has undoubtedly arrived when Capetown should regard itself as a business and trade centre as well as a pleasure resort for visitors. In conclusion, the report outlines four future schemes referred to as Northern, Eastern, Southern, and modified Southern. The Northern scheme providing for 6,000 feet breakwater from Mouille Point and extension in the deep-water area, is not approved of, mainly owing to the expense. The modified Southern scheme provides for extension on the Bay side of the Docks and includes widening the South Arm extension of the breakwater to 1,500 feet and the construction of a mole, possibly from the end of the promenade pier, at a total estimated cost of £3,479,500. The breakwater would take 10 years to construct and the other works six years, so that for the first six years Parliament would require to vote £536,000 per annum, and the remaining four years £65,000 per annum.

Subject to reservations to Captain Mathie, who inclines towards the Eastern scheme, the committee is of opinion that the modified Southern scheme and the Southern scheme would be most suitable. The combined cost would be £6,205,500. In conclusion, the report says the modified Southern scheme will meet the needs of Capetown for any years to come and its adoption will harmonise with any development in an easterly or southerly direction.

SITUATION WANTED—TYPIST.

Experienced and Competent Shorthand Writer and Typist (lady) seeks satisfactory position. Recently employed on a Government Commission.

High Speed Steel.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Steel Makers, Sheffield.

High-speed steel, or tungsten steels as they are sometimes called, are manufactured in the crucible or the electric furnace. The evolution of this steel is very ably described in the official handbook of the Sheffield and Rotherham Chambers of Commerce from information given by Professor J. O. Arnold, D.Met., F.R.S., who was for many years Professor in Metallurgy at the Sheffield University: "In 1740 the standard turning tool in iron and carbon steel contained, as to-day, about 1.25 per cent. carbon. When hardened its efficiency, say in turning was limited by the fact that its cutting strength was thermally unstable and the nose of the tool became soft and broke down with the heat caused by friction of cutting. In 1868, however, Robert F. Mushet, whose inventive genius was always at work, found that tungsten so fortified the hardness of plain carbon steel that the breaking-down temperature was considerably raised, and later he still further fortified the thermal stability of the carbon hardness with relatively small quantities of chromium. At the time spoken of that achievement was the last word in hard steel, but at the Paris Exhibition in 1900 there was displayed a new type excelling it in strength and hardness. It came from America. Realising at once the potentialities of the exhibit, and that if it were allowed a chance its popularity would affect the sales of their own steel, Sheffield and Rotherham manufacturers concentrated on improvements and began that series of experiments which eventually gave to the world modern high-speed steel, a material which has undoubtedly revolutionised engineering output. The main features of this development from Mushet's original steel are: much lower carbon, much higher tungsten and chromium, and the virtual abolition of silicon and manganese. Even with this remarkable progress experimenting did not cease, research work carried on in the manufacturing laboratories of Sheffield University proving the advantage of vanadium as a fortifying element. The net result of these collective Sheffield experiments between, say, 1900 and 1910 was to produce a turning alloy with a thermal stability up to 650 degrees Centigrade—a distinct red, or, in other words, an advance of 400 degrees Centigrade over the plain carbon steel of 1740. In every kind of turning operation the superiority of the latest steel is obvious. It is not too much to say that by the use of high-speed steel in tools engineering output has been doubled. As previously stated, its introduction entirely revolutionised the trend of engineering possibilities, for the new steel was so hard that many of the machines in which the previous steel was used could not stand the strain—the tail, as it were, was too strong for the dog—and had to be replaced by machines of heavier design. With high-speed cutters the old machines used to tremble and vibrate."

The chemical composition, as will be seen from the above, of high-speed steel, in addition to the standard ingredients of carbon tool steel, such as carbon, silicon, sulphur, phosphorus and manganese, we have tungsten, chromium and vanadium, and in some cases cobalt or molybdenum. The following analysis table gives details of the high-speed steels in general use:—Carbon, 0.50 to 0.65 per cent.; manganese, 0.30 per cent.; phosphorus, under 0.02 per cent.; sulphur, under 0.02 per cent.; silicon, 0.15 to 0.30 per cent.; tungsten, 14 to 22 per cent.; chromium, 2 to 4.5 per cent.; vanadium, 0.25 to 0.75 per cent.; and cobalt, 2 per cent.

The low sulphur and phosphorus contents are not possible in steels made in the crucible, but in the electric furnace this can be guaranteed. Tungsten steels with a fairly high carbon content are very retentive of magnetism, and an alloy with 5 per cent. tungsten, 0.65 per cent. carbon and 0.55 per cent. manganese is very suitable for the manufacture of magnets in electric meters. Low carbon tungsten steels do not possess this magnetic retentiveness.

Heat Treatment of High-speed Steel.

Forging.—Do not heat above 1,000 degrees Centigrade, and do not continue forging below 880 degrees Centigrade. If forging is continued below this temperature strains will be set up. After forging, cool slowly and grind the tool to the desired shape.

Hardening.—In turning, slotting and planing tools, etc., the point only should be uniformly heated to a red heat, and then quickly to a dazzling white (1,300 degrees Centigrade). Cool in either oil or air. Milling cutters, dies and drills should not be heated above a yellow colour, and should then be cooled in oil.

Tempering.—For drills for use on mild steel temper to a straw colour, and leave untempered for work on cast-iron.

Grinding.—Wet with a good supply of water to keep the tool from getting hot. Only use water when grinding with a sandstone. When using a carborundum or emery wheel no water must be used. When the steel is in the hardened state always grind without undue pressure, so as not to produce heat which, would draw the temper.

A very interesting experiment can be made in the workshop, and at the same time a very useful test learned. Take a piece of high-speed steel, a piece of high carbon steel, such as an old file, and a piece of mild steel, and by holding them against a dry emery wheel the sparks given off each sample will be entirely different. By this method steel can easily be tested, and, in the event of a mix-up in the works, easily detected and separated.

Owing to a printer's error in our last issue we repeat the following corrected paragraph from Mr. Bethell's article:

Case Hardening.—For plain carbon steels the actual process is as follows: Pack the articles to be case-hardened in an iron box into which a case-hardening compound has been placed, and close carefully with fireclay to make airtight. Heat up uniformly to 900 to 950 degrees Centigrade, and keep at that temperature for a pre-determined period, this period to depend upon the depth of case required. The object of this treatment is to add carbon to the steel. Cool the articles either in air or quench out in oil or water. If the articles were quenched out and fractured to see the grain of the steel they would appear very crystalline and give obvious proof that the steel had been overheated. Therefore to refine the steel heat up to 870 degrees Centigrade, and quench in oil or water. This process refines and toughens the core. Reheat to 750 degrees Centigrade, and quench in water. The object of this last treatment is to refine and harden the case.

British Engineering Standards Association.

SOUTH AFRICAN BRANCH.

The hon. secretary writes:—Enclosed is a copy of the British standard electrical pressures for new systems and installations, which has been published by the British Engineering Standards Association. These standards, after full discussion by the electrical section of the South African branch of the association, have been recommended for adoption in South Africa. In addition to the standardising of electrical pressures, the frequency of 50 cycles per second for all alternating current systems has been recommended. A list of members of the Sectional Electrical Committee of the South African branch is attached, together with a list of the members of the main committee. The association is desirous that recommendation of the above standards should be made known as widely as possible:—Definitions: (1) The term "consumer's pressure" denotes the pressure at the consumer's "terminals" declared by the supplier. (Note.—This definition corresponds with that of the term "declared pressure" in the Electric Lighting Acts.) (2) The term "station pressure" denotes the normal pressure applied to the terminals of the transmission line at the generating station or sub-station. (3) The term "delivered pressure" denotes the normal pressure at the terminals of the transmission line at the delivery end. Specification: (a) Direct current systems and installations: (4) The standard pressures for new systems and installations shall be as follows: Consumer's pressure (declared) 220 volts, station pressure 242 volts; consumer's pressure (declared) 440 volts, station pressure 484 volts. (b) Alternating current (three-phase) systems and installations: The standard pressures

for new systems and installations shall be as follows: Consumer's pressure (declared) between neutral wire and each of the principal conductors 240 volts, station pressure 264 volts; consumer's pressure (declared) between phases 416 volts, station pressure 457 volts. (5) The standard extra high pressures for new systems and installations shall be as follows: Delivered pressure (declared) 3,000 volts, station pressure 3,300 volts; delivered pressure (declared) 6,000 volts, station pressure 6,600 volts; delivered pressure (declared) 10,000 volts, station pressure 11,000 volts; delivered pressure (declared) 30,000 volts, station pressure 33,000 volts; delivered pressure (declared) 60,000 volts, station pressure 66,000 volts; delivered pressure (declared) 100,000 volts, station pressure 110,000 volts; delivered pressure (declared) 120,000 volts, station pressure 132,000 volts. The consumer's or declared pressure in the above clauses shall be the pressure denoted as standards, the station pressure being derived by the addition thereto of the pressure lost in the line when carrying its full load; unless otherwise specified this loss shall be assumed to be such as to give the station pressures shown above. If a higher station pressure than one of the values given above be required, the purchaser shall state such pressure with any inquiry or order for electrical machinery or material.

Compressed-Air Miner's Pick.

A recent number of a German mining periodical shows an air-operated handpick for miners. The tool is shaped like the ordinary handpick, except it has one tine only, and this a very pointed and straight one, the intention apparently being that the point will work its way by percussive action into coal or rock. The device should be very useful in confined spaces where swinging of the pick is difficult or ineffective. The air enters from the end of the wooden handle and passes upwards through the handle to the head of the pick. The instrument has the formidable name of "Pressluftspitzhacke."

An Important Invention.

Mr. E. J. Way, consulting engineer to the New Kleinfontein Company, has invented a machine obviating the rewinding of bioscope films, and thus minimising wear. It is claimed that one film has been projected 3,800 times and remains in perfect condition. The usual vertical reel is replaced by a horizontal table, the projector being fed from the centre of the disc. The film is pushed out with a rotary motion, eliminating tension and avoiding manual rewinding. The film is ready again for projection within a minute, thus reducing the necessity for extra copies. The Cinematographers' Union has testified to the simplicity of operation of the new device. A company has been formed, styled Bioscope Improvements, Ltd., with a nominal capital of £180,000, the working capital of £30,000 having been subscribed privately.

Wire Rope Research.

The engineering experiment station of the Ohio State University desires to collect data—reports of tests and the like—on the strength of wire-rope fastenings, with the object of eventually publishing a bulletin and preparatory to recommending paragraphs on this subject for the safety code of the State of Ohio. Professor W. T. Magruder is in charge of the investigation, and is desirous of making some check tests. He purposes using $\frac{1}{2}$ in. 6 by 19 plough steel wire rope as being a much-used size of typical rope. Some of the questions that have arisen are these: What are the relative strengths of wire rope loops, or eyes, made up with clips and clamps, and of wire rope with sockets of various kinds and constructions, as compared with the rope itself, either when spliced or tested over sheaves? Sockets are usually considered to be a permanent fastening, but when should clips be used rather than clamps? How many fastenings should be used on each loop, or eye? How should they be applied? How tightly should they be drawn up? What effect has the size of the thimble on the strength of the rope?

The Electrification of Railways.

It will be recalled that in the Interim Report of the Electrification of Railways Advisory Committee, issued in 1920, there are two points which have given rise to much comment, namely, the advocacy of a standard system, which shall be direct current at 1,500 volts, and the recommendation that the energy should be generated in the form of three-phase alternating current at the frequency which is in general use in the district. In connection with this general question *The Engineer* has approached Mr. Geo. Gibbs, the great American authority on this subject, and has invited him to express his views. Mr. Gibbs is acquainted with the general conditions surrounding the operation of British railways, having resided in England some years ago for about a year's time, as chief engineer of the British and Continental Westinghouse Companies; he has also spent a portion of his time for the last twenty-five years in England each year, with the exception of those covered by the War; he

Per contra, I am in favour of certain exclusions and the fixing of certain general requirements of any permitted traction system; thus:—

(1) I recommend standardising the location and clearances of third rail and overhead working conductors.

Standards for these have been established for American railways by the American Railway Association. The figures will, of course, differ for British railways. Standardisation of this kind will permit the continued development of both the alternating current and direct-current system of traction and will ensure interchangeability of running requirements between roads using the same character of traction system.

(2) Standardising suitable and safe limits for voltages in each of the two types of working conductors. These should be as follows:—

An Example of Successful Railway Electrification from America.

was, in part, responsible for the plans adopted in the electrification of the Metropolitan District Railway in London and of the Mersey Railway between Liverpool and Birkenhead; and finally, as chief engineer in charge of design and construction, he has been responsible for all the electrification carried out by the Pennsylvania Railroad and its subsidiary companies.

Mr. Gibbs' Statement: Standardisation.

I.—System.—I am not of opinion that at the present time one system of traction at a suitable pressure should be applied as a standard to meet all requirements of railway traffic in Great Britain. Admitting the advantages of standardisation in general, yet I believe the establishment of any one system of electrification as standard for British railways would be a mistake at the present time, because:—

(1) It is too early in the state of the art to determine and fix the features of any system to the extent required for the purposes of complete standardisation, and yet not restrict the future and desirable development of the system selected.

(2) There do not exist sufficient and comparable operating data from which to conclude as to the relative advantages and disadvantages for the future of the two radically different systems most prominently before the railways today, *i.e.*, the "direct current" and the "alternating current." Both systems are workable and in use; each has its advocate in important manufacturing interests, and able professional men differ as to which system should prevail. This competition of diverse minds in the development of these different systems is an important factor in ensuring the future determination of the best system; it should not be discouraged by the premature exclusion of either system from trial in the present development period.

(3) Neither system, as now developed and applied to a typical general case, differs greatly in first, operating, and upkeep costs; therefore railways will not be greatly penalised, except by hampering interchange, by being allowed to work out for the time being the full possibilities of the different systems.

(a) *Third Rail.*—600 volts (nominal) direct current is recommended. A higher voltage than the above is, in my opinion, inadvisable for general railway usage, because employees or others who have access to the right of way cannot be effectively safeguarded from accidental contact with it. Contact with voltages of 1200 to 1500 is generally fatal to human life.

(b) *Overhead Conductors.*—The recommended voltage is 11,000 for the alternating-current system and 3000 for the direct current.

In the case of the alternating-current system the maximum is determined by the practical limit in maintaining insulation; 11,000 volts (nominal) is below this point, but experience indicates it is high enough for the heaviest kind of traction and is suitable for any class. A collector system carrying it can be installed and maintained properly and economically within close permanent way and rolling equipment clearances. It should be noted, however, that in an overhead wire system such as the three-phase, which requires two contact wires, insulated from each other and from earth, and two current collectors of different polarity, the practical voltage limit is considerably lower than 11,000.

In case of a direct-current system maximum voltage is limited by other considerations than that of insulation of the working conductor. The demands of economy in distribution and the problem of successful collection of current for heavy trains suggest the highest possible voltage; on the other hand, the limitations in respect of its utilisation in the train control and motors point to the desirability of low working voltage. For the general case I am of the opinion that 3000 volts is the minimum requirement from the standpoint of economy and successful current collection, and is the present maximum allowable for the other considerations.

II.—Frequency.—(a) Current frequency should be standardised for traction systems in accordance with the requirements of such purpose and not by a compromise with the conflicting requirements of another service.

(b) A frequency of 25 cycles per second is the best for both systems of traction recommended for trial, and should, therefore, be made the standard for traction generating plants.

III.—Generation.—High-pressure three-phase generation is suitable for both alternating-current and direct-current traction systems, and may be made standard.

The voltage at the generating plant may properly depend upon the local situation; it is quite immaterial for standardisation purposes what this actually is, as the voltage is transformed for secondary distribution, and various primary voltages may be utilised in the traction installation of one railway.

A consideration of "frequency" is highly important and no standard should be proposed which will exclude, materially complicate, or hamper the development of either of the two systems suggested.

One of the features making for simplification in the single-phase alternating-current system is that current from the generating plant is used in the working conductors without change, except, if desirable, by altering the voltage in a transformer. It is essential, however, that the "frequency" employed in the working conductors shall not exceed 25 cycles per second. If a higher generating frequency than the above is standardised it would complicate the alternating-current system; thus to utilise 50 cycles it would be necessary either to employ "frequency changers" or to install in the central station separate 25-cycle generators for railway purposes. The latter plan is employed to some extent in America, and it is found practicable for electric supply companies to install in the same station high-frequency generators for commercial purposes and 25-cycle generators for railway work and provide one or two large motor units for interchange of power between the two parts of the station.

With the direct-current system which employs alternating-current generation and transformation and conversion

in sub-stations any desired frequency from 25 to 50 (or more) cycles may be used. Twenty-five cycles is, however, not only a suitable standard for the direct current, but is from some considerations better than a higher frequency. Therefore:—

(1) Three-phase, 25-cycle, generation at any desired voltage or voltages should be specified as a requirement to allow the flexible development of electric traction systems.

(2) Commercial power plants, which employ other frequencies, may be utilised for railway power purposes either directly in case of direct-current traction or by the installation of separate generators and motor generator tie-in sets, or frequency changers in the case of the alternating current traction.

Costs.

The investigation of the Chicago Association of Commerce is probably the best source of information which has appeared to date regarding the details of first and operating costs of electric systems. This report was completed in 1915. It covers a minute investigation of a great railway problem within a compact area of 428 square miles in and around a very large city. Within this area thirty-nine different railway companies operate dense passenger, goods and shunting services over a network of tracks comprising an aggregate mileage of 4,500. The net first cost of the equipment required to operate this entire system electrically was estimated and analysed with great care for three different systems and gave the following results:—Direct current, 600 volts, third rail, 188,132,314 dols.; direct current, 2,400 volts, overhead, 181,891,122 dols.; single-phase alternating current, 11,000 volts, overhead, 178,127,230 dols. In other words, the first cost was substantially the same for all three systems. This conclusion is, of course, for short-haul conditions; for long-distance haulage the showing for the high-tension system, as compared with the third rail, would be better. For average conditions estimates I have made on important projects indicate a first cost difference of 15 to 20 per cent. in favour of the high-tension overhead alternating-current or direct-current trolley systems as compared with the direct-current third rail, and of the two high-tension systems the alternating current appears in every case to cost less than direct current.

As to operating costs, the Chicago report showed, for items affected, a substantial saving per train mile as compared with steam. The saving was least in the case of the 600-volt third-rail system and greatest for the 11,000-volt alternating-current system, but there was not a very great difference between the latter and the 2,400-volt "overhead" system. The conditions, however, in the Chicago district are somewhat peculiar; for the average railway condition, estimates indicate differences of 10 to 16 per cent. in favour of the high-tension trolley systems as compared with the 600-volt direct-current third rail and the high-tension alternating current appears in every case to be more economical than the high-tension direct current.

Selection of System.

The important considerations governing the selection of a system are:—

- (1) Adaptability to all physical conditions of the railways.
- (2) Economy in first and operating costs.
- (3) Flexibility as regards conducting varying kinds and volumes of traffic.
- (4) Suitability for extension.
- (5) Possibilities as regards future advance in the art and improvements in detail.

I would work, as far as consistent with the above, towards the elimination of systems which are applicable to special cases only. This, as before indicated, would narrow the selection to the adoption of one of the high-tension overhead conductor systems.

The 600-volt third-rail direct-current system would only be considered for extensions to existing installations or for very special cases.

The 1,500-volt direct-current system could only be adopted with an overhead conductor and for light traffic requirements; 1,500-volt third rail cannot be used generally because of its danger to life. The 1,500-volt system is an interim development only. Higher voltage direct-current systems, such as the 3,000-volt system, have promise for the future, and their development should be allowed to continue unhampered.

The 11,000-volt alternating-current system likewise has a broad field of usefulness and promises well for future development.

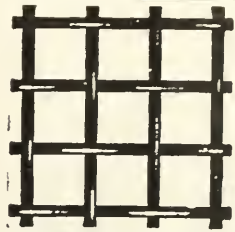

The selection, therefore, of a proper system for general use appears to lie between the 3,000-volt direct current and the 11,000-volt alternating current. I have referred to the existing difference of opinion as to these two systems, and since I am not recommending the elimination of either from adoption at present, it is unnecessary for me to indicate my preference. I should approach any concrete problem upon its merits along the lines laid down, having regard to the latest experience and facts as to the state of the art when decision is to be made.

French and British Reports.

I have looked through the voluminous report of the French Commission on Electric Traction, and, frankly, its conclusions do not seem to be well founded on the data presented. Perhaps the Commission has arrived at a correct conclusion, having regard to the particular conditions in France, but the reasons given for condemning the single-phase system seem inadequate and largely the results of a "scare" as regards the inductive interference question. The Commission seems to have been dominated by telephone and telegraph experts. It also seems to have been greatly influenced by reports of the high cost of maintenance of the alternating current, which, they state, is at least double that of direct current, a conclusion which is absurd. No effort seems to have been made to equate operating condi-

tions in comparing systems, and I doubt if the Commission really had any accurate figures of cost of maintenance of the alternating current. It does not seem to have attached much importance to the future trend of development and possibilities in connection with both alternating-current and direct-current traction.

I was interested, and disappointed, in reading the Interim Report of the Advisory Committee on Electrification of Railways. It would be valuable to know what reasons led the Committee to the adoption of the 1500-volt direct current as standard. I think a mistake has been made, even if it should prove to be the eventual system, because the adoption of any standard now is going to put the development of electric traction in a straight jacket. The development of both the alternating-current and the direct-current systems should continue in order to get the best results finally from electric traction.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS AND TONE SLIGHTLY BETTER—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—
AGRICULTURAL IMPLEMENTS—ELECTRICAL GOODS—OIL PROSPECTS—UNION'S GRAIN ELEVATORS—
CONTRACT—UNION'S TRADE RETURNS, JANUARY-AUGUST, 1920-21—FINANCIAL—METAL MARKET.

General Review.

The position on the whole is regarded in mining circles with more equanimity. The situation at Home, though of course far from satisfactory, is still showing signs of gradual, if slow, improvement. In regard to the key industry, the coal miners are becoming more and more convinced that their only salvation lies in their acceptance of lower wages and of more energy being thrown into their work, thus enabling manufacturers, through lower coal costs, to meet foreign competition. The price of coal and coke in Britain is still falling, with the result that more iron and steel works are resuming operations. The commercial community was relieved by the removal at the eleventh hour of the trouble threatening at the E.R.P.M. mine. Prices generally for timber and iron and steel remain fairly stationary, and are now gradually getting into line with imported goods. Recently merchants have, of course, been selling at a great sacrifice, but the tendency now is towards a slightly higher level more in consonance with prices of goods laid down from Home to-day. Regarding the recent announcement that the Government were using their influence with the banks to extend financial facilities to the farmers, it is generally felt here that such "tiding over," if it came about, would be an undue advantage to one section of the community and at the expense of merchants and others. Despite all troubles, actual and potential, through which we are now passing, there can be no doubt that merchants on the whole are of opinion that we are gradually emerging from the lethargy which has characterised business of late, and that things generally are now shaping towards improving conditions. Every month which now goes by brings us more into line with the stocks which we should be using, and in that way—apart from the serious position of the importer at the present moment and during past months regarding profits, or more correctly, losses, the general position is improving with the passing of time. The slump of the German mark to 750 to the £, as compared with the pre-War exchange of, roughly, 20.40, gives us furiously to think about German reparation settlements; but sufficient unto the day.

Iron and Steel.

There has been a fair amount of business transacted during the past week; inquiries have been more numerous and the tone generally more consistent than for some time past. On the Commercial Exchange there has lately not been so much selling at or below cost. An influential merchant is of the opinion that in a few months' time a lot of people now cutting will be out of stocks, with a consequent rise in prices, when present holders will at last reap their reward. Things were, he thought, settling down more and more to normal again, and he should not be surprised if by the beginning of the New Year an improvement in conditions—slight though it might be—manifested itself. In any case, he said, there were bound to be shortages in certain lines within a very few months. The only special feature of the week calling for remark has been the advance of fencing wire by about 15 per cent., caused, it is understood, by Germany's inability to supply at the present time.

Iron Ore Industry.

Speaking at the 24th annual congress of the Associated Chambers of Commerce of South Africa in Pretoria on Monday last, the Right Hon. Mr. F. S. Malan, Minister of Mines and Industries, said, *inter alia*, that it was not creditable to us as a people that we have not been able to do more with our iron ores. Experts had convinced the Government that both in regard to the available ore and the suitability of our coal and lime deposits all the raw materials required for the development of this industry are present. The Government's and Parliament's sympathy had repeatedly been shown in regard to the development of this key industry, but little progress unfortunately had hitherto been made. Of the four local undertakings, two working scrap iron and two attempting to work up raw ore, the two latter are hampered by want of capital. He said something more should be done to make proper use of opportunities lying to our hands and make this key industry subservient, as it would do more than any other industry, the industrial and economical development of the country. As an illustration of the improvement recently experienced at Home in the iron and steel industry, a number of vessels are leaving Wales with cargoes of metal manufactures for the Far East. Large orders for galvanised sheets have been placed in Britain during the past few weeks.

Under the sliding scale bonus 27,000 Welsh tinplate workers will have their wages reduced a further 37 $\frac{1}{2}$ per cent. owing to the fall in steel bars.

A leading iron and steel importer stated that his English correspondents by the last mail had reported that general conditions there were still uncertain; prices were coming down, except on the Continent, where there has been a sharp advance. Germany has been inundated with orders and been putting up her prices and postponing dates of delivery for all steel products. The French works are getting into the same way. Belgium works have labour troubles and many factories are closed. Prices generally have declined from 15s. to 40s. per ton, the lower price applying to bars and the higher price to sheets and wire, with other products in between. In England labour is gradually recognising the economic factor and is now accepting lower wages all round. America is still out of it, as although prices are lower they are really not competitive, and of course the item of exchange is a factor against America, just as it is in favour of Germany, France and Belgium. This exchange factor is probably the main cause of the present trade uncertainty and lack of confidence, all leading to bad trade conditions. The world's demands are great, but the lack of money must prevent many countries operating to a large extent. America is finding out, however, that it is not an unmixed blessing to have too much money, and with most of the world's gold in their possession trade conditions are worse there than in Britain and unemployment most serious. Until such times as exchanges become anything like normal we can hardly look for that trade boom which our papers are so fond of writing about.

There is a slight revival of trade in the Far East, and there is also improvement in purchases in the Australian trade.

Further Reduction in British Steel.

A fresh reduction in the price of steel has been announced, ranging from £2 to £4 per ton, with effect from 17th inst.

New South Wales Boiler Contract.

The New South Wales Government has placed an order with a Lancashire firm for boilers to equip the electric service for Newcastle, New South Wales, at a cost of £50,000.

Iron and Steel Production Hampered by Cost of Production.

The latest advices from Britain are to the effect that the iron and steel position has not materially improved owing to the cost of production. The price of coke has now been reduced to 32s. 6d. per ton, but ironmasters state that this is still too high, and pending a further reduction they cannot produce at a price to meet Continental competition. British 60 lb. steel rails are now £12 10s. per ton.

Leeuwpoort Tins.

It is rumoured that the price of tin, together with other factors, will prove detrimental to the working of this property, the unstable conditions caused by fluctuations in the price of the metal in the world's money market, causing, we hear, restriction of the mine.

En dit that a hoar frost has been noticed around Krugersdorp district in the way of an attempted flotation. It has been stated by a well known metallurgist that a possible coating of the yellow metal may eventuate in years to come, but at present, the gentleman states, minus the

Fires which Cost £3,000 to Light.

An expert just returned from a visit to the Midlands states in connection with fire lighting of blast furnaces that at the time of writing 37 out of about 300 up-to-date blast furnaces in Great Britain are alight or in the process of lighting. This is the first reply of the ironmasters to the reduction of 15s. per ton in the price of furnace coke. If the further small reduction which is anticipated comes about probably 200 blast furnaces will be in the process of being fired next week. Generally speaking, all the steel-makers, shipbuilders, and allied trades are pausing with a hand on the starting lever waiting on the ironmasters. *Without the blast furnaces in operation no appreciable revival of trade can take place.* It is astonishing to learn that the cost of lighting a big blast furnace is in the neighbourhood of £3,000 and sometimes more. To grasp it one has to realise that the blast furnace is from 80 to 90 feet high with a diameter of about 20 feet. It is built of steel plates and lined inside with a skin of special fire bricks several feet thick, and this skin plays a large part in the process.

Engineering Shops.

Business in these generally is still improving, orders coming in fairly steadily. Those industrial concerns dependent upon the Power Station to any great extent are perturbed at the present state of things, which will cause a lot of hardship to many if the position is as serious as it is alleged.

At the Unemployment Commission last week Mr. A. S. Elston, general secretary (S.A.) of the Amalgamated Engineering Union, in dealing with the general question of the merits of technical education for apprentices, said that while the principle was quite sound, hundreds more lads are being trained at the present time than have any prospect of being absorbed by the skilled trades of the Union when they reach the proper age. Especially was this the case with engineering, where many lads are being trained in certain branches of engineering without any possibility of their being afforded even the opportunity of starting on a practical course of apprenticeship. Efforts should, he thought, be made to point out that other sections of industry and commerce are equally attractive, and methods should be used in order to spread the youth of the country over the various industries.

Timber and Building Materials.

Business has if anything slightly improved during the past few days, but not to any great extent. Prices remain practically unaltered, with, however, a tendency rather to

harden than decline. Latest advices from the Baltic may to the effect that bottom has been reached and that prices may probably advance somewhat in some lines. Stocks locally are good. 3 x 9 deals, 1s. to 1s. 1d.; scantlings—1s.; beaver board, 4½d. to 5d.; floorings, 6½d. to 7d.; ceilings, 5¼d. to 5½d.; Oregon, 7s.; pitch pine, 8s. to 8s. 6d.; corrugated iron, 9½d. to 10½d. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality, 14s. 9d. for second, at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 3d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cub. ft. at the mills; Honduras mahogany, 30s. per cub. ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks, in the absence of much activity in the building trade, are unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 37s. 6d., 47s. 6d., 55s. 3d. for 1 to 3-ply.

Second-hand Iron and Timber.

Business, probably on account of the Jewish holidays, has been rather quieter this week. The price of second-hand iron is still ruling at from 6d. to 7d., timber at from 10d. to 1s. The tightness of money is the chief abstacle to improving conditions, while the continued inactivity in the building trade is a very important factor. Second-hand yards are now well stocked with materials.

Agricultural Implements.

Owing to the present tightness of money and the low price now being obtained by the farmers for their maize, etc., the demand for agricultural implements is now not

very large. It is, however, hoped that the advent of rains, of which we have already had a foretaste, may lead to better conditions.

Electrical Goods.

Business remains much about the same as last reported; there are no alterations in prices to record, although there is a probability that some reductions may occur shortly. Electrical goods are now coming in somewhat sparsely, but merchants are stocked up to the hilt in all lines. Dealers at the moment are, as a matter of fact, marking time, awaiting the development of building operations. A few country orders in the meantime are keeping them fairly busy.

Oil Prospects.

Melbourne cables that consequent on the discovery of distinct traces of mineral oil in the Kimberley district (Western Australia), there has been a rush of applicants for prospecting licences, and leases covering 100,000 square miles in the western portion of the northern territory adjoining Kimberley have also been applied for.

Petrol has declined another 1s. per case, meaning a reduction of about 6s., or about 15 per cent., since the beginning of the year.

It is reported that oil has been discovered on a farm six miles from the Basutoland border and 33 miles from Bethlehem, at 25 feet from the surface, the analysis giving a lubricant and kerosene value of 75 per cent. It is also stated that the Government has become interested in the proposition, who will, it is understood, lend a 6 in. or 8 in. drill to continue the boring operations, which were commenced with a 2 in. drill. It is confidently anticipated that within three months either a "gusher" or an artesian oil well will be struck. It is stated that oil has been traced for six miles, and farms in that area have been acquired.

Rooedeport United Closes Down.

The profit-sharing scheme, which was placed before the mine workers by the management of this company early in September, not having been accepted, it has been decided to close down the mine. It is much to be regretted that this scheme for prolonging the life of the mine has come to naught, but in view of the continued losses month by month (September showed a loss of £1,700) the management had no option but to cease work.

The Union's Grain Elevators.

It is officially announced that the Railway Administration has placed the contracts for these with Mr. A. W. Meukins, whose tender was substantially lower than that of any other firm. The work of constructing the elevators is divided into four separate contracts: Durban terminal elevator, 42,000 tons storage capacity; Capetown terminal elevator, 30,000 tons storage capacity; 17 country elevators

(group 1); 17 country elevators (group 2), of varying storage capacities. The successful tenderer has recently concluded work on the large terminal elevator at Glebe Island, Sydney, and is a man of the highest qualification in regard to elevator construction. The total amount of the contract is said to be about £1,000,000.

Union's Trade Returns for 8 Months ended August 31.

These show a continued heavy fall in imports and a recovery in exports, especially noticeable in August:

	1921.	1920.
Imports	£40,091,767	£67,773,506
Exports	38,645,131	61,014,736

The most encouraging advance has been in the export of corn and grain. During the eight months it has increased from £490,523 in 1920 to £2,086,915 for this year. Shipments of maize in August this year amounted in value to £213,215, compared with only £3,062 last year for the same month; for the eight months the Union exported maize valued at £1,561,590 as compared with £57,636. The principal falls in imports were £5,800,000 in articles of food and drink (principally as regards food on wheat and wheaten flour); cotton manufactures, which fell from £7,429,830 to £5,267,620; woollen goods, which declined by nearly a million; hardware and cutlery from £2,586,487 to £1,592,172; iron and steel manufacturers by over one million in value. There was, however, a gain on machinery from £2,331,900 in 1920 to £3,428,088, mining machinery accounting for an increase of £400,000. Vehicles dropped from £2,713,789 to £1,018,378, and motor cars from £1,142,025 to £434,865. Wood and timber fell from £1,700,705 to £978,297 (flooring and ceiling, other than planed and grooved and house frames accounting for much of the decrease).

Coal Crisis in South Wales Settled.

This dispute, which arose through the Government and the coal owners disagreeing as to the interpretation of certain terms of the strike settlement, has now been settled in favour of the owners by the arbitrator, Sir William Plender. The award has resulted in the restarting of numerous collieries and the easing of the unemployment situation. The matter in dispute was that the Mines Department contended that the liability of the owners for the September wages was 97.57 on the 1915 standard of the wages, while the owners, on the other hand, claimed that their liability should be 76.6.

Financial.

Mr. Charles Maggs has joined the board of the National Bank of S.A., Ltd.

A 6 per cent. Nigerian loan of £3,000,000, issued at 97 and redeemable in 1936-46, is now being underwritten.

Australian Loan of £5,000,000.

A cable from Melbourne states that the House of Representatives has authorised the raising of a loan of £5,000,000.

GOVERNMENT EXAMINATIONS.

METAL MANAGERS EXAM.: Last examination (May, 1921), 15 Metal Certificates were granted in South Africa, and of this number our students secured 10 certificates. Previous examination we secured 7 certificates from 8 entries, and in two other recent examinations 15 passes from 19 entries.

REMARKABLE AND CONSISTENT RESULTS.

COAL MANAGERS EXAM.: Last examination (May, 1921), we secured 3 certificates from 6 entries.

OVERSEAS EXAM.: 21 certificates secured 1920, and 14 certificates to date, 1921.

SURVEY EXAM.: We have secured practically all the certificates granted by the Mines Department during recent years and have obtained 60 certificates to date.

WHY PAY SHOP PRICES?

Write for Furnishing Guide at once as the prices quoted WILL SAVE YOU POUNDS.

We are prepared to accept payment by Six Monthly Instalments. Our Prices will not allow for any longer term. ALL GOODS are CARRIAGE PAID to any Railway Station in the Union.

S. T. GEEN & Co., —HATFIELD HOUSE,—
PRESIDENT - STREET,
JOHANNESBURG.

The Reserve Bank.

According to the weekly statement of the S.A. Reserve Bank, dated October 15, the ratio of liability to the public was 72.7.

Currency and Banking Act.

An important conference was opened on Monday last at Pretoria, presided over by Mr. Burton, the Minister of Finance, at which were present many of our financial authorities. The object of the conference is to discuss the terms of the Currency and Banking Act of 1920 and the inconvertibility of gold certificates—whether according to the Act this should terminate in June, 1923, or the period be extended, and what steps should be taken, if any, in order to avoid undue disturbance of exchange and business.

Wireless Progress.

A cable from Brussels says a contract has been signed for the erection of a gigantic wireless station at Ruyssekede, in West Flanders, which will be in direct communication with the Congo. This station, which will be the most powerful in the world, will, it is expected, be completed within 18 months.

In this connection it is interesting to note that very successful results have been obtained in Cape Town in long distance wireless experiment; all the principal American and European stations are now easily heard. The Windhuk station, when the necessary alterations have been made, and the proposed new station at Nairobi, will form two important links in the Imperial wireless chain.

Brighton Diamond-cutting Works.

The Oppenheimer diamond cutting factories for soldiers are now being re-organised, and it is now hoped that with the present staff of 300 the works will be conducted on a paying basis. Roszelaar and Zouen, Amsterdam, one of the oldest diamond-cutting firms in existence, are to act as technical administrators of the Brighton works, and although the firm will still carry on business at Amsterdam and New York, all the cutting will be done at Brighton.

Goldfields Rhodesian Development Co.

The accounts for the year ended May 31, states a cable from London, show that the available balance is £161,907. A final dividend of 6d. has been declared, making 1s. in the year, and the sum of £99,052 has been carried forward.

The Dunlop Rubber Co. (London) announce that, in view of the serious depreciation of the stocks of rubber and cotton held by them at the end of the financial year, dividends on the preference shares will not be paid.

Metal Market.

Latest London quotations: Standard copper £67 11s. 3d. cash, £68 13s. 9d. forward; electrolytic copper £74 10s. cash, £76 10s. forward; Straits tin £153 7s. 6d. cash, £157 15s. forward; English lead £23 17s. 6d. cash, £23 10s. forward; bar silver 45½d.; fine gold 101s.; quick silver £10 per bottle.

A notice in the current Union *Gazette* invites the attention of the travelling public to the account that the Belgian Government has issued a decree regarding the measures to be taken to combat human tuberculosis in the Belgian Congo. Passengers passing through Africa on their way to this Colony are advised to make themselves acquainted with the regulations of this decree, in order to avoid any inconvenience on reaching their destination. The following is an extract from the decree:—"In order to combat human tuberculosis the Governor-General may impose restrictions to the admission to the territory, require medical certificates, order medical examinations and special disinfection, fix the conditions which dwelling houses and meeting places must satisfy, order treatment in the Government hospitals, require the compulsory notification of the disease, and cause the non-Congolese subjects suffering from open tuberculosis to be repatriated. Defaulters are liable to imprisonment for a period not exceeding three months and to a fine not exceeding 1,000 francs, or to one of these penalties.

Coal-Cleaning.

TWO RECENT DEVELOPMENTS.

Attention was called by Mr. Robert Nelsen at the Civil Engineers' Engineering Conference to the deterioration noticeable since the war in the coal supplied to consumers in respect of the amount of incombustibles contained in it, and he described two processes of recent development which he suggested would in proper combination offer an adequate solution of the problem of cleaning coal.

He stated that 40 separate records from works where a comparison of the ash in pre-war and post-war coal (purporting to be the same class of coal from the same sources) can be directly made indicate that the average increase in the quantity of ash is nearly 63 per cent.; that is, coal that formerly contained 8 per cent. of ash now contains on the average 13 per cent., and coal that formerly contained 12 or 13 now contains more than 20. It has been computed that about 35 million tons of uncleaned slack coal are transported annually in Great Britain, for an average distance of perhaps 50 miles, to be used for steam and manufacturing purposes; and it follows that at least $1\frac{3}{4}$ million tons of material which is worse than useless are annually transported up and down the country, absorbing labour to load it, to unload it, to fill it into furnaces and to take it out again as clinker. If the whole of this recently added 5 per cent. could be got rid of at the pit head, about 2,000 trucks and 40 locomotives, together with all the man-power released, would be permanently available for some useful purpose.

Froth Flotation.

The chief difficulty in washing coal by the older methods is to deal efficiently and effectively with fine coal. Hitherto, coal-washing has been effected by specific gravity between the coal and the dirt. If the dirt is of the same or nearly the same specific gravity as the coal, these methods fail when applied to material below a certain size. The new flotation process for washing fines coal is, however, independent of gravity. The coal to be treated, if not already fine enough, is crushed until the particles pass through a screen about one-tenth linear inch aperture. It is then mixed with three to four times its weight of water, together with a small quantity of reagent. The reagent may be an oil or coal-tar product, and 1 lb. is, generally speaking, required for each ton of coal treated. The mixture is agitated by a power-driven mechanical mixer, and a multitude of minute air-bubbles is produced. To these the coal particles attach themselves, and by them are floated to the surface of the water in the form of a thick coal laden froth. The coal in the froth is removed by a suitable scraper and dried for use, while the ash-forming dirt sinks to the bottom and is drawn off. Once the proper reagent has been found, the working of the process is simple, and given a steady flow of feed and a regular supply of reagent, a flotation machine, it is claimed, will produce clean coal on the one hand, and on the other a residue which is very nearly coal-free.

Apart from valves and piping and the mechanically-driven mixers and scrapers, the ordinary flotation machine is made entirely of wood. It consists usually of from five to ten "mixing" boxes, each with a froth box connected to it. The material under treatment passes from No. 1 mixing box via No. 1 froth box to No. 2 mixing box and so on through the plant, the final reject coming from the last froth box. A machine to deal with 1,000 tons of coal in a 24-hour day measures approximately 37 ft. by $15\frac{1}{2}$ ft. by $15\frac{1}{2}$ ft.

Rheolaveur Process.

A process, called the Rheolaveur, for cleaning coal other than fines (from $2\frac{1}{2}$ in. downwards) comes from Belgium. Its first requirement is a strong and steady flow of water. The water is turned into a trough into which the coal to be treated is also led. The flow of water carries the coal along with it, and the separation of coal and dirt is effected by stratification, the rate of the flow of water being so regu-

lated, and the trough made of such a length, as to allow time for the coal and dirt to stratify. Arrangements are made at intervals to draw off the dirt from the bottom of the trough, and the coal is borne along until, at the end of the trough, there is no more dirt to be drawn off, and clean coal is delivered to the clean coal hoppers. At each drawing-off point a cast-iron box is inserted, from the bottom of which a current of water, controlled by a hand-valve, is made to flow upwards into the trough to prevent coal from being drawn off with the dirt, serving a similar purpose to the upward flow of water in the wash-box of the Draper washer. The water is stored in a tank fixed about 20 ft. above the trough and arranged to give a continuous steady flow.

In washing nuts the strength of the upward current in the first box is kept high so as to allow shale only to be drawn off. This shale forms the reject and at once finds its way to the shale dump. In the second box the strength of the upward current is rather less so as to allow the balance of the shale, and it may be a little coal, to pass through the box. This reject is not sent to the shale dump, but is returned by an elevator to the original trough to be re-washed. In washing nuts two boxes only are necessary, and the coal passing the second box, being dirt-free, is delivered via a moving drainage plate to the nut-coal bunker. In washing small coal four boxes and two lengths of trough, one above the other, are needed.

The advantages claimed for the process are low initial cost, low maintenance and running costs, easy control of working, absence of complicated mechanical parts, and economy of space.—*The Times*.

Carboniferous Glaciation of South Africa.

The above was the subject matter of an exceedingly interesting paper read by Dr. A. L. du Toit before the Geological Society of South Africa at their meeting on Monday evening. Present climatic conditions would lead one to doubt the existence of conditions of extreme cold in our sub-continent in the past, yet abundant geological evidence exists proving that South Africa once formed portion of a huge ice-covered land mass in the distant carboniferous age. Before the deposition of our coal measures this country was subject to conditions of extreme cold such as are seen to-day in the polar regions. Everyone is conversant with the movement of glaciers, and the deposits of debris and morrains formed at their termini. These ice masses, during their slow movements, exert enormous pressure on their beds, and when passing over rocky formations leave the bedrock in a roughly polished state and covered with striations which lie in the direction of movement of the glaciers. These striations are produced by fragments of rocks included in the ice which continually abrade the bed of the glacier. The nature of these rock fragments or boulders enables one to determine from which locality they were derived. When glaciers carrying large quantities of rock fragments and boulders are subject to warmer conditions they melt and deposit their load in the form of a boulder bed. This boulder bed in the course of time becomes covered with other sediments, and finally consolidates, forming a rock known as a till. In South Africa abundant evidence of such a rock is to be found below the coal measures, and the name of Dwyka conglomerate or tillite has been ascribed it. The Dwyka conglomerate is to be found at the base of the rocks of Karoo age, even as far north as the Zoutpansberg district. It presents conclusive evidence of the existence of huge glaciers in carboniferous times. Striations due to the glaciers are to be seen in several parts of South Africa, and a study of their directions as well as the rock material making up the conglomerate shows that three distinct centres of glaciation existed at that period. The most important of these had its origin in the central Transvaal or Bushveld area. The Dwyka conglomerate from this centre of activity contains boulders and fragments of all the prominent rocks existing in central Transvaal at present. Red granites, Magaliesberg quartzites, dolomites, and Pilandsberg volcanic rocks are all represented.

No. 1570.

Four New Views of Randfontein.

Views of the Randfontein Central Mill and Reduction Works and (top left hand picture) New Buildings and Equipment of the Randfontein South Vertical Shaft. A very satisfactory report for the September quarter was issued this week, showing that the quantity of ore crushed during the quarter was 19,500 tons more than during the preceding three months. The revenue was 1s. 9d. per ton higher, and the working costs 1s. 3d. per ton lower, with the result that the working profit for the quarter amounted to £112,699, an increase of £61,818 over the quarter ended 30th June. The development footage sampled totalled 7,560 feet, and gave the following results: Payable, 5,840 feet, having an average value of 24.5 dwts. over 15 inches of reef. Unpayable, 1,720 feet, having an average value of 11.2 dwts. over 14 inches.

Gold and Currency Problem.

MORE PROS AND CONS—WELL-KNOWN MINING AUTHORITY'S VIEWS—"MERELY DEBASING THE COINAGE."

It is gratifying to find that the gold question, as dealt with in our last issue, has provided the topic of the week in mining and business circles, and we have been favoured with many expressions of opinion—some of them favourable, most of them unfavourable—to the views expressed and quoted by us. For the benefit of those who may have missed our last issue, it may be recalled that in our issue of September 3, under the heading "A Real Solution of the Currency Problem at Last," we wrote strongly in favour of the suggestions that the true solution of the gold and currency problem in countries with depreciated currencies, lay in abandoning paper money for gold, no doubt with units containing far less gold than their pre-war money. Since then no less an authority than "Barclay's Bank Monthly Review" came out with support for the proposal, and the Chairman of the Federation of British Industries, Sir Peter Rylands, has also put it forward as the only and the better alternative to deflation. *The Statist*, by last mail, had a long and closely reasoned article in favour of the idea; and we quoted passages therefrom giving the arguments in detail for making "the paper currencies of all countries which were formerly gold using, convertible into gold, not at the pre-war ratios, but at the values as measured by the actual exchange rate with the United States dollar at the time chosen for taking this step, or the average exchange rate over a detailed period." Needless to add, the net effect of the adoption of this proposal, thus backed in such influential quarters, would be to stabilise the "premium" on gold, to the direct and obvious benefit of the Rand gold industry.

An Adverse View.

In the course of conversation during the week with one of the leaders of the industry we learned that these views did not commend themselves, that the cardinal fact that Great Britain still owed the U.S.A. 1,000 millions and that any scheme to increase the value of gold would be merely augmenting the value of that country's great gold reserve were the governing factors in the situation. This authority, for whose opinion we have the greatest respect, went on to say: "To debase our coinage does not alter real values. It is only a pretence and makeshift." He then proceeded to analyse some passages in our last issue. "Take," he said, "your sentence: 'It is necessary to comment on the main principle involved—namely, that Governments which, through the exigencies of War and post-War finance, have allowed the value of their currencies, expressed in terms of gold or commodities (and, of course, the value of their Public Debts), to depreciate by the process of inflation, are to be allowed to fulfil their obligations by repaying them at the depreciated value.'" "This simply means reducing their claim!" Again, take the following passage in your article: "If it were possible to pay off the bulk of our Debt last year, when prices were at the peak, and when, consequently, the commodity value of the Debt was greatly depreciated, it is hardly conceivable that the repayment would occasion a general outcry among the holders, though in reality the Government would be paying back much less than it received." The reply to this is: "That the commodity value of debt rises and falls with commodities is a fact. But if repayment is to be made on the basis of value of the commodities that were supplied and caused the debt, then the only just amount repayable would be the amount that would return with interest the commodities (or money) advanced. That would be a sort of judgment of Solomon and would involve knowing exactly what the debt was due to. But this form might not be acceptable because many of the commodities for war purposes were supplied at abnormal prices, and the same commodities might in times of peace and at leisure be supplied vastly cheaper. Hence the money value of the debt can be the only standard

applied unless the creditor—appreciating that the War was his War too, and that he should bear a share of the abnormal prices—agreed to reduce *arbitrarily* the amount of his claim." Then take the sentence: "We do not suggest, of course, what is obviously impossible—that the Debt should be redeemed in the near future—but if our proposals are carried into effect the real value of the Debt will be more or less permanently fixed, so that the payment of a given nominal amount of the annual interest charge or of the principal would over a number of years represent approximately the same effort on the part of the Government." But once having debased coinage, what is to prevent further debaseure? "Again you say: 'Under existing conditions it is impossible to foretell with certainty the course of prices during the next few years. If the present inflationary finance of the Government should, in conjunction with a trade recovery, bring about a rise in the price level, the commodity value of the Debt would decline, to the disadvantage of the holder. If, on the other hand, prices should fall, the real burden of the Debt would be correspondingly increased. The same applies to private as well as to public debts.' True, but the only cure is the stability of exchange due to gradual parity in the imports and exports." "Finally," said our informant, "debasement is exactly equivalent to issuing paper—to the extent indulged in—and the appetite is apt to grow!" We hope we have printed the views of this authority in as nearly as possible his own words. They certainly supply a useful corrective and we shall take an early opportunity of dealing more fully with them.

New Developments in Ore Treatment on the Rand.

THE ALL-SLIMING PROCESS AND WHAT IT MEANS—AN EXPLANATION BY ITS FIRST ADVOCATES.

By G. A. & H. S. Denny, in the "London Mining Journal."

Experiments on the Springs and Brakpans.

The condition of things in the gold mining industry of the world has been causing considerable discussion recently. The Rand, as the greatest gold producing centre, is naturally the field upon which the interest is focussed. It is incontestable that the continuance of operations there on the present scale is dependent primarily on the status of the gold premium, and that in its turn is governed by the dollar exchange. The highest authorities believe that the premium must continue for a long period, but there is no guarantee that such will be the case. It may change quickly, and therefore the situation is precarious. It is generally believed that, with the disappearance of the premium—which involves the adjustment of exchanges—an accompanying levelling process in the cost of labour and material will automatically arrive to offset the loss. But will it? Certainly something in that direction may be counted upon, but it is expecting too much to suggest that it will do everything. The industry must in any case help itself by improvements in method, and it is encouraging to note recent utterances by leaders of the industry regarding development in ore treatment methods; and in this connection the following extracts from official statements are informative:—

The chairman of the Springs Mines, Ltd., at the meeting held at Johannesburg on May 17, 1921, said: "... Certain tube milling experiments which were initiated at Brakpan Mines are now being conducted at Springs Mines, and if the promise of success which they show is realised, your directors and consulting engineer will take the fullest advantage of these results when considering the advisability of installing additional plant. The success of the experiments is of special importance to the company, because it would enable us to adopt a variation of the existing standard process at a considerably smaller capital outlay."

While the manager of the Brakpan Mines, Ltd., in his report for the year ended December 31, 1920, wrote: "... Tube Mills.—The experimental plant for investigating the problem of feeding tube mills with a product that has not passed through the stamp mill worked very successfully. The experiment was eventually transferred to Springs Mines, where improved facilities were provided."

The £ s. d. of the System.

A perusal of these two extracts naturally gives rise to the questions: "What is the real bearing of these alternative measures on the economic position of the mining industry?" "To what extent is it applicable to existing treatment plants?" "Is its application limited to new installations?" "Will it have any important effect on production cost generally, or is it something entirely for the future?" "How will it affect Brakpan or the Springs Mines returns?" "What benefit in £ s. d. will the shareholder get?" "Does it mean that lower-grade ores can be treated at a profit?" "Can it be applied to the old mines of the Central Rand, to give them a new lease of life?" "Is it, in fact, of material benefit to the shareholders in the Rand gold industry as a whole, or is it merely a point more of metallurgical and technical than of commercial interest?"

These are probable some of the questions that must agitate the mind of the average shareholder who reads the above extracts, and there is nothing in the reports to guide him to the answer.

The literal interpretation of the statement made by the chairman of the Springs Company—viz., "The success of the experiments is of special importance to the company, because it would enable us to adopt a variation of the existing standard process at a considerably smaller capital outlay"—does not suggest that the innovation will give any

reduction of operating costs, nor does it imply that it may have any influence on existing equipments, so that, without further explanation, the statements are vague and indeterminate.

The *African World* of July 30 published an interview with Mr. J. S. Wetzlar, the managing director of the Consolidated Mines Selection Company, who had just returned from South Africa, and at this interview Mr. Wetzlar is said to have expressed the following views:—

"The All-Sliming Process.—The experiments which had been carried on at the Brakpan Mine originally, and now at Springs, for the purpose of seeing whether the stamp battery could not be eliminated, were no longer an experiment. A complete unit was now at work at Springs and was successfully treating the ore. Without going into technicalities, the idea is, roughly, to eliminate the stamp mill and the sands treatment, which would actually result in the all-sliming process, one of the subsidiary advantages of which would be to settle the question of gold thefts. A high percentage of extraction is possible by the process, which will effect a considerable saving in capital expenditure for plant, as well as important economy in working. The success attained meant a great deal for the future of the Rand generally, as well as for the companies with which he was associated, as the question of the provision of further plant for increasing the output would presently have to be settled."

It will be noticed that Mr. Wetzlar goes much further than the chairman of the Springs Company or the manager of the Brakpan Company. (See footnote.)

Treatment of Ore.

In order to understand the trend of these various statements, it is necessary to explain that in ordinary practice the broken ore raised from the mine is first passed over a rough sizing screen, called a grizzly, the function of which is to separate the "fines" from the coarse rock. It must be understood that in blasting the rock underground a certain percentage of "fine" material is made, and this varies in different mines, depending on the nature of the rock, the width of the slope, the particular type of explosive used, etc.

When charged on to the grizzly the "fines" pass through the bars into bins, from which they are conveyed direct to the stamp mill bins. The coarse material passes through one or more crushers, and then goes over sorting tables or belts, and the sorted rock goes to the mill bins to join the "fines." The contents of the mill bins are fed to the gravity stamps.

The experiment made at Springs consists of passing the "fines" direct to tube mills, instead of conveying them to the stamp mill bins, so that gravity stamps for the further reduction of the "fines" are eliminated.

"Fines" may include anything from the fine powder up to 2in. cubes, depending on the spacing of the bars in the grizzly, but in the case under notice probably nothing bigger than 1in. cubes would go direct to the tube mills.

The effect of the alteration is to take a certain amount of work from the stamp mill, thereby leaving that mill with a bigger capacity for coarse rock; and assuming the "fines" to represent, say, 50 per cent. of the total ore from the mine, the stamp mill would be relieved to that extent. The tube mill capacity, however, would have to be increased proportionately, and as the capacity of a tube mill is directly relative to the size of the material in the feed as against the size of the product required from the discharge end, the number of additional tube mills required, and the horsepower absorbed by them, would be dependent on these two points.

By adding tube mills, therefore, to an existing plant the mill capacity would be increased proportionately to the amount of "fines" diverted in the manner suggested. In a new equipment of combined stamps and tube mills the number of gravity stamps for a given output per day would obviously be proportionately less.

It is implied in the official extracts above given that there is a considerable margin in favour of by-passing the "fines" to go direct to the tube mill.

Elimination of Stamp Battery.

By eliminating the stamp mill altogether, as contemplated by Mr. Wetzlar, the process of reducing the ore to a fine powder resolves itself into (1) stage crushing with coarse and fine crushers, followed by rolls or ball mills or edge runners, with final grinding by tube mills or grinding pans; or (2) stage crushing with coarse and fine crushers, followed by tube mills only.

In the first case, the combination of rolls or ball mills with an edge runner of the Chilean mill type would be designed to reduce the ore to approximately 30-mesh, and this would be further reduced in the fine grinding plant to 150 to 200-mesh. In the second case, a coarse product of about 1in. cubes maximum would be fed direct to the tube mills.

The tube mill is essentially a fine-grinding machine, and does its best work within fairly narrow limits—that is to say, its efficiency from a power standpoint will be greater in the second case cited above than the first. For practical purposes, however, the feasibility of satisfying the theoretical requirements must largely depend on the scale of operations. On a small plant the supervisory labour and all overhead charges must be kept down to the lowest limit, and it is usually necessary to sacrifice something in the direction of efficiency in order to save disproportionate charges in other directions. On the other hand, large-scale operations provide the right basis for reducing the comparative weight of overhead charges, whilst, contrariwise, losses in mechanical efficiency become increasingly important.

The development of the mining industry of the Witwatersrand in South Africa has very clearly proved that for the treatment of its low-grade ores there is no alternative to large-scale operations. The capital outlay essential to the establishment of safe development and ore reserve conditions calls for a big turnover to cope with the demands of capital amortisation, interest, and operating profit, and hence the installation of ore treatment plant may only be considered in that light.

The extracts from the official reports above cited do not hint even at modifications of present methods beyond the domain of crushing and grinding, but Mr. Wetzlar boldly suggests that the "all-sliming" principle is to be followed in the subsequent treatment of the ore.

Present Process of Gold Extraction.

In order to make the meaning of this suggestion clear, it must further be explained that present practice on the Rand includes the following operations:—

1. Coarse crushing.
2. Sorting.
3. Fine crushing.
4. Stamp milling.
5. Amalgamation process taking the entire pulp from stamp mill.
6. Classification and separation of coarse material to go to the tube mills.
7. Tube milling of coarse material and secondary amalgamation treatment of finely-ground products.
8. Separation of sand and slime.
9. Separate treatment of sand by percolation methods with cyanide solution.
10. Separate treatment of slime in cyanide solution by decantation method or filter pressing.
11. Extraction process for recovering the gold from cyanide solution.

The All-Sliming Process.

The all-sliming process eliminates:—

1. Stamp milling.
 5. Amalgamation process.
 7. Secondary amalgamation process.
 9. Separate treatment of sand.
 10. Separate treatment of slime.
- and substitutes for these:—

1. Finer crushing and increased fine grinding capacity.
- 5, 7, 9, 10:—

(a) Circulation of cyanide solution through the whole operation of fine grinding classification (so that, instead of erecting huge, cumbersome plants for water settlement of the classified products and subsequent treatment by cyanide, the process of gold solution begins in the fine grinding plant).

(b) Reduction of the whole of the ore to 150 to 200-mesh.

(c) Agitation of the pulp in suitable tanks.

(d) Separation of the gold-containing cyanide solution from the treated fine material by filter pressing.

The objects of the modifications are:—

1. Substantial reduction in capital outlay on plant.
2. Substantial reduction in labour and stores in operating costs.
3. Appreciable increase in recovery.
4. Improved control and checks throughout the operations.
5. Safety from theft.

These indicated improvements are the inevitable result of the alterations in practice above outlined, and their importance to the mining industry of South Africa is incalculable. But revolutions in cost of production are not to be expected from the mere elimination of the stamp mill, quite apart from the fact that many companies are unable to afford the change. That is the only one step in the programme. To achieve any really radical improvement, the whole economics of mining and metallurgy must be attacked.

In a series of short articles, the writers will deal with the salient feature of the mining and metallurgy of the Rand, in the hope that the issues above indicated may be helpfully elucidated. As far as possible, technicalities will be avoided, in order that the issues may be made plain to the non-technical reader.

[Since the above was written the Springs Mines, Ltd., has issued the following notice:—"Directors have decided in extending reduction plant to discard stamp battery and plate amalgamation and adopt all-sliming of ore and direct cyanide treatment. Decision come to as a result of metallurgical experiments, and will result in reduced capital expenditure, probable saving operating costs, increased extraction gold contents."]

Efficiency and Economy on the Mines of the Rand.

By L. P. Sheridan.

The majority of the Rand mines are to-day deep-level. Consequently, owing to pressure at depth, the actual breaking of the rock is an easier process now than in the early days of Rand mining. Hence mining is fast becoming a lost art on these fields. In the department of the actual drilling and blasting of the ore, little hope can be held out for a greater efficiency in the economic use of workers under the present system, *i.e.*, the gang system. Even if the colour bar were removed, the gang system would still survive, a semi-enlightened savage directing drill holes and firing same, instead of the white miner. In this respect it is very problematical if a lowering of working costs would accrue, when we review the psychology and mentality of the ordinary Bantu.

My experience of the latter is, that he merely attains an aptitude to act correctly through the repetition of the act, and not by reasoning the job out. To illustrate my point, I have had the same boss boy assist me for years in starting holes, and while he could approximately point out the correct place to start a hole as regards burden and maintaining a stopping width, he could never determine where the hole would end, *i.e.*, he would either go "heavy" or "light." The inability of the native to take an alignment and keep it is proverbial. I have tried them to take a sighting in a leading, but here they also failed. I have taken the direction of a socket by the orthodox fashion of washing out

Underground on a Rand Mine.

under a force of water, inserted the charging stick, started the hole 6 ins. away, but coming round again found the native deviating and likely to intercept the socket, although I left the charging stick inserted in the hole. I often marvel if the Mines Inspector came round, would he consider that the socket was properly plugged?

To my mind, efficiency can be improved and working costs lowered mainly through the more efficient and economic handling of the broken ore. Here the savage is in his element and primitive environment, the pick and shovel come natural to him. It is a department of mining that is to-day neglected. The men (to my recollection) who are retained as trammers and lashers hold their jobs through being good slave drivers.

The overseer in charge of a shovelling gang should be a good exponent of the navy's art, then he understands his job and can judge if efficiency is being "put in" by every individual of his shovelling gang. Mistakes one often sees are "boys" crowded in the working place without room to use themselves efficiently—old and broken shovels in use—these should be scrapped immediately they show impairment—the unskilled use of the pick—the raking motion not being imparted, picking out the oversize stuff before starting, this is a bluff of the native that "goes"; bad loading

platforms, and worse stope boxes. The modern system on the Rand is to stope out from level to level, leaving no drive pillars, so boxholing no longer prevails. Nevertheless, stope boxes and loading platforms must be installed—in very flat stopes the rails are laid upside the face. The construction of these platforms and boxes has always left much to be desired; instead of being a facility provided by the management for the removal of the ore, they are often a hindrance and obstruction.

The construction of a good stope box connotes that the excavation where the box is to be erected must be of ample dimensions. The stope boxes should be of a standard size and dimensions—the pieces should be interchangeable, and belted together, the members could be made on the surface excepting the bearers or legs, they can be easily assembled, and when required nearer the stope face can be pulled down and re-erected.

The size of a stope box is somewhat determined by the size of the kokopan. The ordinary mine car is 40 in. by 36 in., and stands 42 in. high on rail. Your box has got to discharge into this space and without spillage. To ensure this some designers taper the boxes, the height of sides 36 in., above which should be a strong brow-piece bolted through the stull pieces; this gives strength and rigidity to the structure. A double-box containing above features would be a potent factor in reducing working costs.

Another View Underground on a Rand Mine.

The principle of the Kimberley chute could be introduced in the stope box in this manner, that behind the stopping boards the deals should extend far enough to hold a load for the ordinary mine car, below the stopping boards the floor of the box should extend far enough to provide space for spillage to be lashed back into the box, and thus providing against fouling of the track. To avoid the boxes being damaged by blasting, a good plan is to leave sufficient stuff in and around the boxes to act as a shield against flying rocks. The angle of the floor of the box should be about 25 degrees; this provision prevents the entire weight of the column of ore pressing on the stopping boards; this will allow the boards being easily opened and closed. At will, either box could be used as a waste box, if it is desired to sort in the stope. The waste could be used for pigstyes and walling up the drives, as there are no pillars. Timbermen are often held up for waste for packs, many times having to drill and blast up footwall for their purposes. This sorting is also desirable from the recovery standpoint. The ordinary "underground" man sorts waste because to his mind it contains no gold. Few realise that this waste after cost of haulage and reduction goes to the dumps carrying a few shillings worth of gold to the ton. Many underground officials are out for a tonnage, and tram anything that will help to make up a ton.

If the process of gold recovery was more generally known and instilled into the Rand miner, I think that underground sorting could be introduced to advantage. The æsthetic side of man's nature revolts against the nullifying or destruction of a process that is grand and beautiful in itself, and thus I think miners could be induced to do sorting in their stopes. If 10 per cent. were sorted, a double enhancement of recovery accrues: (1st) the waste sorted out is not enriched by the gold-bearing cyanide solutions; (2nd) a longer period of treatment in the reduction works can be given to the mine-product.

In lashing in a flat place and development ends (drives) chutes and flat sheets should be more extensively used. In flat stopes on the Witwatersrand chutes are frequently installed, but the writer has not seen the use here of the flat sheet in drives. In Rhodesia I tried them to great advantage. When the end is lashed clean put down a flat sheet or deals, say four 9 by 3 fastened together by struts or stays (on bottom side, of course), far enough from the face to allow the bar being rigged—a foot clearance—to foot or hanging wall side can be allowed—lash the stuff from the "dressing down" on to the flat sheet; this will suffice to keep flat sheet being displaced by the cut and round going off. It is possible also to further provide against the above contingency by spragging the deals or flat sheet in position.

The advantages accruing from the above practice are many and self-evident. The shovel glides easily along the smooth surface, the piled up stuff runs to the centre to fill the void left after each shovelful, an end can be lashed clean in 100 per cent. less time and with 200 per cent. less fatigue to the shovellers, a larger shovel can be used; in fact, the ordinary coal shovel is suitable. The present shovelling from a rough floor is slow and laborious, the point of the shovel being obstructed by big pieces of stuff and the uneven surface of the floor. The above suggestion deserves introduction to these fields.

At the risk of being tiresome, I would reiterate that it is only through evolution that the native will become a skilled worker. The period of evolution may be centuries. Any immediate reduction of working costs under the present system must be achieved through using the native as an unskilled worker. The above specific suggestions, to my mind, would reduce working costs, in the number employed, the expense of material involved, lessen the laborious toil of the mines, and thus create a more agreeable atmosphere deep down in this old earth. I would suggest more continuity of supervision from the stope face to the residue

dumps. The different operations and phases in the winning of the precious metal are carried out in snatches as it were, little attention being given to co-ordination. The higher managerial staff doubtless possess, or should possess, the necessary qualifications for their respective departments; yet it appears to me desirable that an official should studiously watch the gold contents from the stope to the strong room, because leakages may occur at any point in the circuit.

Grain Elevators: the Official Explanation.

Tenders for the grain elevators have been carefully considered by the Railway Administration, and it has been decided, subject to the arrangements of certain formalities, to place the whole of the contracts, as detailed below, with Mr. A. W. Menkins, the tenders by that gentleman being substantially lower than those of any other firm or than the lowest tenders for each separate section grouped together. The work of construction of the grain elevators is divided into four separate contracts, as follows: Durban, terminal elevator, 42,000 tons storage capacity; Capetown terminal elevator, 30,000 tons storage capacity; 17 country elevators, group 1, of varying storage capacity; 17 country elevators, group 2, of varying storage capacity. It is stated that Mr. Menkins is a Canadian by birth, and has recently concluded work on a large terminal elevator at Globe Island, Sydney, where he was responsible for the execution of the whole construction work on behalf of the main contractor, the late Mr. Teesdale Smith, and that the successful contractor is a man of the highest qualifications in regard to elevator construction. There is reason to believe that almost the whole of the cost of the buildings, other than for structural steel, will be expended in South Africa, and by far the greater proportion of the machinery will be purchased in Great Britain.

A Visit to the Kilo Goldfield.

RHODESIAN'S TRIP THROUGH CENTRAL AFRICA—MR. H. C. FLETCHER'S INTERESTING JOURNEY.

Mr. H. Clarkson Fletcher, who recently made an extensive tour in Central Africa, has written for the "Bulawayo Chronicle" the following article, which gives an account of the celebrated Kilo goldfields in the Belgian Congo, and an interesting description of a journey through the heart of Africa.

A glance at a good map will show that the Kilo goldfields are situated in the north-east corner of the Belgian Congo, just west of Lake Albert Nyanza. They can be reached via Elisabethville and the Congo River to Stanleyville, but by this route one has a 42-day safari through the 750 miles of equatorial forest which lies between Stanleyville and Kilo. The quickest and easiest route is by rail from Mombasa to Lake Victoria Nyanza. Having received an invitation from the Government authorities to visit this little-known goldfield, I at once decided to make what looked like being a most interesting trip, and left Bulawayo for Beira in June, sailing by a very comfortable boat, the S.S. "Karoa," for Mombasa—a six days' trip—calling at Mozambique, Dar-es-Salaam

On the way to the Kilo Goldfield.

and Zanzibar. I found these old East Coast ports most interesting, especially Zanzibar with its old Arab buildings and mixed population of Arabs and natives, making it a perfect microcosm of the East.

Tanganyika Territory, with its principal port Dar-es-Salaam, swarms with its new Civil Servants busily engaged trying to restore it to its pre-war condition. Here the Indian appears to be taking the place of the white man very rapidly. Already the principal buyers at the Government enemy property sales have been mostly Indian firms, who have also purchased a number of the principal buildings, including the Kaiserhof Hotel at Dar-es-Salaam. Indian penetration on the East Coast is a very real thing. Trade of all kinds on the coast is dead, and will no doubt remain so until the Home markets revive. The Germans apparently fully realise the position and do not appear to be in any hurry to return to their old haunts. In fact, I was told that in many cases German firms have granted their agencies for a short term of years to some of the big Indian firms.

Kenya's £5,000,000 Loan.

I found Mombasa in quite a cheerful mood, Kenya Colony having just been granted a loan of five millions by the Imperial Government, and they are in hopes of getting a further four millions later.

Messrs. Paulings had secured a contract for a new wharf at Kilindini to cost £1,200,000, and I was told that another company was about to spend £500,000 on a wharf scheme at M'Barki.

At Mombasa I had the luck to engage a good Swahili Arab as my personal boy. This is absolutely necessary if one wants to travel with any degree of comfort and not to lose most of one's kit.

The journey by rail from Mombasa to Nairobi proved very interesting. The line, which for some reason was made metre gauge, is run entirely on the lines of the Indian railways. Fares and rates appear to me to be higher than in Rhodesia, and I should say 90 per cent. of the staff are Indians or Goans. Some of the locomotives burn oil fuel. Oil is also used by the Lake steamers. For meals the train stops and one feeds in well-run dak bungalows.

Prospecting in the Congo Free State.

Leaving Mombasa, the line reaches the mainland over the fine Macupa Bridge and gradually rises to the high veld. At Voi—104 miles—a branch line runs south to the foothills of Kilimanjaro, connecting with the Tanga Moshi line. At Magadi—283 miles—a branch line runs to the Magadi soda lake.

Big Game by the Line.

After leaving Simba—231 miles—a considerable amount of game was seen quite near the line. We disturbed giraffe, hundreds of zebra, wildebeeste, hartebeeste and gazelle of various kinds, the numbers increasing when we passed through the game reserve on the Athi Plains near Nairobi. The country from Voi to Nairobi reminded me of the veld round Mafeking—short grass with thorn trees dotted about, and open rolling veld.

Nairobi—330 miles and 5,600 feet—owes its position to being the original railhead, and it would appear that the Indian coolies who were imported to build the line have never left it, as in the Municipal area the Indians outnumber the whites by about nine to one, and a big Indian bazaar is situated in the centre of the town. The residential suburbs are well laid out on the rising ground around the town, and many charming houses and gardens are to be seen. Unfortunately I was there while a bad drought was on, and at a time of year when very little is seen of the sun owing to heavy clouds, but one always has to wear a helmet. I found the two hotels of the town very comfortable and far better than any we have in Bulawayo. Good building stone is obtained locally and there are a number of well-designed buildings in this stone, but the town itself does not compare favourably with Bulawayo or Salisbury.

The whole of the colony appeared to be suffering from a very severe depression, due to the state of the Home markets and the alteration of the currency from the one-and-fourpenny rupee to the 2s. florin.

Beyond Nairobi.

After spending a few days getting together kit and provisions likely to be required on Lake Albert and in the Congo, I left for Kisumu, on Lake Victoria. Leaving Nairobi, the line passes through some very fine scenery and reaches an altitude of 9,000 feet on Mau Summit. All kinds of game can be seen grazing close to the line. At Uplands—6,000 ft.—there is a very fine bacon factory, turning out most excellent bacon and hams. At Lumbwa there is a large creamery which supplies excellent butter to the whole of Kenya and Uganda. I understand that it is now decided to proceed with the construction of a branch line which, starting at Nakuru, will run north-west, tapping the Uasin Gishu Plateau; presumably it will terminate at Port Victoria on Lake Victoria Nyanza. Luckily I had to spend only one night at Kisumu, as the heat, even in the cool season, is very trying. Kisumu—3,700 feet—is the headquarters of the Victoria Nyanza Marine, the Government having a small dockyard there with dry dock and well-equipped workshops.

Next morning I sailed on the mail steamer Clement Hill (1,100 tons, twin screw), reaching Entebbe the next day. Entebbe is the headquarters of the Government, who evidently do not wish to encourage visitors, as the nearest hotel is 28 miles away at Kampala, the native capital. Leaving Entebbe that day, the steamer called at Port Bell, which is connected with Kampala by a railway 6½ miles long, and reached Jinja next day. Here, 20 minutes' walk from the jetty, brings one to the Ripon Falls, the source of the Victoria Nile. The falls are only about 20 ft. high, but a large volume of water falls through three openings in a rocky bar on the lake short and drops into a large pool swarming with big fish and crocs. From Jinja one takes the Busoga Railway, which bumps and rattles along 61 miles to Namagasali, on Lake Kioga. Here the Government have a slipway and shops for repairing the lake steamers and barges. Namagasali is a hot, unhealthy spot, and I was glad to sail the same day in the small stern wheeler S.S. "Speke," reaching Port Masindi—130 miles—next day. Lake Kioga is really a vast papyrus swamp with a few open waterways, which often get choked with dense sudd. What with the heat, mosquitoes and lake flies, I was very glad to get ashore again.

Calling on a King.

From Masindi Port the road runs to Masindi and on to Butiaba, a distance of 100 miles. Passengers and goods are carried in 2-ton Albion motor lorries driven by natives, and I found the trip full of exciting moments, especially when sliding down the 1,500 ft. escarpment to Butiaba on Lake Albert. Masindi, where one spends a night, is a pretty and well laid-out station boasting a District Commissioner and a native king—the King of Bunyoro—who lives in a well-built bungalow. I called, but the king was away, so I signed the visitors' book and left a card. Masindi has figured largely in the history of Uganda, Sir Samuel and Lady Baker making it their headquarters when they came down the Nile to the Albert Nyanza in 1864 and 1872.

Butiaba—2,000 ft. altitude—the headquarters of the Lake Albert Marine, will in a few years be quite an important place. At present it consists of a few bungalows for housing the white staff. From here the S.S. "Samuel Baker," a small flat-bottomed paddle steamer, drawing only 3 ft. of water, leaves twice a month for the Belgian ports on the west side of the lake, and also goes 150 miles up the Nile to Nimule, in the Soudan. I found the steamer ready to sail and, after a rough passage, we reached Kasenyi, on the Belgian side, next morning, having done only 65 miles. The boat was designed for the river and is quite unsuitable for the lake, which is subject to very violent storms. Even an ordinary breeze makes it necessary for her to run to shelter.

Kilo Goldfields.

Kasenyi I found to be a collection of wattle and daub huts placed close to the lake—an eight-mile plain covered with high grass and thick scrub extending to the foot of the escarpment, which runs the full length of the lake, rising to a height of from 5,000 to 6,000 feet. This place is very hot and extremely unhealthy, and one could not help feeling sorry for the few Belgian officials who are here running the post office, customs house, and the Kilo mines transport. I was glad to leave that afternoon by Ford lorry, and after an exciting climb we managed to reach Bagoro, at the top of the escarpment, where we spent the night. Continuing our journey the next day we reached the gold bearing district

Another View in the Congo Free State.

of Kilo and stayed at the Nizi Mine, where the quartz reefs are being crushed by two 4 ft. Chilean mills; and the Nizi River washed for alluvial. From the Nizi I safaried to Kilo—20 miles away—which is the headquarters of the district administration, the Governor having very kindly invited me to stay with him. After a few days spent in inspecting the various reefs and alluvial, I went on 20 miles to the Shari Mine and spent several days inspecting some promising looking quartz reefs and a small steam dredge working rich alluvial in the Shari river. The whole district is one mass of steep hills covered with a big depth of red (gold formation) soil, the hills running down to ravines filled with big trees and dense vegetation, through which flow small alluvial streams. It is a most difficult country to travel in, especially at the time of year I was there. In these latitudes there are two rainy seasons, and at the time of my visit the big rains were just over and the whole of the country was covered with 10 ft. elephant grass, so that no game could be seen except elephant, which could not be got at. There is no accommodation for travellers and no stores can be bought in the country. However, this did not cause me any inconvenience, as I was most hospitably entertained by the Governor and other officials at the various mines.

From Kilo the path to Stanleyville—750 miles—goes through the full length of the vast equatorial forest which stretches the entire distance. I discussed the idea of returning via Stanleyville and Elisabethville, but as it meant walking or being carried for 42 days through black forest, I thought better of it.

The gold-bearing formation appears to extend from Kilo through Mongbwalu, which is an important alluvial centre, to the alluvial diggings at Moto—180 miles. As no reefs have been developed there as yet, I decided not to make this trip and, after spending 14 days in the Kilo district, I returned to Kasenyi. I felt considerably relieved to see the lake again after tramping through so much hilly country and elephant grass under a vertical sun; luckily I kept very fit. From the top of the escarpment the lake, shimmering in the heat, presented a wonderful sight, and it was interesting to realise that one was on the spot where Stanley found Emin Pasha in 1888. Now an up-to-date wireless station transmits messages to Stanleyville.

Prince William of Sweden.

On reaching Kasenyi I found that I had to wait two days for the steamer, not a pleasant prospect, as I had no tent and the heat and mosquitoes were very trying. Luckily, the agent of the Kilo Mines very kindly let me camp in his office. The next day Prince William of Sweden and his party arrived on their way up the Nile to Cairo. He had been out since January with a safari of 400 porters shooting and collecting round Lake Kivu and Rewenzori for the Stockholm Museum. His party consisted of Count Gyldenstolpe, together with a taxidermist and cinema operator. Unfortunately, the Prince had been laid up for two months with spirillum fever at Irumu in the Congo, and was still hardly able to walk. They were anxious to get back to civilisation and were all very pleased when the "Samuel Baker" steamed in next day, and we sailed at once. Instead of returning direct to Butiaba we steamed round the south end of the lake, where we got a good view of Rewenzori, reaching Butiaba the next evening. From there we steamed up the White Nile 150 miles to Nimule, a Sudanese post on the border of the Soudan. Here the Prince was met by the Governor of Mongala and left at once on a six days' safarai to Rejaf, where he would catch the steamer for Khartoum, 10 days' steaming.

Down the Nile.

I found the trip up and down the Nile the most interesting part of my journey. Both Lake Albert and the Nile gave me the impression that one was in an earlier geological age. Here was the source of the mysterious river that had baffled explorers for centuries until Sir Samuel and Lady Baker, after terrible hardships, discovered Lake Albert in 1864.

The river swarms with large crocodiles and hippo, and elephant and various game are to be seen on the banks. It is said that the finest fresh water fishing in the world can be had in Lake Albert, which swarms with fish, the giant perch reaching 200 lbs. weight.

Commander Dugdale, who is in charge, very kindly made the trip more or less of a picnic, and we landed and shot when any game or duck were to be seen. The Prince had a special permit to shoot white rhino, but we only had time to spend one afternoon ashore in the Lado Enclave, or West Nile district, as it is now called. I ran into two, but was unable to get a shot owing to the long elephant grass. The only months for shooting in Uganda and the North-Eastern Congo are December, January and February, when the grass is burnt.

Returning to Butiaba, I left at once for Mombasa, travelling the same route by which I had come. On boarding the S.S. "Clement Hill" at Jinja, I met Monsieur Mazoratti, the new Governor of Ruanda and Urundi, who was going on leave. He had just handed over Kigoia to the British in exchange for these two provinces. We travelled together to Mombasa, and he proved a most interesting companion.

Kenya's Indian Problem.

Nairobi, where I had to spend five days, I found in a state of considerable excitement over the Indian question. Several large meetings had been held and feeling ran high. I was told that the Indians as a whole were quite satisfied with the present conditions and that the agitation was the work of a few extremists of the Gandhi type. It certainly made one think when I saw the members of the Nairobi Club playing an Indian team at cricket on the Sunday I was there.

Owing to climatic conditions, Indians and Goans are necessary for the development of both Kenya and Uganda, but under white supervision. If the Colonial Office gives way to the pressure that is evidently being brought upon it, and the Indians in Kenya are given equal rights with the whites, a great injustice will be done to the present settlers, and the effect will, in my opinion, be felt throughout East and South Africa.

My trip took me exactly three months, and I returned to Bulawayo feeling that, while we have lots of troubles of our own in Rhodesia, I was very thankful that my lot was not cast in a tropical climate under the Colonial or India Office.

Durban Roodepoort Deep.

Total profit for the quarter, £18,807. The improvement in the working profit of £10,418 as compared with June quarter was due to an increase in yield of 352 dwt., and to the price realised for gold being about 5s. 9d. per ounce higher. Development operations were further increased with satisfactory reef disclosures. The Board has decided not to resume shaft-sinking in the new Circular Shaft at present, but the matter will be reviewed again early in next year.

DAVIS - MADE

JOHN DAVIS & SON (DERBY), LIMITED.

THE DAVIS SELF-RECORDING STEEL TUBE MERCURY THERMOMETER OR PYROMETER

with Flexible Connecting Tube. Supplied in nickel-plated iron case, 9in. outside diameter, 8in. chart; arranged for 12 or 24 hours' record as required. For super-heated steam this instrument is provided with an iron protection tube 6in. long and screwed 3/16 in. gas, but extra length can be provided at an additional cost. The tube is filled with mercury or iron filings, but can only be used in a position where it can be suspended vertically, not horizontally or inverted. To specify Davis Thermometers is to take no risks.

Prospecting Activities in South-West Africa.

A report from Port Nolloth states that important mineral discoveries have been made by a prospector in that neighbourhood. He reports having found gold nuggets in the

A Typical Scene in the S.W. Protectorate.

Natives with Rotary Pan—S.W. Protectorate.

Richtersveld, evidently proving the presence of an alluvial gold deposit of importance. A large deposit of low grade copper was also discovered. The copper-bearing reef extends for eight miles and is intersected by bands of native copper. In this connection it might be interesting to note that copper has been worked in the neighbourhood of

Prospecting Activity in the S.W. Protectorate.

O'okiep for several years. This fresh discovery of copper probably has some relation to the existing known deposits. The minerals tantalite and molybdenite have also been found.

The gold was found six miles north-east of the Nemees Copper Mines. The copper belt is about fifteen miles south-east of Ansenkehr Drift, and the molybdenite deposit lies south of Kaboos. Tantalite was found in large quantities in Bushmanland.

Dwelling upon the development of South-West Africa, Mr. Alby Wilmot, at the last meeting of the S.A. National Union, gave some impressions gathered during four weeks' tour in that country. He mentioned the inadequate loading facilities existing at Walvis Bay, and how an improvement in that direction would aid in the development of the copper and tin mines, as well as in the export of marble. These remarks would possibly apply to conditions existing in the southern portion of that province where the above-mentioned discoveries have been made.

New Modderfontein: Quarter's Results.

The payable reef disclosures at the New Modderfontein during the quarter ended September 30 were as follows:— Main Reef Leader: Feet, 2,750; reef width, inches, 19; assay value, dwts., 37.1. Total profit: £440,000. Compared with the previous quarter the working profit shows an improvement of £84,792, due to the higher price obtained for gold, an increase in tonnage output of 17,000 tons, and a reduction in working costs of 1s. 7d. per ton milled. Development operations were further extended and continued to disclose satisfactory values.

Railways and Mines.

HOW LABOUR STULTIFIES PROGRESS.

From a Special Correspondent.

When I first drew attention to the fact that it wasn't very unlikely that twenty gold mines would have to close down, if the vagaries of currency depreciated the premium on gold, the only reply I got was that it possibly would be a very good thing. I'm afraid I am too fond of old institutions to accept the retort, but curiously enough the position of shareholders in gold mines is analogous to that of the public in railways. Both have their directors, and both shareholders and the public have infinite trust in their administration, and lastly, both the shareholders and the public get little return, and live on hope. There is an old mining saying that a rich mine makes a manager's reputation, and a poor one often destroys it. It's the poor one I have to deal with. To my mind, enough has never been said of poor mines and too much has invariably been said of good ones. I think that if the directors of companies here had made the public understand what some of these mines had to undergo during the last 25 years, they would have had greater consideration; as it is, I find intense ignorance of the real condition of things. Directors are primarily the servants of their shareholders. In this autocratic centre it has been a good deal the reverse. To be a shareholders' servant one would think that the shareholders would come first and have their first consideration, and if there was to be a struggle the shareholders' interests would come first every time. It applies just the same to the Government direction of railways, for there you would think the public came first. Unfortunately it is not so. The first duty of a director here is to have no unpleasantness and to avoid a fight or strike. The first duty of the Government is to keep the poor indigent and avoid offending labour, and thereby hangs a tale. Let us take one mining company. There are many, but I don't suppose they care for too much limelight. Take the Luipaardsvlei Gold Mining Company. It was floated perhaps twenty-five years ago. A low-grade mine of the first order. Pathetically, it has always worked just under the Plimsoll line of dividends. As a noble supporter of the Government, and labour, it has done extremely well. I daresay in its twenty-five years it has produced some five million pounds' worth of gold. Magnificent! During the War it was called upon to produce all it could to help the country with its gold, and again magnificently it did it. But of what avail all this noble magnificence and patriotism to its shareholders? Its shares are held in England, its board of directors are there; but for twenty-five years it has been nothing else but a great charitable institution for Government, labour, and its servants, for in all those twenty-five years its shareholders have received but thirty-seven thousand five hundred pounds, or seven and a half per cent. I wonder how the Labour Party would like to invest on those terms?

Recently the local chairman made a fight for fairer treatment; but, barring that, the majority of low-grade mines followed their bell wether and sacrificed their shareholders to the labour butcher without even a bleat of resistance. It's just the same with the railways. I have been told that it would pay the Government to give the railways to companies that would take them over for nothing. Personally, I don't think this necessary. Of course, if the public interests are to be continually sacrificed to labour and political sentiment, it is not unlikely that the losses may go on multiplying until we easily lose twenty millions sterling a year. If they do, then it might certainly be a wise thing to give them away, but, on the other hand, say they were investigated and showed a possible 25 or 30 per cent. margin on different working, might there not be plenty of inducement for capital to interest itself? Now I have grave reason to know what railway mismanagement can do, for I sold recently Grand Trunk bonds that cost 110 for 37—and this was due to its unagement and direction; and knowing this, and feeling the smart of the lash, I have no greater regard for the railway management of the Union than I have for that of the Grand Trunk, and if

the one can smash up I'm not certain that the other can't! If there is a margin on the change of management and the new concern could have a capital of, say, £150,000,000—to buy out the Government—fifty millions could be paid in cash and one hundred millions could bear 4 per cent. interest. The new concern would have to find working capital and capital to build new lines. Given that this could be done, look at the strong financial position of the Union. It could proceed with untold profitable propositions. Why, growing timber alone, it could give employment to its indigents and thereby improve the health and wealth of everyone of them. It could spread the waters of its great rivers over endless stretches. It could settle its waste lands, and for a generation or more have no financial fears. I don't say it can be done to-day. I haven't got the offer in my pocket, but I feel it is a sound commercial scheme. I have seen many railways in Asia, Egypt, and other places, financed by some of the cleverest men living, and I know of none they would sooner have handled than the railways of this Union. Of course, if the matter could not be handled with British capital, it would have to remain as it is; because, with their control would go the manufacture of all the material, and if they went into American hands, it would practically become a trade suzerainty over this Union. I am not sure that American capital would not bid for the project, but I doubt whether those that voted for the maintenance of the British flag at the recent elections would, for pecuniary and other reasons, vote to transfer the country's soul to America. Yet, if what we are going through to-day accentuates, measures will have to be found to remedy these evils. The mainstay of this country, I have to repeat, is gold. We cannot complacently view a large number of mines closing down, and we cannot view complacently the fabulous wages and moneys paid to unskilled labour, whilst the farmer with it all finds himself scabbing for a moratorium. As I have said, it is low-grade mines that have suffered and practically for a generation. They have not only been drained dry by Government and labour, but they have been starved for labour. The richer mines have always been able to arrange their labour so that immense unnecessary development has blazed their riches in the advertisement of untold millions; had some of the lower-grade mines had some of that labour, their unfortunate shareholders might have received dividends; but, being corralled to combine for the gain of the rich and the ruination of the poor, they have, as I have remarked before, followed their bell wether to their slaughter. I am afraid that unless a general amalgamation of the mines can be carried out and such measures as removing the colour bar, or a general lowering of wages for them, there is no salvation, and if there is no salvation, then the shrinkage before us will entail further heavy losses on railways, further heavy borrowings, further moratoriums, and, when too late, a revival of the idea of turning over the non-paying railways to companies. With reduction of rates must come reduced costs; labour must come down, all of it, from top to bottom. Deficiencies cannot be met with fresh taxation on the country's supporters; they cannot be met by continuous borrowing. Political cant must be swept aside, even if votes are to be lost. Let there be an honest attempt to meet difficulties. It may take a strong man to master the position. It is only a strong man that can, but it's no use hanging on the bell-rope when you can't ring up the price of gold. The time may be inopportune to deal with railway finance, it may be inopportune to deal with mining organisation, but it is not too late to deal with the economies, which must be tackled at once; and whatever the unpleasantness, facts and figures alone can give the solution. The public are dead tired of politics and the impossible demands of labour.

METALS, MINERALS, DIAMOND PIPES AND FISSURES.

I have invented an instrument to devine any reef lodcs of metals, coal, oil or water. I can guarantee to locate any of the above mentioned with my instrument.

For particulars apply to: "INVENTOR," Box 837, PRETORIA.

Improvements in Fluid Control for Rock Drills.

DESCRIPTION OF PROVISIONAL UNION PATENT No. 849-21.

The invention as shown in accompanying drawing consists of casing "N" bored out to form a cylinder in which there is a piston or plunger "B." The air for the rock drill enters through port "D," and when the piston is at the position shown in Figure 1, the annular space "C" communicates with the port "D1" on the side leading to the machine or rock drill. The water which is used through the axial tube of the machine or otherwise enters pipe "J," which has a constriction or Venturi contraction at its end, which is so arranged that it is opposite a throat at "J1." A port "L" communicates the water pipe pressure with the chamber "A." When the water is flowing it creates a slight vacuum in the chamber "A1." The pressure in the chamber "A" exerted by the water compresses the springs "I" and puts the piston in the position shown in Figure 1.

When there is no water flowing, the springs "I" have no compression against them from chamber "A," therefore will move the piston upwards, thereby shutting off the air supplying to the machine; also, if there is no free egress of the water through the rock drilling machine or other appli-

Section A-B

ances, the water will fill the chamber "A1" and will be at the same pressure as the water in "A," and the pressure exerted on the base of the piston "B" plus the compression of the springs "I" will again move the piston "B" upwards, shutting off the air. Should there be insufficient pressure in the pipe line to that laid down by the various Government regulations, it can be so arranged that the springs "I" will not be sufficiently compressed by the pressure in chamber "A," so that the annular space "C" does not coincide with the ports "D" and "D1," that there will not be an egress of air.

The claims of this invention are as follows:—

- (1) An apparatus so constructed by means of a Venturi tube or constricted area in pipe line, which causes a differential pressure when the water is flowing so as to shut off the air or motive power to a machine similar to a rock drill, when the water ceases to flow.
- (2) It will also perform the same function when insufficient water is flowing, or
- (3) Water at an insufficient pressure.
- (4) It can also be arranged by the size of constriction or jet at the end of tube "J" to pass any desired volume of water.

- "A"—Chamber on one side of piston "B."
- "A1"—Chamber on other side of piston "B."
- "B"—Piston.
- "C"—Annular ring in piston "B."
- "D"—Inlet air port.
- "D1"—Outlet air port.
- "E"—Packing material.
- "F"—Discs or plates to hold packing material.
- "G"—Nut drawing discs "F" together.
- "H"—End or cover plates.
- "I"—Spiral springs in compression.
- "J"—Inlet water pipe.
- "J1"—Outlet water pipe.
- "K"—Locknuts.
- "L"—Port communicating pressure in "J" with "A."
- "M"—Bolt holes for cover plates.
- "N"—Casing.

A letter from Mr. E. Fraser Jones, relative to the above, appears in our correspondence columns.

EDITORIAL.

THE GOLD QUESTION.

There is reason to believe that the articles in our last issue on "The Solution of the Gold and Currency Problem" and "The Real Value of Gold" have excited much interest and comment, and that they have had the effect of maintaining confidence in the future of the gold mining industry despite the daily weakening in the "premium." Without attempting to repeat or extend the arguments used last week, there are one or two points which may at this juncture be made clear. Thus it should be stated, for the benefit of several correspondents, that the proposal of the London *Statist*, quoted by us, was to make the £1 (paper) convertible into gold at a rate determined by the average level of the New York exchange over a selected period. The effect of this would be to establish a gold parity between sterling and dollars. At present there is none, as British currency is for all practical purposes not a gold but a paper currency. The gold content of the sovereign has obviously at present no influence whatever on the exchange. Here Professor Edwin Canan's latest view may be quoted. He writes: "A good

many of the present currencies, including our own, can easily be got back to their old gold values, and the inconveniences of getting back are, in my opinion, far outweighed by the advantages. Some currencies are too far gone for that, but may be fixed at a rate lower than the old one. Others are perfectly hopeless, and the sooner the world makes up its mind that they are destined for the waste-paper basket, the better both for the countries which own them and the outside world. They will then soon be replaced by sound currency. Historical experience is conclusive on this from the earliest times down to the recent case of Mexico." Professor Canan's view, which we have italicised above, is, it will be seen, practically the same as that which Mr. Samuel Evans expressed at the Crown Mines meeting, and in fairness to Mr. Evans, it should be made clear that he has not committed himself any further than has Prof. Canan. Again, a pointer to the fact that gold is coming into its own is contained in the following extract from Messrs. Samuel Montagu & Co.'s weekly letter dated 22nd September, 1921:—"The Chilean Minister of Finance has decreed that importation duties, warehouse rent, lighthouses and buoys and consular fines will have to be paid in the future in the following way: In July 65 per cent. in gold and 35 per cent. in currency, with the corresponding recharge, and an extra 5 per cent. in gold each month till January, 1922, when 95 per cent. will be payable in gold and 5 per cent. in currency. In February and onwards the total will have to be paid in gold coin." Italy and, we believe, Spain have issued similar decrees in the past month, at least as far as customs dues are concerned, and the net effect cannot but be for good. Every move towards bringing gold back into currency merits our unqualified support; and with the object of obtaining authoritative opinions we have discussed the issues raised last week with several heads of the industry. "Debasing the coinage," it will be noted, is the orthodox criticism of the well-known mining authority whose views are quoted elsewhere in our pages. We leave those views, which we admit are eminently reasonable, to speak for themselves this week, and shall endeavour to deal with them more fully in an early issue.

THE TREATMENT OF RAND ORE.

Metallurgists will be interested in two interesting letters in this issue from no less important authorities in their field than Mr. Alfred James, of London, and Mr. H. S. Denny. Mr. H. S. Denny's letter—to which we gladly give prominence—was evoked by some recent remarks of ours on the introduction of tube-mills; and Mr. James, dealing with some points raised recently in our columns by Mr. Andrew F. Crosse, recalls that we printed in our 21st Anniversary Number in 1912 a valuable account from his pen of the beginnings of the cyanide process on the Rand. We hope in an early issue to reprint some extracts from the paper by Mr. James. In the meanwhile it is noteworthy that the success of the "all-sliming" process at Springs—as already fully dealt with in these columns—has aroused great interest in London and even in America. Messrs. G. A. and H. S. Denny are contributing articles on the subject to more than one of the London papers, in which they voice their well-known views on cyanidation versus amalgamation. In his interesting contribution to our columns recently, Mr. Andrew F. Crosse made some pertinent remarks on the subject. Speaking of the importance of amalgamation, Mr. Crosse compared the neglect to utilise this process, wherever practicable, to the attitude of a shopkeeper who would refuse to deal with any but credit customers. Gold obtained by amalgamation, as Mr. Crosse remarks, is ready cash. In reviewing the recent history of the metallurgy of gold, we note that the *Mining and Scientific Press* says: "It is interesting to note how the mining industry has been swayed locally by fashion; and fashion insists, first of all, on the discarding of what is not strictly up-to-date. All-sliming was and is necessary in Mexico and elsewhere for silver ores, as at Kalgoolie for telluride gold ores, but it was and is unnecessary for the majority of gold ores. Amalgamation was applied during the secondary crushing of Kalgoolie ores because it was practicable and because grinding-pans were

used. Elsewhere tube mills were adopted, in which amalgamation treatment was not always feasible. In Mexico, on silver ore, amalgamation was only partly successful. Silver has a low specific gravity as compared with gold; it occurs mostly as the sulphide; amalgamation was not a logical procedure and was soon displaced by cyanidation. But no similar argument could be advanced in the case of the majority of gold ores; nevertheless, it is apparent that amalgamation has been abolished in many gold-recovery plants because of a desire to be up-to-date. There should be no question of antagonism between amalgamation and cyanidation in the treatment of gold ores. The experienced cyanide engineer will recognise that they are complementary processes, and that the ultimate metallurgical success of cyanidation, as judged by the amount of gold lost in the residue, will depend to a large extent on how great a proportion of the gold has been recovered by amalgamation before cyanidation is commenced. Our Californian contemporary puts the matter so well that we have no hesitation in quoting its conclusions. "There are instances where amalgamation is technically impracticable; in some cases its adoption is economically inadvisable because of the danger of theft. The two processes must go hand in hand, for they are complementary, the success of the entire operation being dependent on the efficiency of cyanidation, and that, in turn, being dependent on the efficiency of amalgamation. In these days of intensive search for something new, one is inclined to undervalue the well-tried aids to success. The scientific application of amalgamation is just as pertinent a study to-day as it should have been before the invention of the cyanide process. In conjunction with cyanidation it is the hope of a waning gold industry; the combination of the two processes will permit the exploitation of low-grade deposits as well as the expansion of the reserves in high-grade mines."

Notes & News.

Rooiberg Ceases Crushing!

In the latest quarterly report of this company it is stated that in view of continued losses due to the low market price of tin, the Directors decided to cease crushing operations at the end of September. As it is essential to keep the Mine dewatered, which necessitates running a portion of the plant, the treatment of alluvial sands and slimes continues, the revenue from which will assist in meeting the necessary monthly expenditure. Underground development will continue in the meantime.

* * *

America's Gold and Prosperity.

Accretions of gold in the United States continue, the extent of this phenomenon being strikingly emphasised in a New York cable received by the London office of the Guaranty Trust Company of New York, which points out that the ratio of reserves to deposits and note liabilities of the New York Reserve Bank has reached 84.1 per cent. More remarkable is the increase in the ratio of gold reserves to notes in circulation, which advanced from 116.7 per cent. to 134.2 per cent. The cable reads: "The Federal reserve system continues to show remarkable improvement, particularly in the New York district. A more remarkable increase occurred in the ratio of gold reserves to notes in circulation (after setting aside the 35 per cent. against deposits required by law), which increased from 116.7 per cent. to 134.2 per cent.—a new high record. There was a substantial improvement throughout the whole system in this ratio, though not so pronounced as in New York. Call money is available at 4 per cent.; four, five and six months' paper at 5½ per cent. to 5¾ per cent. Time money shows a strong undercurrent. Generally money conditions continue to show ease. The New York and Boston Reserve Banks have reduced the rediscounting rate for all class of paper from 5½ per cent. to 5 per cent. Another favourable feature is the strength of the Bond market, particularly in Liberty bonds, and the absorption of Railway Equipment obligations at 5.75 per cent. to 5.80 per cent. basis."

The Professional Chemist.

During the course of his presidential address read before the South African Chemical Institute (formerly the South African Association of Analytical Chemists), Mr. Joseph Lewis, M.A., D.Sc., dwelt briefly upon certain aspects of the chemical profession in the light of modern economic and social ideas:—The nineteenth century, with the birth of the factory system, witnessed the birth and growth of industrial organisations. The present century sees the birth and growth of organisation in every sphere of economic activity: teachers, Government employees, clerks, are all in process of organisation, and it behoves every chemist who desires to obtain fair recognition of his labours to co-operate in the organisation of his own particular profession. The attitude that association is undignified or unworthy of a scientific profession is still held by a few ultra-conservative, but with the passing of the present generation it will be as dead as the dodo. It is being realised that the day of the more or less hand-to-mouth chemist is passing, and that a sound scientific education is an essential foundation for workers in this branch of science. It is gratifying to note that in South Africa the Government has taken a step forward towards the improvement of the status and conditions of employment of its chemists. The subjoined list shows the basic scale recently adopted and at present in vogue in the Union of South Africa:—

	Per annum.
Junior Chemist	£400
Assistant Chemist	550
Associate Chemist	750
Chemist	900
Senior, on fixed scale	1,100

Wages on Coal Mines.

An interesting reply has been made by the S. A. Industrial Federation to the Chamber of Mines in regard to the adjustment of the wages of collieries' employees. In the opinion of the S.A. Industrial Federation, Department of Mining, the Chamber has not proved its case for a reduction of wages. With regard to the cost of living, the Department of Mining is unanimously of opinion that as the workers on collieries have never had a rise of wages commensurate with the cost of living allowance, it is unreasonable to ask for a cut in wages. With reference to leave pay, the Department is of opinion that the only equitable way of dealing with the matter is to give holiday-pay not according to the rate of pay in force at the time the holiday is taken, but based on the average rate of pay in force during the period in which the holiday is earned. If the Chamber proves in future that the economic condition of the coal mining industry is such as to justify a reduction of wages, the Department of mining is strongly of opinion that such reduction should begin at the top and not at the bottom. The statement suggests that if combined action were taken to bring pressure to bear on the Government to make it possible for the products of the country to be carried to the best markets, either coastal or inland, and so allow the coal industry to expand, much better results would accrue than by nibbling at the wages of the employees, which can only effect to an almost negligible degree the economic position mentioned in the Chamber's letter.

* * *

Transvaal and Rhodesian Estates.

The meeting of this company was held the other day in London. M. H. G. Latilla presided, and delivered a far-sighted address on the company's affairs in the course of which he did not fail to deal with the general financial position at the present time. He made a remark that ought to be stereotyped for reference, that "every investment tends nowadays to become a lock-up." He declared the policy of the board to be that of conserving the company's resources, which can be done without "either anxiety or misgiving." The principle producer at the present time is the Fred mine, as to which the chairman said the position is encouraging with regard to the immediate future, but

not without an element of doubt if one takes a longer view. The exploratory work has given negligible results, but there is a possibility that between the ore shoots a new ore body will be opened up in what has hitherto been regarded as unpayable ground. The Fred mine made a profit last year of £25,569, as against £27,892 in 1919 and £20,479 in 1918. The recoverable gold in the ore reserves is estimated at £150,000, and, taking gold at about its present price, the value would be nearer £200,000. The reserves are expected to show no decrease during the present year, but the known ore shoots appear to be diminishing in size and depth. The directors have in view the acquisition of a similar property. The chairman attached much importance to the company's chrome and asbestos interests at Umvankwe. He described the chrome deposits as the "biggest and richest yet opened up anywhere in the world." He is certain that sooner or later the demand for chrome will assert itself, and then the company will come by its own. Recent developments justify what he said. Asbestos is being regularly shipped, and the demand for it is world-wide. Special attention was drawn to Maraisdrift—on the Far East Rand. The chairman did not hesitate to say that it contains "the most profitable gold reef in the world to-day." Land sales have been diminished by the world-wide depression; but still, there was a good demand in the early part of the year, and sales were made to the value of £24,000. The company has large interests in Salisbury, the capital of Rhodesia, and, therefore, the future government of that territory deeply concerns it. The board are favourable to union with South Africa, and General Smuts has said that Rhodesia would be treated in a broad and generous spirit. Mr. Latilla mentioned the curious fact that there are as many shareholders in the company as there are voters in Rhodesia. The constituency is widely scattered, and the whole white population only consists of 10,000 people.

* * *

A New Type of Concentrator.

Many attempts have been made by inventors to devise a machine for separating the waste matter in old mine dumps and forming a concentrate sufficiently rich in gold content to repay extraction. Among recent inventions is a machine of the rotary type which aims at effecting the elimination of all material which from its fineness may be regarded as having only unpayable gold contents. The principle of the arrangement is that of a trommel, and the machine when set up is not unlike the tumbler or tippler used for dumping rock or blueground in the mines. A framework made of ½ in. steel angle iron rivetted together forms the support for the trommel. This trommel is circular in shape, about four feet in length, and rotates on an axle through its centre. The axle in turn rests on two trunnions, one at either extremity. A small gear is so arranged on the principle of a rack and pinion so as to enable the trommel to be turned by direct or secondary action from the source of power, steam or electricity. The rate of rotation depends on the quantity of stuff to be treated per hour. With a three feet diameter trommel and a 400 mesh screen it is estimated that 4,000 tons of residues per day of 10 hours can be treated. The machine is operated in the following manner: The plant is erected at a point below the dump to be treated, water pressure through nozzle is applied to the dump, and the resulting pulp sand and water with slimes is conducted by launders to the top of the trommel. A valve regulates the flow of the pulp from the launder over the trommel, which is revolving at a certain speed. A separation of all grains of a size greater than the mesh used to cover the trommel is made in this way. The fines are allowed to run to waste. The sands or concentrates are now dealt with by means of grinding pans or tube mills, and the resultant slimes run into cyanide tanks for treatment in the usual way. It will be seen that its action is very similar to that of a spitzkasten, with this difference that it effects the separation of the particles by sizing, and not by specific gravity. The inventor claims that the machine has proved efficient in practice when in use on a local dump. Should this claim be substantiated commercially, it would result in the recovery of a considerable amount of the gold now lying in the residues, as a one dwt. assay value in the dump will give a very handsome return on the operating costs of the plant.

The Drop in Prices of Mine Supplies.

To support its contention that prices of mine supplies are falling, the Mining and Scientific Press of San Francisco publishes the following comparative list of prices in August of this and last year. Nearly all these figures, it is stated, were obtained from the purchasing agent for an important group of mines that has its main office in San Francisco; they represent actual purchases made during August, 1920, and August, 1921, and are accurate:—

	August 1920.	August 1921.	Decrease Percent.
Rock-drills, a standard sinker...	\$170.00	\$170.00	0.0
Carbide, per ton	155.00	155.00	0.0
Blacksmith coal, per ton... ..	34.00	31.00	8.8
Drill-steel, hollow round, per lb. ...	0.19	0.16½	13.2
Fuel-oil, in tank cars, per bbl. ...	2.20	1.60	27.3
Packing, a standard kind, per lb. ...	1.05	0.92	12.4
Mine cars, a standard car... ..	189.00	134.50	28.8
Rail, in ton lots, per 100 lb.	5.00	3.25	35.0
Pipe, black, standard 2½ in.	41.15	28.20	31.5
Powder, 40% gelatine, ton lots ...	21.25	19.00	10.6
Fuse, standard brand, per M ft. ...	18.78	16.66	11.3
Caps, No. 6 per M	10.20	8.50	16.6
Mine timbers, Douglas fir	36.00	23.00	36.1
Copper wire, weather-proof, per lb. ...	0.42½	0.20½	51.8
Wire rope, plow-steel, 6-19, per ft. ...	0.29	0.25	13.7
Rubber belting, a standard brand, per ft.	0.95	0.71	25.2
Average decrease, %... ..			20.14

With respect to rock-drills it is said that the peak was reached in 1919, when prices averaged about 70 per cent. higher than in 1913. As compared with most equipment of similar character, the increase was moderate; this fact is advanced by manufacturers as justifying the retention of prices to-day that are identical with those of 1919 and 1920; nevertheless it is said that the diminished cost of the alloyed steels and other semi-finished materials and of skilled labour required in the manufacture of rock-drills will result in a lower schedule of prices early in the coming year. Carbide is the only other item that has remained stationary.

* * *

Occurrence and Utilisation of Minerals.

The Mineral Resources Committee of the Imperial Institute has arranged for the issue of this series of monographs on mineral resources in amplification and extension of those which have appeared in the bulletin of the Imperial Institute. The monographs are prepared either by members of the Scientific and Technical Staff of the Imperial Institute or by external contributors, to whom have been available the statistical and other special information relating to mineral resources collected and arranged at the Imperial Institute. "Silver Ores," by H. B. Cronshaw, B.A., Ph.D., A.R.S.M. Price, 6s. net. Publishers: John Murray, Albemarle Street, London, W. Chapter 1 of the book deals with silver ores, their occurrence, character and uses. The statistics arranged in the form of numerous tables and graphs form an interesting study of the production and value of silver from the year 1860 to 1919. The properties and uses of silver, its various ores, and metallurgical treatment of the latter, are briefly described, and form a fitting introduction to the more detailed descriptions which follow. Chapters 2 and 3 deal with the sources of supply of silver ores in the British Empire and foreign countries respectively. As a producer of silver, South Africa does not rank high, due chiefly to the fact that only lately have attempts in that direction been made. "Petroleum," prepared jointly with H.M. Petroleum Department with the co-operation of H. B. Cronshaw, B.A., Ph.D., A.R.S.M. Price, 5s. net. Publishers: John Murray, Albemarle Street, London, W. Owing to conditions brought about by the war, and maintained after its termination, the uses of petroleum and its products are more and more being felt. This led to the publication of this summary of the petroleum resources of the Empire. The publication deals with the characteristics, occurrences, mining, refining and uses of petroleum. Diagrams of production are also shown. Chapters dealing with sources of supply in British and foreign countries are given. South African activities in oil production resulted chiefly in negative results; hence very little space is devoted to this country therein.

The Mile at pre-war cost

All users

Apex Mines Quarterly Report.

The tonnage of coal sold for the three months ended 30th September, 1921, was 49,014 tons. The working profit for the same period was £5,797. The capital expenditure was £138.

The Lonely in September.

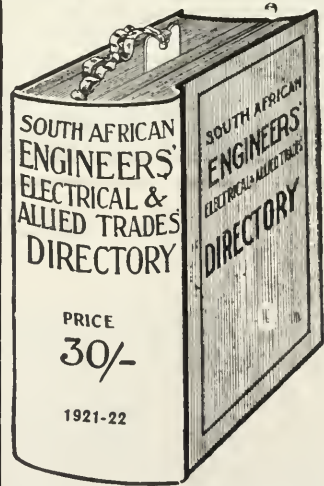

The following are details of the Lonely Mine output for the month of September, 1921:—Mill ran 678 hours; crushed, 4,950 tons; fine gold recovered, 1,525.123 oz.; value, £6,412 16s. 6d.; slimes treated, 4,950 tons; fine gold recovered, 2,893.424 oz.; value, £12,168 11s. 8d.; total fine gold, 4,418.547 oz.; total value at 84s., £18,581 8s. 2d.; profit, £6,047 5s. 1d.

Surveying and other Scientific Instruments.

A presentation copy of the latest edition of the catalogue of Surveying and other Scientific Instruments by T. Cooke and Sons Ltd., has just come to hand. It includes all such apparatus as is in ordinary use among engineers and surveyors. Through their catalogue they take this opportunity of reintroducing themselves to the older Members of the Profession, so many of whom are numbered among their clients, and at the same time desire to offer their best services to the younger generation.

For the information of the latter they state that their record of service now covers 80 years, and they claim that their reputation as Opticians and Scientific Instrument Makers is second to none.

The current edition of this price list is now about to go to press, and will undoubtedly be obtainable from their South African agents.

Letters to the Editor.

THE REAL VALUE OF GOLD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Permit me to further trespass upon your courtesy to finally reply to Mr. Blenkinsop, who, in answer to my criticism of his (and Mr. S. J. Speak's) proposal to permanently raise the price of gold to six guineas per fine ounce, evaded the issue. From his last letter it would appear that what is meant is that gold is to be converted into a greater number of coins per ounce fine than at present; in other words, as I have already pointed out, 42,416 present-day sovereigns shall be converted into 63,000 coins, and your readers are asked to believe that each of the 63,000 coins (not guineas by the way) will purchase as much commodities as each of the more valuable 42,416 coins (sovereigns; verily, a "new way to pay old debts.") Last week I put the question: Why fix the new price at £6 6s. 2 and I have not been answered. Perhaps you, sir, will enlighten me. *The Statist*, from which you so liberally quote, proposes to so debase the sovereign that the ounce fine will have a face value of £5 13s, this being arrived at on the basis of New York exchange for September, which was an average of 3.656 dollars to the £; but, should this system come into operation, how will it affect our indebtedness to America? Shall we be able to get New York to accept a coin of 84.892 grains fine in exchange for 3.656 dollars in place of the 113 grains fine of the present sovereign? Evidently *The Statist* does not think so, as it admits that the question of debts owing abroad must be postponed. Finally, as a complete answer to the proposal to debase our gold currency, allow me to refer you to your own quotation from the *Spectator*, which reads, *inter alia*, "After all, it does not really matter whether we give few or many tickets for a thing. What does matter is that they should always be of equal exchange value for the same commodity and should be for a perfectly stable and trustworthy standard against which we can measure the fluctuating values of commodities."

Yours obediently,

LEWIS WATKINS.

[This matter is dealt with in our leading columns.—Ed.]

THE BEGINNING OF THE CYANIDE PROCESS ON THE RAND.

To the Editor, *S.A. Mining and Engineering Journal*.

Dear Sir,—There would seem to be some discrepancy between your original accounts of the introduction of the cyanide process and that published by you in your issue of June 18, 1921.

Mr. Andrew F. Crosse evidently cannot intend his article to be taken seriously: he does himself the injustice of stating that in 1891, when gravity percolation tailing plants were successfully at work at the Robinson and other mines, and were making fame for themselves by their successful work, he still "had honestly to confess that" he "knew nothing about the solubility of gold in alkaline cyanide."

Two interesting papers presented in recent years to scientific institutions have been prejudiced by the inclusion of inaccurate hearsay accounts of the beginning of the cyanide process on the Rand. It was with the idea of presenting to the future historian an authoritative statement of the subject that, availing myself of your invitation, I contributed to your twenty-first anniversary number in September, 1912, an article based on the official records.—Yours faithfully,

ALFRED JAMES.

[We hope in an early issue to reprint portions of the article in our anniversary number by Mr. Alfred James.—Ed.]

ROCK DRILL CONTROL.

To the Editor, *S.A. Mining and Engineering Journal*

Sir,—With reference to your current issue of the SOUTH AFRICAN MINING JOURNAL, I notice you publish a description of a system of rock drill control actuated by water flow. I herewith enclose a description and a tracing showing an apparatus, which I have recently patented, to accomplish the same object. (The description is printed elsewhere in this issue—Ed.) The principle of operation depends upon what is known as a "Venturi contraction" in a pipe line, which causes a differential pressure when water is flowing at different points of the same pipe line. It may interest your readers to know that this seemingly paradoxical hydraulic law was known even to the ancient Romans, but first established as a scientific fact in 1796 by the Italian philosopher, Venturi, then professor of physics at the University of Bologna. This law is explained at length in the ninth edition of the *Encyclopædia Britannica* under hydro-mechanics, paragraphs 7 and 28; but, briefly, it is that water flowing through a pipe of diminishing area loses the pressure which it exerts laterally as it gains in velocity, so that at the throat of the Venturi tube, which unites two truncated cones, it is only a question—within certain limits of pressure—of obtaining a sufficiently high speed in order to entirely lose all pressure and exert instead a vacuum. Conversely, water flowing through an expanding cone loses speed and gains head; consequently, the Venturi tube produces a great depression in the hydraulic gradient at the throat, but restores it to practically its original level at its outlet. This apparatus needs no alteration whatsoever in the rock drill, as it can be placed at the pipe line end of the air hose, and the air and water hoses for the machine connected on to it. This apparatus will cut off the air supply to the machine when:—

- (1) There is a choke in the tube, which prevents the water from flowing;
- (2) When insufficient water is flowing;
- (3) Water at an insufficient pressure;

and it can also be arranged, by the size of the constriction or jet, to pass any desired volume of water. I trust you will have an opportunity of allotting space to have this inserted in your next issue.—Yours faithfully,

E. FRASER JONES

THE INTRODUCTION OF TUBE MILLS ON THE RAND.

Mr. H. S. Denny Sets Out the Facts.

To the Editor, *S.A. Mining and Engineering Journal*.

Dear Sir,—In your issue of September 3, page 1759, you state that I advocated the introduction of tube mills "to reduce to a slime the concentrate produced by vanners. It was not till May, 1904, that the first tube mill working in circuit was started on the Glen Deep Mine, followed by one for crushing vanner concentrates on the New Goch a few days later."

I hasten to correct the impression that is given by this statement.

The machine used for the reduction of vanner concentrates was a Krupp ball mill (facing page 154, "Proceedings of the Chemical and Metallurgical Society," South Africa, 1903 and 1904), and this recommendation had nothing to do with the tube mill advocacy.

On page 221 I stated:—"Firstly, I do not believe in vanners, and we only use them at the New Goch Mines because they were already installed when we took it over, and we have had to make the best of a bad job. The cost of concentration alone with this method was, in June of last year, £560, and, as shown in my paper, the total cost of concentration and treatment of concentrates, taken over a period of five months, amounted to £6.12 per ton. Truly a monstrous cost! The very fine rich concentrates caught

by vanners offer no great difficulty to the ordinary cyanide process, and therefore it would seem possible that, as spitzlutte will separate the bulk of the heavy product, we only require hydraulic classification, with subsequent sliming and rapid cyaniding of the product."

We only used the vanners because they had been installed in the Goch plant before we took it over, and we threw them out as soon as we conveniently could.

The tube mill for the Goch Mine was installed for the purpose of regrinding a hydraulically separated coarse product from the mill pulp in order that the capacity of the mill might be increased, and the extraction improved as shown in the following extract (page 171):—

"One feature of milling which has occupied our attention in connection with the group of mines with which I am connected is that of coarse grinding to, say, 200 mesh, and returning everything over 300 mesh to be recrushed in the mill, the balance going forward to the cyanide treatment direct. This would undoubtedly largely increase the capacity of the mills, but amalgamation would not be so good as with fine crushing. With subsequent sliming in a tube mill and *secondary amalgamation* it may, however, prove to be practicable."

*This was the first suggestion it was a secondary amalgamation process.

The Goch tube mill was ordered long before the Glen Deep, and it arrived on the fields long before the Glen Deep Mill. At the time that I advocated the tube mill, John R. Williams, who I understand was subsequently responsible for the Glen Deep Mill, said (page 215):—

"May not finer crushing be one of the necessary variations?" to which I replied: "I think not. *Fine grinding* is what I pin my faith to."

Replying further to Mr. Williams, I said:—"He states that there is every special differentiation of feature in the Witwatersrand ores, from the Robinson to the Heriot, necessary to warrant extraordinary variation in the mesh of mill screening, and he cites as an instance the Ferreira Deep, where, after many experiments, 1,000 mesh has been finally adopted as the most suitable. I feel quite certain that in the case under notice, *with the assistance of a simple classifier*, after the mill pulp has passed over the plates, *and fine grinding and cyaniding of the heavier product*, the necessity for reducing to 1,000 mesh in the mill could be avoided, whilst *simultaneously the mill capacity would be largely increased*, and the *total extraction quite as high, if not higher.*"

The Glen Deep Mill got to work a few days before our mill at the Goch, but it was put in precisely for the purpose advocated and set out as per extract taken from page 171. The fact that the Glen Deep Mill got to work a few days before ours was a disappointment to us that was largely compensated for in the knowledge that our proposals were being adopted, and it had no bearing on the original advocacy of the use of the tube mill.

Figures were given proving finally that there was no difficulty in recovering a high extraction from slimes and finely ground concentrates in a very short time. We had not at that time proved that finely ground sands would give the same results, but we had no doubt on the point and we were then conducting experiments to prove it. On page 170 I said:—

"Assuming that the experiments on sands are successful, the outcome is to show that *in one operation, our sands slimes and concentrates can be treated together* in a very much simplified form to that obtaining to-day. Personally, I believe that on most of our ores here the efficiency of a stamp mill reaches its limit at between 200 and 300 holes to the square inch, and that from that point the further reduction of the ore is more economically and successfully accomplished by *means of attrition, such as that obtaining in a tube mill.* This is to say that the cost of reducing from a 300 mesh to a 40 000 is done at considerably less cost by attrition than percussion."

On page 158 I stated:—"I confidently look forward to the time when the huge plants, necessitated by the prolonged percolation methods in vogue to-day, will give way to something very much more simple and effective, both

in design and operation, and although, as elsewhere shown, our experiments on the short treatment of sands have not thus far resulted in a success that would justify too much optimism, I cannot but feel that on an ore offering to the metallurgist so few difficulties as that of the Witwatersrand, *the time is not far distant when the present difficulties will be overcome.*"

*Within three years a great deal had been done at the Meyer and Charlton.

On page 226 I stated:—"In West Australia, in using flint mills, it is stated that the larger percentage of the product will pass through a mesh of 220 holes to the linear inch. No screens are used on the machine and, once it is set, that product must be constant. In practice the slimes are passed through a classifier after leaving the flint mill, and anything coarser than about 200 holes to the linear inch is returned to the flint mill. *Our flint mill at the New Goch Mines is being set up to give results on these lines.*"

This extract shows very clearly the purpose for which the Goch Flint Mill was being installed.

On page 224 I stated:—"The tendency appears to be to slime everything, and treat the pulp after amalgamation by a simple agitation method in one operation."

On page 219 I stated:—"Despite Mr. Williams' statement, I venture to predict that he will before very long find that *sliming of his heavy products in flint mills*, with subsequent treatment by agitation—as suggested in my paper—is the correct treatment."

On pages 216 and 217 I stated:—"In the detailed results of many interesting experiments on "Witwatersrand concentrates, sands and slimes, carried out carefully and over a long period on a scale considerably larger than any laboratory work, *I do claim* to have given the first complete set of figures bearing on the *successful application of this principle to our ores*, and although the flint mill for *regrinding is glibly spoken of as a matter of common knowledge*, I know of no metallurgist on these fields who publicly advocated its use or submitted details of it prior to the figures given by me in July. The fact that the principle of fine grinding was recognised and referred to some years ago is substantially nothing. The important point is to prove its advantages to ourselves, and in this respect I believe I have been in some measure successful. We are more interested in what is being done in the way of actual work in the present than in references made in 1897, which were not turned to any practical advantage. *To-day there is more than one flint mill actually erected on the Rand for the specific purpose of regrinding classified products from the mill, and this is tangible evidence that the whole question of sliming by this means is to be put to practical proof at once, and I predict* that in the next few years the *flint or tube mill* will be as well known as the stamp mill, but for the cause of this innovation we have surely to look nearer home than to references made in 1897. In all due modesty, I think *I may fairly claim* to have given some impetus to the movement."

*This was in reply to the discussion on my paper nearly a year after the original paper was read.

A glance through the above extracts will serve to very clearly show *the purpose for which I advocated* the tube mill and briefly stated it was *firstly to get increased stamp duty and higher recovery*, with the suggestion that *eventually we should do away with the separate treatment of sands and slimes and adopt the "all sliming" process.*

In a joint contribution by Mr. G. A. Denny and myself to the South African Association of Engineers, we were able to give actual results from the Meyer and Charlton and Goch plants showing the advantages of circulation of cyanide solution, fine grinding and tube mill, etc., and we then unhesitatingly confirmed, as the result of the work done on these two mines, the advocacy of the "all sliming" process.

I must apologise for taking up so much of your space, but I feel sure that in the circumstances you will be only too glad to correct the impression that might be gathered from the extract from the journal referred to in the opening paragraph of this letter.—Yours faithfully,

H. S. DENNY.

The Week in the Sharemarket.

ANOTHER QUIET WEEK—LONDON MARKET WAITING—BUSINESS STEADY, BUT VERY RESTRICTED.

Business continues to be very quiet and restricted. Nothing yet seems to be known in regard to the ex-enemy share question, and the London market is unsettled by the news from the Continent and the Irish crisis. The gold "premium" continues to sag despite the views held in some well-informed quarters that something may yet be done to secure a permanent increase in the price of gold. On Thursday, on High Change, business was a little better and prices were generally steadier under the lead of Gedulds, which were 1s. higher at 47s. 6d. bid. The Options were about 1s. 3d. higher at 8s. sales. Van Ryn Deeps were 6d. higher at 69s. 6d. buyers after business at 69s. 3d., and State Mines were harder at 79s. sales. New State Areas, though lower on balance, were above the lowest price of Wednesday at 21s. 3d. sales and buyers and were again largely dealt in ex London. Most of the other leading stocks were a shade harder without business. Coronation Syndicates were bought at 6s. 3d., Randfontein Estates at 14s. 3d. S.A. Alkali were 1s. lower at 14s. 9d. and 14s. 6d. sales. P.P. Cements and Transvaal Silvers inactive. Nothing was done in diamond or tin shares, and Union Loans were also passed without business. The only bright spots in the market are the facts that the September quarter profits, owing to the "premium," ensure good dividends at Christmas, and the excellent development in the No. 7 shaft horizon at the Geduld. This was so well received in London that the shares appreciably firmed up. The week's fluctuations are as follow:—

Union Mineral Statistics.

The following abstract is taken from the statistics for the month of September, issued by the Department of Mines and Industries, for the Union of South Africa:—

	Output. (ozs.)	Value.
Gold	692,356	£2,940,942
Silver	72,332 (carats)	12,659
Diamonds	53,080 (tons)	201,048
Coal	990,315	£20,469
Copper ore and conc.	96	3,699
Tin conc. and metallic	151	12,059
Other base metals	—	£9,176
Total	—	£3,600,552

Gold value calculated at standard rate of £4.24773 per oz. fine.

Gold shows a decrease in output amounting to £98,471 in value under the output for August. Silver, diamonds and tin show an increased output amounting in value to £1,713, £25,440 and £4,712 respectively. Coal shows a big drop amounting to £27,579 in value, while the output of base metals has also fallen by £1,231. On the whole the value of the mineral production for September was £91,717 less than that for the previous month.

Foreign Exchange and American Trade.

By P. J. Stevenson, American Trade Commissioner.

The upset commercial balance of the world is emphasised by the present foreign exchange situation, which is of importance to the merchant and trader. Nowhere in the world is it of more practical interest than in South Africa. For here the exchange has a two-fold bearing. In the first place, it has furnished 23.1 per cent. more income to the gold mining industry in the first six months of 1921 than the standard rate would have yielded. It needs no elaboration to explain what the gold "premium" means, for from that 23.1 per cent. comes a large share of the working profit of the industry, which means so much to the agricultural, commercial and industrial life of South Africa. And further, it keeps going many properties which otherwise would have to face immediately the question of closing down, with all of the attendant hardships. In the second place, the merchant or manufacturer who imports from overseas is vitally interested in foreign exchanges.

It is often said that the American business man or banker is making a great profit out of exchange. Such a statement hardly needs refutation. The exporter sells for dollars and he gets not a penny more when the local buyer has to pay 5s. 8d. for a dollar than when the price is 1s. 1½d. He gets one dollar in either case. Neither does the banker, American or local, get it. The banker is buying and selling exchange at the same time. If the price of dollars in terms of sterling has advanced and it is necessary to pay more sterling for a dollar, the banker must pay the higher price just the same as if exchange were wool or any other commodity. Perhaps the most convincing fact, however, is that the American manufacturer, exporter and banker has been seeking relief from a fluctuating exchange, just the same as the British and other nationalities have.

There are others that think speculation in exchange has been an important factor. It would be foolish to deny that there has been gambling in exchange on a large scale. Temporary changes, a few points up or a few points down, may have resulted, but speculation has not depreciated sterling, or any other money. There is always going on, even in normal times, a large volume of intelligent speculation that serves to balance the price of many world commodities such as wool, wheat, grains, and even exchange. But the volume in New York is probably not one-tenth of what it is in London.

Neither can the exchange problem be solved by any plan of international co-operation, for there is no "short-cut." The most clever financiers of England, the Continent and America have given their best thought to the problem, but to no avail. There is no way of making the franc or mark worth its normal value except by giving it that value intrinsically. Gold is still the fundamental money of the world. Exchange is still merely the gold value of one currency in terms of the gold value of another. It is quite true that unbalanced trade and disorganised credit have their effect, together with speculation and other factors, such as political developments, that result in temporary changes, but the fundamental factor is the gold value of a country's currency. And it should be emphasised that London, as the most financially-wise community in the world, has more to do with estimating the value of the franc, lira, mark, dollar and even of the pound itself than has Paris, Berlin or New York.

From a study of world price exchanges, it is a fair conclusion that the world is still buying and selling goods and commodities upon a gold-price basis. Trade balances are not being settled in gold, nor are many countries as yet attempting to put their currencies on a gold basis, but it is evident that prices the world over have a close general relationship to what local currencies are worth in exchange for gold.

In fact, it is just this relationship that makes American prices competitive in spite of the high quotation of the dollar compared with other moneys. In many instances buyers in other countries can buy more cheaply in the United States than elsewhere, notwithstanding the exchange situation. It has been found that American goods on landed costs have actually been cheaper, grade for grade, and quality for quality. It is admittedly not true in every case. The Continent has bought American cotton more cheaply in England than in America, while Germany has been underbidding the world, without regard to exchange conditions, in conducting her campaign for export trade. America has this advantage, that as other currencies tend to improve, it is going to be desirable to buy in dollars because they will otherwise be faced with the necessity of buying other moneys on a rising market. In fact, it is even now just as cheap to buy in dollars low gold-priced goods in America as it is to buy deflated currencies cheap and pay out correspondingly more to get the same gold-priced commodities. It is easy to look at the high-priced dollar and to forget that behind it are really low-priced goods. The idea that America's trade with South Africa or any other part of the world is to be killed by exchange has no foundation in fact.

There is too much talk about "rectifying" the foreign exchanges. Take the mark as an example. Germany is said to have had recently 80 billions of paper marks. There was 1½ cents' (¾d.) worth of gold to the dollar back of it before the Reparations demand. On April 21 Germany's money had an international value of 1,120,000,000 dollars. To "rectify" the mark means putting 17,944,000,000 dollars of value in that paper money and further valorising a mass of credits and book assets, besides which the 18 billions is probably small by comparison at 15 times its present valuation! If it were possible of achievement, it would produce an economic catastrophe.

It should be plain that a nation cannot do a paying business by selling its products on the cheapness of impaired money. There would be no wisdom in having a sound currency if trade could thrive on cheap paper money. Germany must either raise prices to meet the loss or she is going to find a hole in her balance-sheet. Germany may be using the Governmental control of prices, exchange, and commerce to sell at the cost of production or below. Then the loss is absorbed by the whole nation. Some offerings have been made merely to disorganise foreign markets. Goods have been sold in sterling or other currencies in expectation of a rise in marks. There has been some selling of goods as a result of forced liquidation. There may be a combination of these possibilities in combination with genuinely low-cost production and a small margin of profit. It is to low production costs that English and American producers must look, rather than to an artificial exchange price.

Summarising the question, foreign exchange is the result of definite causes. It is not a separate, detached field of finance. Fundamentally, it reflects gold values, but also trade balances and the other factors taught by the economists. Certainly there is no cause for alarm over German competition, for if depreciation were a genuine aid to building up trade, Poland and Austria and Russia would far outstrip the rest of the world.

MINES DEPT. EXAMS.

CERTIFICATES AWARDED INSTITUTE.

OVERSEERS' CERTIFICATES (Metal).

Our Passes	Rest of S.A.
1920 (12 months) 66%	34%
1921 (6 months) 64%	36%
No failures for 6 months, 1921.	

MANAGERS' CERTIFICATES.—Our record is 100% passes. 1912-20 we claimed 165 certificates; 40 in 1919-20; last 3 Exams., 29 certificates (total). 10 Coal Certificates in last 3 Exams.

TUITION (Metal or Coal) by class, correspondence or privately

The above passes are based on official returns; any claims based on number of entries are obviously unreliable.

Our Pioneers.

By James Cumming.

When I scanned the faces of those pioneers who foregathered at the Grand National Hotel, Johannesburg, at their annual dinner on Wednesday night I cast my mind back, through the long vista of years, to the very early days of the Witwatersrand Goldfields—to the days when Johannesburg was non-existent—to the days when a tent and a blanket were all that the pioneer possessed beyond his indomitable pluck and perseverance—I raise my hat to the memory of those splendid men, who were founders of an industry the influence of which is to-day a great power throughout the world.

Long prior to the inception of the Rand Pioneers (Incorporated), in those very early days, in 1886—thirty-five years ago, when I first saw the Rand—that hardy band of men, most of whom, alas, have gone over to the "other side," were the real pioneers of the greatest goldfield the world has ever known, and I was glad to see some few among the number present at the annual dinner.

On every goldfield, the real pioneers—the Voortrekkers—have been very seldom the men who have reaped the ultimate reward of the great adventure. It was the same here. Out of the thousands of men who trekked here, in the days of Ferreira's Camp, the Natal Camp, how very few have reaped a reward for their efforts and hardships. But they tried. They made the supreme effort, and even if they failed, they could hold up their heads and say "We did our level best." In many cases the man who succeeded in making money took it out of the country. It was the "battler," the man with the real pioneering instincts, the man with the stamina, who remained to explore further afield and to still enlarge this great goldfield.

From the days of the Californian and Australian "rushes" of the early 50's, from the days of the Pilgrim's Rest in the 70's, from the days of De Kaap in the 80's, and from the early days of the Witwatersrand it has not been the pioneer, who has borne the heat and turmoil of the day, who has reaped the profits.

The hand of true friendship should be held out to the real pioneer by the younger generations. As educational assets the pioneers of the early days will be of the highest value. They can tell us and our sons the story of the past, and in telling it they can give us many a lesson for the future—for the future greater South Africa, which will arise when all our wonderful resources come to be explored and exploited to their fullest extent.

The scope of the Rand pioneers is not confined to the days of the past—or even the days of the goldfields. In days to come, a great South Africa is looming on the horizon—a South Africa which will eclipse the South Africa of the past half-century, as that 50 years has eclipsed the days of Van Riebeeck.

When we think of such names as Bantjes, Struben, Knight, Phillips, Farrar, Dalrymple, Leonard, Webb, Jeppe, Lys, Meyer, Charlton, Hosken, Niven, Bloch, Alexander, Wolhuter, Simpson and dozens of others who helped to build the Rand and South Africa thirty and more years ago, it must surely stimulate everybody on these fields, old and young alike, to put forward the most strenuous efforts for the future.

PARTNER WANTED.

Wanted experienced partner with £1,200, for developed and equipped small mine in healthy locality, or would let on tribute, with option of purchase.

ENGINEERING SECTION.

The Howick Falls Hydro-Electric Power Plant.—III.

By H. W. Miller.*

The old type of mechanical governor proved totally inadequate for the needs of efficient speed control in connection with hydraulically driven electric generators. The hydraulic type of governors was first evolved, but later oil pressure was used instead of water, as sticking due to gritty water often resulted and the water also caused corrosion of the mechanical parts. The automatic oil pressure type of governor has been steadily improved and has now reached a high state of perfection, possessing all the qualities required by modern practice for effective and reliable speed control.

The governor consists of the following principal parts:—

- A. Oil pressure pump driven by pulley.
- B. Oil pressure receiver.
- C. Servo-motor or hydraulic cylinder.
- D. Distributing valve.
- E. Centrifugal pendulum driven by pulley.
- F. Relay motion of anti-racing mechanism.

The principle of operation of the governor is as follows:

Assume for the moment that the turbine is running at normal speed, when consequently the pendulum sleeve L would be in its central position as indicated on the diagram; if now the load on the turbine is decreased the pendulum sleeve L would rise, in turn lifting the piston of the distributing valve D, through the lever O with point Z as a fulcrum, causing the oil pressure from the pressure receiver B to be admitted on the left side of the servo-motor C, thus closing the guide vanes. When the governor shaft R turns, however, the relay motion gear will come into operation, lowering the connecting rod J and move the piston of the distributing valve D back to its central position with the governor sleeve L as a temporary fulcrum. If the load had been increased, the operation would have been exactly the reverse.

The function of the relay motion gear is one of the most important in the operation of the governor, as by its action it prevents the governor closing or opening the guide vanes more than is necessary to re-establish equilibrium between the load and the corresponding output of the turbine.

Owing to the inertia or momentum in the turbine parts, some little time must elapse before the speed of the turbine has readjusted itself to the new conditions of load, and but for the relay motion gear, the guide apparatus would during this time have continued to move until it reached a position far beyond the correct point, corresponding to the load, and consequently the governor would "hunt" until the correct position was attained.

By means of the small handwheel K on the relay motion gear, the compensating rod J can be either shortened or lengthened, thus enabling the speed of the turbine to be slightly increased or decreased during running independent of the load on the turbine. This function can be clearly seen from the diagram, as if for instance the handwheel K is

screwed upwards it will lift the piston in the distributing valve D through the lever O with L as a fulcrum admitting the oil pressure on the left side of the servo-motor C and closing the guides, thus reducing the speed, or if the handwheel K is screwed further up, it will cause the guides to be totally closed, thus forming a convenient method of shutting down the turbine. If it is desired to slightly increase the speed, the handwheel would have to be screwed down, the operation being the same but in opposite direction.

It will be observed that in the above type of governor each position of the turbine guides corresponds to a certain position of the pendulum sleeve, and consequently the turbine will run at a slightly different speed at various loads, the maximum speed occurring when the turbine is running at "no load," and the minimum speed at "full load," the speed variation depending on the difference in speed of the governor pendulum at the upper and lower limits of the governor sleeve L, which is termed the "degree of irregularity," usually about 3 to 5 per cent.

When the turbine is driving electric generators, it is often necessary to maintain a constant speed at all loads, and for this purpose the governor is provided with a constant speed or compensating device.

The principle of this device is that instead of the relay motion gear forming a rigid connection between the pendulum lever and the governor shaft, the connecting rod J is fitted with an oil dashpot with springs which, after each regulating movement, brings the pendulum sleeve back to its central position, thus maintaining a constant speed independent of the load of the turbine.

The dashpot M consists of a cylinder with a piston and intercommunicating pipe allowing the oil in the cylinder to flow from one side of the piston to the other, the rate of the flow being controlled by the adjustable screw N.

Assume again that the turbine is running at normal speed with the pendulum sleeve and distributing valve in their central position. If now a load change in either direction occurs, the pendulum sleeve will move the distributing valve and the turbine gates will either open or close.

At the same time, the relay motion gear will come into operation and as the oil in the dashpot M cannot pass quickly enough from one side of the piston to the other, the connection between the pendulum lever and governor shaft can be considered as rigid, and the dashpot cylinder will follow the movement of the piston and bring the distributing valve back to its central position.

The springs P attached to the dashpot cylinder, each of which is compressed or under tension, according to the direction of the movement of the piston, will, however, bring back the cylinder and thereby the point Z to its previous position, the piston remaining stationary. It will be observed that the speed at which this movement takes place can be controlled by the adjusting screw N on the dashpot. With the movement of the point Z, the distributing valve will again cause the guide vanes to either open or close, thus

* From a Paper read before the S.A.I. of E.

adjusting the speed until the pendulum sleeve takes up its central position corresponding to constant speed of the turbine.

For a Pelton wheel the governor is usually connected with the spear shaft, thus controlling the speed by reducing the water jet issuing from the nozzle. As Pelton wheels are generally supplied through pipe lines, often of considerable length, it is necessary to provide a by-pass valve, operated direct by the governor in order to avoid undue pressure rises in the pipe line. The by-pass or relief valve has, however, several disadvantages which have been eliminated in the construction and design of the

Combined Spear and Deflector Regulator.

The characteristics of the system are:—

1. Quick acting—consequently close speed regulation.
2. Slow alteration of the velocity of the water in the pipe line—consequently avoidance of water hammer or undue pressure rise.
3. Economy of water.

The general arrangement and design of the system consists of the following principal parts:

A represents a standard circular type of inlet nozzle with internal spear regulator, the shaft B of which is directly connected to the piston moving in the dashpot C. D is the deflector which deflects the water jet from the Pelton wheel, and is supported on a spindle and bearing carried off the lower parts of the nozzle casting. The governor shaft of the automatic oil pressure governor is connected direct to the lever E, which is keyed on the shaft M, the deflector being operated positively from this shaft by means of lever and connecting rod.

Shaft M also carries a double lever F, which is provided with spindle and square steel block working inside the box G in spear regulator shaft M, lever F having sufficient travel in the box G, independent of any movement of the spear, to allow the deflector to be moved far enough into the jet by the governor to practically deflect all the water below the Pelton wheel buckets.

The spear shaft is provided with a helical spring H which always has a tendency to close the nozzle, and this shaft is provided at its outer end with an oil dashpot C, the piston of which is provided with a flat valve J allowing rapid movement of the spear shaft in the opening direction when oil can freely pass from one side of the piston to the other through the holes under the valve plate.

For any movement in the closing direction of the spear shaft, the valve J is closed and oil must escape from one side of the cylinder to the other through the small adjustable valve K. Under normal working conditions, the spear regulator would be open a sufficient distance to pass the quantity of water required to maintain normal speed with the load carried by the Pelton wheel, and the deflector would be in such a position that its forward edge would be just clear of and above the jet of water.

In this position the square block on lever F would be at the rear end of box G, the oil pressure of the governor pressing against the spring H preventing the spear regulator from moving forward.

In the event of any load being taken off the plant, the governor would immediately move the deflector into the jet, the lever F taking up approximately the position indicated on the diagram, as the spear rod B would be prevented from quick forward movement by the dashpot.

Immediately this occurred, the spear would slowly travel forward, its rate being adjusted by the valve K, and as the spear reduced the quantity of water discharged by the nozzle the deflector would be gradually brought back by the governor.

(To be continued.)

Alloy Steels.

By Jonas Bethell, of Messrs. Spear & Jackson, Ltd., Etna Works, Sheffield.

Alloy steels may be generally classified as those usually low in carbon, containing some metal or metals added for the specific purpose of giving the steel certain properties not found in plain carbon steels. These steels differ very considerably and small variations of a single alloying element frequently makes differences in the physical properties of the steel, appearingly out of all proportion to the said variations, over and above these changes the varying of the carbon content also produces a change. The method adopted in adding these alloys is by means of a ferro-compound with high content of the required alloy and is added to the steel either in the furnace or in the ladle. The former is decidedly preferable, but the loss owing to oxidation is generally high in the Siemens-Martin process, and in the electric process no loss occurs, owing to the fact that the slag is in a reducing and not oxidising condition. Alloy steels must be treated according to their composition and purposes for which they are intended, and therefore we find the heat treatment of steels differing very considerably, and this side of the steel industry (heat treatment) has perhaps made greater strides than any other during the last 15 or 20 years. As new steels are discovered, new heat treatment is perfected and recommended. It is to alloy steels that we look for future developments and improvements in the steel industry. Roughly speaking, we may divide alloy steels into three classes: 1, tool steels; 2, structural steels; 3, steels for electrical purposes.

No. 1. Under this heading we include high speed steels, with which I have already dealt in detail, and special tool steels containing varying amounts of tungsten, chromium, vanadium, manganese, etc. These are given various brands by the manufacturer, describing them as "self-hardening," "oil-hardening," "water-hardening" special tool steels and detailing the specific purposes for which they are recommended. If you are a user of special tool steels make sure of the correct heat treatment, otherwise you may not be obtaining the best possible results from them.

Stainless steel used for articles subject to erosion is an alloy steel containing approximately 14 per cent. chromium. This steel is difficult to work but it has advantages over the 25 per cent. nickel stainless steel, for it not only offers greater resistance to corrosion, but it is readily softened and easy to machine, subsequent hardening presenting no difficulties. On the other hand, the nickel steel is difficult to machine even after softening and presenting exceptional difficulties in hardening. Stainless steel is in its ideal condition, i.e., most resistant to the corrosive effect of acids when in the hardened and polished state. An alloy steel is highly recommended for pneumatic tools which have to stand excessive shocks and vibration.

No. 2. Structural steels are those used in the automobile and general machinery industries, the objects of using alloy steels for these purposes being numerous. They give increased strength with the same or an actual reduction of weight over ordinary steels, offer greater resistance to shock, are capable of resisting wear, at the same time capable of withstanding the vibrations and shocks experienced on the road in the case of motor-cars, or in the moving parts of other machinery. Steels recommended for motor-car parts comprise: Tungsten steel for valves, chrome-vanadium and nickel-chromium case hardening steels for cam shafts, chrome-vanadium and nickel-chromium steel for gear and propeller shafts, steering parts, front axle, etc., silico-manganese (high silicon), vanadium and chrome-vanadium steels for springs and so on, each steel requiring heat treatment suitable for the particular work it has to do. A high manganese steel is extensively used in this country in the rock breaking and crushing machinery. Tramway crossings and bends subject to heavy wear are also made from this material.

No. 3. Foremost among the steels for electrical purposes we have magnet steels containing tungsten or tungsten and chromium. Non-magnetic steel, containing 25 per cent. nickel, is used for dynamos, cover plates of lifting magnets, parts of compasses, etc. For the cores of static transformers a silicon alloy steel is recommended, steel of this type giving a greater electrical efficiency than that of any other known steels, that is to say, electrical losses are small when transforming from a high to a low voltage. The alloying elements used in the manufacture of steels, therefore, include tungsten, vanadium, chromium, nickel, molybdenum, silicon, titanium, cobalt, etc.

TO MINING OR LAND COMPANIES.

Position wanted as Manager of Planting Company, large Farm or Estate. Fifteen years' experience in various parts of the world. Sound technical and scientific training. Knowledge of surveying. TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS ENCOURAGING—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—OILS AND COLOURS—ELECTRICAL GOODS—BRITAIN'S UNEMPLOYED AND TRADE—EXPORT CREDITS SCHEME AND ENGINEERING TRADE—UNION'S INDUSTRIAL DEVELOPMENT—FINANCIAL—METAL MARKET.

General Review.

The slight improvement in business conditions referred to in our previous notes has been maintained this week, during which, although nothing outstanding has occurred, the volume of transactions put through has been fairly good. Prices on the whole are not inclined to go lower, but, in view of the present unsettled European political outlook and the not altogether satisfactory position of our own labour troubles, merchants are disinclined just now to indent as freely as they would wish, and are perforce content to pursue their hand-to-mouth policy. There is no doubt, however, that as regards general business and prices, the present month has shown a distinct advance on the previous month's trading, and, given more stable conditions generally, there seems little in the way of a gradual return to more normal conditions. Meanwhile, British manufacturers are gradually coming into line with their Continental rivals in respect of steel goods, to which the recent big reductions in prices referred to under the rubric of Iron and Steel bear testimony. The fact of the matter is that German manufacturers are so overwhelmed now with orders that they find it absolutely impossible to execute a tithe of them, with the result that dates of delivery are becoming impossible of fixation within reasonable commercial limits. This congested state of affairs is bound ultimately to react in favour of British manufacturers, and with the Allies' control of raw materials, will contribute towards stabilising commercial conditions in the near future. Prices of materials remain, as stated, fairly stationary, except for heavy mining material, which still inclines to an easier tendency. Building materials have made no advance in the absence of the anticipated building spurt, but experts are of opinion that we shall see a distinct improvement in this direction within the next three or four months.

Iron and Steel.

Business this week has been quite good by comparison with recent weeks; prices, with a few exceptions, are inclined to harden, and inquiries have been more numerous than for quite a while. Steel plates are firming up, and although business is not very great at the moment, inquiries point to a more satisfactory position—given fairly satisfactory trade conditions—in the near future.

OSBORN'S

PATENT

"Daly" Tappets and W. & S. Tube Mill Liner.

WRITE FOR DESCRIPTIVE BOOKLET.

Samuel Osborn (South Africa), Ltd.,
SHEFFIELD AND JOHANNESBURG.

Union Steel Corporation (S.A.), Ltd.

The managing director states that inquiries are increasing and that there is a likelihood of some very big orders being placed with the company very shortly. The directors are determined to meet foreign competition; they find that a lot of the imported Continental steel at low prices has been far from satisfactory. The Union Steel Corporation's shoe and die business is increasing, and they are now installing plant for forging shoes, which have hitherto, as a war measure, been cast and pressed.

Engineering Shops.

Inquiries among these elicit the fact that the improvement in conditions noticed lately is steadily increasing and that orders are now coming in fairly freely.

Second-hand Machinery.

The market in second-hand machinery, etc., is slightly better, but stocks are running short, so it behoves those who are holding back from purchasing to take advantage of the low prices now ruling for their many requirements, as shortly a rise is predicted and new goods will have to be purchased to replace stocks. Second-hand plates are now ruling: $\frac{1}{2}$ up to $\frac{1}{4}$ inch, £12 10s. to £15 a ton. When one considers the year 1917, when the same second-hand plates were fetching close on £55 and new plates up to £100 a ton, the present difference in prices will be appreciated. New plates to day are about £20 to £25 as against pre-war rates of £12 to £14. Generally there are inquiries for boilers and engines. These are mostly used for brick-making and industrial works. There is still a scarcity of loco-type boilers. Many outlying villages are installing plant for wood-cutting and other industrial work. Johannesburg is still the centre from which to obtain anything in the way of second-hand machinery; the Colonies are practically cleared out, and have to apply to Johannesburg for their requirements. 10 H.P. loco-type boilers (second-hand) rule at about £250, 25 H.P. at about £500. Business generally in the second-hand machinery market is getting better.

Reduction of Steel Prices in Britain.

Unless the price of steel is reduced to something like pre-war figures the steel works must be closed down, Lord Invernain recently declared. With a view to stimulate trade, steel manufacturers have issued revised price lists, which show substantial reductions. Since January last Scottish prices have been reduced 50 per cent., but only 25 per cent. of the workers are employed, and only 15 out of 112 furnaces are operating, as quotations are still higher than those from the Continent. British steel prices have now been reduced to: Ship, bridge and tank plates, joists and heavy rails, each £10 10s.; and boiler plates, £16 per ton.

Cessation of Tin Mining in Cornwall.

The last of the Cornish tin mines closed down some nine months ago. The tin district, containing Redruth, Camborne and a few townships and villages, and measuring about six miles by four, has now entirely ceased working, and every mine is shut down, which, in the absence of any other industrial activity, means total collapse to the district. About 12,000 men are thereby directly affected. Lack of capital and the great slump have prevented development work and the replacing of obsolete plant. All these mines, which are in the meantime deteriorating, are awaiting economic readjustment in the matter of receipts approximating costs, which, however, appears to be as far off as ever.

American Notes.

While the United States Steel Corporation continues to report decreases in unfilled orders, and most of the widely known producers of steel are waiting for something to turn up, there are some developments in this part of the field which may have considerable meaning. Steel ingot production is, however, increasing, and products for structural purposes are being turned out in larger quantities in response to demand. The American Radiator Company, which enjoys a high standing not only in America but in Europe, has raised its prices and is now swamped with orders.

The Kewanee Boiler Company, having a much larger function in the world than would be indicated by the small Illinois town where its works are located, has no considerable amount of its own products on hand, has abandoned plans based on the dullness heretofore prevailing, and will start at once on a new programme. Picklands and Brown, well known everywhere as producers of pig iron, have had a business during the past month twice as great as that of the corresponding period of last year, and their prices are up from 18 dollars at the low to 22 dollars. They have no furnaces in blast now, but their yards contain a large supply of pig iron. No one of these concerns is large by comparison with the United States Steel Corporation, but all are highly responsible and evidence as to the condition of business coming from them is of much value. When the grand movement forward starts, it will not be first answered by the biggest Corporations. It will be a result of revivals at any points, an accumulation of small orders, a movement on the part of individuals in response to the demands of their own business. For that reason it is not expected that there will be anything spectacular springing up all of a sudden some day, but a steady expansion. There is no revival yet in the iron and steel interest broadly considered, but there is here and there considerable gain, part of which is no doubt due to the natural lift in affairs during the last three months of the year, when money is realised from the products of the soil and when in the course of their labours the farmers find that they are short of everything. In normal times it might be expected that the great importation of gold into America would cause a revival in business, and eventually those importations will have an effect, but at the present time the tide of liquidation is so strong as to counteract influence coming from the precious metal. One hears of large hoards that are ready to be loaned or to be put into active business.

Timber and Building Materials.

Business has been fairly satisfactory this week. Stocks are plentiful, prices are gradually stabilising, there is a firmer tone in building materials owing to heavy buying in the United Kingdom. 3 x 9 deals, 1s. to 1s. 1d.; scantlings, 1s.; beaver board, 4 $\frac{1}{2}$ d. to 5d.; floorings, 6 $\frac{1}{2}$ d. to 7d.; ceilings, 5d. to 5 $\frac{1}{2}$ d.; Oregon, 6s. to 7s.; pitch pine, 7s. 6d. to 8s. 6d.; corrugated iron, 9 $\frac{1}{2}$ d. to 10 $\frac{1}{2}$ d. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality, 14s. 9d. for second, at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 2d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cubic ft. at the mills; Honduras mahogany, 30s. per cubic ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks remain unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag, 8 lb. bag 1s.; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 36s. 6d., 46s. 6d., 55s. for 1 to 3-ply. Things are still quiet as far as building operations are concerned; there are no shortages, either of operatives or material. It is generally thought that from about February next a distinct advance will take place, with steadily improving conditions in the meantime, apart from the holiday and stock-taking months of December and January.

Second-hand Iron and Timber.

The second-hand iron and timber yards have been far from active this week, very little business having been done, as a matter of fact, for some weeks. Stocks are abundant and dealers are only too anxious to reduce them. Prices remain at from 6d. to 7d. for iron and 10d. to 1s. for timber. The present financial stringency and the continued pause in building operations are making themselves felt equally in new and second-hand concerns.

Oils and Colours.

White lead in oil, small sizes, 10 $\frac{1}{2}$ d. lb., 39s. 9d. per 50 lb kegs; English red lead, 10d. lb. in 6 $\frac{1}{2}$ lb., 12 $\frac{1}{2}$ lb. and 25 lb. kegs, 9d. lb. in 50 lb. kegs; dry white lead, 1s. 6d. per lb.; linseed oils, raw or boiled, small bottle, 1s. 9d. each, 7 lb. tins, 8s. 3d. each; 4 Imperial galls., 40s.; spirits of

turpentine, small bottle, 2s. each, 9s. 6d. per .83 Imperial gallon; oxide in oil, 25s. to 45s. per 50 lbs.; oxide, dry, 14s. 6d. per 100 lbs.; putty, finest linseed oil, in 100 lb. drum bulk, 5d. lb.; English putty, in bladders, 7½d. lb.; colours, ground, in oil, 42s. 6d. to 75s. per 50 lbs.; dry colours, 6d. to 11s. 6d.; colours, ground in water, 1s. to 2s.; in turpentine, 3s. to 10s. 6d.; motor colours, ground, in gold size, 3s. to 5s.; ready mixed paints, all colours, 1s. 6d. lb. in 1 lb., 2 lb., 3 lb., 7 lb. and 14 lb. tins.; 70 lb. drums, 1s. 4d. lb.; aluminium paint, 25s. per half imperial gallon., 45s. per imperial gallon; roof paints, 16s. 6d. per 14 lb. tin., 75s. per 70 lb. drum; leadless flat wall paint, 27s. 6d. per 5-6th imperial gallon, 33s. 6d. per imperial gallon; enamels, 16s. 6d. to 30s. per .416 imperial gallon; gold enamel, 2s. 6d. and 4s. 6d. per box; varnishes, 25s. to 47s. per imperial gallon; pumice stone, 1s. 3d. lb.; glass paper, 1s. 3d. per dozen, 50s. per ream of 480 sheets; bees' wax, 1s. 6d. lb.; carbolineum, 5s. per 5-6th imperial gallon tin, 23s. 9d. per 4 imperial gallon tin; bottles, 2s. 3d. each; alum, in powder, 9d. lb.; creosote, 4s. 6d. per 5-6th imperial gallon tin; gum arabic, 3s. 6d. lb.; methylated spirits, 5s. 6d. per tin., 5-6th imperial gallon bottles, 1s.; resin, 8d. lb.; caustic soda, 1s. 3d. lb.; seccotine, 1s. tube.; tallow, 1s. lb.; coal tar, 4s. 6d. per .83 imperial gallon, 17s. 6d. per 4 imperial gallons; Stockholm tar, 9s. 6d. per .83 imperial gallon, 47s. 6d. per 5 imperial gallons; common glue, 10d. lb., good quality, cake, 1s. 6d.; finest Russian, 1s. 9d.; English gold leaf, plain, 3s. 9d. per book, transferred 4s. 3d. per book; aluminium leaf, plain, 1s. 9d. per book; transferred, 2s. per book.

Electrical Goods.

Dealers were more hopeful this week as to business in the near future. They confirm the improvement which has taken place during the past two or three weeks, and state that trading is now quite good again both in town and country. A leading importer said he had this week had visits from residents of Ermelo, Vereeniging, and from Kimberley, all of whom purchased electrical materials, stating that in their opinion things were now about to move. He thought people were beginning to realise that better times were in store and were now more inclined to be enterprising than for some considerable time; those who have been keeping their pockets tight are now loosening them. He himself felt confident that things in the electrical world would now slowly but gradually improve. There are no alterations to report in prices, which remain very steady, with, if anything, a tendency to rise. Stocks in all lines are now full, and consignments continue to arrive in fair quantities from Britain, America and the Continent. Those from the latter destination continue still to be much below British quotations, but signs are not wanting that a gradual levelling up is taking place, and it will not surprise dealers if within a few months' time the present discrepancy between the prices of British and Continental electrical materials, with one or two exceptions, disappears to a considerable extent.

Mr. Lloyd-George's Proposals re Unemployment and Trade.

The Prime Minister's proposals for the extension of trade and assistance in raising capital for industrial undertakings have been well received in commercial circles, which consider them both sound and workable. The Government, it is understood, offered to leave the management of the credits system in the hands of the leading bankers, but the latter decided that the scheme should be managed by a committee within the Overseas Trade Department, while offering on their part to give every assistance to the carrying out of the scheme. Referring to the unemployment question, which was the worst experienced for a century, the Prime Minister affirmed that the Government had done everything in its power to alleviate the same by the export credit scheme, the distribution of relief to unemployed under an insurance scheme, and the provision of work by the Cabinet Unemployment Committee. He stated that £637,000 had been voted for the settlement of ex-service men in the Dominions, where already 60,000 had settled, and Government proposed to ask Parliament for another £300,000 for the purpose of meeting the rush of further applicants. He said we were more dependent than ever on the Dominions for trade, and the more men settled under the British flag the better for

trade and employment in Britain. There were signs of a revival in some industries in Britain, but it would be sanguine to predict an early return to normal. We had to convert the world's need for our goods into a demand, and a demand into payment. With regard to the export credit scheme, Mr. Lloyd George said the Government had decided to guarantee 100 per cent. of the cost, instead of 85 per cent., but the exporter would be liable on recourse to 57½ per cent. risk; therefore the Government's risk would remain at 42½ per cent. The Government was prepared to enter into enterprises such as railway extensions, electrification of waterways, etc., which would produce immediate relief. The Government's liability under this proposal would be limited to £25,000,000 sterling. The Government further proposed to allocate £10,000,000 sterling for relief works. The cost of production, however, must be reduced to employers and workers must come together in an endeavour to reduce wages.

In the House of Commons Mr. Chamberlain stated that unemployment will be considerably relieved by the construction of the enormous quantities of machinery, etc., required to build a new deep-water harbour at Takoradi, Gold Coast, which it is estimated will cost about £10,000,000. Inquiries for machinery are now being sent out, and the first working party of British engineers will leave in two months' time.

Export Credits Scheme and the Engineering Trade.

Mr. Lloyd George has announced that the Government was prepared, in the case of very considerable engineering and other orders from foreign Governments, to grant an extension of credit for repayment, where desirable, even for five, six or seven years, by which means, he thought, very considerable orders, especially for the engineering trade, which was suffering most from unemployment at present, could be secured. These proposals have been very favourably received in the House of Commons. Mr. Asquith urged the development of a more extensive trade with the Dominions, which supplied, he said, Britain with essential commodities. There was, in his opinion, no reason why inter-Imperial trade, assisted on sound lines by the State, should not exceed altogether European trade which Britain had lost through the war. Mr. Clynes (Labour), while emphasising that wages did not constitute the sole element, agreed that workers should endeavour to contribute to reducing the costs of production.

The Union's Industrial Enterprise.

In an able address to the members of the South African Mutual Life Assurance Society, the Chairman, Mr. Christian Silberbauer, said, *inter alia*, that he was optimistic as to the future of South Africa. We had so many resources within ourselves that any set-backs such as we were now experiencing should only be temporary. There were several reasons for a brighter outlook. One was the industrial expansion of the country with, as a natural result, a tremendous increase in our factories. Thirty years ago, when South Africa may be said to have awakened to industrial life, we had 550 factories, which had increased to-day to 6,000, employing 143,000 workers, white, coloured, and native, and paying out £14,500,000 annually in salaries and wages. This naturally meant a great distribution of capital and reacted beneficially on other sections of the community.

Industrial Development.

Mr. J. Waldie Pearson, K.C., presiding at the last monthly meeting of the South African National Union, said that there was generally a more optimistic outlook as to the future of the Union's industrial growth. He again emphasised the necessity for a better organisation of the agricultural industry and instilling new life into the societies and farmers' associations by the circulation of literature that made an appeal to the farmer, by lectures and demonstrations, etc. It must, he said, be brought home to every agriculturist that the Government was doing a great deal to help the industry, and that it was for the farmer to take full advantage of that assistance. With regard to manufactured articles, Mr. Pearson urged the necessity of showing the public what was being done in this direction by well-organised exhibitions at various centres, which would be bound to arouse interest in

the matter. Although the imports so far for 1921 were considerably below those for 1920, they still included many articles which could and should be produced in the Union, and the decrease already shown would soon be accentuated if the public were shown that we could supply a good article. But in order to do that, advertising on a large scale was necessary. He thought that the more forward policy initiated by the Railway Administration in the matter of excursions would, by the more intimate acquaintance with all parts of the country, mean a greater circulation of money, and consequently more development. Too much was, he thought, made generally of the present depression, which had been equalled if not exceeded in the previous history of the country. Greater development of the primary industries of the Union, in which the various classes of mining must be included, would, he was assured, soon bring about a condition better and more permanent than we had yet experienced.

Financial.

London advises that discount has declined to 2.68 per cent. on tendering of Treasury Bills.

Commonwealth's £5,000,000 Loan.

This loan, which is redeemable between 1931 and 1941, will, it is announced, consist of £1,000,000 of new money, while the balance will be made up by redeeming bills, amounting to £2,000,000 sterling, and other debts amounting to £2,000,000 sterling.

Australia's Shipping Line.

Sir Joseph Cook, Treasurer, announced in the House of Representatives that the Commonwealth Shipping Line had made a profit of £467,000 in 1920. This is a great contrast to the result of the activities of both Britain and America in the shipping line.

Metal Market.

The Metal Market was disturbed during the week by the collapse of the mark and the threatened strike in America, but recovered somewhat towards the close. There were heavy liquidations in copper. Tin was firmer, and still higher prices are anticipated. Lead was stronger. Spelter weakened on the heavy sales from the Continent, but recovered later. Tin plates were stiffer owing to shortage of supply. Latest quotations: Standard copper, £66 1s. 3d. cash, £67 3s. 9d. forward; electrolytic copper, £73 cash, £75 forward; Straits tin, £158 7s. 6d. cash, £160 10s. forward; English lead, £24 cash, £23 15s. forward; bar silver, 40½d. gold, 104s. 6d. per oz.

Mcderfontein B Quarterly Report.

The payable reef disclosures were as follows:—Main Reef Leader: Feet, 1,365; reef width, inches, 16; assay value, dwts., 45.1. Total profit: £301,308. The additional tube mill unit is running satisfactorily. A considerable increase in development footage has been accomplished. The total figure includes 1,020 feet of development from the south-eastern shaft, of which 315 feet disclosed reef of, on

the whole, unpayable character. At the south-western shaft 316 feet of ore passes and cross-cutting was done. During the current quarter the change over from sinking equipment to the permanent hoisting arrangements at the south-western shaft will be completed, and this, together with the haulage to the central shaft, will enable ore from the south-western section of the mine to be handled in a more economical manner. The operations of recent months have resulted in a yield considerably higher than the value of the ore reserves as recalculated at December 31, 1920. The reason for this higher yield is that actual stoping values have proved, during the period in question, to be in excess of block values. In stoping it is by no means uncommon to find the value of the ore proving higher or lower than the assay indicated. The ore reserves at December 31 last were calculated as usual upon a fairly conservative basis, but the unexpectedly high yield of recent months induces the Board to issue these few words of explanation.

THE NEW JOHANNESBURG.

OUR LATEST BUILDINGS AND THEIR SIGNIFICANCE—A BRIEF SURVEY OF THE POSITION AND OUTLOOK—"WILL JOHANNESBURG LAST?": AN OFT-DEBATED QUESTION—DEVELOPMENT WORK ALONG THE REEF—SOUTH AFRICA'S RESOURCES AND LEADERS—A DIVIDEND MARKET BEFORE CHRISTMAS?

The question "Will Johannesburg Last?" often has been asked in these columns, and invariably the replies to this momentous query have been of a most conflicting nature. In this issue we reproduce photographs which portray four new and costly Johannesburg buildings which testify to the sincerity of the optimism as to the future of the town which is held in some quarters. These edifices do not necessarily provide a sufficient answer to the question which has so often been debated in the "Mining Journal," but their roofs and spires at least point to some silver lining to the present drab clouds which envelope us. The significance of these buildings and the general position and outlook for Johannesburg and South Africa are briefly touched on in the accompanying article.

The new buildings just erected in Johannesburg and which are illustrated on the accompanying pages help one to sound a note of optimism in a town which is very drab and grey at the present.

Johannesburg, in common with every other place in the world, is suffering severely from the prevailing and universal depression. The share market, which always is the barometer of the situation in the Golden City, after its fleeting activity of a few weeks ago is again in the doldrums, and pessimistic brokers are recalling the bad times which succeeded the abnormal spurt after the Boer War, when the prospect of leasing the Stock Exchange to the Municipality for the purpose of selling vegetables was discussed by gloomy operators.

Scarcity of Cash.

On all sides one hears that money is exceedingly tight. Capital for the moment is most difficult to obtain, and there are attractive first mortgage debenture propositions which cannot raise the money they require at 9 per cent.

New Municipal Power Plant Sub-Station.

Yet in some quarters it is believed that there may be a more or less active dividend market before the close of the year and it is common talk that a settlement of the enemy shareholding difficulty is at last in sight.

Pessimism on the Rand.

For the time being the mining industry on the Rand seems to be sailing on an even keel, but the price of gold keeps at a considerably lower figure than it was expected would prevail, and is indeed at a lower figure than might reasonably be asked for the product of low-grade mines working at an abnormal rate of expenditure. It is scarcely conceivable that the miners can really be serious in their ridiculous demand as expressed by their leaders for a reversion to the rates of pay obtaining previously to the recent protracted settlement. Development work along the Reef continues

near future regain some of the prosperity which we enjoyed a year or so ago.

Our New Buildings: What Do They Signify?

There are, at any rate, those who believe in the future of the country and in the future of Johannesburg, this glorified mining camp, which is the hub of South Africa.

The new buildings of the Golden City which are portrayed in this issue are at least substantial testimonies in solid stone and brick and mortar to the view that the fall of Johannesburg is not yet.

We reproduce on our frontispiece this week a photograph of the new and completed home of the Transvaal Chamber of Mines, an impressive edifice which has been erected on a well and appropriately chosen site adjacent to the Stock Exchange.

New Branch of the Standard Bank, corner of Eloff and Market Streets.

much as ever, and although it is reported that the Ferguson section of the Randfontein Mines has been closed down on account of poor values, one learns as an offset to this report that disclosures are very satisfactory in some areas of the Far East Rand, and particularly so at Geduld.

It is hardly likely that there can be any substantial improvement in world trade conditions generally until the political situation and financial outlook in Europe becomes more satisfactory.

The Country and its Leaders.

But South Africa and Johannesburg may seek consolation in this fact, that the clouds, dark as they may be here, are more lugubrious in other countries, and with more enterprise and foresight on the part of our political and industrial leaders, there is no reason why the Union with its vast natural resources and many advantages should not in the

We give, too, photos of the new Eloff Street branch of the Standard Bank, a palatial warehouse recently completed in Market Street, and the new sub-station of the Municipal Power Plant.

Contracts for the erection of these were of course signed some time ago when the sun shone more brightly upon us than it does to-day. And they do not necessarily provide a complete and final answer to the question of whether Johannesburg will last, which has so often been debated in the columns of this journal.

A Comforting Reflection.

Yet these costly new piles at least provide solace for the ordinary Johannesburger in one respect. He can, at any rate, console himself with the reflection that if he is a fool to believe in the future of Johannesburg, there are much bigger fools who are chasing the same golden rainbow.

THE NEW JOHANNESBURG.

A Large and Palatial Warehouse just completed in Market Street.

Concerning Mines and Men.

Mr. Owen Letcher having returned from India has resumed editorial control of the *S.A. Mining and Engineering Journal*.

* * *

Mr. C. W. Francis Harrison, Special Commissioner of the Federation of British Industries, who has been on a visit to South Africa, is leaving shortly on his return to England.

* * *

Mr. S. Seruya, for many years the popular and respected Portuguese Vice-Consul for Portugal here, left the Rand this week for Lisbon. Mr. Seruya is being succeeded by Mr. J. P. Ferreira.

* * *

Mr. G. Bendien, joint manager in Johannesburg of the National Trading Company, is leaving shortly to take up the position of manager of the branch of the same London firm in Holland.

* * *

The certificates issued by the Mines Department for the period ending 31st October, 1921, were as follows:—Mine Managers (Metalliferous Mines): A. R. Bauristhene, P. O'B. Frost, J. J. Griffiths, J. E. Gudmundson, F. J. Hosking, K. J. MacWilliam, A. G. McAlister, A. P. Mellet, H. A. Mills, N. H. Menro, R. R. Vail. Collieries: A. F. Campbell, P. Gerrard, W. Tarran. Non-flery Collieries: P. A. Creewel, L. H. Maasderp, H. P. Townsend. Open-cast Diamond Mines: H. L. Olyer. Mine Overseers (Metalliferous Mines): J. H. C. Bell, C. E. Roy, K. B. Wood. Not available in Phthisis Mines: C. J. Richards.

A very pleasant bridge drive and social gathering took place in the Recreation Hall, O'okiep, Namaqualand, on the 21st October, 1921, the occasion being the celebration of their silver wedding by Dr. M. W. W. Cowan, M.B., Ch.M., Edin., and Mrs. Cowan, who are highly esteemed throughout the district where the doctor had practised for over 26 years. A presentation, consisting of a very handsome solid silver tea and coffee service and salver, the latter suitably inscribed, and a case of ladies' silver-backed hair brushes, silver-topped scent bottles, and silver manicule set, was made by W. F. Kitto, Esq., Superintendent of the Cape Copper Co., Ltd. Mr. Kitto, on behalf of the people of Namaqualand, in a very appropriate speech, voiced the goodwill and affection of the people present, and also those who were unable to attend. Representatives from outlying villages attended to convey the wishes of those centres, and the well-filled hall bore ample testimony to the esteem and regard in which the worthy genial doctor and Mrs. Cowan are held in these far-reaching parts of Namaqualand.

Oil in Mozambique.

It is understood that a prominent Rhodesian geologist, who recently has been investigating the mineral prospects of an extensive tract of country in Mozambique, has pronounced his opinion that there are excellent indications of discovering oil near Inyaninga in that territory. This pronouncement has been arrived at after a most careful examination of the stratigraphical features and a correlation of strata with the oil-bearing rocks of Madagascar. It is proposed to commence boring operations in the near future, and for this purpose it is intended to employ machinery at present in use on the Beira-Zambesi Railway.

Union Corporation.

SIR HENRY STRAKOSCH AND MR. RONKETTI LEAVING FOR SOUTH AFRICA.

EXCELLENT DEVELOPMENT VALUES CONTINUE AT GEDULD—No. 3 EAST RAISE DISCLOSES OVER 1,000 INCH-DWTS.—MODDER DEEP'S PROFIT IN SEPTEMBER QUARTER, £265,263.

We learn that Sir Henry Strakosch, of the Union Corporation, intends leaving England for South Africa on the 18th inst. Sir Henry is, of course, well known on account of his long and intimate connection with the Union Corporation, and more especially in connection with his association with the Union's currency problems and the formation of the South African Reserve Bank.

We understand, too, that Mr. V. J. Ronketti left England yesterday for South Africa, and that on arrival he will assume the important position hitherto occupied by the late Major Macormack, as chairman of the Union Corporation Companies.

* * *

Geduld Proprietary Mines.

The report of the Geduld Proprietary Mines for the quarter ended 30th September gives the following particulars in regard to development operations at that property:—Total

Sir Henry Strakosch.

development footage, 4,846 ft.; total footage sampled, 3,260 ft. The payable reef disclosures were as follows: 1,145 feet having an average assay value of 17.5 dwts. over 41 inches. Up to the 30th September the total footage of reef exposed and sampled at No. 7 Shaft on the 7th level and in the raises and winzes therefrom was 5,770 feet, of which 62 per cent. is payable, having an average value of 16 dwts. over an estimated stopping width of 66 inches. The three faces being advanced in this area since the end of September continue to show very satisfactory results, particularly No. 3 East Raise, which is now 814 feet above the 7th level. The values disclosed average over a thousand inch-pennyweights. Productive results for the quarter were:—Tons milled, 134,800; total yield ozs., 47,462; working revenue, £261,334; total profit, £111,531; working costs per ton, 23s. 5d.

* * *

The Modderfontein Deep Levels.

At the Modderfontein Deep Levels the outstanding features of the quarter's operations were as follows:—Total

development footage, 2,196 ft.; total footage sampled, 1,045 ft. Payable reef disclosures were as follows: 885 feet, having an average assay value of 15.8 dwts. over 41 inches. Results for quarter: Tons milled, 129,900; total yield ozs., 72,150. Working revenue, £397,254; total profit, £265,263; working

The Modder Deep.

costs per ton, 21s. 9d. The working revenue was arrived at by taking the gold produced during the quarter at the following estimated prices: July, £5 12s. 6d. per fine oz.; August, £5 11s. 6d. per fine oz.; September, £5 10s. per fine oz.

Bantjes Development Operations.

The work accomplished in the 11th level west drive by the Consolidated Main Reef Mines and Estate, Limited, during the quarter ended 30th September, 1921, was as follows:—Main Reef Leader: Footage sampled, 130 ft.; reef width, 4 inches; reef value, 2.5 dwts. Main Reef: Footage sampled, 85 ft.; reef width, 19 inches; reef value, 1.9 dwts. The waste parting between the Main Reef Leader and the Main Reef is 60 inches. The drive was advanced 161 feet during the quarter.

North-West Cape Oil Prospecting.

Nothing daunted by Dr. Wagner's report, the North-West (Cape Colony) Prospecting Syndicate held an enthusiastic annual meeting the other day at Kimberley, at which Mr. J. Lawrence, in charge of the work at Dubblede Vlei, reported that the borehole had now reached a total depth of 1,728 feet. He further wrote that Mr. Hutcheson said there was more oil on the water every foot they went down. Mr. Liddlell read extracts from a letter he had received from Mr. S. G. Hutcheson, the assistant drillman at Dubblede Vlei, as follows: "With regard to the work that is going ahead, the indications are improving with every foot drilled. The core now shows evidence of a distinct change, which augurs well for the future. The flow of gas has been particularly strong of late, and will return two or three times during drilling operations. The flow of oil is also improving, rising as it does now in one continuous film, with occasionally large patches. A flow of gas always precedes a freer flow of oil, which indicates alternate layers of rock and sands. . . . I think all things now point to a definite and final refutation of the geologist's report. I am most optimistic about this place, and feel sure that your courage in continuing will be amply repaid."

The build of the Drill

SIXTY FIVE years ago the first Climax Drill was made. Its manufacture marked an era of progress in mining machinery because that Climax Drill was built for service. Each year Climax Drills have been improved to meet the demands of modern mining conditions, until, at the present time, they stand alone for drilling speed, low cost of maintenance and popularity.

The Last Word on Rand Metallurgy.

By F. Wartenweiler, A.I.M.M.

Mr. F. Wartenweiler, the well-known Corner House metallurgist, is the new President of the C.M. & M. Society. His inaugural address, dealing with the subject of which he is an acknowledged master, is therefore of unusual interest and value. We give some extracts below.

Underground Features.

In dealing with the metallurgy of the Witwatersrand, it is often taken for granted that the initial steps begin after the ore has been hoisted to the surface and delivered to the reduction department. On some mines this can be accepted as the starting point for the beneficiation of the

dilution, cannot be ignored without the payment of the penalty, scale in pipes, or the purchase of an expensive precipitant.

The precise chemical control appeals to the economist and mineowner as a means of saving tons of steel and other corrosive material used underground, not to mention that of cyanide at the surface plant. As an example the experience of one mine may be mentioned where, by careful control, cyanide consumption has been lowered from 0.28 lb. to 0.18 lb. per ton ore treated.

Acidity in mine water has been known to be sufficiently high in some old workings to blister the flesh of men coming in contact with it, as the episode of a mine manager who had such a practical though painful demonstration. We have also heard of miners who have suffered from the burn of strong alkalinity by coming in contact with an accumu-

Modern Rand Metallurgy— A View at Springs Mines.

ore. On others, however, natural chemical processes, which affect the subsequent treatment, begin in the stope, the ore pass and the pump sump, and it is due to the recognition of this fundamental fact that one large group has begun ore treatment underground and has extended the responsibility and usefulness of the chemist and metallurgist. I allude to the chemical control of neutralisation of acid mine water by means of lime, the settlement of sludge, its subsequent disposal, and the maintenance of a favourable composition of water for re-use in dust allaying, in which there are pitfalls unseen except by the trained chemist. The precipitation, from a super-saturated mine water, of the calcium sulphate formed in neutralising or its prevention by adequate

lation of milk of lime in some back water underground. The one points to the moral of the usefulness of information on the degree of acidity; the other, of wastefulness of lime when not applied under precise control or at the most effective place.

The practice of underground support by means of ore packs is well known and has been described at our meetings by several members in an interesting manner. In view of the chemical and physical alterations taking place in these packs, the question arises whether such a method of mining affects the subsequent extraction of gold, and to what extent. No satisfying answer has been forthcoming, perhaps due to lack of opportunity for a definite test.

Sand filling, which has returned hundreds of thousands of tons of residue sand to the place of origin, the stope, has found its way back to the reduction plants in small quantities, particularly on outcrop mines, where ground movements and consequent break away of sand barricades take place. The incidence of this acid material in the extraction of gold from the clean current ore is noted by reduction men to be adverse.

Crushing and Sorting.

Crushing and sorting operations so closely related locally as to be dealt with under one heading is such an important and comprehensive subject that it could easily form the sole basis of a paper. Interest seems to have lagged of late years. Is it because the existing plants are considered capable of fulfilling all requirements from the point of view of efficient crushing, sorting, and low cost of operation? Not until you make a close study of various types of stations now in operation are you impressed with the variety of objectives originally affecting the design of each.

The early designers, in the pre-conveyor belt days, built skywards and in conjunction with rotary sorting tables often employed crushers at the highest point of the structure for cracking large rock prior to sorting. Many of these old plants continue in operation, and excellent work can be obtained. Sorting to the extent of 16 per cent. has been carried out in a station of this type by picking out the valueless class of reef in addition to the usual quartzite and dyke waste.

We then come to the type of station employing conveyor belts and in which sorting and crushing in two stages is practised. Although the high sorting percentage possible with such a design has fulfilled the most sanguine expectations in this direction, lack of native labour and the economic factor has usually retired it in favour of the simple straight line design now found on our later plants. Such a station with trommel washing or with washing on a sharply inclined portion of the sorting belt lends itself, by reason of simplicity, to minimum capital and running expenditure.

One of the latest plants provides for the crushing of all the ore coming from the mine, including the grizzly by-pass, called unsortable fines, which comprise as high a proportion of the ore milled as 40 per cent. This is an innovation and the object is three-fold:—First, the avoidance of sending slushy fines to the stamp mill bins, the moisture from which leads to decay of timber and battery foundations, rusts steel and indirectly causes stem and cam shaft breakage through irregular feed; second, all material passing a ½ inch punched screen is sent to its most efficient grinding machine, the tube mill; thirdly, the chemical motive, which allows thorough neutralisation with lime water of that portion of the mine delivery which benefits by such treatment. It is of interest to note that as much as 15 per cent. of the ore milled is by-passed by this method.

With the realisation of the expense of conveyor belt wear and tear, the re-adoption of preliminary cracking large rock is being considered in order to reduce incidental rough usage. Also washing trommels stationed at the primary bins are favoured for the elimination of the slushy fines, so that no belt need become a conveyor of a material which, having the property of mobility, is preferably transported by the impulse of a modern centrifugal pump. The sorting percentage becomes a function of the number of native sorters and the amount of waste present. This last depending so often on underground conditions and the reef formation. It is, perhaps, not always realised that many mines, owing to peculiarities in their payable ore channel, present individual problems in sorting which must be studied separately if this important part of ore dressing is to be conducted on an intelligent and scientific basis.

Regarding crushers, which are taken so much for granted, the two standard types, jaw and gyratory, continue to hold the field. That stamping efficiency is greatly advanced by careful maintenance of their wearing parts and by close setting has always been known, and has again reached the practical stage since manganese steel need no longer be devoted solely to armament purposes.

Stamping.

The Californian stamp and its first cousin, the Nissen, have survived. There are those in our society who hold the view that these will continue to crush Witwatersrand blanket ore at least during our generation. Others feel that improved modern ball or tube mill development will seal their doom as an economical stage crushed. The question is extensive in its bearings and is most important. Working experiments have recently been conducted on this very point at one of the Far East mines. To what extent the crusher and the tube mill can economically encroach on the domain of the stamps, squeezing it out of existence between their extended functions, is a point for careful trial on an extended

working scale. Let us offer the columns of our journal, as in the past, for the discussion of developments on this subject.

It is on this mining field that the heavy gravity stamp has reached its highest state of perfection. The 1,850 pound Californian stamp at the Government Areas mill crushes 28.5 tons per 24 hours through a screen aperture 0.625 of an inch square, while at New Modderfontein the 1,900 pound Nissen stamps 31.5 tons through a somewhat finer screen.

If you are statistically inclined, the size and power of the stamp mills on the Witwatersrand may be illustrated in various ways. For example, if all the 10 stamp batteries were placed adjoining they would make one continuous line extending for a distance of two and a half miles. If all the stamps were combined into one, the blow of this mammoth stamp would be equivalent to a weight of 5,200 tons dropping eight inches 99 times per minute.

The roar of stamp mills since the early Californian days has followed the axe of the pioneer in many parts of the world, and whatever may be their ultimate fate, to those of us who have spent many working hours in a stamp mill, the surf-like roar of its many batteries will remain impressed in our minds as symbolical of the restless and untiring energy of the gold mining industry.

Tube Milling.

Tube milling practice nowadays appears to be rather one of detail. The tube mills are called upon to grind to a finer degree of comminution than ever, one plant delivering a final product of which 90 per cent. passes the 90 linear mesh screen. Good practice now demands a coarse feed, the newer installations feeding $\frac{1}{2}$ inch maximum size. The trials referred to previously experimented with feed as coarse as that fed to stamps.

Scoop discharges of varying effective lift with screen openings of ample size to permit free discharge of the spent pebble are generally adopted except on old plants where the use of small motors does not permit the resulting high power load. Shell liners of the Osborn and El Oro type find general favour. These are keyed and require no holding bolts. End liners are either cast or forged from discarded stamp mill shoe shanks or dies.

No recent data has been published of the merits of the short 6 ft. diameter by 16 ft. length tube in comparison with the orthodox size, 5 ft. 6 in. diameter by 22 ft. There are also a few 6 ft. diameter by 20 ft. mills in operation whose performances have yet to be compared.

Since the trials of the Giesecke ball mill, to my knowledge, no further attempts have been made with steel balls. How effective a modern large diameter ball mill would be on the basket ore leads to interesting speculation. It should be recognised though that this ore is one of the hardest and most abrasive known, and a steel ball which readily crushes porphyry ore may prove impotent on basket. There are undoubtedly degrees of hardness and toughness in the ore delivered to reduction plants scattered from Randfontein to Springs, and it may be no idle speculation to look forward to the discovery of an ore that will lend itself to a change in grinding medium.

Amalgamation.

Like taxes, the ancient amalgamation recovery method is still with us and is responsible for from 40 to 70 per cent. of the assay value of our mill feed. While, with our system of classification, preferential amalgamation really takes place in practice, the question arises whether this could not be intensified and mechanical contrivance and concentration called in. The day of the non-amalgamating plant and the extraction of all recoverable gold by cyaniding may arrive. In fact one mine has committed itself and elsewhere working trials having this in view have been projected and are only awaiting opportunity and adequate support. Undoubtedly the knowledge that visible coarse gold is found in certain portions of the richer mines has acted as a deterrent with responsible officials. Aside from any technical advantage, the introduction of a method which reduces or eliminates the risk of mercury poisoning would seem to have human merit.

Cyaniding and Chemical Treatment.

No fundamental changes have been effected in cyaniding in the last few years. Considerable experimentation, however, has been conducted quietly, resulting in gains here and there. The practicability of collecting sand and its treatment in the same tank is well established at one of the most recently erected plants. Careful classification is a corollary. The importance of close classification and the advantage of fine grinding of the pyritic portion of the ore is receiving constant attention by reduction officials.

Cyanide solution strengths have been on the down grade and with the adoption of de-aeration of solutions prior to precipitation they will continue on this course. The saving of cyanide and zinc resulting from this constant pressure of experimentation with lower and lower cyanide strengths and with improved precipitation technique has been considerable. On one group alone it has amounted to a quarter million sterling in five years.

Precipitation has received due attention and on some of the plants a feed rate per diem of 2.3 tons of slime solution per cubic foot of zinc shaving in extractor boxes is current practice. The Chamber of Mines financed extensive trials on the de-aeration of cyanide solution and, resulting from these, mechanical de-aeration has been decided on at five reduction works, of which three installations are in operation. The expectation of direct and indirect economy promises to be fulfilled. Interesting details, it is hoped, will be brought forward for discussion this year.

Precipitation research has not been lacking within recent years; the margin of possible improvement, however, is small, and any new process calling for a new installation with heavy capital expenditure is severely handicapped by economic considerations.

Oxidising re-agents, by reason of rapidity of reaction and expense, do not find favour these days. Their effect is evanescent and apt to be harmful. The economical and satisfactory supply of oxygen continues to be derived from free air. Experience with de-aeration has taught us how readily air dissolves in solution and how watchful one must be to prevent this at certain stages of the cyanide process.

Vacuum filters are now accepted by the majority as standard slime washing equipment for new plants. Their washing is controllable, depending so much less than the decantation process on ratio of dilution and on the weather. Many installations maintain a consistent daily capacity rate of 3.5 tons dry slime per leaf.

Smelting and Refining.

No innovations have been introduced in recent years into refining and smelting on the individual mines. The large refinery erected near Germiston by the Chamber of Mines for the purpose of refining the gold output of the Witwatersrand by the chlorine process is about to operate and will no doubt offer a most interesting study to our technical men. We hope to be favoured with a description of its technology in due course.

Acid treatment of the gold-zinc slime from precipitation remains general practice, although with the precipitation improvements referred to this will possibly be discontinued. Subsequent calcination and pot smelting or reverberatory lead smelting is the practice according to preference or works convenience. Small blast furnaces are found useful for smelting by-products on the larger mines. For others the Witwatersrand Co-operative Smelter, a most excellent institution, fills all requirements. The treatment by cyanide of the "black sand" or pyritic by-products from amalgamation has received attention by many of our members and is well established.

Periodically, schemes for utilising the zinc sulphate liquor, now wasted, are brought forward. Many of them are ingenious and have undoubted merit, and I confidently look forward to an economic utilisation of this liquor.

In concluding the foregoing traverse of local metallurgy, I venture to reiterate that sound development is visible, and in the words of the young assayer who found a large looking speck of gold unweighable, is at least equivalent to "two traces."

Oil Shale Distillation.

COMMERCIAL CONSIDERATIONS.

The commercial utilisation of oil shale involves three distinct steps, production of the raw material, manufacturing this into finished and saleable forms, and marketing the finished products. All these steps are inter-related. Each presents its own peculiar problems. All these problems must be solved before success can be obtained. Each requires the best technical ability in its particular field. Finally, the several diverse operations must be welded into one harmonious whole which will require executive ability of the highest order.

As there are no commercial shale operations in this country the exploitation of our oil shale means the development of the industry and the training of the operating personnel as the business develops. All the competent investigators who have studied the matter are agreed that, to be successful, the business must be prosecuted on a large scale, not less than 1,000 tons per day, and that it will require the very best engineering, technical, and business skill backed by large financial resources.

Although conditions in Scotland are somewhat different from those prevailing in this country, a study of the oil-shale industry there, where it has been commercially successful for many years, is of interest in connection with our shales as it presents the only index of what we can expect to accomplish. There is enough similarity to be of assistance in guiding the development of the South African oil-shale industry. For this reason a brief sketch of the Scotch practice is given below.

Scotch Practice.

The Scotch shales occur in a geological formation which has been extensively tilted and folded. It is mined underground by methods similar to those employed in working pitching coal veins. The roof is supported by pillars and usually about 25 per cent. of the shale is left in worked-out ground in this form. An average of about four long tons of shale a day is produced for each man working at the face. The shale from the mines is crushed by large, toothed rolls so that nothing larger than two inches in diameter goes to the retorts.

The retorts are vertical and tapered, being about two feet in diameter at the top and three feet at the bottom. The shale is fed by gravity through a hopper at the top which holds several tons. The upper part of the retort is a one-piece iron casting about 12 feet high. It is in this that the bulk of the oil distills. The vapours and gases are removed under slight suction through a pipe which forms part of the top of the casing. The lower part of the retort is built of fire brick and is about 18 feet high. In this part the shale is brought to its maximum temperature, about 1,750 deg. F., and most of the ammonia and water gas are formed through the action of steam on the carbon and nitrogenous material remaining in the shale. The spent shale is discharged through a sealed hopper at the bottom of the retort by a suitable mechanical arrangement. The whole operation is continuous. The throughput of such a retort is between four and four and one-half tons per day. The steam, which is admitted to the hopper containing the hot, spent shale at the rate of 750 to 1,000 pounds of steam to 2,240 pounds of shale, serves for the following purposes: to cool the spent shale, to carry the heat from the spent shale into the retort, to form water gas from the fixed carbon, to form ammonia by reacting with the nitrogen in the shale, to sweep the oil vapours out of the retort, and to effect a better transfer of heat from the walls of the retort to the centre of the charge.

Four retorts are usually set together in a common furnace, and sixteen of these units of four constitute a bench which is two retorts wide and thirty-two long. The retorts are heated by burning the permanent gases which result from the distillation of the shale. Scotch shale which yields 25 imperial gallons of oil per long ton, or more, will also yield enough fixed gases to heat the retorts. When the permanent gases are insufficient to heat the retorts, producer gas is manufactured and used for this purpose.

In Scotland no use has ever been found for the spent shale and its disposal is one of the items of expense connected with the industry. Attempts to make use of it for road material and brick making have been unsuccessful.

The oil vapours, gases, and steam from the retorts pass into a common header and thence through air-cooled, vertical condensers. The oil and water vapours from the condensers run into separators where the oil is separated from the ammonia water. The non-condensable gases are passed through scrubbers in order to remove the light oils and ammonia and are then used as fuel for heating the retorts. This gas, with the gases from the oil stills, constitutes a large part of the fuel used at the plant.

After being separated from the ammonia water the crude shale oil is transferred to the crude stills where it is separated into various fractions by distillation. The scrubber oils are also distilled and the light oils thus obtained are added to the corresponding products from the distillation of the crude shale oil.

The refining of shale oil is much like that of petroleum, although the operations are more complex and more expensive. Shale oil differs from crude petroleum in containing certain organic compounds that have a particularly bad odour and must be removed before the product is marketable. Also, shale oil is more highly unsaturated than petroleum and hence requires more careful refining. The removal of unsaturated products and compounds having a bad odour necessitates several distillations and acid and alkali treatments which increase the refining costs and losses. The average refining loss for shale oil in Scotland is about 25 per cent. as compared to about 7 per cent. in completely refining petroleum.

The ammonia water obtained from the scrubbers and separators is distilled, and the ammonia so obtained is passed into sulphuric acid producing ammonium sulphate.

The shale now being retorted in Scotland yields an average of about 24.5 U. S. gallons of crude oil and about 37.5 pounds of ammonium sulphate per short ton. The gas yield is about 9,800 cubic feet per ton of shale retorted; its heating value is about 210 B. t. u. per cubic foot.

The products obtained by refining the crude shale oil are motor gasoline, illuminating oils, gas and fuel oils, lubricating oils, paraffin wax, and coke. The yield of these different products varies and depends to a certain degree both on the nature of the shale and on the conditions of retorting and refining. As a rule, three grades of lubricating oil are made, none of which is suitable for steam cylinders, internal combustion engines, or heavy duty bearings.

The industry was first started on a commercial scale in Scotland about 1860. In 1871 there were 51 companies engaged in the industry while at present there are only six. The successful companies have been those that, efficiently organised, have been able to employ the best technical skill, utilize labour-saving devices, and operate on a large scale. The industry has been favoured by several factors, such as relatively low cost of labour, large yields of ammonium sulphate, high price of competing petroleum products, and the situation in a densely populated industrial region where supplies and a market were close at hand.

From 1871 to 1916 the production of shale oil increased from 593,310 barrels to 1,965,000 barrels and the production of ammonium sulphate from 2,350 to 59,400 tons. This indicates that increasing effort has been directed toward the recovery of ammonium sulphate. Undoubtedly, the increased recovery of ammonium sulphate has had considerable to do with the success of the industry in Scotland.

On the London Metal Exchange on Tuesday standard copper closed at £66 6s. 3d. cash and £67 3s. 9d. forward; electrolytic copper at £73 cash and £75 forward; Straits tin at £155 10s. cash and £158 forward; English lead at £23 17s. 6d. cash and £23 forward; bar silver at 40½d.; and fine gold at 104s. 9d.

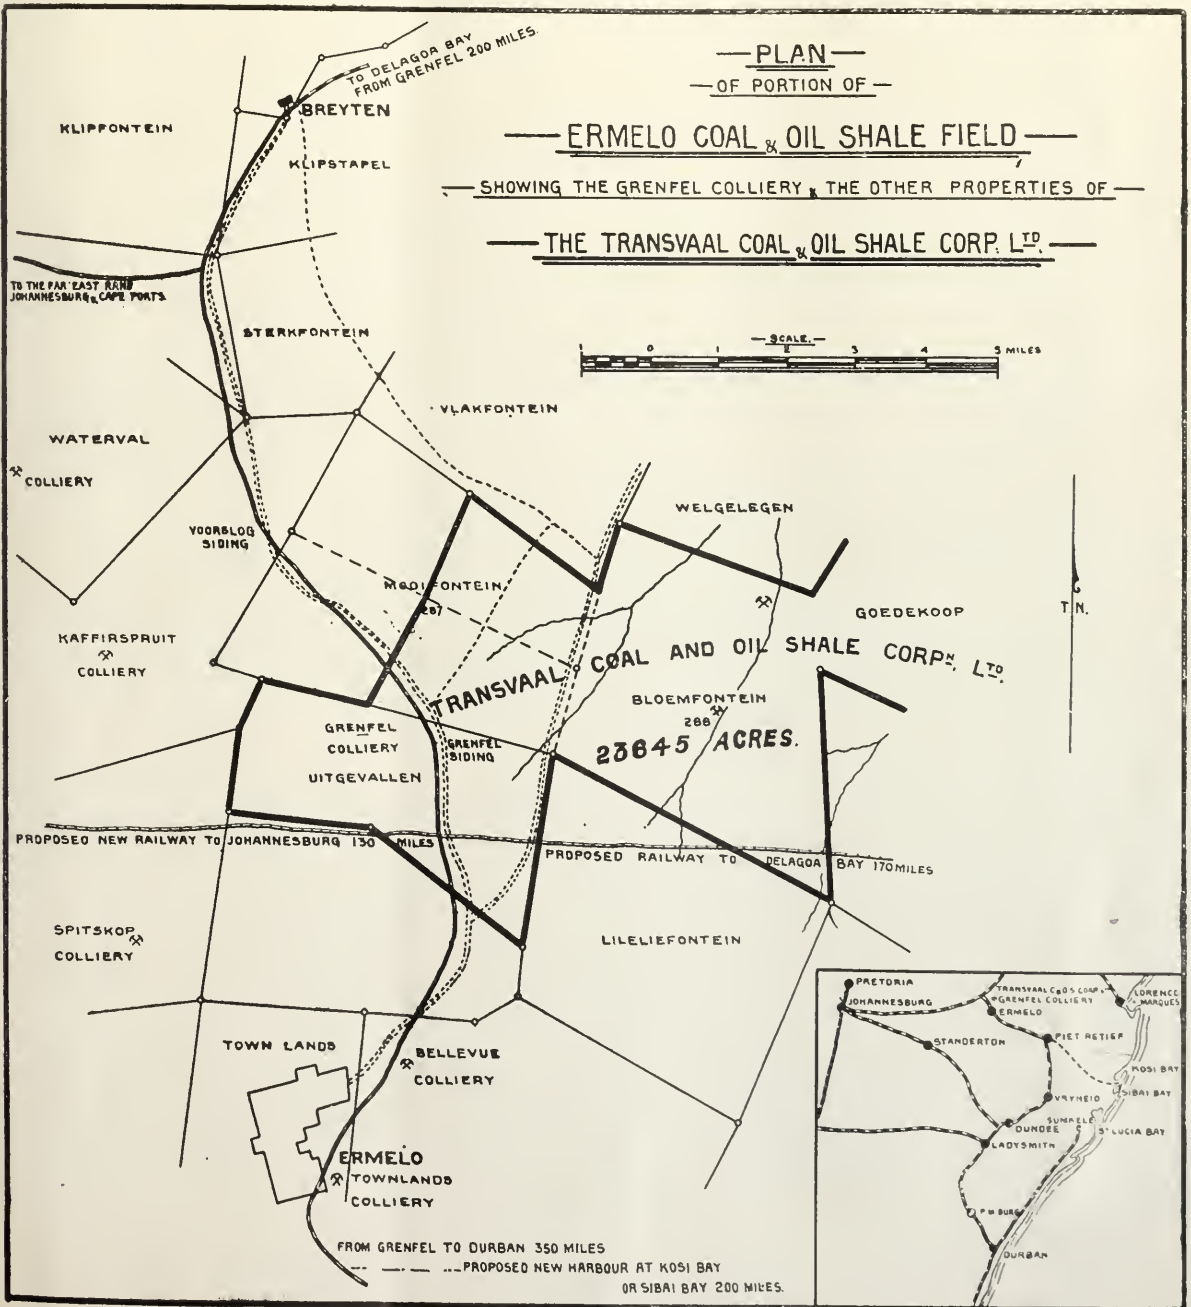

A New Coal and Oil Shale Flotation.

A BLELOCH ENTERPRISE WITH A WORKING CAPITAL OF £105,000—PROSPECTIVE PROFITS RUNNING INTO MILLIONS—NEW OIL DISTILLING PROCESS.

The latest Bleloch enterprise is the Transvaal Coal and Oil Shale Corporation, with a nominal capital of £275,000, and a working capital of £105,000. The assets to be acquired by the venture include a five-sixths interest in the Grenfel Colliery, in the Ermelo district, mineral rights over 2,132 acres on Mooifontein, freehold and mineral rights over 2,432 acres, and options over a further 9,697 acres of the farm Bloemfontein adjoining Mooifontein. The assets also include freehold of the Carlis portion of Mooifontein.

The whole of the cash capital of the Company has been guaranteed by the South African Nitrate and Potash Corporation, Ltd. The South African Nitrate and Potash Corporation, Ltd., now offers a limited number of shares to the

investing public in South Africa and the United Kingdom as follows:—100,000 10 per cent. Cumulative Preference Shares at 20s. per share, with option rights until 31st December, 1922, on 50,000 Ordinary Shares of 25s. per share—that is, an option on one Ordinary Share for every two Preference Shares taken up. The Ordinary Shares will be entitled to all the net profits over and above £15,000 per annum required to pay the 10 per cent. on the preference shares. The Grenfel Colliery has already been fully described in these columns, and in addition to it the rich oil shales and torbanite in the areas acquired will be exploited by the new company.

Samples of the torbanite have been forwarded to Mr. E. H. Cunningham Craig, B.A., F.P.S.E., M.Inst.P.T., Consulting Geologist, London. Mr. Craig is making a special technical report, which will be issued with the prospectus in England, and will be circulated to all shareholders in South Africa as soon as it arrives. The main railway line which connects with Natal and the Delagoa Bay harbours, the Transvaal, and thence on the Cape, passes through Mooifontein, and a siding on the Grenfel Colliery is in operation. The tonnage of torbanite on Mooifontein is estimated at 2,000,000 tons, from which it is estimated that a profit of £3 per ton may be obtained when worked by the new Ironside process. The tonnage of oil shale on the properties is placed at 20 millions, from which a profit of £1 per ton is expected, when treated by the same process. The estimated coal tonnage is 168,000,000 tons, on which an estimated profit of 2s. 6d. per ton is estimated. From the torbanite alone the Company anticipates a profit of £6,000,000.

The Ironside Process.

Added to the prospectus is an interesting description of the new Ironside process. According to the description, this process of distilling oils from shales and bituminous coals has been invented by Mr. T. G. Ironside, M.A., B.Sc. (Edin.). Mr. Ironside's invention constitutes a completely new method of extracting the oils and other valuable by-products from oil shales and bituminous coals. By his method the oils are extracted with extraordinary rapidity. Within half a minute after the shale or coal is placed in the distilling chamber the oil begins to run out through the condenser pipe. The capital cost for a distillation plant on this method will be only a small fraction—probably not more than one-eighth or one-tenth of the cost for a plant on the old retorting methods. An estimate for a plant built on the old method to treat 50 tons per day comes to £28,000. The cost for a distillation plant to treat 50 tons a day by the Ironside method will probably not be more than £3,000 to £3,500. Moreover, the extraction of the oils is more complete and satisfactory. A larger yield of the higher grade oils is assured, owing to the even and comparatively low temperature which can be easily maintained throughout the operation.

The prospectus states:—The process must necessarily revolutionise the oil position, not only in South Africa, but in the United Kingdom and elsewhere throughout the world wherever oil shales and bituminous coals are available. To the Transvaal Coal and Oil Shale Corporation the process means production of oils within the next few months at trifling cost for the retorting plant and with very great profits. The top seam of coal, which has very high volatile contents and which contains the rich layer of torbanite—the richest oil shale yet found in South Africa—is now of extraordinary value. Many millions of pounds sterling worth of oil which this valuable seam contains in the Company's properties will now be available for immediate production. The tonnage which this combined seam of highly bituminous coal, torbanite and oil shale carries in these properties is estimated to run into 100,000,000 tons. Even with a considerable reduction in the world prices for oil, every ton should show a minimum profit of 10s. Last year America put down 36,000 boreholes, which cost £150,000,000, all of which has to be included in the cost of production of oil from wells. In view of the great capital expenditure thus required constantly to establish and bring in new wells, and in view of the very short life of most of these wells when brought in, in view, too, of the comparatively rapid exhaustion of even rich and extensive oil fields in almost all oil well countries, the time may not be far distant when the principal source of the world's oil supplies will be from the distillation of oil shales and from coals rich in volatile matter. The Ironside process bids fair to make it possible to produce crude oil from such shale and bituminous coals at costs which will allow competition on level terms with oil from wells. In that invention, therefore, it may be said that South Africa has "struck oil." The Transvaal Coal and Oil Corporation holds in the Grenfel area, and the great areas adjoining on Mooifontein and Bloemfontein, practically

inexhaustible supplies, not only of highly bituminous coals and of ordinary oil shales carrying 20 to 30 gallons of oil per ton, but also an estimated tonnage of at least 2,000,000 tons of the rich torbanite mineral described in the prospectus, yielding up to 70 gallons of crude oil (specific gravity 0.880 at 20° Centigrade) per ton—unique almost in the world.

The Company is now about to erect the first Ironside Retort at Grenfel, and it is expected to be producing crude oil by about March next. It will therefore be the first producer of oil on a commercial scale in South Africa, and the pioneer in an industry which before long may rival the gold industry in magnitude and value. A complete refining plant would, it may be added, enable the production from the crude oil of lubricating oils and other products of still greater value. It is estimated that the cost of an Ironside plant, including condenser, to treat 50 tons per day will not exceed £3,500. This, with the £5,000 estimated for the primary refining plant as above and allowing £1,500 for contingencies, brings the estimate of the total capital cost for the first plant to £10,000.

Central Mining—Rand Mines Group.

The following are results from some of the subsidiaries for the quarter ended 30th September, 1921:—

White vs. Native Labour.

By J. E. Parker.

The extraordinary times we are passing through, and the conditions prevailing at this period, bring very forcibly before us the extreme artificiality of the whole labour position in this country, with the natives who are so many times numerically stronger than the white man. The policy of employing the native to the exclusion of the white labourer is open to serious criticism, when compared to the money value of labour returned for wages, food, medical, housing, recruiting, compound management, police, sanitary, and other incidentals which are inseparable to labour of the native class; other countries with a similar climate and conditions as apply to South Africa, and employing white labour only, are more progressive, and this unit of cost in production is considerably lower and of higher quality than in this country with a so-called cheap native labour.

the future of this country, and its position as a competitor in the world's markets for manufactured goods of which we have an abundance of raw materials at hand, an ideal position for trade, with assets second to none.

Our progress during the last decade has not been due to any gradual influx of emigrants, bent on the betterment of their condition, which the cramped nature of the older countries cannot vouchsafe, neither has the Government fostered or catered for this class of worker, who has enriched other countries and colonies by giving a handsome return in labour. Owing to mistaken views held by the majority of the people's representatives, the advent of any new comer is looked upon as presaging the ultimate ruin of the South African. Whether this is a natural fear, or the first sign of degeneration, is difficult to say, probably a little of both.

A Group of Rand Mine Workers.

The Fundamental Mistake.

It has always been the prevailing opinion that our native is the cheapest unskilled labourer in the world, and in estimating costs, it is usually on this erroneous assumption that we generally have failed to make good; this opinion may have had its foundation in the very early days when labourers could be hired by the week or month for a yard of "linbo" or a few "beads," and when quantity was of more consequence than quality. These days are of the dim and distant past; we have progressed beyond this period, and require labourers of the semi-skilled type, men who can use their mental and physical powers in work of a productive nature, for it is in work of this class that we seem so hopelessly outclassed by the foreigner, who employs white labour and is able to undersell the locally produced article.

As labour represents the biggest item on the debit side of all manufactures, I would commend a close study of this question to both employers and employed, as bearing upon

Our progress has been entirely due to the mineral wealth and the influx of foreign capital for the development of the mines, which have induced workers from many climes to settle in this country. Their energy and hard-earned capital are being utilised to exploit the productiveness of the land, of which they have become the true pioneers.

The inherent pushfulness of the white race in opening up new works has created such a demand for unskilled labour—of which the native is the only form recognised—and the supply not being equal to the demand, it has not been necessary for him to qualify for his position, either by industriousness or efficiency, wages have risen enabling him to live in unaccustomed luxury, which in his natural state he could never have dreamed of, not to mention its appalling effect on his morality; but with the high wages paid, the quality of his labour remains practically at the old standard, and generally speaking he is the most inefficient, and therefore the most costly, labour in the world, proving not only

a hindrance to the skilled workers who have to deal with him, but a source of great and unnecessary expense to the employer.

Ocular Demonstration.

As evidence in the above contention it is only necessary to observe the native at work on the mines, roads, farms, or towns, and the number in attendance on the individual white worker, and compare their labour with what obtains in the white man's realm; one white labourer would be expected to do an amount of work equalling the joint labour of at least three natives, and in a more thorough and workmanlike manner, which is conclusive evidence of the costliness of native labour when all its extraneous costs of recruitment, feeding, compound, and other charges previously mentioned are debited.

The manner in which the native is allowed to squat on the land, and the large reserve areas granted to him by the Government are much to blame for his apparent indifference. If these lands were cultivated, they would yield all the necessaries required for his sustenance, instead of which his own innate laziness compels him at certain seasons of the year to seek work from the white man in order to provide for the next period of inertness. Bearing in mind the fact that the race for existence is always with the stronger peoples, and the natives being in such overwhelming numbers, there must come a time when the white man in this country must yield to the inevitable, and the problem to be faced sooner or later is, whether we shall be able to make of this a white man's country, or allow it to revert to the natives. Unfortunately what should be our unskilled white labourer, owing to his environment, is quite unfitted, without passing through a probationary period, to take the place of the native. Being already contaminated, he has neither the

energy or inclination, nor has he the experience in handling such tools as are necessary in manual work; not having been brought up to understand the dignity of labour—which, of course, is nauseating to him—and few are suitable to act as supervisors; hence the existence of so many indigent whites, who are an encumbrance to the country and a standing disgrace to the ineptitude of our administrators.

Higher Education.

The higher education in our schools and colleges will not do much towards improving the general status of the labourer in this country, aiming as it does at making embryo managers or supervisors, a class which is already overstocked and, except these few youths who have parents sufficiently well provided with the necessary capital to place their sons on farms or in business, the outlook for the great majority is not very promising.

To provide a remedy should be the first consideration of the Government; the necessary capital to provide for such schemes as the following need not occasion any difficulty in obtaining. This country is ideally situated in that respect, for we have a commodity in gold which can never suffer from over-production, and lands now lying idle which only require water conservation schemes established to make it equal to the best in productiveness in the whole world.

With the capital acquired, the gold reef areas held by the country should be opened up for the benefit of its people, and not given over to the speculators for the enrichment of the foreign shareholder. These mines could be worked by white labour, which would be under efficient and expert instructors, trained in actual practice as well as in theory, who would impart their knowledge to the workmen in the various branches, using the most up-to-date tools and machines, and all work to be done under contract on similar lines and conditions as prevail in other countries where white labour only is employed.

Such mines would not only act as an education to the men and provide employment for many thousands, but would prove a highly remunerative proposition, circulating money within the country and therefore benefiting its citizens generally.

From each mine so started the nucleus of the running staff for those to follow would be obtained, and so on, opening up, developing, and finally producing and circulating its gold, which would be the basis of great commercial possibilities.

The working of the low-grade mines by the Government on these lines, even though they barely met expenditure, would pay the country better than doling out a bare existence to the unemployed for work of an unproductive nature. In the case of the low-grade mine there would always be a big percentage returned into circulation at a very small cost to the country.

To those who are more fitted for husbandry, suitable lands should be prepared and, under proper supervision of an expert manager, who will control and advise the worker and give him all the assistance necessary to start him under the most favourable conditions, payments to be made on results of working, and every inducement advanced to encourage the worker to take up land on his own account after a given period, during which he may have proved his fitness to occupy such land.

With regard to these farms which have native squatters equal on them, owners should be compelled to accept an equal number of white men, on the same terms and conditions, providing there is suitable land for cultivation.

Afforestation to be undertaken wherever possible, which in time to come will yield a very handsome profit.

Around these industries would spring up other allied trades requiring many more workers. The country should be thrown open to emigrants, and only these of the very best type admitted after the strictest examination, a guarantee of employment being the best inducement to such emigrants.

All profits accruing from these national undertakings would be utilised in furthering the extension of this policy, thereby creating a more equally distributed population, and contributing to a white South Africa a race of virile men, nurtured by a wonderful climate, and a fitting example to their successors.

It may be that certain readers will consider these schemes prejudiced in favour of the white labourer. It must be borne in mind that the majority of all peoples are the toilers, or manual workers—this country being no exception. The present condition of the poor white who has been brought to his condition by force of circumstances, unaccustomed as he is to any form of manual labour, is a very deplorable one indeed, and must become greatly intensified as time goes on. My object, therefore, in putting forward these schemes is to endeavour to break through the common prejudice against employing unskilled white labour and to find a means of providing men with a decent and respectable existence. The fact that numbers of these men in times of great depression

employed on Government relief works (usually pick and shovel) have proved expensive in amount of labour returned, is no criterion as to their fitness when trained in the proper use of these tools; besides, under proper organisation each branch would be composed of specially selected men. It would be like comparing the ordinary labourer with the skilled navvy, which is equally ridiculous. The avenues of employment outlined would really be quite apart from work now being done by the native, and for the time being would not interfere with him in any way. As the population of whites increased with the opening up of further industries, so would agriculture and the country generally, in which case there would be ample scope for the native in those lines for which he has especial aptitude. With the improvement of the white man's condition and the balance of numbers being in his favour, a great social improvement would be manifest throughout the country. The native, due to the spirit of emulation, would also improve; the kraal and the compound will disappear, and along with them their vile associations.

As I write I have before me several lists of unemployed, and apart from the unskilled labourer, every branch of the mineworker, from manager to trammer, is enumerated. These men are ready to take up any employment whatever. With the almost certainty of other mines closing down in the near future, what hope have these men of receiving the help required, what of their families? These are not the ordinary poor white, but are skilled tradesmen. Surely it would be possible for the Government to take over one of the best conditioned "derelict" mines for the benefit of these unemployed. These men are not afraid of work, and with the Government's assistance in technical advice and management, and with the strictest economy in working, it would have to be a very low-grade property indeed that could not be made to pay ordinary wages. With the exception of the general manager, who will be appointed by the Government (his sympathies must also be in favour of white labour), there need be few overseers. Most of the men being highly skilled, the ordinary overseer would be superfluous. It must also be clearly understood that every man is a worker. At the end of each month when the returns are in hand, and after payments for stores, etc., have been provided for, the balance of cash to be pooled and apportioned out to the men, using as a basis the percentage of difference between the various grades of workmen on other mines, a deduction of 10 per cent. monthly to be made for contingencies, this item to be carried forward in order to provide for any emergency. The control would be by board, composed of one man from each section, with the manager as chairman.

Of course, this would only be considered in the light of a temporary arrangement to tide over the depression, and not in any way to take the place of the proposal put forward, in which the Government are asked to open up other reef areas for the employment and training of white labour only.

[We print this article as an interesting contribution to the subject of labour economics, but are not in agreement with our correspondent on all the points which he brings forward. —Ed., S.A.M.J.]

Ventilation and Miners' Phthisis.

II.

MORE POINTS FROM MINE INSPECTORS' REPORTS.

Negligence and Carelessness of Miners.—It would appear that some miners only use the dust-allaying appliances for fear of the consequences of being caught and reported, the benefit to their own health not being considered by them. This conviction is brought home to one by, in the first instance, the number of cases where one finds these regulations have been only partly complied with; secondly, by the number of cases of natives drilling dry reported to inspectors by mine officials; and thirdly, by the number of convictions obtained against the miners themselves for breaches of the Phthisis Regulations. If a shift boss in his daily visit of a working place can catch persons disregarding regulations, one must suppose that the offence often occurs. Many miners, apparently, do not fear phthisis, as they know that the examination by the Medical Bureau is so thorough that they will be warned of the first symptoms of the disease, and they also know that the first symptoms have very little effect upon their health if they leave the mine at once. Some of the miners make no secret of the fact that they look forward to receiving their compensation money, and this perhaps may be the reason for the carelessness of the miners towards the regulations framed for the prevention of phthisis.

Main Ventilation.—During the year there has been no radical change in the main ventilation scheme of any mine in this district. On the whole, the main ventilation on the mines in this area may be said to be very fair. The quantity of air downcasting is, with one exception, more than sufficient; it is the effective distribution of this air which still needs better attention. Systematic inspections have revealed that the laying-out of ventilating districts and the suitable splitting of air currents on some mines has been tackled in a very indifferent way.

Ventilation of Dead Ends.—Little development is now proceeding in the mines around Germiston, and such as has been done has not warranted any considerable expenditure on subsidiary ventilating appliances. On the Sub Nigel, however, where conditions are similar to those in the Boksburg district, and great distances have been driven, risen and sunk with the utmost possible speed, the consideration of the problem of ventilating their dead ends became imperative. A system of exhaust ventilation has been adopted. Galvanised iron ventilation pipes, 14-inch, 16-inch, 20-inch diameter, are carried within 100-300 feet of the face, according to the conditions. The vitiated air at the end of the tunnel is drawn into and through these pipes by means of small fans up to 25 inches diameter, either electrically or air driven. By adopting this method, it is claimed that the greater length of the tunnel has fresh air constantly, and that those travelling in it, especially after the blast, do so in fresh air, at any rate up to the end of the ventilation pipe, a short time after the blast, thus allowing work to proceed quicker than otherwise would be the case where air is blown in. Against the advantage claimed above, it must be born in mind that the length of tunnel beyond that end of the ventilation pipe which is effected by exhausting, is small, and with the necessity for keeping the end of the pipe at some distance from the face, there arises the necessity for considerable additional ventilation by means of compressed air at the face, especially after blasting, in order that the vitiated air may be expelled towards the ventilation pipe. Considerable time and energy have been expended by the manager and officials in performing these ventilation schemes, and a point has now been reached where a satisfactory method of effectively dealing with a difficult problem has been achieved at a minimum of cost.

Back Stopes.—Systematic inspections, coupled with the monthly returns giving the percentage of CO₂ and quantity

of dust present in the air, have shown that the ventilation of these workings in several instances is not as it should be. To attempt to apply any hard and fast rule as to a system of ventilation to be adopted is out of the question, as conditions vary so much. In cases where the monthly returns twice repeated indicate that ventilation is unsatisfactory, investigations have been made and action taken.

General.—Since the introduction of the komimeter, it has been made apparent that ventilation plays a most important part in the health conditions of phthisical mines. By proper use of water and appliances, the quantity of dust produced is enormously reduced; but as no reliance can be placed upon the continued and proper use of water, dust is frequently formed and escapes into the air. With ample ventilation, quantities of such dust which under feeble ventilation would be injurious, would in all probability be quite harmless. Not only will increased ventilation prove beneficial in dealing with the dust that gets into the air due to the non-use or misuse of water, but will also remove or dilute the air containing very minute dust particles upon which water has apparently no appreciable effect. During the year under review, there has been in general, as in past years, the same co-operation between mine managements and this department with regard to the prevention of phthisis. As evidence of this, it has not been necessary to proceed against any manager for breaches of the phthisis regulations, and in only one instance has it been necessary to issue a mandatory letter in this connection. The water supply in general is adequate, and on the whole good. Systematic inspections have shown that any unsatisfactory conditions are the result of negligence or ignorance on the part of the underground employees, either official or miners. There are, it would appear, still to be found both miners and natives who do not seem to appreciate the danger of dust. With the latter it is perhaps understandable, but with the former, unless we attribute it to callousness or the desire for compensation, it is difficult to understand.

Machine Drills.—During the past year, as a result of continued tests, the dry jack hammer type of machine has proved to be a dangerous dust producer. The use of this machine has been prohibited after the 1st of April, 1921. When it became apparent to managers that the dry jack hammer was to be prohibited, they were forced to find an efficient substitute. The axial water feed, or "wet" jack hammer, did not, apparently, find favour. With solid steel and water externally applied, it was found that there was a limit to the depth of hole which could be drilled below a certain angle, on account of the difficulty of sludging. In order to obtain a greater depth of hole, various schemes have been tried, amongst which the Simmer and Jack method has, it would appear, proved a success. The manager of the Simmer and Jack has converted all his dry jack hammer machines into solid steel throughout the mine. Ordinary 7-8 inch hammer steel is used, a slight flat is put on the steel for the last 12 inches, and a half turn put in about 8 inches from the cutting edge; this twist acts as an impeller, the sludge being driven away from the cutting edge or drawn away, according to the direction of rotation. Machines of either directions of rotation are in use, and work satisfactorily. The mine is, however, standardising on the machine rotating clockwise, and the twist giving an injection action is put in the steel; this ensures that the sludge is removed from the cutting edge. The dust results, according to the company's dust sampler, are good; the average number of "particles" for jack hammer stopes having dropped from 172 to 119 per c.c., and now results of 50 are regularly being obtained in these stopes. The management states that any high dust results now obtained in jack hammer stopes will be, in their opinion, due to other causes, such as lashing stuff not properly wetted, etc. The Geldenhuis Deep management is also using solid steel, but in this case either water or air can be supplied to the hole through a narrow pipe inserted in it. This method is perhaps not quite as satisfactory as the Simmer and Jack twisted steel from the point of view of dust prevention; the introduction of air into a hole during drilling lends itself to abuse should the water supply be insufficient, with the possibility that conditions almost similar to those obtaining with the "dry" jack hammers might occur.

Leyner Type of Machine Drill.—The Leyner type machine is not largely used on any mine in this district, with the exception of the Sub Nigel. Dust samples taken during the year where these machines were working gave for the most part unsatisfactory results. On the assumption that the dust produced by this type of machine could be satisfactorily low with good water pressure, if the tube and shank end of the drills were in good condition, considerable attention was paid to these parts. It was shown, however, that even with these things in order, unsatisfactory dust results could be obtained, and it was then found that, in sharpening the steel, the 3-8-inch hole was considerably restricted by the "dolly pin," and in many cases not more than a 1-8-inch hole was left at a short distance back from the bit, so that the amount of water flowing through the steel beyond this point was quite inadequate to effectively wet the rock at the cutting edge, and with the admission of air to the bottom of the hole, conditions similar to those obtaining in the dry jack hammer might be created, and account for the production of dust. The restricted hole also caused increased togging at the chuck, owing to the excess of water escaping. As a result, apparently, of this demonstration of a further possible cause of dust production, a circular was issued by the Chamber of Mines (rather late in the day) drawing attention to the necessity for maintaining the hole in the steel at full bore. Axial water feed drills passing water only, such as the Hydromax, Ingersol and Waugh, are in fairly general use for raising, back stoping, etc.; with these machines the dust results obtained are on the whole good. As the restriction of the hole in the steel is as likely with this type of machine as with the Leyner type, it would seem to point to the fact that the admission of air down the steel is the principal cause in the production of dust. The regulation recently framed prohibiting the use of machines "passing air only" down the steel, might with advantage be altered to "passing any air" down the steel. No new type of axial water fed machine has been put into commission in this district during the period under review, and no use has been made of either the Switt or Ferreira attachments for reciprocating machines.

Grizzleys.—Bad dust results are still often obtained at grizzleys. These grizzleys are generally in dead ends and badly ventilated; the use of sprays or atomizers does not seem to prevent dust. At places where large tonnages are handled, it would seem that more attention must be given to the ventilation of these points; better ventilation, in conjunction with atomizers, could not fail to give satisfactory results.

Records.—The records called for under Regulations 59 and 161 (10) have all been examined during the year. It can be said that these records are now becoming a valuable source of information both to managements and to this department. If all the mines would adopt the konimeter, a still greater knowledge of mine conditions will be available.

C. J. Gray, I.M., Johannesburg.

In the absence of a satisfactory statistical basis, all opinion as to the progress made in the fight against miners' phthisis must be rather uncertain; but I think that, on the whole, some slight advance was made during the year, while the prospect of future marked advance certainly became brighter. Established practice in use of water for dust prevention was well maintained. Improvements which were made in general ventilation should be distinct gains. Improvements in ventilation of sinking shafts, greater care to use drills producing comparatively little dust in these shafts, and closer attention to the conditions at commencement of shift in development drives, though conditions are not yet satisfactory in sinking shafts or drives, have also lessened risk of exposure to dangerous dust. Apart from care in selection, upkeep, and working of the drills, a really good special means of ventilation is necessary in a sinking shaft or development end, and that is not yet generally provided and used. Early in the year, use of drills (dry jack hammers) passing compressed air alone through the jumper steel seemed to be extending; but proof that such drills produced undesirable amounts of dust, followed by the decision to prohibit use of such drills from 31st March, 1921, which was come to at a conference called by the Government

Mining Engineer on 1st July, stopped further installation of such drills, and encouraged alteration of those installed. Most of these machines now use solid steel, but some have been altered so as to pass water as well as air through the steel (wet jack hammers). When solid steel is used, success or failure in preventing dust arising depends upon the care or negligence of the persons working the drill in applying water at the hole. In the machine with hollow steel, addition of water to the air-feed to the drill bit does not get over the difficulty completely, as experience shows that the risk of partial or complete failure of the water feed, owing to danger to the water tube or other cause, is such that the drills often make much dangerous dust, but the addition of water feed is certainly an improvement. The difficulties with the air and water feed to the bit in the wet jack hammer are those experienced with the water Leyner type of drill, the water feed arrangements being similar. Much attention was given to the dust results from the water Leyner during the year, and greater care and more general realization of the risk of derangement of the water feed probably reduced the amount of dust from those machines, but it was not reassuring to find late in the year, on an inspection of the steel, that at one mine in the district 100 per cent. of the shanks had holes too small to permit of entry of the water tube, and therefore that, apart from any accident or ill-treatment of the machine underground, the water feed could not be satisfactory.

NEW PATENTS.

962. The Climax Rock Drill and Engineering Works, Ltd., Stella Buildings, cor. New and Rissik Street Johannesburg.—Improvements in automatic rock drill control device.
963. Joseph Green, 35, Grosvenor Road, Kimberley, and presently 47, Bloemhof.—Improvements in diamond washing apparatus.
966. The Victoria Falls and Transvaal Power Co., Ltd., 2, Robertson Campbell McLean. Both of Consolidated Buildings, Johannesburg.—Improvements in or relating to the distribution of fuel over furnace grates.
969. Herbert George Dempster, Seaforth, Richmond, Natal. Improvements in means for fixing rails to railway sleepers.
973. Richard Harrison, Umtati, Southern Rhodesia.—Improvements in or relating to brazed joints of pipes.
974. John Harris, Henley-on-Klip, Transvaal.—An improved buffer for use on railways and the like.
975. British United Shoe Machinery (S.A.), Ltd., 86, Adderley Street, Port Elizabeth.—Improvements in or relating to machinery for grading sheet stock and dealing with the same in accordance with grading.
979. Alexander Spencer, 2, Central Buildings, Westminster, London, S.W.1, England.—Improvements in central buffing and draw gear for railway and like vehicles.
980. Andrew Barks, c/o Messrs. Niven and Mitchell, Ltd., 11, General Mining Buildings, and P.O. Box 922, Johannesburg.—An improvement in retorts for the recovery of by-products from coal and oil shale and other materials.
981. James August McGeorge, Rooms 37 and 38, African Buildings, Church Street, Pretoria.—Improvements in connections for pipes, bars and the like.
983. 1. William Henry Dyson, 2, Leslie Aitchison, Both of 2, Ringwood, Normandy, near Guildford, Surrey, England.—Improvements in and relating to the detection of high frequency currents.
983. 1. William Henry Dyson, 2, Leslie Aitchison, Both of 2, Ringwood, Normandy, near Guildford, Surrey, England.—Improvements in or relating to the treatment of ores and residues for the purification or concentration of the metallic values.
981. Marconi's Wireless Telegraphy Co., Ltd., Marconi House, Strand, London. Improvements in and relating to the detection of high frequency signalling currents.
987. 1. Robert Edwin Bateman, 2, Sidney Harold Hill's. Both of Simmer and Jack Gold Mining Co., Germiston.—Improvements to automatic valve controlling devices applicable to rock drilling machines and the like.

The following were Monday's cable rates of exchange:—London on Paris, 53 francs 37 centimes per £ (on October 27, 54.10); London on New York, 3 dollars 92 cents per £ on October 27, 3.93; New York on London, 3 dollars 93 cents per £ (on October 27, 3.93½); New York on Paris, 7 37 cents per franc (on October 27, 7.27); Berlin on London, 716 marks per £ (on October 27, 682); Berlin on Paris, 13 marks 12 pfennige per franc (on October 27, 12.65); Berlin on Amsterdam, 62 marks 30 pfennige per florin (on October 27, 59); Berlin on New York, 181 marks 50 pfennige per dollar (on October 27, 173.80)

EDITORIAL.

THE MOZAMBIQUE CONVENTION.

During the past week or two public interest in the problems of the future status of the Mozambique Convention has been much increased by the remarks of the Prime Minister on the subject and by the despatch of a Union Government expedition to survey a new port on the Zululand coast. It need hardly be said that Lourenco Marques has read with deep interest the speech delivered by General Smuts at the congress of the Chambers of Commerce in Pretoria, and has noted the likelihood of a new Union port being established between Durban and Delagoa Bay with grave concern; for it is impossible to consider the revision of the Convention without reference to the significance of the Prime Minister's hint that the Transvaal mines may not be in such great need of Portuguese East African natives as

they were a dozen years ago, when the terms of the Convention were framed. And it is also not easy to believe that the projected opening up of Kosi Bay is an undertaking which has been engaged on by the South African Government without fully considering the effect upon Delagoa's trade which the introduction of a new harbour on the East Coast inevitably would have. That, at any rate, is the view held in Portuguese territory, and, whilst it may be a mere coincidence that the Zululand harbour project—which this paper was the first to draw attention to nearly a year ago—is at last receiving the Government's serious attention at a time when the future trade relations of the Union with Portuguese East Africa require earnest consideration, it will be appreciated that our friends in Delagoa are freely speculating as to the Union's future policy with regard to Portuguese territory.

Before proceeding to a further examination of these matters it may be as well if we recount in brief the essential clauses of the Mozambique Convention, the terms of which are not perhaps so thoroughly understood in this country as they might be. The Transvaal-Mozambique agreement is a convention entered into between the Transvaal Government and the Government of the Province of Mozambique in 1909, to remain in force for ten years from that date, and thereafter either party to the agreement may give one year's notice of intention to terminate it. The present convention replaced the *modus vivendi* which had been signed on the 12th December, 1901 (with addition signed on the 15th June, 1904). The existing agreement is, as was the *modus vivendi*, a commercial agreement between two adjoining Colonies having many identical interests. It deals with Customs matters, the circulation of commerce, native labour, and railway traffic between the two territories, and under these heads provides for the free entry into the Colonies of the products of the soil of either and for the recruitment of native labour in Mozambique for the Transvaal mines. Approximately 100,000 Portuguese natives are constantly employed in the mines of the Transvaal. It was also provided that by the periodical revision of railway rates it would be ensured that from 50 to 55 per cent. of the railway traffic to what are known as the "competitive areas" of the Transvaal should come through Lourenco Marques. Owing to the conditions brought about mainly by the War this percentage fell to much less than that provided for in Part II. of the convention, and in consequence the Portuguese authorities have denounced the treaty and asked for a new convention.

The whole subject bristles with difficulties, and wise and generous statesmanship is called for on both sides in the framing of the new agreement. Special interest, therefore, attaches to the Premier's recent remarks as to the native labour supply of the Mozambique territory to the Transvaal mines. It has always been held that the Union cannot dispense with labour from this source, despite the shadow of waning output which has fallen on the Rand. But the Prime Minister's remarks have given the impression that our mines are not so dependent on East Coast labour as they used to be. The interpretation put upon his speech by Delagoa Bay is that either it was made seriously, and must be dealt with in a serious spirit, or else it is "pure bluff," in which latter category it would seem to give colour to the view that it was somewhat natural that General Smuts should endeavour to minimise the advantages the Union obtained from the operation of the existing convention. Assuming that General Smuts spoke seriously, a possible decision on the part of the Union Government not to press for labour from the Mozambique Province would be not altogether unwelcome in the coastal territory, according to some students of the problem, who contend that farming and other industries in Southern Mozambique, which are to-day faced with the greatest difficulty in securing a sufficiency of boys, would benefit immediately, and, as a consequence, would be able to enlarge their field of operations.

There may be much more behind all this banter of words and interpretations than at first sight meets the eye. It may be that the eyes of our farseeing Prime Minister are

set upon the vast labour resources of Tanganyika territory. Then again, it is not improbable that East Coast labourers, no matter what the convention may decide on in regard to them, will always seek work in the markets which offer the largest rewards. At any rate, the Prime Minister's remarks have riveted attention and have set many minds wondering as to what exactly his words were intended to convey. Add to this the fact that the Union Government evidently is now desirous of establishing a new port on the East Coast at a point which lies almost in a direct line with the busiest industrial centre of South Africa, and it is scarcely surprising to find that Delagoa Bay is greatly wondering what its commercial relations with the Union may be in a few years' time. But whatever modification of the convention may be proposed or decided on, we feel sure that there is a very earnest desire on the part of the Union Government to perpetuate the amicable relations which always have existed between ourselves and our eastern neighbours. And this desire is, we are assured, heartily reciprocated by the inhabitants of the Province of Mozambique.

KEY INDUSTRIES AND OVERSEA COMPETITION.

Extraordinary interest has been aroused by the announcement that the contract for steel pipes for the Rand Water Board had gone to Germany. Following so closely on the giving of the big contract for grain elevators by the Railway Administration to an American firm, the whole question of public policy towards local industries on the one hand and British manufacturers on the other is raised, and demands serious consideration. A fortnight ago we dealt at considerable length with the grain elevator contracts, and we gave expression to what we consider the perfectly legitimate grievance of the unsuccessful local tenderers on the subject. Our article has evoked many expressions of appreciation from the tenderers, but it is disappointing to find that its main object—which was to extract from the Railways a statement of the amount of the successful tender—has not been achieved. It may be remembered that we asked the Administration, in justice to the local firms who had gone to considerable expense and trouble in submitting tenders, to publish the figures at which Messrs. Menkin had contracted to do the work. That figure, however, has not yet been vouchsafed to us, and so seriously is the matter regarded by prominent local industrialists that we shall be surprised if the whole matter is not brought up as one of urgency at the next session of the Union Parliament. The Water Board contract is not exactly a parallel case, but it furnishes certain features which may usefully be discussed here. Of course the reason why the German firm was successful is the exchange position, which enables the German manufacturer to underbid all rivals by a wide margin. What has happened in this case has happened in many others which do not come to light. We recently cited the experience of a new cement manufacturing company which placed its order for plant and machinery in Germany simply because no British manufacturer could come any way near the figure of the German tenderer. The advantageous position of German trade owing to the exchange factor is seen in every sphere of business, and it has even made its effect felt in freight and shipping circles, the German passenger lines now offering fares at about a third of those of the British lines. Until the chaotic state of the exchanges is settled these anomalies, we suppose, must continue, and from the strictly business point of view doubtless people cannot be blamed for taking advantage of them. But a bigger question emerges when we come to consider the placing of these spectacular public contracts with foreign firms. This country is going through critical years of growth in several industries, such as iron and steel. These, as they term them in Great Britain, are "key industries," and as such they merit a special need of Government support and encouragement. Hitherto the latter has taken the form mainly of fine words and unctuous platitudes. When it comes to doing something practical the Government finds itself unable to

take the smallest step to translate its smooth phrases into tangible assistance. For instance, it is, we believe, an open secret that the Newcastle Iron and Steel people satisfied the Government that with a little direct financial assistance they could successfully compete for the making of cast-iron pipes for the Water Board. But the Government, though sympathetic, was powerless to help, and this unique opportunity of giving a young and promising "key industry" a magnificent "leg-up" has been lost in favour of Germany! Facts such as these emphasise the need for some more consistent public attitude towards our young industries. Of course we must be business-like, but the question is whether in the long run it may not be better business to make a sacrifice in favour of the development of local "key industries" which may at some future time—as Great Britain found in many directions during the War—be necessary to our economic and national existence.

Notes & News.

Failure of a Large Cape Enterprise?

Disquieting rumours for some time past have been afloat regarding a large land settlement enterprise in the Eastern Province of the Cape Colony. The company in question has been liberally backed by one of the leading mining and financial corporations of the Rand, and, according to information which has just reached us from an unimpeachable source, the affairs of the concern have now reached a crisis of a most serious nature. Though a discreet silence has been preserved in regard to this enterprise for a long time past, it generally has been known that the scheme was encountering big difficulties. Even the strong financial support lent it by a Big House has not apparently been enough to materialise the roseate hopes held out to those who have been induced to settle on the land in question. To these latter people, many of whom have staked their all in the proposition, and who are now, so we hear, unable to obtain transfer of title deeds, we offer our sincere condolences. This paper is not an agricultural journal, and for that reason we do not propose to discuss this ill-starred venture further. But the fact that several men whose names are well known in the local mining world are closely identified with the enterprise has induced us to mention the reported failure of the scheme. Incidents of this nature cannot but have an ill effect upon the country. They will contribute towards keeping agricultural immigrants from South Africa and will doubtless tend towards negating the work which is being carried on by the 1820 Settlers' Committee, which aims at populating certain areas of the Union with overseas settlers possessed of capital.

* * *

Miners' Phthisis and Collieries and Tin Mines.

In the course of his annual report, issued this week, Dr. Watkins-Pitchford, Chairman of the Miners' Phthisis Medical Bureau, writes:—In 33 of the 398 new cases of "pure" silicosis with which we are now dealing, the previous mining work had been carried on in collieries only. The average duration of work in scheduled mines which preceded the development of silicosis in these cases was 9 years and 7 months; for all the new cases it was 9 years and 8 months. Twenty of the 33 men had worked in collieries for less than 10 years; the average duration of their work on the Reef was 9 years and 1 month. Eight of the men had worked in collieries for from 10 to 20 years; the average of their work on the Reef was 10 years and 6 months. Five of the men had worked in coal for 20 years or longer, and the average of their underground work with us, prior to the appearance of silicosis, was 9 years and 8 months. These results, taken in conjunction with similar returns for last year, appear to indicate that previous colliery employment has no marked influence in retarding the development of silicosis. In my last annual report the somewhat surprising fact was recorded that those of the new silicotics whose previous employment had been in tin mines only showed a longer average "effec-

tive period" prior to the appearance of silicosis than that for all new cases. The same fact has again to be reported this year. Twenty-seven of the new cases had previously been tin-miners only—practically all of them in Cornwall—for an average of 6 years and 9 months; the mean of their times of employment on the Reef, before silicosis appeared, was 11 years and 5 months, as contrasted with an average of 9 years and 8 months for all new cases. This phenomenon is probably one of both survival and inheritance. The tin miners who work with us are not only survivors in their own generation, but they are also the offspring of a race of men who have occupied themselves in mining since prehistoric times, and it is not unreasonable to suppose that some measure of natural selection has resulted from the latter fact.

The Birth of the Rock Drill.

In one of his articles on "Everybody's Business," in the *Saturday Evening Post*, Floyd W. Parsons told the following story:—The birth of the air drill occurred under circumstances that can hardly be termed auspicious. Back in 1871 a mechanic named Ingersoll came to New York with models of some of the newest inventions. Among other things, he had a device built like a good-sized pistol, with which he could throw a line through a second-storey window in case of fire. One day he was riding in a horse-car and explaining this particular model to a man who sat beside him. On an opposite seat sat a prominent contractor, who had undertaken a big excavating job, and who was therefore interested in inventing a machine that could drill the rock encountered in the excavation work. After the mechanic had finished his story the contractor inquired: "Why don't you invent something worth while? For instance, why don't you develop a rock drill? Such a machine would be largely used because of its saving of hand labour." "I could do it all right if I only had the money," replied the mechanic. "How much money do you want?" Ingersoll replied that it might take as much as 50 dollars to make the model, and immediately the contractor handed that amount of money to the stranger, at the same time giving him his card and telling him to go ahead. Work on the drill was commenced, and during the course of its building the mechanic went back to the contractor for many times 50 dollars. At last the machine was finished and a test was staged. Many difficulties arose, and numerous changes were made in the general design of the drill. Finally, however, the device was perfected and put in practical use, and has continued from that day, with various modifications, up to the present time.

* * *

Wages of Colliery Employees.

Recently, after a proposal by the Chamber of Mines Collieries Committee to award the wages of colliery employees on a sliding scale varying with the cost of living, the S.A. Industrial Federation replied that the Transvaal Chamber of Mines had not proved its case for a reduction of wages in the case of colliery employees. The secretary of the S.A.I.F. has now received the Chamber's reply, which states, *inter alia*, that the colliery employees as a whole have at least been treated as favourably as, and latterly more favourably in regard to increases of wages than, any other employees engaged in the mining industry, and that in the interests of the South African coal trade generally a lower cost of production is imperative.

* * *

The Busy Man's Page.

On account of delay in the arrival of the overseas mail, we are unavoidably prevented from giving our usual weekly digest of technical literature.

New Eland Finances.

The New Eland Diamond Mining Company, like all the others, suffered a severe setback when the diamond market went to pieces. At the annual meeting, held a few days ago, it was shown that the company is husbanding its resources against the day of recovery. The company's profit for the year under review was £12,112 as against £19,394 for the previous year. This is explained by the higher working costs and the lesser value by 2s. 8d. per carat. The higher working costs are attributable to the increased cost of stores and to the difficulty of getting ground, a difficulty which had now been overcome. The chairman, Sir Thomas Cullinan, stated at the meeting that for the past two or three years the profits had gone into development and equipment. This sound policy he maintained was the only course which would ensure future profits, and he really thought they had now arrived at that stage of progress when shareholders might anticipate a fair return from profits so long held back and put back into the mine. The chairman also mentioned that for the past three years the yield had been much the same. There were 1,244,551 loads in reserve, which, based on the past year's working, gave development twelve years ahead of the plant, but taking 800 loads a day, which the manager stated could now be handled, there was a little over five years' work ahead of the gear. They would therefore see that expenditure on development work need not be so heavy for the future.

* * *

Gold Accumulations in the U.S.A.

The New York correspondent of the London *Daily Telegraph* recently stated that the avalanche of gold which is constantly pouring into the United States of America from Europe is causing considerable concern among the officials of the New York Assay Office, the vaults of which are now clogged with the accumulation of gold in bars, strips, and coin. This is because that country is now the great creditor country of the world, while the exchanges of many countries are depreciated, so that wherever possible gold is shipped to New York because of its value in the exchanges. According to *Bradstreet*, on the 1st April, 1921, the United States' gold holdings aggregated 3,001,487,915 dollars. Since that date approximately 40,500,000 dollars arrived at New York alone, and upwards of 3,300,000 dollars was in transit from Europe, while domestic production in previous few weeks added to the figures. The total indicated stocks, including the shipment en route, was then in the neighbourhood of 3,045,300,000 dollars, while exports during the month were negligible. The figure just given compares with the high record of gold holdings of 3,095,077,000 dollars in July, 1919. The steady accumulation of gold has been reflected in the statements of the Federal Reserve system, as the combined report showed gold reserves of 2,298,071,000 dollars, as against the high mark of previous years of 2,201,804,000 dollars, reached on 6th June, 1919. The actual gold imports from 1st January to 10th April of this year totalled 201,271,594 dollars, and exports in the same period were less than 5,000,000 dollars. It is stated that gold has been coming into the United States from all parts of the world. This can be understood when all the world wants to deliver gold to the country in order to liquidate debts. New York bankers are somewhat perturbed at such a large increase in the precious metal, because it may tend to inflation.

* * *

Gold Producers' Association.

The *Australasian* of the 20th August states that sales of standard gold through the Gold Producers' Association, Ltd., during July amounted to 89,888 oz. (a mint par value of £350,000). The estimated net price received was £5 1s. 9d. per oz., or equal to £5 11s. per fine oz., while the average gross price in London for the month was £5 12s. 9d. per fine oz. After making provision for contingencies, the association earned £444,636 net premium during the past half-year. This sum represented £1 per oz. of standard gold, or approximately £1 1s. 10d. per oz. of fine gold produced by members, as shown by the mint certificates lodged with the

association during the last accounting period. On 30th May, £144,523 was distributed as an interim payment, and the balance will be payable on 25th August. The paper quoted adds that the secretary of the association has stated that the Mount Morgan Gold Mining Company, Limited (Queensland), has lodged an appeal against its assessment by the Queensland Commissioner of Taxes for income tax on gold premium, and that the case will come before the Queensland court shortly. During the half-year ended 30th June the quantity of gold obtained by members of the Gold Producers' Association was 444,636½ standard oz. The whole of this gold was sold before 31st July, the accounts having been kept open for one month in order to dispose of all gold available for sale, and thus avoid any carryover. Sales of gold during the term returned a net premium of £462,254, equal to £1 0s. 9½d. a standard oz., or £1 2s. 8.18d. a fine oz.

* * *

Trade Conditions in America.

South African imports into the United States during September showed a gain over the August figures, according to cable advice from the Department of Commerce to the American Trade Commissioner, Mr. P. J. Stevenson. September imports were 400,000 dollars compared with 355,000 dollars in August, probably due to the increased demand for raw materials for manufacturing purposes. American exports to South Africa, however, declined to 900,000 dollars as against 1,600,000 dollars in the previous month and 1,400,000 in July. Business conditions in the United States may be described as showing distinct signs of improvement. Production is on the increase, with a resulting decrease in unemployment, although the number of unemployed is still large. The alarming figure of nearly 6,000,000 unemployed, which has been so widely quoted, has in reality little practical significance, as it is merely the difference between the peak of employment under war and post-war conditions, and the present number employed in the same industries. As a large percentage of this number has returned to former employment on farms or in homes, the figure of six millions hardly represents the present situation. This is also borne out by the large labour supply that has been available for harvesting the wheat crop in the Middle West. Another indication of improvement is in the financial situation. Money is easier and available in large volume at lower interest rates. This is largely due to the liquidation of "frozen credits" and the decrease in loans on Governmental bonds. Prices, however, have been unsteady, as compared with one or two months ago, when they were stiffening. This is probably due to wage reductions, as raw material prices have reached pre-war levels in many lines. Crop conditions are satisfactory on the whole. The wheat crop has been only slightly below 1920, while corn is 10 per cent. above the average. The potato and oats yields will be below normal. The marketing is proceeding without financial difficulties, and has been helpful in furnishing freight for the railroads.

* * *

Centrifugal Concentrators.

Very satisfactory news is to hand from Natal in regard to the results being obtained by the Mauss continuous centrifugal separator in its application to sugar production. It appears that the inventor's estimates of extraction are being exceeded in practice, and those interested are naturally jubilant. The inventor, Mr. W. Mauss, is now in England superintending the manufacture of his machines.

* * *

The Rooiberg Minerals Development Co., Ltd.

Report on the operations of the company for the year ended 30th June, 1921:—Development: During the year 6,442 feet of development was carried out at an average cost of 37s. 5d. per foot. Mining and concentrating: Tons milled, 27,745; average assay, 1.63 per cent. M.T.; concentrates recovered, 500 tons; value of concentrates, 67.57 per cent. M.T.; working revenue, £66,387; working costs, £65,762; working profit, £625.

Tranevaal Gold Mining Estates, Ltd.

Report of Directors for the quarter ended 30th September, 1921:—Development footage, 9,358 feet; tons milled, 47,055. Working profits for quarter: Central Mines, £7,531—4s. 1d. per ton; Elandsdrift Mine, £4,544—19s. 8d. per ton; Vaalhoek Mine, £921—3s. 3d. per ton; total, £12,996. General remarks: The work-profit is based on an average net realisation of £5 9s. 7d. per fine ounce of gold.

Phthisis on Outside Mines

In the course of his annual report, issued this week, the Chairman of the Miners' Phthisis Medical Bureau, Dr. Watkins-Pitchford, says:—In pursuance of the recommendations of the Miners' Phthisis Commission of 1918, an enquiry was instituted into the production of silicosis by certain mines and quarries outside the area of the Witwatersrand. This enquiry, in so far as it related to the health of the employees, was entrusted to the Bureau. Two members of the Bureau (Drs. L. G. Irvine and R. M. Truter) were accordingly delegated to associate themselves with nominees from the Department of Mines as a Joint Committee to visit and report upon the mines and quarries to which attention had been drawn. The report of this Joint Committee was presented to you in January, 1920. Although the investigations were conducted with assiduity and thoroughness, the positive evidence obtained was surprisingly meagre. The following industrial centres were visited: (1) the Worcester, Consort, and New Fortuna Mines (gold mines in the Barberton district); (2) the Rooiberg, Leeuwpoot, Zaaiplaats, and Groenfontein Mines (tin mines in the Waterberg district); (3) the Messina Mine (copper mine in the Zoutpansberg district); and (4) the Ben Accord, and McIlrath's Quarries (in the Pretoria district). The conclusions arrived at concerning employment at these various centres may be briefly summarised as follows:—With regard to (1)—All the gold mines of the Barberton district are capable of producing silicosis; but if, as hitherto, the mines are not worked intensively, the amount of silicosis will be slight. The gold-bearing bodies are, in almost every case, essentially quartzitic. (2) Underground work performed over long periods in any of the tin mines mentioned is capable of producing, and has produced, an appreciable but not serious amount of pulmonary fibrosis. No case of definite silicosis was encountered. The rocks concerned comprised granite and Waterberg quartzites. (3) A certain, although not a serious, amount of pulmonary fibrosis appears to be produced by long-continued employment, especially upon machine-drills, at Messina. The mine works "a vertical alteration in the red granite." (4) An appreciable but not serious degree of pulmonary fibrosis may be produced by prolonged work at the Ben Accord quarry. No case of definite silicosis has been brought to light, although the dust conditions, especially at the crusher station, could not be worse. The rock dealt with is nerite—a mixture of labradrite, pyroxene, and hypersthene, but without any free silica. In McIlrath's quarry the rock worked is quartzite; for this reason the risk of producing silicosis must be considerable, although the clinical evidence obtained was not, by itself, sufficient to substantiate this, or any, conclusion. As a sequel to the report upon these investigations, the Bureau was requested to assist in the drafting of a Bill which it was proposed to introduce with regard to the production of silicosis by mines which have not hitherto been included in the schedule. A series of suggested clauses was accordingly sent to the chairman of the Miners' Phthisis Board.

Miners' Phthisis Examinations.

In the course of his annual report, issued this week, Dr. Watkins-Pitchford, Chairman of the Miners' Phthisis Medical Bureau, writes, *inter alia*:—The statutory purpose of the initial examination (to ascertain whether the applicant is free from disease of the lungs and physically fit in other respects for underground work) has not been changed. Its scope with respect to men who have previously worked underground, and who have temporarily abandoned this occupation, has, however, been enlarged. Under the 1917 Act a miner who had not worked underground during the preceding four years was required to submit himself to the initial examination before again undertaking such work; the 1919 Act (section 12 (4) reduced this period of permissible absence to two years. This change has increased the number of applications for the initial examination from amongst the ranks of those who have worked previously in the mines, and has, at the same time, given rise to a certain amount of discontent in consequence of the rejection of a certain proportion of such applicants. This matter will be referred to again under the section dealing with the periodical examinations. A further departure introduced under the 1919 Act (Regulation 23 (1) (2) has been the separation of the rejected candidates into two classes: (1) those who may apply for further examination after the lapse of three months; and (2) those who may not apply again, because "the bodily condition of the applicant is such as to preclude all possibility of his ever being physically fit for underground work." Thus the rejected candidates are now divided into the two classes of temporarily, and permanently, unfit. 4,613 youths and men of European blood were examined as candidates for regular employment underground, and a summary of the results of their examination is given in Schedule V. It will be observed that 70.26 per cent. of the candidates were of South African birth, and 29.74 per cent. of oversea birth. Fifty-seven per cent. of all candidates were permanently rejected on account of respiratory defect or other physical unfitness, whilst 16 per cent. were temporarily rejected with the option of applying again. The percentage of rejections is the highest hitherto recorded, a fact which is mainly due to the recognition of an "Ante-primary" stage of Silicosis by the 1919 Act. As this new provision requires the Bureau to certify that the earliest detectable signs of silicotic damage to the lungs have come on during and in consequence of employment in our mines, it is obviously necessary for the Bureau to satisfy itself that the initial pulmonary condition of the candidate miner is above the suspicion of damage of any sort. The complaint has been heard somewhat frequently of late that the Bureau's standards of fitness for underground work are unnecessarily high, and that adherence to them needlessly deprives the industry of recruits and inflicts an unjustifiable hardship on many of those who seek for employment. The reply to such criticisms is that the standard of fitness is a high one only in so far as it relates to the condition of the lungs and the physical capacity for resisting the development of silicosis and tuberculosis. The adoption of a high standard in these respects is obviously in the interests of the candidate, for no employment, however lucrative, will compensate for the loss of health or life. Apart from the condition of the lungs and the indications of capacity to resist pulmonary disease, the standard has always been, and still is, very low; the main criterion in these other matters is the absence of defects which might cause danger to other workers. Thus the presence of any condition which might suddenly render a man helpless whilst engaged in dangerous work is practically the only ground for rejecting a candidate whose "respiratory physique" is satisfactory. That a lowering of the standards for the initial examination is not called for on economic grounds is indicated by the fact that only 51 per cent. of those who have hitherto passed the examination have secured employment underground.

GOVERNMENT EXAMINATIONS.

MINE MANAGERS' EXAMINATION

Total certificates (metal) granted to date 1921 — 36
 Secured by students of Messrs. Lucas & Wolfe — 21
 Balance for S.A. — 15

In addition to above we obtained 5 coal certificates last two examinations

OVERSEERS' EXAMINATION

During 1918 and 1919 we secured the majority of the certificates granted. 21 certificates in 1920, and 23 certificates to date 1921 (metal and coal)

SURVEY EXAMINATION

We have obtained practically all the certificates granted by the Mines Dept. during recent years and have secured 62 certificates to date

CORRESPONDENCE TUITION IN ALL SUBJECTS WHERE PERSONAL TUITION IS IMPOSSIBLE

The Quarter with the Barnato Group.

PROGRESS REPORTS FOR THE THREE MONTHS ENDED SEPTEMBER 30.

The Mining Companies' Directors' reports of the Johannesburg Consolidated Investment Co., Ltd., for the quarter ended 30th September, 1921, have the following:—

Consolidated Langlaagte Mines.

Crushed, 130,300 tons. Total working revenue, £216,213 or 33s. 2d. per ton crushed; total working costs, £154,062, or 23s. 8d. per ton crushed; sundry revenue, £940; total profit for quarter, £63,091, or 9s. 6d. per ton crushed. No allowance has been made in the above for Colonial taxation, nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £3,360, and Debenture interest to £344. The quantity of ore crushed during the quarter was 3,400 tons more than during the preceding three months. The revenue was 1s. 11d. per ton higher and the working costs 9d. per ton lower, with the result that the working profit was £18,630 higher than for the previous quarter. The development footage sampled totalled 2,185 feet, and gave the following results: Payable, 1,176 feet, having an average value of 39.41 dwts. over 16.17 inches of reef; unpayable, 1,009 feet, having an average value of 8.98 dwts. over 13.54 inches. The average number of natives at work underground during the quarter was 2,914, as compared with 2,918 for the previous quarter.

Government Gold Mining Areas.

Crushed, 425,000 tons. Total working revenue, £944,046 or 44s. 5d. per ton crushed; total working costs, £450,659, or 21s. 2d. per ton crushed; sundry revenue, £2,158; total profit for quarter, £495,545, or 25s. 3d. per ton crushed. No allowance has been made in the above for Government's share of profits nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £28,900. The quantity of ore crushed during the quarter was 26,000 tons more than during the previous three months. The revenue was 2s. 2d. per ton higher, and the working costs 10d. per ton lower, with the result that the profit at £493,387 for the quarter was £88,672 higher than for the preceding quarter. The development footage sampled totalled 4,470 feet, and gave the following results: Payable, 2,970 feet, having an average value of 15.2 dwts. over 52 inches of reef. Reef partly exposed, 80 feet, having an average value of 1.2 dwts. over 76 inches. Unpayable, 1,420 feet, having an average value of 3.4 dwts. over 44 inches. The average number of natives at work underground during the quarter was 6,597, as compared with 6,404 for the previous quarter.

The Langlaagte Estate and-Gold Mining Co., Ltd.

Crushed, 123,200 tons. Total working revenue, £209,223 or 34s. per ton crushed; total working costs, £159,422, or 25s. 11d. per ton crushed; sundry revenue, £921; total profit for quarter, £50,722, or 8s. 1d. per ton crushed. No allowance has been made in the above for Colonial taxation, nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £8,303. The quantity of ore crushed during the quarter was 6,100 tons more than during the previous three months. The working costs were 1s. per ton lower, and the revenue 1s. 4d. per ton higher than for the previous quarter, with the result that the working profit was £16,030 higher than for the quarter ended 30th June last. The development footage sampled totalled 2,549 feet, and gave the following results: Payable, 1,451 feet, having an average value of 26.2 dwts. over 17 inches of reef. Unpayable, 1,098 feet, having an average value of 8.3 dwts. over 15 inches. The average number of natives at work underground during the quarter was 2,749, as compared with 2,804 for the preceding quarter.

New Primrose.

Crushed, 65,500 tons. Total working revenue, £79,957, or 21s. 5d. per ton crushed; total working costs, £63,833, or 19s. 6d. per ton crushed; sundry revenue, £558; total

profit for quarter, £16,682, or 1s. 11d. per ton crushed. No allowance has been made in the above for Colonial taxation nor the Provincial Gold Profits Tax. The quantity of ore crushed was 1,500 tons more than during the preceding three months, the revenue was 2s. 3d. per ton higher, and the working costs 10d. per ton lower, with the result that the working profit for the quarter was £10,373 higher than for the previous quarter. The average number of natives at work underground during the quarter was 1,283, as compared with 1,299 for the previous quarter.

New Unified.

Crushed, 33,900 tons. Total working revenue, £41,387, or 24s. 5d. per ton crushed; total working costs, £33,929, or 20s. per ton crushed; sundry revenue, £160; total profit for quarter, £7,618, or 4s. 5d. per ton crushed. No allowance has been made in the above for Colonial taxation nor the Provincial Gold Profits Tax. The quantity of ore crushed was 400 tons more than during the previous quarter. There was a decrease in the working costs of 7d. per ton, and an increase in the revenue of 1d. per ton, with the result that the working profit was £1,109 higher than for the preceding quarter. The average number of natives at work underground was 611, as compared with 628 for the previous quarter.

Randfontein Central Gold.

Crushed, 392,500 tons. Total working revenue, £632,989 or 32s. 3d. per ton crushed; total working costs, £520,290, or 26s. 6d. per ton crushed; sundry revenue, £3,731; total

profit for quarter, £116,130, or 5s. 9d. per ton crushed. No allowance has been made in the above for Colonial taxation nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £57,180, and Debenture interest to £32,895. The quantity of ore crushed during the quarter was 19,500 tons more than during the preceding three months. The revenue was 1s. 9d. per ton higher, and the working costs 1s. 3d. per ton lower, with the result that the working profit for the quarter amounted to £112,699, an increase of £61,818 over the quarter ended 30th June. The development footage sampled totalled 7,560 feet, and gave the following results: Payable, 5,810 feet, having an average value of 21.5 dwts. over 15 inches of reef. Unpayable, 1,720 feet, having an average value of 11.2 dwts. over 14 inches. The average number of natives at work underground was 10,494, as compared with 10,713 for the previous quarter.

Van Ryn Deep.

Crushed, 151,000 tons. Total working revenue, £458,975 or 60s. 9d. per ton crushed; total working costs, £207,260, or 27s. 5d. per ton crushed; sundry revenue, £3,299; total profit for quarter, £255,014. No allowance has been made in the above for Colonial taxation nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £30,247. The quantity of ore crushed during the quarter was 600 tons more than for the preceding three months. The revenue was 4s. 8d. per ton higher, and the working costs 3d. per ton lower, with the result that the profit for the quarter was £38,187 higher than for the previous quarter. The development footage sampled totalled 1,123 feet, and gave the following results: Payable, 763 feet, having an average value of 29.8 dwts. over 18 inches of reef. Unpayable, 360 feet, having an average value of 4.7 dwts. over 50 inches. The average number of natives at work underground during the quarter was 3,132, as compared with 2,961 for the preceding quarter. The mill was stopped from midnight on Sunday, 4th September, to 6 p.m. on Thursday, 8th September, owing to a strike of the reduction workers, and this accounts for decreased tonnage and increased working costs in that month.

Witwatersrand.

Crushed, 119,000 tons. Total working revenue, £168,399 or 28s. 4d. per ton crushed; total working costs, £134,744, or 27s. 8d. per ton crushed; sundry revenue, £5,438; total profit for quarter, £39,093, or 5s. 8d. per ton crushed. No allowance has been made in the above for Colonial taxation, nor the Provincial Gold Profits Tax. The expenditure on capital account amounted to £1,303. The quantity of ore crushed was 10,300 tons more than for the preceding three months. The working costs were 2s. per ton lower, and the revenue 4d. per ton higher, with the result that the working profit was £15,374 higher than the working profit for the quarter ended 30th June last. The development footage sampled totalled 1,220 feet, and gave the following result: Payable, 590 feet, having an average value of 13.3 dwts. over

32 inches of reef. Unpayable, 630 feet, having an average value of 1.6 dwts. over 36 inches. The average number of natives at work underground during the quarter amounted to 2,242, as compared with 2,178 for the preceding quarter.

New State Areas, Limited.

The expenditure on capital account for the quarter amounted to £95,661, of which £14,580 was spent on development, £5,869 on ventilation, and the balance on compressor plant, pumping plant, and other surface works. A total of 4,657 feet of development was accomplished, 1,624 feet being on reef. South Shaft—550 feet sampled and all found payable, the average being 13.9 dwts. over 24 inches. North Shaft—1,060 feet sampled, 329 feet being payable, having an average value of 12 dwts. over 30 inches; 740 feet were unpayable, having an average value of 1.6 dwts. over 17 inches. North Shaft development is improving. 1,115 feet were driven in the connecting drive.

General.

The declared profits have been arrived at by adding together the published monthly figures. The value of the gold was taken as follows:—July, £5 12s. 6d.; August, £5 11s. 6d.; and September, £5 10s. 6d., which averages 6s. 4d. per fine ounce more than the previous quarter.

The Chemical, Metallurgical and Mining Society.

A feature of the meeting of the above society held at the Scientific and Technical Club, recently, was the presidential address delivered by Mr. F. Wartinweiler. His paper formed a very interesting and thorough account of advances made in metallurgical practice on the Rand. Among many others the following points were discussed. The harmful effects of acid mine waters were fully dealt with, and the several benefits accruing to the neutralisation of the acidity dwelt upon. The deaeration of solutions was also discussed, and researches on that point mentioned. The saving in cyanide as well as zinc consumption resulting from the adoption of this process was well brought out. The president dwelt at some length upon the need for research in industrial problems, and also called attention to the importance of publishing the results of such investigations. The importance of a properly equipped research institution to modern mining and industrial practice was well emphasised. An example of the utilisation of by-products from the mining industry was cited in the works of the Witwatersrand Co-operative Smelting Works. A subject requiring investigation was brought to the notice of the audience in the utilisation of the zinc contained in solutions which came from the extract boxes after the precipitation of the gold. At present this zinc goes to waste, and if utilised might prove to be an asset to the industry.

Progress on Consolidated Mines Selection Group.

The following is a report on the operations of the company for the quarter ended 30th September, 1921:—

	Stamps working.	Tons milled.	Working Costs per ton milled.
Brakpan Mines	115	174,100	25 10
Springs Mines	80	117,750	29/ 5
Totals and averages...	195	291,850	27 7.5
	Value of Gold declared.	Yield per ton.	Working profit based on standard value of gold.
Brakpan Mines	£280,974	32 3.33	£55,436
Springs Mines	222,995	37 10.51	49,630
Totals & averages	£503,969	35 0.92	£105,066
	Working profit per ton.	Estimated premium on gold.	Total estimated profit.
Brakpan Mines	6/4.42	£83,419	£138,855
Springs Mines	8/5.16	67,183	116,814
Totals & averages	7 4.79	£150,602	£255,669

Development Work: Brakpan Mines.

The linear development amounted to 7,052 feet, of which 3,567 feet were on reef, averaging 8.81 dwts. over a reef width of 34.40 inches. Of the footage on reef, 1,415 feet, equivalent to 40 per cent, of the sections sampled, were payable, and averaged 13.18 dwts. over 43.83 inches. In addition to the above footage, a commencement was made with the cutting of the No. 3 shaft station, and development work was continued from No. 4 shaft. The details are given in this report under these headings.

Development Work: Springs Mines.

The linear development amounted to 5,939 feet, of which 3,803 feet were on reef, averaging 22.53 dwts. over a reef width of 14.75 inches. Of the footage on reef, 1,640 feet, equivalent to 43.1 per cent, of the sections sampled, were payable, and averaged 35.65 dwts. over 18.32 inches. The above footage includes development work from No. 3 shaft.

Transvaal Silver and Base Metals.

The report of the directors of the Transvaal Silver and Base Metals, Ltd., for the quarter ended September 30 states that the development footage sampled totalled 1,940 feet, and gave the following results: Payable, 670 feet,

having an average value of 12.1 per cent. lead and 11.0 ozs. standard silver over 29 inches (worth, at to-day's prices, 95s. 7d. per ton); unpayable, 1,270 feet, having an average value of 1.9 per cent. lead and 2.1 ozs. silver over 33 inches (worth 13s. per ton).

The Brakfontein shaft has been stripped to three compartments and timbered to a depth of 132½ feet. Sinking has been commenced. It is proposed to sink the shaft a further 100 feet to the second level, and to open up the mineral-bearing lodes, both at this plane and at the first level. In order to expedite development, it has been arranged to transfer the small Tangye compressor, which is now out of use, from No. 1 shaft to Brakfontein, and to erect two additional loco. boilers at this point.

The old first level of the mine, which extends for a total distance of 130 feet, has been re-sampled, and shows the following results over that portion of the lode which is exposed in the drive: Payable, 70 feet, having an average value of 12.0 per cent. lead and 12.6 ozs. silver over 35 inches (worth 100s. 10d. per ton); unpayable, 60 feet, having an average value of 0.8 per cent. lead and 0.9 ozs. silver over 42 inches (worth 7s. per ton).

Driving was commenced towards the end of the quarter on the 1st Level East, the results being as follows: Payable, 27 feet, having an average value of 7.0 per cent. lead and 3.6 ozs. silver over 55 inches (worth 45s. 7d. per ton); unpayable, nil.

The new power plant has been completed and is running smoothly. The sorting and crushing station is ready for use, except for certain minor details which are now in hand. In regard to the concentration plant, the bulk of the foundation work has been completed, the main steel floor for the jig house has been erected, the jigs have been built, and the main supply bin has been framed. The ball mill house framing will be closed in shortly, and the Hardinge ball mills are under erection. The desulphurising plant and first unit of the smelting plant have been completed recently, and are now in operation producing lead bullion on a limited scale from hand-picked ore.

Safety Electrical Appliances for Mines.

One of the drawbacks of using electrical apparatus in fiery mines is that explosions taking place inside switch boxes and other apparatus are liable to produce a flame outside, and ignite the gas in the mine. It is practically impossible to make the casing of the electrical apparatus strong enough to withstand the force of such explosion; and if a safety valve is fitted to prevent the cracking of the casing it is likely to permit the flame to escape with disastrous results. A solution of this difficulty has been devised by an electrical company in Great Britain. The cover of the casing is held down by bolts with a spring cover so arranged that when an explosion occurs the whole cover lifts by not more than one thirty-second of an inch. This lift is sufficient to relieve the internal pressure, but the gases, in escaping through the narrow passage between broad pieces of metal, are cooled sufficiently to prevent the passage of flames. Stringent tests of this ingenious device have proved it to be completely successful.

The New Battle of the Ports.

GOVERNMENT'S SURVEY EXPEDITION TO KOSI BAY AND LAKE SIBAYI—DELAGOA AND DURBAN STIRRED.

Coaling at Durban.

Map showing the situation at Kosi Bay, Lake Sibayi, St. Lucia Bay and Richards Bay.

Coaling at Delagoa.

Interest in the possibility of opening up a new port on the Zululand coast has been quickened during the week by the despatch of a vessel by the Government to examine the coast and by the speech by the Prime Minister on the Union's relations with Delagoa Bay.

Lake Sibaya and Kosi Bay, which the Union Government are surveying with a view to new harbour developments, are not very well known, but those who know them speak highly of them. It is claimed that they serve the Eastern Transvaal as well as Delagoa, as regards the coal mines at Witbank, and are vastly superior as regards all the district lower down. A railway up the Pongola to Paulpietersberg has many advocates. The distance from Paulpietersberg, as the crow flies, is only 120 miles. The railway is up a natural valley, and it can be made to handle coal, and the railway graded to carry coal down in maximum loads with minimum expenditure. The distance by rail would be about 150 miles from the sea to Paulpietersberg, and from there to Breyten by the existing line is 135 miles. Breyten would thus be 288 miles from the new port. Witbank is 280 miles from Delagoa. The claims of Richards Bay are also being advanced in the Union Parliament.

The New Battle of the Ports.

By a Special Correspondent.

The announcement that the Government had ordered a vessel to survey the coast of Zululand with a view to determining the merits of its different natural harbours created great interest this week. In May last you printed an interesting article from your correspondent, Mr. A. Danks, on the subject, in which the merits of the several possible harbours were discussed, and you might profitably reprint the map then specially drawn showing the relative positions of Kosi Bay, Sibai Bay and St. Lucia Bay on the coast. It has been pointed out that Durban opposition to the project of another Natal port may be feared, but on closer examination it is seen that a Zululand port is essential for the development of a part of the Eastern Transvaal which is not now adequately served by any port. Coal cannot, of course, stand a haulage of 300 miles when it is possible to reduce the distance to 150 miles. It is believed in well-informed quarters that Sibai is bound to be the chosen harbour, as Kosi Bay is too near the Portuguese border, and its development would be seriously hampered by that fact. St. Lucia Bay is ruled out because of its shallowness, the bay, though extensive, being little more than a huge lagoon. It is suggested that a railway up the Pongola Valley would offer the most advantages though its construction might involve the erection of many bridges, as it would be necessary to cross and recross the river several times. From Piet Retief, the suggested jumping off point on the existing railway, to the sea is only 110 miles, and the distance that a good railway would demand need not exceed this by more than 25 per cent. The line would, of course, have to be a mineral one, built to carry coal economically. Were Piet Retief chosen as the point of departure of the new line, it would doubtless in time become the Germiston of the Eastern Transvaal. With the construction of a short connecting line from Piet Retief to Wakkerstroom, the whole railway system of the Eastern Transvaal would be linked up. The present line from Piet Retief to Ermelo runs through one of the best coal and shale fields in the country, and the building of a line to the coast would greatly facilitate the development of those areas. Moreover, a branch line from the projected Pongola line would directly open up Swaziland. In regard to the question of capital expenditure on a new port, it is pointed out that the example of the Canadian Pacific Railway might be followed, and the great expanse of Government ground rendered valuable by the new scheme might be sold to defray the capital expenditure. All these considerations will doubtless be taken into account when the proper time arrives. In the meanwhile, it is all to the good that the railway and harbour development of such a highly mineralised and hitherto neglected part of the country should have public attention called to it.

Gold Production for September.

The official returns issued by the Chamber of Mines for September show the following:—

	Tons milled.	Yield dwts. per ton.	Working revenue per ton.	Working costs per ton.	Total profit.
Witwatersrand	1,997,086	6.704	36/8	25/2	£1,151,127
Outside districts	29,320	8.183	45/7	35/6	14,813
Totals & averages	2,026,406	6.725	36/9	25/3	£1,165,940

Compared with the corresponding figures for August, there is a decrease in tonnage crushed equal to 53,562 tons. The working revenue has fallen by eightpence per ton, and although working costs are threepence per ton lower, the profits have diminished by £74,156. The grade of ore treated

is .001 dwts. per ton higher. The decreased profit is attributable to the decreased tonnage crushed as well as the falling of the value of gold.

New Uses of Asbestos.

Asbestos twine is used in laboratories to bind together parts of apparatus exposed to fire and strong acids. A number of household articles, and especially kitchen utensils, are made out of asbestos. Fibre felts made out of pure asbestos fibre are used in large quantities for insulating the heat radiating surfaces of automobiles, the insulation of electric service wires, and the manufacture of sadiron holders, etc. Asbestos can be used for all kinds of purposes—for purposes as widely different as cloth, twine and textiles, and solid building material.

Indian Ocean Coal Trade.

WELSH COMPETITION—SOUTH AFRICA'S FIGHT— BETTER QUALITY DEMANDED.

Mr. Alexander Aiken, presiding at the annual meeting of the Coronation Collieries, held during the week, was not in a very optimistic mood. He declared that the immediate prospects of the South African coal trade are not too bright. The output capacity for which South African collieries are equipped cannot be disposed of to-day, and expansion is thus of no advantage to either the industry or the country unless the market for South African coal can be extended. For such extension the shipping trade has to be looked to, and it follows that the special requirements of this trade must be catered for if South African coal is to hold its own against outside competition. It has for several years been believed that South Africa could safely rely on holding the trade round the Indian Ocean as far east as Singapore, but recently Welsh coal has been on offer at prices considerably less than we in South Africa could compete against. The reason largely lay in the freights to be paid from Delagoa Bay

A Scene at the Coronation Collieries.

compared with Cardiff, and in railway charges to the former port. With regard to the latter item, the Railway Administration has met the coal producers in a substantial manner; but shipping freights are more difficult to manage. On the other hand, South African coal is much cheaper at pit-head than Welsh coal, and a big cut in prices has been made in order to hold the business. Efforts in holding the trade should not cease there; attention should also be paid to the quality of the coal exported. Although Transvaal coal averages higher in ash value than Welsh coal, attempts should be made to keep this value as low as possible in order to further stabilise the Indian Ocean coal trade. Recently the percentage of ash in coal taken on board an Indian Ocean steamer from Delagoa Bay was far in excess of the average ash content of Transvaal coal. The shipping trade requires the best quality of coal obtainable, and in order that we should hold the Eastern market it is essential that the quality of our export coal should be as high as possible.

Mr. H. S. Harger on Diamond Trade Prospects.

The return to Johannesburg of Mr. Harold Harger, F.G.S., the well-known South African geologist, after a year spent in investigating the diamond mines of Brazil is (writes the Johannesburg correspondent of the *Cape Times*) an event of considerable importance, not only from a geological point of view, but as affecting the prospects for the future with regard to our own South African diamonds. As a result of his tour, he is able emphatically to state that Brazil, which is the second largest producer of diamonds in the world, is not likely either now or in the near future to be a dangerous competitor of South Africa, and this opinion is formed by Mr. Harger after visiting all the leading diamond mines in Brazil. "There has been an impression in diamond mining circles for some time past," said Mr. Harger to a representative of the *Mail*, "that all Brazilian workings were on alluvial gravels. That is true as regards certain districts, but in the diamantina district in the State of Minas Geraes, diamonds are being won from actual mines, some of which have a very considerable area. These are not alluvial gravels, but consist of a very much weathered talcose product, and are being worked at a depth of 130 feet, while another is down to a depth of 100 feet. The diamonds from these mines are of a very fine quality, quite equal to the best stone that South Africa can produce, a much higher percentage being suitable for gems than is found in South African parcels. On the whole the stones are small, but I saw one of 85 carats, and the largest that has been found was nearly 200 carats. Both diamonds and semi-precious gem stones are being cut in Brazil, but in most cases the cutting is not good. In one or two cases cutters have been brought out from Europe, and are now turning out stuff on much more desirable lines than the natives of the country have done in the past. There are no automatic diamond-cutting machines such as they have in Europe, but they use the old-fashioned wheel, which is driven by power. The output of the mines at present is small, and as the stones are of exceptionally good quality, they find a ready market, despite the present stagnant state of the diamond market. Both cut and uncut stones find a ready market in Europe, where the bulk of the Brazilian output goes, and not to the United States, as might be supposed, in view of the fact that America is the largest purchaser of diamonds in the world. America certainly is a purchaser, but only to a limited extent." When Mr. Harger left Rio de Janeiro a month ago, there was a distinctly improved demand, both from America and Europe, for one-carat and two-carat stones suitable for setting in jewellery for the Christmas trade, and even cables were arriving trying to get parcels for this purpose. Mr. Harger said he was absolutely convinced that a recovery in the diamond trade generally would not be long delayed. Two years ago there were nine million pounds' worth of diamonds on the market, but these stocks were being absorbed, and when that process was completed a revival could be looked for. The financial position of the world, and particularly of America, and the present rate of exchange were, of course, at the root of the trouble.

The Diamond Outlook.

The prospects of the diamond market mean so much to South Africa that every utterance on the subject from competent observers is carefully noted. At the New Eland meeting a few days ago Sir Thomas Cullinan made an interesting statement. "Of course, as you all know," he said, "there is very little sale for diamonds just now, but I feel sure we need only to exercise a little more patience until normal conditions return. We may perhaps have a surprise in store, as the diamond market seems to go contrary to all rules and expectations, as, for instance, when the War started we shut down, as we were told our product, being a luxury, was not wanted. What happened? A big demand set in, whereupon we immediately resumed work. So it would appear that to prophesy is futile—as one is generally wrong, notwithstanding past experience. The role of the prophet I leave to others. Your directors are, however, very keenly watching the diamond market, and you may rest assured no time will be lost in resuming work immediately the opportunity comes."

The Week in the Sharemarket.

STEADY WITH BETTER TONE—STATES AND GEDULDS MAINTAIN LEAD—BUSINESS STILL RESTRICTED.

The market opened on Monday steady but quiet. A lead is still being awaited from London, and the indications, at least, are more favourable in that quarter. State Mines, for instance, were bought at the beginning of the week for London, and Gedulds maintained the interest noted in this column last week, consequent on the good development in the No. 7 Shaft. Practically all the reports for the quarter ended September 30 have now been published, and all are favourably regarded with one or two exceptions. The price of gold, at any rate, was satisfactory during the period, and this will have its due effect on the December dividends. The latest quotation for gold is a little disappointing, and is said to be due to speculation in the price between London and New York. A flutter was caused in the market on Tuesday by a rumour that gold had touched 107s. 6d., but this proved to be based on a cable error. The latest price remains about 104s. 9d. The London market was closed on Tuesday, which did not make for activity on this side. It is hoped that we may soon have news of the ex-enemy share question, and on this, combined with Christmas dividends, the market now pins its hopes. Prices were a trifle higher all round on Thursday—State Mines being notably better—though business was very restricted, and in tin, diamonds and industrials there was practically nothing doing. The week's quotations are as follows:—

Letters to the Editor.

THE PROBLEM OF THE GOLD STANDARD.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Some years ago a philosopher wrote a learned book called "The Riddle of the Universe." In this way he called the attention of thoughtful men to the fact that the Biblical account of God and things pertaining to the unknown and unknowable was not necessarily the only solution possible, and he brought forward many arguments, weighty and pertinent, which theologians did and do find it difficult, if not impossible, to answer. In our own day we also are brought face to face with a condition of things unparalleled in the known history of the human race. The collapse of the ancient Roman world state was doubtless in a large measure due to a similar concatenation of forces as those which have brought about our present day calamity. There is nothing in the ancient classics which gives us much light on the matter of finance and currency, and the science of economics was not brought into fruition until many ages after the Roman state became only a name. We may, however, gather this forceful reminder of the intimate relations existing between credit and production from our knowledge of the fact that Romans degenerated from a nation of frugal living, hard working, and hard fighting people to a condition of parasitism and effeminacy which ended in the enfeeblement of the central authority as well as of the people, and that the collapse of the tribute due to various causes meant at once the vanishing into thin air of the national credit and of the impoverishment of a people at once too proud to labour and too craven to fight.

Up to the year 1914 the basis of economic thought was centred in the conditions and principles enunciated in the monumental work of Dr. Adam Smith. "The wealth of nations" marked as great an epoch in the history of credit and currency as did that erudite work of a later day, Darwin's "Origin of Species," or as it is better known, "Evolution," in the realms of science and biological research. A brilliant succession of able writers in our own and in other countries developed the new science of economics and made its application to all questions of the production, distribution and enlargement of credit or wealth of universal acceptance without doubt or question existing as to its truth and infallibility. The functions of currency, the law of rent, the law of diminishing return, the law of supply and demand—to name only a few of the formulae found in any text book of economics—were all accepted as fundamentally exact and absolutely incontestable and inviolate. On this base of solid reasoning and demonstrable truth was laid the superstructure of the great financial edifices known as the banks, and of the still greater controlling agencies associated with, but completely masters of, the banks, the international financial inagnates, at whose nod nations were made strong or weak, and at whose word nations armed themselves and thereafter fell upon each other tooth and nail, so that a few men might fasten still more strongly their financial fetters about the necks of a helpless and ignorant people. During the 100 odd years of industrialism, gigantic forces have built themselves up and gripped the world with tentacles stronger than steel, so that for the possession of oil wells in the Gehenna of Basra, or exclusive privileges in Panama, or the right to exploit an ignorant and misgoverned country like Turkey, millions of earth's fairest manhood have been destroyed, many countries have been laid waste, the strength of the inhabitants has been undermined by malnutrition and the hideous ravages of war, and the unhealthy aftermath of riotous abandonment, moral and physical, of the peoples who have suffered, victors and vanquished both, until all incentive to labour has been quenched, and drunken with the evil precedent of, and association with, the feasibility of turning out wealth by means of the printing machine just as easily as printing a newspaper, European civilisation is in danger of becoming once again overwhelmed

and submerged under the enervating influence of a worthless currency, an inextinguishable debt, and an aversion to adequate production of the essential elements in the rehabilitation of the modern world.

In face of all this we are now called upon to return as quickly as possible to the pre-war gold standard. In other words, we are asked to add enormously to the weight of the millstone already around our necks in order to maintain our "national credit." As though the "national credit" depended upon our impoverishing ourselves and our children's children in order to pay money for value which the nation certainly did not receive. If we desire fairness and impartiality in the matter of duly discharging our national obligations, both internal and external, we must realise once and for all that our gold standard is purely arbitrary and has not in itself any peculiar virtue which it would be sacriligious to tamper with, the Act of Parliament, known as the Bank Charter, passed in 1844 at the instance of Sir Robert Peel, was a measure brought about through a mistaken notion that gold, once established as a standard of value by Act of Parliament, could be maintained at that value for ever irrespective of the fact that all other commodities were and are constantly changing in value, both relative to one another and to the common medium of comparison gold. The fact that 113 grains of gold at the time of the passing of the Act was the relative value of the standard compared with other commodities at that precise moment did not thereby make it everlasting in its ratio of value to all other commodities, nor indeed even to itself, since the actual purchasing power of gold changes according to its relative scarcity, irrespective of its value as against other standards of exchange.

As a standard of value, then, gold is useless, and when we are asked to consent to a return of a certain value of gold as ascertained to be the case on a given date, say 1914, it may be advisable to consider exactly what is the meaning of this request, especially in so far as it affects our own interests nationally and individually. On the present day purchasing value of the sovereign we can get in commodities about one-half the 1914 quantities. Our commitments during the years of that war were financed on an inflation basis, *i.e.*, the banks were asked by the Government to issue loans guaranteed by the nation on terms to be arranged by the banks themselves. It was all along assumed that the national credit was not at par value, and we have the paradox that the banks which alone and unaided externally would not have been able to get a penny of the public's money, were able to get many thousands of millions of pounds worth of credit which passed through their books, and in the process thereby lost a not inconsiderable part of the whole amount promised. What with underwriters' commissions, issuing the loans below par, payment of large rates of interest, collection expenses, distribution charges and many others, the banks did a handsomely lucrative business for themselves out of the national necessities, and yet the only power enabling them to do all this, and incidentally to enrich themselves in the process, was that of the very national credit which they arrogantly affected to despise, and voted at as low a price below par as they dared and demanded for their aid as large a rate of interest as they could wring from pliant servants of the State. Here, then, is the crux of the present evil condition of the nation. The national credit is pledged for a very large amount of money, only a part of which was really received by the State. So far as regards the internal portion of this debt, the Government would be abundantly justified in wiping it off the debit side of the ledger, and this will almost certainly be done sooner or later with due provision for such of the poorer citizens as would thereby be impoverished unduly by the process. The external debts are in a different category, and would have to be met in some way. Here, then, is a possible way out. By negotiation with our principal creditor, the United States of America, we ought to be able to pay our debts in terms of the relative purchasing power of the pound sterling at the time the debt was contracted. It might justly be pointed out to the U.S.A. that if they receive the actual value of their goods sold to us in terms of the pound value at that time, they should be satisfied with such payment, especially as they could not honestly desire

blood money. Our own country would then be able to do the same thing towards the debtor nations of Europe, and in this way a long step forward towards stabilisation would be taken, and such a measure would go far towards reviving the now practically dormant trade of the Continent.

However, so long as gold is considered to be in itself something valuable and not merely a convenient token of exchange, so long will it be impossible to avoid fluctuations and financial crisis. The fact is gradually emerging from the clouds of ignorance and fear on the part of the people that after all it may not matter so very much if we never restore the old gold standard. They read of the calculated stock of gold held on deposit in the vaults of the world's banks—about 10,000 millions sterling—and then that the total indebtedness of the nations is so immeasurably in excess of this amount as to make the gold held but as a drop in the bucket, and then again the enormous money values chiefly represented by bills of exchange and such like, by which the world's business is conducted and carried forward, and it is apparent that it is really a case of the tail wagging the dog instead of being otherwise. In short, the real factor of value in the world's affairs is that of the national credit, and the promise to pay according to agreement is the only safe basis for international trade. And now what exactly does this credit amount to. Surely it does not bind the nation to pay any exorbitant price which may be asked by creditors, rather is it the payment of that price which is the result of fair and honest dealing on the part of the principals on equitable, just and reasonable payment for value received. If we take this basis for the payment of our national obligations, we shall find our burdens considerably reduced in weight as to be quite supportable. The result of any such arrangement as this would in practice take the form of an amendment of the Bank Act, which, while retaining nearly all the clauses in the present law to rearrange the wording of that clause dealing with the fixation of the standard value of the pound sterling as to make it read thus: "That this value, 113 grains of pure gold to the pound sterling, shall be its value at the time of the passing of the Act, and that the value of the pound sterling in grains of pure gold shall at all times bear the same relation to the average price of commodities in general as the prices of such commodities bear to each other over a given period and in a given place. This would mean that the gold pound would fluctuate in value or in gold contents with the fluctuations of commodities over a given period. Such a ratio would, while constantly changing, be always equitable and just as a measure of value. Since its actual purchasing power would be constant, it would remain so under all conditions. It would at once tend to stabilise wages and prices and would do away with the gold market since no dealings in gold would be profitable under such conditions. Credit would function as it ought to, untrammelled and unhindered. Crises in trade and industry would be mitigated and would in time cease. The nation would repossess itself of its credit, and in so doing would be no longer subject to the manipulation of high finance, and a new era of peace and prosperity would result.—Yours, etc.,

T. H. JONES.

" THE LAND WITHOUT A LEADER."

The following somewhat belated letter from an occasional correspondent on the subject of the lengthy article appearing in our issue of July 2nd, 1921, has reached us:—

" JAPHET, OF JOHANNESBURG."

The above heading is taken from *South Africa*, dated 2nd September, 1921, and is in the form of a reply to "a Johannesburg contemporary," which has evidently demanded a "leader of men" for South Africa.

The leader under the above heading is good reading, but has the author lived in South Africa? Does he realise that the reason why South Africa is the best country in the world is similar to the reason why the Army of the British Empire is the best Army in the world: simply because Tommy sees his officers through?

But after the Great War the Tommy we knew of old has changed. In the old days he did not care about the reason why; to-day, however, he is beginning to ask and ponder for himself. And he wants a Man—the right Man with a very good reason—to push him back to his old state of "follow my leader." The thinking man of the rank and file will not follow a leader who to-day praises the country to its uttermost, and to-morrow damns it to the nethermost, because he has suddenly discovered that it is necessary to reduce its servants' remunerations. The people of a nation can surely expect from their leader the foresight of a few weeks, and if they get an optimistic and a pessimistic speech within a short period—without any particular reason, save shortsightedness—they cannot be blamed for looking for a Man.

Reference here is being made to the real workers, the middle classes who have forged the country ahead in spite of every obstacle (and many have been placed in their way), and not to the "labour" classes, who do not labour, but merely "oversee," who are led by the minority, and cannot work if they would for fear of that damning brand "scab," but who will one day arise in revolt against the tyranny of trades unionism and have their present leaders starve if they will not work. This is as it should be, and would have been long ago had it not been for the native, who is at once our salvation and our curse—our salvation inasmuch as he who striketh too much will find the colour bar removed and his services no longer required. Our curse, since, had it been otherwise, the "labour" class would have been a working class, and not "overseers," and South Africa would have been a self-supporting export country at least fifty years ago.

Yes, we want a Man who will not stifle enterprise with unnecessary taxation, who will distribute tribute fairly, and who will not burden one section for the benefit of another section, who will not leave obvious loopholes for the favoured section who grow fat and prosperous on a debit profit and loss account, who will run the railways for the progress of the country, and not merely to pay the debts of the country.

Had the critic of "Japhet" lived in South Africa he would understand that the real leader of men in South Africa must be an independent man, otherwise his life will be crushed out of him by the all-powerful thumbs of politics and gold—two tyrannous gods who have ruled South Africa to its detriment for a century.

The Man we want must be for South Africa, to steer our ship in the squadron of Empire, and he will find in the crew the finest material to work upon; but he must not interfere with the skippers of the ships fore and aft. The man we want will find enough to do to keep his own deck swabbed and the metal of his guns clear and bright. If he does this he will find many a good A.B. to fire at the right moment, if only he is Man enough to give them the right lead, and if for good reason—although mistakes may be made—he will find the same A.B.'s willing and ready to fire again at his command.

Give us the Man! Show us the Man! And if you can, the A.B. will be there at the salute. But—where is the leader of this splendid A.B. material? We have not noticed the mention of his name in the "Japhet" critic's very excellent article, save one long deceased.

The Sub-Nigel Meeting.

A full report of the speech made by Mr. D. Christopherson at the Sub-Nigel meeting will be found in another part of this issue. Shareholders will find the chairman's detailed explanation of the development position of particular interest, and it may be said that despite some discouraging features, the prospects are on the whole most satisfactory. The fact that the proceeds of the gold "premium" have been offset by the increase in working costs since 1916 is a significant reminder of the ever-present necessity for bringing down costs as the "premium" runs off. Costs at the Sub-Nigel have always been high because of its peculiar mining conditions, but none the less the mine must have relief from the abnormally high level reached during and since the war.

ENGINEERING SECTION.

The Howick Falls Hydro-Electric Power Plant.—IV

By H. W. Miller.*

It will be observed that under any load the position of the deflector is just clear of the required jet necessary to pass the correct amount of water corresponding to the load, thus eliminating any "dead" movement, and, in the case of the load being thrown off, it would cut the jet immediately.

This fact is most important, and is a special feature of this system, whereas in most existing designs the deflector has only one fixed position at all loads, and thus has to travel a considerable distance before coming into contact with the jet, which naturally is detrimental to the obtaining of close speed regulation.

In the event of any load being added to the plant, the governor would move the lever E in the opposite direction, taking the deflector away from the jet, and as the block on lever F would be in contact with the outer side of the box G, the spear regulator would have a positive movement in the opening direction in proportion to the movement of the governor, movement in this direction of the spear being free.

Hand Operation.

The nozzle can be regulated by hand by means of a hand-wheel on the governor, which would operate the deflector and spear in combination in the same manner as when operated by the governor itself.

In the event of a breakdown of the governor oil pumps, or failure of oil pressure from any other cause, the governor would then be unable to hold the spear shaft back against the pressure of spring H, and the Pelton wheel would then be automatically and slowly shut down by the combined action of the spring and dashpot.

In connection with the dashpot for obtaining constant speed, the governor is fitted with an equalising device in order to obtain a speed variation between "full" and "no load" from zero up to about plus or minus 5 per cent. for paralleling purposes. This arrangement consists of a lever connected to the dashpot support on one hand and to the governor shaft on the other hand, the latter connection being carried out by means of an eccentric, the radius of which can be adjusted to obtain the required permanent speed variation.

When the lever is in the centre of the regulating shaft, no movement is obtained and the turbine is running at constant speed at all loads, but if the lever is altered an eccentric movement is obtained which neutralises the effect of the movement of the dashpot and a permanent speed variation is obtained, the degree of which is adjusted by the length of the eccentric radius.

Each unit is connected to the main branch pipe by a 10-inch pipe, controlled by a 10-inch diameter sluice valve, so that each turbine is quite independent of the other. A tachometer is fitted to each machine, as well as a pressure

gauge to show the pressure of water at the nozzle, and these instruments are essential to the operator in starting up and controlling the machines in work. The governor controls the action of the jet, and the time of closing of the spear is adjustable by the cataract device on the needle valve spindle, but in this case, owing to the large area of the supply pipe, with two units at work and taking the quantity of water required for full power, the velocity of the water in the main pipe is so moderate as to preclude the risk of any great hydraulic surge, even if the needle valve closed unduly quickly, a contingency which might occur if the attendant was neglectful of the filling of the cataract cylinders, failure to regulate the bye-pass control valves on the cataract cylinders or from any mechanical defect that might arise from loosening of parts and the numerous reasons for imperfect working of machinery. Even when the additional third unit is installed, with the three machines on full load, a speed of closing of from five to six seconds will not cause undue surges on the pipe line, even if two governors acted simultaneously, a most unlikely contingency. The static head in this case being 320 feet, the pressure is not sufficient to give cause for apprehension from this cause, but in Burma, where I installed a plant working under 2,100 feet static head, the matter of the time of closing of the needle valve was one of the greatest importance, as when filling the pipe line there we did have one hydraulic surge which caused considerable damage and delay.

Owing to it being necessary to effect some alterations to the details of the plant as supplied by the makers, and consequently only one unit being operated singly when the plant was first started up for beneficial work, we were not able to carry out the tests we had hoped to be able to conduct on the completion of the work, but doubtless at a later date and a convenient opportunity some really good efficiency tests can be conducted, but when the machines were put to work one could not fail to be struck with the high mechanical efficiency of the turbines. A careful test was made of both machines running light, merely keeping the switch boards excited but no current being taken out of the boards, with a constant depth of water of two inches flowing over the notch of Lea recorder, the horse-power developed by the two plants so running was 41.21 as measured. As each turbine is fully capable of developing 175 h.p. under the conditions as installed, this gives an efficiency for the combined electrical and hydraulic plants of 88 per cent.

A Lea recording instrument has been installed at the end of the tail race before it empties into the river, and the charts give useful records of the work done. At the time the writer was present the work being performed in the factory was so irregular and intermittent that a study of the charts then being taken from the machine is not likely to prove of

* From a Paper read before the S.A.I. of E.

much interest, but they at least serve to show the water consumption by the wheels and the sensitive action of the governors, which responded to the slightest change of load.

The foregoing remarks constitute a somewhat sketchy description of a modern hydro-electric plant as installed in South Africa. I am of opinion that it would be wise to extend this system of power transmission, which although expensive to instal in most instances from a capital outlay point of view, has other advantages, many of which are not apparent at the first glance. One of these is the aid the use of water power affords towards the conservation of a country's fuel resources, a matter of some importance when the varied uses to which coal can be employed, other than for mere power production, are considered. A point that strikes me in connection with this system of power production is that it forms an insurance against any stoppage of the fuel supplies from a number of causes. Take for example the electrification of the railways; in the event of any dispute in the mining of coal the hydraulic plants would serve as a very important stand-by and at least prevent a total stoppage of the train services. I don't suppose this view of the case will appeal to the Socialistic gentlemen amongst the Labour Party, but nevertheless it is a point worthy of some consideration. There are quite a number of places in South Africa where there are sources of water power, but hitherto there has not been sufficient inducement to exploit them, and as long as coal can be produced cheaply so long will these sources remain undeveloped. One cannot help being struck with the hurried efforts now being made in England to improve the thermal efficiencies of the many heat plants now that coal can no longer be produced for the small price per ton that ruled before the war, but I suppose so long as an article can be procured cheaply so long will it continue to be wasted. The wise man, however, is he who looks well into the future, and I commend a study of the potentialities of South Africa in regard to hydraulic power to those in authority and to all who have the future welfare of this country truly at heart.

Improved Drop Hammers.

A battery of drop hammers recently supplied by a British firm to the engineering workshops of a Chinese railway possesses several interesting features. It includes three hammers, one of 30 cwt., one of 15 cwt., and a third of 7 cwt. All three hammers are lifted by wheels on a single overhead shaft, driven by an electric motor through a closed gear box which reduces the speed. The ropes supporting the hammer blocks are raised on grooved drums, to which they are held by special friction blocks; at any desired

moment the friction block is raised and the hammer falls. The mechanism of control is so simple that a child could operate the largest hammer with ease. Each hammer can be lifted to any height and allowed to fall, or it can be held stationary at any point. Before being installed the battery was subjected to the severest tests, all three hammers being held suspended while the motor continued to run, but not the slightest tendency to overheating showed itself in the lifters. No other drop hammer, it is confidently stated, was ever subjected to so arduous a test.

The Simplest of Steam Traps.

Among the innumerable forms of steam trap none could be neater or more effective than a new form recently brought out by a British firm of engineers. The working part of the trap is a small flat sealed chamber shaped like the vacuum box of an ordinary aneroid barometer. This chamber is filled with a volatile spirit and its vapour. When steam is passing the spirit is heated, the chamber expands and closes a valve attached to it, thus shutting off the steam. When any water collects the spirit is cooled, the chamber contracts, and the valve opens, allowing the water to escape. The flow of steam through the opening heats the chamber again and so closes the valve. Either side of the valve can be used as the inlet.

New African Railways.

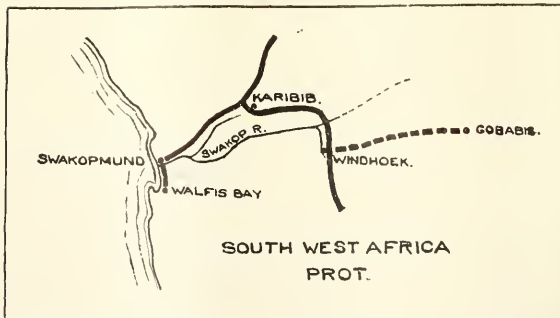

The Beira-Zambesi Railway.

The Beira-Zambesi Railway, which will form an important link in the chain of inter-continental communications, is now nearing completion. It is in fact expected to be put into commission about March next, and simultaneously new pier and wharfage facilities at Beira will be available in order to cope with the augmented trade of the port. Some considerable time will elapse before the Zambesi is spanned by the big bridge which will cross the river above Chindio, but with the exception of this comparatively small link, there will be direct communication between the Shire Highlands and the Union, and when the projected line from Luchenza to Fort Johnstone is completed, the south shores of Lake Nyasa will be linked up with Table Bay.

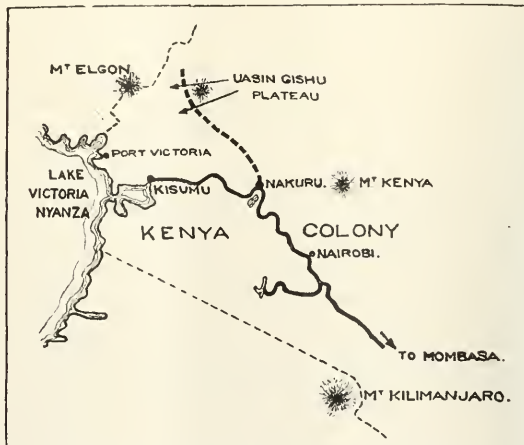

A contract has been signed with Messrs. Norton Griffiths & Co. for construction of a railway from Nakuru on Uganda Railway to Turbo on the fertile Uasin Gishu plateau to north-east of Victoria Nyanza. Work—to cost £2,000,000—will shortly commence. The new railway will, it is anticipated, be continued later into Uganda and form the connecting link between Mombasa and the Cape to Cairo route.

Another new railway proposed is to run from Windhuk, capital of the South-West Protectorate, easterly to Gobabis, for about 132 miles at a cost estimated at £726,000. Gobabis is one of the chief settlements in the eastern portion of the Protectorate, and, having numerous fresh water springs in its vicinity, is the centre of one of the few districts where agriculture is feasible. Maize is the principal crop.

The three maps given herewith exhibit the routes of these three new railway lines.

New Railway for the S.W. Protectorate. A projected line from Windhuk eastwards, which will open up a rich agricultural area.

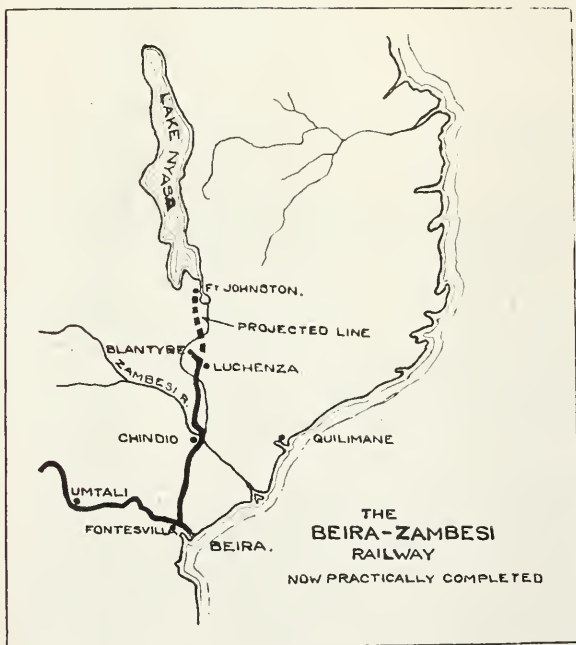

The New Plateau Railway in Kenya, "the highest line in the Empire."

The Geology and Mineral Resources of the Serb-Croat-Slovene State.

The official report of the geologist attached to the British Economic Mission to Serbia has just been published by His Majesty's Stationery Office in London. This report is the result of investigations carried out in Serbia during the summer of 1919, and a considerable amount of information has also been drawn from the mining literature of the district. The result is a most interesting and comprehensive report to which has been added a bibliography of the principal publications dealing with the mining industry and a useful glossary of the principal Serbian mining terms.

The main bulk of the report deals with the geological structure and mineral resources in detail, and an appendix gives the mining laws and regulations for the Kingdom of Serbia. Mr. D. A. Wray, the writer, has wisely not confined himself entirely to an account of the deposits within Serb-Croat-Slovene territory, but has treated the formation and deposits as a whole even when they cross a territorial frontier. Some excellent maps and diagrams have been included, together with photographs of the various workings in Yugoslavia.

The report may be seen at the office of His Majesty's Senior Trade Commissioner in South Africa, Goldfields Buildings, corner of Fox and Eloff Streets.

Electrification of Railways.

LESSONS FOR SOUTH AFRICA FROM THE REPORT OF THE IMPERIAL ADVISORY COMMITTEE.

Last October an interim report was issued by the Electrification of Railways Advisory Committee appointed by the Minister of Transport.

The Committee has now issued its final report, dated June 30th, 1921, in which it confirms the recommendations of the interim report, and supplements them. With regard to contact rail collection of current, the Committee points out that the conductor rails must be so arranged that the same trains shall be able to run on railways employing a 1,500-volt supply and on those using 600 or 750 volts. The top-contact rail is generally used for the lower voltages, but the under-contact rail is also in use, and possesses advantage with regard to interference by the accumulation of ice and snow, and also with regard to the protection of men working on the track. Suitably designed shoes can be run interchangeably with either the top or under-contact type of rail. The Committee does not recommend the exclusive use of either type, leaving the door open to improvement in the design of either or both.

The Committee considers that a standard position outside the tracks should be defined within certain limits for the contact surface of the contact rails in relation to the position and level of the running rails, and recommends that in respect of new electrically-operated lines and extensions to existing lines the following regulations should be issued for securing interchangeability of running:—

- (1) The contact surface shall be in the horizontal plane.
- (2) The gauge measured between the centre of the horizontal contact surface of contact rails and the gauge line of the nearest rail of the corresponding track shall be 1 ft. 4 in.
- (3) The vertical height of the contact surfaces above the plane of the top table of the running rails shall be:—
 - (a) for top-contact rails 3 in.
 - (b) for under-contact rails 1½ in.
- (4) The vertical height of the contact rail (including, where required, the protection over the top of the rail) above the plane of the top table of the running rails shall be such as to provide the necessary clearance from the load gauges from time to time in use.
- (5) The under-contact rail, where employed, shall provide for the engagement of the contact shoe being made from the side nearest to the running rails.
- (6) Above the level of the under-contact surface (3) (b) no part of the contact rail construction shall be at a less distance than 1 ft. 1½ in. from the gauge line of the nearest track rail, and below the level of the under-contact surface (3) (b) at a less distance than 1 ft. 7½ in. from the gauge line of the nearest track rail.
- (7) The vertical distance between the under side of any contact shoe in the free position and the plane of the top table of the running rails shall not be less than 1½ in.

Existing equipments which do not conform to the above may be continued in use and may, subject to the approval of the Minister, be extended.

Similarly with regard to overhead collection, the following recommendations in respect of new lines and new electrical equipment of existing lines are made:—

- (1) The standard clearances, after allowance has been made for curvature and super-elevation, including any movements of the live wire or conductors and lateral movements of the collectors, under any circumstances likely to arise, shall be:—
 - (a) Between the underside of any overhead live wire or conductor and the maximum load gauge likely to be used on the line:—
 - (i) In the open, 3 ft.
 - (ii) Through tunnels and under bridges, 10 in.
 - (b) Between any part of the structures and the nearest point of any live overhead wire or conductor, 6 in.

- (c) Between rail level and overhead conductors:—
 - (i) At accommodation and public road level crossings, 18 ft.
 - (ii) At places where there is a likelihood of men in the conduct of their duties having to stand on the top of engines or vehicles, 20 ft.
- (d) Between any part of the collector gear and any structure, 3 in.

In the case of the electrical equipment of existing lines the dimensions stated in (a) (ii) and (b) may each be reduced to 4 in. as a minimum; cases of exceptional constructional difficulty may be considered by the Minister as special cases, and existing equipments which do not conform to the above may be continued in use.

(2) The horizontal distance of the contact wire from the plane through the centre line of the track and perpendicular to the surface of the track rails shall be within the following limits:—

- (a) At a height of 18 ft. above sea level, 1 ft. 3 in.
- (b) At a height of 4 in. above the maximum load gauge likely to be used on the line, 1 ft. 9 in.
- (3) The weight and construction of the contact wire and supports shall be suitable for the passage of collectors exerting an upward pressure of from 25 to 40 lb.
- (4) The width of the renewable contact surfaces of the collectors at right angles to the track shall not be less than 4 ft. and the extreme width over the horns of the collectors shall not exceed 7 ft. 6 in.

In the case of those railways that have already equipped any or all of their lines with overhead contact wires which do not conform to the above recommendations, the employment of these may be continued in use and may, subject to the approval of the Minister, be extended.

Having regard to the practicability of further standardisation of equipment by regulations, the Committee confirms the views expressed in the interim report to the effect "that such regulations should put no avoidable difficulties in the way of the adoption in future, with the approval of the Minister, of any improvements in methods or appliances which may from time to time become available with increasing knowledge and experience," and does not consider it desirable, in the interests of railway electrification, that further regulations (other than those recommended in this report) should be issued for the time being.

In October, 1920, the terms of reference were extended to cover the questions (1) whether any regulations should be made to limit the drop of potential in an uninsulated return conductor on electrically-operated railways; and (2) if any such limits are desirable, what limits these should impose, and under what conditions. On these points the Committee says:—

- (1) The evidence given by the railway companies operating electric railways indicates that the cases of harmful effects due to a drop in potential substantially in excess of that allowed by Tramways Acts in earthed railway conductors have been few and unimportant, and readily corrected by the railway companies themselves on their own initiative.
- (2) The clauses for the protection of observatories inserted in the Acts of railway companies applying for powers to operate their railways electrically have had, and continue to have, a retarding effect on railway electrification. The committee, having heard in evidence officers concerned with the observatory instruments likely to be affected by the operation of electric railways, is of the opinion that the interests of observatories would in any case be sufficiently protected if the scope of the clauses referred to were limited to the portions of electric railways within the vicinity of the observatories.
- (3) Some railways, by virtue of the wording of their Acts, are under no necessity to apply for new powers for electrifying their systems, and are therefore not placed under

the disadvantage with respect to limitation in the drop of potential by their Acts as in the case of the other companies.

Having regard to these considerations and to the views expressed in the interim report, as well as to the difficulties in imposing any definite limit to the voltage drop owing to the variety of conditions which present themselves along different portions of any railways, the Committee recommends that:—

(1) It is not desirable that regulations should be issued to limit the drop of potential in an uninsulated return conductor on electrically-operated railways.

(2) In cases where it is found impossible to dispense altogether with the present obligations which are imposed upon railway companies by the protective clauses inserted by the Board of Trade and other authorities into the Acts of the companies, these obligations should be specified definitely in each particular case.

The various recommendations are thus summarised:—

Standard System of Power Generation.—Three-phase alternating current.

Standard System of Power Distribution.—Direct current.

Standard Pressure.—1,500 volts at sub-station bus-bars; in special cases a multiple or sub-multiple of 1,500 volts, if approved by the Minister.

Standard Collection.—Contact rail and/or overhead contact wires.

Contact Rail Standards.—Top-contact or under-contact rail, with the contact surface in a horizontal plane installed at a gauge of 1 ft. 4 in. from the gauge line of the nearest track rail.

Overhead Contact Wire Standards.—Installed normally over the centre of the track at a height of 3 ft. above the maximum load gauge likely to be used on the line, and at a maximum height of 20 ft. above track rail level.

Limitation of drop in Earthed Return Conductors.—No regulations to be issued.

Diagrams showing the suggested positions of contact rails and wires are appended to the report.

Boring Methods and Machinery.

By G. Ireland, Boring Engineer, Union Irrigation Department.

Since the establishment of the Boring Branch of the Irrigation Department in 1904 close on 8,000 boreholes with a total footage of over 1,060,000 feet have been drilled throughout the Union of South Africa. The aggregate yield from these borings is approximately 135,000,000 gallons of water per 24 hours.

The provision of this large water supply has been a substantial factor in the development of the country and in view of the extent and importance of water boring in South Africa it may be of interest to briefly review the history of drilling in this and other countries.

The drilling of boreholes or vertical shafts of small diameter for the purpose of obtaining fresh water or brine, and in the search for minerals and oil is an ancient practice, so old that no dates can be fixed of the earliest methods.

The Chinese used crude machinery before the Christian era, and their early writings contain references to boring appliances. To the Chinese belongs the credit of reducing well drilling to a science.

A narrative published by the Jesuits in the 17th century describes the Chinese methods of boring "by an iron hand hung from the end of a cord."

During the 19th century the drilling of wells in France, England and Germany to depths of close on 2,000 feet aroused wide interest in the engineering world, and these operations were contemporaneous with a remarkable development in the art of boring in America due to the discovery of petroleum. In the Pennsylvania oil fields wells of 2,000 to 4,000 feet deep were drilled. The first deep well in the celebrated Oil Creek region, according to a published account of the early development of the field, was drilled by Jonathan Watson in 1866 to a depth of 2,130 feet.

Although boring for water has been practised in South Africa for some 35 or 40 years, the advantages of this method of providing pure water supplies do not appear to have been generally appreciated by the agricultural community until within the past 20 years. Mineral prospecting holes have been bored with diamond drills since the discovery of the Witwatersrand Gold Fields, and in the initial water boring operations in Cape Colony, Free State and Natal. This type of machine was almost exclusively employed both by the state departments and private boring contractors.

The continued use of the diamond drill was undoubtedly in a great measure responsible for the apathetic attitude of the farmers to boring, as the small diameter of holes drilled with this type of machine allowed of only a small proportion of the water developed being utilised except in the case of artesian or flowing supplies.

The increasing scarcity of diamonds suitable for drilling and the consequent high cost of the work led to the introduction of the American built percussion or "jumper" drill some 14 years ago and the employment of this type of machine gave a distinct fillip to the boring in South Africa.

Small steam driven drills with a boring capacity of 200 or 300 feet were first experimented with in Cape Colony, and although these were found more or less suitable for dealing with the comparative soft shales and sandstones, they proved to be too light for boring in the harder geological formations. More powerful drills were imported and the feasibility not only of penetrating the hard compact rocks at reasonable cost, but of finding large water supplies in and under these formations having been demonstrated, the popularity of boring was considerably enhanced.

There is, unfortunately, a remarkable paucity of literature on boring, and this particular class of work is seldom, if ever, dealt with in technical journals, although scattered accounts of drilling methods and machinery employed under specific conditions appear from time to time in articles dealing with matters involving boring.

In the absence of recognised text books on the subject, the driller is perforce, when in difficulties, thrown back on his resources and experience.—*S.A. Irrigation Quarterly.*

Welding Steel with Copper.

The persistently high cost of labour and material has forced manufacturers to give the keenest attention to every promising source of economy in production. For this, among other reasons, there has been a revival of interest in a unique welding system developed in Great Britain a few years ago, and since put into commercial operation. This system depends upon the fact that if a piece of copper on an iron plate is heated in an atmosphere of hydrogen to the smelting-point of copper, the copper will spread over the iron in a thin penetrating film like butter on hot toast. So, if the copper is melted between two pieces of iron it welds them together in an amazingly intimate fashion, the copper film actually working itself in between the crystals of the iron. By this process machine parts which can most conveniently be made in two pieces can be efficiently joined together without the complication of screws. In effect it enables the cheapness of separate manufacture to be combined with the strength and convenience of the solid combination. Steam turbine blades and the cage or body of a high speed centrifugal governor for small steam turbines are among the articles which have been successfully made by this simple and ingenious process.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS SLUGGISH—IRON AND STEEL—TIMBER AND BUILDING MATERIALS—TRADE NOTES.

General Review.

Business during the past week has been somewhat restricted, and transactions on the Commercial Exchange have been fewer than for some considerable time. Merchants, in view of the European political situation and the not too stable local labour conditions, are refraining from indenting, and awaiting events generally. Prices of iron, steel and timber are much about the same, with, however, a tendency somewhat downwards in respect of heavies. Mining circles are undoubtedly concerned at the present price of gold and its downward trend, with its only too probable effect on our low-grade mines. A very prominent merchant this week said he had seen a farmer from Salisbury, who said that he was getting only 3s. 9d. per bag for mealies, which cost from 6s. to 7s. per bag to grow; this comparing with about 30s. per bag, the selling price of some twelve months ago. Generally it may be said that the mines are buying in the restricted way which they have pursued for many months past, and, in view of next month's stocktaking operations, no big forward move is looked for this side of 1921.

Iron and Steel.

Business has been fairly satisfactory this week without outstanding features. Merchants are still awaiting a lead from the other side.

Latest quotations:—Dunswart, 26s. 6d. per 100 lbs. basis price; Union Steel Corp., Ltd., 30s.; imported iron and steel flats, small, 37s. 6d. to 45s.; larger sizes, 36s. 6d. to 47s. 6d.; $\frac{1}{4}$ in. and 5-16 in. rounds, iron and steel, 39s. 6d.; $\frac{3}{8}$ in. iron, 36s.; $\frac{1}{2}$ in. and $\frac{5}{8}$ in. iron, 35s.; steel, 39s.; $\frac{3}{4}$ in. round iron, 35s.; steel, 38s.; $\frac{7}{8}$ in. and upwards round iron and steel, 36s.; channels and joists, 42s. 6d.; shafting, $\frac{3}{8}$ in., $\frac{1}{2}$ in. and $\frac{3}{4}$ in., 9d. a lb.; 1 in., 8 $\frac{1}{2}$ d.; 1 $\frac{1}{2}$ in. to 2 in., 7d.; larger sizes, 6 $\frac{1}{2}$ d.; steel plates, 1-16 in. and $\frac{1}{8}$ in., 24s. to 25s.; 3-16 in. and upwards, 24s.; spring steel, 7 $\frac{1}{2}$ d. to 8 $\frac{1}{2}$ d. a lb.; bolts and nuts, hexagon, round, $\frac{3}{8}$ in., 9d. to 1s.; $\frac{1}{2}$ in., 47s. 6d.; to 52s. 6d. per 100 lbs.; $\frac{5}{8}$ in. and $\frac{3}{4}$ in., 45s. to 50s.; hexagon nuts, $\frac{3}{8}$ in., 11d.; $\frac{1}{2}$ in., 10d.; $\frac{5}{8}$ in. and $\frac{3}{4}$ in., 9d. lb.; fish plates, bolts and nuts, $\frac{3}{8}$ in., 8d. lb.; $\frac{1}{2}$ in., 6d.; $\frac{5}{8}$ in., 5 $\frac{1}{2}$ d.; $\frac{3}{4}$ in., 5d.; dog spikes, 35s. per 100 lbs.; rivets, $\frac{1}{4}$ in., 11d.; $\frac{3}{8}$ in., 9d.; $\frac{1}{2}$ in. and $\frac{5}{8}$ in., 45s. per 100 lbs.; brass rods, round, $\frac{3}{8}$ in., 1s. 5d.; $\frac{1}{2}$ in., 1s. 4d.; $\frac{5}{8}$ in. and upwards, 1s. 3d.; brass rods, hexagon, 1d. lb. extra; copper rods, round, $\frac{3}{8}$ in., 2s. 4d.; $\frac{1}{2}$ in., 2s. 3d.; $\frac{5}{8}$ in. and upwards, 2s. 1d. lb.; tool steel, 3s. 6d. to 3s. 9d. lb.; brass sheets, 2s. 2d. to 2s. 3d. per lb.; 2s. 4d. for the lighter gauges; copper tubes, solid drawn, $\frac{1}{4}$ in., 3s. 9d. per lb.; $\frac{3}{8}$ in., 2s. 11d. per lb.; 7-16 in., $\frac{1}{2}$ in. and 9-16 in., 2s. 9d. per lb.; $\frac{3}{8}$ to 1 $\frac{1}{2}$ in., 2s. 6d. per lb.; 1 $\frac{1}{2}$ in. to 2 in., 2s. 3d. per lb.; 2 $\frac{1}{2}$ in. to 3 in., 2s. 6d. per lb.; 3 $\frac{1}{2}$ in. to 4 $\frac{1}{2}$ in., 2s. 8d. per lb.; copper rods, $\frac{3}{8}$ in., 2s. 5d. per lb.; $\frac{1}{2}$ in., 2s. 4d. per lb.; $\frac{5}{8}$ in. to 2 $\frac{1}{2}$ in., 2s. 2d. per lb.; copper sheets, 2s. 2d. to 2s. 3d. per lb.; fire box copper, 2s. 9d. per lb.; phosphor tin, 3s. 3d.; ingot tin, 2s. 4d.; drill steel, 7d. and 8d.; hollow, 9d.; 1 $\frac{1}{4}$ in., 9d. to 10 $\frac{1}{2}$ d. Wire nails, 35s. to 47s. 6d.; shovels, 60s. to 65s.; wheelbarrows, 52s. 6d. to 55s.; picks, 37s. 6d. to 67s. 6d.; pick handles, 35s.; barbed wire, "Shorthorn," 69 lbs., 13 $\frac{1}{2}$ gauge, 21s. 6d. per coil; plain galvanised fencing wires, No. 8 gauge, 100 lb. coils, 25s. per coil; No. 10 gauge, 100 lb. coils, 27s. 6d. per coil; No. 12 gauge, 100 lb. coils, 30s. per coil; Bulb Tee fencing standards, 14 lb., 27s. 6d. per doz.; 12 lb., 24s. per doz.; black bal'ng wire, 14 gauge, 20s. per coil 100 lbs.; screening, 3s. to 9s. 6d. per

square yard; cyanide for outside mines, 1s. 6d. to 1s. 7d.; zinc shavings, about 1s. per lb.

Engineering Shops.

It is satisfactory to report that the improvement noted recently is being well maintained and that local manufacturers are fairly busy.

American Notes.

A more hopeful feeling exists in America as regards general business, and the outlook is more favourable. It is thought that the depression is passing and giving place to a more stable state of affairs. The steel industry is showing signs of improvement, the Pittsburgh district production advancing to about 40 per cent. The steel companies are more optimistic, as Government railways intend to place large rail orders in Canada.

German Competition.

Several German engineering papers are advertising for tenders for pipes, which they specially state are suitable for the South African market, in quantities as follow: 25,000 ft. of 8 inch, 10,000 ft. of 10 inch. German firms here are securing large orders for electrical machinery, one firm in particular has secured a large order from the Rand Water Board.

SAMUEL OSBORN (South Africa) LTD.,
SHEFFIELD and JOHANNESBURG.

It is reported that Mr. Struben will arrive here from London some time next month. We understand that his return visit is in connection with the companies in which he is interested, which have for some time been dormant. His visit should revive activities in the near West Rand so urgently looked for.

Indian Steel Works.

Large steel works, it is reported, are being established at Behar, with a potential output of three-quarters of a million tons of pig-iron and half a million tons of steel annually. It is noteworthy that the belief is prevalent that India is capable of producing the cheapest steel in the world.

A cable from New York announces that the Steel Corporation has reduced the price of steel rails by seven dollars per ton.

Timber and Building Materials.

The expected spurt in building operations has not eventuated, and things are not at the moment too brisk; there is, however, still a fair amount of business going in the way of repairs, and merchants generally look to improving conditions between this and 1922.

Prices: 3 x 9 deals, 1s. to 1s. 1d.; scantlings, 1s.; beaver board, 4½d. to 5d.; floorings, 6½d. to 7d.; ceilings, 5d. to 5½d.; Oregon, 6s. to 7s.; pitch pine, 7s. 6d. to 8s. 6d.; corrugated iron, 9½d. to 10½d. Furniture timber: Burmah teak, 18s. 6d. per cube here for first quality, 14s. 9d. for second, at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 2d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cubic ft. at the mills; Honduras mahogany, 30s. per cubic ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks remain unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag, 8 lb. bag 1s.; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 36s. 6d., 46s. 6d., 55s. for 1 to 3-ply.

Second-hand Iron and Timber.

Dealers are still having a slack time, but appear to be fairly unanimous as to an approaching improvement, which, in their opinion, cannot well be delayed. They say, and with right, that the cost of materials is now as low as it is likely to be for some considerable time (timber prices have firmed up considerably on the other side), and labour shows a reluctant but welcome downward course.

Electrical Goods.

Business in electrical wares has, dealers report, been satisfactory during the past week, locally and outside, with very fair inquiries. Prices show no alteration, with the exception of tubing, which has declined again to 10s. 6d. as against 12s. 6d. recently, and about 15s. during previous months. As a matter of fact, everybody seems to be selling tubing at a big loss, owing to the general feeling that it will come down considerably at Home; but at the present time this would cost about 13s. 6d. landed here.

There are at present no indications of any reductions occurring either in British or Continental quotations; as a matter of fact, prices according to latest schedules are firming both at Home and on the Continent. America is slowly forging ahead, but on account of exchange difficulties is very much handicapped.

Reduced Freights.

The South African Conference Lines have decided to reduce their freights on wire, iron and steel to 35s. per ton, in addition to certain reductions on other specified articles. Owing to scarcity of freights, some Commonwealth steamers presently returning to Australia are being put out of commission for the time being.

Petrol and Paraffin Prices.

Last week's *Government Gazette* publishes the current price of petrol and paraffin. Petrol (all brands) is not to be sold at a price exceeding 28s. 3d. per case at the ports;

Shell brand, 34s. 3d.; Pegasus, 31s. 9d.; Zenith, 32s. 3d. At other places the cost of transport and railage is to be added. Retail prices at the ports: 28s. 3d. (all brands), plus 15 per cent.; Shell, 5s. 2d. per tin; Pegasus and Zenith, 3s. 11d. All other places (all brands), 28s. 3d. per case, plus 15 per cent., plus transport, etc., Shell, 5s. 8d.; Pegasus, 4s. 5d.; Zenith, 4s. 5d. per tin. Petroleum as a maximum is fixed at the ports to the retailers at 17s. 9d. per case. At other places the above price plus charges. Consumers' prices, at ports and all centres less than 400 miles therefrom, 20s. per case of two large tins, or 24s. 6d. per case of ten small tins, or 2s. 7d. per tin. At places 400 miles or more from the nearest port, 20s. 3d. or 24s. 9d. per case, plus charges. Bottle prices at the ports, 6d.; elsewhere, 7d.

British Coal Industry.

It is announced that sixteen collieries in Lanarkshire, in addition to the many pits permanently abandoned as an outcome of the coal strike, will be closed indefinitely owing to the lack of markets and the inability of the owners to avoid a loss on every ton produced. Some collieries are being temporarily closed in the Swansea district through the depression in trade.

British Coal Position.

The situation is far from assuring. What with the exhaustion of the Government subsidy of £10,000,000 and the large reductions in miners' wages now due, the position is unsatisfactory and likely to cause trouble. Owing to the present prices many pits, it is said, are likely to close down, but until the price of coal is very considerably reduced there is no prospect of any resumption of activity by blast furnaces. At the moment very little pig iron is being produced, and what little steel is being made is only by the use of imported pig iron. Notwithstanding recent reductions the price of coal is, roughly, about one half more than that produced in Germany, which means that if the United Kingdom is again to recover her coal position, the cost of coal production—in other words to-day the wages of the miner must be reduced. The Miners' Federation, in view of the present coal impasse, has submitted to the Government a scheme whereby the maximum price of industrial coal shall be fixed at 30s. per ton delivered, including cost of railway freightage, and that the Government should for a period make up the difference to the coal owners and railway companies. The scheme would involve a Government grant of about £10,000,000 sterling.

Dear Coal.

Ironworkers state that it is impossible to produce profitably with coal at its present price, against which coalmasters state that they are losing on every ton of coal produced and that they are faced with the alternatives of running at a loss, closing down, or making arrangements with the workers for an economic adjustment of wages.

Unic Trade for October.

The Customs imports, exports and revenue collections for October were:—

	Value of Imports.	Value of Exports.	Gross Revenue.
Capetown	£714,975	*£3,386,647	£99,038
Port Elizabeth	815,007	126,450	86,956
East London	251,762	261,796	29,802
Durban	1,614,255	893,696	132,137
Johannesburg	nil	nil	68,180
Lourenco Marques ...	399,469	nil	15,642
General Post Office ...	nil	nil	26,777
Other ports & stations	34,711	10,916	14,902
Total	£3,831,079	£1,979,505	£173,434

*Includes £2,983,299 gold exported at Capetown.

A ballot of Engineering and Shipbuilding Unions in Britain in respect of munitions bonus has resulted in a majority against the pending strike.

Railway Earnings.

These for the week ended October 22 were £395,000, £39,500 below the estimate. The total from April 1 to October 22 was £12,131,925, which is £62,790 below the estimate for that period.

London Railway Electrification Scheme.

The South-Eastern Railway is about to electrify the whole system. The British Government has now under consideration a scheme which if adopted will give employment to 20,000 men for two years. The object is to develop and extend the London tubes, and the scheme involves an expenditure of some £6,000,000.

British Trade Statistics, 1913 and 1920.

A Blue Book recently issued shows that the value of imports in 1913 was £769,000,000 and in 1920 £678,000,000. Exports in 1913 were of the value of £525,000,000, as compared with £1,334,000,000 in 1920.

Chain of Sample Rooms.

A scheme for the developing of British trade in markets oversea, under the auspices of the Federation of British Industries, has been launched. Belgium (Brussels) has already been infiltrated, and very shortly all the Dominions will be.

Strengthening of Pacific and Atlantic Naval Stations.

The British Admiralty, it is announced, intends to spend £2,000,000 in converting Singapore into a first-class station. An alternative base of lesser importance than Singapore will be created in Australia. The Bermudas, on the Atlantic side, will also be converted into a first-class naval base.

New docks are about to be constructed on the Clyde, which will give six large parallel basins with direct entrance from the river and will add about seven miles of quays to the accommodation of the port, at a cost of about £2,000,000. At the port of London a new cargo quay, 1,000 feet long, has just been inaugurated, and plans for a large passenger stage at Tilbury and for big extensions to dock accommodation are being prepared.

Harnessing French Tides.

A 100,000,000 dollar project for harnessing the tide in the Bay of Mont Saint Michel has been proposed by a group of American engineers to the Chamber of Commerce of the town of Granville, France, department of Manche. The plan involves the construction of 13 miles of barrier in the bay, consisting of coifers in which turbines and alternators would be installed. Through the rise and fall of the tide it is hoped to develop 6,000,000 kilowatt hours a year. The French Ministry of Public Works, in the meantime, is going ahead with arrangements for an experiment in developing the hydraulic force of the tide on the Finistere coast.

The French have also some ambitious plans for the development of the Rhone River. It is planned to make this waterway into a water transport line that will rival the

Rhone, and will serve for the irrigation of over 600,000 acres of land. Also, 900,000 kilowatts of cheap electric current is to be made available, thus saving coal imports to the value of at least 600,000,000 francs a year. River ports will have to be improved, or if necessary created and joined by rail with the main land arteries of traffic. The Rhone River flows west and south from the Lake of Geneva to the Mediterranean Sea.

Financial.

London advises that the Government will shortly issue £20,000,000 of 3 per cent. local loans stock at 52.

Metal Market.

Latest London quotations: Standard copper, 955 6s. 6d. cash, forward £66 6s.; electrolytic copper, £72 cash, £74 forward; Straits tin, £155 15s. cash, £158 2s. 6d. forward; English lead £24 2s. 6d. cash, £23 15s. forward; bar silver, 39 5-8d.; fine gold, 101s. 1d. per ounce.

"The Millionaire":

A PEN PICTURE.

By W. P. Taylor.

When I say he is a millionaire, I don't really mean it, not any more than some people have called me a millionaire. I suppose they thought I would fall to the honour. Honestly speaking, I never did. I dare say, if I took the trouble to count up all the money I ever made, I have made a million, but there are two sides to the scale, and as fast as fortune emptied her tributes on the one side, something always went wrong, and the weights on the other side constantly let me down. I'm afraid I am pretty nearly in the same boat as a good many of our old-time millionaires. This one standing at the corner of the Central News Agency was, at any rate, a real, or as you hear them say, a real Mackay millionaire. Pucker Kimberley blue white, for I only tell what I saw. To-day he furtively glances about him. After waiting and looking about, he restlessly darts to the Post Office, and his figure may be seen moving along Fox Street, the Stock Exchange, or Rand Club. His clothes are thin and shabby. For winter, they are very thin; not cloth, but worn cotton, the pattern faded; summed up—old, worn, faded. His collarless shirt is often covered with woollen muffler, but as the weather brightens he discards wool, and his weather-beaten frame secums molycoddling. A rag hat loosely hangs down; it nearly covers his hair, which is fairly long; it shades his face under its folds and it hides his eyes, and from its depths he peers furtively. Sometimes he looks through glasses, bluish glasses, as the day brightens to hard glare, but when the shades lengthen he peers from under the rag hat's loose rim with one eye. The other eye is false. The millionaire with the rag hat has but one eye, and yet, in his days of power, it was a matter of no moment. As he stands with all the latest fiction at his back, peering from the corner of the Central News, no one would buy his romance in preference to those books, and yet, if truth is stranger than fiction, there is a living novel moving unwritten and unnoticed. If Cecil Rhodes struck an awakening chord and forced mankind to observe a figure moving to a goal; if, as he moved along a wonderful path, he had to tread beside a mate and hold a guiding hand, might he not have had as a companion the millionaire with rag hat? He might. In verity, he did. Yet at these corners there congregate our stiff, our men of the veld, who found and lost and who are too feeble to find again; men who managed mines and drew big pay, some with a tightness in chest that gives them a pension dearly earned. Some drink and dream; needy stiff's borrow from the man who sold his body for high pay, and though he bought his silver dearly he gives it away as generously as a child; but the man with the rag hat is not of these. For he is restless and alone. He never has a mate; he always is expectant. Rarely does he speak, rarely is he spoken to. His life has not always been a silent one, but now he moves and acts with a silent purpose. He has not always stood at corners waiting for a word. I have seen him in the city, garbed in frock coat and top hat, and in company with the foremost brokers on 'Change. I have seen him, earlier still, beside the great Cecil, looking into their mines. His name was a talisman, his word was law. He carried out chapters of work, chapters of the most difficult, and his iron will and determination entitled him to foremost place in Rhodes' most difficult task. He was incessantly called upon; he carried out what others could not undertake. He was fit to stand beside and to walk with Africa's great hero of Imperial advancement, and aid him in his most arduous

work. His name was good on documents for untold wealth, and I have seen him throughout all this. He now stands, a world of real romance before the imaginations of the scried rows of coloured novels in the Central News' window, and as I saw him there, I wondered what were his thoughts. Did he invent the wonder ship that was adopted in the war? Are there other practical thoughts to his credit, or are they but wild imaginations of a haunted brain? I do not know. I do know I have seen him flitting in wide stretches. In Hyde Park the mild spring sunshine warned the flowering chestnuts, laburnums scented the air; in such softness I suddenly felt the dry atmosphere of Africa. I saw a figure—it peered with one eye from colouring to colouring. The same worn thin, shabby clothes, the same hard figure; it was my friend the millionaire with the rag hat. I spoke to him. He told me of diamond mines and lodes of silver, and travelling back to his wealth. I lost him for many years; I saw him again at Kimberley. Sometimes he is to be seen in the Northern Transvaal towns. Single-handed, he fights his way; mysteriously he moves to old haunts. If he does not actually have wealth, he dreams of it. He is secretive; his confidence is never given; he fears. What does he fear? Is it the ghost of the man that passed him in the race? Whether he fears the shades of death or men who live, his wealth—if there be wealth—is his secret. If he has wealth and brings it to the world, his weirdness is unsurpassed and his secret guarded with steel. I know of secrets—reefs with untold wealth, great slabs of quartz with yellow gold kneaded through its hard face, hundreds of ounces to the ton. I know the river on whose banks fabulous riches lie undisturbed; but the man who found it and held its secret is dead, his shrunken corpse beside his wealth; his secret will never come from him, his mouth is filled with the veld's clay, and his secret is sealed forever.

I know; what do I not know? And like the man with the rag hat, we all have our secrets. Yet he is fearful. From whence his fear? What evil demon brought him his curse? Was it the loss of his great fortune, the fortune he had schemed and worked for? Standing before that wealth of modern romance and looking into the void, this silent figure, far from idle chatter, ever moving through strong deep currents, carrying his secrets in silence, past life's passions, sometimes looks back and furtively peers forward. Look back, my friend; you have lived. Look back. Your wealth has done you little good, but take this consolation, it has perhaps done as much or more than some of your wealthier brothers. You live and have your philosophy, your secret hopes. Your philosophy may be a true one. Theirs is gone; they are with all that death has embraced, and their philosophy is with them. Their wealth enplanted has fertilised no growth. Yours has circulated in the world's stream, and though you cannot see its colour in the currents, it lives and flows. In all there are no monuments for posterity. In greed they gathered charity; they never gave but to inscribe a name in gilt, and when their last oxygen passed back to its early atmosphere, charity felt an icy breath pass her wondering cheek. It was in words "that evil was wrought by want of thought, as well as by want of heart." Look back; you will not see a multitude of despoiled widows and orphans. You were no mean ticky snatcher; your wealth was not attained rigging gold shares. There is nothing for you to undo. With your mind, wealth might have been a power. Theirs was but sciled paper, and marked no purpose. Well, they are dead. They had nothing in the making, nothing in the keeping, and their gold is nothing to them now. The world lost in their gain; it gained nothing in their death. Trees may sway in the wind beside their graves, and sigh, but the world has forgotten them. They passed as empty shadows and forget to inscribe their names. Did they forget, or was it shame? You, my poor millionaire with the rag hat, would inscribe your name. It loomed largely once. Your actions moved swiftly, silently, relentlessly, successfully, but broke suddenly.

Ah, well, I leave you in the deep labyrinth of your speculation, and as restlessly you move I wonder if under that loose hat there actually does remain a deep secret filled with purpose, and that some unknown strength leads you to hope.

“The Rand’s Low Grade Tonnages” in this Issue.

The South African Mining & Engineering Journal

THE ONLY WEEKLY MINING PAPER IN THE CONTINENT OF AFRICA.

Established 1891.

Vol. XXXII., Part II

JOHANNESBURG, TRANSVAAL, SATURDAY, NOVEMBER 12, 1921.

No. 1572

A Central Rand Low Grade Mine.

The necessity for reducing Rand working costs to such an extent that our vast low-grade tonnages can be worked at a profit is dealt with at length in this issue. The above photograph depicts the surface works of the Village Deep, a mine which, on account of its depth and low-grade character, would benefit materially from the suggested amendment of the Mining Regulations.

VAST STOREHOUSES OF WEALTH LOCKED BY THE KEY OF HIGH COSTS—HOW TO OPEN THE DOOR TO PROSPERITY—ALL-ROUND BENEFITS FORESHADOWED—A STUDY IN PENNYWEIGHTS—FACTS AND FIGURES IN GRAPHIC FORM—THE EPHEMERAL PREMIUM—HOW TO SET OUR INDUSTRIAL HOUSE IN ORDER—THE PRIME MINISTER PROPOUNDS A PARTIAL SOLUTION—AMENDMENT OF THE MINING REGULATIONS—THE BOGEY OF THE COLOUR BAR—THE MEN'S LEADERS REJECT THE PROPOSAL—ANOTHER CONFERENCE—“ THE ONLY WAY ” TO EXPANSION.

Presiding at the annual meeting of the Nourse Mines, Limited, a few days ago, Mr. E. G. Izod sounded an optimistic note in regard to that company and the whole Witwatersrand when he said the Nourse Mines is only one of many mines on the Rand which have vast stores of gold locked away in its ore reserves. “ I cannot believe,” continued Mr. Izod, “ that any community of white, progressive people, such as we have in South Africa, will continue to be so apathetic towards the great possibilities of the mine as to allow this gold to lie fallow for all time.” We do not always find ourselves in accord with Mr. Izod's utterances, but in respect of his remark as quoted above, we think he has sounded a note which should become a clarion

call throughout the length and breadth of this country. The whole future of the Witwatersrand, and in large degree that of South Africa, is wrapped up in the problem of how to work low-grade tonnages at a profit. There are immense quantities of such ore standing developed or partially developed in the mines to-day, and there are further immeasurable areas of conglomerate beds of poor content to be exploited.

Accumulations of the Years.

These developed and partially developed tonnages represent the accumulation of years of work and of many thousands of feet of sinking, drilling, raising and winzings. It is quite impossible to exaggerate the importance to

The Turf Mines Headgear of the Village Deep, the deepest only one of many mines which would benefit substantially b discussed

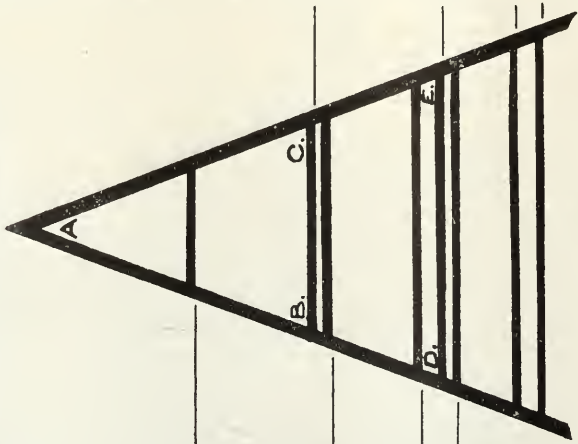

shaft on the Rand. This low-grade and deep proposition is y the suggested amendment of the Mining Regulations in this article.

Jhannesburg, to the Rand, and to the whole of the Union, of realising the colossal amount of wealth locked up in these low-grade reserves of ore. If these immense tonnages could be made to disgorge their auriferous content, many scores of millions of pounds would be put into circulation, the life of the industry—and particularly the life of the Central Rand

All-Round Benefits.

Everyone would benefit and benefit enormously from a prolongation of the lives of the mines and from the lifting—or at least the partial lifting—of the shadow of waning production which darkens the future of the gold mining industry of the country. The shareholders would benefit thereby, the

**VARIATION OF ORE RESERVE
WITH WORKING COSTS AND PREMIUM.**
NOT MATHEMATICALLY CORRECT.

GOLD AT 85/- PER OZ.		ORE RESERVES.		GOLD AT 105/- PER OZ.	
WORKING COST PER TON.	GRADE JUST PAYABLE DWTS/TON.			GRADE JUST PAYABLE DWTS/TON.	WORKING COST PER TON.
25/2	6.0			5.0	25/2
21/-	5.0	3.9	21/-		
17/1	3.8	3.3	17/1		
16/-	3.8	3.1	16/-		

THE ORE RESERVE FOR ANY SET OF CONDITIONS OF WORKING COSTS AND PREMIUM IS REPRESENTED BY THE TRIANGLE ABOVE THE BASE LINE OPPOSITE THOSE CONDITIONS. FOR EXAMPLE, THE TRIANGLE A.B.C. REPRESENTS THE ORE RESERVE WHEN GOLD IS AT 105/- PER FINE OZ. AND WORKING COSTS AT 25/2. IF WORKING COSTS FALL TO 21/- UNDER THOSE CONDITIONS, THEN THE ORE RESERVE IS INCREASED BY B.C.E.D. AND BECOMES TRIANGLE A.D.E.

—would indefinitely be prolonged, the unemployment problem would largely be solved, merchants would greatly increase their turnovers on account of the stores consumed and the wages paid out in the process of mining and milling these ores, and the economic pulse of the whole country would be quickened.

workers would benefit, the railways, the revenue of the State, the merchant, the taxpayer, the man out of a job, the man in affluence and the man in debt, all speedily would feel the beneficial effects resulting from the assured prospect of obtaining from the gold mines of the Rand an additional large amount, perhaps as much as two or three hundred

million pounds worth, of gold. This vast storehouse of wealth is locked to-day by the keys of high working costs. The gold contained in these many millions of tons of low-grade ores can only be realised in one way, and that is by working the conglomerate beds which contain this gold, and it is a moral certainty that no company or group of companies will undertake to mine, hoist, mill and cyanide this vast accumulation of low grade ore and develop other large low-grade sections unless there is the prospect of earning from such operations a fair measure of profit.

Price of Gold and Cost of Working.

Even with the price of gold standing at 25 per cent. above its normal value, it is impossible to work the great bulk of this low-grade ore. Only the higher grade sections of this tonnage or limited blocks of poor value adjacent to areas of profitable content can be exploited. With gold standing at its present day price of, say, 105s. per ounce, and with

per ton, and in September of this year they were 25s. 2d. per ton. Fortunately for the Rand, the gold premium stepped into the breach in 1919 and temporarily arrested the destructive process of transferring tonnages previously accounted "payable" into the arena of unprofitability. But the gold premium is a purely ephemeral thing, and the only businesslike way of facing the proposition is to look at the problem of the low-grade areas from the angle of a normal price for gold.

Profits from "Unpayable" Ore.

In nearly every quarterly and annual report that is issued one reads that development for the period was so many thousand feet and that of the tonnage of ore exposed only a certain portion was payable. In the case of numerous mines only about 50 per cent. of the ore developed is capable of being worked at a profit under the conditions obtaining to-day. We cannot increase the quantity of gold in the

WORKING COSTS PER TON

WORKING REVENUE PER TON

This diagram exhibits working costs and revenue per ton in 1914 and at the present day. It shows, too, that but for the gold premium the margin of profit for the whole Rand would be exceedingly small.

working costs at 25s. 2d. per ton, ore containing an average gold content of less than 5 dwts. per ton is unprofitable. It is a perfectly simple and easily understandable axiom that if a thing costing 25s. 2d. cannot be sold for more than 25s. 2d., no sane company will take the trouble or lose the money entailed in its production.

How Expenses Have Risen.

We feel quite certain that the public generally do not adequately appreciate the position in regard to the vast low-grade tonnages of the mines and the necessity that exists for bringing these ores within the scope of industry. Since the outbreak of the Great War these accumulations have been enormously augmented by the automatic transfer of ore from the payable to the unpayable side of the ledger through increased costs of production. In 1914 working costs on the Rand averaged 17s. 1d. per ton. By 1919 they had risen to 22s. 11d. per ton, and the working profit had declined to 5s. 6d. per ton. Costs last year were 25s. 8d.

conglomerate beds. But it should be within the bounds of possibility to so reduce the cost of working that a large proportion of this payable tonnage can, instead of remaining fallow in the mine, be rendered productive.

Millions and Millions of Tons.

How many millions of tons of ore which are to-day lumped under the category of "low-grade" because working expenses are so high that they cannot be worked at a profit, exist in the mines of the Rand, it would be very hard to say. But we do know that the quantity is enormous and that with each decline in the cost of production a certain amount of this ore can be worked at a profit. And as the cost declines, larger and still larger tonnages cross the border line which separates unpayability and industrial stagnation from profitability and prosperity. In order to illustrate in graphic form the incidence of decreased working costs upon low-grade tonnages, we reproduce herewith charts which should enable lay readers to visualise the essential factors in the proposition.

A Graphic Representation.

In the first diagram the pyramid represents low-grade tonnages, and by its sides are depicted columns representing the amounts of gold in terms of dwts. per ton required to realise the expenditure. But in this connection it should be borne in mind that the assay value in situ of the blocks is more than the recoverable value because there are inevitable losses both in mining and extraction. The values in situ may, however, roughly be taken to represent the border line between profit and loss, and it will be observed that as costs decline more and more tonnage is brought within the scope of economic working. It is not contended that the dimensions and scale of the diagram are mathematically correct, or that the proportions are accurate. No complete computations of low-grade ore

the face of a downward trend of gold prices, allowed to continue, we shall be guilty of allowing a sterilising influence as blighting and destructive as the sands of the Sahara or the Kalahari, to creep into and extend within the vitals of our livelihood.

Plain and Simple Logic.

These facts are indisputable, and to contend that if working costs are not reduced by means of a decrease in the aggregate sums of money disbursed on working account, then they must be reduced by means of an augmented product is plain and simple logic; and, moreover, this process of setting our industrial house in sound economic order must not long be delayed. Many of our mines are on their last legs.

EFFECT OF PROPOSED AMENDMENT
ON WORKING HOURS
FOR NATIVES.

OLD **AMENDED**
REGULATION. **REGULATION.**

HOURS PER DAY

OUTPUT PER
NATIVE.

THIS DIAGRAM PORTRAYS THE EFFECT THE PROPOSED AMENDMENT OF WORKING HOURS FOR RAND MINE BOYS WOULD HAVE UPON OUTPUT.

reserves classified according to value in respect of all Witwatersrand mines are available; but the principle portrayed in the chart is correct, and some little study of the diagram will assist in a proper comprehension of the immense importance attaching to the task of making low-grade ores profitable to work.

How High Costs are Sterilising the Rand.

If and when gold comes back to normal selling value and costs remain at their present level, only six dwt. ore will pay to work, and the vast accumulations of low-grade rock, which it is impossible to exploit save at a loss, will further be increased. By maintaining costs at their present high level the Rand is rendering a vast acreage of its golden farm barren and unproductive, and if this destructive process is, in

Inflated costs are hastening their doom. The majority of these properties, once they are closed down, cannot be reopened, and when pumping operations in them cease the operations of adjacent concerns will be jeopardised by influx of water from the idle mines.

A Refusal to Listen to Reason.

In the face of all these irrefutable facts, it is as deplorable as it is amazing that the men's leaders have stated their refusal to acquiesce in the alteration of that portion of the mining regulations which is concerned with the number of hours worked by natives. On Friday week the Prime Minister addressed a deputation from the Mine Workers' Union on the subject. The position of the mines has evidently become so grave that the counsel of an even weightier personage

than the President of the Chamber of Mines or the head of a mining house is needed; it is so acute that it has called for the intervention of the Prime Minister himself. We feel quite sure that only the gravity of the position induced Gen. Smuts to plunge into the maelstrom of Rand industrial problems with all their concomitant political complexities and dangers.

The Premier's Panacea.

In the course of his speech, General Smuts is reported to have said: " Looking for a solution of the troubles that face our industry and the danger that threatens our existence in future, I would not look to white labour, I would not look to the removal of the colour bar, and I would not look to the importation of more native labour into the mines, but I would look to one matter, and to one matter only, and that is the working efficiency of the natives that we have here." Admirable as the Prime Minister's speech may have been in its moderation and statesmanlike in its outlook, we cannot help feeling that the view expressed in the foregoing remark does not go far enough.

What About White Efficiency?

The working efficiency of our native labour is but one aspect of the matter. There is plenty of scope for increasing the efficiency of our coloured workers. But there is far more scope for improving the efficiency of their white overseers.

European Miners in a Rand Stope.

If we can obtain more and better working value from Jim Fish and Sixpence, it will be a distinct gain for this struggling industry. But it is idle to look for much improvement from the natives so long as our so-called " miners " of European descent are still in a truculent mood and are not themselves prepared to put their shoulders to the wheel and assist and help in the effort to reduce working costs by every means in their power.

The Ephemeral Premium.

In his address the Prime Minister wisely reminded his hearers that the gold premium was nothing more than a mere fortunate accident. *Inter alia*, he expressed a view that often has been given prominence to in the columns of this journal when he said we do know, that unless we are prepared to incur the gravest risks in regard to the future of this industry, we ought to see, and start early to see, that we are not dependent merely on the gold premium, but that our industry is on such a basis that it can continue to run on for the future, whatever happens to the gold premium.

The Prime Minister, in his speech, pointed out that under the conditions of working as they exist to-day, and under the mining regulations as framed, and the conditions of working that have developed under those regulations, the native worker does not work eight hours underground, but according to the report of the Low Grade Mines Commission he works an average of five hours underground. He spends

a long time underground. He goes down in the morning before the white man, and he sits there and waits until everything is in order and properly prepared and inspected, in accordance with the mining regulations, and then he starts his work. He then leaves the working place, again ahead of the white man, and what with the time wasted in this preliminary inspection and in his clearing out, again ahead of the white man, the result is that while the white man has his eight hours underground, the black man has hours less—five, according to the report of the Low-Grade Mines Commission. General Smuts expressed his views on this matter very fully and frankly, and said: " It is intolerable to have a black labour force, which was intended to work at least eight hours a day, but which, under the regulations as they exist, only work five hours a day, while the white man has to be there for eight hours a day. Not that the native is not underground all the time. He is, and longer than the white man, but under our working arrangements he is debarred from working during that time, and you can see what a difference that makes to the working of the mines. I say it is our duty to apply this eight hours day, which is in force for white men, and is the law of the land for underground mining—it is our duty to apply that to the black man in the same way. If the white man has to work eight hours

General Smuts, Prime Minister of the Union, who has made a telling appeal to the mine workers to set our industrial house in order.

underground to do his daily task, then it is the duty of the black man to do so, too, and we ought to frame our regulations and our law, and arrange our working conditions in such a way that he can do that.

The Proposed Amendment.

And what is proposed now in the amendment which the Minister of Mines has notified to you, is this, that whilst adhering to the principle already laid down, namely, that there shall be a previous inspection before the gang goes into the working place—by another body—that more latitude should be allowed, and the personal supervision of the white ganger, or inspector, or whatever he is called, should not be so close and detailed that he spends too much time over that. The whole idea is to make that a little more elastic."

There was at this conference no suggestion to interfere in any way with the terms of the arrangement recently arrived at by the Federation and the Chamber in regard to white miners' wages or hours. There was, in fact, no suggestion to interfere with the European miner's status in any way, except to better it,

A Proposal Rejected.

The Premier's speech was replied to by several members of the deputation from the Mine Workers' Union. Mr. E. S. Hendrikz, the acting general secretary, was the principal spokesman. The general keynote of the reply in connection with the suggested alteration to the mining regulations indicated very clearly that the mine workers were under the impression that this was not only an attempt to get in the thin end of the wedge for the removal of the colour bar, but that it was practically a case of driving the wedge home; that, in fact, it meant the removal of the colour bar. The speakers stated definitely that they would never agree to the removal of the word "personally" from Regulation 106 (7a) of the Mining Rules and Regulations. This regulation is to the effect that the ganger or miner shall "personally" supervise the dressing down or pulling down of all dangerous rock prior to the commencement of mining operations.

Mr. Hendrikz said that should the amendment suggested by the Government be gazetted, within 48 hours afterwards a general strike would be declared, not only on the Reef, but also throughout the whole of the coal mines.

This terminated the proceedings. The proposal for a conference has been taken up by the Prime Minister, and the first meeting between the Government, the Chamber of Mines and the workers took place on Thursday.

Another Conference.

We can only hope that this conference (like other recent round-table chats concerning this unfortunate industry) will not last for several weeks, perhaps months, and that in the meantime numerous mines will get so far into the mire of financial difficulties that it will be too late to rescue them even if our autocratic democrats consent to the amendment of the regulations.

What It All "Boils Down" To.

We have dealt with these two immensely important matters—the problem of the low-grade ores and the Prime Minister's earnest appeal for assistance for an industry in jeopardy—because the essence of both these subjects may be crystallised into this, that there is urgent need for better labouring efficiency in and on our mines to-day. There is urgent need of this in order that working costs

Going on Shift. White and Native Miners at a Rand Headgear.

The Premier's Disappointment.

General Smuts, in reply, indicated that he had placed the position before them quite clearly and frankly in the hope that he would be able to get their assistance, but instead of offering any solution to the problem—although they were all agreed that some means should be devised whereby a fuller use should be made of the time spent by the natives underground—he was met with a threat of a strike.

A Conference Suggested.

Mr. Hendrikz then suggested that a conference should be called between the Chamber of Mines and the Mine Workers' Union, at which the Government should also be represented, the conference to be held preferably under the chairmanship of the Minister of Mines, when the mine workers would be prepared to submit proposals to attain the desired object without any drastic alterations to the mining regulations now in force.

may be brought down to such a level that the Rand mining industry, upon which the livelihood of each and all of us depends, may be placed on an enduring basis of economic security which will not only insure the continuation of work at many of the poorer mines, but will also admit of the working of our vast resources of low-grade ores which are locked to-day by the keys of high cost of production.

TRANSVAAL G.M. ESTATES.

The following are the particulars of the output for the month of October in respect of the above company:—
Central Mines: Tons crushed 12,500, yielding 3,701 ozs. fine gold.
Elandsdrift Mine: Tons crushed 1,520, yielding 961 ozs. fine gold.
Vaalhoek Mine: Tons crushed 2,020, yielding 759 ozs. fine gold.
Estimated value of month's output, £27,659; estimated profit for month, £4,308. The month's results are based on value of gold of £5 1s. 6d. net per fine oz.

The Origin of the Diamond.

A SCIENTIFIC INQUIRY—CAN ARTIFICIAL BRILLIANTS BE PRODUCED?

By James Ennis.

The following article and the remarkable photograph accompanying it constitute an interesting contribution to the Romance of Science, and we publish them in the hope that they will stimulate thought and elicit correspondence in regard to this entrancing subject. It is some years now since the famous Lemoine experiments momentarily startled the diamond world, and we publish the interesting views of Mr. Ennis on the birth of the diamond, not with any intention of further depressing an already over-nervous industry, but purely with a view to ventilating the scientific aspect of a most difficult subject as viewed by a contributor who has devoted a vast amount of study to the matter.

The production of the pure diamond gem crystal from its natural elements may now be considered as a possibility of the future. Artificial production of pearls, rubies and sapphires are present achievements. The success of the Japanese in the production of the pearl by pearl culture has been attained through the thorough manner in which they have studied nature's method of production. Prolonged investigations along these lines have secured for them a great scientific achievement to the confounding of the pearl experts. The culture of the pearl is dependent upon the mode of suggestion—secret incitement—being compatible with co-existing conditions favouring production at incipient stages. Knowledge is that all bivalves do not produce pearls.

The production of crystals is not governed or restricted by like conditions. This is evidenced by the unrestricted production of artificial crystals. Paris produces rubies and sapphires, synthetically, to the extent of 5,000,000 carats annually. They do not reveal any differentiation to the real gem unless subjected to the searching investigation of the Rontgen rays. Why are these artificial gem stones not so perfect as to pass out as being pervious to the Rontgen rays—the supreme test? It would appear that although the method of manufacture crudely approaches the manner in which they are produced by nature, the faculty have not yet definitely determined the constituents employed by nature in the production of these gems. Will the most precious of all gems, the diamond, lead the way to this determination, and furnish the key to the solution of this problem, which has engaged the unremitting efforts of the savants of the world? The opinion of the discoverer of the parent rock of the diamond, with its true constituents in juxtaposition to the actual crystallisation, is emphatic in the affirmative. The possession of the constituents of the diamond, with a studious conception of the mode of production as exhibited by nature, constitutes a definite basis for laboratory investigations. In co-ordination with existing artificial crystallisation, the possibility of the production of the perfect gem should not be insurmountable.

Sir William Crookes on the Constitution of the Diamond.

Hypothesis has long held the minds of scientists in the matter of probable recognition of the constituents of the diamond. Pure carbon has been the accepted rule of conjecture. The late Sir William Crookes has, however, qualified the theory of the mineralogist respecting the physical and chemical properties of the diamond. "I need scarcely say (he writes) the diamond is almost pure carbon." Converted to ash when subjected to a temperature of from 760° to 875° C., by far the largest constituent of the ash is iron. This definition at one time seemed to coincide with

the opinion of the writer. A diamond recovered by him on the alluvial fields revealed what appeared to be, by the aid of a field glass, a substance within the gem having the appearance of an entomolite. Inter-penetration seems futile to conceive. In the sun's rays a glint, as of metallic substance, was discerned which placed the possibility of iron being the foreign substance. No aid could be obtained from microscopic observation. The inference therefore of the presence of iron was allowed to remain. Since the accurate demonstration of crystallisation of the gem has revealed its secret to the studious observer, the final inclination of

A remarkable copyright Photo illustrating the Birth of a Diamond.

opinion has set the phenomenon to be not a foreign substance, but an imperfection of the gem in its crystallisation. Incipient crystallisation, leaving a microscopic cavity, would show the facet of the cavity as a reflecting object to the observer.

The Great Cullinan.

Referring to Sir William Crookes' description of the Cullinan diamond, he observed "at one part near the surface there was an internal crack, showing well the colour of thin plates." The constituents of the diamond, from which nature has evolved the gem, displayed the lamina and the iridescence in much splendour. The recognition of the elements of the diamond has revealed the affinity of purpose in nature's production of minerals. Nature's revelations render the attendant efforts of production of those who have in the past endeavoured to emulate nature particularly abortive in perspective. Hanmay in 1880 endeavoured to produce diamonds from lithium, bone oil and paraffin. Friedlander fused clivine and stirred it with a rod of graphite. Moissan employed a crucible of carbon in which he placed a mixture of pure iron and pure carbon and the whole was subjected to the heat of the electric furnace. The mask which held the smiling gem of nature beams with indulgence upon the futile efforts of these alchemists, witchery emulators. A groping for the sunbeams in the midnight watch! All honour is due to the laudable efforts of these patient investigators. Yet it would seem feasible to imagine that the diamond has its home of production. To assume that the elementary knowledge of this conclusive fact has escaped

the intuition of the thoughtful mind seems remarkable. To the student of nature, who has devoted years to the subject within the environments of that particularly favoured area of the world's surface where the diamond has been so productive, it denotes a want of perception. Excerpts from various writers on the hypothetical origin of the diamond divulge a stereotyped deduction of intense heat, extreme pressure and the product of great depth.

Driving a Coach and Four through Theories.

The closing of this article will show how beautifully characteristic is the crystallisation of the diamond in its simplicity of structure and how singularly tender was nature at its birth. The history of the diamond would be incomplete even in its most vague form of understanding unless the origin of the gem had been discovered. Numerous writers, who have taken up the task of writing on diamonds, have found the subject of the origin a point on which they touch with hesitation and vagueness. Satisfaction is generally found by them in quoting Gardner Williams' oft-quoted confession, "I have been frequently asked 'what is your theory of the original crystallisation of the diamond?' and the answer has always been, 'I have none, for after seventeen years of thoughtful study, coupled with practical research, I find that it is easier to drive a coach and four through most theories (he could well have gone the full strength and included 'all theories,' for in this he would have been justified) that have been propounded than to suggest one which would be based on any non-assailable data." Unassailable data is now extant in the discovery of the parent rock and evidence of the complete crystallisation of the gem.

A Remarkable Photograph.

A unique photograph of the true matrix of the diamond, clearly defining the caste of origin, has been copyrighted in Pretoria by the discoverer. The delicate striated grooves are well brought out in this photograph as a featured characteristic of the South African gem. This feature is referred to in W. F. P. McLintock's (B.Sc.) guide to the collector of gem stones in the Museum of Practical Geology, thus—"Another point of interest well brought out by the octahedral crystals from South Africa is that the edges of the octahedron are replaced by striated grooves which show that what appears to be a simple crystal is in reality a compound or twin form." The crystallisation of the diamond as shown in the photograph is manifestly genetic. The expulsion of the elements of the diamond through the interstices of the rock is equally manifest. The visionary incipency and matured crystallisation within the influence of the simultaneous crystallisation of the matrix is a unique exemplification of the varied forms the diamond assumes. The made or twin stone may well be conceived as the result of fractional suspension of consolidation. Equally demonstrative is a specimen in the possession of the discoverer, showing the crystallisation of the cleavage. Contrary to all accepted impressions, the cleavage is hereby proved to be not a shattered or broken crystal, but a crystal formed in the matrix clearly defining the crystallisation as a cleavage. Respecting the Cullinan diamond, Sir William Crookes defined it "as a fragment, probably less than half, of a

distorted octahedral crystal; the other portion still awaits discovery by some fortunate miner." This impression has been held as a generally accepted phase of phenomena pertaining to cleavage. Nature has divulged the secret of the cleavage, and revealed possibly why the visionary other half of the Cullinan has never been recovered. Sir William Crookes states that "more diamonds are formed in fragments and splinters than in perfect crystals; and it is noteworthy that although these splinters and fragments may be derived from the breaking up of a large crystal, yet in only one instance have pieces been found which could be fitted together, and these occurred at different levels. Does not this fact point to the conclusion that the blue ground is not their true matrix? Nature does not make fragments of crystals."

Evidence of Malformation.

Does not the foregoing strengthen the evidence of malformation. This characteristic cannot be easily ignored in the evidence of the varied forms of crystallisation which is a distinctive feature of the diamond. Nature has left the evidence of this malformation in a distinct caste of apparent fracture. The possibility, therefore, is that more extended investigation may reverse the opinion that nature "does not make fragments of crystals." Nature may make crystals in fragments, i.e., incomplete crystallisation. On the alluvial fields "patches" of diamonds are recovered within a very small area. These phenomena are demonstrated in another specimen in the discoverer's possession, whereby the parent rock exhibits the crystallisation of a patch of crystals. The adamantine sheen or lustre retained in the casts of several specimens, especially the one exhibited in the photograph, is so perfect in its fresh appearance and brilliancy that the crystallisation could well be assumed to have

been a crystallised manifestation of but yesterday instead of in ages past. This is remarkable because of the circumstances which surround the manner in which they were discovered. Out of the granitic magma, surcharged with all the constituents of the alluvial gravel in all its varied forms, and endowed with the remarkable variety of mineralisation, a superficial lava has issued forth from gash and deeper seated veins. Flowing over the heated magma, the gravel or pebbles have segregated out, each with its characteristic type of mineralisation. Nature has hidden her secret in complete dissimulation. The only clearly defined vein the discoverer has recognised, held as contents crypto-crystalline quartz, Scherb quartz, scintillating with a myriad points of crystals; quartzite, etc., with a lava filling. The assumption geologically entertained that gravel is the detritus of rocks, water worn and rounded by sub-aerial conditions, is crude to the imagination of any who have studied the otherwise perfectly characteristic typification of the gravel on the alluvial fields. Gravel found on the elevated kopjes is a phenomenon no longer demanding an explicit explanation of its presence and origin. So perfectly undisturbed are the gravel patches and areas that to the studious mind each pebble is recognised to be *in situ* where sub-aerial influences have been withheld favouring conditions preventative to its disturbance. The prevailing recognition of the rotten granite on the part of the alluvial diamond seekers as the formation favouring that where diamonds may be found, clearly supports the opinion that the granitic formation is that in which the contemporaneous veins have discharged the superficial lava. The oxidation of the iron as a constituent of the lava has caused the "red brick" appearance of the most favoured ground sought out by the experienced diamond seekers. When the pseudo-lime formation is found to be favourable to the recovery of diamonds, these phenomena are due to the lava being subjected to sulphuretted influence during the passage of the flow, which has converted the lava into a compact sheet of hard or variable soft lime in appearance. The pebbles are here *in situ* in the lava from which they have segregated and remained embedded in the flow. The lava of the "red" ground has disintegrated under sub-aerial influences, leaving the gravel free in the friable soil.

A Scientist's Goal of Success.

Crystallography of the diamond, as pertaining to the manner of crystallisation of the alluvial gem by nature, is a subject which has now passed from the hypothetical to the substantive. The discoverer, who has surmounted the considered impossible achievement of discovery and recognition of the birthplace of the diamond, has reached the goal

of success which has been to the scientist, geologist, and others the ambition and desire of a life's interest. The mystification of the origin of the elusive gem has held the most thoughtful of men bound to conjecture, visionary as alchemy. Nature has hidden her secret in diversification and in the manner which crystallisation has been varied. This has rendered the discovery more elusive than the gem itself. Diversity as existing between hypothesis and nature's simple mode of crystallisation is set forth in the fulness of imagination by Sir William Crookes:—"I have done my best to explain the fiery origin of the diamond, and to describe the glowing, molten, subterranean furnaces where they first begin mysteriously to take shape. I have shown that a diamond is the outcome of a series of titanic earth convulsions, and that these precious gems undergo cycles of fiery, strange and potent vicissitudes before they can blaze on a ring or a tiara."

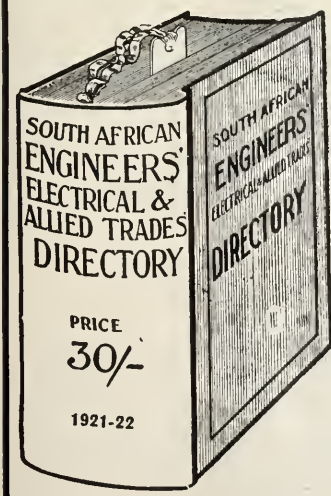

In such manner has the world's imagination been drawn to the brink of this awful visionary birthplace of the gem. How transcendently diverse is nature's revelation. This purest of all nature's manifestations in crystallography divests itself of this lurid stigma of its origin. The foliation of the rose is an index as free from complexity as the foliated laminae of the diamond, which, by its striation at the edges, and which in some crystals embraces the whole gem, proclaims in the most assertive language of nature that, figuratively, the diamond blossomed as a rose.

The Prospect of Producing Artificial Diamonds.

The discovery of the vein stone of the diamond, nature's crucible, has opened up the problem anew respecting the possibility of reproducing the pure gem. Attempts to reproduce the diamond synthetically have failed. This conclusion is apparent to the observer who has had the unique opportunity of investigating the methods of nature's mode of production. Endeavours to reproduce the diamond have failed primarily because the constituents employed in these attempts have been the outcome suggested by hypothesis.

A One Million Pounds Colliery Scheme.

In spite of the difficulties which hinder the development of collieries in Great Britain, one large colliery company has decided to spend over one million pounds on extending electrical working in its various mines. The main power house is to be extended until it becomes the largest private electric power station in the country. One of the resulting changes in the pits will be the complete electrification of all plant which can be suitably operated by electric power. A considerable reduction in working costs will be effected.

American Capital for the Rand.

AN INTERESTING LETTER FROM NEW YORK.

The possible association on a large scale of American capital with South Africa is a theme that is being much debated at the present time. Although nothing definite is known, it is, in usually well-informed quarters, believed that more dollars are likely to find their way into this country in the near future than ever have come here in the past. The first-hand information on this subject, contained in the following article, comes from a reliable New York correspondent of the "Mining Journal," and is at least interesting.

It has so often been rumoured that big American interests are about to take a large hand in the development of the Witwatersrand that the public has grown more or less sceptical about these reports. It is, however, fairly generally known that for some months past representatives of one of the largest financial groups in the United States have been touring South Africa and have been investigating various mineral and industrial propositions. Their work has been quiet and unostentatious and various motives have been imputed to them. But whatever the objects of their visit may be, one can safely assume that the representatives of one of the very biggest of the firms in the States are not out here on a health trip.

We have from time to time heard much of and hoped for a great deal from the entry of American capital into this country. Years ago there were rumours that New York financiers were going to acquire Randfontein, and in 1919 an offer from the States to finance the Western Rand Estates was unfortunately refused at a time when negotiations had progressed satisfactorily almost to the point of consummation.

American Capital in South Africa.

More recently we have had the active co-operation of American capitalists in the development of the Anglo-American—Consolidated Mines Selection—Consolidated Diamonds group of interests, and in the Congo Diamond Fields. Thomas F. Ryan and his associates have brought the Kasai areas to a state of production on a fairly large scale. But there have been no very extensive inroads made by Yankee capital into the fields of South African industry. American capital has a stay-at-home tendency, yet signs are not lacking that the dollar is seeking avenues of use and employ-

ment in parts of the Old World as well as the New, and the fact that no other undeveloped country has such vast and varied resources as South Africa assumes a fresh measure of interest when taken in conjunction with the knowledge that envoys of one of the biggest corporations in the United States have been touring the Union, presumably with the intention of spying out the land and the acquisition of attractive interests.

This view is, too, supported by a letter just received from an esteemed and well-informed correspondent in New York. Writing from New Jersey, under date September 29, our correspondent says:—

"Yesterday I was in the office of a friend of mine, the editor of the ————. He was just busy on an article on the South African gold fields. I gave him a lot of information. I learned that ———— & Co. are going into the South African gold business, and this may lead to the placing on this market of some stocks they are to control of some new ventures on the Rand."

FIRST-AID ACTIVITIES.

St. John and Red Cross Joint Demonstration.

The importance of a knowledge of first-aid to the injured is not, as yet, fully realised by the community as a whole, and in order to arouse the interest of the public in this valuable means of saving life and limbs, a big first-aid demonstration is to be held at the Wanderers' Hall, Johannesburg, on Saturday, the 17th December. The demonstration is being organised jointly by the Order of St. John and the South African Red Cross Society, and it is expected that ambulance teams from the other provinces will attend to compete.

There will be separate competitions for both male and female adult teams, each consisting of five members, while the juniors will also be catered for, in that teams of Girl Guides, Boy Scouts and Wolf Cubs will each have separate competitions arranged for them.

The teams for each event will be selected by the several organisations concerned. Keen and interesting contests are anticipated, particularly as this will be the first occasion upon which ambulance teams representing St. John and the Red Cross will meet in friendly competition.

On the evening preceding the competitions (Dungaan's Day) there is to be a grand St. John and Red Cross Ball at the Wanderers, which function H.R.H. Princess Arthur of Connaught has promised to attend. The arrangements for the Ball are being made by a large and influential committee, presided over by Mrs. Chas. Marx, O.B.E.

Rand Company Meetings.

New Modder's Wonderful Year.

Sir Evelyn Wallers on the Modder East.

How the Premium Affects the Nourse and Cons. Main Reef.

Annual meetings of four important mines of the Central Mining-Rand Mines group were held during the past few days, and full reports of the speeches from the chair at each meeting will be found elsewhere in this issue.

Three-quarters of a Million from the Premium.

The New Modder, which is, of course, the show mine of the group, has had another record year, the scale of operations and the working profit being the greatest ever attained by the company. The total profit reached the magnificent figure of £1,720,202, of which, however, £751,427 was obtained from the gold "premium." Development has yielded most satisfactory results during the year, the net outcome being that all ore mined was replaced, and indeed the ore reserves at 8,884,600 tons, of a value of 8.4 dwt., show a small increase in tonnage when compared with the previous year. During the past four months, *i.e.*, since the end of the financial year, working costs have shown an encouraging decrease, and development has been most satisfactory. A feature of the New Modder meeting is the picture of the development position which the chairman gives each year, and on this occasion Sir Evelyn Wallers showed that of the mine's 1,264 claims, 361 are worked out, 378 represent the intact developed area, and 525 claims still remain to be developed. In other words, about 28 per cent. of the property has been worked out and 72 per cent. remains, including the developed area. Well might the chairman conclude by expressing his satisfaction not only with the extraordinary soundness and strength of the position of the mine, but also with the excellent year's work of the general manager and staff of the mine.

Position at the C.M.R.

Mr. Max Honnet, who presided at the Consolidated Main Reef meeting, had a somewhat different tale to tell. But for the enhanced price of gold, operations for the year would have resulted in a heavy loss. As regards the future of the mine, Mr. Honnet reminded shareholders that for a long time past work had been concentrated on one limited area of the property. That area which was considered to possess the best prospects has fulfilled its promise and has produced a large tonnage during the last two years, upon which the position has been maintained. Unless other payable zones are encountered to the east or west, the ore reserve is bound to decrease in quantity, and the company may be obliged sooner or later to consider reducing its scale of operations. Exploratory work is being continued, and the chairman reminded shareholders that "in gold mining you never know what may turn up."—with which philosophic consolation shareholders in the "C.M.R." must be content to face the uncertain future.

The Outlook for Nourse Mines.

At the Nourse Mines annual meeting the chairman, Mr. E. G. Izod, dealt in detail with the more promising development figures and also made several pertinent remarks on the subject of working cost reduction. He described the mine as a 6½ dwt. proposition, which is not a low-grade one, and said, "It is beyond all reason to contemplate that our mine will work at a loss if gold falls below 96s. per fine ounce, which figure represents the average cost of production of a fine ounce of gold by the mine for the expired portion of the current financial year." Mr. Izod's very sincere warning in regard to the need for reducing the white wages bill is commended to the attention of every white workman on the Reef, and will doubtless weigh with the men's leaders in the present discussion between the latter and the Government and the mines.

Troubles of the Modder East.

At the Modder East meeting, Sir Evelyn Wallers, who presided, gave a very clear picture of the position and prospects of this property. He showed that it is really a very significant example of the absolute necessity for getting the working costs on these fields down to a figure which will represent safety to this community and to the country generally. The chairman's further remarks in elaboration of this theme should be carefully pondered by the public generally because they apply to every section of the community. Shareholders in the Modder East will note that the policy of the Board, although necessarily of rather a "waiting" character, is yet clearly enough defined as summed up in the concluding words of the chairman: "Under present working conditions we must continue to mine ore from our richer blocks somewhat out of proportion as compared with the remainder of our reserves, and we shall do so in the hope and the expectation of efficiency and working costs reaching the position to which I have referred. In that event the position of the company would be such that there is every probability of obtaining the financial facilities necessary to provide for our own equipment, but it would be idle to-day to discuss the nature of the detailed arrangement that may be involved. In the meantime, the policy pursued should enable us to earn profits that will be expended as heretofore in pushing our work of development—the essential feature at the moment." Plainly, the Modder East is most vitally concerned in the efforts now being made to reduce costs and increase efficiency on the Rand.

Concerning Mines and Men.

Mr. A. F. Williams, General Manager of De Beers, has been on a visit to the Rand in connection with the Advisory Board of Science and Industry, of which he is a member.

* * *

Mr. Hugh Marriott, consulting engineer to the Central Mining and Investment Corporation in London, will arrive on the Rand next week on a visit of some months.

* * *

Sir George Smith, J.P., of the well-known firm of Messrs. Bickford, Smith & Co., Ltd., fuse manufacturers, died in Truro, Cornwall, in mail week. Sir George's firm has been supplying fuse to the mining industry on the Witwatersrand for a great number of years. The deceased knight has not long survived his local representative, Mr. J. H. Houghton, who died in Cornwall towards the end of last year whilst on a visit to his native country, the first for nearly 50 years. Sir George was deputy chairman of Nobel Industries, Ltd., of which Bickford, Smith & Co., Ltd., the British South African Explosives, Ltd., and Kynoch, Ltd. (the two latter undertakings having factories in South Africa, at Modderfontein and Umbogintwini respectively), are constituent companies. With Lady Smith, Sir George visited South Africa some eight years ago and made a fairly lengthy stay in Johannesburg, where he met many of the heads of the industry.

GLYNN'S LYDENBURG, LIMITED.

The following are the particulars of the output for the month of October in respect of the above company, which kindly insert in the next issue of your paper:—Tons crushed, 4,003, yielding 1,593 fine ounces; estimated value of month's output, £8,069; estimated profit for month, £2,435.

Note.—The month's results are based on value of gold of 55 ls. 6d. net per fine ounce.

The Macduff Coal Company.

A SENSATIONAL PETITION—LIGHT ON COMPANY FLOTATION METHODS.

The case mentioned hereunder is sub judice, and we refrain therefore from commenting on it.

An *ex parte* application was made by James Howard Pim, sole liquidator of J. R. Macduff and Co., Ltd. (in liquidation) before Mr. Justice Ward, on November 3, in the Witwatersrand Court, to appoint a commission to examine under oath various persons alleged to have been connected with the Macduff Company.

The persons specifically mentioned were Jack Andrew Cohen, John Robertson Macduff, James Gunson Lawn, John Frederick Rutherford, James Huskisson Crosby, Herbert Williams, secretary of the company, and John Munro, joint managing director of the Johannesburg Consolidated Investment Company.

Mr. L. Greenberg, instructed by Messrs. Hayman and Godfrey, appeared for the petitioner, who set out that the Macduff Company was placed in final liquidation on June 30, 1921. This company, he said, was registered as a private company on March 30, 1920, with a nominal capital of £60,000, divided into 60,000 shares of £1 each, whereof 53,000 had been issued.

The first directors were Jack Andrew Cohen (chairman), who held 18,000 shares, Henry Adler, who held 18,000, and John Robertson Macduff, who held the remaining 17,000 shares, and 250 shares standing in Adler's name and 250 in Cohen's name also belonged to Macduff.

About October, 1920, it was alleged, Adler sold to the Johannesburg Consolidated Investment Company, Ltd., his entire shareholding, and on November 3 Adler transferred 7,750 shares to the Investment Company direct, and 5,000 shares to James Gunson Lawn, managing director of the Investment Company, and 5,000 shares to John Frederick Rutherford, an official of that company. It was clear, said the petitioner, that they were purely the nominees of the Investment Company, and Cohen was closely associated in business with the Investment Company.

Reconstruction Agreement.

The petitioner further stated that on November 25, 1920, an agreement was entered into in London between the Macduff Company and the Investment Company, whereby the latter undertook to reconstruct the Macduff Company and to form a new company with a capital of £1,000,000 in shares of £1 each, the new company to purchase the assets and undertaking, and to take over the liabilities of the Macduff Company as at October 1, 1920. The Macduff Company was to receive £50,000 in cash and 150,000 tully paid out shares; and the Investment Company was to apply for, or cause to be applied for by responsible subscribers, 550,000 shares in the new company, paying 4s. per share on application and the balance as required. And it was to receive in consideration of its obligation 300,000 fully paid shares in the new company.

James Huskisson Crosby, also an official of the Investment Company, petitioner went on, was appointed alternate director of the Macduff Company, on June 24, 1920, to Jack Andrew Cohen. Rutherford was appointed a director on April 21, 1920, and Lawn on November 1, 1920. Cohen resigned his directorship on April 22, 1921, and Macduff resigned on May 3, 1921.

Petitioner said he believed that all the shares held by Crosby, Lawn and Rutherford were the shares of the Investment Company, and that they were merely its nominees, and that the board of directors of the Macduff Company was entirely controlled by the Investment Company. In terms of the agreement with the Investment Company, meetings of the Macduff Company had to be convened for the purpose of passing special resolutions for the voluntary liquidation of the company and authorising the liquidator to enter into the reconstruction agreement. The calling of these meetings was from time to time postponed by the directors of the Macduff Company, the first postponement, at the latter end of March, being at the special request of the Investment Company.

The reconstruction agreement was in the highest degree favourable to the Macduff Company.

Matter of General Knowledge.

It was announced in the annual report of the Investment Company after its meeting on November 23, 1920, that they had acquired the business of the Macduff Company, which was being reconstructed with a capital of £1,000,000. This became a matter of general knowledge, and, in the opinion of the petitioner, induced the creditors of the Macduff Company to trade with it.

Petitioner alleged that on or about April 30, 1921, the Investment Company purchased from J. R. Macduff his shareholding in the Macduff Company, namely, 17,500 shares, for £23,000 cash, and a debt of £5,775 due by Macduff to the company on a promissory note was cancelled. About the end of April, 1921, the Investment Company purchased from Cohen his shareholding of 17,750 shares for £20,000 cash. The shares so purchased were transferred to the Investment Company, and its nominee, Crosby, who received 5,000 shares. In consequence all the 53,000 issued shares in the Macduff Company had been held by the Investment Company and its nominees from this date.

The petitioner said that he found from the books and records of the Company that at the time the shares were so purchased by the Investment Company from individual shareholders the Macduff Company could not meet its engagements, and was, in fact, insolvent, and the shares were valueless. Also that this position must have been apparent to the Macduff directors, who one and all were representatives of the Investment Company.

Agreement Had Lapsed.

On June 1, 1921, the Investment Company wrote to the Macduff Company stating that as the special resolutions had not been passed by the Macduff Company, the Investment Company considered the agreement for reconstruction to have lapsed, and added that as the Investment Company on June 1, 1921, held a majority of the shares in the Macduff Company, it was impossible for the Macduff Company to pass the special resolutions. The board of directors of the Macduff Company, which then consisted solely of nominees of the Investment Company, took no steps whatsoever on receipt of this letter, held no meeting until June 15, and then only resolved that this letter should be recorded. At this board meeting they also resolved that in view of the financial position of the company they would not oppose the Bellevue Colliery's petition for the liquidation of the company.

The petitioner submitted that from the foregoing it would appear that the Investment Company with its nominees, the directors of the Macduff Company, endeavoured to arrange for the lapsing of the reconstruction agreement to the prejudice of the Macduff Company and its creditors, and the petitioner believed that the persons mentioned were capable of giving information concerning the trade dealings, affairs or property of the company.

Company's Liabilities.

The statement of affairs of the Macduff Company as on June 16, 1921, the date of the wind-up order, showed a deficiency of £49,231 12s. 2d. of assets to meet liabilities, without bringing the Company's issued capital of £53,000 into account. This deficiency was certainly an understatement, as the assets had not realised the values placed upon them in the statement of affairs, and additional liabilities might result from claims against the company amounting to over £300,000 in connection with which arbitrations were now pending.

The petitioner prayed that an order might be granted in terms of section 151 of the Companies Act of 1909, summoning before the Court, or a commission, the persons specified:

and that J. G. Lawn, John Mumro, and J. H. Crosby be ordered to produce all minutes of the Investment Company relating to the Macduff Company and all correspondence between the Johannesburg and London offices of the Investment Company in connection with the Macduff Company between any of the directors of the Macduff Company or John Mumro and S. B. Joel or G. Inroth, two of the directors in London of the Investment Company; and the petitioner also asked for leave to employ attorneys for all necessary legal work in connection with these proceedings, and for any further legal proceedings and actions that the petitioner might find necessary to bring or defend in connection with the winding-up.

An order was granted, Advocate G. Hartog being appointed commissioner.

MacDuff:

Bleed, bleed, poor country!
Great tyranny, lay thou thy basis sure,
For goodness dare not check thee! Wear thou thy
wrongs,
The title is affeer'd! Fare thee well, lord;
I would not be the villain that thou think'st
For the whole space that's in the tyrant's grasp,
And the rich East to boot. . . .
Sinful MacDuff,
They were all struck for thee! Naught that I am,
Not for their own demerits, but for mine,
Fell slaughter on their souls.

—"Macbeth," Act IV., Scene 3.

Position at Zaaiplaats Mine.

Mr. W. J. Gau, Consulting Engineer to Zaaiplaats Tin Mining Co., in the course of his annual report, writes:— During the past year the results from the mining operations have on the whole been disappointing and no developments of any importance can be recorded. The most promising indications in the No. 13 section, when followed up, did not lead to the opening up of any further ore bodies nor could any definite indications be found as to the extension of the main ore body. A certain amount of good grade ore was obtained from the No. 6 crosscut pipe and the Government lease section, and it is these sections which, in my opinion, still hold out very considerable hope of opening up fresh ore bodies, and, when underground operations are again resumed, should be the first points of attack. The large tonnage of ground treated from the valley alluvium continued to give fair results, but the low price of tin and temporary difficulties of working, and disposal of tailings led to the suspension of operations towards the latter part of the financial year. The tin bearing alluvium in the valley still remains a valuable asset to the company. The severe drop, and the continued low price which has taken place in the price of tin rendered it impossible to carry on operations on any extensive scale at a profit, and it was necessary to introduce a severe scheme of retrenchment. By means, however, of the treatment of old accumulated ore dumps, reclamation ore from the upper sections of the workings, and ore from surface prospecting, it has so far been possible to derive sufficient revenue to preserve the assets of the company and to enable operations to be resumed at full capacity and a minimum cost, should the price of tin warrant it. On the whole the results of the exploration work on the various sections of the Stavoren Mine have given encouraging results. All work had unfortunately to be suspended under the curtailment scheme. The outlook of the property is promising and should become a profitable venture with an improved tin market.

BARNATO GROUP.

Operations for the month of October, 1921:—

Mine.	Tons Crushed.	Revenue from Gold
Consolidated Langlaagte	45,000	£68,099
Government G.M. Areas	140,000	309,087

Note.—The above results are arrived at by calculating the gold at £5 3s. per fine ounce.

FOR SALE.

TWO CAMPBELL TREBLE RAM PUMPS.

Rams 10 inches diameter, 15 inches stroke, each capable of delivering 25,000 gallons per hour when running at 35 revolutions per minute against a total head of 190 feet, including suction, delivery and calculated friction due to 1,320 yards of pipe 9 inches diameter.

TWO CAMPBELL OIL ENGINES

for above, complete with water tanks. Speed, 210 revolutions per minute, diameter and stroke of piston, 12 inches by 22 inches, specified to develop 42 B.H.P. maximum or 37 B.H.P. minimum at or about sea level on heavy fuel oil.

The whole of the above were manufactured by the Campbell Gas Engine Co., Halifax, England, and were inspected and passed by the Crown Agents for the Colonies previous to despatch.

The pumps and engines were never erected and are in perfect condition as delivered. Adequate spares included.

Full particulars and specifications may be obtained from the Director of Public Works, Zanzibar Government.

S. P. BLAND,
Ag. Director of Public Works, Zanzibar.

October Gold Output : Group Returns.

	Estimated Premium taking Gold at £5 3s. 6d. per fine oz. less exchange on remittances.	Total Estimated Profit.
Brakpan Mines	£19,110	£38,877
Springs Mines	15,106	30,550

Totals and averages £34,216 £69,427

Note.—Brakpan placed to gold reserve, 4,540 fine ounces; total reserve at date, 12,358 fine ounces.

WITWATERSRAND DEEP, LIMITED.

The estimate of results for the month of October, 1921, is as under:—Tons milled, 33,170; gold recovered, 9784.639 ounces; average of stamps running, 180; stamps running time, 20,756 days; tube mills, 5. The working expenditure, including head office charges for the month, is £42,496, or 25s. 7d. per ton. The estimated working revenue based on an estimate of £5 3s. per fine ounce (less 1s. 3d. realisation charges) is £49,779 or 30s. per ton. The estimated working profit is £7,283 or 4s. 5d. per ton, from which is to be deducted the capital expenditure for the month of £1,913, leaving a surplus of £5,370.

UNION CORPORATION GROUP.

Particulars of operations on the producing mines of this group for the month of October, 1921:—

Company.	Stamps.	Tons Crushed.	Fine Ozs.	Revenue (Including Sundry Rev.) Total	Profit Per ton
Geduld Prop.	100	46,500	17,282	£88,907	38/3
Modder Deep	70	43,300	24,119	123,456	57/0
Totals and averages	170	89,800	11,401	£212,363	47/4

Company.	Total.	Costs Per Ton.	Profit (Incl. Sundry Rev.) Total.	Profit Per ton
Geduld Prop.	£52,903	22/9	£36,004	15/6
Modder Deep	45,379	20/11	78,077	36/1
Totals and averages	£98,282	21/11	£114,081	25/5

The above results are arrived at by calculating the gold produced at £5 3s. per fine ounce. Realisation charges in excess of normal are debited direct to revenue.

GENERAL MINING & FINANCE GROUP.

The October operations of the producing mines of this group were as follow:—

Company.	Tons Crushed.	Total Cost.	Cost per Ton.	Total Revenue.	Profit.
Aurora West... ..	10,130	£13,151	25.96	£13,954	£803
Meyer & Charl. ...	14,500	18,109	24.98	43,390	25,281
New Goch... ..	17,200	18,778	21.83	19,664	886
Rood. United... ..	20,500	22,648	22.10	20,930	*1,718
Van Ryn Est.	33,800	41,776	25.09	48,407	6,631
W. Rand Cons. ...	34,100	42,571	24.97	47,291	4,720

129,730 £157,033 24.21 £193,636 £38,321 +1,718

*Loss. †Less loss.

In calculating the revenue, gold has been taken at a value of £5 3s. per fine ounce, less estimated realisation charges.

Rodepoort United.—The negotiations for working this mine on a co-operative basis having failed, a gradual suspension of operations has been decided upon. All development has been stopped, but production on a limited scale will probably continue for a further short period before the mine finally closes down.

CONSOLIDATED GOLD FIELDS.

The following are particulars in regard to the outputs for the month of October, 1921, of the undermentioned companies of the Consolidated Gold Fields Group:—

Company.	Stamps Running.	Tube Mills.	Tons Crushed.	* Gold declared. Fine ozs.	Profit.
Simmer and Jack... ..	320	7	60,000	13,941	£9,000
Robinson Deep... ..	145	9	61,300	19,167	20,087
Sub Nigel	30	2	10,200	5,810	7,288

Totals 495 18 131,500 38,918 £36,375

Total gold in reserve (fine ounces): Simmer and Jack, 1,200; Robinson Deep, 1,495; Sub Nigel, 2,380.

The revenue derived from gold for the month of October is calculated at the rate of £5 3s. per fine ounce, less estimated gold realisation and exchange charges of 1s. 6d., or a nett figure of £5 1s. 6d. per fine ounce.

Glynn's Lydenburg.

NEW WORKING POLICY.

PREMIUM SAVES THE SITUATION.

The report to be laid before the shareholders of Glynn's Lydenburg at the annual meeting on December 22 will contain details of the company's new working policy. The programme of new development and prospecting which has been sanctioned by the directors will call for the expenditure of considerable sums of money. Progress will depend upon the labour available and other circumstances, but as far as possible work will be energetically pushed ahead. The resultant call upon the company's finances will be heavy, and, although the cash position is quite satisfactory, the profits earned from the mine will have to be largely, if not entirely, devoted to new exploration for some time to come. Under these circumstances the payment of dividends cannot be continued on the basis of monthly profits earned as hitherto. The directors are satisfied that provision for the future life of the company is now the first call upon its resources, and that the best interests of shareholders will be served thereby. It will be the policy of your directors for the future to conserve funds as much as possible, devoting them in the first place to the accomplishment of the new shaft sinking and development programme, and passing or curtailing dividends to such extent as may be necessary until such time as security for the future is reasonably assured.

Mr. R. A. Barry was appointed consulting engineer in April last, and, on his advice, the directors have authorised an extensive programme of development and exploratory work in areas not previously opened up. The main drive south in the Werf Mynpacht and its extension has continued to expose payable ground over too long a distance to be worked solely from the existing approach. A vertical shaft is therefore to be sunk some 1,600 feet ahead of the face to a depth of approximately 350 feet, and development will then be undertaken of the area south and south-west of the present mine, linking up eventually with the present workings. The authorised programme also provides for the further exploration of the southern section of Compound Hill and South Hill. The work has been started, and will be carried on as energetically as circumstances permit. Towards the end of the financial year a re-arrangement of reduction methods was introduced, which is giving satisfactory results, at the same time effecting certain economies in working.

The net profit for the year amounted to £22,191 0s. 7d., to which must be added the sum of £28,835 19s. 6d., brought forward from the previous year (less the sum of £9 10s. paid in respect of dividends previously cancelled), and £19 10s. 1d. Unclaimed dividends written back in terms of Article 127, making a total of £51,037 0s. 2d.

During the year the Transvaal Chamber of Mines decided to erect and operate a refinery on the Witwatersrand to refine the products of the gold mining industry of the Transvaal. The directors have entered into an arrangement with the Rand Refineries, Limited, for the refining of the company's gold. Legislation has been foreshadowed affecting the surface rights of ground held under mining title, and also the control and supply of electricity throughout the Union. The directors caused certain representations to be made to the Union Government on these matters. During the year a Departmental Committee was appointed by the Minister of Mines to investigate the control of that committee was highly favourable to this company and its officials. During December, 1920, there was an outbreak of smallpox at Sabie, seven cases being notified. The outbreak was fortunately controlled and no serious results arose therefrom. The company has resigned from membership of the Transvaal Chamber of

Mines, and it has also introduced sundry economies in administration, including the discontinuance of the services of Paris correspondents. Working costs have remained at a high level during the past year, but there is now some slight relief through a decrease in the price of stores. Under the head of White Labour also a reduction in the cost of living allowances, which have been paid since the 1st November, 1919, has been arranged, and will take effect as from the 1st October, 1921.

In the course of his annual report, the Consulting Engineer, Mr. R. A. Barry, writes:—During the year now under review the enhanced price of gold has once more saved the situation. The working profit was £15,504, but had gold realised only standard value this profit would have been converted into a working loss of £6,319. The following figures show concisely the results, comparatively with the previous year:—

	Year ended 31/7/20.	Year ended 31/7/21.
Total tons milled	39,554	40,140
Yield per ton—dwt.	7.752	7.625
Yield per ton—value	40/3	43/0
Working costs—per ton	33/1	35/3
Profit per ton	7/2	7/9
Profit	£14,201	£15,504
Sundry revenue	£4,795	£6,687
Ore reserves—tons	134,870	125,868
Average value—ore reserves		
—dwt.	8.3	7.7

From these figures it will be seen that the general position is less satisfactory. Working costs remain high, whilst the average gold contents of the ore reserves are lower, showing a further decline on last year's estimates. With increasingly difficult mining problems to face, working costs must tend to increase, added to which the high price of stores and white labour militates seriously against any reduction in expenditure. There is now some sign of improvement in these latter two factors, but with regard to mining difficulties the tendency is in the opposite direction. Future results obviously depend closely upon the price of gold, every fluctuation of which will have its immediate effect upon profits. Any appreciable fall, if unaccompanied by a corresponding reduction of working costs, would wipe out the present somewhat narrow margin of profits from the mine. The remaining factor, grade of ore, does not at present give much encouragement, but your property is an extensive one, and not without indications of values at various points, still unexplored. An active policy of development has now been undertaken with a view to opening up and testing the large extent of ground not previously explored. This will include the sinking of a vertical shaft in the southern extension of the Werf Mynpacht, which area appears to offer good prospects of opening up a new mine. Simultaneously the southern portion of the Compound Hill—South Hill area will also be attacked. By this means reliable data will be secured of the value of the company's hitherto untouched ground on which its future so largely depends. The energetic fulfilment of this programme constitutes a first call on the available labour and resources of the company.

TO MINING OR LAND COMPANIES.

Position wanted as Manager of Planting Company, large Farm or Estate. Fifteen years' experience in various parts of the world. Sound technical and scientific training. Knowledge of surveying. Two years late war as Captain in Royal Engineers. Highest diplomas and credentials. Can commence duties immediately. Apply—

The Week in the Sharemarket.

LABOUR QUESTIONS OVERSHADOW EVERYTHING—A PERIOD OF READJUSTMENT—DIAMONDS, BASE METALS AND OILS STAGNANT.

The market has been quiet and almost inactive during the week, labour questions overshadowing everything. Other factors, of course, have to be considered, such as the wild and disquieting depreciation in the German mark, the Irish trouble, and the drop in the "premium." But the strike at the Crown Mines and the talk of strikes if the Government insists on amending the mining regulations, have created a mere nervous feeling, which has extended to the market for Rand shares in London. It is all to the good that the Government has at last begun to show signs that it appreciates the desperate position of the low-grade mines, and whatever may be the result of the conferences of this and last week, the ultimate effect must be beneficial to the industry. It is a time for plain speaking, and all concerned must be made to realise the simple facts of the position. While things thus remain in the melting pot, we can hardly expect any share market activity, and the only signs of life on Thursday were afforded by Bantjes and Knight Centrals, that animation, paradoxically enough, being said to be due to the prospects of their imminent dissolution! In diamonds nothing was done, the hopes of an improvement in that section being seemingly as far off as ever. After all, diamonds constitute what is known as a "fancy market," and a revival may come upon us just when least expected. The prophets who predicted, a little while ago, a good diamond market at Christmas, are now pinning their hopes on a revival in March, and the fact is, no one really knows. Base metal and colliery shares, for obvious reasons, remain in the doldrums, and even oil shares are affected by the prevailing conditions. The week's drooping quotations are shown hereunder:—

The Modder East Meeting.

At the Modder East meeting there was considerable discussion after the Chairman had made his speech, and Sir Evelyn Wallers, who presided, had numerous questions to answer. The remarks and queries of Mr. Lewin, Mr. Benjamin and others were not recorded in the daily Press, nor have they been handed to us with the chairman's speech. We have, however, through the courtesy of the Modder East Company, been allowed to see a verbatim report of the proceedings, and we understand that a condensation of the criticisms and questions of shareholders will, as usual, be attached to the official account of the meeting when that document is printed and circulated to shareholders.

* * *

The Water Board Contract.

We understand that the big Water Board contract for steel pipes for the first portion of the ten million gallon scheme was obtained by the National Trading Co. of Cullinan Buildings, the agents for the Mannesmann Tube Co. of Dusseldorf. The value of the order is slightly under £300,000. The National Trading Co. secured the contract in conjunction with Mr. Robert Todd, the local representative of the Mannesmann Co., who has for many years represented the Dusseldorf firm in this country. It may be mentioned that the Mannesmann Co. is one of the largest manufacturers of steel piping in the world, and is also extensively engaged in making tramway, lighting and telegraph poles. The Mannesmann Co. has four great works in Germany and has also a large factory in Austria. Before the War it had a world-wide export connection, and it is now making a big effort to regain something of its former overseas trade in this country. The National Trading Co. is now engaged in perfecting its organisation for the sale of Mannesmann products all over the sub-Continent. British and American tube manufacturers will doubtless learn with interest of this revival of activity on the part of their former German rival, and it is unnecessary for us to point the moral as far as the British working man is concerned!

Dixon's Waterproof Grease

WIRE CABLES are too expensive to be treated carelessly. The outside of the cable needs to be well lubricated, and so does the inside to prevent chafing of the individual strands. Many cables fail because the strands in the centre break, although to all appearances the rope is in good condition.

DIXON'S WATERPROOF GRAPHITE GREASE has no equal as a rope lubricant. It is heavy bodied (dense) and adhesive, possessing great lubricating value and endurance. Yet it penetrates to the innermost strands, keeps them well lubricated, and thus minimizes internal friction. Even the acid or alkaline waters of mines have no effect on this remarkable grease.

Equally good for Heavy Gears, Conveyor Idlers, Pump Plungers, Elevator Plungers, Piston Rods, etc.

EDITORIAL.

LABOUR AND THE COAL TRADE.

The colliery section of the Transvaal Chamber of Mines has delivered a very straight talk to the Industrial Federation, and through it to the white employees, on the subject of reduced wages. The proposal to reduce wages by the collieries was made, it will be remembered, some time ago, and a round-table conference was held between representatives of both sides. On October 22 a lengthy written statement was sent to the Chamber by the Federation on behalf of the men, setting out reasons why the latter regarded the case for a reduction of wages as not proven. This has evoked from the Chamber the straight talk already mentioned, which most effectively demolishes the arguments brought forward by the men. The Chamber lays stress on the fact that an all-round reduction will have to be made if the coal trade is to be held, and that the governing factor

in the end will be pence per ton. The collieries are faced with two alternatives. One is that if they continue working at the present narrow margin they must limit their output to the requirements of the "best-pay" trade; and as tonnage is an important factor in the cost of production, such limitation must bring about an increase in the cost per ton, which in turn would handicap all other industries which use coal, and tend to create further unemployment. The other alternative is to bring about a decrease in cost of production, and to hold and even to increase the present trade, thus maintaining and possibly increasing the field of employment on the coal mines, railways and harbours and in industries which use coal. This can only be done by fostering the overseas trade, and to do this prices must be cut to meet the world competition. The Chamber shows how trade once lost is difficult to recover, and that the cost of oil fuel has been so reduced as to render it a formidable competitor. The second alternative is that which the collieries propose to pursue, and they are not prepared to sit still and see the coal trade they have built up drift to other countries. As it is, the Chamber points out, the position in regard to the overseas trade is most serious and is rapidly becoming worse. Between October 1 and October 24 the 15 colliery companies associated with the Chamber lost in the aggregate no less than 84 working days, owing to the absence of orders for coal as distinct from stoppages due to the shortage of trucks, which were experienced when orders were plentiful. As white employees are being paid full time in respect of the stoppage referred to, the falling off in trade is becoming a very serious matter to some collieries, which, unless an improvement can be effected, will shortly be compelled to operate on a small scale with a decreased personnel, or possibly to close down. In conclusion, it is bluntly stated that the Federation's reply is disappointing to the Chamber in that, although the economic position of the coal trade was disclosed orally and by letter, it appears to have been completely ignored. "To say that a case for a reduction in wages on the collieries is 'not proven' is to ignore the position of the trade throughout the world and all the independent authoritative information available on the subject." Finally, the Chamber reminds the Federation that it originally suggested in its letter of September 27 that the urgency of the position required that the reductions should operate as from November 1, 1921; and now asks that the Federation will take such steps as are necessary to put the whole position as disclosed in this and previous correspondence clearly before the men without further delay.

THE PREMIER'S APPEAL.

In the opening article of this issue we comment at considerable length on the paramount importance of reducing working costs on the mines of the Witwatersrand and on the meeting between General Smuts and representatives of the Mine Workers' Union last week-end. The two subjects are closely interwoven and may well be considered under the same heading. The Prime Minister's mission was to represent to the miners' deputation the extreme urgency of doing something to relieve the present distressing economic situation prevailing on the Rand, and particularly to advise the amendment of the existing mining regulations with a view to securing more work from the native employees. There was no suggestion whatsoever to interfere with the working hours of the European miners or to in any way interfere with the arrangement recently arrived at between the Chamber of Mines and workers. Mr. Hendrikz, the spokesman of the Miners' Union, however, seems immediately to have jumped to the conclusion that General Smuts was merely paving the way towards the breaking down of the colour bar. It is, of course, a belief generally held throughout the length and breadth of this country that most people are more or less enmeshed in the subtle nets of the financial intelligentsia of the Big Houses. But surely it was little short of a gratuitous insult to the Premier to threaten his suggested small measure of relief for the struggling mines

with a strike and openly accused the General of complicity with the Chamber of Mines after his painstaking and lucid explanation of the case and of the partial remedy, which has incidentally been approved of by those Labour stalwarts, Messrs. Forrester Brown and Pohl. General Smuts put his position quite plainly to Mr. Hendrikz. He is reported to have said:—

"You seem to think that I am holding a brief and representing the Chamber of Mines. I have nothing to do with that. I have been dealing with our officials, and the State Mining Engineer and the inspectors of mines, with the Mining Department, to see from the Government's point of view what could be done. What the Chamber of Mines claims is something quite different. They want the removal of the colour bar and the importation of more natives, and I say that those two things we cannot do. But I am prepared to do something else, and that is what not only the majority, but also the minority of the Low Grade Mines Commission reported. What I am doing to-day is reported by the men whose names I have read to you—the representatives of the workers themselves, and, after all, I am entitled to be guided by men like Mr. Forrester Brown and Mr. Pohl, if they say that that is the solution."

Mr. Hendrikz: "Unfortunately, we do not agree with those two men, and have never agreed with them from the time they reported."

The Prime Minister: "I know, but do you blame me? They have agreed on the system, and I say let us try it."

Mr. Hendrikz: "No, the Government is trying to get in a roundabout way what the Chamber of Mines wants."

Nothing, however, resulted from this meeting, but Mr. Hendrikz graciously assented to a round-table conference to debate the question. The matter is one of such extreme urgency and importance that the Government has lost no time in pushing on with it. Mr. Hendrikz, on Tuesday, received a letter from the Secretary of Mines and Industries, informing him that the Prime Minister had arranged for the requested conference to take place on Thursday November 10, at 2.15 p.m., at the New Law Courts, Johannesburg. At this conference representatives of the Chamber of Mines have been present to meet representatives of the South African Mine Workers' Union. The Prime Minister expressed a desire that the outlines of any proposals which the Mine Workers' Union intended to bring forward at the conference with a view to increasing underground efficiency on the mines should, if possible, be communicated to him before the conference. As any decisions arrived at at the conference may have an important bearing on the position of members of other unions affiliated to the South African Industrial Federation, and as the Federation were asked to discuss the questions raised with the Government, the Federation were invited to send representatives, and agreed to do so.

And there the matter rests for the present. We can only hope that some tangible good will come of a further discussion, but the autocratic attitude of "my dear Hendrikz" and his extremist associates, as exhibited at last week's meeting coupled with the absurd strike at the Crown Mines, hardly appears to create a favourable atmosphere in which to debate the question. It should be clear that the vital importance of the issues of this conference cannot be exaggerated, and it is hoped some channel of agreement may be found to get over the difficulty.

Notes & News.

Union Currency.

We understand that there is no truth in the report circulated from Pretoria last week that the Government contemplated introducing another Currency Bill during the next session of Parliament. The recent conference at Pretoria broke up without coming to any decision in the matter.

Bethlehem Oil.

The Bethlehem Oil Syndicate has appointed Mr. A. B. C. Cohen to superintend drilling operations on its property, which, it may be remembered, is on the borders of Basutoland.

* * *

Angola Oil.

Angola Oilfields, Ltd., is the name of a new company registered in London with a nominal capital of £1,000,000 in £1 shares. The objects are to adopt an agreement with Trade and General Trust, Ltd., to acquire and turn to account petroleum, asphalt, naphthaline, coal or oil-bearing lands in any part of the world, and to carry on the business of miners, prospectors, explorers, refiners of and dealers in petroleum and other mineral oils and the products thereof, carriers, wharfingers, shipowners, etc. The number of directors is to be not less than three nor more than seven. The registered office is at Capel House, 52, New Broad St., E.C.

* * *

The Gold Question.

From the Australian papers to hand by last mail we learn that a cablegram from Johannesburg, which was published in the Australian morning press of August 27, stated that it was rumoured on the Stock Exchange here that arrangements were being made for the sale forward of the gold produced in South Africa for two years, thereby saving the industry from the calamities which would attend a heavy drop in the gold premium, and enabling the low-grade mines to continue operations. As this was a matter of particular interest to the Australian gold producers, a cablegram was sent to the Transvaal Chamber of Mines, Johannesburg, asking for confirmation and particulars, and a reply was received from them, stating that they had no knowledge of any such arrangement.

* * *

Cam and Motor Rich Assays.

At the end of August the Cam and Motor Gold Mining Company, of Rhodesia, announced rich developments at its bottom level. A further statement announces, it will be seen, further rich assays at the same (the eleventh) level: "No. 11 level—South drive advanced 50 ft. to 550 ft.; average 434s. over 53 ins., reduced to 68s. Last 135 ft., average £10 10s. over 55 ins. reduced to 50s.; lode not fully exposed. Crosscut at 540 ft., average £30 2s. over 164 in. reduced to 68s. Other development satisfactory." The working results for September were as follows: Tons treated 13,900, yielding 4,771 oz. fine gold; value, £20,233; from premium, £5,500; less royalties, £1,286; sundry revenue, £54; making a total of £24,501. Costs, £19,241 (including development redemption £2,085). Profit, £5,260 (August, £4,057). Capital expenditure, £3,519 (including development, £560).

* * *

A World's Monetary Conference.

Writing in the *Quarterly Report* issued by the Swedish Kreditaktiebolaget, Professor Gustav Cassel suggests a world monetary conference "to settle the general monetary policy to be pursued, and the practical steps to be taken in order to stabilise as soon as possible the internal purchasing power of currencies, as well as of the value of gold." This conference, he thinks, might be invited by the British Government, and that of the U.S.A. would, of course, also be represented; but otherwise it should consist of leading experts and experienced financiers without reference to nationality. The chaos in monetary conditions, the Professor adds, is due not merely to the old fine machinery of international payments having been shattered or greatly impaired, but to its having been looked to for miracles of payment far beyond even its pre-War capacity. He believes, too, that the establishment of equilibrium in the balance of credit of the United States is still an unsolved problem. In any world policy the first practical step can only be to arrest further issues of paper.

The Blackhill Strike Settled.

The dispute at the Clydesdale Colliery, Blackhill, where the men ceased work because of considerations arising out of the retrenchment of two senior men, has been called off. It has been agreed that a Board of Reference shall be held at the Chamber of Mines this morning to consider the matter.

* * *

The Crown Mines Strike.

No further development up to Thursday evening had occurred in the dispute at No. 5 shaft of the Crown Mines, where 400 men are on strike. The Chamber of Mines shows no intention of departing from its attitude that it would be subversive of discipline on the mines, and prejudicial to efficiency, if the wages and conditions of employment of officials were to be determined by the Chamber with unions whose members are subordinate to the officials. Meanwhile, the Mine Workers' Union is notifying members to keep away from the shaft until further notice, and shaft stewards are warned that they are to take no instructions from anyone unless signed by Messrs. Andrews and Richardson, chairman and vice-chairman of the Strike Committee.

* * *

The October Output.

Owing to October's five Sundays, the mine working days were the same number as in the shorter calendar month of September. A gratifying increase of nearly 17,000 fine ounces has to be recorded, but the value has decreased by no less than £155,729. This has been brought about by a fall of 7s. per ounce in the gold premium, which for October has been taken at £5 3s., against £5 10s. in September. The increased output is likely to be attributable to the improved native labour returns, which are in the neighbourhood of 3,000 more than in September. The following are the detailed figures:—

Total output	707,825	ozs.
Increase	16,729	ozs.
October value	£3,645,299	
September value	£3,801,028	
Witwatersrand	690,348	ozs.
Increase	16,191	ozs.
Outside districts	17,477	ozs.
Increase	538	ozs.

The Outlook for Copper.

Since cotton, through its dramatic turn three weeks ago, served to enliven the whole financial movement in the United States, there is naturally curiosity (says *The Toronto Globe*) as to what commodity may be the centre of the next turn. Arguments are being presented that it may be copper's opportunity. It is reported that 40,000,000 lbs. of copper were marketed in August, and the forecast has been made that the sale in September will prove to be 60,000,000 lbs. That would remove 100,000,000 lbs. in two months from the great accumulation of copper burdening the inventories of the producers. The market for copper is greatly dependent on restoration of normal conditions, including requirements for building and for industries allied with electricity. Japan, Germany and three or four other nations have been heavy buyers of copper in the past, but they have not helped recently in any large way to reduce the stock of accumulated copper in the United States, estimated at 400,000,000 lbs. "It is evident, however," says our Canadian contemporary, "that it would not take many months on the recent scale of buying to restore confidence in the industry and reduce supplies to such an extent that the refineries, which have been closed down for months past, would find it necessary to reopen. It may be that some time in the fall the copper situation will be as suddenly reversed from stagnation to activity as has been the case with cotton," says a writer in *The Wall Street Journal*. "Of course, the cotton market throughout the world is of larger proportions than the copper market. Nevertheless, American copper is one of the chief raw materials upon which other nations must rely in order to quicken their industries, facilitate the reconstruction of telephones and the rebuilding of electric railroads."

Gold Fields Rhodesian Dividend.

Considering that it was an unpropitious period for the operations of mining finance concerns, the Gold Fields Rhodesian Development Company proves to have done not badly during the year ended 31st May last. From the brief preliminary figures issued with the announcement of a final dividend of 6d. per share—making a total of 1s. for 1920-21, the same as for the preceding year—it would appear that the Company netted a profit of £112,800, against £127,800 for 1919-20. The total dividend will absorb about £13,000 more than was earned in the past financial year, but even so the carry-forward will amount to the very respectable sum of over £99,000.

* * *

V.F.P. and the Low-grade Mines.

Presiding at the annual general meeting of the V.F.P. Co., Ltd., in mail week, the Marquess of Winchester said that the year's revenue amounted to £808,419, as compared with £829,470 in the preceding year. The net result for the year, after making provision for all taxation, was a profit of £173,161. Adding this to the amount brought forward from the previous year made the total balance to the credit of the profit and loss account £267,482. In respect of this balance the preference shareholders had received three dividends, two each of 3 per cent. and one of 4 per cent., all less income-tax, and the ordinary shareholders had received a dividend of 5 per cent. less income-tax in respect of the year 1920. Those dividends were paid on July 8, 1920, January 8, 1921, and June 16, 1921, and absorbed £175,000, leaving a balance remaining to the credit of the profit and loss account of £92,482, which had been carried forward to the current year. At previous meetings he had referred to the position of the low-grade mines, who took their share of the power supply, and he had emphasised the importance to the power company of the continuance of mining operations by those consumers. It was a matter of satisfaction that, for the most part, those mines were still at work, and where mines had closed they had found an increase in demand by other consumers who had been able to absorb the displaced native labour.

F.B.J. and the Grain Elevator Contracts.

Protests have recently appeared in our pages regarding the placing of the contract for grain elevators with an American firm, and we note that Mr. G. H. Loeck, Assistant Director of the Federation of British Industries, has addressed, under date October 15, the following communication to the Secretary, Railways and Harbours Board, Pretoria:—"The Federation of British Industries has been watching with considerable interest the plans of the South African Government for the erection of grain elevators both at ports in the Union and also up-country. When the South African Government raised a loan in this country some weeks ago to the amount of £6,000,000, the Federation noticed that the prospectus announced that the money was being raised for "railways, harbours, irrigation, land settlement and other public works." It was confidently expected, and we think quite rightly, by manufacturers in this country that a large proportion of the necessary work entailed by the various Government schemes above referred to would be placed in this country. Almost subsequent to the successful floating of the loan it was persistently rumoured that your Government had already given a large contract involving an expenditure of over £1,000,000 to an American firm. If this contract has actually been placed, nothing more can be said upon this point, but the Federation regards it as particularly unfortunate that there are further and widespread rumours to the effect that your Government inclines towards giving the work on the up-country elevators to other firms in the United States. Writing on behalf of British manufacturers as a whole, the Federation would like to state that, while the Federation does not ask for the placing of contracts in this country on sentimental grounds, it does feel that at the present time, when money is scarce and unemployment is rife, Dominions borrowing capital in Great Britain should give priority to British tenders, always provided that those tenders are competitive as regards price, and bearing in mind the high quality of British material."

The annual meeting of De Beers will be held on Friday, December 9, at Kimberley.

METAL REPORT.

Messrs. Henry Bath and Son, Ltd., metal report, October 17th, 1921, to hand by this mail, states:—

The gradual but steady decrease in the cost of living bringing lower wages in its train is now clearly affecting the majority of industries in this country, where slightly lower working costs continue to be shown month by month. More manufacturers are re-opening their works, and although great hardship is still being experienced in many quarters, the outlook is improving.

Copper.

Rather more activity has been shown during the past fortnight. In the first few days, under the influence of stronger advice from America and considerable sales reported there, good buying of standard copper took place in our

The Pilgrims Rest Goldfields.

SMALL MINES AND DIGGERS CONTRIBUTE ONE-THIRD OF OUTPUT—ANNUAL PRODUCTION WORTH OVER HALF A MILLION.

In the course of a paper submitted to the Chemical and Metallurgical Society, Mr. H. C. F. Bell (of the Pilgrims Rest Consolidated Goldfields, Ltd) said:—A great deal has been written lately about the decline of the Rand, and the question of finding new goldfields. It, therefore, seems opportune to give some notes on one of the oldest goldfields in South Africa, namely, the Pilgrims Rest district. The magnitude of the Rand is so great that very little thought is given to outside mining ventures by either mining men or investors. The Pilgrims Rest official mining district is approximately 110 miles wide by 140 miles long. It includes 93 proclaimed farms, 127 farms available for prospecting, and nine concession farms. In the year 1920 the district produced 106,823 fine ounces of gold, which, if valued at 105s. per ounce, would be worth £560,820 15s. This represents an average production of £46,735 worth of gold per month, and of this amount approximately one-third is produced by small mines and diggers. The two largest mining companies at present working are the Transvaal Gold Mining Estates, Ltd., and the Glynn's Lydenburg, Ltd.

There seems to be a prevalent idea amongst some people that the T.G.M.E. hold most of the district and all the plums. This is not so, though it is admitted that some of its properties are the best in the district. There is still room for, and there will certainly be many more, good mines. An old official of the T.G.M.E. recently told the writer of a story of an incident which happened 25 years ago. He had not been out very long from the Old Country when he decided to get his wife out, and when he told the general manager of his intention, the reply came, "Don't be a fool; the mine will be worked out in twelve months' time." The mine is, however, still going strong.

Similar incidents are still happening in the district, and will probably go on happening for another fifty years. Until the world's trade is adjusted to a stable and balanced state the price of gold is likely to remain at a premium. Gold mining will, therefore, be a profitable industry for a long time to come. The present world output is far below the pre-war output. A large number of mining men are being turned out of the Rand mines by the Phthisis Board, and many others are leaving before they lose their good health. Some of these have saved money, and want to acquire small mines either on tribute, or as their own concerns. If such people think of trying their luck in the Pilgrims district they would do well to seek advice and help from someone who knows it, or the people of the district itself. It is not an easy matter for a stranger to come into the district for a few days, or even weeks, and expect to get hold of a small property.

Revision of the Gold Law.

Apart from the possibilities open to smaller men, sufficient mineralised areas are available, and warrant the most thorough and systematic prospecting by strong exploration

companies. The T.G.M.E. have spent a great deal of money on prospecting, but the work has all been on their own farms. One thing which is essential is a revision of the gold law. A great deal has been written on this subject lately, and it is certain that, if many of the recent suggestions be put into force by Parliament, prospecting and mining will be greatly stimulated all over the Union.

The Pilgrims Rest district contains no less than 19 different reefs, which have been, or are, worked, also very many "leaders." The reefs here are totally unlike the "basket" of the Rand. They are true quartz reefs, and lie conformably with the strata dipping at about four degrees west. In thickness they average approximately 12 ins., but various thicknesses are obtained from two inches to 10 feet. The texture is of disintegrated nature, the predominant constituent being quartz. The colour is usually reddish brown, owing to the presence of oxide of iron. The oxide of iron is the residue from the decomposition of iron pyrites, which, at one time, existed in the reef. The presence of "reef gold" (as distinct from "leader gold") is directly associated with the presence of decomposed or undecomposed iron pyrites. The reef is usually friable and easy to pick. When blasting is necessary the holes are set so that the concussion of the charge will loosen the reef and not blast out a bench, as is the case on the Rand. The only exception is on the sandstone reef mines near Sabie, where the reef is unoxidised. Most of the ore is got from the stope faces by picking. Four lb. picks are used. Each pick-boy has two pick-heads and one handle. While he uses one pick the other is taken away by a piccanin. Each stope has what is called a jumper piccanin. He is a small boy, whose rate of pay is usually from 7s. 6d. to 17s. 6d. per month, and his work is to keep the stoping boys supplied with sharp drills and picks. Reef and waste are picked alternately. After the reef is picked down and shovelled away, the footwall is usually brushed up by each pick boy so that the "fines" of the reef will not be lost with the waste. The waste is then picked down and packed behind the stoping boys. Each stope has a timber boy who puts in props to support the hanging. Each prop has a good head board. When the reef lies in soft decomposed ground a stope width, sufficiently big for a boy to sit up in, is carried, but when the country rock is hard then the stopes are kept as narrow as possible so as to avoid blasting. Many stopes are to be found which have stoping widths varying from 12 to 18 inches, and this on a reef dipping at only four degrees. Such a thing on the Rand is unthinkable. In these narrow stopes picking is substituted by chiselling. The reef is chiselled out until near the end of the shift, when each boy drills several short holes. These are blasted at the end of the shift to loosen the reef for the following day.

The Glynn's Reef at Sabie is particularly adapted for clean mining. The reef can be picked out and sent to the mill with the inclusion of only two or three inches of waste. The country rock is usually fairly hard. In some places there lies over the reef a slate from 6 in. to 12 in. thick, which can be barred down and used for waste packing. This has the double advantage of saving timber and of giving a comfortable stope-width. It is evident, therefore, that under such conditions a 12 in. reef, valued at only 10 dwt., can be made to pay. In some mines where the ground is fairly soft, a 5 in. reef, valued at 11 dwt., can be made to pay. This fact must not be lost sight of by people interested, or who have the opportunity of being interested in local mines or enterprises.

Alluvial Deposits.

Having dealt in detail with the various reefs of the district, Mr. Bell said: Apart from the alluvial deposits mentioned under the heading "Black Reef Series," there is still some gold in the famous Pilgrims Creek, but the best of it

has been taken out, and that which remains lies under thick overburden. It will probably be worked on a large scale at some distant future date by the owners, the T.G.M.E. There must be a great deal of rich alluvial wash in the leader area stretching from the farm Lisbon to Marieps Kop, but unfortunately a great deal of St has been covered with very thick surface soil. A considerable amount of alluvial gold has been won on the north and south sides of Spitzkop mountain, also at Hendriksdal and Ross Hill. These places are not totally worked out, but the remaining ground is difficult to handle. Large quantities of alluvial gold have been won from the farms Nooitgedacht, Finsbury and Natalshoop. At the time of writing this, there is news of a rich strike of alluvial gold not far from Lydenburg. Though there is very little alluvial digging going on now, the news of "rich strikes" is periodically heard.

The production of iron pyrites has become an established industry in the district. The main producers are the mines on the sandstone reef at Sabie, next to these are the Rietfontein and the Dientje gold mines. The New Lisbon Berlyn Co.'s mine at Frankfort contains an enormous quantity of sulphide ore, but unfortunately this ore and that at Dientje are too refractory for the ordinary treatment of iron pyrites now in vogue at the various explosive and chemical works. There are several other places in the district where sulphide ores exist, notably at the North Clewer Mine of the Pilgrims Rest Consolidated Goldfields, Ltd. There is a considerable tonnage of pyritic ore in this mine already developed and carrying a high percentage of sulphur and excellent gold values. Recent practical tests made on the ore were very satisfactory. Unfortunately, all the local pyritic ores cannot be disposed of on account of the fact that many of the companies who are producing explosives and sulphuric acid, are importing most of their requirements from Spain; consequently the demand for local concentrates is decreasing. Only a few weeks ago, Kynochs, Ltd., closed down a part of the roasting plant which was used to treat the local pyrites, and converted it to treat Spanish ore. It is hoped that the Government will investigate this question thoroughly and help to build up our local industry, as it would be a calamity if local mining propositions which have been equipped and started working have to be closed down because they cannot compete with the Spanish ore. The loss to this country is greater than at first appears, for most of the local pyritic ores contain high gold values, whereas the imported ores contain no gold at all.

Modder Deep Progress.

The Modder Deep has issued another excellent quarterly report for the period ended September 30. The footage developed was 2,196 ft., of which 1,015 ft. were sampled. The payable reef disclosures were 885 ft., having an average assay value of 15.8 dwts. over 41 inches. The total profit for the three months was £265,263.

Letters to the Editor.

CREEPING PARALYSIS.

How to Stop It.

Mr. W. E. Bleloch's Remedy.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—The Rt. Hon. the Minister of Mines and Industries and Professor Lehfeldt were both busy last week with the future of the Rand Gold Mining Industry, prophesying and implying, and one would almost say rejoicing, that its end is not far off, and seeing that the Prime Minister has taken an equally gloomy view, no doubt on account of the conclusions of despair of the Director of the Geological Survey, I venture to send you as a timely antidote the following further remarks on one part of Dr. Rogers' recent paper dealing with the extensions of the Reefs of the Far East Rand in the Heidelberg district.

In the paper referred to Dr. Rogers stated that:—

"The other source of confusion is the assumption that individual conglomerates have lithological characters peculiar to them and that these characters persist on the several horizons where the conglomerates are developed."

It will be obvious, sir, that in a similar superior and assumptive style one might say: *"The other source of confusion is the assumption that individual conglomerates have no lithological characters peculiar to them, etc., etc."* I prefer, however, not to follow Dr. Rogers' assumptive method of argument, and instead I state that:—

It is a demonstrable fact that "the individual conglomerates do have lithological characters peculiar to them and that these characters do persist on the several horizons where they are developed."

Dr. Rogers' regrettable and disastrous error arises through his own most dangerous assumption of distinctive lithological character, not for recognisable sedimentary deposits, but for certain igneous rocks by which he identifies the wrong beds of conglomerates or blanket reefs at Heidelberg as the same as the right beds of conglomerates or blanket reefs in the Far East Rand. Naturally he finds these different reefs different, and consequently he has to adopt the erroneous conclusion that each individual reef changes in character from district to district. We find, on the contrary, that with correct identification of the several conglomerates or blanket reefs at Heidelberg with the same reefs in the Far East Rand there is no such change of character or material in the individual reefs from one area to another.

We find that the individual reefs obviously and conspicuously maintain their distinctive character and material; that they are made up of pebbles and matrix peculiar to them over the many tens of miles of country where they have up till now been located and exposed. That is to say, that although Dr. Rogers and Dr. Mellor may call the Government Reef by its right name at Krugersdorp while they call it "Main Reef Leader" at Heidelberg, we find that it remains the same Government Reef at both places distinctive and unmistakable in pebbles, matrix and character, as well as in geological position and order of bedding. Dr. Rogers and Dr. Mellor may change the name of that reef at Heidelberg, but they cannot change its spots. It still remains the same old, unreliable and unpayable Government Reef there as it has proved to be everywhere else. If development in the Heidelberg district is to be encouraged on that reef, and on that reef only, as the Government cables to the High Commissioner last year decreed, and all other reefs are debarred, then of course, as predicted by Professor Lehfeldt, the end of the industry is certainly in view.

With these facts in sight I will proceed to say that while it is unfortunately true that the Government Reef remains the Government Reef, it is most fortunately equally true that the Nigel Reef remains Nigel Reef and the Van Ryn Reef remains Van Ryn Reef, not only on the Far East Rand, but at Heidelberg and everywhere. Both of these payable reefs continue distinct in character and material each from the other and from all other reefs, and each remains in itself its own distinctive character in pebbles, matrix and material and in appearance, from district to district, over distances exceeding 100 miles. Fortunately, too, the Van Ryn Reef in its extensions in the Heidelberg district, so far as it has been opened up and developed, has given evidence of having the same carrying gold values as it has in the great gold field of the Far East Rand.

The Prime Minister described last week the "creeping paralysis" which with alarming rapidity is destroying our chief mining industry. I submit that one obvious way to stop that disastrous progress toward extinction is to get ahead with a real and natural expansion and growth of the industry and that the only real and natural expansion possible, at once the quickest and best is to be achieved by the immediate opening up and development of new outcrop mines on the extensions southwards of the Van Ryn Reef, our great pay reef of the Far East Rand, the richest and most reliable gold reef ever found. To accomplish this we want (a) a public and definite withdrawal of the uncalled for and insane Government interference by cable which kept away a round million of cash working capital from that urgently necessary work, and (b) complete and immediate removal of the extortionate burdens of claim licences and other Government impositions on the initial stages of mining, which kill all new mining enterprises.

I can assure you, sir, and I can assure the Prime Minister and the Minister of Mines and Industries, and Professor Lehfeldt and Mr. Hendricks and the Mine Workers' Union and this threatened commercial and industrial community, that a regenerative policy which includes these two things is what is chiefly wanted to cure the creeping paralysis diagnosed by General Smuts.

I submit, that seeing the wrong reef of Dr. Rogers has years ago been proved unpayable and unreliable, encouragement should immediately be given to the development on the right reef—the true Van Ryn Reef opened up in the Nigel Area by the Southern Van Ryn Reef G.M. Co., Ltd., on Tulipvale and Klippoortje, and by Houtpoort, Ltd., on the Townlands of Heidelberg by Dr. Hans Sauer, and on Boschfontein by the Nigel Transvaal Goldfield, Ltd., and I go further and say that without development on that reef there can be no expansion and little hope. With it I am convinced that we would soon have in the Heidelberg district another and a greater Far East Rand.—Yours faithfully,

W. BLELOCH.

A PLEA FOR INFLATION.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—May I express the hope that the unfortunate public will give up its bad habit of supposing "economic experts" know what they are talking about. These gentry seem to be invariably wrong. America was to capture the world's trade; she is rapidly losing it. The German mark would appreciate; it has done the reverse. And the means adopted by a committee of experts to stabilise the Indian currency produced effects exactly opposite from those anticipated. The latest decision of our local experts, appointed to deal with the South African currency problem, is that we must return to the gold standard. In other words, our position is to be improved by further deflation. We are to be made richer later on by being made poorer first. We cannot restore the gold standard without deflating, and deflation

entails more restriction of buying power. Yet it is just this lack of buying power, or defect of demand, which is the root cause of the depression.

There is one aspect of the economic situation which has been almost entirely overlooked, and that is that neither now nor at any time is the buying power distributed sufficient to purchase the output of commodities. Prices are fixed to cover items in "cost" which are not balanced by buying power. The only road of escape out of this infernal mess is by inflating and by fixing prices. Inflation always induces trade activity until prices rise, and thus again make the demand inadequate to induce the desired output. Prices should be fixed to show a fair profit, and credit gradually released until the demand threatens to overrun the supply. A committee of ordinary educated persons (not experts) could be appointed to devise the financial machinery.

No doubt the problem is immensely complicated by the dishevelment of the foreign exchanges and the diminution of buying power overseas. But because Mrs. Smith, of Peckham, cannot buy an ostrich feather is no good reason for preventing Mrs. Jones, of Bloemfontein, from doing so should she desire that adornment. Because the demand from Europe for our goods is enfeebled is not the best possible justification for freezing the life blood of our internal trade—and that blood is financial credit. Every country is waiting for some other country to begin putting its house in order. It reminds me of the rhyme once familiar to school boys:

"My Lord Chatham, with his sword drawn,
Stood waiting for Sir Richard Straughan;
Sir Richard, longing to be at 'em,
Stood waiting for the Earl of Chatham."

I submit, sir, that such an attitude would be considered admirable by no one but a Minister of State, or an economic expert jaundiced by thinking in terms of gold instead of in terms of commodities and of life.—Yours truly,

P. E. BARKER.

[We understand that the recent conference of experts, held at Pretoria, failed to come to any decision.—Ed., "S.A.M. & E.J."]

GOLD LAW REFORM.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—In view of the inevitable closure of some of the poorer Rand mines, attention should be paid to the gold-bearing areas outside the Rand. Their locality and value have often been pointed out in your columns and elsewhere. They belong to land companies and private owners, and access to them can only be obtained with great difficulty and on terms that render the permission valueless. To proclaim them as public goldfields under the present law is useless, since proclamation is only made after the owner has beached off the accessible faces and watercourses. They could be opened to the public without breach of equity by commuting owners' rights for a tribute of, say, 2½ per cent., which is more than they have any right to expect, since these rights were commandeered from the State in order to be conferred on a favoured class. There is talk about subsidising fresh industries to fill the inevitable gap. Here is an industry that needs no subsidy and merely awaits removal of the embargo placed on it by successive gold laws.—Yours truly,

C. HOWARD.

ARE WE TO BE RUINED BY DEFLATION?

Professor Lehfeld's Views Criticised.

To the Editor, *S.A. Mining and Engineering Journal*.

Sir,—Recently we had added to the saying of a "spineless herring" the "American haddock without a backbone"—and a lot of trouble that unfortunate fish has caused mankind. In addition to the withdrawal of spine and bone we have to-day the process of deflation. We are all to be deflated. Henri Fabre tells of the delightful way in which

the firefly operates on a shelled snail and with what wonderful sensations the snail dreams out its existence, as the firefly absorbs its coagulated flesh. Deflation is another process. Inflation I understand thoroughly. Inflated with optimism and false representations has brought me down from my pedestal many a time; but I never thought this of deflation. To-day, we are all being deflated. There is, as they said in the good old road agents' days in the Western States, a general "hold-up." It commences at the banks. Nothing is attractive. "Sorry, nothing doing!" Then you move about and just as men saw during the flu their early encasement for resurrection purposes, so do they hang their heads and deflate. Everybody, of course, doesn't deflate. For instance, if the mines have to bring down costs, they deflate the man that has to do it. If the storekeeper has to pay down his overdraft, he is deflated and sells his 15s. shirts at 8s. 6d. The man who grows mealies is deflated in every direction. The man who grows potatoes is deflated down to 8s. 6d. a bag, and the gentleman who buys inflates them to £1 and deflates the consumer, but if I went into all the ins and outs of inflation and deflation I would probably fill a 6s. novel and make a fortune, which is distinctly inflation, and I am writing a simple little tale of world wide import on deflation. Deflation has come to us from Europe. It seems to have been bred out of currency; from currency it got into trade. Political purposes have adopted it, and God help the country and everything pertaining to it when the deflating instruments prick it in the wind. The resources of this country have been boomed most systematically in Europe and every known business of inflation has been used there to attract young Englishmen with fifteen hundred pounds apiece. Recently the Minister of Mines and Professor Lehfeld surveyed the country and its gold position, and we imbibed our first dose of scientific deflation. Professor Lehfeld's deductions are professional and put before the public for serious consideration, and although I may appear to write lightly it is not without appreciation of the true worth of his deductions that I approach the subject. In fact, I may say that with all due deference to Professor Lehfeld and His Honour the Minister of Mines, the gold industry of this country is so vast a subject with limitations so wide and unfathomed, that it would require a very great deal more than an academic statement to deflate it. If I had started looking for things without the necessary inflation the Minister of Mines and others would probably not have been employed for deflating purposes. Impelled by burning instincts, we worked and sought and found. In those days there were no deterrents. There was co-operation, and step by step men worked and found their goal. To-day, what incentive is there, when the chief advisers of this country tell you "gold has found its zenith and from now on its production must decrease"? The volume of trade and agriculture is held up and shown to over-balance gold. The cost of gold's production is deducted from its price. Now, where does the cost of production of that gold go to if it does not go to support agriculture and industries? There is the field of raw industries here as well as anywhere else in the world, but the production of gold has given us a great additional internal market. From that market, agriculture and industry have moved to what they are to-day; now we are invited and encouraged to see that great market diminish and agriculture and industry move into its place. Before accepting this statement, look at produce; look at the moratorium farmer; look at the wonderful strides of the great Pretoria steel industry! Look at it! Mr. Malan has drawn attention to it forcibly enough. He has also decried gold and posted telegrams to the world about gold reefs. He may have been right, but it is the same Mr. Malan and the properties have different owners! However, regarding gold: There are hundreds—perhaps thousands—of millions of tons of low-grade ore in this country, which Mr. Malan is paid to find out all about and how it can be treated. Recent experiments show the day is not far off when it will all be remedied without the aid of a stamp mill. There is a process called the oil separation, which should be commended to Mr. Malan. Its process is to-day treating *ninety millions of tons of ore in countries other than South Africa*. The whole face of districts here

carry low-grade ores, hundreds of miles of them; they have not been touched. We have been educated by mine owners and Governments to look for gold from a few deep mines whose wealth decreases with depth and whose numbers are in imminent peril of being reduced from some fifty to thirty. If they do, Professor Lefheld's deductions will be proved to the hilt, but why should they be? Of course, if gold is to be deflated and it costs over five pounds to produce an ounce of it, one can readily understand "the Devil will be amongst the tailors," and this country's premier industry will get a pretty black eye. I do not view the matter as complacently as Professor Lefheld or the Minister of Mines do, although, as some people argue, if twenty mines do succumb it might tend to bring people to their senses; it certainly will bring the Government and the Minister up with the round turn they have required for many years. Whilst Professor Lefheld talks of the gold industry declining, there are the discoveries of the Western Rand lying dormant; there is a great stretch of formation between the Western Rand Estates and the gold mines in Potchefstroom. There is the Far East Rand and its prohibited areas to the south, and there is the immense stretch of the southern rim of the Rand conglomerates showing sporadic gold, but not wanted to resuscitate this great dying industry. Deflation is no new game. It has been played upon this Rand ever since its discovery. It was played in many a mining camp in America before that. It's simply capital holding up enterprise. All the gold mines that are worth anything, or supposed to be worth anything, boom because certain cliques hold the shares. They may not be worth anything; they may be mines such as Bantjes, Vogel Deeps, and one or two others that have been boomed to death by their cliques, and as long as these cliques have power nothing in the country but theirs is good. To-day gold mining isn't popular, because there is the danger in the metal's depreciation, there is labour danger, and there is Government's warning, but for all that I know of a little mine that has arisen out of the discarded debris of a low-grade non-payer; it has paid for all its improvements out of its profits, increased its stamps, and makes good profits. Now, if this can be done on low-grade ore, working at a fairly high cost, what can be done with oil separation and improved methods of reduction? No one has the individual producer's interests at heart except himself. Mr. Trevor, at Pretoria, is sanguine of that class of expansion, but I doubt if the Minister of Mines has ever studied the subject. It is like Professor Lefheld's advice to have the country surveyed to obtain its agricultural value. Why, of course it should be, but if its results are on a par with the mineral survey it won't be of much use. The amateur way of developing a country like this is to put men at the head of departments who do not understand their business. If a man is a schoolmaster, let him stick to education. If he is a mining engineer, let him rise in the mining departments, but here you have a great part of a continent and its Ministers spend happy days visiting great stretches and making speeches on sporadic discoveries. There is no precedent followed in its fundamental building. This country should long ago have had a proper agronomical survey, every part of it. Its bottom land, its bench land, and its mountain land should have been planned and its capacity valued for whatever its various parts could produce. It would then be found that valuable stretches were being wasted by black, by white, and by land companies. The actuary could figure out future displacements and the benefits that citizens would derive thereby. The apple belts, the peach belts, citrus, and various other products of value could all be determined, and it would be only thus the country's capacity for holding white population could be determined. It is useless estimating that ten millions could be supported. Ten millions are no use. The 1820 settlers multiplied from 5,000 to 150,000 in 100 years, and that happened under exceptionally hard conditions. There are some seven million natives in the State who multiply much faster than whites. There is a terrible struggle between black and white to-day to occupy the land. The rapid evolution of the native will accelerate more and more as time goes on. What is the winning factor in the game? It is the female

labour of the black man. The Kafir with his women can produce a bag of mealies at half what a white farmer can. If this is so, the white man requires cheap motive power. He has it. Within reasonable time crude oil will be produced at 6d. a gallon, and land ploughed with a fraction of what it costs to-day. Ploughing is 40 per cent. of the work for a crop. Crude oil will push the native back, but it won't stop his breeding. Seven million natives can produce one hundred millions under our benign protection. Looking ahead, as America did, when it laid out its great country for future generations, provision should be made. It may be necessary to re-arrange the disposition of its natives. So far, provision has only been made for a black man. When you see the scientists and Ministers deploring the want of land for its future white inhabitants, is it not time to study the question of housing our future whites? Our blacks can exist under more difficult positions. Whites can produce valuable products intensively; blacks to-day live on great stretches of most valuable country and produce only a tithe of what they should. A white man is worth £30 to the State in taxes, a native 12s. When economy is studied the truth of these figures will be discovered. In their discovery the possible homes for many millions of whites will be found, but it is necessary, if this country is being governed and developed for white as well as black, to lose no time to get beyond Professor Lefheld's guesswork and find out exactly where whites are to live and what they are to do. The black man can be accommodated, as I have pointed out, on land that will sustain him, whilst the white man can occupy his former reserves. If we have not the minds to consider these questions and lay the foundations securely for our future population, our coming generations will suffer, and the downfall of the white will be the outcome of to-day's weakness. It is not, therefore, deflation that we should fall down before to-day. It is the practical solution of what we see and the wise preparation for what is to come. We must give up looking down deep level mines. We must study the thousands of millions of tons of low-grade ore throughout the Union. We must give every attention to the newly-discovered methods of producing gold and oil cheaply and encourage individual enterprise in every district to work and produce gold and oil. The farmer will find markets at his door and bless the movement, and from this will come renewed activity. There are sixty thousand million tons of coal in the country. For God's sake don't let us deflate this. Let us rather hold up our heads and inflate our lungs with South Africa's heaven-sent atmosphere. Let us as a superior race face our future with hope and confidence, but let us discard the bugbear of fear and deflation, and finding out the true resources of this great land work with wisdom and in our forecast have a true appreciation of the white man's necessities and protect them thoroughly.—Yours, etc.,

ECONOMIST.

A Mutable Electric Sign.

Dwellers in cities have become quite accustomed to the large electric signs which flash out a variety of messages. They have little idea of the complicated mechanism which is required to provide a series of messages, or the ingenuity involved in their design. The latest type, which has been evolved by a British inventor after more than ten years experiment, constitutes a remarkable advance on existing types. Letters, words, sentences, and designs are produced by pneumatic power from movable spheres, each six inches in diameter. By day the spheres twinkle white or in contrasting colours as fancy may dictate, and at night they are automatically illuminated electrically. A sign may be withdrawn and another inserted in its place without stopping the machinery; in fact a whole speech could be expressed line by line, and thus delivered more effectively than by megaphone. There is no end to the variety of letters and words which may be made to appear on this sign. The mechanism depends on a simple arrangement of perforated sheets.

ENGINEERING SECTION.

The Hartebeestpoort Dam.

By L. L. R. Buckland.

The Hartebeestpoort Dam is located in a poort in the Magaliesberg range through which the Crocodile River cuts its way about 25 miles from Pretoria on the Rustenburg Road. It is being built by the Union Irrigation Department for the conservation of irrigation water and will feed two canals approximately 30 miles long, one on each bank of the river, supplying water to 15,000 morgen of excellent ground, of which two-thirds is owned by the Government, lying in the warm and sheltered valley of the Crocodile.

The dam is of the constant-angle arch type and will have a total height of 198 feet above lowest foundation where it is 72 feet thick; the depth from bedrock to river bed level varies from 25 to 35 feet. The width of the poort at river level is 150 feet, but the crest length of the dam will be 450 feet with a width of 15 feet, over which the main road to Rustenburg will pass. At the crest the radius of the arch is 225 feet to the downstream face.

On the left flank a trough spillway, 125 feet wide on the line of the dam and 415 feet long, is being excavated to deal with the maximum probable flood; the spillway will be bridged to carry the main road from the dam.

The flow of the Crocodile at the poort varies from 40 cusecs in the winter to 200 in the summer, with floods up to 12,000 cusecs fairly frequently and as high as 140,000 cusecs on occasion. As winter floods are rare and have seldom exceeded 600 cusecs, the diversion works were designed to cope with that flow during the low-flow period from May to September, large floods being unknown before October.

Work is being carried out entirely by white labour and was commenced in 1918 when a light railway, 9 miles long, was laid from the works to Brits West, a siding on the Pretoria-Rustenburg line. At the same time quarters, offices, workshops and power plant were laid out. Lack of working space in the poort led to the adoption of electric power, and two Bellis and Morecom sets, with a third one added later as a standby, supply power at 2,200 volts, which is transformed down to 500 volts for use.

To enable the work of placing the foundations to be accomplished in the dry, two curved concrete coffer dams were started. After the upstream dam was completed by divers, it was discovered that solid rock had not been reached. The downstream coffer dam was, therefore, carried down to boulders only. A second diversion rockfill weir was built above the upper concrete diversion dam. It was decided to tunnel through the right bank and completely divert the river through the tunnel. The tunnel, which is 240 feet long, 12 feet wide, and 6 feet deep, with a grade of 1 in 200, was worked from both ends, the headings meeting after six weeks. The river is led into the tunnel from the rockfill diversion weir by a short concrete approach flume, also 12 ft. x 6 ft., and at the outlet another short length of concrete flume delivers the water into a corrugated iron flume, supported on timber piles, which takes the water well clear of the site.

The construction of the diversion weir was commenced early in May, 1921, when the tunnel and most of the inlet and outlet fluming was almost complete. 9 in. x 3 in. deals were driven into the sand and gravel to form close piling, which was backed by rock-fill and faced with a clay blanket which was carried 60 feet upstream along the river bed to reduce seepage.

The river was diverted entirely on the 24th May, and excavation commenced in earnest. The leakage through the weir was inconsiderable and easily dealt with by an 8 inch centrifugal pump. A 10 inch sand pump was installed as a standby—but was never called into use. By this date a commencement had been made with the erection of the concreting plant.

During this critical period, labour troubles were at their worst, and at times the wastage exceeded the supply of fresh labour. The men were restive and unsettled, and this unrest held the work up considerably and threw a large burden of unproductive overtime upon the staff.

The material in the river bed was mainly sand, gravel being reached at a depth of 15 to 20 feet, although under the left bank a number of boulders, ranging in size up to 30 cubic yards, had to be broken up before removal.

Before the diversion of the river some preliminary excavation of sand was done by two 6 in. sand pumps mounted on barges. Just prior to the closure of the diversion weir one of these pumps was moved upstream, but the other was left to assist in the dewatering of the foundations, sinking with the water surface until it was left high and dry at the end.

A 5-ton crane was erected on each bank to command the greater portion of the excavation. Grabs of 2/3 cubic yard capacity were used with these cranes for a short time, but it was found the cranes would not stand up to the heavy work and a graded wire-rope haulage, which was installed subsequently, successfully dealt with the 8,000 cubic yards of material that was removed. The material was all lifted by hand into "Cocopans" and run out direct, the maximum weekly output being 2,300 cubic yards.

Two 6 inch centrifugal pumps (additional to the 8 inch pump behind the weir) were installed to keep the excavations dry from the seepage which came back from the river below the lower coffer dam. These were successful, although the greatest difficulty encountered was to keep the sumps below the general level of the excavation. The favourite time for the pumps to fail seemed to be during the period 11 p.m. to 7 a.m., or the "Graveyard Shift," much to the annoyance of the mechanical assistant, who was repeatedly called away from a warm bed down to the icy river. However, by the middle of July rock was exposed over the whole area. It is a somewhat seamy quartzite, the bedding planes dipping downstream at approximately 20 degrees. It is rather fissured on the flanks, but generally good on the bottom except for some dykes of basic igneous rock—lampphyre—which weathers remarkably rapidly, and some small faults.

All these were followed up and thoroughly cleaned down before concreting commenced. The major portion of the rock required very little stepping except on the flanks, thorough scrubbing sufficing before concrete was placed. A "cut-off trench," 6 ft. wide and from 5 to 10 ft. deep, was excavated right across the poort just at the upstream face of the dam wall.

On July 29 work was sufficiently advanced to commence placing concrete. It had been found impossible to erect, in the short time available, the concreting plant in such a position as to command the dam during its whole construction, and in order to bring the wall above river-bed level during the short period before summer floods could be expected, a purely temporary lay-out had to be adopted on the right bank low down in the poort itself at a height just sufficient to command the wall up to the required river level. A quarry was opened at the back of a large boss of rock known locally as the "Pimple," from which the rock was allowed to roll down the hillside for tramping to the crushers, whence a conveyor belt raised it to the main bins above the mixers.

Sand-collection proved a difficulty at first, but the problem was solved by a method which, at first in the nature of an experiment, was found to work wonderfully well. A sump, consisting of a section of 4 ft. diameter concrete piping, was sunk close to the spoil dump of the sand removed from the excavation. The suction pipe of a 6 in. sand pump was inserted into the sump near the base; water was syphoned into the sump through a 6 in. pipe from the adjoining flume, and sand was shovelled in through a screen. The pump delivered the sand through some 600 feet of piping to a sandbag dam, near the mixing plant, where the water was allowed to drain off. From this dam the sand was lifted by cranes to temporary storage bins of 150 cubic yards capacity, whence it was tramped to the main bins. Cement was brought to the bins by a 1-ton cableway from the main store on the left bank. This cableway was also of value for the general transport of materials to the river bed. The concrete mixing plant is in two complete units, each consisting of rock, sand and cement bins from which the materials run through gates into adjustable measuring boxes from which they pass to the mixer through a chute. The gates from the measuring boxes to the chute are operated by compressed air.

As the materials pass into the mixer, of one cubic yard capacity, a measured quantity of water is added. The mixers tip direct into one cubic yard capacity cocopans which are hand tramped to the wall. All the concrete was placed by the two 5-ton cranes which, re-erected in commanding positions, lifted the pans off their frames, and tipped them

into the wall. The whole of the concreting plant was designed on the works, and the results obtained have been extremely gratifying.

It was decided first to carry the front section of the dam, some 20 feet wide, up to six feet above river bed so that in case of a bigger flood than 600 cusecs the upstream rockfill weir would not have to be renewed. Two 8-hour shifts were worked on concreting from 7 a.m. to 11 p.m., with a night shift from 11 to 7 doing any cleaning up necessary to give the morning shift a clean start. A bonus system was instituted based on the yardage placed, and this roused keen competition between the two shifts. The limiting factor was the quarry. Rock could not be supplied as fast as the mixers demanded it, but nevertheless excellent results were obtained, the maximum outputs of concrete being 40 cubic yards per hour, 429 per day, and 2,060 per week. The narrow front wall grew at such a pace that trouble was experienced with the shuttering, and the remainder of the dam was carried up as a whole.

On September 7 the task aimed at was accomplished, and with a total of 9,500 cubic yards placed the whole wall was 6 feet above river-bed level. Plenty of time before floods was still on hand, and consequently additional concrete was placed, a wall 10 feet high being carried up along half of the front face of the dam and a 5 ft. wall along the remainder of the face, thus enabling work to be carried on over one-half, should a flood too great for the tunnel come down and overtop the lower portion of the wall, when concreting is recommenced.

The whole of the plant in the river bed is now being dismantled and re-erected on the top of the left bank in a position to enable the construction of the remainder of the dam—which it is hoped to resume in December—to proceed uninterruptedly to a finish.

The Hartebeespoort Canals, as far as construction is concerned, are an organisation independent of the dam. Up to the present but little work has been done on them, about 200 white labourers are employed, but lack of funds prevents any extensive operations. Available funds have been carefully guarded to ensure that there is no shortage as far as the dam is concerned.—From *S.A. Irrigation Magazine*.

ANSWERS TO CORRESPONDENTS.

A letter awaits Mr. T. Hutt, prospector, at this office.

E.G.W., Gwanda.—We suggest that you communicate with the President of the Chemical, Metallurgical and Mining Society of South Africa, Technical Societies Club, Fox Street, Johannesburg.

Railway Electrification.

LESSONS FROM AUSTRALIA—SUCCESSFUL FRUIT OF SCHEME RECOMMENDED BY MR. C. H. MERZ.

Victoria is the only State in Australia which has any electric railways, as distinct, of course, from tramways. Only a few of the suburban lines of Melbourne have so far been electrified, but the expensive change over from steam to electric traction has already justified itself from every point of view, writes the Melbourne correspondent of the *Daily Telegraph*. It has given us the best suburban train service in Australia—a five-minute service at the rush hours and a ten-minute service at other times. It is also paying for itself handsomely, and if all goes well with the construction work now in hand, every Melbourne suburban railway line will be run by electricity within eighteen months. The 700,000 suburban residents of Melbourne will all then be sharers in the faster and more frequent train service which electric traction alone can make possible, and Melbourne as a city will gain from the reduction of the smoke evil.

It was in 1908 that Mr. Charles H. Merz, of Messrs. Merz and McLellan, Westminster, presented his first report on the electrification of the suburban railways of Melbourne, by direction of the then Premier, Sir Thomas Bent. If the State could have been convinced at that time of the general additional conveniences and rapid means of transportation offered there would have been no hesitation in accepting the scheme as it stood. But it involved a large capital outlay, and there was strong opposition from the Parliamentarians representing country constituencies. . . . The wonder is that the scheme was ever approved in a Parliament like that of Victoria, in which country representatives have always predominated. That the project was sanctioned was due to Mr. W. A. Watt, who became Premier a few years after Sir Thomas Bent. Having realised for himself the value of the scheme, he threw his whole heart into the task of winning Parliamentary sanction for it, but it needed the full force of his strong personality and his great gifts of eloquence to bring this about. He triumphed in the end, and Melbourne residents owe him much for the fight he put up.

War Interruptions.

No large construction scheme could possibly have been begun at a worse time. The work had hardly been entered upon when the War broke out. There was no power station. The plant required had not been agreed upon, and many of the essentials were in an embryonic stage only. There were many interruptions due to the War. Machinery which was being imported was sunk by submarines, and war conditions sent up the cost of the scheme enormously. The first electrified line, a stretch of 18½ miles, between Sandringham and Essendon, was opened in May, 1919. Now we have four other lines, totalling 25½ miles, running by electricity, and they have been running long enough for the financial results to be analysed. To operate the present electric service the chief power house consumes 54,000 tons of coal a year, costing £70,000. To provide, with steam locomotives, an equally frequent service, but at much slower speeds, would require 97,000 tons of coal, costing £128,000 a year. A steam train requires three men to operate it, whereas electric trains are run by two. The rolling-stock used on the electrified lines has been reduced by fifty locomotives and twenty-five cars. This means a saving of £50,000 a year in wages and rolling-stock maintenance. Since the electric service was begun there has been a large growth of revenue on all the suburban lines, but the increase on the electric lines has been considerably above the average. This is undoubtedly due to the better service provided by electric traction, for the electric trains travel at 30 per cent. higher speeds than the steam driven local trains. The value of the additional revenue directly traceable to electrification amounts to £95,000 a year. Thus, in coal, wages, rolling-stock maintenance and increased revenue, the monetary

benefits of the electrification of five lines amount to £191,000 a year. In addition, electric traction has postponed the necessity for costly duplications and extensions, which would otherwise have been necessary. In this way it is saving at least £150,000 a year in interest on the capital outlay thus deferred.

Electric Goods Trains.

When the whole scheme is completed we shall have ninety-eight miles of electrified suburban railways, and it is claimed that no other city in the world of the same size will have such rapid suburban transportation as the city of Melbourne. The capital cost of the whole of the electrification scheme will be £5,000,000. The total estimated additional interest and working expenses for the complete scheme is £500,000. Against this has to be set the economies and additional revenue resulting from electrification. So far only a third of the scheme has been completed, but, as has been shown, the partial scheme is already showing a financial advantage amounting to £191,000 a year. In order to eliminate waste and to effect further economies in staff, it is intended to introduce electric locomotives for suburban goods work and for shunting purposes. As the traffic on main country lines develops, it will become justifiable to electrify busy sections which are within reasonable distance of a cheap power supply.

THE FIRST STEP IN S.A.R. ELECTRIFICATION.

At a special meeting of the Railway Board, held on Wednesday, a final decision was come to on the question of railway electrification. The pros and cons of making a start with the electrification of the Durban-Maritzburg section of the line were discussed, and it is understood that a decision was reached in favour of proceeding with the work. It is believed that this decision was influenced by the receipt by the Board of a brief but strongly worded statement on the subject of railway electrification drawn up by the two chief engineering societies of the country, the S.A. Institute of Engineers and the S.A. Institute of Electrical Engineers. Notwithstanding the severe financial struggle through which the country is passing, the decision of the Railway Board will, we feel sure, be welcomed, as a valuable extension of the transport facilities of the country, making in the long run for considerable economy.

A New Flow Meter.

Many ingenious devices have been invented to measure the rate at which water or other fluid is flowing along a pipe, and one of the simplest and most effective is a new type produced by a leading British firm of instrument makers. The essential part of the instrument is a small paddle wheel placed inside the pipe so that it rotates as the fluid moves along. This paddle wheel has attached to it a magnet, and in a separate steel chamber immediately outside there is another magnet which rotates like the first. When the paddle wheel moves and carries its magnet round with it, the movement of this magnet pulls the second magnet round, and the speed of this second magnet therefore indicates the rate of the flow in the pipe. The advantage of this arrangement is that the indicating part of the mechanism is quite distinct from that through which the fluid is passing. All risk of the fluid finding its way into the indicating chamber is avoided, and the instrument is therefore particularly well suited for use where crude or hot oil is employed. The makers suggest that this instrument is well adapted to measuring the rate of flow of oil in lubricating systems, and also the flow of oil fuel or cooling water in oil engines.

TRADE AND INDUSTRIES SECTION.

Week in the Mining Material & Engineering Trades

BUSINESS RESTRICTED—IRON AND STEEL—DUNSWART'S NEW FURNACE—TIMBER AND BUILDING MATERIALS—ELECTRICAL GOODS—EXPLOSIVES—LOW GRADE MINES. NATIVE LABOUR EFFICIENCY AND FALLING GOLD PREMIUM—GERMAN ACTIVITIES—FINANCIAL—METAL MARKET.

General Review.

The Commercial Exchange this week has been rather quiet, and business, apart from the usual beginning of the month demands from the mines, restricted. Mining and building materials remain on the whole without quotable change of prices, except in the case of fencing material, some brands of which have hardened somewhat, but Continental wire quotations are checking any undue inflation in this article. Speaking generally, in view of the approaching stocktaking month before us and other factors which are looming somewhat prominently at the moment, no improvement in general business conditions is expected before we are well into 1922. As we have maintained for some time past, the industry is reaching, slowly perhaps, but surely, bed-rock in respect of accumulated stocks, and that this prediction will be verified in next month's stocktaking is generally believed. This should give a fillip to business; the industry cannot continue indefinitely on a starvation basis. Uneasiness prevails in many circles that the gold premium may drop below the point at which many of our lower grade mines will be able to work at a profit. Although no drastic decline in the rate is anticipated for some time, the fact is not being lost sight of by the commercial community that this premium is in its very nature a very precarious prop to the Rand gold mining industry, which must sooner or later give way and leave us in difficulties unless we have in the meantime, as the Prime Minister recently said, put our house in order by bringing about great reductions in the costs of production. It would indeed be a pity if some of our propositions—which, given reasonable working conditions, could continue profitable operations for many years to come—were compelled to close down when the gold premium approaches normal again, as assuredly it will sooner or later. The general position as regards working costs was very appositely stated by Sir Evelyn Wallers at the meeting of the Modder East and confirmed by chairmen's statements at other meetings of the week. The further collapse of the German mark to over 1,000 to the English pound is causing grave anxiety on both sides of the water; the huge increase in the paper circulation in Germany angers badly for forthcoming reparations commitments and, in the opinion of some experts, for Germany's present and future economic welfare. In the meantime German factories are overwhelmed with orders, and dates of deliveries are stated at anything from six to twelve months from receipt of orders. Turpentine, owing to shortage, has hardened from 100s. to 105s.

Iron and Steel.

Overseas, according to latest cable advices, iron and steel appears to be settling down on definite lines, and it is thought that the worst of the Continental competition has been seen. Locally business during the past week has been confined within narrow limits, and the Commercial Exchange has exhibited little activity. There has been a fair demand for steel plates, which in many sizes have a firming tendency. Large inquiries exist for mine trucks, and, whereas until recently these were made locally, a German firm has within the past few days secured a large order at a price at which it is impossible for local merchants to manufacture these trucks—much to the disappointment, it is needless to say, of local firms.

Steel Making: Opening of Electric Furnace at Dunswart.

The formal opening of the new industry which the Dunswart Ironworks Company have established near Benoni took place last Saturday, when a number of interested engineers and others were present. This company have since 1911 been engaged in converting scrap iron into bar and sheet iron. A furnace, with a capacity of nearly 70 tons, which will give an output of nearly 500 tons per month, has been laid down capable of taking a current of 6,600 volts through three 9-inch graphite electrodes. Scrap iron thus treated is reduced to a molten condition in five hours. The metal thus melted will be turned into ingot moulds. These ingots are subsequently treated in the cogging mill. The experimental results have been entirely satisfactory, and the works are capable of turning out steel castings up to seven tons weight. The party were much interested in the inspection of the new works and the casting of the ingots, which the management are prepared to test against the best Sheffield alloy steel. As the Dunswart Ironworks had the distinction of producing the first puddled iron in South Africa, so now they can claim to be the pioneers of turning out the first tool steel produced in South Africa. The Dunswart Company will now be in the position to supply the mines with manufactured steel, and the highest results are guaranteed. As a matter of fact some elisels manufactured from the steel produced are already in use, with very satisfactory results.

Engineering Shops and Industrial Opinions.

Business in the engineering shops continues to show a steady improvement, orders being very fair and full time being worked. In this connection the partner of an influential engineering firm said in the course of a chat that we found on every hand to-day labour in conflict with the employer, but in no case could it be generally said that the employer is making more than a living. He suggested that labour should reconsider its attitude and be perfectly sure that it quite understands where the shoe pinches. Leaving out of the question the profits disclosed in the case of Messrs. John Orr & Co., Kimberley, and others, there was, he thought, no industrial, mining, farming or any producing concern to-day making more than a living, and this has been so for a number of years, ever since the War began. There is no owner of industry or shareholder in a mine who can be accused of making exorbitant profits. Whether the same can be said for the commercial community is a horse of another colour, and it is a matter of opinion whether the big profits from time to time disclosed as made by commercial magnate houses are in the best interests of the country or not. Big industrial undertakings such as the mines, through benefit societies, etc., ensure that their employees are not overcharged in such matters as medical attention and medical supplies by chemists, etc. Speaking regarding the mines, he thought the time was about ripe when this principle should be more generally applied. What, he said, was

to hinder industrial bodies from insisting that their employees should be supplied with at least the necessities of life at a low price, or at a price showing only a reasonable profit to the distributor? He thought that labour might be likened to a mad bull, which is being pricked and goaded in some instances to desperation, but only sees the red rag and not its real tormentors. Labour, he said, is suffering; employers and producers are suffering; who is benefiting?

Timber and Building Materials.

Inquiries this week have been small and the amount of business transacted not very extensive. Merchants generally do not look for any decided improvement this year. Stocks of timber are plentiful, and though prices remain unchanged, advices from the Baltic indicate that present quotations may harden very shortly.

Prices: 3 x 9 deals, 1s. to 1s. 1d.; scantlings, 1s.; beaver board, 4 $\frac{1}{2}$ d. to 5d.; floorings, 6 $\frac{3}{4}$ d. to 7d.; ceilings, 5d. to 5 $\frac{1}{2}$ d.; Oregon, 6s. to 7s.; pitch pine, 7s. 6d. to 8s. 6d.; corrugated iron, 9 $\frac{1}{2}$ d. to 10 $\frac{1}{2}$ d. Furniture timber: Burnah teak, 18s. 6d. per cube here for first quality, 14s. 9d. for second, at the coast; American oak, 1s. 2d. at the coast; Japanese oak, 1s. 2d. at the coast; West African mahogany, 1 in. to 4 in. thick, 27s. per cube at the coast; Rhodesian mahogany, 8s. 6d. per cubic ft. at the mills; Honduras mahogany, 30s. per cubic ft.; American yellow pine, 1s. 8d. to 1s. 9d. per ft. of 1 x 12 here; American pine shelving, 1s. per ft. Bricks, in the absence of building activity, remain unchanged at 70s. for blue stock; 60s. for mixed; £4 10s. to £5 for wire cuts; £5 for pressed per 1,000 at kilns; white lime, 7s.; unslaked, 10s. 6d. per 180 lb. bag, 8 lb. bag 1s.; blue lime, 3s. 9d.; blue plaster lime, 4s. 9d.; cement, 11s. 6d. a bag; damp course and roofing, 36s. 6d., 46s. 6d., 55s. for 1 to 3-ply.

Second-hand Iron and Timber.

There is no change to report in the second-hand iron and timber yards; business has been quiet with but few inquiries. Prices are unchanged at about 6d. to 7d. for iron and 10d. to 1s. for timber.

Blue Hydraulic Building and Plastering Lime.

Trade in this section has been more or less steady, speaking generally of conditions throughout the country, and it is evident that as soon as things improve and money becomes easier the building trade will begin to advance. The lime trade at the coast has fallen somewhat. This has been caused by the importation of large quantities of cheap cement, which is being used for brick mortar by most of the contractors there. Prices to-day are: Building lime, 3s. 9d. per bag; plaster lime, 4s. 9d. per bag. These prices are based on standard products, but one or two merchants are occasionally cutting the above prices with inferior lime. The large works outside Krugersdorp have liquidated, having had a short existence, mainly due to the failure of their gas-fired kiln. The works are in the market now as a going concern, but no doubt they will eventually have to dispose of the works for the value of the plant alone. Speculators are nervous about going into the lime business just now, owing to the keen competition.

Electrical Goods.

Business in this section is still improving both in town and country; inquiries and orders are very encouraging. Prices remain much about the same, with no immediate prospect of any change. Britain, although doing its best to meet Continental competition, has as yet advised no declines, and dealers are of opinion that the present low prices of Germany as compared with Home products are likely to continue, at any rate for some time. In especial, cleats are being received from Germany at practically half the British prices, in which respect the former country is favoured by having the raw material in abundance and of superior quality, and so are able to knock us completely out of the market. A prominent importer said that one of the biggest electrical wares firms in England, Messrs. MacIntyre, Burslem, had reported that it was impossible for

them to compete with Germany in this line. As regards the Power Station, the new auxiliary plant of 6,000 set has already been installed about a couple of months, but has been of comparatively little help as far as new current is concerned. A little relief has been given, but not until another set of 6,000 is installed can the public expect any large accession of current. This set, we understand, is already ordered, but not expected until February next. Electrical goods dealers report generally that financial restrictions have eased off recently and the banks are not worrying so much about obligations as hitherto. One merchant, doing a very large business, said accounts of nine, ten and twelve months' standing are now coming in by degrees, and he really thought things were now getting better.

Explosives.

The British South African Explosives Co., Ltd., state there is no change to report generally in conditions; they are using up stocks purchased by them at high prices, and no reductions can be expected before some time next year. The stoppage of diamond mining has, of course, affected the diminution of accumulated stocks very appreciably. A shipment of nitrate, arrangements for which were made a year ago, has just arrived, which, if it could now be utilised, would effect a saving in explosives of several shillings a case, but the present high-priced stocks have first to be worked off. Glycerine, the most important constituent of explosives, is still very strongly held at Home.

Cheaper Coal in Britain.

An official of the National Wages Board expresses the opinion that the minimum wages under the coal settlement will apply to most districts by December. He estimates that many collieries will then be able to sell coal at 20s. a ton f.o.b.

A cable from Melbourne states that a scheme has been tentatively adopted to convert all the Australasian railway systems into a standard 4ft. 8½ in. gauge at an estimated cost of £57,000,000, for which it is proposed that the Commonwealth float a loan.

Lost the War, but may Win the Peace.

The real "German peril" in regard to the industrial situation in Germany is beginning to excite interest, not to say apprehension, in all countries of the world. The reason is that Germany is busy. Capital there is ready to accept reduced profits, and labour is accepting lower wages and longer hours, and giving greater skill and efficiency, in the material effort of a nation submerged in debt to dig out. The result is that German products are selling throughout the world cheaper than those of other nations. This invasion by Germany requires just as serious consideration as a military invasion, and will signify industrial disaster if it is not met by equal efficiency. While labour is well employed in Germany, Britain and the United States have millions of idle men, many of them on strike. Neither capital nor labour can afford to fight each other when its home field is open to or threatened by the invasion of foreign competitors willing to produce at profits and wages and hours which capital and labour at home are not willing to accept. How far this threatened invasion may penetrate is not the only serious consideration. Paralysis of industry means not only the home market unguarded, but abandons the foreign market, which is scarcely less essential to the prosperity of our industry. Times of depression call for the most strenuous and intelligent effort. It is much more necessary to be up and doing when business is dull and

needs pushing than when business is active and goes without pushing. Less of unnecessary expense and of waste in management, a disposition to accept smaller profits, a willingness to be satisfied with reduced wages, and a serious determination to increase efficiency in labour are the essentials in righting our position at the present time. Germany has gone farther in radical reductions of cost of production than we need to go, but the example which her practice affords is deserving of our serious consideration.

Germany's Cotton Activities.

At the recent London wool sales Germany bought large parcels, and is said to have obtained as much as three months' credit from Dutch, Swiss and American bankers, which would enable the importing mills to manufacture and dispose of the woven goods, and thus meet their obligations at due date. Germany's imports of American cotton this season were 374,000 bales, compared with 335,000 imported by England.

American Enterprise in Middle Europe.

Negotiations have been completed in Paris whereby the vast estates of Archduke Frederick of Austria and his son, Archduke Albrecht—estimated to be worth more than £50,000,000—were taken over by an American syndicate, which includes many of the most prominent American business men. Vast land and industrial holdings purchased include the great steel works and mines in Feschen, which are partly in Czecho-Slovakia and partly in Poland, and numerous other industries, factories, etc.

Near West Rand.

We hear that some small properties of five to ten stamps are being profitably worked in this district, and that one of them has made a clear profit of upwards of £1,000, which is a proof that the Rand is not exactly finished yet.

S.A. Reserve Bank.

The statement of liabilities and assets as on the 5th inst. showed the ratio of cash reserves to liabilities to the public to be 73 per cent.

A British West Africa 6 per cent. loan of £5,000,000 is being underwritten at 95. The money will be devoted to railway, harbour and other general developments, which it is expected will result in large increases in the production of raw materials. This loan is, it is said, the first instalment of a plan for thoroughly developing Colonial natural resources, which, it is stated, will amount to some £50,000,000 within the next five years.

British Empire Exhibition Fund.

Up to the present upwards of £700,000 has been guaranteed towards this movement, the objects of which we have referred to in previous notes.

Metal Market.

Latest London reports state that the metal market has shown little change during the past few days. Copper has been firm, and Straits tin fairly well supported. Lead has received a slight set back. Tin plates have been strong, and, owing to increased orders, the number of mills in operation is likely to be increased. Standard copper, £67 17s. 6d. cash, £67 5s. forward; electrolytic copper, £73 10s. cash, £75 10s. forward; standard tin, £153 17s. 6d. cash, £150 12s. 6d. forward; foreign lead, £23 12s. 6d. cash, £23 7s. 6d. forward; quicksilver, £9 15s. per bottle; bar silver, 39½d.; fine gold, 10½s. 1d. per ounce.

NEW MINING COMPANIES.

We are indebted to the Mines Department for the following interesting list of new mining companies registered in the Union in the ten months ended October 31 last. It will be seen that a round dozen of the registrations are concerned with gold, three with diamonds and with oil, six with coal, and one each with asbestos, silver and lead, and mica. The majority of these companies are registered in the Transvaal, but three are registered in the Orange Free State and One in the Cape Province:—

Rietfontein and Sabie G.M. Co., Ltd.; registered address, P.O. Delmore; Transvaal—gold.

Nigel (Transvaal) Goldfields, Ltd.; Box 3692, Johannesburg; Transvaal—gold.

Bechuanaland Asbestos Co., Ltd.; Kuruman; Cape Province—asbestos.

Consolidated Silver and Lead Mines, Ltd.; Box 1196, Johannesburg; Transvaal—silver and lead.

Transvaal Coal and Oil Shale Corporation, Ltd.; Box 3692, Johannesburg; Transvaal—coal.

French Rand, Ltd.; Box 94, Johannesburg; Transvaal—gold.

North Oogies (Witbank) Collieries, Ltd.; Box 1167, Johannesburg; Transvaal—coal.

D.B. Prospecting Syndicate, Ltd.; Box 1586, Johannesburg; Transvaal—coal.

Transvaal Coal Corporation, Ltd.; Box 2269, Johannesburg; Transvaal—coal.

Himeville Oils, Ltd.; 5 and 6, Club Arcade, Durban; Natal—oil.

Durban Roodepoort Mining Syndicate, Ltd.; Box 98, Roodepoort; Transvaal—gold.

Premier Oil (Shale) Syndicate, Ltd.; Box 7286, Johannesburg; Transvaal—oil.

New Deep Water Diamonds, Ltd.; Box 1744, Johannesburg; Transvaal—diamonds.

Gold and Base Metal Concentrating Co., Ltd.; Box 53, Pretoria; Transvaal—gold.

South African Coal Estates (Witbank), Ltd.; Box 5036, Johannesburg; Transvaal—coal.

Boshof Oils, Ltd.; Box 2641, Johannesburg; Orange Free State—oil.

Shamon Mica Mines, Ltd.; 207, Main Street, Johannesburg; Transvaal—mica.

Station Colliery, Ltd.; Box 5379, Johannesburg; Transvaal—coal.

Klerksdorp Gold Recovery, Ltd.; Box 4378, Johannesburg; Transvaal—gold.

Haynard Syndicate, Ltd.; Box 92, Durban; Transvaal—gold.

Leeuwvult Diamond Syndicate, Ltd.; Box 2641, Johannesburg; Orange Free State—diamonds.

New Southern Van Ryn G.M. Co., Ltd.; Box 3692, Johannesburg; Transvaal—gold.

Bourke's Luck Syndicate, Ltd.; Box 1411, Johannesburg; Transvaal—gold.

Consolidated Oils, Ltd.; Box 454, Johannesburg; Orange Free State—oil.

The Tributaries, Ltd.; Box 1744, Johannesburg; Transvaal—diamonds.

Fox Mining Syndicate, Ltd.; Box 4078, Johannesburg; Transvaal—gold.

Monarch Syndicate, Ltd.; Box 388, Pretoria; Transvaal—gold.

Northern Development Syndicate, Ltd.; Box 6442, Johannesburg; Transvaal—gold.

Madagascar Railways to be Electrified.

It is understood that the electrification of the chief railway lines in Madagascar over a total distance of 360 kilometres has been decided upon by the Government of that island.

COMPANIES STRUCK OFF.

The following companies appear in the list of those struck off the register, and therefore dissolved:—Lancaster Gold Mining Company, Ltd.; Transvaal Oil Shale Syndicate, Ltd.; The Rietspruit Diamond Syndicate, Ltd.; Weigel Exploration Company, Ltd.; C.L.S. Syndicate, Ltd.; The South Midas, Ltd.; The Eclipse Brick Company, Ltd.; Komati Exploration Syndicate, Ltd.; The Mia Mia Syndicate, Ltd.; Macdonald Estates, Ltd.; Good Hope Tin Syndicate, Ltd.; Goffe and Company, Ltd.; New Banket Reefs, Ltd.; Guy Fawkes Tributing Syndicate, Ltd.; Christiane Asbestos Company, Ltd.; The African Roof Cooling and Preservation Company, Ltd.; Rand Securities, Ltd.; African Madagascar Agencies, Ltd.; Broad Roberts, Ltd.; Meat Exporters Alliance, Ltd.; Moonstone Diamond Syndicate, Ltd.; Satic (South African Technical Industries Company), Ltd.; Pyramids Diamond Works, Ltd.; The Adelaide Timber Company, Ltd.; British Re-inforced Concrete Sleeper Company, Ltd.; Pretoria Base Metals, Ltd.; African Alca, Ltd.; Dominion Industries, Ltd.; Garrard's Garage, Ltd.; H. and S. Syndicate, Ltd.; Brown's Motors (Africa), Ltd.; Matzap Diamonds, Ltd.; Frank S. Corder, Ltd.; South African Motor and Cycle Importers, Ltd.; and Norton's Outcrop Syndicate, Ltd.

ALLEN, WACK & SHEPHERD Ltd.

General Import and Export Merchants,

VENDORS OF

BUILDING MATERIALS & HARDWARE

Distributing Agents for

STANDARD OIL COMPANY OF NEW YORK

Lubricating Oils and Greases,

JOHANNESBURG, TRANSVAAL, SATURDAY, NOVEMBER 19, 1921.

No. 1573.

Where Another Strike Started.

No. 5 Shaft of the Crown Mines, where the men have been on strike for a week. The matter is commented on elsewhere in this issue. On Thursday night the deadlock existing between the management and the men took a more serious turn, and at the moment of going to press it is stated that an ultimatum is being sent by the Unions concerned to the Chamber of Mines.

RESULT OF THE MINING CONFERENCE.

AMENDMENT OF THE REGULATIONS AGREED TO—A TRIUMPH FOR THE PREMIER—A MEASURE OF RELIEF INADEQUATE TO MEET THE INDUSTRY'S PRESENT NEEDS—SIR EVELYN WALLERS EXPOUNDS THE CHAMBER'S VIEW—OPINIONS OF THE MEN.

The sub-committee on the mining regulations met at Room No. 31, New Law Courts, Johannesburg, on Tuesday, the Prime Minister (the Hon. J. C. Smuts) being in the chair. There were also present: The Hon. F. S. Malan (Minister for Mines and Industries), Mr. Warrington Smyth (Secretary for Mines and Industries), Sir R. N. Kotze (Government Mining Engineer), Mr. Malcolm Ferguson (Inspector of Mines, Krugersdorp), Sir Evelyn Wallers, Prof. J. G. Lawn and Mr. F. G. A. Roberts (Chamber of Mines), Mr. E. S. Hendrikz and Mr. George de Meillon (S.A. Mine Workers' Union), Mr. J. Thompson (Acting President, S.A. Industrial Federation), and Mr. J. George (Department of Mining Industry, S.A. Industrial Federation).

After an hour and a half of discussion the suggested amendment to a portion of the mining regulation dealing with the working hours of natives was agreed to by all parties. The regulations, as accepted, were as follow:—

in the work of making safe. He shall not permit any person, other than those required to assist him, to enter the working place until it has been made safe.

(3) At any mine included in the list of mines framed under section I of Act No. 40 of 1919, the ganger or miner making the examination prescribed in sections (1) and (2) shall also thoroughly wet the reef, sides and floor, as well as the broken rock, before admitting to the working place the members of the gang other than those required to assist him in making safe.

(4) If the working place becomes, or is found to be unsafe during the shift, the ganger or miner in charge shall take measures for making it safe and for safeguarding the persons in the working place whilst it is being made safe.

(5) Equal present Regulation 102 (1).

(6) Equal present Regulation 102 (2).

The Hon. F. S. Malan (Minister for Mines and Industries) stated that the regulation will be issued immediately.

The Great Randfontein Central Mill. As pointed out by Sir Evelyn Wallers at the Conference, Randfontein, despite the gold premium, earns no dividends for shareholders under present conditions of high costs.

Regulation 106 (7) (a) to be deleted and (b) to become Regulation 106 (7).

Regulation 102 to read as follows:—

102 (1). Save as is provided in section (2) of this regulation, each working place shall before the commencement of a shift be thoroughly examined by a competent ganger or miner, who shall remove or make secure any loose or loosened rock, mineral, or ground, which might endanger the safety of persons. He may be assisted in this work by other persons working under his personal supervision and control, and where he deems it necessary in his actual presence, and shall take adequate precautions for their safety while they are engaged in the work of making safe. He shall not permit any person, other than those required to assist him, to enter the working place until it has been made safe, and his responsibility for the safety of any person lawfully present in the working place shall continue until the ganger or miner in charge of the oncoming shift enters the working place.

(2) If the working place is not examined and made safe prior to the commencement of the shift as provided in section (1), it shall be examined and made safe by the miner or ganger in charge of the shift at its commencement and also after any blasting that may take place during the shift. He may be assisted in this work by other persons working under his personal supervision and control, and where he deems it necessary in his actual presence, and shall take adequate precautions for their safety while they are engaged

So much for the acceptance of this much-debated amendment. The results of carrying the new regulation into force and the question whether this amendment will secure a sufficient measure of relief for our languishing industry, are discussed in the leading article appearing in this week's issue.

At this point it may be well to touch on some of the points elucidated at the conference and briefly to discuss the present position of and outlook for the mining industry of the Witwatersrand, particularly with regard to the selling price of our product and the cost of production.

The fact that the only two Rand Gold Mining stocks which appreciated in price on last week's sharemarket were Bantjes and Knight Centrals, both of which companies are said to be in imminent danger of dissolution, was commented on in our last issue.

A Paradox with a Moral.

That the shares of these two concerns should move up on liquidation prospects, whilst the price of the stocks of companies in the heyday of their lives should weaken, affords a striking commentary on the present parlous plight of the Rand mining industry. It simply means this: that the outlook at the present time is so unpromising in the face of a falling gold premium, high working costs, and the approaching exhaustion of several of our old Central Rand mines, that the prospect of liquidating a company

and selling up its assets is more entrancing to shareholders than is the continuation of mining operations. That such a state of affairs should exist clearly proves that something is radically wrong with our industrial house. The point need not be laboured that something is wrong, and most radically wrong, with the gold mining industry of the Witwatersrand. Moreover, it is not necessary to point out what is wrong with the mines. It is common knowledge that working costs are far too high and that working efficiency is far too low.

The Premium in Danger.

We have frequently pointed out that the majority of our mines are merely existing through and by the grace of the premium. General Smuts emphasised this point at the first meeting with the miners' deputation, and referred to the possibility of the total disappearance of the premium consequent on the abolition of the war debts and the re-establishment of parity as between British and United States currencies. The cancellation of the colossal debts contracted by the Allies during the War is generally regarded as the easiest solution of the present world depression. It is

Important figures at the recent Conference. Mr. H. O. Buckle, President, Transvaal Chamber of Mines.

argued that the chaotic exchanges which undoubtedly are in large degree responsible for trade depression and financial stringency would return to normal by the writing off of war debts.

Question of War Debts.

It is, of course, common knowledge that nothing has been said in official American circles to warrant the belief that the United States—the greatest creditor nation of the world—is prepared to cancel the colossal sums owing her by Great Britain, that on the contrary President Harding's policy does not incline towards such action, and that public opinion in America is against such a sacrifice. Yet the view is widely held that in this direction relief from the present universal poverty and chaos may best be sought.

Colour has been lent to this view by the sensational fall in the value of the mark, which in financial quarters is regarded as a sign of Germany's intentions to publicly declare herself bankrupt and to dare the Allies to do their worst. The Washington Conference, too, although it will deal primarily with disarmament and questions concerning the Far East, will, it is hoped in some optimistically inclined quarters, pave the ground for a consideration of the problem of adjusting the world's tangled finances.

Civilisation is undoubtedly at the cross-roads to-day, and no one can foretell what the next few months will bring forth or what effect events in Europe and America will have upon our own affairs on the Rand. It is, at any rate, clear that there is dire need of re-organising the gold mining industry of South Africa so that the mines can continue working without the fortunate accident of the premium. The conferences of Government, Chamber of Mines and miners on Thursday of last week, and on Tuesday, were held with a view to affording the industry much-needed relief through amendment of that portion of the mining regulations which deals with the number of hours worked by natives underground.

Far-reaching Reorganisation Required.

But the meetings of the conference have clearly shown that a much larger measure of relief than can be expected from the mere re-drafting of a paragraph in the mining regulations are required if the mining industry of the Rand is going to survive and if widespread unemployment and distress is to be averted.

The full official reports of the conferences occupy a vast amount of space in the daily papers. They take up more room than this journal possibly can devote to the subject.

Arguments at the Conference.

The whole scope of inquiry of the conference is, however, of such paramount importance that we shall accord

Sir Evelyn Wallers, who ably stated the case for the Chamber at the Conference.

as much space as we can to the speeches of the representatives of the Government, the Chamber, and the men.

In the first place we would draw attention to a communication received from an esteemed correspondent on the subject. Without necessarily agreeing with his interpretation of the cause of the decline in the gold premium, we commend this letter, which is written by a gentleman in Rhodesia, and who sees the Rand from afar, to the common-sense instincts of all who are dependent upon the mining industry for a livelihood. The letter is as follows:—

There can only be one inference read into the continued appreciation of British sterling in the U.S.A., and that is the, as yet unpublished, arrangement come to between the heads of international finance to cancel the debts as between the Allied Nations, an arrangement which only awaits the endorsement of the conference now taking place between the representatives of the Allies in America. How, otherwise, can we construe this continued appreciation of British sterling at a time when the great sea-side movement of crops from America to Europe is in progress, and when by all the rules of finance and commerce the exchange should be going steadily against Great Britain? Having realised this fact, what then is going to be the effect on the South African gold industry? Firstly, the so-called premium will disappear, and quite suddenly. I should not be surprised to wake up one morning within the next two months and find the premium a thing of the past. That means, if the industry

is run on the present abnormal and expensive basis, that the unclosed low-grade mines will close down, like an oyster shell, suddenly; that a period of unexampled depression will ensue, and that unemployment, at present a pressing problem, will be inexpressibly more acute. Will not the leaders of the S.A. Miners' Federation see these facts as they stand at present. Have they to wait until the cloud-burst is right upon their trust before thinking of moving into the shelter of conciliatory bargaining and fair dealing?"

This letter goes straight to the kernel of the present conference. It echoes in a very eloquent and plain-speaking manner the view expressed by Sir Evelyn Wallers at last week's conference.

The Chamber's Case.

After General Smuts had opened the conference and explained its objects, and after Mr. Hendrikz, on behalf of the Mine Workers' Union, had debated at great length the question of deleting one word in the mining regulations, Sir Evelyn Wallers, upon the invitation from the Premier, stated the Chamber's case as follows:—
